Oracle Communications Messaging Server Reference

Release 8.1
F15150-02

Contents

Preface

This technical reference manual documents the various options and facilities provided by Oracle Communications Messaging Server.

The preface covers the following:

- Audience
- Documentation Accessibility
- Related Documents

1.1 Audience

This document is intended for Messaging Server administrators and developers who want to configure and manage their Messaging Server infrastructure.

1.2 Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc

1.3 Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

1.4 Related Documents

For more information, see the following documents in the Messaging Server documentation set:

- *Messaging Server Installation and Configuration Guide*
- *Messaging Server Installation and Configuration Guide for Cassandra Message Store*
- *Messaging Server Release Notes*
- *Messaging Server Security Guide*
- *Messaging Server System Administrator's Guide*

Part I Configuration syntax

In Unified Configuration, nearly all configuration options are stored in the `config.xml` Message Server unified configuration file, as XML elements; a few, security-related, options (*e.g.*, unix user ids) are stored instead in the `restricted.cnf` file. However, under normal circumstances, the Messaging Server unified configuration file `config.xml` is not---indeed should not be--- inspected or editted manually by the Messaging Server administrator. Instead, normally Messaging Server's `msconfig` utility is used to examine the configuration and make configuration changes.

Options in the unified configuration file `config.xml` generally are typed XML elements. The `msconfig` utility performs type checking on configuration settings it makes. See Option value syntax for further details.

The `instancename` and `rolename` options discussed in Options for migrating to Unified Configuration set the context for option values.

Sets of commands for `msconfig` may be scripted using the Recipe language.

A few special symbolic names may be used in option values, or in the Recipe langauge.

Another language used by multiple components of Messaging Server, including the MTA and the Message Store (for purge operations), as well as by external components such as some email user agents, is the Sieve language.

Several components of Messaging Server make use of the TCP wrapper concept, for access controls.

Chapter 1 Option value syntax

Option settings in Unified Configuation, that is, values in the file `config.xml`, generally are typed XML elements. The `msconfig` utility performs type checking on the configuration settings it makes, and the `msconfig` utility will issue an error if an attempt is made to set an invalid value. The immediate validation and feedback the `msconfig` utility provides on configuration option settings is one of the advantages available by using the Unified Configuration. In contrast, with a legacy configuration, errors in option setting syntax or option values might not be reported until a process attempted to execute; for instance in the case of the MTA, perhaps not until an `imsimta cnbuild` or similar command were issued.

Note: The errors reported by the `msconfig` utility are typically *much* easier to understand and hence correct than the general XML errors that would be reported by an XML validation of `config.xml`. This is a significant reason why it is important to use `msconfig` to inspect and modify the MTA configuration, rather than attempt to modify `config.xml` directly.

The `msconfig` utility can show the type of any option, and the default value, if any, using the `-type` switch and `-default` switch, respectively; for instance:

```
# msconfig
msconfig> show mta.enable -type
mta.enable>: bool
msconfig> show mta.enable -default
mta.enable: 0
```

The `msconfig` interactive help text for an option may also provide additional guidance on proper values for an option; for instance,

```
msconfig> help option enable
```

The `msconfig` utility knows the type permitted for each option and will issue a (reasonably clear) error if an attempt is made to set an invalid value. For instance:

```
msconfig> set mta.enable "localhost"
Error setting option mta.enable: Option value is not a valid value for the option (-23)
```

1.1 Available Types

For the underlying `config.xml` Unified Configuration, quite a few different XML types are defined and can potentially be declared as valid for various option values, including but not necessarily limited to (as this list can be expected to grow) those shown below. Note that NUL characters are not allowed in string types. Note also that all list types are space separated lists; in particular, CRs and LFs are not allowed, leading and trailing spaces are not allowed, and runs of two or more (unquoted) spaces are not allowed.

- *String and character types*

  - UTF8 string
  - UTF8 character
  - UTF8 text node
  - String (UTF8)
  - Non-empty string (UTF8)
  - ASCII string
  - Non-empty ASCII string
  - ASCII character
  - Printable ASCII string
  - Printable ASCII character
  - Printable ASCII string list
  - Enumerated string case-sensitive
  - Enumerated string case-insensitive
  - Name
  - Name list
  - URL

- *Numeric types*
  - 32 bit integer
  - List of 32 bit integers
  - Unsigned 32 bit integer
  - List of 32 bit unsigned integers
  - Unsigned 64 bit integer
  - Unsigned 16 bit integer
  - List of unsigned 16 bit integers
  - Boolean
  - Boolean true-only
  - Floating point
  - Unsigned octal (maximum length 9 octal digits)
  - Enumerated 32 bit integer values

- *Time types*
  - ISO 8601 time
  - List of ISO 8601 times
  - ISO 8601 duration
  - List of ISO 8601 durations
  - ISO 8601 duration OR time

- *Host, domain, and IP types*
  - Domain
  - Domain and port
  - Host
  - Host and port
  - IPv4
  - IPv4 list
  - IPv6
  - IPv6 list
  - IPv4 literal
  - Domain literal list
  - IPv4 and post
  - Host list
  - IPv4 range

- *File and directory types*

  - MTA-specific directory path
  - MTA-specific file path
  - MTA-specific file path list
  - Directory path
  - Absolute directory path
  - File path
  - Relative path
  - Path
  - File name
- *Password type*
- *LDAP types*
  - LDAP URL
  - LDAP attribute name
  - LDAP DN
- *Address types*
  - RFC 822 address
- *Bit mask*
- *Various enumerated types*

1.2 ISO 8601 P format

The ISO 8601 P, or ISO 8601 duration, format is:

`P`*`year`*`Y`*`month`*`M`*`week`*`W`*`day`*`DT`*`hour`*`H`*`minute`*`M`*`second`*`S`

where the values *`year`*, *`month`*, *etc.*, are integer values specifying a duration or an offset (delta) from the current time. The initial P is required; other fields may be omitted, though the T is required if any time values are specified.

Note that all of the letters in ISO 8601 P values must be written in upper case.

For example, `PT1H` means a one hour duration or offset.

Besides the `backoff` channel option and a few alias options, also several MeterMaid `local_table` options take ISO 8601 P arguments.

1.3 ISO 8601 format

The ISO 8601, or ISO 8601 time, format is either specified in Greenwich Mean time (GMT or Zulu):

`yyyy-mm-dd``T`*`hhmmss.ss`*`Z`

or with an optional time zone offset:

`yyyy-mm-dd``T`*`hhmmss.ss`*`+`*`hh:mm`*

or

`yyyy-mm-dd``T`*`hhmmss.ss`*`-`*`hh:mm`*

The hyphens in the date portion are optional and may be omitted; though for a negative time zone offset, a hyphen/minus must of course be specified. Spaces are ignored. Year is specified in four digits, each of month, day, hours, and minutes is specified in exactly two digits (using a leading zero for values less than 10), and seconds is typically specified in exactly two digits (using a leading zero for values less than 10) or optionally can include a decimal point followed two more digits specifying hundredths of a second. Hours are specified on a 24 hour clock. For instance:

```
2013-05-22T12:30:00-08:00
```

Note that prior to Messaging Server 7.0, only a somewhat more restricted format was supported: hyphens were not permitted in the date, nor was a time zone offset permitted (Z was required), nor were fractions of a second (hundredths of a second) permitted.

The `imsimta test -time` utility may be used to test the validity of an ISO 8601 time string, as well as convert it into the (perhaps more familiar) date-time format used in RFC 822 header fields, such as Received: and Date: header fields.

1.4 MTA URL types

A number of MTA options, channel options, alias options, *etc*., allow values of various URL types. Such URL types may include:

- `file:` -- used to refer to files stored in the local filesystem
- `ldap:` -- used to refer to data stored in the LDAP directory
- `ldaps:` -- used to refer to data stored in the LDAP directory, accessed via LDAP+SSL
- `pabldap:` -- used to refer to data stored in a Personal Addressbook LDAP directory
- `pabldaps:`
- `extldap:`
- `extldaps:`
- `ssrd:`
- `mailto:`
- `data:` -- URIs make it possible to specify data directly, in the URI itself
- `http:`
- `imap:` -- access data using IMAP. The credentials specified by the `imap_username` and `imap_password` MTA options are used to log in to the IMAP server and the URL is resolved with the URLFETCH IMAP command. Note that `imap:` URL resolution is part of the server-side support for the BURL SMTP extension (used to implement forwarding of messages without having to download them) so any usage of such URLs by the MTA must take into account the fact that there's only one set of such login credentials.
- `imaps:` -- access data using IMAP+SSL.
- `metermaid:`
- `memcache:` -- new in MS 8.0

- `redis:` -- new in MS 8.0.2.3

In addition, some such options may also support a non-URL form argument, assumed to be of an especially "appropriate" type for that option, depending upon the option. For instance, some options assume a file-path argument when no URL prefix is present, while other options might assume an e-mail address argument when no URL prefix is present.

Some MTA options, channel options, or alias options may allow use of certain substitution sequences in their value settings. The most general list of such substitution sequences may be found in the discussion of LDAP URL substitution sequences. However, some (but only some!) of these substitution sequences are also valid in other types of URL settings for certain MTA option or channel option or alias option settings. See discussion of specific options for details.

Note that in order to use as option values forms of URL that involve querying some external-to-the-MTA component, such as an LDAP URL, or the special "Personal Addressbook" (`pabldap:`) form of URL, or an IMAP (BURL) URL, or a MeterMaid URL, or a Memcache URL, typically configuration of just *how* the MTA should connect to that other component is necessary -- that is, configuration of just how to properly interpret such values is necessary. See MTA options such as the LDAP bind and connect MTA options, LDAP external directory lookup MTA options, LDAP PAB MTA options, BURL MTA options, Memcache MTA options, MeterMaid MTA options, or Redis MTA options for performing such configuration.

1.4.1 LDAP URL substitution sequences

When specifying LDAP URLs for MTA use, various substitution sequences, as shown in Table of LDAP URL substitution sequences, are generally available.

Table 1.1 LDAP URL substitution sequences

Substitution Sequence	Description
`$$`	Literal $ character
`$~`*`account`*	Home directory of user *`account`*
`$?`*`string`*`?`	(New in 8.0) Apply the Message Store's `hashdir` algorithm to *`string`* to produce a directory path
`$\`	Force subsequent material to lower case
`$^`	Force subsequent material to upper case
`$_`	Leave case as-is for subsequent material
`$|/`*`table-name/argument`*`|`	Call out to mapping table*`table-name`*, probing with *`argument`*; if the mapping table is found and a $Y, $y, $T, or $t is returned, then use the returned string. Note that the slash shown before and after the *`table-name`* can in fact be any character; a character should be used that doesn't conflict with the expected characters in either *`table-name`* or *`argument`*.
`$A`	Address
`$`*`n`*`A`	Insert the *`n`*th character of the Address
`$B`	LDAP user root; *i.e.*, the value of the `ugldapbasedn` base option (in legacy configuration, the `local.ugldapbasedn` configutil parameter), or as

	overridden by the MTA-specific `ldap_user_root` MTA option
`$C`	LDAP domain root; *i.e.*, the value of the `dcroot` base option (in legacy configuration, the `service.dcroot` configutil parameter), or as overridden by the MTA-specific `ldap_domain_root` MTA option
`$D`	Domain name
`$E`	Synonymous with `$1E`; that is, substitute in the value of the LDAP attribute named by `ldap_spare_1`
`$`*n*`E`	Substitute in the value of the LDAP attribute named by the `ldap_spare_n` MTA option, where *n* is in the range 1-18 (any other value is equivalent to 1); note that `ldap_spare_6` was added for Messaging Server 7.0-3.01; `ldap_spare_7` through `ldap_spare_18` were added for Messaging Server 7.2-7.02.
`$F`	Delivery filename; some syntax checking is done if the "name" is a file URL (`file:` syntax)
`$G`	Synonymous with `$2G`; that is, substitute in the value of the LDAP attribute named by `ldap_spare_2`
`$`*n*`G`	Similar to `$`*n*`E`, but with the default for *n* being 2 rather than 1
`$H`	Host name (first portion of fully qualified domain name)
`$I`	Host domain (the canonical domain name for the domain the user is in), unless the host domain is the same as the `defaultdomain` option (in legacy configuration, the `service.defaultdomain` configutil parameter), or the MTA-specific override option `ldap_default_domain`; when the host domain matches the `defaultdomain`, then a null string is substituted
`$1I`	Host domain (the canonical domain name for the domain the user is in), unless the host domain is the same as the `defaultdomain` option (in legacy configuration, the `service.defaultdomain` configutil parameter), or the MTA-specific override option `ldap_default_domain`; when the host domain matches the `defaultdomain`, then the entire substitution operation fails.
`$2I`	Host domain (the canonical domain name for the domain the user is in), unless the host domain is the same as the `defaultdomain` option (in legacy configuration, the `service.defaultdomain` configutil parameter), or the MTA-specific override option `ldap_default_domain`; when the host domain matches the `defaultdomain`, then no domain is inserted and also the leading character is removed. This substitution is typically used to remove a leading

	percent character, %, for such cases of the default domain.
$3I	Host domain (the canonical domain name for the domain the user is in), unless the host domain is the same as the defaultdomain option (in legacy configuration, the service.defaultdomain configutil parameter), or the MTA-specific override option ldap_default_domain; when the host domain matches the defaultdomain, then no domain is inserted and also the next character in the template is omitted. This substitution is typically used to remove a trailing slash character, /, for such cases of the default domain.
$J	Host domain minus its first chunk
$K	Filter constructed from the user and group object classes, as specified via the ldap_user_object_classes and ldap_group_object_classes MTA options
$L	Username minus any special leading characters such as ~ or _
$M	uid; when the LDAP URL relates to a user address, this would be the actual uid value (or whatever LDAP attribute is named by the ldap_permid MTA option, and if that attribute is not present, the attribute named by the ldap_uid MTA option), but in other contexts may have another meaning (as for instance, $M substitutes the detailed verdict string for spam/virus filter package integration spamfilter*N*_action_*M* MTA options)
$*n*M	New in MS 6.2. Insert the *n*th character of the uid (or an " a" if the uid has no *n*th character)
$N	Construct a comma-separated list of attributes (normally those to return in reverse_url lookups, hence a comma separated list of the attributes named by the ldap_capture, ldap_recipientlimit, ldap_recipientcutoff, ldap_sourceblocklimit, ldap_preferred_language, ldap_personal_name, ldap_primary_address, and ldap_equivalence_addresses MTA options, as well as (in MS 6.2 and later) ldap_source_conversion_tag, and (in MS 6.3-0.15 and later), ldap_blocklimit, ldap_source_channel, the ldap_source_optin*N* MTA options, ldap_preferred_country, and the ldap_spare_*N* MTA options)
$O	(New in MS 6.1p1/6.2) Substitute the source route
$4O	(New in MS 6.1p1/6.2) Substitute the source route if present; if no source route is present, then instead remove the following character (normally used in a

	pattern to remove the colon character subsequent to the---nonexistent---source route)
$P	Program name, that is, the value of the attribute named by the ldap_program_info MTA option (hence normally the value of the mailProgramDeliveryInfo attribute)
$Q	Filter for address reversal in iMS 5.2p2; that is, a filter constructed from the attribute names listed in the ldap_mail_reverses MTA option (or the appropriate default attribute names, depending upon the schema tag, if ldap_mail_reverses is not set); this substitution sequence was typically used as the filter in reverse_url lookups in iMS 5.2, but with the Messaging Server 6.0 MTA, the $R substitution sequence is normally used instead
$S	Subaddress
$2S	Subaddress if present, but if there is no subaddress, then remove the leading character (used to remove the plus character, +)
$R	Filter for mail aliases; that is, a filter constructed from the attribute names listed in the ldap_mail_aliases MTA option (or with legacy configuration in the local.imta.mailaliases configutil parameter); as of MS 6.0 and later, also typically used as the search filter for reverse_url address reversal lookups
$T	Turn domain name *chunk1.chunk2...chunkn* into dc=*chunk1*,dc=*chunk2*,...,dc=*chunkn*
$U	The username portion of the address (that is, the local-part sans subaddress and sans any leading backwards-single-quote, tilde, or underscore character)
$*n*U	Insert the *n*th character of the username
$V	The base DN returned by calling domainMap on the domain in the address; note that this can be affected by the domain_uplevel MTA option
$1V	A variant on the $V substitution, where if the $V domainMap sort of lookup fails (no inetDomainBaseDn or aliasedObjectName matching the domain name is found), then this $1V substitution instead returns the DN of the top of the user and group tree, that is, the value of the ugldapbasedn base option (in legacy configuration, the local.ugldapbasedn configutil parameter) or as overridden via the MTA-specific ldap_user_root MTA option
$X	mailHost
$*n*X	Insert the *n*th component of the mailHost

Chapter 2 Options for migrating to Unified Configuration

There are three options in legacy configuration that provide meta-data for migrating from legacy configuration to Unified Configuration.

2.1 `instancename` Option

The `instancename` option specifies the name of this host's instance in the deployment. This option is used as a transition option when migrating to a Unified Configuration. Only used for purposes of migration.

2.2 `rolename` Option

The `rolename` option specifies the name of the role this host fulfills in the deployment (e.g., backend-store, frontend-mta, relay). This option is used as a transition option when migrating to a Unified Configuration. It may also be used briefly when adding a new system to an existing deployment via the Deployment Map server. In that setting, the Deployment Map client briefly runs, registering the node with the server and reporting as its role, the string value set with this `rolename` option.

2.3 `plugins` Option

The `plugins` option enables notifications via ENS and/or JMQ by specifying a library name of "`libibiff`" or "`libjmqnotify`" respectively. Each library name should then be followed by an instance name preceded by a "`$`" character. Each library/instance pair should be separated from the next by a "`$`" character. Several instances of plugins may be specified with different instance names. The name given in the instance field for each specified plugin is the name used to look up the configuration for that plugin. The instance name "`ms-internal`" is reserved.

This option is not used for Unified Configuration.

Support for JMQ is deprecated and will be removed in a future release.

Chapter 3 Special symbolic names

A few special symbolic names may be used in option values in `msconfig`, as well as in recipes. (These names tend to correspond to former, now obsolete, MTA Tailor options; as such, while the MTA Tailor options per se no longer exist for purposes of *setting* directory locations, file names, or values, these corresponding special symbolic names can also still generally be used in MTA contexts, where they now are interpreted as having values relative to SERVERROOT.)

```
IMTA_ROOT:    -> <serverroot> "/"
IMTA_LIB:     -> <serverroot> "/lib/"
IMTA_BIN:     -> <serverroot> "/lib"
IMTA_TABLE:   -> <configroot> "/"
IMTA_PROGRAM: -> <dataroot> "/site-programs/"
IMTA_DL:      -> <dataroot> "/dl/"
IMTA_LOG:     -> <dataroot> "/log/"
IMTA_QUEUE:   -> <dataroot> "/queue/"
IMTA_HTTP:    -> <dataroot> "/www/"
IMTA_HOST:    -> local.hostname
IMTA_DEFAULTDOMAIN -> service.defaultdomain
IMTA_LIBUTIL  -> <serverroot> "/lib/libimtautil.so"
IMTA_LIBMAP   -> <serverroot> "/lib/libimtamap.so"
IMTA_TMP      -> tmpdir
IMTA_LANG     -> langdir
IMTA_VERIFY_RETURN -> return_verify
IMTA_RETURN_CLEANUP_PERIOD -> return_cleanup_period
IMTA_RETURN_SPLIT_PERIOD -> return_split_period
```

The SERVERROOT value is used to construct the DATAROOT value (either `/var/`SERVERROOT or SERVERROOT`/data`) and CONFIGROOT value (either `/var/`SERVERROOT`/config` or SERVERROOT`/config`).

Chapter 4 Recipe language

Recipe files are used to automate configuration management tasks within the `msconfig` utility. Recipe files are expressed using a domain specific language. Since recipe files are intended to manipulate configuration information, many parts of which most naturally appear as names and string values or lists of strings, the recipe language is rather string oriented. The primary inspirations for the recipe language is the Icon programming language designed by Ralph Griswald as well as the IETF's Sieve mail filtering language.

Recipe file syntax includes C-like expressions, operators, and assignments, Sieve-like conditionals, and loops. The available data types are integers, strings, and lists.

Like `msconfig` itself recipes can only be used with a unified configuration.

Note that `imsimta test -expression -xc` can be used to test the syntax of recipe operations.

Recipes are typically written to operate in several phases:

1. Checks are done to make sure the right conditions exist for the recipe to be effective. If the desired conditions aren't met the recipe can either issue a warning or exit with an error.

2. The recipe asks a number of questions to determine exactly what changes should be made.

3. The recipe optionally uses the `continue` function to make sure the user wishes to proceed if any warnings were issued.

4. Finally, the recipe implements the requested changes.

Note that while this is the typical ordering, recipes are not constrained to use it and may use other approaches if appropriate.

4.1 Comments

The # character indicates that the remainder of a line is a comment.

4.2 Integer values

Integers are expressed as decimal values with an optional sign. An optional base specification prefix can be used to write values in other bases:

```
2%10 == 2
16%ff == 255
2%-1010 == -10
```

All integers are represented internally as signed 32 bit values.

4.3 String values and list values

As recipe files are intended for manipulating configuration files and parameters, which are generally thought of most naturally as strings or lists of strings, the recipe language is rather string oriented.

A string value is written simply as characters within double quotes, *e.g.*,

```
"a sample string"
"strings may
include line breaks"
```

Backslashes have special meaning in string values:

```
"\""     - quote
"\t"     - tab
"\r"     - carriage return
"\n"     - line feed
"\\"     - backslash
"\uNNNN" - Unicode character, must specify exactly 4 hex digits
           (new in MS 8.0.2.3)
```

A list value is written as a comma-separated list of elements, delimited by brackets, *e.g.*,

```
["e1", "e2", "e3", "e4"]
```

As of MS 8.1.0.1 trailing commas are allowed in lists, making them easier to maintain:

```
["c1", "c2", ]
```

Note that the elements of a list are always strings.

4.3.1 Optlists

Optlists are regular lists with an even number of elements. The elements are processed in pairs: the first element in a pair is the "name" element while the second element is the "value" element. A number of the built-in functions are designed to work with optlists. The special case of empty string as the first element in a pair is used to represent annotations; in this case the second element of the pair contains the annotation text.

4.4 Variables

Variables may have integer, string, or list values. Variables are created by assigning them a value; no type declarations are necessary. Variable names are case-insensitive.

```
v = 1;
w = "this is a test";
x = ["a", "b", "c"];
```

Variables may be used in most places where a string, integer, or list value is expected, including in list constructs. Given:

```
s = "string";
l = ["list"];
```

the following expressions are true:

```
[s] == ["string"]
[s,s] == ["string", "string"]
[s,l] == ["string", "list"]
[l,l] == ["list", "list"]
```

4.4.1 Variable indices

Substrings and sublists may be referenced through the use of indices. Indices into strings and lists point not at characters, but between characters, as for strings in the Icon programming language. That is, 1 points just before the first character, 2 between the first and second character, *etc*., and 0 points just after the last character, -1 points between the penultimate and last characters, -2 between the antepenultimate and penultimate characters, *etc*. The expression `s[i]` returns the character immediately following the interstice pointed to by the index.

For instance, if

```
s = "abcdef";
```

then the following expressions are true:

```
s[1] == "a"
s[3] == "c"
s[6] == "f"
s[-1] == "f"
s[-4] == "c"
s[-6] == "a"
```

whereas `s[0]` is illegal as it is trying to return the character after the last one in the string.

When a range is specified, then the substring between the two indices is returned. There is no question about whether this is inclusive or exclusive as the indices point at interstices. Thus again taking as a sample string:

```
s = "abcdef";
```

the following expressions are true:

```
s[1,0] == s
s[1,0] == "abcdef"
s[1,2] == "a"
s[2,0] == "bcdef"
s[2,-1] == "bcde"
s[-3, -1] == "de"
s[i,i] == ""  # when 1 <= i <= length(s)+1
              # or -length(s) <= i <= 0
s[1,i+1] == left(s,i)
s[-i,0] == right(s,i)
```

Indices can be used on the left hand side of assignment statements. For example, after the assignment

```
s[1] = "z";
```

`s` will have the value "`zbcdef`".

List indices operate in a similar fashion, except that indices refer to list elements rather than characters. Single value list indices return a string while two-valued indices return a sublist. So if `l` is given a value

```
l = ["a","b","c",d","e","f"];
```

the following expressions are all true:

```
l[1] == "a"
l[3] == "c"
l[6] == "f"
l[-1] == "f"
l[-4] == "c"
l[-6] == "a"
l[1,0] == ["a", "b", "c", "d", "e", "f"]
l[1,2] == ["a"]
```

```
l[2,0] == ["b", "c", "d", "e", "f"]
l[2,-1] == ["b", "c", "d", "e"]
l[3,-1] == ["c", "d", "e"]
l[-3,-1] == ["d", "e"]
```

Note that parentheses may be used in place of square brackets for indexing.

4.5 Statements

The if...then...else... statements in the recipe language are akin to those of the Sieve email filtering language:

```
if expression { ... }

if expression { ... }
else { ... }

if expression { ... }
elsif { ... }

if expression { ... }
elsif { ... }
else { ... }
```

A general loop construct is also provided, with the syntax:

```
loop {
      ...
      exitif (expression);
      ...
      nextif (expression);
      ...
     }
```

A loop may contain zero or more `exitif` and/or `nextif` statements. The loop terminates if the argument to `exitif` evaluates to `true`. New in 8.0.2.3, `nextif` can be used to cause the loop to restart if the associated condition evaluates to `true`.

Loops may be nested:

```
loop {
      ...
      loop {
            ...
            exitif (expression-1); # Exit from inner loop #1
      }
      ...
      exitif (expression-2); # Exit from outer loop
      ...
      loop {
            ...
```

```
            exitif (expression-3); # Exit from inner loop #2
        }
    }
```

Assignment statements are akin to those of the C programming language.

```
a = "string";
b = 2;
c = d = ["list"];
```

4.6 Operators

The recipe language provides a variety of prefix, postfix, and infix operators. The following table lists the available operators in order of decreasing precedence.

Table 4.1 Operators in Order of Precedence

Operator	Description	Precedence
?*v*	Force interpretation of *v* as a variable, rather than as a pre-defined function	19
***f*(...)**	Function call	18
Index		
***sl*[*i*]**	Return the *i*th character of string/list *sl*+	17
***sl*[*i*,*j*]**	Return the *i*th through *j*th characters of string/list *sl*+	17
***sl*(*i*)**	Return the *i*th character of string/list *sl*	17
***sl*(*i*,*j*)**	Return the *i*th through *j*th characters of string/list *sl*	17
Increment/decrement		
***v*++**	Return *v* and then increment its value (*v* must be a variable with an integer value)	16
***v*--**	Return *v* and then decrement its value (*v* must be a variable with an integer value)	16
++*v*	Increment the value of *v* and then return it (*v* must be a variable with an integer value)	16
--*v*	Decrement the value of *v* and then return it (*v* must be a variable with an integer value)	16
Unary bitwise and logical		
~*n*	Bitwise not	15
!*n*	Logical not	15
Arithmetic and concatenation		
-*n*	Integer negation	14
+*n*	Integer plus	14
n * *m*	Integer multiplication, string/list cross product	13
n / *m*	Integer division	13
n % *m*	Integer modulus	13

n **+** *m*	Integer addition, string/list element by element concatenation	12
n **-** *m*	Integer subtraction	12
n **.** *m*	String/list concatenation	12
n **<<** *m*	Left shift	11
n **>>** *m*	Right shift	11
Comparisons		
n **<** *m*	Less than	10
n **<=** *m*	Less than or equal to	10
n **>=** *m*	Greater than or equal to	10
n **>** *m*	Greater than	10
n **==** *m*	Equal to	9
n **!=** *m*	Not equal to	9
Infix bitwise		
n **&** *m*	Bitwise and	8
n **^** *m*	Bitwise xor	7
n **|** *m*	Bitwise or	6
n **contains** *m*	String/list *n* contains string *m*. The position of the first match in the string is returned if *n* is a string; the position of the first matching string in the list is returned if *n* is a list.	5
n **matches** *m*	String/list *n* is matched by the glob pattern*m* true/false is returned if *n* is a string, the position of the first matching string in the list is returned if *n* is a list.	5
Infix logical		
n **&&** *m*	Logical and	4
n **^^** *m*	Logical xor	3
n **||** *m*	Logical or	2
Conditional		
p **?** *n* **:** *z*	*n* if *p* is nonzero, *z* otherwise	1
p **? :** *z*	(New in MS 8.1.0.3) *p* if *p* is nonzero, *z* otherwise	1
p **?** *n*	(New in MS 8.1.0.3) *n* if *p* is nonzero, *p* (0) otherwise	1
Assignment		
v **=** *e*	Assign *v* the value of *e* (*v* must be a variable)	0
v **+=** *e*	Add/concatenate the value of *e* to *v* (*v* must be a variable)	0
v **-=** *e*	Subtract the value of *e* from *v* (*v* must be a variable with an integer value)	0
v ***=** *e*	Multiply/cross product *v* by the value of *e* (*v* must be a variable)	0
v **/=** *e*	Divide *v* by the value of *e* (*v* must be a variable with an integer value)	0

v **&=** *e*	Bitwise and *e* into *v* (*v* must be a variable with an integer value)	0
v **|=** *e*	Bitwise or *e* into *v* (*v* must be a variable with an integer value)	0
v **^=** *e*	Bitwise xor *e* into *v* (*v* must be a variable with an integer value)	0
v **<<=** *e*	Left shift *v* by *e* (*v* must be a variable with an integer value)	0
v **>>=** *e*	Right shift *v* by *e* (*v* must be a variable with an integer value)	0
v **.=** *e*	Concatenate the value of *e* onto *v* (*v* must be a variable)	0
v1 **:=:** *v2*	Exchange the values in *v1* and *v2* (*v1* and *v2* must both be variables)	0

[+] Most operators are available for use in Sieve filters, as well as in recipes, *except* for use of square brackets, `[...]`, for indexing into strings or lists. Sieve filter syntax uses square brackets to indicate Sieve lists, so in Sieve filters the alternate syntax for substring indexing of `(...)` must be used.

4.7 Functions

The recipe language provides a large number of built-in functions. The following table lists all of the built-in functions in alphabetical order; subsequent subsections describe all recipe-specific functions in groups. For general string/list/integer functions, see Symbol table functions.

Table 4.2 Alphabetical List of Built-in Functions

Function	Description
abs(*i***)**	Return the absolute value of the numeric value *i*.
add_alias(*s*,*c*[,*e*]**)**	New in 8.0.1.2. Adds an alias named *s* containing the optlist *c* and, optionally, additional alias entries from the list *e*. An error will be returned if the alias already exists. Each element of the optlist specifies an alias option and its corresponding value. An empty string must be specified for alias options that do not accept a value.
add_channel(*s*,*c***)**	Adds a channel named *s* containing the optlist *c*. An error will be returned if the channel already exists. Each element of the optlist specifies a channel option and its corresponding value. An empty string must be specified for channel options that do not accept a value.
add_group(*g*,*c***)**	Adds a group named *g* containing the optlist *c*. An error will be returned if the group already exists. Each element of the optlist specifies a group element and its corresponding value.
add_mapping(*s*,*c***)**	Adds a mapping named *s* containing the optlist *c*. The mapping must not already exist. Each element of the optlist specifies either a mapping rule or an annotation. The name part of an optlist element specifies the rule pattern while the value part specifies the rule template.
allof(*i1*[,*i2*...]**)**	Returns a nonzero (true) value if all of *i1*, *i2*, ... are nonzero; returns `0` otherwise.

any(*s1*,*s2*)**	Return 2 if any character in *s1* appears as the first character of *s2*; return 0 otherwise.
anyof(*i1*[,*i2*...]**)**	Returns a nonzero (true) value if any of *i1*, *i2*, ... are nonzero, returns 0 if all are zero.
append_alias(*s*,*c*[,*e*]**)**	New in 8.0.1.2. Append the alias options specified in the optlist optlist *c* and, optionally, the alias entries specified by the list *e* to the alias named by *s*. The alias will be created if it doesn't already exist.
append_group(*s*,*c***)**	Appends the contents of optlist *c* to the group named *s*. The group will be created if it doesn't already exist. Each element of the optlist specifies a group element and its corresponding value.
append_mapping(*s*,*c***)**	Appends the contents of optlist *c* to the mapping named *s*. The mapping will be created if it doesn't already exist. Each element of the optlist specifies either a mapping rule or an annotation. The name part of an optlist element specifies the rule pattern while the value part specifies the rule template.
append_rewrites(*c***)**	Appends the contents of optlist *c* to the current set of rewrite rules. Each element of the optlist specifies either a rewrite rule or an annotation. The name part of an optlist element specifies the rule pattern while the value part specifies the rule template.
argc	(New in 8.0) Returns the number of additional arguments given to the `msconfig run` command.
argv(*n***)**	(New in 8.0) Returns the *n*th argument given to the the `msconfig run` command as a string. The value *n* must be between 1 and **argc** inclusive.
bal(*c1*,*c2*,*c3*,*s***)**	Scan *s* looking for an occurrence of a character in *c1* that is balanced with respect to *c2* and *c3*. Returns the position of the first balanced *c3* character in *s* if one is found, `length(s)+1` if no *c3* character is found but the string as a whole is balanced, or 0 if the string isn't balanced.
call_user(*s1*,*s2*,*e*[,*e2*...]**)**	Call the routine named *s2* in the external library image *s1*, passing the argument *e* (and optionally additional, comma-separated arguments).
chr(*i1*[,*i2*...]**)**	Returns a string containing successive characters with decimal values *i1*, *i2*, ...
continue([*s1*[,*s2*]]**)**	The `continue` function does nothing if no warnings have been issued during the execution of the recipe. If one or more warnings have been issued by the recipe, the administrator is prompted with the string *s1*. An empty response or a response beginning with "Y" (yes) or "T" (true) will cause the script to continue running; any other response will cause the script to abort. A default prompt of "`Some warnings have occurred. Do you want to continue [N]? `" will be used if no value for *s1* is specified. An optional argument *s2* may be supplied as a default response to `continue`; for instance, `continue("Continue [y]? ","Y")` will mean that a user empty (carriage return) response will mean to continue.
continue	The `continue` function does nothing if no warnings have been issued during the execution of the recipe. If one or more warnings have been issued by the recipe, and `continue` was not provided with a prompt string, then the administrator is prompted with the default prompt "`Some warnings have occurred. Do you want to continue`

	`[N]?` ". An empty response or a response beginning with "Y" (yes) or "T" (true) will cause the script to continue running; any other response will cause the script to abort.
decode *[:e] s*	Decodes the string *s* from the specified encoding *:e*. The *:e* nonpositional parameter must be one of :base64, :base85, :hex, :idn, or :quotedprintable. The default is :hex.
default	Undoes the effect of `instance` or `role`: options are interpreted as being of their preferred flavor.
defined(*s***)**	Returns `1` if *s* is defined as a variable; return `0` otherwise.
delete_alias(*s***)**	New in 8.0.1.2. Delete the alias named *s*. No operation is performed if the alias does not exist.
delete_channel(*s***)**	Delete the channel named *s*. No operation is performed if the channel does not exist.
delete_file(*s***)**	New in 8.0.1.2. Delete the file named *s*. Returns `1` if the delete operation succeeded, and `1` if not.
delete_group(*s***)**	Delete the group named *s*. No operation is performed if the group does not exist.
delete_mapping(*s***)**	Delete the mapping named *s*. No operation is performed if the mapping does not exist.
delete_options(*l***)**	Deletes all values associated with the options specified in the list *l*.
delete_optlist(*o*,*n*...**)**	Delete option *n* from optlist *o* and return the resulting modified list. The original optlist is returned if the specified option does not appear in the optlist. Additional option names can be specified to delete multiple options from the optlist. As of MS 8.0.1.3, *n* can be a two element list specifying a name/value pair to be removed from the list.
delete_rewrites(*l***)**	Delete the rewrite rules specified in list *l*. No operation is performed if such rewrite rules do not exist.
delete_statefile(*v***)**	Delete the specified statefile variable *v*. The function returns `true` if the delete operation was successful; `false` if statefile support is not enabled.
deploymap ...	(New in MS 8.0.1.1.0) Perform various operations on and obtain data from the deployment map.
deploymap :add *[***:deployment** *d]* **:host** *h [***:role** *r]*	(New in MS 8.0.1.1.0) Add host(s) *h* with role *r* to deployment *d* in the deployment map. *h* may be either a string or list. An error occurs if any of the hosts already exist. The current deployment is used if *d* is not specified; if there is no current deployment, then the first deployment in the deployment map is selected; a deployment with the default name "`site-01`" will be created if no deployment exists in the deployment map. No role with be associated with the host(s) if *r* is not specified. Returns the number of modifications that were made to the deployment map.
deploymap :add *[***:deployment** *d]* **:host** *h* **:property** *p*	(New in MS 8.0.1.1.0) Add property/properties *p* to host *h* in deployment *d*. Host *h* will be created if it does not already exist. The current deployment is used if *d* is not specified; if there is no current deployment, then the first deployment in the deployment map is selected; a deployment with the default name "`site-01`" will be

	created if no deployment exists in the deployment map. Returns the number of modifications that were made to the deployment map.
deploymap :add *[***:deployment** *d]* **:host** *h* **:property** *p* **:role** *r*	(New in MS 8.0.1.1.0) The host *h* is created in deployment *d* with role *r* and properties *p*. The host must not already exists. The current deployment is used if *d* is not specified; if there is no current deployment, then the first deployment in the deployment map is selected; a deployment with the default name "`site-01`" will be created if no deployment exists in the deployment map. Returns the number of modifications that were made to the deployment map.
deploymap :create	(New in MS 8.0.1.1.0) Create a new, empty deployment map. Note that if you write this out using `msconfig`'s `DEPLOYMAP WRITE` command you will delete all your existing entries!
deploymap :delete :deployment *d*	(New in MS 8.0.1.1.0) Delete the deployment named by string *d* from the deployment map. Deleting a nonexistent deployment is a no-op. Returns the number of modifications that were made to the deployment.
deploymap :delete *[***:deployment** *d]* **:host** *h*	(New in MS 8.0.1.1.0) Delete host(s) *h* from deployment *d*. *h* can be either a string or list. Deleting a nonexistent host is a no-op. The current deployment is used if *d* is not specified; if there is no current deployment, the first deployment in the deployment map is selected. Returns the number of modifications that were made to the deployment map.
deploymap :delete *[***:deployment** *d]* **:host** *h* **:role** *r*	(New in MS 8.0.1.1.0) Delete any role associated with host(s) *h* in deployment *d*. Deleting a nonexistent role is a no-op. An error occurs if host *h* does not exist. The current deployment is used if *d* is not specified; if there is no current deployment, the first deployment in the deployment map is selected. Returns the number of modifications that were made to the deployment map.
deploymap :delete *[***:deployment** *d]* **:host** *h* **:property** *p*	(New in MS 8.0.1.1.0) Delete any properties for host(s) *h* (which may be a string or list) in deployment *d* that match the glob-wildcarded values in string or list*p*. The current deployment is used if *d* is not specified; if there is no current deployment, the first deployment in the deployment map is selected. Returns the number of modifications that were made to the deployment map.
deploymap :dump	(New in MS 8.0.1.1.0) Returns a string containing an outline of the entire deployment map.
deploymap :list...	(New in MS 8.0.1.1.0)
deploymap :read *s*	(New in MS 8.0.1.1.0) Reads a JSON-format deployment map from string *s*.
deploymap :rename *s* **:deployment** *d*	(New in MS 8.0.1.1.0) Renames deployment *d* to *s*. *d* must specify an existing deployment; *s* must be a nonempty utf-8 string. Returns the mumber of modifications that were made to the deployment map.
deploymap :rename *[***:deployment** *d]* *s* **:host** *h*	(New in MS 8.0.1.1.0) Renames host *h* in deployment *d* to *s*. The current deployment is used if *d* is not specified; if there is no current deployment, then the first deployment in the deployment map is selected. Host *h* must already exist and *s* must be a valid domain name. Returns the mumber of modifications that were made to the deployment map.

deploymap :set *[*:**deployment** *d]* **:host** *h* **:role** *r*	(New in MS 8.0.1.1.0) Sets the role for host(s) *h* in deployment *d* to *r*. *h* can be either a string or list. The specified host(s) *h* must already exist in the deployment. The current deployment is used if *d* is not specified; if there is no current deployment, then the first deployment in the deployment map is selected. Returns the number of modifications that were made to the deployment map.
deploymap :write	(New in MS 8.0.1.1.0) Returns the contents of the current deployment map as a JSON-formatted string. Note that no mechanism is provided in the recipe language to update the active deployment map; this can only be done at the `msconfig` level.
description(*d***)**	The `description` function is used to provide a description of the function of a recipe. The value of the string argument *d* is displayed when the recipe is processed by the `msconfig directory` command. Note that *d* must be a literal string enclosed in quotes; it cannot be an expression. When the recipe is executed the `description` function does nothing other than return the value of its argument *d*.
edit(*s***)**	Place the value of the string *s* in a temporary file and invoke the external editor specified by the `EDITOR` environment variable on the file. When the editor returns the `edit` function returns the (possibly modified) file content.
encode *[:e] s*	Encodes the string *s* into the specified encoding *:e*. The *:e* nonpositional parameter must be one of :base64, :base85, :hex, :idn, :param, :quotedprintable, or :url. The default is :hex.
error(*s***)**	Issue error string *s* back to administrator executing the recipe.
exists_alias(*s***)**	New in 8.0.1.2. Returns a nonzero integer (specifically, the number of entries in the alias group) if the alias named *s* exists, zero if it does not.
exists_channel(*s***)**	Returns a nonzero integer (specifically, the number of channel options set on the channel) if the channel named *s* exists, zero if it does not.
exists_file(*s***)**	Returns `1` if the file named by *s* exists, `0` if it doesn't. If only a file name is specified with no path, `msconfig` looks in the MTA configuration directory, `IMTA_TABLE:`.
exists_group(*s***)**	Returns a nonzero integer if the group named *s* exists, zero if it does not.
exists_mapping(*s***)**	Returns a nonzero integer if the mapping named *s* exists, zero if it does not.
exists_option(*s***)**	Returns the number of values currently set for the option *s*. A value of `0` is returned if the option isn't set.
exists_optlist(*o***,***s***)**	Returns `1` value if the the optlist *o* contains an option named *s*, `0` otherwise.
exists_statefile(*v***)**	Returns 1 if the statefile variable named *v* is defined, 0 if it is not, and -1 if statefile support has not been enabled with the `--statefile` switch.
find(*s1***,***s2***[,***i***,***j***])**	Returns the position of the first occurrence of *s1* in *s2*`[`*i*`:`*j*`]`. The entire string is searched if `i` and `j` are omitted.
find(*s***,***l***[,***i***,***j***])**	Returns the position of the first list element from *l*`[`*i*`:`*j*`]` that matches *s*. The entire list is searched if `i` and `j` are omitted.

get_alias(*s*)	New in 8.0.1.2. Returns the definition (alias options) of the alias named *s* as an optlist. An empty list is returned if the alias does not exist.
get_channel(*s*)	Returns the definition (channel options) of the channel named *s* as an optlist. An empty list is returned if the channel does not exist.
get_default(*s*)	Returns the built-in default for the specified option *s* as a string. An empty string is returned if the option has no default. A error occurs if the option does not exist. New in MS 8.0.2.1.
get_group(*s*)	Returns the content of the group named *s* as an optlist. An empty list is returned if the group does not exist.
get_mapping(*s1*[,*s2*[,*s3*]])	Returns the content of the mapping named *s1* as an optlist. An empty list is returned if the mapping does not exist. Optionally, strings *s2* (string with wildcards to match patterns) and *s3* (string with wildcards to match templates) may be specified, to restrict which entries of the named mapping to return. If not specified, *s2* and *s3* each default to "*", meaning that *all* of the entries of the named mapping will be returned.
get_msconfig_info(*s*)	New in MS 8.0.2.3. Return the value of the msconfig information item *s*. An error occurs if an unknown item is specified. Note that *s* is not case sensitive.
get_option(*s*)	Returns the value of the option named *s* as a string. An error will occur if the specified option name is invalid or matches multiple options. An empty string is returned in two cases: if the specified option is a valid no-value option that is set, or if the specified option is valid but not set.
get_option_modification_locations	(New in 8.0.6) Returns a list of locations in the current recipe where a configuration modification occurred.
get_options(*s*)	Returns the names and values of the options named *s* as an optlist. (Note that when an option is set in both role and instance flavors, only the instance is returned.) An empty list is returned if the specified option is valid but not set.
get_optlist(*o*,*s*)	Returns the value of the option named *s* from the optlist *o* as a string. An empty string is returned if the specified option is not in the optlist.
get_path(*r*)	(New in 8.0) Returns a path to a directory in the server instance. The argument *r* can be one of "`server`", "`data`", or "`config`", which will return the path to the server root, the data root, or configuration root directories, respectively.
get_rewrites[(*p*[,*t*])]	Returns the selected set of rewrite rules as an optlist. *p* specifies a glob-style pattern to apply to the pattern part of each rewrite rule; only rules that match the pattern will be returned. Similarly, *t* specifies a glob-style pattern to apply to the template part of each rewrite rule; only the rules whose templates match the pattern will be returned. Both arguments are optional; if neither is specified then all rewrite rules are returned.
get_statefile(*v*)	Returns the value of the statefile variable named *v*. An empty string is returned if the specified variable is not in the statefile or statefile support has not been enabled with the `--statefile` switch.
get_system_info(*s*)	New in 8.0.1.2. Return the value of the system information item *s*. An error occurs if an unknown item is specified. Note that *s* is not case sensitive.

getenv(*s***)**	Return the value of the environment variable *s*. An empty string is returned if *s* is not defined. Note that *s* is case sensitive.
hash *[:e] [:h] v*	Returns the hash of the value *v*. *v* may be either a string or a list; if a list is specified, a separate hash is computed for each element and returned as a new list. The hash *:h* may be any of `:md2`, `:md4`, `:md5`, `:sha1`, `:sha256`, `:sha512`, `:ripemd128`, or `:ripemd160`; the default is `:sha1`. (Support for `:sha256` and `:sha512` is new in MS 8.0.2.3.) An encoding may optionally be applied; *:e* may be any of `:hex`, `:quotedprintable`, `:base64`, `:base85`, or `:binary`. `:binary`, or no encoding, is the default.
hash_hmac *[:e] [:h] k v*	Returns the hmac of the value *v* using key *k*. *v* may be either a string or a list; if a list is specified, a separate hmac is computed for each element and returned as a new list. The underlying hash function *:h* may be any of `:md2`, `:md4`, `:md5`, `:sha1`, `:sha256`, `:sha512`, `:ripemd128`, or `:ripemd160`; the default is `:sha1`. (Support for `:sha256` and `:sha512` is new in MS 8.0.2.3.) An encoding may optionally be applied; *:e* may be any of `:hex`, `:quotedprintable`, `:base64`, `:base85`, or `:binary`. `:binary`, or no encoding, is the default.
instance	Operate on `instance` options.
integer(*e***)**	Converts *e* to an integer. If *e* is already an integer, it is returned unchanged; if *e* is a string, it is read as a sequence of ASCII digits. If *e* is a list, it must contain one element and that element is treated in the same way a string would be.
keywords(*l***)**	The `keywords` function is used to provide a list of keywords associated with a recipe. The value of the list argument *l* is displayed when the recipe is processed by the `msconfig directory` command.
lcase(*e***)**	Converts any upper case characters in *e* to lower case. If *e* is a number, it is converted to a string.
ldap_init(*o***)**	(New in MS 8.0.1) Initializes the built in LDAP client. This call must be performed prior to using any of the other `ldap_*` functions. The client uses the current settings of the configuration options `ugldaphost`, `ugldapbinddn`, `ugldapbindcred`, `ugldapport`, and `ugldapusessl` when it initializes. The single argument *o* is an optlist specifying override values for any or all of these options. The optlist may be empty. Repeated calls will shut down and reinitialize the LDAP client with new settings. The LDAP client is shut down automatically when the recipe terminates.
ldap_ldif(*s***[,***f***])**	(New in MS 8.0.1) Apply the LDIF specified in the string *s* to the LDAP directory. Any LDAP error that occurs will be treated as a recipe warning (but see the bit 12 in the flag argument). The optional argument *f* is a bit-encoded integer specifying a number of flags. The currently defined flag bits are: • Bit 0 (value 1) - if set, continue processing after any error, • Bit 1 (value 2) - if set, treat "entry exists" on add as success, • Bit 2 (value 4) - if set, allow no-such-object if hint present, and

	• Bit 12 (value 4096) - if set, treat any LDAP error that occurs as a recipe error. An integer count of the number of successful modifications performed is returned. `ldap_init` must be called before calling `ldap_ldif`.
`ldap_search(`*`o[,n]`***`)`**	(New in MS 8.0.1.1.0) The `ldap_search` function takes an optlist argument specifying at least the `basedn` for the search, and optionally also the attribute to return (`attrs`), the `scope` of the search, and a filter (`filter`) for the search. Valid values for the "`scope`" are: `base`, `onelevel` (or `one`), `subtree` (or `sub`). An optional second integer argument specifies the number of entries to return, and defaults to `-1` (return all entries) if omitted. The function returns an optlist containing the attribute-value pairs matching the search.
`left(`*`s1,i[,s2]`***`)`**	Returns the leftmost *`i`* characters of *`s1`*. If *`i`* is greater than `length(`*`s1`*`)` the result is padded with *`s2`*. As much of *`s2`* as is necessary will be used; if *`s2`* is too short it will be used multiple times. *`s2`* defaults to a space if it is omitted.
`left(`*`l1,i[,l2]`***`)`**	Returns the leftmost *`i`* elements of *`l1`*. If *`i`* is greater than `length(`*`l1`*`)` the result is padded with *`l2`*. As much of *`l2`* as is necessary will be used; if *`l2`* is too short it will be used multiple times. *`l2`* defaults to one empty list element if it is omitted.
`length(`*`s`***`)`**	Returns the number of 8-bit characters in the string *`s`*.
`length(`*`l`***`)`**	Returns the number of elements in the list *`l`*.
`list(`*`s,n`***`)`**	Returns a list *`n`* elements long with each element equal to *`s`*.
`list(`*`l,n`***`)`**	Returns a list consisting of *`n`* copies of *`l`*.
`list_names(`*`s[,n]`***`)`**	Returns the options whose name begins with the specified string *`s`* as an optlist. The optional integer second argument specifies whether or not to retain backslash characters in the options' values; the default is `0` (false).
`make_path(`*`p`***`)`**	Converts a path *`p`* using `IMTA_TABLE:` and similar MTA-specific constructs into a proper file path. Note that the path that's constructed may only be valid on the system where `msconfig` is running.
`match(`*`r,s`***`)`**	Returns `1` (true) if the regular expression *`r`* matches a substring of string *`s`*, `0` (false) otherwise. Note that the pattern *`r`* may be prefixed with "`^`" (match beginning of line) and suffixed with "`$`" (match end of line) to require a full string match. The regular expression vocabulary is compatible with that of the TCL/TK scripting language.
`map(`*`s1,s2,s3`***`)`**	Returns a string obtained by mapping characters of *`s1`* that occur in *`s2`* into corresponding characters in *`s3`*. Characters that don't appear in *`s2`* are unchanged.
`max(`*`i,j[,...]`***`)`**	Returns the largest element in a set of integers.
`max(`*`s1,s2[,...]`***`)`**	Returns the largest element in a set of strings.
`min(`*`i,j[,...]`***`)`**	Returns the smallest element in a set of integers.
`min(`*`s1,s2[,...]`***`)`**	Returns the smallest element in a set of strings.
`ord(`*`s`***`)`**	Returns the ordinal value of the first character of *`s`*, which must contain at least one character.

pop(*l***)**	Returns the first element of list *l*. The element is deleted from the list. *l* must be a variable with a list value.
prepend_alias(*s***,***c***[,***e***])**	New in 8.0.1.2. Prepends the contents of optlist *c*, and, optionally, the alias entries from the list *e*, to the alias named *s*. The alias will be created if it doesn't already exist.
prepend_group(*s***,***c***)**	Prepends the contents of optlist *c* to the group named *s*. The group will be created if it doesn't already exist.
prepend_mapping(*s***,***c***)**	Prepends the contents of optlist *c* to the mapping named *s*. The mapping will be created if it doesn't already exist.
prepend_rewrites(*c***)**	Prepends the contents of optlist *c* to the rewrite rules.
print(*s***)**	Print the string *s* on the administrator's terminal.
push(*l***,***s***)**	Adds the string *s* to the beginning of list *l*. The list *l* is updated as well as being returned. *l* must be a variable with a list value.
put_optlist(*o***,***s***,***v***...)**	Put the option *s* with the value *v* in optlist *o* and return the resulting modified list. The option's value is replaced if the option is already present. Additional name-value pairs can be specified in the call to put multiple options on the optlist.
random(*n***)**	Returns a random integer value between 0 and *n-1*.
randomseed(*n***)**	Seeds the random number generater function random with the integer seed value *n*.
read(*s1***[,***s2***[,***s3***]])**	Read and return a string from the administrator terminal, prompting with the string *s1*. The optional string argument *s2* provides a default value for the function to return, if the administrator does not enter an explicit value (merely enters a null response). New in MS 8.0.2.3, the string argument *s3* specifies the name of a statefile variable whose value is used if present or will be updated with whatever value is entered.
read_file(*s***)**	Reads and returns the content of the file named by *s*. `msconfig` looks in the MTA configuration directory, `IMTA_TABLE:`, if *s* specifies only a file name with no path. An error occurs if the file doesn't exist or cannot be read. Line feeds are used as line separators.
read_optlist(*s***)**	Converts a string *s* containing options into an optlist which is returned. The string *s* should be formatted with options expressed as *name=value* delimited by CR or LF. Leading space or horizontal tab characters prior to a *name* will be ignored (though space and horizontal tab are allowed and retained within a *value*). Comments, which start with exclamation point `!` or hash character #, will be ignored.
read_password *[***:minlength** *n1] [***:maxlength** *n2] [***:upper** *n3] [***:lower** *n4] [***:digit** *n5] [***:symbol** *n6] [s1] [s2]*	Read a password from the administrator terminal, returning it as a string. Optional parameters may be used to specify requirements that the password must meet: `:minlength` default is `-1` (no minimum), `:maxlength` default is `-1` (no maximum), by default no requirements are placed on number of upper case characters, lower case characters, digits, or symbols (respectively, `:upper`, `:lower`, `:digit`, `:symbol`). The administrator is prompted with string *s1* (default "`Password: `") and optionally may be prompted to verify the password with string *s2* (default "`Verify `").
repl(*s***,***j***)**	Returns a string consisting of *j* concatenatations of *s*.

repl(*l*,*j***)**	Returns a list consisting of *j* concatenatations of *l*.
replace_alias(*s*,*c*[,*e*]**)**	New in 8.0.1.2. Replaces the alias named *s* with the contents of optlist *c* and, optionally, alias entries from the list *e*. The alias will be created if it doesn't already exist.
replace_channel(*s*,*c***)**	Replaces the channel named *s* with the contents of optlist *c*. The channel will be created if it doesn't already exist.
replace_group(*s*,*c***)**	For the group named by string *s*, replace its options with those in the optlist *c*.
replace_mapping(*s*,*c***)**	Replaces the contents of the mapping named *s* with the contents of optlist *c*. The mapping will be created if it doesn't already exist.
replace_rewrites(*c***)**	Replaces the current rewrite rules with the rewrite rules specified in the optlist *c*.
resolve_option(*o***)**	The string value *o* is run through the option name resolution process and the resolution results are returned as a bit-encoded integer. The option need not exist in the current configuration and is not modified in any way. Currently four bits are defined: Bit 0 (value 1), if set, indicates the path specified was valid, bit 1 (value 2), if set, indicates the name specifies a valid option (as oppose to, say, the name of an option group), bit 2 (value 4), if set, indicates that the option has been deleted and is effectively a no-op, bit 3 (value 8), if set, indicates that the option is restricted, and bit bit 4 (value 16), indicates that this is an instance-only option.
restricted(*p***)**	The `restricted` function is used to control or check the recipe's ability to modify the values of restricted options. If the `-restricted` switch was given to the `run` command, the `restricted` function returns a value of `1` (true) unconditionally. If `-restricted` wasn't specified, the argument *p* will be evaluated to determine if the user should be prompted. A zero value will return a value of `0` (false). A nonzero value will prompt the user for permission to modify restricted options. A response beginning with "`Y`", "`y`", "`T`", "`t`", or "`1`" will enable modification access to restricted options and the function will return a value of `1` (true). A response beginning with "`N`", "`n`", "`F`", "`f`", or "`0`" will return a value of `0` (false). Any other response will cause the prompt to be repeated.
reverse(*s***)**	Reverses all the characters in string *s* and returns the result.
reverse(*l***)**	Reverses all the elements in list *l* and returns the result.
right(*s1*,*i*[,*s2*]**)**	Returns rightmost *i* characters of *s1*. If *i* is greater than `length(`*s1*`)` the result is p added with *s2*. As much of *s2* as is necessary will be used; if *s2* is too short it will be used multiple times. *s2* defaults to a space if it is omitted.
right(*l1*,*i*[,*l2*]**)**	Returns rightmost *i* elements of *l1*. If *i* is greater than `length(`*l1*`)` the result is padded with *l2*. As much of *l2* as is necessary will be used; if *l2* is too short it will be used multiple times. *l2* defaults to one empty list element if it is omitted.
role	Operate on `role` options.
set_channel(*s*,*c***)**	Modify the channel named by *s* with the channel options specified by the optlist *c*. The channel will be created if it doesn't already exist.

set_option(*s*[,*v*]**)**	Set option *s* (for options that take no value), or set option *s* to the string value *v*. An error will occur if the specified option name is invalid or matches multiple options.
set_options(*o***)**	Set zero or more options specified in optlist form. Option names and values are taken from optlist *o* in the obvious way. An error will occur if any of the specified option names are invalid or match multiple options.
set_statefile(*v*,*s***)**	Set the statefile variable *v* to the value *s*. The function returns `true` if the delete operation was succesful; `false` if statefile support is not enabled.
sign(*i***)**	Returns `-1` if *i* < `0`, `0` if *i* = `0`, `+1` if *i* > `0`.
sort(*l1*[,*i*[,*l2*]]**)**	Sorts the elements of *l1* to be in ascending order if *i* <> `0` and descending order if *i* = `0`. *i* defaults to `1` if it is omitted. If *l2* is present, its elements are shifted in the same way as elements in *l1* are shifted.
split(*s*[,*c*[,*i*]]**)**	Produces a list of elements consisting of pieces of *s* delineated by characters in *c*. If omitted, *c* defaults to a comma. If *i* is `0` or `1`, zero length elements are preserved; if *i* is `2`, they are not. If omitted, *i* defaults to `1`.
split(*l*[,*c*[,*i*]]**)**	Produces a list of elements consisting of pieces of elements of *l* delineated by characters in *c*. If omitted, *c* defaults to a comma. If *i* is `0`, boundaries between the original elements aren't preserved and zero length elements can be output; if *i* is `1`, boundaries are preserved and zero length elements can be output; if *i* is `2`, boundaries aren't preserved and zero length elements are omitted. If omitted, *i* defaults to `1`.
string(*e***)**	Converts *e* to a string. If *e* is already a string, it is returned unchanged. If *e* is an integer, it is converted to a string. If *e* is a list, the string that results from concatenating the elements of *e* is returned.
string(*l*,*s***)**	Converts the list *l* to a string, inserting the string *s* between each pair of elements of *l*. So for instance `string(["a","cd","e"],"01")` would return the string `"a01cd01e"`.
string(*i*[,*j*[,*k*]]**)**	Converts the integer *i* to a string, optionally padding with zeros (on the left) so that the length of the string is *j*, and optionally outputting the result in the radix specified by *k*. So for instance `string(15,8,2)` returns `00001111`.
strongrandom(*n***)**	Returns a string containing the specified number of bytes of random value.
translate(*s1*,*s2*,*s3***)**	Interprets the string *s1* as being in the character set specified by *s2* and returns a version translated into the character set specified by *s3*.
trim(*s*[,*c*]**)**	Returns *s* with any trailing characters found in *c* removed. *c* defaults to space and tab if omitted.
trim(*l*[,*c*]**)**	Returns list *l* with any trailing characters found in *c* removed from each element. *c* defaults to space and tab if omitted.
type(*e***)**	Returns "`integer`" if *e* evaluates to an integer, "`string`" if *e* evaluates to a string, and "`list`" if *e* evaluates to a list.
ucase(*e***)**	Converts any lower case characters in *e* to upper case. If *e* is a number it is converted to a string.

unset_alias(*s*,*v*)	New in 8.0.1.2. Remove the option or options specified in the string or list *v* from the alias named *s*. Note that this function is unsuitable for use on alias entries.
unset_channel(*s*,*v*)	Remove the option or options specified in the string or list *v* from the channel named *s*.
unset_option(*s*)	Removes option *s* from the configuration. An error will occur if the specified option name is invalid or matches multiple options.
validate_option(*s1*[,*s2*])	Validate the option named *s1*: that the option name is valid and, if the optional value *s2* is supplied, that the value is a valid value. Unlike `set_option`, `validate_option` does not set the option to the specified value: it merely checks validity.
warn(*s*)	Print warning text *s* to the administrator's terminal, and update the internal setting (which may be tested via `continue`) that a (an additional) warning has occurred.
write_file(*s1*,*s2*)	Writes the contents of string *s2* into the file named by *s1*. `msconfig` writes to the MTA configuration directory, `IMTA_TABLE:`, if *s1* is merely a file name with no patch. An error occurs if the file cannot be opened or written. Line feeds should be used as line separators in the string.
write_file(*s1*,*l*[,*s2*])	Writes the contents of the list *l* into the file named by *s1*. Each list element written is terminated by the value of *s2*; line feed is the default terminator if *s2* isn't supplied. An error occurs if the file cannot be opened or written.
write_optlist(*o*)	Convert the optlist *o* to a series of "*name=value*" lines and return the resulting string containing those lines. The string is in a format suitable for writing to a file with `write_file`.
yesno(*s1*[,*m*[,*s2*]])	Prompt at the recipe administrator's terminal with prompt string *s1*. A response of "`y`", "`Y`", "`t`", "`T`", or "`1`" will be accepted as meaning yes; a response of "`n`", "`N`", "`f`", "`F`", or "`0`" will be accepted as meaning no; these are the valid responses. *m* is an integer value to use as the default if the administrator merely returns (NULL response). *s2* is a warning string to output if the administrator's input was not in the valid set of responses.

4.7.1 Configuration option access

The primary purpose of the recipe language is to manipulate the various option settings in a Messaging Server configuration. This functionality is provided by a number of separate functions. These functions all accept either an option name or optlist containing option name/value pairs as arguments. Some functions allow incomplete option names and/or wildcards while others do not.

The existence of an option setting can be determined with the **exists_option** function. This function accepts an option name string as an argument and returns a count of the number of options set in the configuration that match the name. `0` (false) is returned if no options are set that match the name. For example:

```
exists_option("os_debug")      -> 0  (os_debug is not currently set)
exists_option("channel:tcp_*") -> 42 (42 options are set on tcp_ channels)
```

As of MS 8.0.2.1, the default value for an option setting can be determined with the **get_default** function. It returns the built-in default for the option. An empty string is returned if the option has no built-in default value. An error occurs if the specified option does not exist.

The **list_names**(*s*[,*n*]) function returns, as an optlist, a list of the options (and their values) whose names begin with the specified string *s*. The optional integer second argument, *n*, specifies whether or not to retain backslash characters (for quoting special characters) in the options' values; the default is 0 (false).

The **get_option** function returns the value of a single option. An error will occur if the name given matches multiple options or does not exist. An empty string will be returned in either or two cases: if the specified option name is valid and the option is a no-value option which is set, or if the specified option name is valid for a valued option which is not set. (So note that get_option is not sufficient for checking whether a no-value option is set; instead use exists_option to check on a whether or not a no-value option is set.)

```
get_option("mm_debug")        -> 0       (mm_debug is set to 0)
get_option("os_debug")        -> ""      (os_debug, valued option, is not set)
get_option("slave_debug")     -> ""      (slave_debug, no-value, may be set)
exists_option("slave_debug") -> 0        (slave_debug not set)
get_option("*_debug")         -> <error> (multiple *_debug options)
```

The function **get_options**(*s*) returns an optlist containing the names and values of the options with name *s*. (So note that unlike get_option, the result returned by get_options has no ambiguity and differentiates between set no-value options *vs.* unset valued options.) Note that when both role and instance flavors of an option are set get_options returns only the instance flavor of the option.

The function **set_option**(*s*[,*v*]) sets the option named *s* for options that take no value, or sets the option names *s* to the value *v* for options that do take a value. The function **set_options**(*o*) sets the option-value pairs in the optlist *o*.

The **unset_option**(*s*) unsets (deletes) the option named by the string *s*. The **delete_options**(*l*) function deletes (unsets) the options named in the list *l*.

New in MS 8.0.2, recipes support a **resolve_option** function. This function accepts a single string argument which then undergoes the option resolution process. The result of that process is then returned as a bit-encoded integer. The bits are:

Table 4.3 resolve_option return bits

Bit	Value	Meaning
0	1	Set if name resolved, clear if name invalid
1	2	Set if the string specified a valid option name, clear otherwise (Note that an option string can specify the name of a group, in which case this bit will be clear but bit 0 will be set.)
2	4	Set if option has been deleted and no longer has any effect
3	8	Set if option is restricted
4	16	Set if option is targeted for use in instances only

The **validate_option**(*s1*[,*s2*]) function validates that the specified option name is valid, and that the specified value is valid. It does *not* actually set the option to the specified value. For instance:

```
validate_option("service:SMTP.enable","test")     -> 0
validate_option("service:SMTP.enable","0")        -> 1
```

The **instance** and **role** functions tell the recipe to set the specified flavor of option. The **default** function tells the recipe to set options according to the option's own preferred flavor (which note is `role` for all but a few options).

For enabling modification of restricted options, see also the `-restricted` switch to the `run` command, or the **restricted** operation.

4.7.1.1 Configuration group access

In Unified Configuration, some options may be set under a named group. So there are function to access/set/delete/*etc*. an entire such named group of options.

The **add_group**(*g*,*c*) function adds the group named (by the string value of) *g* with options specified by the optlist *c*; the function returns `1` if this operation was successful, or `0` if there was an error (such as in the case where the specified group name already existed). For example, the call:

```
add_group("dispatcher.service:SMTP_SPECIAL",
          ["enable", "1",
           "tcp_ports", "28225",
           "image", "IMTA_BIN:tcp_smtp_server",
           "parameter", "CHANNEL=tcp_special"
           "logfilename", "IMTA_LOG:tcp_special_server.log"])
```

adds a Dispatcher service named `SMTP_SPECIAL`, which will be a "special" SMTP server listening on port `28225` running the channel `tcp_special`.

The **append_group**(*s*,*c*) function appends to the group named (by the string value of) *s* the options specified by the optlist*c*; the function returns `1` if this operation was successful, or `0` if an error occurred. (The group will be created if it does not already exist; that is, `append_group` on a previously non-existent group is not an error.)

The **delete_group**(*s*) function deletes the group named (by the string value of) *s*.

The **exists_group**(*s*) function returns `0` if the group named (by the string value of) *s* exists, or the number of options set in the group if the group does exist.

The **get_group**(*s*) function returns the content of the group (the option names and values) as an optlist.

The **prepend_group**(*s*,*c*) function prepends to the group named (by the string value of) *s* the options specified by the optlist*c*; the function returns `1` if this operation was successful, or `0` if an error occurred. (The group will be created if it does not already exist; that is, `prepend_group` on a previously non-existent group is not an error.)

The **replace_group**(*s*,*c*) function replaces the group named (by the string value of) *s* with options specified by the optlist*c*; the function returns 1 if this operation was successful, or 0 if there was an error (such as in the case where the specified group name does not already exist).

4.7.2 System information

New in 8.0.1.2. The get_system_info function provides access to various pieces of static information about the system msconfig is running on. The function accepts a single case-insensitive string as its only argument specifying the piece of information to return.

In the following table, the Messaging Server version is taken to be "a.b.c.d" and the product build date is "yyyymmdd".

Table 4.4 get_system_info information items

Item	Return Type	Example Value	Description
ms_build_date	string	"yyyymmdd"	The date the current system was built from source.
ms_build_date_int	integer	yyyymmdd	The date the current system was built from source.
ms_version	string	"a.b.c.d"	Messaging Server version
ms_version_int	integer	aabbccddd	Messaging Server version, expressed as a single integer computed by the formula ((a * 100 + b) * 100 + c) * 1000 + d. This form is intended to be used in comparison operations.
ms_version_major	string	"a"	Messaging Server major version.
ms_version_major_int	integer	a	Messaging Server major version.
ms_version_minor	string	"b"	Messaging Server minor version.
ms_version_minor_int	integer	b	Messaging Server minor version.
ms_version_update	string	"c"	Messaging Server update version.
ms_version_update_int	integer	c	Messaging Server update version
ms_version_patch	string	"d"	Messaging Server patch number.
ms_version_patch_int	integer	d	Messaging Server patch number.
ms_version_build	string	""	Messaging Server build number.
ms_version_build_int	integer		Messaging Server build number.

4.7.3 msconfig information

New in 8.0.1.2. The get_msconfig_info function provides access to various pieces of information about how msconfig was invoked and its current status.

The following information items are currently supported:

Table 4.5 get_msconfig_info information items

Item	Return Type	Example Value	Description

noprompt	boolean	false	Returns `true` if `msconfig` was invoked with the -noprompt switch.
statefile_name	string	file.state	The name of the statefile specified with the -statefile switch.

4.7.4 Environment access

The recipe language can find out the values of environment variables, or find file path specifications using Messaging Server's basic environment variable values or (for the MTA) special symbolic names.

The **`getenv(`***`s`***`)`** function returns the value of the environment variable named *s*, or the empty string if no such environment variable is defined.

The **`get_path(`***`s`***`)`** function takes a string `"server"`, `"data"`, or `"config"` as argument, returning the file path specification of the SERVERROOT, DATAROOT, or CONFIGROOT, respectively.

The **`make_path(`***`s`***`)`** function will return a file path specification by converting any environment variable or special symbolic name in the string argument `s` into its path equivalent.

The **`get_option_modification_locations`** function will return a list of locations in the current recipe where a configuration modification occurred. This action also clears the internal list, so subsequent calls will only return any additional modifications that have occurred. An empty list is returned if the configuration has not been changed by the current recipe.

4.7.5 `msconfig` information operations

The **`argc`** function returns the number of additional arguments given to the `msconfig RUN` command.

The **`argv`**`(`*`n`*`)` function returns, as a string, the *n*th argument given to the `msconfig RUN` command. The value *n* must be between `1` and `argc` inclusive.

The **`description`**`(`*`d`*`)` function sets a string to display when the recipe is listed by the `msconfig DIRECTORY` command. Note that *d*must be a literal string enclosed in quotes; it cannot be an expression. When the recipe itself is executed, the **`description`** function does nothing other than return the value of its argument *d*.

The **`keywords`**`(`*`l`*`)` function specifies keywords to display when the recipe is listed by the `msconfig DIRECTORY` command.

4.7.6 File operations

Although recipes primarily operate directly on Messaging Server configuration data without any need for explicit file operations, situations may arise where additional files need to be read or written. Accordingly, a set of file manipulation functions is provided in the recipe language.

If no explicit path is given in the file name, the file location defaults to the config root directory. Explicit paths may be specified or any of the following special prefixes may be used:

```
IMTA_ROOT:     -> <serverroot> "/"
```

```
IMTA_LIB:     -> <serverroot> "/lib/"
IMTA_TABLE:   -> <configroot> "/"
IMTA_PROGRAM: -> <dataroot> "/site-programs/"
IMTA_LOG:     -> <dataroot> "/log/"
IMTA_QUEUE:   -> <dataroot> "/queue/"
IMTA_HTTP:    -> <dataroot> "/www/"
```

For manipulating paths in file names, see also the `get_path` and `make_path` functions.

The **`exists_file(`***`s`***`)`** function returns `1` if the file named by *`s`* exists, `0` if it doesn't.

Files may be read with **`read_file(`***`s`***`)`**. The contents of the file named by *`s`* are returned as a string. Line feeds are used as line delimiters in the string. For example:

```
split(trim(read_file("a.a"),"\n"),"\n")
```

returns the contents of the file with each line as a list element and any trailing blank lines removed.

There are two ways to write files. **`write_file(`***`s1`***`,`***`s2`***`)`** writes the contents of string *`s2`* to the file named by string *`s1`*. **`write_file(`***`s1`***`,`***`l`***`[,`***`s2`***`])`** writes the contents of the list *`l`* into the file named by *`s1`*. Each list element written is terminated by the value of *`s2`*; line feed is the default terminator if *`s2`* isn't supplied. In either form an error occurs if the file cannot be opened or written.

(New in MS 8.0.1.2) The **`delete_file(`***`s`***`)`** function deletes the file named by the string *`s`*, returning `1` if the delete operation was successful, or `0` if not.

Unless `-trusted` was specified for the `msconfig` invocation, the utility will check whether to perform a requested `delete_file` operation:

```
Allow recipe to delete file [Y, N, A]?
```

and if such prompting is disallowed (`-noprompt` specified), will not execute the delete operaiton and instead issue an error:

```
Delete_file not allowed to prompt for permission in -noprompt mode
```

4.7.7 Terminal I/O operations

The recipe language has a few terminal I/O primitives.

The **`print(`***`s`***`)`** operation prints a string to the terminal of the administrator executing the recipe.

The **`warn(`***`s`***`)`** operation prints a warning string to the terminal of the administrator executing the recipe, and updates the internal setting (which may be tested via **`continue`**) that a warning (an additional warning) has occurred.

New in MS 8.0.2.3, warn without any arguments returns the number of warnings that have been issued during the current run.

The **`error(`***`s`***`)`** operation issues a specified error string back to the administrator.

The **continue(***[s1[,s2]]***)** operation asks the administrator whether to continue after a warning. (Note that the prompt string argument *s1* and default response string argument *s2* are optional, with a default prompt string and empty response string, interpreted as false, used they are omitted. So merely **continue** is also valid syntax.)

The **yesno(***s1[,m[,s2]]***)** operation asks the administrator to respond with a yes or no response.

The **read(***s1[,s2[,s3]]***)** operation reads a string input from the terminal of the administrator executing the recipe. *s1* specifies the prompt to print on the terminal, *s2* specifies a default to return if no value is entered or `--noprompt` was specified when msconfig was invoked, and (new in 8.0.2.3) *s2* specifies the name of a statefile variable whose value is used as a default and updated with any value that's entered. The `--statefile` switch must be specified on the msconfig command line for *s2* to have any effect.

The **read_password** operation obtains a password string from the administrator executing the recipe.

If the `-restricted` switch was specified on a `run` command, the **restricted** operation merely returns a `1` unconditionally. But otherwise, the **restricted** operation prompts the administrator for whether or not to enable modification access to restricted options.

4.7.8 Statefile operations

The functions *exists_statefile*, *get_statefile*, *set_statefile*, and *delete_statefile* can be used to check the existence of, get, set, and delete statefile variables, respectively. Note that *exists_statefile* returns -1 and the other functions are no-ops if statefile suport is not enabled by specifying the `--statefile` switch on the msconfig command line.

4.7.9 Alias creation and manipulation operations

Messaging Server 8.0.1.2 now provides a set of recipe functions to create and manipulate aliases.

An MTA alias consists of a named set of option-value pairs, always containing one ore more `alias_entry` options which specify the alias expansion addresses. A single alias is represented in the recipe language using an optlist, and a number of functions are provided to access and manipulate aliases. All of these functions accept the unquoted name of the alias as the first argument. This name may be specified in any case and is converted to lower case.

Alias existence can be checked with **exists_alias**. A nonzero value is returned if the named alias is already part of the configuration; zero if it isn't.

The contents of an alias definition can be retrieved as an optlist using the **get_alias** function. For example, if the configuration has a `users-prefix@example.com` alias:

```
user-prefix@example.com: [prefix_text] Prefix text, user1@example.com, user2@example.com
```

The call `get_alias("user-prefix@exmaple.com")` will return an optlist:

```
["alias_prefix_text", "Prefix text",
 "alias_entry", "user1@example.com",
```

```
 "alias_entry", "user2@example.com"]
```

Note that alias options that do not accept a value will appear with a zero length string as the value.

The **add_alias** function is used to add a new alias to the configuration. A second argument is required specifying the various alias options as an optlist. An optional third parameter can also be specified containing a list of alias entries; these are converted to `alias_entry` alias options. An error is returned if the alias already exists. For example, the call:

```
add_alias("list@example.com",
          ["envelope_from", "list-error@example.com"],
          ["list1@example.com, "list2@example.com])
```

adds this alias to the configuration:

```
list@example.com: [envelope_from] list-error@example.com, list1@example.com, list2@example.com
```

The **replace_alias** function is the same as `add_alias`, except that any alias with that name that already exists will be removed prior to the addition.

The **append_alias** function is also the same as `add_alias`, except that specified alias options and entries will be appended to any existing alias definition.

The **preend_alias** function is also the same as `add_alias`, except that specified alias options and entries will be preended to any existing alias definition.

The **delete_alias** function deletes the named channel from the configuration. No operation is performed if the alias doesn't exist.

The **unset_alias** function takes two arguments: The name of an existing alias and a list of alias options to delete from it. Note that unset_alias is not designed to work on alias entries.

4.7.10 Channel creation and manipulation operations

An MTA channel consists of a named set of option-value pairs, usually containing an `official_host_name` option. A single channel is represented in the recipe language using an optlist, and a number of functions are provided to access and manipulate channels. All of these functions accept the name of the channel as the first argument. This name may be specified in any case and is converted to lower case.

Channel existence can be checked with **exists_channel**. A nonzero value is returned if the named channel is already part of the configuration; zero if it isn't.

The contents of a channel definition can be retrieved as an optlist using the **get_channel** function. For example, if the configuration has a `tcp_tas` channel:

```
tcp_tas deliveryflags 2 mustsaslserver smtp allowswitchchannel maytlsserver
tcp_tas-daemon
```

The call `get_channel("tcp_tas")` will return an optlist:

```
["official_host_name", "tcp_tas-daemon",
 "deliveryflags", "2",
 "mustsaslserver", "",
 "smtp", "",
 "allowswitchchannel", "",
 "maytlsserver", ""]
```

Note that channel options that do not accept a value appear with a zero length string as the value.

The **add_channel** function is used to add a new channel to the configuration. A second argument is required specifying the various channel options as an optlist. An error is returned if the channel already exists. For example, the call:

```
add_channel("tcp_aol", ["official_host_name", "tcp-aol",
                        "single_sys", "",
                        "randonmx", "",
                        "noswitchchannel", "",
                        "pool", "SMTP_POOL",
                        "smtp", ""]);
```

adds this channel to the configuration:

```
tcp_aol single_sys randommx noswitchchannel pool SMTP_POOL smtp
tcp-aol
```

The fact that a channel is represented as an optlist makes it easy to add a channel based on an existing one:

```
add_channel("tcp_new",
            put_optlist(get_channel("tcp_local"),
                        "official_host_name", "tcp-new"));
```

The **replace_channel** function is the same as add_channel, except that any channel with that name that already exists will be removed prior to the addition.

The **delete_channel** function deletes the named channel from the configuration. No operation is performed if the channel doesn't exist.

Finally, the **set_channel** function changes an existing channel. The second argument to **set_channel** must be an optlist containing the channel options to set. Existing options will be overridden; new options will be added. For example, given the channel:

```
tcp_intranet loopcheck maysaslserver mx pool SMTP_POOL \
 saslswitchchannel tcp_auth single_sys smtp \
 allowswitchchannel maytlsserver
tcp_intranet-daemon
```

The call:

```
  set_channel("tcp_intranet", ["master_debug", "",
                               "nomx", "",
                               "daemon", "router.example.com",
                               "multiple", ""]);
```

will modify the channel to be:

```
tcp_intranet daemon router.example.com loopcheck master_debug \
 maysaslserver multiple nomx pool SMTP_POOL \
 saslswitchchannel tcp_auth single_sys smtp \
 allowswitchchannel maytlsserver
tcp_intranet-daemon
```

4.7.11 Rewrite rule creation and manipulation operations

MTA rewrite rules are represented in Unified Configuration a list of `rule` values under the `rewrite` group. Each such rule value has a pattern and a template, separated by white space. The recipe language supports a number of functions which operate on rewrite rules; for rewrite rule values, such functions use an optlist specifying pattern-template pairs. For instance, the call:

```
append_rewrites([".lmtp", "$E$F$U%$H.lmtp@lmtpcs-daemon",
                 ".lmtp", "$B$F$U%$H@$H@lmtpcs-daemon"])
```

adds rewrite rules:

```
msconfig> show rewrite * .lmtp*
role.rewrite.rule = .lmtp $E$F$U%$H.lmtp@lmtpcs-daemon
role.rewrite.rule = .lmtp $B$F$U%$H@$H@lmtpcs-daemon
```

Note how, in contrast to many other recipe language function uses of optlists, when it comes to the rewrite rule creation and manipulation functions, the optlist arguments used are not specifying option-value pairs, but rather are specifying (an ordered rule list of) pattern-template pairs.

The recipe language functions available specifically for creating or manipulating rewrite rules are:

- **append_rewrites**(*c*)
- **delete_rewrites**(*l*)
- **get_rewrites**[(*p*[,*t*])]
- **prepend_rewrites**(*c*)
- **replace_rewrites**(*c*)

4.7.12 Mapping creation and manipulation operations

An MTA mapping consists of a named and possibly annotated set of pattern-template pairs. A single mapping is represented in the recipe language using an optlist, and a number of functions are provided to access and manipulate mappings. All of these functions accept the name of a mapping as the first argument. This name may be specified in any case and is converted to upper case.

Mapping existence can be checked with **exists_mapping**. A nonzero value is returned if the named mapping is already part of the configuration; zero if it isn't.

The contents of a mapping can be retrieved as an optlist using the **get_mapping** function. For example, if the configuration has a PORT_ACCESS mapping:

```
PORT_ACCESS

! Handle internal IP addresse
  *|*|*|*|*                     $C$|INTERNAL_IP;$3|$Y$E
  *                             $NEXTERNAL
```

The call `get_mapping("PORT_ACCESS")` will return an optlist:

```
["", " Handle internal IP addresses\n",
 "*|*|*|*|*", "$C$|INTERNAL_IP;$3|$Y$E",
 "*", "$NEXTERNAL"]
```

Note that the comment appears as name-value pair with an empty string as the name.

The **add_mapping** function is used to add a new mapping to the configuration. A second argument is required specifying the content of the mapping as an optlist. An error is returned if the mapping already exists. For example, the call:

```
  add_mapping("test_mapping", ["a","b","c","d","","Last","e","f"]);
```

adds this mapping to the configuration:

```
TEST_MAPPING

  a b
  c d
! Last
  e f
```

The **replace_mapping** function is the same as **add_mapping**, except that if the mapping already exists its contents will be replaced.

The **delete_mapping** function deletes the named mapping from the configuration. No operation is performed if the mapping doesn't already exist.

Finally, the **append_mapping** and **prepend_mapping** functions add entries to an existing mapping. The second argument to these functions must be an optlist containing the entries to add. Both functions are equivalent to **add_mapping** if the specified mapping doesn't already exist. For example, given the mapping:

```
TEST_MAPPING

  c d
```

then the calls:

```
prepend_mapping("Test_Mapping", ["a","b"]);
append_mapping("test_mapping", ["e","f"]);
```

will modify the mapping to be:

```
TEST_MAPPING

  a b
  c d
  e f
```

4.7.13 Deployment map operations

The `deploymap` recipe language function's semantics closely follow those of the DEPLOYMAP `msconfig` command.

All of the deploymap recipe and msconfig support was added in the 8.0.1.1.0 release of Messaging Server.

4.7.13.1 Add operations

```
deploymap :add :deployment d
```

Adds deployment *d* to the deployment. Adding a deployment that already exists is a no-op.

```
deploymap :add [:deployment d] :host h [:role r]
```

Adds host(s) *h* with role *r* to deployment *d* in the deployment map. *h* can be either a string or a list. An error occurs if any of the hosts already exist. The current deployment is used if *d* is not specified; if there is no current deployment the first deployment in the deployment map is selected. A deployment with the default name of "`site-01`" will be created if no deployment exists in the deployment map. No role will be associated with the hosts if *r* is not specified.

```
deploymap :add [:deployment d] :host h :property p
```

Add property/properties *p* to host *h* in deployment *d*. Host *h* will be created if it does not already exist. The current deployment is used if *d* is not specified; if there is no current deployment the first deployment in the deployment map is selected. A deployment with the default name of "`site-01`" will be created if no deployment exists in the deployment map.

```
deploymap :add [:deployment d] :host h :property p :role r
```

The host *h* is created in deployment *d* with role *r* and properties *p*. The host must not already exist. The current deployment is used if *d* is not specified; if there is no current deployment the first deployment in the deployment map is selected. A deployment with the default name of "`site-01`" will be created if no deployment exists in the deployment map.

All add operations return the number of modifications that were made to the deployment map.

4.7.13.2 Create operations

```
deploymap :create
```

Create a new, empty deployment map. Note that if you write this out using `msconfig`'s `deploymap write` command you will delete all your existing entries!

4.7.13.3 Delete operations

```
deploymap :delete :deployment d
```

Deletes deployment *d* from the deployment map. Deleting a nonexistent deployment is a no-op.

```
deploymap :delete [:deployment d] :host h
```

Deletes host(s) *h* from deployment *d*. *h* can be either a string or a list. Deleting a nonexistent host is a no-op. The current deployment is used if *d* is not specified; if there is no current deployment the first deployment in the deployment map is selected.

```
deploymap :delete [:deployment d] :host h :role
```

Delete any role associated with host(s) *h* in deployment *d*. Deleting a nonexistent role is a no-op. An error occurs if host *h* does not exist. The current deployment is used if *d* is not specified; if there is no current deployment the first deployment in the deployment map is selected.

```
deploymap :delete [:deployment d] :host h :property p
```

Delete any properties for host *h* in deployment *d* that match any of the glob-style wildcard(s) *p*. Both *p* and *h* can be a string or a list. The current deployment is used if *d* is not specified; if there is no current deployment the first deployment in the deployment map is selected.

All delete operations return the number of modifications that were made to the deployment map.

4.7.13.4 Dump operation

```
deploymap :dump
```

Returns a string containing an outline of the entire deployment map.

4.7.13.5 List operations

```
deploymap :list :deployment [d]
```

Returns a list of all the deployments in the deployment map that match the pattern *d*. All deployments are returned if *d* is omitted.

```
deploymap :list [:deployment d] :host [h] [:online | :offline]
```

Returns a list of all of the hosts in deployment *d* which match the pattern glob-style pattern *h*. The current deployment is used if *d* is not specified; if there is no current deployment the first deployment in the deployment map is selected. All hosts are returned if *h* is not specified.

```
deploymap :list [:deployment d] [:host h] :role [r] [:online | :offline]
```

Returns a list of all the unique roles of the hosts in deployment *d* matching the glob-style pattern *h*. The current deployment is used if *d* is not specified; if there is no current deployment the first deployment in the deployment map is selected. *r* is an optional glob-style pattern used to filter the roles that are returned. A list of all the roles associated with all of the hosts is returned if `:host` *h* is not specified. Note that the expression:

```
string(deploymap :list :host h :role)
```

can be used to obtain the role of host *h* as a string.

```
deploymap :list [:deployment d] :host :role [r] [:online | :offline]
```

Returns an optlist containing a list of all the hosts in deployment *d* and their associated roles. Hosts that do not have roles are not returned. The current deployment is used if *d* is not specified; if there is no current deployment the first deployment in the deployment map is selected. *r* is an optional glob-style pattern containing one or more wildcards or two or more non-wildcard strings used to filter the roles that are returned.

Note that a sublist `l` of the first elements in an optlist `t` is easily extracted with a loop of the form:

```
l = []; loop {exitif t == []; l = pop(t); pop(t);}
```

```
deploymap :list [:deployment d] :host :role r [:online | :offline]
```

Returns a list of all the hosts in deployment *d* with role *r*. *r* must not contain more than one element or any glob-style wildcard characters; if it does an optlist is returned as described above. The current deployment is used if `d` is not specified; if there is no current deployment the first deployment in the deployment map is selected.

```
deploymap :list [:deployment d] [:host h] [:role r]
          :property [p] [:online | :offline]
```

Returns a list of property values for hosts matching *h* in deployment *d* and with a role matching *r*. The current deployment is used if *d* is not specified; if there is no current deployment the first deployment in the deployment map is selected. If `:host` *h* is not specified the properties of all hosts are returned. No role check is performed if *r* is not specified. *p* is an optional glob-style pattern used to filter the properties that are returned.

```
deploymap :list [:deployment d] :host [:role r] :property p [:online | :offline]
```

Returns a list of hosts in deployment *d* which have properties matching *p*, and optionally, a role matching *r*. The current deployment is used if *d* is not specified; if there is no current deployment the first deployment in the deployment map is selected. *p* must be a string or list of glob-style patterns.

In all of these operations the `:online` and `:offline` parameters will limit hosts to those known to be online or offline, respectively.

4.7.13.6 Read operations

```
deploymap :read s
```

Reads a JSON-format deployment map from string *s*.

4.7.13.7 Rename operations

```
deploymap :rename n :deployment d
```

Renames deployment *d* to *n*. *d* must specify an existing deployment; *n* must be a nonempty utf-8 string.

```
deploymap [:deployment d] :rename n :host h
```

Renamed host *h* in deployment *d* to *n*. The current deployment is used if *d* is not specified; if there is no current deployment the first deployment in the deployment map is selected. Host *h* must already exist and *n* must be a valid domain name.

All rename operations return the number of modifications that were made to the deployment map.

4.7.13.8 Set operations

```
deploymap :set [:deployment d] :host h :role r
```

Sets the role for host(s) *h* in deployment *d* to *r*. *h* can be either a string or list. The specified hosts must already exist in the deployment. The current deployment is used if `d` is not specified; if there is no current deployment the first deployment in the deployment map is selected.

All set operations return the number of modifications that were made to the deployment map.

4.7.13.9 Write operations

```
deploymap :write
```

Returns the contents of the current deployment map as a JSON-formatted string. Note that no mechanism is provided in the recipe language to update the active deployment map; this can only be done at the `msconfig` level.

4.7.14 Optlist manipulation operations

As previously described, an optlist is a list containing an even number of strings which are interpreted as name-value pairs. A number of functions are provided to manipulate these sorts of lists.

An optlist can be created and populated just like any other list. Alternately, the **`put_optlist`** function can be used to add elements to an empty optlist. Optlists can also be read from files in *`name=value`* format. For example:

```
o = []; # Empty optlist
o = ["A","B"]; # Optlist containing a single option A with value B
o = ["A","C", "B", "D"]; Optlist containing two options A and B with values C and D
o = put_optlist([], "A","C", "B", "D"); # Same as previous optlist
o = read_optlist(read_file("optlist.txt"); # Read optlist from file optlist.txt
```

You can get option values from an optlist or check if a given option exists. For example, given an optlist `o = ["A", "C", "B", "D"]`, the following results would be returned:

```
get_optlist(o, "A") -> "C"
get_optlist(o, "B") -> "D"
get_optlist(o, "E") -> ""
exists_optlist(o, "A") -> 1
exists_optlist(o, "N") -> 0
```

Options can be set or deleted from an optlist. Note that it is common to assign the results of these functions back to the same optlist.

```
o = put_optlist(o, "E", "F"); # Add option E with value F to optlist o
o = delete_optlist(o, "A"); # Delete option A from optlist o
```

And in MS 8.0.1.3 or later:

```
o = delete_optlist(o, ["A","B"]); # Delete option A with value B from optlist o
```

Optlists can be written out as *`name=value`* format files:

```
write_file("optlist.txt", write_optlist(o));
```

4.7.15 LDAP operations

(New in MS 8.0.1) The recipe language can access LDAP. Several functions exist for such operations.

The **ldap_init**(*o*) function initializes the built in LDAP client. It must be called prior to using any of the other recipe language ldap_* functions.

By default, the LDAP client uses the current settings of the ugldaphost, ugldapbinddn, ugldapbindcred, ugldapport, and ugldapusessl base options when it initializes. The single argument *o* is an optlist specifying override values for any or all of these options. The optlist may be empty. Repeated calls will shut down and reinitialize the LDAP client with new settings. The LDAP client is shut down automatically when the recipe terminates.

The **ldap_ldif**(*s*[,*f*]) function applies the LDIF contained in the string *s* to an LDAP directory. (Details of which LDAP directory -- and how to connect to it -- must previously be established via an ldap_init call; attempting to call ldap_ldif before ldap_init will result in an error.)

By default, any LDAP errors that occur attempting to perform the operation of applying the LDAP will be treated as a recipe warning, but see bit 4096 of the optional flags argument *f*. The optional flag argument *f* is a bit-encoded integer specifying flags; the currently defined flag bits are:

Table 4.6 ldap_ldif optional flag argument bits

Bit	Value	Usage
0	1	If set, continute processing after any error.
1	2	If set, treat "entry exists" on add as success.
2	4	If set, allow no-such-object if hint present.
12	4096	If set, treat any LDAP error that occurs as a recipe error.

The ldap_ldif function returns an integer count of the number of successful modifications performed.

(New in MS 8.0.1.1.0) The **ldap_search** function takes an optlist argument specifying at least the basedn for the search, and optionally also the attribute to return (attrs), the scope of the search, and a filter (filter) for the search. Valid values for the "scope" are: base, onelevel (or one), subtree (or sub). An optional second integer argument specifies the number of entries to return, and defaults to -1 (return all entries) if omitted. The function returns an optlist containing the matching attribute-value pairs.

4.7.16 Random value generation

The **strongrandom**(*n*) function returns the specified number of bytes of random value. This is a cryptographically strong generator.

The **random**(*n*) function returns a uniformly distributed random number between 0 and n-1. The linear congruential generator described in "Random Number Generators: Good Ones Are Hard To Find", S. Park and K. Miller, CACM 31 No. 10, pp. 1192-1201, October 1988 is used to generate these numbers. The sequence is initially seeded with the sytem time.

An explicit 32 bit integer seed for the **random** function can be specified by calling the **randomseed**(*n*) function. This may be useful for debugging purposes. A value of 0 will cause the sequence to be reinitialized from the system clock.

4.7.17 Call-out to routine in external library

The **call_user**(*s1*,*s2*,*e*[,*e2...*]) function lets recipes call out to routines in external libraries. The argument *s1* specifies the path to the external library (assumed to be in IMTA_LIB if a full path is not provided); the argument *s2* specifies the routine name; and argument(s) *e*, *e2*, *e3*, *etc.*, specify the arguments to provide to routine *s2*. The result of the routine call is returned as the result of call_user.

call_user performs a call of the routine named *s2* of the form:

```
s2(int argc, struct argv, char *reason, int *rlength);
```

This feature is intended for calling out to site-supplied external routines.

4.8 User-defined routines

As of the 8.0 release, the recipe language supports user-defined routines:

```
sub routine(p1, ...) {
    ...
    return expression-1;
}
...
variable = routine(expression-1, ...);
```

Up to 20 parameters are allowed. Parameters are passed by value and evaluation is lazy: An unused parameter is never evaluated. Parameters are only evaluated once, so it is easy to force evaluation to occur at the beginning of the routine:

```
sub f(x, y, z) {
    x; y; z;
    ...
}
```

The entire parameter list can be omitted if the routine requires no parameters.

Routines may call themselves recursively, e.g.,

```
sub factorial(n) {if n <= 1 {return 1;} else {return n * factorial(n-1);}}
```

Note, however, that since there is currently no mechanism for forward declarations of routines, two or more routines cannot call each other recursively.

Routines can reference and modify global variables. Local variables can also be defined by placing the my control command immediately prior to the first use of the variable:

```
sub fib(n) {
    my s = [1, 1];
    my a = 1;
    my b = 1;
    loop {
        exitif --n < 2;
        my c = a + b;
```

```
            s .= c;
            a = b;
            b = c;
        }
        return s;
    }
```

Autoincrement, autodecrement, and the various augmented assignment operators (`+=`, `.=`, and so on) are all allowed on parameters and local variables. So is the exchange operator `:=:`; however, exchange cannot be used with a global variable on the right hand side and a local variable or parameter on the left hand side.

4.9 Preprocessing Directives

The recipe language provides a very limited preprocessor facility as of the 8.0.1 release. The following preprocessing directives are supported:

Table 4.7 Preprocessor Directives

Directive	Description
`%define` *name* [*value*]	Define the preprocessor symbol *name*. A optional value can be specified but nothing presently makes use of such values.
`%elifdef` *name*	Combines `%else` and `%ifdef`.
`%elifndef` *name*	Combines `%else` and `%ifndef`.
`%else`	Invert the processing state of the preceding `%ifdef` or `%ifndef`
`%endif`	Terminates the innermost `%ifdef` or `%ifndef` processing block. The processing state reverts to that of the enclosing block if there is one.
`%ifdef` *name*	Only process subsequent material up to a matching `%else` or `%endif` if *name* is defined.
`%ifndef` *name*	Only process subsequent material up to a matching `%else` or `%endif` if *name* is not defined.
`%include` *filename*	Include the content of the file *filename* in the recipe at the point where the `%include` directive appears. If a path is not provided in the file specification a series of paths will be checked: (1) The paths to any nested include files, innermost first, (3) The path to the recipe file specified in the RUN command, (4) `CONFIGROOT/recipes/`, and `SERVERROOT/lib/recipes/`. Checking (4) and (5) is new in MS 8.0.1.2.0.
`%undef` *name*	Remove a previous definition of *name*.

Preprocessing directives must appear in column 1 to be recognized. Note that preprocessor directives have lower precedence than quoted strings, so directives won't be recognized inside of multiline quoted strings.

4.10 Random number generation

Messaging Server uses the special device /dev/urandom for direct generation of random numbers on all platforms. The direct uses of random numbers include:

- The recipe language's strongrandom function.
- The strongrandom function provided for use in system-level sieves.
- Generation of authentication nonce values.
- Generation of initialization vectors when encrypting store message files
- Generation of recall/tracking secrets for message tracking and recall
- Generation of an internal key used for password obfuscation while preserving the ability to perform comparisons in the msconfig differences command.

Note: Random numbers needed for SSL/TLS operations are generated by the underlying cryptographic libraries.

Contrary to popular belief, /dev/urandom provides a high quality cryptographically secure random number source on all modern versions of Linux and Solaris. And with the possible exception of Solaris SPARC, the inclusion of entropy obtained from the HRNG provided by all recent Intel CPUs eliminates any "low entropy" conditions on startup.

For the one remaining case of Solaris SPARC, anyone concerned about a lack of entropy on startup can implement the following two procedures that preserve the entropy in the entropy pool across reboots:

```
echo "Initializing random number generator..."
random_seed=/var/run/random-seed
# Load and then save some entropy from the pool
if [ -f $random_seed ]; then
  cat $random_seed >/dev/urandom
else
  touch $random_seed
fi
chmod 600 $random_seed
dd if=/dev/urandom of=$random_seed count=1 bs=512
```

This first procedure should be run as root at system startup. The second procedure is:

```
# Carry a random seed from shut-down to start-up
# Save some entropy from the entropy pool
echo "Saving random entropy..."
random_seed=/var/run/random-seed
touch $random_seed
chmod 600 $random_seed
dd if=/dev/urandom of=$random_seed count=1 bs=512
```

This second procedure should be run as root at system shutdown as well as periodically.

Finally, a Messaging Server-specific trick that can be used to provide more entropy when unified configuration is used is to hash the Messaging Server configuration file and use the result as a source of entropy. This can be done with a command of the general form:

```
openssl dgst -sha512 /var/opt/sun/comms/messaging64/config/config.xml >/dev/urandom
```

This provides significantly more entropy than expected because every the configuration generation utilities in Messaging Server tag each option value with a last modified time.

Chapter 5 Sieve filters

RFC 5228 (Sieve) (originally RFC 3028 (Sieve)), later updated by various extensions and proposed extensions, defined a language for specifying processing of messages appropriate for performing upon message delivery. Such processing might include: filing those messages meeting specified criteria into special folders rather than simply delivering into the INBOX, redirecting (so-called "forwarding") messages meeting specified criteria to additional recipients, setting IMAP flags for messages meeting specified criteria, generating new notification messages when certain sorts of messages are delivered, returning "vacation" messages, discarding messages matching specified criteria, *etc.*

The MTA supports a hierarchy of Sieve filters applicable to messages. At the user level and domain level, this includes user personal Sieve filters, so-called "head of household" or "parental" Sieve filters, and domain level (domain wide) Sieve filters. And certain user LDAP attributes are interpreted by the MTA as specifying a Sieve "`vacation`" action---so essentially converted on-the-fly into a Sieve pseudo-script---and then merged with whatever other, explicit, user Sieve actions apply. The MTA also supports system (MTA) level Sieve filters, including channel level Sieve filters (for either or both of destination channels and source channels) and an MTA-wide Sieve filter.

The MTA's spam/virus filter package integration also takes the form of Sieve filter scriptlets, where the MTA is configured to interpret possible spam/virus filter package verdicts as requests to apply specified Sieve filter actions.

An important (and rather complex) topic is the interaction and hierarchy of how the MTA merges these multiple "levels" of Sieve scripts (and pseudo-scripts), and which Sieve filter actions take precedence, when multiple levels of Sieve script apply to a message. See the Sieve hierarchy topic for further discussion.

The MTA evaluates and applies applicable Sieve scripts (per its Sieve hierarchy rules) during message enqueue processing. While system-level Sieve scripts are often applicable (depending upon type and configuration) early in a message's lifetime, such as upon initial message submission to an MTA, user-level Sieve scripts for local recipients tend to be applicable instead at the time of enqueue to a delivery channel (enqueue to an `ims-ms` channel or `tcp_lmtpcs*` channel).

A separate and different use of Sieve filters is available to the Message Store, for message expiration purposes. If enabled with the `expiresieve` Message Store option, the Message Store can use Sieve filter tests to determine which messages to expire. Besides using Sieve filter tests in normal expiration rules (expiration rules defined via either Message Store expirerule options or for greater flexibility and performance `store.expirerule` files), new in MS 7.0.5 the `imexpire` utility also supports invoking spam/virus filter packages to scan messages post-

delivery for spam or virueses, integrating application of the verdicts from such spam/virus filter package via Sieve filter scriptlets.

5.1 Sieve language

The Sieve filter language was originally defined in RFC 3028 (Sieve: A Mail Filtering Language), since updated by RFC 5228 (Sieve: An Email Filtering Language). The Sieve language provides a way to analyze Internet format messages (RFC 822 messages), and perform processing appropriate for performing upon message delivery. Such processing might include: filing those messages meeting specified criteria into special folders rather than simply delivering into the INBOX, redirecting (so-called "forwarding") messages meeting specified criteria to additional recipients, setting IMAP flags for messages meeting specified criteria, generating new notification messages when certain sorts of messages are delivered, returning "vacation" messages, discarding messages matching specified criteria, *etc.* Additional RFCs, proposed extensions, and MTA-private extensions, have further extended and modified the Sieve language; see Sieve supported extensions for a list.

The RFCs defining standard Sieve features, and the Internet drafts for proposed Sieve extensions, are the most definitive resource for undering Sieve language syntax. For RFCs, see

```
http://tools.ietf.org/rfc/
```

and for Internet drafts, search in the "Individual Submissions" area at

```
http://tools.ietf.org/id/
```

Here follows a very brief overview of Sieve.

A Sieve script consists of a sequence of commands. Commands are tests, actions, or control structures. (There are some special cases in the MTA's Sieve implementation, as for instance the MTA allows "`size`" to be used not only in its standard capacity as a test, but also as a function call. And new in MS 8.0, the MTA supports private operators "`memcache`" and "`metermaid`" which have uses both as actions and as tests.) Many actions and tests may take arguments, both positional and tagged, or have modifiers.

The values in Sieve scripts are generally strings or non-negative integers. However, values are also subject to a few alternate forms; see in particular the `variables` and `encoded-character` extensions. And the MTA's Sieve implementation supports use of signed integers (and in particular, negative integers). Furthermore, the MTA's Sieve implementation supports the use of expressions in places where the base Sieve specification expects values.

Many Sieve extensions, both standard and at proposal stage, plus additional extensions private-to-the-MTA, are supported by the MTA, adding various additional actions, commands, and control structures to the base Sieve language. Extensions, especially standardized extensions, generally need to be enabled using a "`require`" control structure. An attempt to use an invalid action, test, or control structure will result in an "`Undefined function or variable "name" referenced`" error. As of MS 7.0, the MTA supports the Sieve "`ihave`" extension, which allows Sieve scripts to test which extensions are available. An attempt to "`require`" an unsupported or unenabled Sieve extension will result in an "`Unknown function required: name`" error. (Such errors are reported in an email message to the Sieve "owner" -- the user to whom the Sieve belongs in the case of user-level Sieves, or the postmaster in the case of system-level Sieves.)

Note that in addition to supporting private extensions, more generally the MTA also supports an extended Sieve syntax, including allowing expressions where Sieve expects arguments, and allowing assignment statements. The MTA also supports extending the Sieve language via

custom tests defined via MTA mapping tables. And because the MTA's Sieve implementation is built on top of the MTA's implementation of string and mathematical operation processing, the MTA's Sieve implementation supports some string functions and mathematical functions (and supports additional numeric forms, such as negative integers) not part of the base Sieve specification.

Note that as the Sieve filter language has been undergoing rather rapid development, support for additional language elements will likely be added in future. See release notes for current versions of the MTA software for notices of additional language element support.

5.1.1 Brief overview of Sieve language elements

For convenience, Sieve language elements provides a tabular overview of Sieve language elements, grouped into:

- Control structures,
- Actions,
- Tests,
- Functions,
- Values,
- ADDRESS-PARTS,
- BODY-TRANSFORMS,
- COMPARATORS,
- DATE-PARTS,
- ENVELOPE-PARTS,
- ENVIRONMENT-ITEMS,
- MATCH-TYPES, and
- MIMEOPTS.

Sieve language elements summarizes the basic Sieve language elements (but not the subelements that are standard under an element), plus any supported extension elements and extension subelements. For full descriptions of Sieve language elements, see the referenced RFCs and drafts. In Table of Sieve language elements, arguments/values are shown in italics, optional elements are enclosed in square brackets ([]), choices are enclosed in angle brackets (<>) with the distinct choices separated by the forward slash character (/), default choices are shown in bold type, and optional repetition of an element is indicated with the asterisk character (*).

Table 5.1 Sieve language elements

Element syntax				
Modifier	Source	Restrictions	Main capability	Description
Modifier			Additional capability	
Control structures				
`{...}`	RFC 5228			Block of commands
`error` *string*	RFC 5463		`require "ihave";`	Terminate Sieve script with runtime error
`foreverypart` [`:processnestedmessages` / `:retainnestedmessages`] [`:name` *string*] *command-block*				
	RFC 5703		`require "foreverypart";`	(New in MS 8.0) Loop through the MIME parts of a message
`:name`	RFC 5703			Specify a name for this `foreverypart` loop for reference in enclosed `break` or `continue` statements
`:processnestedmessages`	Private			(New in 8.1) Process the inner parts of any nested messages (default)
`:retainnestedmessages`	Private			(New in 8.1) Treat nested messages as leaf parts
`break` [`:name` *string*]	RFC 5703			(New in MS 8.0) Break out of a `foreverypart` loop
`:name`	RFC 5703			Terminate closest enclosing loop having specified name

`continue` [`:name` *string*]	Private			(New in MS 8.0) Pass control to the bottom of the `foreverypart` loop
`:name`	RFC 5703			(New in MS 8.0) Pass control to the bottom of the closest enclosing `foreverypart` loop having specified name
`loop` [`exitif` *expression*]* [`nextif` *expression*]* *command-block*				
	Private	system-level		General loop
`exitif`	Private	system-level		Exit a `loop` structure
`exitif`	Private	system-level		(New in 8.0.1.3) Proceed to the next iteration of the `loop` structure
`if` *test command-block* [`elsif` *test command-block*]* [`else` *command-block*]				
	RFC 5228			Branch-on-condition control structure
`elsif` *test command-block*	RFC 5228			Next case of branch-on-condition structure
`else` *test command-block*	RFC 5228			Final case of branch-on-condition structure
`require` *capability-list*	RFC 5228	`strict_require` MTA option		Declare that a Sieve script may use the named extension(s)
`stop`	RFC 5228			End processing
`sub` *name*[(*variables-list*)] `{...}`				
	Private	system-level		(New in MS 8.0) Define a subroutine
`my` *var-name* [`:=` *value*]	Private			(New in MS 8.0) Declare a variable is local
`return` *value*	Private			(New in MS 8.0) Exit subroutine, returning *value*
Actions				
`addconversiontag` *string-or-list*				
	Private	system-level		System-level Sieve action to add the specified conversion tag(s) to the message
`addflag` [*variable-name*] *list-of-flags*				
	RFC 5232	(`max_variables` MTA option, if using optional variable argument)	`require "imap4flags";` (or `require ["imap4flags", "variables"];` if using optional variable argument)	Add the specified IMAP flag(s) to the message
`addheader` [`:last`] *header-field-name value-string*				
	RFC 5293	`max_addheaders` MTA option		Add the specified header line (by default, at the beginning of the existing message header)
`:last`	RFC 5293			Add the specified header line at the end of the existing message header
`:replace`	Private			Add the specified header line, removing any previously present such header line(s)
`addprefix` *string*				
	Private			Add prefix text to the beginning of the first plain text part of the message
`addsuffix` *string*				
	Private			Add suffix text to the end of the first plain text part of the message
`addtag` *string*				
	Private			Add a tag (prefix text) to the Subject: header line
`adjustcounter` [`:channel` *channel-name*] [`:duplicate`] *counter-name* [*value*]				
	Private	system-level		(New in MS 8.0) System-level Sieve action to adjust value of a system Sieve accessible MTA counter
`:channel`	Private	system-level		Name of channel, one of whose counters is to be adjusted; the current source channel is assumed if no channel is explicitly specified
`:duplicate`	Private	system-level		By default, "`adjustcounter`" is suppressed if the Sieve script is reevaluated (as when a Sieve script that uses an envelope "To" test applies to a message addressed to multiple recipients); specifying the "`:duplicate`" modifier means that the "`adjustcounter`" action will be performed even upon reevaluation
`capture` [**`:dsn`** / `:message` / `:journal`] [`:header`] *repository-address*				
	Private	system-level+		Capture a message copy for legal intercept, archival, message replay, or similar purposes
`:dsn`	Private	system-level		Generate an encapsulated (DSN format) capture message; "`:dsn`" is the default

:header	Private	system-level		Capture message contains only the header of the original message, not the body; cannot be combined with ":message"
:journal	Private	system-level		Generate a MS Exchange "journal" format capture message
:message	Private	system-level		Generate a capture message as a pure, unencapsulated message
debug *list-or-string*				
	Private	mm_debug MTA option		Output the specified debug string; when mm_debug is 2 or more, the string is output to a debug log file, or with imsimta test -expression -mm -debug=2 the specified string is output to the terminal
deleteheader [:index *value* [:last]] [MATCH-TYPE] [COMPARATOR] *header-field-name-string* [*value-patterns-list*]				
	RFC 5293		require "editheader";	Delete the specified header line; (note that per RFC 5293, attempts to delete Received: or Auto-submitted: header lines will be ignored). As of MS 8.1.0.1, glob-style wildcards may be used in the field name.
:index	RFC 5293			Separate though equivalent to the RFC 5260 ":index" MATCH-TYPE: attempt to match (and hence potentially delete) only exactly the specified occurrence of the specified header line, by default starting counting from the beginning of the message header
:last	RFC 5293			For the ":index" modifier, count backwards from the end of the message header
discard [*log-string*]				
	RFC 5228, plus private logging argument	filter_discard and log_filter MTA options, logging channel option		Discard message (do not deliver, just delete); a *log-string* may be specified to be included in the log_filter field in MTA message transaction log entries
ereject *reason-string*				
	RFC 5429	enable_sieve_ereject MTA option	require "ereject";	Refuse message during SMTP transaction (or generate DSN if SMTP level rejection is not possible); note that use of non-US-ASCII characters in the *reason-string* prevents the SMTP level rejection
extracttext [MODIFIER] [:first *number*] *variable-name*				
	RFC 5703	max_variables MTA option	require ["extracttext", "foreverypart", "variables"];	(New in MS 8.0) Store extracted message text into a variable
:first	RFC 5703			Extract only the first N characters of the current MIME body part into a variable
:encodeurl	RFC 5435			In a variablesset command or an extracttext command, perform percent-encoding (as per RFC 3986) of the string value
:length	RFC 5229			Decimal number of characters in the extracted string, converted to a string
:lower	RFC 5229			Convert upper case characters to lower case
:lowerfirst	RFC 5229			Convert first character to lower case if it is a letter and upper case; rest of extracted string left unchanged
:quoteregex	Private			In a variablesset command or extracttext command, backslash quote any characters requiring quoting for regex, namely asterisk, question mark, or backslash (*, ?, \)
:quotewild	Private			Prefix "*", "?", "\" characters with "\"
:quotewildcard	RFC 5229			Prefix "*", "?", "\" characters with "\"
:upper	RFC 5229			Convert lower case characters to upper case
:upperfirst	RFC 5229			Convert first character to upper case if it is a letter and lower case; rest of extracted string left unchanged
fileinto *folder-name*				
	RFC 5228	max_fileintos MTA option, fileinto and flagtransfer channel options	require "fileinto";	Deliver into specified folder
:copy	RFC 3894		require "copy";	Modifies the fileinto and redirect actions so that the action is performed without affecting Sieve's "implicit keep"
:flags	RFC 5232		require "imap4flags";	Used with keep or fileinto to deliver the message with exactly the specified IMAP flag(s)
:owner	Private			Do the "fileinto" to the Sieve owner's address, rather than to the user's address; cases where the Sieve owner is different than the user on whose behalf the Sieve is being applied (hence cases where this argument would be relevant) might be "head of household" Sieves or system Sieves, when one might want to perform a "fileinto" to a folder belonging to the "head of household" or postmaster, respectively, rather than to a folder belonging to the original message recipient

`hold`	Private	system-level+		When specified in a system-level Sieve script, sideline a message as a `.HELD` file in the MTA queue area; ignored (no error) in user-level Sieve scripts
`importanceadjust` *value-string*				
	Private			Set or adjust a message's importance
`jettison` [*log-string*]				
	Private	`filter_jettison` and `log_filter` MTA options, `logging` channel option	`require "jettison";`	Non-overridable discard; a *log-string* may be specified to be included in the `log_filter` field in MTA message transaction log entries
`keep`	RFC 5228			Deliver message "normally"
`:flags`	RFC 5232		`require "imap4flags";`	Used with `keep` or `fileinto` to deliver the message with exactly the specified IMAP flag(s)
`memcache`	Private	`memcache_host`, `enable_sieve_memcache` MTA options		(New in MS 8.0) Used as an action to manipulate data via the memcache protocol; used as a test to access data via the memcache protocol
`:add` [`:host` *host-string*] [`:tableprefix` *prefix-string*] [`:duplicate`] [`:timeout` *timeout-number*] *key-string value-string*				
	Private			Add a new entry with the specified key, value, and timeout. The operation only succeeds if the entry does not already exist. The operation returns TRUE if the entry is added successfully, FALSE if it is not.
`:adjustdown` *value* [`:host` *host-str*] [`:tableprefix` *prefix-str*] [`:duplicate`] [`:quotatimeout` *quotatimeout-num* [`:penalize`]] [`:timeout` *timeout-num*] *key-str*				
	Private			Decrement the entry with the specified key by the specified adjustment value. The entry must be an unsigned integer written in string form or a throttle entry.
`:adjustup` *value* [`:host` *host-str*] [`:tableprefix` *prefix-str*] [`:duplicate`] [`:quotatimeout` *quotatimeout-num* [`:penalize`]] [`:timeout` *timeout-num*] *key-str*				
	Private			Increment the entry with the specified key by the specified adjustment value. The entry must be an unsigned integer written in string form or a throttle entry.
`:append` [`:host` *host-string*] [`:tableprefix` *prefix-string*] [`:duplicate`] *key-string value*				
	Private			Append the specified value to the entry with the specified key. (Returns TRUE if the operation is successful, FALSE if it is not.)
`:fetch` [`:host` *host-string*] [`:tableprefix` *prefix-string*] *key-string*				
	Private			Fetches the value of the entry with the specified key, or return an empty string if the entry doesn't exist. For throttle or reservation entries the current hit or reservation count, respectively, is returned.
`:prepend` [`:host` *host-string*] [`:tableprefix` *prefix-string*] [`:duplicate`] *key-string value-string*				
	Private			Prepend the specified value to the entry with the specified key. (Returns TRUE if the operation is successful, FALSE if it is not.)
`:remove` [`:host` *host-string*] [`:tableprefix` *prefix-string*] [`:duplicate`] [`:lockout` *lockout-numeric*] *key-string*				
	Private			Remove the entry with the specified key. (Returns TRUE if the operation is successful, FALSE if it is not.)
`:replace` [`:host` *host-string*] [`:tableprefix` *prefix-string*] [`:timeout` *timeout-value*] *key-string value-string*				
	Private			Update the value and timeout of an (existing) entry. (Returns TRUE if the operation is successful, FALSE if it is not.)
`:store` [`:host` *host-string*] [`:tableprefix` *prefix-string*] [`:timeout` *timeout-value*] *key-string value-string*				
	Private			Creates a new entry or updates an existing entry with the specified key, setting the entry to have the specified value and timeout. (Returns TRUE if the operation is successful, FALSE if it is not.)
`metermaid`	Private	`enable_sieve_metermaid` MTA option		(New in MS 8.0) Used as an action to manipulate data stored in MeterMaid; used as a test to access data stored in MeterMaid
`nonotify`	Private	system-level		System-level Sieve action to suppress all applications of either form of `notify` action
`notify :method "email"` [`:id` *string*] `:options` *recipient-addr* [*subject-str*] [< `:days` / `:hours` / `:seconds` > *num*] [`:low` / **`:normal`** / `:high`] [`:mime`] [`:message` *message-str*]				
	draft-martin-sieve-notify-01	`max_notifys` MTA option	`require "notify";`	Generate a new message, typically some form of notification message
`:high`	`draft-...-01`			Urgent priority
`:id`	`draft-...-01`			
`:low`	`draft-...-01`			Non-urgent priority
`:method`	`draft-...-01`			The type of notification to generate: only `"email"` is supported
`:normal`	`draft-...-01`			Normal priority

:options	draft-...-01			:method-specific options; for the "email" method, the option value is the recipient email address to which to send the generated notification
:echo	Private			
:mime	Private			The specified message body is a MIME entity, including MIME headers as well as content
:days	Private	notify_minimum_timeout, notify_maximum_timeout, and notify_timeout_default MTA options		Specify duplicate notification timeout in units of days
:hours	Private	notify_minimum_timeout, notify_maximum_timeout, and notify_timeout_default MTA options		Specify duplicate notification timeout in units of hours
:seconds	Private	notify_minimum_timeout, notify_maximum_timeout, and notify_timeout_default MTA options		Specify duplicate notification timeout in units of seconds
notify [:from *string*] [:importance < "1" / "2" / "3" >] [:options *string-list*] [:mime] [:message *string*] *method-string*				
	RFC 5435	max_notifys, notify_ignore_errors MTA options	require "enotify";	Generate a new message, typically some form of notification message
:fcc	draft-ietf-extra-sieve-fcc-02.txt			Specify mailbox to receive copy of any generated notification
:from	RFC 5435			Specify author (From address) of notification
:importance	RFC 5435			Specify priority, where 1 corresponds to urgent priority, 2 corresponds to normal priority, and 3 corresponds to non-urgent priority; the default is 2 (normal)
:options	RFC 5435			
:message	RFC 5435			
:echo	Private			
:mime	Private			The specified message body is a MIME entity, including MIME headers as well as content
:days	Private	notify_minimum_timeout, notify_maximum_timeout, and notify_timeout_default MTA options		Specify duplicate notification timeout in units of days
:hours	Private	notify_minimum_timeout, notify_maximum_timeout, and notify_timeout_default MTA options		Specify duplicate notification timeout in units of hours
:seconds	Private	notify_minimum_timeout, notify_maximum_timeout, and notify_timeout_default MTA options		Specify duplicate notification timeout in units of seconds
novacation	Private	system-level		System-level Sieve action to suppress all applications of the vacation action
override	Private		require "override";	(New in MS 8.0) Mark this Sieve script as determining the disposition of a message
redirect [MODIFIERS] *address*				
	RFC 5228	max_redirects, max_redirect_addresses MTA options		"Forward" message to specified recipient address(es)
:copy	RFC 3894		require "copy";	Modifies the fileinto and redirect actions so that the action is performed without affecting Sieve's "implicit keep"
:keepmailfrom	Private			Retain original envelope FROM address on redirect; :keepmailfrom is the default unless :notify is specified in which case the default switches to :resetmailfrom
:list	RFC 6134	SIEVE_EXTLISTS mapping table, max_redirect_addresses MTA option	require "extlists";	Externally stored list of addresses to which to forward with redirect action
:noresent	Private	sieve_redirect_add_resent MTA option		Do not add Resent-*: header lines upon redirect
:notify	RFC 6009		require "redirect-dsn";	Set message's NOTIFY parameter on redirect
:resent	Private	sieve_redirect_add_resent MTA option		Add Resent-*: header lines upon redirect
:resetmailfrom	Private			Reset envelope FROM address to Sieve owner on redirect
:ret	RFC 6009		require "redirect-dsn";	Set message's NOTIFY RET (return-of-content) parameter on redirect

`redis`	Private	`redis.hostlist`, `redis.port`, `redis.servicename`, and `enable_sieve_redis` MTA options		(New in MS 8.0.2.3) Used as an action to manipulate data via the redis protocol; used as a test to access data via the redis protocol
`:add` [`:set`] [`:sortedset`] [`:score` *score*] [`:tableprefix` *prefix-string*] [`:duplicate`] [`:timeout` *timeout-number*] *key-string value-string*				
	Private			Add a new entry with the specified key, value, and timeout. The operation only succeeds if the entry does not already exist. The operation returns TRUE if the entry is added successfully, FALSE if it is not. When a set or sorted set is specified the entry is added to the set; if the set doesn't exist it will be created with the single specified. A score of 0 is used if no score is specified for a sorted set entry.
`:adjustdown` *value* [`:tableprefix` *prefix-str*] [`:duplicate`] [`:quotatimeout` *quotatimeout-num* [`:penalize`]] [`:timeout` *timeout-num*] [`:sortedset`] *key-str* [*set-member*]				
	Private			Decrement the entry with the specified key by the specified adjustment value. The entry must be an integer written in string form, a throttle entry, or a sorted set. Note that *set-member* can only be specified if `:sortedset` is also specified. The adjusted value is returned.
`:adjustup` *value* [`:tableprefix` *prefix-str*] [`:duplicate`] [`:quotatimeout` *quotatimeout-num* [`:penalize`]] [`:timeout` *timeout-num*] [`:sortedset`] *key-str* [*set-member*]				
	Private			Increment the entry with the specified key by the specified adjustment value. The entry must be an integer written in string form, a throttle entry, or a sorted set. Note that *set-member* can only be specified if `:sortedset` is also specified. The adjusted value is returned.
`:append` [`:tableprefix` *prefix-string*] [`:duplicate`] *key-string value*				
	Private			Append the specified value to the entry with the specified key. (Returns TRUE if the operation is successful, FALSE if it is not.)
`:fetch` [`:set`] [`:sortedset`] [`:withscores`] [`:tableprefix` *prefix-string*] *key-string*				
	Private			Fetches the value of the entry with the specified key, or return an empty string if the entry doesn't exist. For throttle or reservation entries the current hit or reservation count, respectively, is returned. Set and sorted set members are returned as lists. `:withscores` in conjunction with `:sortedset` causes set members and their associated scores to be returned as pairs in the list.
`:remove` [`:tableprefix` *prefix-string*] [`:duplicate`] *key-string*				
	Private			Remove the entry with the specified key. (Returns TRUE if the operation is successful, FALSE if it is not.) Note that `:remove` works regardless of data type; there is no need to specify additional parameters when dealing with sets or sorted sets.
`:replace` [`:tableprefix` *prefix-string*] [`:timeout` *timeout-value*] *key-string value-string*				
	Private			Update the value and timeout of an (existing) entry. (Returns TRUE if the operation is successful, FALSE if it is not.)
`:store` [`:set`] [`:sortedset`] [`:score` *score*] [`:tableprefix` *prefix-string*] [`:timeout` *timeout-value*] *key-string value-string*				
	Private			Creates a new entry or updates an existing entry with the specified key, setting the entry to have the specified value and timeout. (Returns TRUE if the operation is successful, FALSE if it is not.) When a set or sorted set is specified the entry is added to the set; if the set doesn't exist it will be created with the single specified. A score of 0 is used if no score is specified for a sorted set entry.
`refuse` *string*				
	Private	++	`require "refuse";`	Refuse message, at SMTP level if possible, falling back to generating MDN
`reject` *string*				
	RFC 5429		`require "reject";`	Refuse message
`removeconversiontag` *string-or-list*				
	Private	system-level		System-level Sieve action to remove the specified conversion tag(s) from the message
`removeflag` [*variable-name*] *list-of-flags*				
	RFC 5232	(`max_variables` MTA option, if using optional variable argument)	`require "imap4flags";` (or `require ["imap4flags", "variables"];` if using optional variable argument)	Remove the specified IMAP flag(s) from the message

`replaceheader` [`:index` *value* [`:last`]] [`:newname` *header-field-name-str*] [`:newvalue` *string*] [COMPARATOR] [MATCH-TYPE] *header-field-name-str* [*value-patterns-list*]				
	draft-degener-sieve-editheader-00		`require "editheader";`	Replace a header line
`:index`	`draft-...-00`			Separate though equivalent to the RFC 5260 "`:index`" MATCH-TYPE: attempt to match (and hence potentially replace) only exactly the specified occurrence of the specified header line, by default starting counting from the beginning of the message header
`:last`	`draft-...-00`			For the "`:index`" modifier, count backwards from the end of the message header
`:newname`	`draft-...-00`			Change the name of all matching header fields to the specified new name
`:newvalue`	`draft-...-00`			Change the value of all matching header fields to the specified new value
`set` [MODIFIERS] *variable-name string-value*				
	RFC 5229	`max_variables` MTA option	`require "variables";`	Set a variable to a value
`:encodeurl`	RFC 5435			In a `variables set` command, perform percent-encoding (as per RFC 3986) of the string value
`:length`	RFC 5229			Decimal number of characters in the value string, converted to a string
`:lower`	RFC 5229			Convert upper case characters to lower case
`:lowerfirst`	RFC 5229			Convert first character to lower case if it is a letter and upper case; rest of string left unchanged
`:quoteregex`	Private			In a `variables set` command, backslash quote any characters requiring quoting for regex, namely asterisk, question mark, or backslash (*, ?, \)
`:quotewild`	Private			Prefix "*", "?", "\" characters with "\"
`:quotewildcard`	RFC 5229			Prefix "*", "?", "\" characters with "\"
`:upper`	RFC 5229			Convert lower case characters to upper case
`:upperfirst`	RFC 5229			Convert first character to upper case if it is a letter and lower case; rest of string left unchanged
`setconversiontag` *string-or-list*				
	Private	system-level		System-level Sieve action to set the message to have exactly the specified conversion tag(s)
`setenvelopefrom` *address-string-or-list*				
	Private	system-level		(New in MS 8.0) System-level Sieve action to override a message's original envelope From address
`setflag` [*variable-name*] *list-of-flags*				
	RFC 5232	(`max_variables` MTA option if using variables; with LMTP delivery, see also the `flagtransfer` channel option)	`require "imap4flags";` (or `require ["imap4flags", "variables"];` if using variables)	Set the message to have exactly the specified IMAP flag(s)
`setmtpriority` *integer-or-string*				
	Private	system-level		(New in MS 8.0) System-level Sieve action to set a message's MT-PRIORITY
`setnotify` *string-or-list*				
	Private	system-level		System-level Sieve action to set the DSN NOTIFY parameter (defined in RFC 3461); the value may be the string `"NEVER"`, or one (or a list) of the strings `"FAILURE"`, `"SUCCESS"`, `"DELAY"`
`setoperation` < `"SUBMIT"` / `"PASSTHROUGH"` / `"RELAY"` / `"DEFAULT"` >				
	Private	system-level		(New in MS 8.0) System-level Sieve per-recipient override of type of enqueue operation being performed
`setpriority` *string-or-numeric-priority-value*				
	Private	system-level		System-level Sieve action to override message's effective processing priority
`setreturn` < `"FULL"` / `"HDRS"` / `"HEADERS"` >				
	Private	system-level		System-level Sieve action to set the DSN RET parameter (defined in RFC 3461)
`spamadjust` *numeric-value-string*				
	Private			Set a message's "spam level"
`transactionlog` *string-or-list*				

	Private	system-level, `log_transactionlog` MTA option, `logging` channel option		(New in MS 8.0) System-level Sieve action specifying additional string to include in the MTA message transaction log file
`vacation` [`:days` *number*] [`:subject` *string*] [`:from` *address*] [`:addresses` *string-list*] [`:mime`] [`:handle` *string*] *reason-string*				
	RFC 5230	non-system-level, `max_vacations` and `vacation_template` MTA options	`require "vacation";`	Generate a vacation auto-response (an "I'm on vacation" sort of message)
`:addresses`	RFC 5230			Additional addresses to consider as "belonging" to the user, and hence whose presence on a recipient header line of an original message satisfies one requirement for vacation message generation
`:days`	RFC 5230	`autoreply_timeout_default`, `vacation_minimum_timeout`, and `vacation_maximum_timeout` MTA options		Specify timeout in days
`:echo`	Private			Modifier on `vacation` to produce a "processed" MDN response
`:fcc`	draft-ietf-extra-sieve-fcc-02.txt			Specify mailbox to receive copy of any generated vacation notice
`:from`	RFC 5230			Address to use in the From: header line of the generated vacation message
`:handle`	RFC 5230			Explicit label for this vacation operation, to be used instead of the usual argument-based label, so that vacation actions with different arguments may have a coordinated label and thereby respect each other's prior execution (and not generate yet another vacation message)
`:headers`	Private			Modifier on `vacation` to produce a response containing header lines, rather than the default MDN called for by the standard
`:hours`	Private	`autoreply_timeout_default`, `vacation_minimum_timeout`, and `vacation_maximum_timeout` MTA options		Specify the `vacation` action's autoresponse period in hours, rather than the normal days
`:mime`	RFC 5230			The *reason-string* is a MIME entity, including MIME headers as well as content
`:noaddresses`	Private			Modifier on `vacation` to suppress the MTA'S normal requirement (as per RFC 5230, Section 4.5) to only respond if the recipient address or one of its aliases appears explicitly on a recipient header line
`:noheadercheck`	Private			(MS 8.0.2.3) Modifier on `vacation` to suppress the MTA'S normal requirement (as per RFC 5230, Section 4.6) to only respond if various headers, e.g., List-ID:, are not present in the original message
`:reply`	Private			Modifier on `vacation` to produce a pure reply, containing only the reply text, rather than the default MDN called for by the standard
`:seconds`	RFC 6131	`autoreply_timeout_default`, `vacation_minimum_timeout`, and `vacation_maximum_timeout` MTA options	`require "vacation-seconds";`	Specify `vacation` action's autoresponse period in seconds, rather than the normal days
`:subject`	RFC 5230			Text to use in Subject: header line of generated vacation message
`virusset` *numeric-value-string*				
	Private			Set a message's "virus level"
`warn` *string-or-list*				
	Private	system-level, `log_filter` MTA option, `logging` channel option		(New in MS 8.0) System-level Sieve action specifying (an additional) string to appear in the " `warn`" clause in the `log_filter` field of MTA message transaction log entries
Tests				
`address` [ADDRESS-PART] [COMPARATOR] [MATCH-TYPE] *header-list value-list*				
	RFC 5228			Match Internet address in structured headers
`:aindex`	Private			Match against Nth address on header line
`:index`	RFC 5260		`require "index";`	Match against Nth named header line for `address`, `header`, or `date` tests
`:last`	RFC 5260		`require "index";`	Used with " `:index` to match against Nth named header line, counting backwards, for `address`, `header`, or `date` tests
`:mime` [`:anychild`] [MIMEOPTS]				

	RFC 5703		`require "mime";`	Alter `address`, `exists`, or `header` tests to check aspects of structured MIME header lines
`:anychild`	RFC 5703		`require "mime";`	Modify `:mime` to look inside any nested parts
`:raw`	Private analogue of RFC 5173			(New in MS 7.0.5) Do not MIME decode any RFC 2047 MIME encoded-words
`:text`	Private analogue of RFC 5173			(New in MS 7.0.5) Perform MIME decoding of any RFC 2047 MIME encoded-words
`allof` *test-list*	RFC 5228			Logical AND of tests; *test-list* has the form `(`*test* [`,` *test*]*`)`
`anyof` *test-list*	RFC 5228			Logical OR of tests
`body` [COMPARATOR] [MATCH-TYPE] [BODY-TRANSFORM] *value-list*				
	RFC 5173	`enable_sieve_body` MTA option	`require "body";`	Match content in the body of an email message; (only supports `:contains` and `:is`MATCH-TYPES, and a limited set of COMPARATORS)
`currentdate` [`:zone` *time-zone*] [COMPARATOR] [MATCH-TYPE] *date-part value-list*				
	RFC 5260		`require "date";`	Compare against current date-time
`:zone`	RFC 5260		`require "date";`	Specify a time zone offset to which to shift the current date-time prior to testing
`date` [`:zone` *time-zone* / `:originalzone`] [COMPARATOR] [MATCH-TYPE] *header-name date-part value-list*				
	RFC 5260		`require "date";`	Match against date from a header line
`:originalzone`	RFC 5260		`require "date";`	Test retaining the time zone offset of the original date time
`:zone`	RFC 5260		`require "date";`	Specify a time zone offset to which to shift the date-time prior to testing
`duplicate` [`:handle` *string*] [`:header` *header-name* / `:uniqueid` *value*] [`:seconds` *timeout*] [`:last`]				
	`draft-bosch-sieve-duplicate-09`	`max_duplicates`, `duplicate_tracking_url` MTA options	`require "duplicate";`	(New in MS 8.0) Test whether "the same" message was (recently) already received
`:handle`	`draft-bosch-sieve-duplicate-09`		`require "duplicate";`	Distinguish, via handle name, this duplicate test from other duplicate tests
`:header`	`draft-bosch-sieve-duplicate-09`		`require "duplicate";`	Use as unique ID (for duplicate detection) the content of the specified header field
`:last`	`draft-bosch-sieve-duplicate-09`	`duplicate_timeout_default`	`require "duplicate";`	Modify `:seconds` interpretation (or if `:seconds` was not specified, use `duplicate_timeout_default` value) interpreting as seconds within which a "duplicate" message must have been received (counting from the most recent check of the same unique ID) to count as a duplicate
`:mime`	Private		`require "mime";`	
`:anychild`	Private		`require "mime";`	
`:seconds`	`draft-bosch-sieve-duplicate-09`	`duplicate_timeout_default`, `duplicate_minimum_timeout`, `duplicate_maximum_timeout` MTA options	`require "duplicate";`	Seconds within which a "duplicate" message must have been received (counting time from the first message with the same unique ID) to count as duplicate
`:uniqueid`	`draft-bosch-sieve-duplicate-09`		`require "duplicate";`	Use the specified value as the unique ID (for duplicate detection)
`envelope` [COMPARATOR] [ADDRESS-PART] [MATCH-TYPE] *envelope-part-list value-list*				
	RFC 5228		`require "envelope";`	Match SMTP envelope address
`environment` [COMPARATOR] [MATCH-TYPE] *environment-item value-list*				
	RFC 5183		`require "environment";`	Match against operating environment information
`exists` *header-list value-list*				
	RFC 5228			Test whether specified header(s) are present in a message
`:list`	Private enhancement of RFC 6134	`SIEVE_EXTLISTS` mapping table	`require "extlists";`	Match against externally stored data in `address`, `envelope`, and `header` tests; MTA private additional functionality is that "`:list`" is also supported on the standard `exists` test, as well as on extension tests `currentdate`, `date`, `environment`, `hasflag`, `spamtest`, `string`, and `virustest`, and on `deleteheader` and `replaceheader` actions
`:mime` [`:anychild`] [MIMEOPTS]				
	RFC 5703		`require "mime";`	Alter `address`, `exists`, or `header` tests to check aspects of structured MIME header lines
`:anychild`	RFC 5703		`require "mime";`	Modify `:mime` to look inside any nested parts
`:regex`	Private enhancement	`enable_sieve_regex` MTA option	`require "regex";`	Regex match type

	of `draft-murchison-sieve-regex-08`			
`false`	RFC 5228			Always evaluate to FALSE
`hasflag` [MATCH-TYPE] [COMPARATOR] [*variable-list*] *list-of-flags*				
	RFC 5232	(`max_variables` MTA option if using optional variable argument)	`require "imap4flags";` (or `require ["imap4flags", "variables"];` if using optional variable argument)	Test whether the message has the specified IMAP flag(s)
`:list`	Private enhancement of RFC 6134	`SIEVE_EXTLISTS` mapping table	`require "extlists";`	Match against externally stored data in `address`, `envelope`, and `header` tests; MTA private additional functionality is that "`:list`" is also supported on the standard `exists` test, as well as on extension tests `currentdate`, `date`, `environment`, `hasflag`, `spamtest`, `string`, and `virustest`, and on `deleteheader` and `replaceheader` actions
`header` [COMPARATOR] [MATCH-TYPE] *header-list value-list*				
	RFC 5228	`defer_header_addition` and (new in MS 8.0) `sieve_received` MTA options		Match header
`:mime` [`:anychild`] [MIMEOPTS]				
	RFC 5703		`require "mime";`	Alter `address`, `exists`, or `header` tests to check aspects of structured MIME header lines
`:anychild`	RFC 5703		`require "mime";`	Modify `:mime` to look inside any nested parts
`:raw`	Private analogue of RFC 5173			(New in MS 7.0.5) Do not MIME decode any RFC 2047 MIME encoded-words
`:text`	Private analogue of RFC 5173			(New in MS 7.0.5) Perform MIME decoding of any RFC 2047 MIME encoded-words
`ihave` *capability-list*				
	RFC 5463		`require "ihave";`	Test which Sieve extensions are available
`importancetest` [COMPARATOR] [MATCH-TYPE] *value*				
	Private			Test a message's importance
`memcache`	Private	`memcache_host`, `enable_sieve_memcache` MTA options		(New in MS 8.0) Used as an action to manipulate data via the memcache protocol; used as a test to access data via the memcache protocol
`memcache :adjustdown` *value* [`:host` *host-string*] [`:tableprefix` *prefix-string*] [`:duplicate`] [MATCH-TYPE] [COMPARATOR] [`:quotatimeout` *quotatimeout-numeric* [`:penalize`]] [`:timeout` *timeout-value*] *key-string* [*test-string*]				
	Private			For the entry with the specified key, adjust the value down as specified and compare that adjusted value against the specified *test-string* value, which same *test-string* then becomes the entry's new value. MATCH-TYPE and COMPARATOR default to '`:value "lt"`' and '`comparator "i;ascii-numeric"`', respectively.
`memcache :adjustup` *value* [`:host` *host-string*] [`:tableprefix` *prefix-string*] [`:duplicate`] [MATCH-TYPE] [COMPARATOR] [`:quotatimeout` *quotatimeout-numeric* [`:penalize`]] [`:timeout` *timeout-value*] *key-string* [*test-string*]				
	Private			For the entry with the specified key, adjust the value up as specified and compare that adjusted value against the specified *test-string* value, which same *test-string* then becomes the entry's new value. MATCH-TYPE and COMPARATOR default to '`:value "gt"`' and '`comparator "i;ascii-numeric"`', respectively.
`memcache :fetch` [`:host` *host-string*] [`:tableprefix` *prefix-string*] [MATCH-TYPE] [COMPARATOR] *key-string* [*test-string*]				
	Private			For the entry with the specified key, compare its current value against the *test-string*, setting the value to *test-string*. The test always fails if the entry does not exist. MATCH-TYPE and COMPARATOR default to `:is` and `"i;ascii-casemap"`, respectively.
`memcache :release` [`:duplicate`] [`:host` *host-string*] [`:tableprefix` *prefix-string*] [`:timeout` *timeout-value*] *key-string*				
	Private			Implement a generic reservation capability. :release releases a previous reservation made with :reserve. The test returns TRUE if the reservation if a reservation is successfully released, FALSE otherwise.
`memcache :reserve :quota` *quota-numeric* [`:duplicate`] [`:host` *host-string*] [`:tableprefix` *prefix-string*] [`:timeout` *timeout-value*] *key-string*				
	Private			Implement a generic reservation capability. :reserve attempts to take out a reservation for the specified *key-string*. *quota-numeric* specifies the maximum number of reservations that are allowed. The test returns TRUE if the reservation if the reservation is taken out successfully, FALSE otherwise.

				Multiple reservations may be taken out by multiple :reserve operations. Note that each :reserve should be matched by a subsequent :release.
`memcache :throttle :quota` *quota-numeric* [`:duplicate`] `:quotetimeout` *quotatimeout-numeric* [`:limit`] [`:penalize`] [`:host` *host-string*] [`:tableprefix` *prefix-string*] [`:timeout` *timeout-value*] [MATCH-TYPE] [COMPARATOR] [`:adjustup` *adjustment-value*] [`:adjustdown` *adjustment-value*] *key-string* [*test-string*]				
	Private			Implement the MeterMaid throttle capability. The throttle value is incremented by default, though "`:adjustup`" or "`:adjustdown`" may be used to specify a non-default adjustment of the value. Then if none of MATCH-TYPE, COMPARATOR, nor *test-string* are specified, the test returns TRUE if the throttle is engaged, or FALSE if it is not engaged (or an error occurs). If any of the MATCH-TYPE, COMPARATOR, or *test-string* parameters is specified, then the throttle entry's value is adjusted and then the specified Sieve test is applied to the value. The default MATCH-TYPE is `:value "gt"` and the default COMPARATOR is `i;ascii-numeric`.
`metermaid`	Private	`enable_sieve_metermaid` MTA option		(New in MS 8.0) Used as an action to manipulate data stored in MeterMaid; used as a test to access data stored in MeterMaid
`:adjustdown` *adjustment-value* [`:host` *host-string*] [`:duplicate`] [MATCH-TYPE] [COMPARATOR] *table-string key-string* [*test-string*]				
	Private			Decrement the entry with the specified key in the specified table by the specified adjustment value.
`:adjustup` *adjustment-value* [`:host` *host-string*] [`:duplicate`] [MATCH-TYPE] [COMPARATOR] *table-string key-string* [*test-string*]				
	Private			Increment the entry with the specified key in the specified table by the specified adjustment value.
`:fetch` [`:host` *host-string*] [MATCH-TYPE] [COMPARATOR] *table-string key-string* [*test-string*]				
	Private			If none of MATCH-TYPE, COMPARATOR, nor *test-string* is specified, the specified entry's value is returned as a string, or an empty string is returned if the specified entry doesn't exist. If any of MATCH-TYPE, COMPARATOR, or *test-string* is specified, test against the current value of the specified entry (MATCH-TYPE and COMPARATOR default to '`:is`' and '`:comparator "i;ascii-casemap"`', respectively), returning FALSE if the specified entry does not exist.
`:greylisting` [`:host` *host-string*] [`:duplicate`] [MATCH-TYPE] [COMPARATOR] *table-string key-string* [*test-string*]				
	Private			If none of MATCH-TYPE, COMPARATOR, nor *test-string* are specified, then return TRUE if greylisting is engaged, while FALSE is returned if greylisting is not engaged or an error occurs. If any of MATCH-TYPE, COMPARATOR, or *test-string* is specified (MATCH-TYPE and COMPARATOR default to '`:is`' and '`:comparator "i;ascii-casemap"`', respectively), then increment the throttle and then apply the Sieve test to the value.
`:remove` [`:host` *host-string*] [`:duplicate`] *table-string key-string*				
	Private			Remove the entry with the specified key from the specified table. Returns TRUE if the operation is successful; FALSE if it is not.
`:store` [`:host` *host-string*] *table-string key-string value-string*				
	Private			Creates a new entry or updates an existing entry with the specified key in the specified table. Returns TRUE if the operation is successful; FALSE if it is not.
`:throttle` [`:host`: *host-string*] [`:duplicate`] [MATCH-TYPE] [COMPARATOR] *table-string key-string*				
	Private			MeterMaid throttle functionality. If none of MATCH-TYPE, COMPARATOR, nor *test-string* is specified, return TRUE if the throttle is engaged, or FALSE if the throttle is not engaged or an error occurs; if any of these three parameters is specified, then increment the throttle and then apply the Sieve test to the value. (MATCH-TYPE defaults to '`:value "gt"`' and COMPARATOR defaults to '`:comparator "i;ascii-numeric"`'.)
`not` *test*	RFC 5228			Reverse value of test argument
`notify_method_capability` [COMPARATOR] [MATCH-TYPE] *notification-uri notification-capability value-list*				
	RFC 5435		`require "enotify";`	Test whether a capability of a method of notification is available to be performed as desired
`:list`	Private enhancement of RFC 6134	`SIEVE_EXTLISTS` mapping table	`require "extlists";`	Match against externally stored data in `address`, `envelope`, and `header` tests; MTA private additional functionality is that "`:list`" is also supported on the standard `exists` test, as well as on extension tests `currentdate`, `date`, `environment`, `hasflag`, `notify_method_capability`, `spamtest`, `string`, and `virustest`, and on `deleteheader` and `replaceheader` actions

`redis`	Private	`redis.hostlist`, `redis.port`, `redis.servicename`, and `enable_sieve_redis` MTA options		(New in MS 8.0.2.3) Used as an action to manipulate data via the Redis protocol; used as a test to access data via the Redis protocol
`redis :adjustdown` *value* [`:tableprefix` *prefix-string*] [`:duplicate`] [MATCH-TYPE] [COMPARATOR] [`:quotatimeout` *quotatimeout-numeric* [`:penalize`]] [`:timeout` *timeout-value*] [`:sortedset`] *key-string* [*test-string*]				
	Private			For the entry with the specified key, adjust the value down as specified and compare that adjusted value against the specified *test-string* value, which same *test-string* then becomes the entry's new value. MATCH-TYPE and COMPARATOR default to '`:value "lt"`' and '`comparator "i;ascii-numeric"`', respectively.
`redis :adjustup` *value* [`:tableprefix` *prefix-string*] [`:duplicate`] [MATCH-TYPE] [COMPARATOR] [`:quotatimeout` *quotatimeout-numeric* [`:penalize`]] [`:timeout` *timeout-value*] *key-string* [*test-string*]				
	Private			For the entry with the specified key, adjust the value up as specified and compare that adjusted value against the specified *test-string* value, which same *test-string* then becomes the entry's new value. MATCH-TYPE and COMPARATOR default to '`:value "gt"`' and '`comparator "i;ascii-numeric"`', respectively.
`redis :expire` *timeout-value* [`:duplicate`] [`:tableprefix` *prefix-string*] *key-string*				
	Private			New in MS 8.1.0.6. Sets the expiration time in seconds for the specified entry. A time of 0 will cause the entry to be be deleted immediately. Negative values will cause the entry to be preserved indefinitely.
`redis :fetch` [`:tableprefix` *prefix-string*] [MATCH-TYPE] [COMPARATOR] *key-string* [*test-string*]				
	Private			For the entry with the specified key, compare its current value against the *test-string*, setting the value to *test-string*. The test always fails if the entry does not exist. MATCH-TYPE and COMPARATOR default to `:is` and `"i;ascii-casemap"`, respectively.
`redis :release` [`:duplicate`] [`:tableprefix` *prefix-string*] [`:timeout` *timeout-value*] *key-string*				
	Private			Implements a generic reservation capability. :release releases a previous reservation made with :reserve. The test returns TRUE if the reservation if a reservation is successfully released, FALSE otherwise.
`redis :reserve :quota` *quota-numeric* [`:duplicate`] [`:tableprefix` *prefix-string*] [`:timeout` *timeout-value*] *key-string*				
	Private			Implements a generic reservation capability. :reserve attempts to take out a reservation for the specified *key-string*. *quota-numeric* specifies the maximum number of reservations that are allowed. The test returns TRUE if the reservation if the reservation is taken out successfully, FALSE otherwise. Multiple reservations may be taken out by multiple :reserve operations. Note that each :reserve should be matched by a subsequent :release.
`redis :throttle :quota` *quota-numeric* [`:duplicate`] `:quotetimeout` *quotatimeout-numeric* [`:limit`] [`:penalize`] [`:tableprefix` *prefix-string*] [`:timeout` *timeout-value*] [MATCH-TYPE] [COMPARATOR] [`:adjustup` *adjustment-value*] [`:adjustdown` *adjustment-value*] *key-string* [*test-string*]				
	Private			Implements the MeterMaid throttle capability. The throttle value is incremented by default, though "`:adjustup`" or "`:adjustdown`" may be used to specify a non-default adjustment of the value. Then if none of MATCH-TYPE, COMPARATOR, nor *test-string* are specified, the test returns TRUE if the throttle is engaged, or FALSE if it is not engaged (or an error occurs). If any of the MATCH-TYPE, COMPARATOR, or *test-string* parameters is specified, then the throttle entry's value is adjusted and then the specified Sieve test is applied to the value. The default MATCH-TYPE is `:value "gt"` and the default COMPARATOR is `i;ascii-numeric`.
`metermaid`	Private	`enable_sieve_metermaid` MTA option		(New in MS 8.0) Used as an action to manipulate data stored in MeterMaid; used as a test to access data stored in MeterMaid
`:adjustdown` *adjustment-value* [`:duplicate`] [MATCH-TYPE] [COMPARATOR] *table-string key-string* [*test-string*]				
	Private			Decrement the entry with the specified key in the specified table by the specified adjustment value.
`:adjustup` *adjustment-value* [`:duplicate`] [MATCH-TYPE] [COMPARATOR] *table-string key-string* [*test-string*]				
	Private			Increment the entry with the specified key in the specified table by the specified adjustment value.
`:fetch` [MATCH-TYPE] [COMPARATOR] *table-string key-string* [*test-string*]				
	Private			If none of MATCH-TYPE, COMPARATOR, nor *test-string* is specified, the specified entry's value is returned as a string, or an empty string is returned if the specified entry doesn't exist. If any of MATCH-TYPE, COMPARATOR, or *test-string* is specified, test against the current value of the specified entry (MATCH-TYPE and COMPARATOR default to '`:is`'

				and ' `:comparator "i;ascii-casemap"`', respectively), returning FALSE if the specified entry does not exist.
`:greylisting` [`:duplicate`] [MATCH-TYPE] [COMPARATOR] *table-string key-string* [*test-string*]				
	Private			If none of MATCH-TYPE, COMPARATOR, nor *test-string* are specified, then return TRUE if greylisting is engaged, while FALSE is returned if greylisting is not engaged or an error occurs. If any of MATCH-TYPE, COMPARATOR, or *test-string* is specified (MATCH-TYPE and COMPARATOR default to ' `:is`' and ' `:comparator "i;ascii-casemap"`', respectively), then increment the throttle and then apply the Sieve test to the value.
`:remove` [`:duplicate`] *table-string key-string*				
	Private			Remove the entry with the specified key from the specified table. Returns TRUE if the operation is successful; FALSE if it is not.
`:store` *table-string key-string value-string*				
	Private			Creates a new entry or updates an existing entry with the specified key in the specified table. Returns TRUE if the operation is successful; FALSE if it is not.
`:throttle` [MATCH-TYPE] [COMPARATOR] *table-string key-string*				
	Private			MeterMaid throttle functionality. If none of MATCH-TYPE, COMPARATOR, nor *test-string* is specified, return TRUE if the throttle is engaged, or FALSE if the throttle is not engaged or an error occurs; if any of these three parameters is specified, then increment the throttle and then apply the Sieve test to the value. (MATCH-TYPE defaults to '`:value "gt"`' and COMPARATOR defaults to '`:comparator "i;ascii-numeric"`'.)
`size` < `:over` / `:under` > *limit-value*				
	RFC 5228			Test size of message
`:over`	RFC 5228			Match if message size is over specified value
`:under`	RFC 5228			Match if message size is under specified value
`spamtest` [COMPARATOR] [MATCH-TYPE] *value*				
	RFC 3685		`require "spamtest";` or `require "spamtestplus";`	Test a message's "spam level"
`:list`	RFC 6134	`SIEVE_EXTLISTS` mapping table	`require "extlists";`	Match against externally stored data in `address`, `envelope`, and `header` tests; MTA private additional functionality is that "`:list`" is also supported on the standard `exists` test, as well as on extension tests `currentdate`, `date`, `environment`, `hasflag`, `notify_method_capability`, `spamtest`, `string`, and `virustest`, and on `deleteheader` and `replaceheader` actions
`:percent`	RFC 5235		`require "spamtestplus";`	Test a message's "spam level" as a percentage value
`string` [MATCH-TYPE] [COMPARATOR] *source-string-list value-list*				
	RFC 5229	`max_sieve_string_size` MTA option	`require "variables";`	Test the (string) value of variable(s)
`:list`	Private enhancement of RFC 6134	`SIEVE_EXTLISTS` mapping table	`require "extlists";`	Match against externally stored data in `address`, `envelope`, and `header` tests; MTA private additional functionality is that "`:list`" is also supported on the standard `exists` test, as well as on extension tests `currentdate`, `date`, `environment`, `hasflag`, `spamtest`, `string`, and `virustest`, and on `deleteheader` and `replaceheader` actions
`true`	RFC 5228			Always evaluate to TRUE
`valid_ext_list` *extlist-names-list*				
	RFC 6134		`require "extlists";`	Test whether an external list specification is valid (both syntactically and semantically)
`valid_notify_method` *notification-uris-list*				
	RFC 5435		`require "enotify";`	Test whether notification methods are supported and syntactically valid
`virustest` [COMPARATOR] [MATCH-TYPE] *value*				
	RFC 3685		`require "virustest";`	Test a message's "virus level"
`:count`	RFC 5231		`require "relational";`	Match type for numeric comparison on number of occurrences (as of MS 8.0.1.3, :count may also be used as a modifier to other match types in header and address tests to count and test the number of matches that occurred)

:list	RFC 6134	SIEVE_EXTLISTS mapping table	require "extlists";	Match against externally stored data in address, currentdate, date, envelope, exists, and header tests, as well as in the string test when the variables extension is enabled, and in spamtest and virustest tests when those extensions are enabled
:regex	draft-murchison-sieve-regex-08	enable_sieve_regex MTA option	require "regex";	Regex match type
:value	RFC 5231		require "relational";	Match type for comparison on string values
test-name string	Private	FILTER_*test-name* mapping table		Custom test *test-name*: probes mapping table FILTER_*test-name* with *string*, evaluating to TRUE if mapping table sets $Y flag, or FALSE otherwise
Functions				
sub *name*[(*variables-list*)] { ... }				
	Private	system-level		(New in MS 8.0) Define a function/subroutine
my *var-name* [:= *value*]	Private			(New in MS 8.0) Declare a variable is local
return *value*	Private			(New in MS 8.0) Exit subroutine, returning *value*
translate *string-or-list source-charset dest-charset*				
	Private			(New in MS 8.0.1) Perform character set conversion, returning translated string or list
test-name string	Private	FILTER_*test-name* mapping table	require "variables";	Custom test *test-name* used as a function: probes mapping table FILTER_*test-name* with *string*, returning mapping's string result in variable ${0} and mapping's flag result in variable ${1}
...many-other-functions...	Private			See Symbol table functions
Values				
non-negative-integer	RFC 5228			Non-negative integer, range 0 to 2,147,483,647 (2^31 - 1); suffixes "K" (1024 or 2^10), "M" (2^20), or "G" (2^30) are permitted
negative-integer	Private			Negative integers are also supported by the MTA
"*utf-8-string*"	RFC 5228	max_sieve_string_size MTA option		String of characters represented in UTF-8; note that non-printing characters such as CR and LF are permitted, and so in particular strings can span multiple lines
"*character*"	RFC 5228			\\ represents the backslash character, \" represents the double quote character, and otherwise the backslash is ignored as if it were not present
text:*multiline text ended by CRLF.CRLF*	RFC 5228			More convenient way to enter multiline text strings; note must dot-stuff (as with SMTP messages)
["*s1*", "*s2*", ..., "*sN*"]	RFC 5228	max_sieve_list_size MTA option		List of strings
"${hex:*hex-pair-sequence*}"	RFC 5228		require "encoded-character";	*hex-pair-sequence* is one or more hexadecimal-encoded characters, space separated; *e.g.*, "{hex: 40 24}" represents "@$"
"${unicode: *unicode-hex-sequence*}"	RFC 5228		require "encoded-character";	*unicode-hex-sequence* is one or more Unicode hex-encoded characters, space separated; *e.g.*, "${unicode: 0000040}" represents "@"
${*variable-name*}	RFC 5229	max_variables MTA option	require "variables";	*variable-name* may be a variable identifier, or digit(s) identifying the variable, *e.g.*, ${a} refers to the variable named "a", while ${0} refers to the 0th variable; variable namespaces are not currently supported (so in particular variable names may not include any periods); note that variable substitutions are *not* supported in "body" test arguments
expression	Private			The MTA supports a variety of string and numeric operators and functions, and supports expressions to compute values; see Operators in Order of Precedence and Symbol table functions
ADDRESS-PARTS				
:all	RFC 5228			Entire address
:comment	Private			Extract any parenthetical comment appearing after an address
:detail	RFC 3598		require "subaddress";	Extract subaddress (*e.g.*, folder name) in address and envelope tests
:display	Private			Extract the display-name phrase (the optional text appearing outside of and specifically in front of the actual address, the actual address being the part enclosed in angles)
:domain	RFC 5228			Domain portion of address: the portion to the right of the @ character

:localpart	RFC 5228			RFC 822 "local-part" of address: the portion to the left of the @ character
:user	RFC 3598		require "subaddress";	Extract username (*i.e.*, local-part minus subaddress) in address and envelope tests
BODY-TRANSFORMS				
:raw	RFC 5173		require "body";	Interpret message body as an unprocessed "blob"; in particular, do not interpret MIME structure nor decode any content-transfer-encoding
:text	RFC 5173		require "body";	Decode MIME encoded text
COMPARATORS				
:comparator "i;ascii-casemap"	RFC 5228, RFC 4790			Treat uppercase and lowercase characters in the ASCII subset of UTF8 the same
:comparator "i;ascii-casemap-compress"	Private		require "comparator-i;ascii-casemap-compress";	(New in MS 8.0.1.2) Similar to "i;ascii-casemap", except that all internal folding white space characters (space, tab, carriage return, line feed) are replaced by a single ASCII space, and those at the beginining and end of the strings are removed. This is done to both the target and pattern strings prior to comparison
:comparator "i;ascii-casemap-collapse"	Private		require "comparator-i;ascii-casemap-collapse";	(New in MS 8.0) Similar to "i;ascii-casemap", except that all folding white space characters (space, tab, carriage return, line feed) are removed from both the target and pattern strings prior to comparison; this comparator is recommended for working around standards-incompliant client behavior regarding white space, folding white space, and MIME encoded-words
:comparator "i;ascii-integer"	Private		require "comparator-i;ascii-integer";	(New in MS 8.0) Test signed or unsigned integer values; (not supported on "body" tests)
:comparator "i:ascii-numeric"	RFC 4790		require "comparator-i;ascii-numeric";	Compare arbitrarily sized, unsigned integer numbers stored as octet strings, (in particular, disregard leading zeros, and truncate at the first non-digit character); see RFC 4790, Section 9.1.1 for further details; (not supported on "body" tests)
:comparator "i;octet"	RFC 5228, RFC 4790			Compare octets
:comparator "i;octet-compress"	Private		require "comparator-i;octet-compress";	(New in MS 8.0.1.2) Similar to "i;octet", except that all internal folding white space characters (space, tab, carriage return, line feed) are replaced by a single ASCII space, and those at the beginining and end of the strings are removed. This is done to both the target and pattern strings prior to comparison
:comparator "i;octet-collapse"	Private		require "comparator-i;octet-collapse";	(New in MS 8.0) Similar to "i;octet", except that all folding white space characters (space, tab, carriage return, line feed) are removed from both the target and pattern strings prior to comparison; this comparator is recommended for working around standards-incompliant client behavior regarding white space, folding white space, and MIME encoded-words
:comparator "i;utf-8"	?		require "comparator-i;utf8";	(New in MS 8.0) (not supported on "body" tests)
DATE-PARTS				
date	RFC 5260		require "date";	Date in "*yyyy*-*mm*-*dd*" format
day	RFC 5260		require "date";	Two digit day, "01", ..., "31"
hour	RFC 5260		require "date";	Two digit hour, "00", ..., "23"
iso8601	RFC 5260		require "date";	Date and time in restricted ISO 8601 format
julian	RFC 5260		require "date";	Modified Julian Day, that is, the date expressed as an integer number of days since 00:00 UTC on November 17, 1958 (using the Gregorian calendar); this corresponds to the Julian Day minus 2400000.5
milliunixepoch	Private		require "date";	(New in 8.1.0.6) Date and time in integer milliseconds since Unix epoch
minute	RFC 5260		require "date";	Two digit minute, "00", ..., "59"
month	RFC 5260		require "date";	Two digit month, "00", ..., "12"
second	RFC 5260		require "date";	Two digit second, "00", ..., "60"
std11	RFC 5260		require "date";	Date and time in a format appropriate for use in a Date: header field (RFC 822 format)
time	RFC 5260		require "date";	Time in "*hh*:*mm*:*ss*" format
unixepoch	Private		require "date";	(New in 8.1.0.6) Date and time in integer seconds since Unix epoch

weekday	RFC 5260		require "date";	Day of the week expressed in range "0" (Sunday) to "6" (Saturday)
year	RFC 5260		require "date";	Four digit year, "0000", ..., "9999"
zone	RFC 5260		require "date";	Time zone in use, in +*hh*:*mm* or -*hh*:*mm* format
ENVELOPE-PARTS				
from	RFC 5228		require "envelope";	Envelope From address
to	RFC 5228		require "envelope";	Envelope To address
auth	Private		require ["envelope", "envelope-auth"];	Access message's AUTH value
conversiontag	Private	system-level	require "envelope";	In system-level Sieve, access message's conversion tag(s)
envid	RFC 6009		require ["envelope", "envelope-dsn"];	Access message's envelope-id value
orcpt	RFC 6009		require ["envelope", "envelope-dsn"];	Access message's ORCPT value
notify	RFC 6009		require ["envelope", "envelope-dsn"];	Access message's DSN NOTIFY value
ret	RFC 6009		require ["envelope", "envelope-dsn"];	Access message's DSN RET value
ENVIRONMENT-ITEMS				
domain	RFC 5183		require "environment";	Preferably the value of ldap_default_domain MTA option, next the value of received_domain MTA option, or if neither are defined the value of the L channel official_host_name
host	RFC 5183		require "environment";	L channel official-host-name
location	RFC 5183		require "environment";	Type of service evaluating the Sieve; "MTA" for MTA evaluation
name	RFC 5183		require "environment";	"IMTA" for MTA evaluation
phase	RFC 5183		require "environment";	Phase of processing; possible values are "initialize", "connect", "mail" (reported at both HELO and MAIL FROM command stages), "rcptin", "rcptout", "datastart", "dataend", and "pre" (the default value)
remote-host	RFC 5183		require "environment";	Current source system
remote-ip	RFC 5183		require "environment";	Source IP
version	RFC 5183		require "environment";	MTA version string (akin to version reported in Received: header line)
vnd.oracle.last-verdict	Private		require "environment";	(New in MS 7.0.5) Prior Sieve's explicit handling action (see discussion of MTA's Sieve hierarchy)
vnd.oracle.max_mime_width	Private		require "environment";	(New in MS 8.0.2.2) The maximum number of MIME parts found in any multipart in the message.
vnd.oracle.message-hash	Private		require "environment";	(New in MS 8.0) Return any message hash calculated by the generatemessagehash channel option; the query will fail if no message hash was generated
vnd.oracle.mime_levels	Private		require "environment";	(New in MS 8.0.2.2) The number of accessible MIME levels in the current message, i.e. the MIME "depth" of the message.
vnd.oracle.mt-priority	Private		require "environment";	(New in MS 8.0) Match against message's current MT-PRIORITY value
vnd.oracle.notifycount	Private		require "environment";	(New in MS 8.0.1.2) Return the count of the number of notification messages the current sieve has enqueued.
vnd.oracle.notifyquota	Private		require "environment";	(New in MS 8.0.1.2) Return the number of additional notify actions the current sieve is able to perform.
vnd.oracle.operation-type	Private		require "environment";	(New in MS 8.0) Match against message's current type of enqueue operation
vnd.oracle.reevaluate	Private		require "environment";	(New in MS 8.0) TRUE or FALSE according to whether this Sieve script is being reevaluated
vnd.oracle.tracking-id	Private		require "environment";	(New in MS 8.0) Return the tracking identifier for the current message; the query will fail if there's no tracking id

vnd.oracle.vacationcount	Private		require "environment";	(New in MS 8.0.1.2) Return the count of the number of vacation messages enqueued by the current sieve. Note that this is not necessarily the same as number of vacation actions performed since any number of conditions can turn a vacation action into a no-op.
vnd.oracle.vacationquota	Private		require "environment";	(New in MS 8.0.1.2) Return the number of additional vacation actions the current sieve is able to perform.
vnd.oracle.warnings	Private		require "environment";	(New in MS 8.1.0.3) Returns the text of any warnings that have been issued since any previous environment test of this item, or since the start of script execution if no previous tests have been made. The environment call fails if no warnings are available to return.
vnd.sun.authenticated-sender-address	Private		require "environment";	Match against sender address associated with the authentication for the SMTP session
vnd.sun.authenticated-sender-id	Private		require "environment";	Match against user identity associated with the authentication for the SMTP session
vnd.sun.autoreply-internal	Private		require "environment";	TRUE or FALSE according to whether the autoreply criteria have been met for use of the "internal" autoreply response text stored in LDAP
vnd.sun.destination-channel	Private		require "environment";	Match against message's destination channel
vnd.sun.source-channel	Private		require "environment";	Match against message's source channel
custom-item-name	Private	$+E*item-name*|*item-value* in an *_ACCESS address mapping table	require "environment";	Arbitrary, custom environment items for a message may be set from the FROM_ACCESS or *_ACCESS recipient accress mapping tables, for subsequent use in environment tests
MATCH-TYPES				
:aindex	Private			Match against Nth address on header line
:contains	RFC 5228			Substring match
:count	RFC 5231		require "relational";	Match type for numeric comparison on number of occurrences; (not available for use with "body" test)
:index	RFC 5260		require "index";	Match against Nth named header line for address, header, or date tests
:last	RFC 5260		require "index";	For the :index modifier, count backwards from the end of the message header
:is	RFC 5228			Exact match
:list	RFC 6134 and private enhancements	SIEVE_EXTLISTS mapping table	require "extlists";	Match against externally stored data in address, envelope, and header tests; MTA private additional functionality is that ":list" is also supported on the standard exists test, as well as on extension tests currentdate, date, environment, hasflag, importancetest, memcache, metermaid, spamtest, string, and virustest, and on deleteheader and replaceheader actions
:matches	RFC 5228			Wildcard match; (not supported on "body" tests)
:regex	draft-murchison-sieve-regex-08	enable_sieve_regex MTA option	require "regex";	Regex match type; (not supported on "hasflag" or "body" tests)
:value	RFC 5231		require "relational";	Match type for comparison on string values; (may not be specified on "body" tests)
MIMEOPTS				
:type	RFC 5703		require "mime";	For Content-type: MIME header field, parse and test the value of the MIME type; for Content-disposition: MIME header field, parse and test the disposition value; for other MIME headers, use a blank string
:subtype	RFC 5703		require "mime";	For Content-type: MIME header field, parse and test the value of the MIME subtype; for other MIME headers, use a blank string
:contenttype	RFC 5703		require "mime";	For Content-type: MIME header field, parse and test the combined value of the MIME type and subtype; for Content-disposition: MIME header field, parse and test the disposition value; for other MIME headers, use a blank string
:param	RFC 5703		require "mime";	Parse the header for MIME parameters, returning true if any value found matches any of the test string values

+Only displayed in `imsimta test -expression -mm` if executing process has "world" privilege

++Prior to MS 6.2, only permitted in system-level Sieves; nowadays supported in arbitrary Sieves

5.1.2 Sieve supported extensions

In addition to the core Sieve functionality specified in RFC 5228 (Sieve), the MTA's Sieve implementation supports a great many standardized extensions, plus many additional private-to-the-MTA extensions. Standardized extensions supported include:

- Body extension (RFC 5173). The body test provides the means to test material in the message body. Note that there are are number of restrictions on the implementation of body. (7U2)
- Copy extension (RFC 3894). Copy is a simple extension that allows the "`redirect`" and "`fileinto`" actions to be used without canceling the default action of saving the message to the "inbox". (6.1)
- Date extension (RFC 5260). The date test provides the means to test fields in date-time values. (7U4)
- Editheader extension (RFC 5293). The "`addheader`" and "`deleteheader`" actions provide the ability to alter the message header. As of MS 8.1.0.1, the "`deleteheader`" action has been extended to allow glob-style wildcards in the field name. (Obviously this capability should be used with great care, as not only does it make it possible to delete entire swathes of header information, it also is an expensive operation to perform. In particular, leading wildcards in the field name should be avoided if at all possible.) Additionally, the "`replaceheader`" action described in draft-degener-sieve-editheader-00 has been implemented. This provides an especially convenient way to add tags to subject fields.
- Encoded-character extension (RFC 5228). This extension provides a way to specify Unicode characters by numeric value in Sieve character strings. Additionally, `\r`, `\n`, and `\t` can be used to represent carriage return, line feed, and tab characters respectively in quoted strings. (7.0)
- Envelope extension (RFC 5228). This extension consists of an "`envelope`" test that can access MAIL FROM and RCPT TO address information. (Other extensions have made additional items available to the "`envelope`" test.)
- Envelope-dsn (RFC 6009). This extension provides access to additional envelope information provided by the delivery status notification SMTP extension. (7U2)
- Environment extension (RFC 5183). Environment provides scripts access to information outside of the current message. (7.0U1)
- Ereject extension (RFC 5429). This extension updates the definition of the "`reject`" action to allow messages to be refused during the SMTP transaction (rather than being accepted and then generating an MDN), and defines the "`ereject`" action to require messages to be refused during the SMTP transaction. (6.1)
- Extlists extension (RFC 6134). This extension adds the "`:list`" match-type to the "`address`", "`currentdate`", "`date`", "`deleteheader`", "`envelope`", "`environment`", "`hasflag`", "`header`", "`replaceheader`", "`spamtest`", "`string`", and "`virustest`" tests. "`:list`" in turn allows the test to check values against externally stored information. (7U1)
- Fcc extension (draft-ietf-extra-sieve-fcc-02.txt). This extension adds support for delivering a copy of any generated message to the `notify` and `vacation` actions to the mailbox specified by a :fcc nonpositional parameter.
- Fileinto extension (RFC 5228). This extension adds the "`fileinto`" action for specifying a folder where the message is to be delivered.

- Ihave extension (RFC 5463). "`ihave`" makes it possible to write scripts that use a given extension if it is available but continue to operate if it is not. (7.0)
- Index extension (RFC 5260). The index extension adds a "`:index`" nonpositional parameter to the address, date, and header tests, which in turn provides the means to check a specific instance of header fields that occur multiple times. (7U4)
- Imap4flags extension (RFC 5232). Imap4flags provides the means to set IMAP flags on messages delivered to the message store. (6.3P1)
- Mime extension (from RFC 5703). The "`mime`" extension provides facilities for testing headers in inner MIME parts of messages. (7U1) New in MS 8.0 is support for the "`extracttext`" and "`foreverypart`" Sieve extensions from RFC 5703. New in MS 8.1 is the ability to control whether or not the foreverypart Sieve control looks inside of nested messages or treats them as leaf parts. The `:processnestedmesssages` argument tells foreverypart to look inside and is the default. `:retainnestedmessages` causes nested messages to be treated as leaf parts. (8.0, 8.1)
- Notify extension (RFC 5435) and the mailto notification method (RFC 5436). Notify with the mailto method provides the means to send an notification email about the current message being processed. Note that an earlier draft of the "`notify`" action is also still supported. (6.2, 7.0.5)
- Relational extension (RFC 5231). Relational adds relational comparisons (less than, greater, than, *etc.*) to the "`header`", "`address`", and "`envelope`" tests (and other extension tests as they have subsequently been defined). It also adds the ability to count ("`:count`") the number of entities that match the test criteria (6.0). As of MS 8.0.1.3, :count may also be used as a modifier to other match types in header and address tests to count and test the number of matches that occurred.
- Redirect-dsn extension (RFC 6009). This extends Sieve's "`redirect`" action to provide control over delivery status notification parameters with two new arguments "`:notify`" ("`:notify` support was actually added for 6.3p1, prior to its standardization) and "`:ret`". (6.3p1, 7U2)
- "`spamtest`", "`spamtestplus`", and "`virustest`" extensions (RFC 5235). The tests defined by these extensions provide a means for Sieve scripts to access spam and virus filter "scores". ("`spamtest`" and "`virustest`" 6.0; "`spamtestplus`" 6.3)
- Subaddress extension (RFC 3598). Subaddress "`:user`" and "`:detail`" tagged arguments for the "`envelope`" and "`address`" tests to access information embedded in the local part of an address. (iMS uses a plus sign as the separator between user and detail information in the local part.) (6.0)
- Vacation extension (RFC 5230). The "`vacation`" action defined by this extension can be used in user-level Sieve scripts to generate "out of office" messages in response to incoming email.
- Vacation-seconds extension (RFC 6131). This extends the vacation time to allow specification of timeout values in seconds rather than minutes; in particular, it adds a "`:seconds`" parameter to the "`vacation`" action.
- Variables extension (RFC 5229). The core Sieve language does not provide any means of saving state from one statement to the next. This extension adds variables to the language. (6.2)

In addition to the above standardized extensions, the MTA also supports some private extensions:

- The "address" test supports a private ":aindex" tag. This ":aindex" tag accepts a positive integer as an argument. If ":aindex n" is specified, then only the nth address in each header field will be tested. Note that ":aindex" (selecting which address out of multiple addresses) may be combined with ":index" (selecting which header line out of multiple header lines), to cause the test to operate on a single address in a single header line. (7.0.5)

- The "address" test supports two new, private, part modifiers, ":display" and ":comment". The ":display" modifier causes the "address" test to operate on the display-name phrase; note that the display-name phrase is the optional text appearing outside of and specifically in front of the actual address, the actual address being the part enclosed in angles. The ":comment" modifier causes the "address" test to operate on any parenthetical comments that appear after an address. (7.0.5)

- The "addconversiontag", "removeconversiontag", and "setconversiontag" actions allow operating on the MTA's private conversion tag mechanism. ("addconversiontag" and "setconversiontag" 6.0; "removeconversiontag" 7.0u3) Also, in system-level Sieves, the "envelope" test accepts "conversiontag" as a field specifier value, checking the current list of conversion tags, one at a time. (This test only "sees" the set of conversion tags that were present prior to Sieve processing; the effects of "setconversiontag" and "addconversiontag" are not visible.) (6.3)

- The "addprefix" and "addsuffix" actions are available for adding a string argument as text at the beginning or end, respectively, of the first plain text part of a message. (7.0u3)

- The addtag action provides a convenient way to add a prefix string, that is, a "tag", to the beginning of the Subject: header line. (6.0)

- The "adjustcounter" action is available for system Sieve filters to manipulate any of the eight signed, 64 bit counters accessible from Sieve filters. (8.0)

- The "capture" action (and the deprecated synonym "monitor"). Two optional nonpositional parameters, ":dsn" and ":message", were added for MS 6.3; ":journal" (to generate Microsoft® Exchange "envelope journaling" format) was added for 7.0u2; ":header" (which can be used as a modifier with either :dsn or :journal) was added for 8.0. (6.3, 7.0u2, 8.0)

- In addition to standard Sieve comparators, the MTA also supports some non-standard Sieve comparators.

- The "debug" action takes a string argument, and makes that string available for logging to a debug log file if MTA debugging is enabled at mm_debug=2 level or higher.

- The MTA supports the proposed Sieve duplicate extension specified in RFC 7352. (8.0)

- The envelope-auth extension adds a "auth" part to the envelope test, providing access to the SMTP AUTH value.

- The "hold" action causes a message to be sidelined in the MTA queue area as a .HELD file.

- The "importancetest" test and "importanceadjust" action allow multiple Sieve scripts to cooperate in making a determination of a message's importance, much like the way that the "spamtest" and "spamadjust" extensions allow multiple Sieve scripts to cooperate in determing whether or not a message is spam.

- The "jettison" action causes a message to be unconditionally discarded; this is a "non-overridable" discard (for use by system-level Sieve scripts).
- The "loop" construct is supported in system-level Sieve scripts. (7.0.5)
- The "memcache" operator permits querying and updating a memcache server from Sieve scripts. (8.0)
- The "metermaid" operator permits querying and updating MeterMaid from Sieve scripts. (8.0)
- The "override" action is supported in system-level Sieve scripts; the capability string is "override". (8.0)
- The "nonotify" action is supported in system-level Sieve scripts. It suppresses all uses of the "notify" and "enotify" extensions (all applications of either form of the "notify" action). (8.0)
- The "novacation" action is supported in system-level Sieve scripts. (6.1)
- By default, the MTA supports a relaxed use of "require" clauses in Sieve scripts, in that the MTA permits "require" clauses to be sprinkled throughout a Sieve script (rather than, as the Sieve standard specifies, having all "require" clauses at the beginning of the Sieve script). This is especially useful in conjunction with the MTA's support for combining multiple Sieve scriptlets such as those resulting from spam/virus filter package integration, or from user LDAP attribute mailVacation* settings. However, enforcement of per-the-Sieve-standard "require" clause location may be selected by setting the strict_require MTA option.
- The ":raw" and ":text" modifiers defined for the "body" test may now also be used in "header" and "address" tests. Similarly to when used with "body", the ":raw" modifier specifies that MIME decoding should be performed; in the case of "address" and "header" tests, the MIME processing in question is the decoding of MIME encoded-words (see RFC 2047 for the definition of encoded-words). ":text" is the default for "header" and "address" tests on ":comment" and ":display" address parts. ":raw" is the default for other sorts of "address" tests. (7.0.5)
- The proposed "regex" extension adds a ":regex" match type. (6.1)
- The ":resent" and ":noresent" arguments are supported on the Sieve "redirect" action, for controlling whether Sieve "redirect" actions cause addition of Resent-* header lines. (6.3p1)
- The ":resetmailfrom" and ":keepmailfrom" parameters are supported on the Sieve "redirect" action, to control whether or not the original message's envelope From address is used on the redirected message (*vs.* using the Sieve owner's address as the envelope From address for the redirected message). (6.3p1)
- The "setenvelopefrom" action, to override a message's original envelope From address, is available for use in system-level Sieves. (8.0)
- The "setmtpriority" action is available for system-level Sieves. It accepts a single integer or string argument and sets the current MT-PRIORITY to the argument value. This action is only allowed in system-level Sieves and the argument must be in the -9 to 9 range of valid MT-PRIORITY values. (8.0)

- The "setnotify" and "setreturn" actions are available in system-level Sieves. (7.0u1)
- The "setoperation" action is available for system-level Sieves, to set the enqueue operation mode to "submit", "passthrough", "relay", or "default". (8.0)
- The "setpriority" action is available for system-level Sieves, to set an effective message processing priority. It takes a single string argument which must be one of "non-urgent", "normal", or "urgent". Note that this priority is NOT stored in the message header and only affects processing at this particular stage of message transfer. If multiple "setpriority" actions are specified in different system-level Sieves, the one in the most specific Sieve wins. (7.0u4)
- The "spamadjust" and "virusset" actions are supported; they tell the MTA how to set the spam or virus score which a standard "spamtest" and "virustest" test, respectively, would then test. (6.0)
- The "strongrandom" function takes as an argument an integer value n specifying the number of bytes of (cryptographically strong) random material to return. "strong" is permitted only in system-level Sieves; (attempts to use "strongrandom" from user-levels Sieves are prohibited because of performance concerns).
- The "random" function takes as an argument an integer specifying an upper limit n on the range of values to return; a uniformly distributed random number between 0 and n-1 is then returned. The linear congruential generator described in "Random Number Generators: Good Ones Are Hard To Find", S. Park and K. Miller, CACM 31 No. 10, pp. 1192-1201, October 1988 is used to generate these numbers; a separate sequence seeded from the system time is used for each sieve evaluation. An explicit 32 bit integer seed can be specified by calling the "randomssed" function. (This may be useful for debugging purposes.) A value of 0 will cause the sequence to be reinitialized from the system clock.
- The "transactionlog" action is available for system-level Sieves. It takes a single string argument. All of the "transactionlog" actions in all of the applicable Sieves are concatenated into a single string, which is then available for inclusion in the MTA message transaction log file; see the log_transactionlog MTA option. (8.0)
- The translate function is available, to convert a string from one charset to another. (8.0.1)
- The warn action is available, to cause additional text to be added to the "warn" clause in the log_filter field of the MTA message transaction log file. (8.0)
- Custom tests may be defined via MTA FILTER_testname mapping tables. (Updates to MS 6.2 and updates to MS 6.3)
- Subroutines are supported. (8.0)
- Trailing commas are now allowed in string lists. (8.1.0.1)

Finally, one of the most important of the MTA's extensions to Sieve is the MTA's support of a hierarchy of Sieve filters.

5.1.2.1 Sieve address test

The "address" test is a standard part of the Sieve language. However, MTA support for the "address" test deserves a few special comments.

In regards to "address" tests, note that the MTA supports the "subaddress" extension (capability name "subaddress") defined in RFC 3598, which makes available ":user" and ":detail" tagged arguments.

New in Messaging Server 7.0.5, the Sieve "address" test supports several enhancements:

- The Sieve "address" test now uses the MTA's heuristic address parser (instead of the strict address parser). This helps "address" tests work even when the overall header contains one or more syntax errors.
- The "address" test supports a private ":aindex" tagged argument. This ":aindex" tag accepts a positive integer as an argument. If ":aindex n" is specified, then only the nth address in each header field will be tested. Note that ":aindex" (selecting which address out of multiple addresses) may be combined with ":index" (selecting which header line out of multiple header lines), to cause the test to operate on a single address in a single header line.
- The "address" test supports two new, private, part modifiers, ":display" and ":comment". The ":display" modifier causes the "address" test to operate on the display-name phrase; note that the display-name phrase is the optional text appearing outside of and specifically in front of the actual address, the actual address being the part enclosed in angles. The ":comment" modifier causes the "address" test to operate on any parenthetical comments that appear after an address.
- The ":raw" and ":text" modifiers defined for the "body" test may also be used in "address" tests (as well as "header" tests). Similarly to when used with "body", the ":raw" modifier specifies that MIME decoding should be performed; in the case of "address" and "header" tests, the MIME processing in question is the decoding of MIME encoded-words (see RFC 2047 for the definition of encoded-words). ":text" is the default for "header" and "address" tests on ":comment" and ":display" address parts. ":raw" is the default for other sorts of "address" tests.

5.1.2.2 Sieve body extension

New in Messaging Server 7.0u2, the MTA supports the Sieve body extension specified in RFC 5173 (Sieve Body Extension), with the following restrictions:

- The only match types supported are :contains and :is; while :matches and :regex are not supported. This is likely to be a permanent restriction due to the possible performance impact of supporting these match-types.
- The only body transforms supported are :raw and :text; while :content is not supported. This restriction is likely to be lifted in a future release.
- Variable substitutions are not allowed in body test arguments. If they are used an error is likely to occur. This is so that a list of all arguments to body in all scripts can be computed in advance and searched for in a single pass. If this restriction were to be lifted, it would be easy to construct scripts that would require an arbitrary number of passes over the message, which is unacceptable in a server environment. As such, this should be considered to be a permanent restriction. For example, this script will fail:

```
require ["variables", "body"];
```

```
set "a" "testing";
if body :contains "${a}" { discard; }
```

- The `:text` body transform operates on all message parts with a text type or a 7bit/8bit encoding. If a charset other than utf-8 is specified on a text part, then that part is converted to utf-8 before being searched.

Note also that new in Messaging Server 7.0.5, `imexpire` supports use of the Sieve body extension.

The availability of the body test is controlled by the `enable_sieve_body` MTA option. A value of 0, the default, disables the extension. A value of 1 enables the extension for use in all Sieves. A value of 2 enables the use of body in system-level Sieves only. Each Sieve script that wishes to use "`body`" must also declare it using the "`body`" capability:

```
require "body";
```

5.1.2.3 Sieve copy extension

The MTA supports the Sieve copy extension specified in RFC 3894 (Sieve Extension: Copying Without Side Effects), which adds a `:copy` parameter to the Sieve `fileinto` and `redirect` actions allowing these actions to be used without cancelling the default save-to-inbox Sieve effect. The capability name is "`copy`":

```
require "copy";
redirect :copy "another-mailbox@domain.com";
# A copy of the message will still be retained/delivered "normally"
```

5.1.2.4 Sieve discard and jettison actions

In addition to the standard "`discard`" action, the MTA also supports a private "`jettison`" action (capability name also merely "`jettison`") which causes a "non-overridable" discard. "`jettison`" is similar to "`discard`" in that it causes messages to be silently discarded. The difference between "`jettison`" and "`discard`" is that unlike "`discard`", which does nothing but cancel the implicit "`keep`", "`jettison`" forces a "`discard`" to be performed. The behavioral difference is only relevant when multiple Sieves are involved. For example, a system-level "`discard`" can be overridden by a user Sieve explicitly specifying "`keep`", whereas a system-level "`jettison`" will override anything done by a user Sieve.

Whether the MTA immediately discards a message upon a Sieve "`discard`" or "`jettison`" action being applied, *vs.* routing such messages to the `filter_discard` channel (for a short period of retention before being permanently deleted) may be configured via the `filter_discard` and `filter_jettison` MTA options. Configuring use of the `filter_discard` channel allows a system administrator to, if desired, "fetch back" messages a user has very recently, mistakenly, discarded via a Sieve filter. As such,it may be useful either for debugging purposes, or for assisting users prone to setting up overly aggressive discarding via personal Sieve filters. (Technical note: When the MTA routes a discarded message to the `filter_discard` channel, the MTA also sets a bit in the message envelope that means that subsequent "`discard`" or "`jettison`" actions will be ignored. This has no effect for the discarded messages that remain in the `filter_discard` queue until eventually deleted from disk. However, if instead a "retrieval" procedure is performed on such a message, such

as if a system administrator moving a message from the `filter_discard` channel to the `reprocess` channel for subsequent processing, the bit permits delivery to proceed bypassing any "`discard`" or "`jettison`" actions.)

When discarded messages are deleted immediately (rather than being routed to the `filter_discard` channel), note that that is logged in MTA message transaction logging as if the message had been enqueued to the `bitbucket` channel, though in reality no such enqueue is performed and instead the message temporary file is merely deleted from disk.

As of Messaging Server 7.0u4, the "`discard`" and "`jettison`" Sieve actions now accept a single, optional string parameter. This parameter value, if specified, is logged as part of the `log_filter` filter result field in the MTA message transaction log, assuming of course that the associated Sieve is the one that determines the disposition of the current message. Note that this argument is nonstandard; however, since the main application is in system-level Sieves, this should not present a portability problem in practice.

Note that effects similar to "`discard`" or "`jettison`" may be obtained via `*_ACCESS` mapping table `$V`, `$v`, `$Z`, or `$z` flag use.

Note that application of "`jettison`" will disable user-level Sieve "`vacation`" or "`notify`" actions that might otherwise apply. (Prior to Messaging Server 7.0.5, "`jettison`" would cancel all "`notify`" actions; as of Messaging Server 7.0.5, system-level "`notify`" actions are not cancelled by "`jettison`".)

5.1.2.5 Sieve date and index extensions

As of Messaging Server 7.0u4, the MTA supports the Sieve date and index extensions defined in RFC 5260 (Sieve Email Filtering: Date and Index Extensions). (Note that prior to Messaging Server 7.0u4, certain parts of these extensions, notably the "`currentdate`" test and parts of the "`date`" test, had already been made available.) The "`date`" test matches dates off header lines; the "`currentdate`" test matches the current time (the time at which the Sieve script is evaluated); and the "`index`" extension adds "`:index`" and "`:last`" arguments to the "`address`", "`header`", and "`date`" tests. The capability strings are "`date`" (which enables both "`date`" and "`currentdate`" tests) and "`index`":

```
require ["date","index"];
```

Some examples of "`date`" or "`currentdate`" use:

```
    require ["date", "vacation", "relational"];
    if anyof(currentdate :is "day" "05",
             currentdate :is "day" "10",
             allof(currentdate :is "weekday" "2",
                   currentdate :value "gt" "14",
                   currentdate :value "lt" "22"))
    { vacation "I'm working at the hospital today";
      redirect "hospital-address"; }

require ["date", "relational", "vacation"];
if allof(currentdate :value "ge" "date" "2007-06-30",
         currentdate :value "le" "date" "2007-07-07")
```

```
{ vacation :days 7  "I'm away during the first week in July."; }

require ["variables","date","relational"];
set "startDateTime" "2007-01-18T00:00:00Z";
set "endDateTime" "2007-01-19T00:00:00Z";
if allof(currentdate :value "ge" "iso8601" "${startDateTime}",
        currentdate :value "le" "iso8601" "${endDateTime}")
  { redirect "user+wherever@domain.com"; }
```

Note that "`currentdate`" and "`date`" by default returns time values in the server local time zone, meaning that ISO 8601 strings such as `2007-01-19T00:00:00-08:00` may be returned. Alternatively, one may use '`:zone "+hhmm"`' in the test to force shifting (conversion) of the original time zone to the specified time zone prior to performing the test. In contrast, specifying "`:originalzone`" for a "`date`" test forces use and retention of the time zone offset originally present.

The Sieve extlists extension, among other things, also adds a "`:list`" match type to the "`date`" and "`currentdate`" tests.

When considering "`:index`", note that as of Messaging Server 7.0.5 the MTA supports a private "`:aindex`" tag on Sieve address tests. This "`:aindex`" tag accepts a positive integer as an argument. If "`:aindex n`" is specified, then only the `n`th address in each header field will be tested. Note that "`:aindex`" (selecting which address out of multiple addresses) may be combined with "`:index`" (selecting which header line out of multiple header lines), to cause the test to operate on a single address in a single header line.

5.1.2.6 Sieve duplicate extension

As of the 8.0 release, the MTA supports the Sieve duplicate extension specified in RFC 7352. The "`duplicate`" test is intended to assist in detecting and handling cases of so-called "duplicate" messages such as cases where a user receives both a personally addressed copy as well as a mailing list copy of a message.

The capability string to enable use of the "`duplicate`" test is "`duplicate`":

```
require "duplicate";
```

Furthermore, to permit "`duplicate`" tests, the `max_duplicates` and `duplicate_tracking_url` MTA options must have, respectively, a positive value and a valid URL value. The `max_duplicates` MTA option controls how many "`duplicate`" tests may be performed in a single Sieve script; the default is 2.

In the MTA's implementation, the MTA maintains a memcache database recording "recent" duplicate message tracking data: this database is what allows comparing a current message with a prior message to detect a "duplicate". The `duplicate_tracking_url` MTA option specifies where this duplicate tracking information should be stored; at present the value must be a `memcache:` URL of the form:

```
memcache://host:port/key-prefix
```

If the host isn't specified, it defaults to the value of the memcache_host MTA option. It is an error for memcache_host not to be set in this case. If the port isn't specified, it defaults to the value of the memcache_port MTA option; if that option in turn isn't specified, the default is 11211, the usual port for memcache servers. *key-prefix*, if specified, is prepended to the keys the duplicate extension sends to the memcache server.

Note that "duplicate" tests are performed during Sieve evaluation, but no memcache updates are performed at the Sieve evaluation stage. It is only after the message has been successfully processed that updates are done.

Also note that duplicate information is implicitly qualified by the owner of the Sieve. In the case of system-level Sieves, this will be the applicable postmaster address, so system-level Sieves operate in shared namespace(s). Note that the ":handle" argument of the "duplicate" test can be used to force system-level Sieves to operate in their own namespace.

The syntax for the "duplicate" test is:

```
duplicate" [":handle" handle-string]
           [":header" header-name-string /
           ":uniqueid" value-string]
           [":seconds" number] [":last"]
```

where the default is to test for previously seen (within a short period of time) values of the Message-id: header line, or previously seen values of another header line instead if ":header" is specified, or previously seen other values constructed as the Sieve chooses per the ":uniqueid" argument string. The time period for which the "seen" values are retained, so the time period within which duplicates may be detected, may be controlled by use of the ":seconds" argument, or if not specified defaults to the value of the duplicate_timeout_default MTA option.

As of the 8.0 release, warnings that occur during Sieve evaluation such as issues with the duplicate extension (or issues involving the memcache protocol or the vacation extension), plus any specifically specified warnng text specified via the Sieve "warn" action will result in a "warn" clause in the log_filter field of MTA message transaction log entries.

5.1.2.7 Sieve editheader extension

The MTA has supported the addheader action (prior to its standardization) since circa MS 6.1, and the standard deleteheader action and proposed replaceheader action since MS 6.3. The standard capability string in order to use an addheader or deleteheader action, as defined in RFC 5293 (Sieve Email Filtering: Editheader Extension), or a replaceheader action, as defined in draft-degener-sieve-editheader-00, is "editheader", although note that the MTA does not enforce this for the addheader action (addheader may be used without a "require" clause):

```
require "editheader";
```

The MTA has a configurable limit on how many addheader actions will be permitted in a single Sieve script, max_addheaders. The default is 10. As of the 8.0 release, this limit only applies to user-level Sieves.

When specifying a header label in an `addheader` action, note that the header label length is limited to 256 characters, and may not contain any eight bit characters (characters above ASCII position 126) nor control characters (characters below ASCII position 33) as well as not containing the colon character, `:`.

Note that it may often be useful to make use of the Sieve `variables` extension along with `editheader`, and perhaps especially in conjunction with the "`replaceheader`" action. This is illustrated in the following example in which a site's broken DMARC usage, which could break mailing lists *for innocent other members of the list* is ameliorated by forcibly modifying the (broken domain's) addresses so as not to trigger bounce messages for messages from this broken domain to other list recipients thereby causing the innocent list members to be removed from mailing lists.

```
require ["editheader","variables"];
if address :domain :is "From" "dmarcbrokenusage.domain.com" {
# dmarcbrokenusage.domain.com addresses that include phrase and/or comment:
 replaceheader :newvalue "${1}<${2}@dmarcbrokenusage.domain.com.invalid>>${3}"
         :matches "From" "*<*@dmarcbrokenusage.domain.com>*";
# Simple dmarcbrokenusage.domain.com addresses:
 replaceheader :newvalue "${1}@dmarcbrokenusage.domain.com.invalid"
         :matches "From" "*@dmarcbrokenusage.domain.com";
 addprefix text:
Due to dmarcbrokenusage.domain.com's broken use of DMARC, the From: address
in this message has been replaced by <original-address>.invalid.

To reply to the original sender of this message, remove the .invalid
from the end of the domain.

.
}
```

5.1.2.8 Sieve envelope extension

The capability string in order to use an `envelope` test, as defined in RFC 5228, is "`envelope`":

```
require "envelope";
```

The "`envelope`" test has been further extended by additional RFCs to allow access to additional envelope fields, including the "`envelope-dsn`" extension defined in RFC 6009 for access to the information provided by the DSN SMTP extension, and the the "`envelope-auth`" extension, for access to the SMTP AUTH value; while other RFCs extend "`envelope`" as well as other Sieve operations, including the "`subaddress`", "`extlists`", and "`relational`" extensions which among other effects also supplement the range or types of allowed "`envelope`" tests. And the MTA's private conversion tag mechanism can also be accessed from "`envelope`" tests using the private "`conversiontag`" part.

In order to use such supplementary "`envelope`" parts, the additional extension, as well as "`envelope`" itself, must be listed in a "`require`" action (all except for "`conversiontag`" which does not need a "`require`" action); *e.g.*:

```
require ["envelope","envelope-dsn"];
require ["envelope","envelope-auth"];
require ["envelope","subaddress"];
require ["envelope","extlists"];
require ["envelope","relational];
```

The "`envelope`" test takes a string or list argument.

In addition to supporting the standard `envelope` test arguments specified in RFC 5228 and the other extensions mentioned above, the `envelope` test supports a `conversiontag` argument. This test checks the current list of tags associated with the current recipient, one at a time. Note that the `:count` modifier (from the "`relational`" extension), if specified, allows checking of the number of active conversion tags. This type of envelope test is restricted to system-level Sieves. Also note that this test only "sees" the set of conversion tags that were present prior to Sieve processing: the effects of "`setconversiontag`" and "`addconversiontag`" actions are not visible.

When using an "`envelope`" test from a non-channel application or utility such as `imexpire`, note that the External filtering context MTA options may be relevant.

5.1.2.9 Sieve environment extension

New in Messaging Server 7.0-3.01, the Sieve environment extension specified in RFC 5183 (Sieve Email Filtering: Environment Extension) has been implemented. All of the items defined in the RFC are provided, namely: `domain`, `host`, `location`, `name`, `phase`, `remote-host`, `remote-ip`, `version`. Additionally, the `vnd.sun.source-channel` item returns the name of the current source channel and the `vnd.sun.destination-channel` item returns the name of the current destination channel.

New in Messaging Server 7.3-0.01, the `vnd.sun.autoreply-internal` item returns `TRUE` or `FALSE` according to whether the autoreply criteria have been met for use of the "internal" autoreply response text. Also new in Messaging Server 7.3-0.01, the MTA supports two new Sieve environment items, `vnd.sun.authenticated-sender-address` and `vnd.sun.authenticated-sender-id`. The former provides access to the sender address that's associated with the authentication state for the SMTP session. The latter provides similar access to the user identity.

New in 7.0.5, the MTA supports the new Sieve environment item `vnd.oracle.last-verdict`. When the Sieves associated with a recipient are evaluated in order, each evaluation that performs an explicit handling action sets this item as it finishes so the next Sieve in the sequence can check it. A Sieve script that doesn't perform an explicit handling action will leave this item unchanged. Possible values that can be set are:

- `refuse`
- `reject`
- `ereject`
- `jettison`
- `fileinto`
- `redirect`
- `keep`
- `discard`

Note that testing the `vnd.oracle.last-verdict` environment item makes the Sieve script recipient-specific in the same fashion an `envelope "To"` test does, and will result in this and subsequent Sieves being reevaluated for every recipient. Although any script can test this item, it is intended for use when other applications and utilities such as `imexpire` ask the MTA to perform antispam and antivirus checks.

New in 8.0, the MTA supports a new Sieve environment item, `vnd.oracle.mt-priority`. This item returns the current MT-PRIORITY value as a string.

New in 8.0, the MTA supports a new Sieve environment item, `vnd.oracle.operation-type`. This item returns the current type of enqueue operation that is underway. The possible values are "`DEFAULT`", "`SUBMIT`", "`RELAY`", and "`PASSTHROUGH`".

New in 8.0.1.2, the MTA supports new Sieve environment items, `vnd.oracle.notifycount`, `vnd.oracle.notifyquota`, `vnd.oracle.vacationcount`, `vnd.oracle.vacationquota` The "count" items return the number of notification or vacation messages the current sieve has enqueued. The "quota" items return the number of additional notification or vacation actions the current sieve is allowed to perform.

Two additional private Sieve environment items have been added in MS 8.0.2.2. `vnd.oracle.mime_levels` returns the number of accessible MIME levels in the current message, i.e. the MIME "depth" of the message. `vnd.oracle.max_mime_widh` returns the maximum number of MIME parts found in any multipart in the message.

Arbitrary, custom environment items may be set via the `FROM_ACCESS` mapping table or any of the recipient `*_ACCESS` mapping tables using the `$+E` flag. The value of such a custom environment item may subsequently be tested in a Sieve script. For instance, the following `FROM_ACCESS` entry defines, for messages coming in via the SMTP port from the `tcp_local` channel (the Internet), the custom environment item "`heloname`", giving it the value "`yes`" of the name the SMTP client claimed on the HELO/EHLO line:

```
FROM_ACCESS

   TCP|*|25|*|SMTP/*/*|MAIL|tcp_local|*       $C$+Eheloname|$2
```

A Sieve script may then test this custom "`heloname`" environment item:

```
require ["environment","fileinto"];
# First, check if heloname item is set:
if environment :contains "heloname" "" {
# If heloname item IS set, then check its value:
  if environment "heloname" :is "Bogus Name" {fileinto "bogus"; }
}
```

5.1.2.10 Sieve ereject and reject and refuse extensions

The original Sieve specification, RFC 3028, defined the optional "`reject`" extension and action as being required to result in a Message Disposition Notification. RFC 5429 redefined "`reject`" to allow it to refuse messages during the SMTP transaction (rather than accepting messages and generating back a separate MDN), and defined the "`ereject`" action to require messages to be refused during the SMTP transaction. The MTA also supports the nonstandard

"refuse" action, capability name "refuse", which was an earlier draft approach similar to "ereject": note that "refuse" attempts to do an SMTP level rejection but falls back to an MDN when SMTP level rejection is not feasible (as for instance in the case of a multi-recipient message where not all recipients are to be rejected, or when the acceptalladdresses channel option is set), whereas "ereject" will, if SMTP rejection is not feasible, discard messages with forged return-path or fall back to a DSN. The capability name for "reject" with its original behavior (MDN generation) is "reject"; the capability name for the "ereject" action and for the updated behavior from the "reject" action is "ereject".

Note that "ereject", as per its design from RFC 5429, is only intended to be made available on ingress MTAs capable of returning an SMTP level error directly to remote systems in other administrative domains; the enable_sieve_ereject MTA option which enables "ereject" availability is on by default, but may (and should) be disabled on "internal" MTA hosts.

When "refuse" support was first added (MS 6.1), "refuse" was only supported in system-level Sieve scripts. That restriction was removed for MS 6.2. Also, prior to Messaging Server 7.0, a "refuse" for any recipient caused an SMTP-level "refuse" for all recipients; as of Messaging Server 7.0, instead "refuse" performs an SMTP-level rejection only if "refuse" applied to all recipients and otherwise falls back to generating an MDN regarding the "refuse" recipient(s). Also as of Messaging Server 7.0, a "refuse" in a more general (*e.g.*, sytem-level) Sieve will override actions taken by more specific (*e.g.*, user-level) Sieves.

Each of "ereject", "reject", and "refuse" takes a single string argument specifying error text to include in the SMTP error or notification message.

Note that "ereject, "reject", and "refuse" cannot be combined with anything except "discard", "capture", "vacation", or "hold".

Note that any Sieve "notify" actions in a user-level Sieve script will be automatically cancelled when the overall Sieve verdict is "ereject", "reject", or "refuse" (or "jettison"); but "notify" action in a system-level Sieve script will, as of Messaging Server 7.0.5, be honored despite the overall verdict, thus making it possible to use "notify" for some limited administrative auditing purposes.

New in 8.0, the "reject", "ereject", and "refuse" actions will parse any extended SMTP error code (*e.g.*, "5.7.2") that appears at the beginning of the action's string argument in any system-level Sieve script, and use it in preference to the default 5.7.1 extended SMTP error code. This feature is not available to user-level Sieve scripts.

5.1.2.11 Sieve external lists

RFC 6134 (Sieve Extension: Externally Stored Lists) defines a Sieve extension for external lists, EXTLISTS, which is intended for cases where a Sieve script would like to consult an externally-stored list: this might be data in an LDAP directory, a flat file containing a list of something, a database, a personal addressbook, *etc.* In order to use a Sieve external list, a Sieve script must, per Sieve syntax, declare that it will use this extension via

```
require "extlists";
```

The MTA's implementation of EXTLISTS operates as follows. Sieve scripts may use the ":list" argument in a "redirect" action or in tests such as "address", "envelope", "header", "string", "spamtest", or "virustest", *etc.*, or in the test component of the

"deleteheader" or "replaceheader" actions, to indicate a wish to access an "external list". The MTA then makes use of the SIEVE_EXTLISTS mapping table to determine the meaning and contents of the referenced external list.

When an external list is referenced in a Sieve script, via a ":list" argument, *e.g.*,

```
if address :list" "from" "pab" { keep; }
```

or

```
redirect :list "friends";
```

the MTA uses the list name (as well as other data) to construct a probe into its SIEVE_EXTLISTS mapping table. In the case of tests, the probe syntax is:

test-name|*sieve-owner*|*spare_4-value*|*spare_5-value*|*spare_6-value*|*list-name*|*argument-value*

Here *test-name* can be any of hasflags, address, envelope, spamtest, virustest, header, string, environment, currentdate, date, replaceheader, deleteheader. The *sieve-owner* is normally the (canonical address of the) "owner" of the Sieve---so the user's address for user-level Sieves, or normally the postmaster address for system-level Sieves; or the field can be blank if the Sieve has no owner address. The *spare_4-value*, *spare_5-value*, and *spare_6-value* fields contain the values of those LDAP attributes named by the MTA's ldap_spare_4, ldap_spare_5, and ldap_spare_6 MTA options associated with the current envelope recipient; these ldap_spare_* options have no defaults, so by default no values appear here. Furthermore, even if ldap_spare_* MTA options are defined, the *spare_** fields will be blank if the current recipient address was not obtained from an LDAP entry. (And prior to Messaging Server 7.2-0.01, the ldap_spare_* fields would be blank for system Sieve probes; as of Messaging Server 7.2-0.01, the current recipient address's LDAP attribute values are used even for system Sieve probes.) The intention is that such ldap_spare_* MTA options (and corresponding attributes) may be defined and used to store, or a per-user basis, information about how to construct appropriate access URLs for different "types" of external lists: for instance, one of these attributes might store a value which is a sort of template for constructing lookups of lists in that user's personal addressbook, while another of these attributes might store a value which is a sort of template for constructing lookups of lists in that user's calendar (so a CardDAV lookup template). The *list-name* is the argument to the ":list" parameter; for instance, in the examples above "pab" and "friends", respectively. (In fact, consulting multiple external lists is supported, in which case the multiple list names are present in the probe, separated with the vertical bar character.) Finally, the *argument-value* is whatever string from the message corresponds to the Sieve test.

For "redirect" actions, the syntax is:

redirect|*sieve-owner*|*spare_4-value*|*spare_5-value*|*spare_6-value*|*list-name*

where note that there is no final *argument-value*. (The Sieve external lists draft has another, alternate construct for "redirect :list", where the argument assumed above to be a list name is instead a URL to which to do the redirection. While the MTA is capable of supporting such usage, enabling it by matching and returning the argument blindly would be extremely dangerous and is *not* recommended. Recommended configuration and usage is instead to have the SIEVE_EXTLISTS mapping table: (1) expect and match only when a list name is the

argument, and (2) construct and return a sensible URL based upon that list name as well as the other fields of the probe.)

The `S` flag will be set if the Sieve is a system Sieve, and may be tested in the template using the usual `$:S` (flag set) or `$;S` (flag clear) flag test syntax.

The mapping template must set the `$Y` flag if the test succeeds and $N if the test fails. $F may be set to report an error; in this case the mapping result will be used as the error message.

Failure to set $Y, $N, or $F will cause an "unknown list" error to be signaled.

Note that $Y takes precedence over $N, so a single mapping template can set $N before performing a lookup, $Y after, and both the success and failure case will be handled.

In the case of a successful `redirect` action, the template should return a URL pointing to the desired list of addresses.

In addition, if a Sieve test or "`redirect`" making use of a Sieve external list employs any of the `spare_*` fields, then the mapping template must also set the `$*` flag. `$*` tells the Sieve machinery that the test is recipient-specific and the script must be reevaluated for each recipient. Failure to set `$*` can lead to botched test results for multiple recipient messages.

An MTA-specific extension to the Sieve external lists draft is that the MTA will also potentially return properties associated with list entries. If Sieve variables are enabled, then the use of "`:list`" with a test sets variables in a fashion similar to "`:matches`": that is, `${0}` is set to whatever was found on the list, `${1}` is set to the first property value associated with the list entry, `${2}` is the second property value, *etc.* When variables are enabled, the result of the mapping consists of properties separated by vertical bars.

So for instance, suppose a site has the `ldap_spare_5` MTA option defined naming an LDAP attribute in which the users store the leading portion of the LDAP URL for where each user's own, personal, PAB information is stored; for instance, suppose that in the user attribute `psroot` is each user's PAB DN location information in a form of:

```
ldap:///user's-pab-dn
```

Then suppose further that the site wants users to be able to access their personal PAB information for `:list` use in their personal Sieve filters. In particular, the site wants the list named "`pab`", if used in an `address`, `envelope`, or `header` test, to mean "any address found in the user's own PAB", and for any other, more specifically named list *`list-name`*, to mean the contact entries in a user's own PAB that are in the *`list-name`* PAB group; that is, the contact entries marked with "`memberOfPiGroup=`*`list-id`*" where the *`list-id`* was defined in a group entry in the user's PAB (an entry with `objectClass=PiTypeGroup` and with `displayName=`*`list-name`* and `piEntryID=`*`list-id`*). Also suppose that the site uses the `piEmail1` attribute to store the address most suitable for using to send to users. Then the site might want an `ldap_spare_4` setting of

```
# msconfig set ldap_spare_4 psroot
```

where in legacy configuration mode, the setting would be made in the MTA option file as

```
LDAP_SPARE_4=psroot
```

And the might would also want a `SIEVE_EXTLISTS` mapping table including entries such as:

```
SIEVE_EXTLISTS

! Check for the special case of testing whether an 'address' is merely
! present in the user's PAB somewhere -- the test of external list "pab":
!
! test-name|sieve-owner|spare_4|spare_5|spare_6|pab|address-from-message
!
  address|*|*|*|*|pab|*   \
$N$]pab$1?piEmail1?sub?(|(piEmail1=$=$4$_)(piEmail2=$=$4$_)(piEmail3=$=$4$_))[$Y
  envelope|*|*|*|*|pab|*  \
$N$]pab$1?piEmail1?sub?(|(piEmail1=$=$4$_)(piEmail2=$=$4$_)(piEmail3=$=$4$_))[$Y
  header|*|*|*|*|pab|*    \
$N$]pab$1?piEmail1?sub?(|(piEmail1=$4)(piEmail2=$4)(piEmail3=$4))[$Y
!
! Note that no entry to allow redirect to the pseudo-list "pab" is included
! above: this is intentional as making it "too easy" for users to resend to
! all their contacts seems unwise. Instead, redirect is enabled below merely
! for specifically named and defined PAB groups.
!
! Now check for named groups (named external lists); that is, for a named
! group, find the piEntryID for that group.
!
! test-name|sieve-owner|spare_4|spare_5|spare_6|group|address-from-message
!
  address|*|*|*|*|*|*   \
$CGROUP|address|$2|$5|$]pab$1?piEntryID?sub?(&(objectClass=piTypeGroup)(displayName=$4))[
  envelope|*|*|*|*|*|*   \
$CGROUP|envelope|$2|$5|$]pab$1?piEntryID?sub?(&(objectClass=piTypeGroup)(displayName=$4))[
  header|*|*|*|*|*|*   \
$CGROUP|header|$2|$5|$]pab$1?piEntryID?sub?(&(objectClass=piTypeGroup)(displayName=$4))[
  redirect|*|*|*|*|*   \
$CGROUP|redirect|$2|$]pab$1?piEntryID?sub?(&(objectClass=piTypeGroup)(displayName=$4))[
!
! Now find contact entries that have the correct piEntryID, probing with
!
! GROUP|test-name|spare_4|address-from-message|piEntryID
!
  GROUP|address|*|*|%*    \
$N$]pab$0?piEmail1?sub?(&(memberOfPiGroup=$2$3)(|(piEmail1=$=$1$_)(piEmail2=$=$1$_)(piEmail3=$=$1$_)))[$Y
  GROUP|envelope|*|*|%*    \
$N$]pab$0?piEmail1?sub?(&(memberOfPiGroup=$2$3)(|(piEmail1=$=$1$_)(piEmail2=$=$1$_)(piEmail3=$=$1$_)))[$Y
  GROUP|header|*|*|%*    \
$N$]pab$0?piEmail1?sub?(&(memberOfPiGroup=$2$3)(|(piEmail1=$=$1$_)(piEmail2=$=$1$_)(piEmail3=$=$1$_)))[$Y
!
! Note redirect case needs to return PAB URL itself, rather than lookup result.
! It is assumed that for all lists, the most appropriate user addresses to use
! for redirection are stored in the users' piEmail1 attribute.
!
  GROUP|redirect|*|%*   pab$0?piEmail1?sub?(memberOfPiGroup=$1$2)$Y
```

Note here how the user's initial portion of an LDAP URL value, stored in the attribute named by `ldap_spare_5`, is converted by the `SIEVE_EXTLISTS` mapping table into the MTA's `pabldap:` URL format (the format that tells the MTA that this is an LDAP URL for querying the PAB directory---the LDAP directory that the MTA locates via its `ldap_pab_*` options). For the special case of an "`address`" or "`envelope`" test against the so-called list named merely "`pab`", the user's own entire PAB is searched, looking for entries where the test argument matches the value of any of the attributes `piEmail1`, `piEmail2`, or `piEmail3` in a PAB entry. For other named lists/groups, the list/group name is used to attempt to locate a corresponding entry (with `objectClass` of `piGroupType` and a `displayName` matching the specified group/list name), and when found, retrieve the `piEntryID` value that indicates that group/list. Then a second lookup is performed, to find those contact entries that have

a `memberOfPiGroup` value for the group/list in question. In the case of an "`address`" or "`envelope`" test against named lists, the user's PAB is searched looking for entries where both the list ID is present in the entry in a `memberOfPiGroup` attribute, and the entry's `piEmail1` value matches the test argument. Just in case a user configures a "`header`" test for address matching purposes (though note that this is poor user practice, as "`address`" or "`envelope`" tests are more appropriate for such purposes), "`header`" tests are set up similarly, though including matching against alias values (`piEmail2` and `piEmail3` in addressbook attributes, analogous to the MTa's usual `mailAlternateAddress` and `mailEquivalentAddress` attributes) as well as against the canonical `piEmail1` (analogous to MTA's `mail` attribute) value. And in the case of a "`redirect`" action, the mapping returns not the actual addresses, but rather a "`pabldap:`" URL specifying where to find the appropriate addresses to which to redirect; this URL will be the new address (the address to which to redirect) enqueued to the reprocess channel, which in turn will perform the actual list expansion (expand that URL into the addresses it specifies). Note that the `max_redirect_addresses` MTA option limits how many addresses will actually be used from such a list; additional addresses will be ignored.

With Sieve access to user personal PAB's set up as above, then users can make use of the addresses in their PAB in various ways in their Sieve scripts.

As a simple example, suppose that a system-level Sieve would do a

```
discard;
```

on a message for whatever reason: perhaps because a spam/virus filter package callout returned a verdict suggesting that a message is spam; perhaps due to the source-IP being suspect; whatever. But if a user wishes to keep any message purporting to come from one of their known correspondents, then that user might use a personal Sieve filter with explicit `keep`" and "`fileinto`" actions to override the system-level "`discard`", *e.g.*,

```
require ["envelope","extlists"];
...other-actions-such-as-list-fileintos...
if envelope :list "from" "pab" { keep; }
```

Or for another example, suppose that a system-level Sieve filter (perhaps configured as part of a spam/virus filter package callout so configured via a `spamfilterN_action_M` MTA option value) has a Sieve effect of:

```
require ["spamtest","relational"];
if spamtest :value "ge" "200" { discard; }
```

Then a user might use a Sieve test and action such as:

```
require ["envelope","extlists"];
if envelope :list "from" "pab" { spamadjust "-10000"; }
```

In this example above, the user adjusts the spamtest value downward (drastically) for any sender address found in the user's own PAB. With such a drastically lowered spamtest value, the message will likely be safe from any system-level Sieve spamtest that might otherwise choose to discard or reject the message. (And the user's Sieve can continue on to do any further `fileinto`" or other operations that may seem desirable to the user. Leaving open the potential for the user's own Sieve to perform further actions, such as "`vacation`" or

"fileinto" or "redirect", is a reason why a user might prefer to do a "spamadjust" rather than an explicit "keep" for known senders.)

Or the user's Sieve might do more subtle adjusting and testing:

```
require ["envelope","extlists","fileinto","spamtest","relational"];
   /*  First, lower the spam score for senders in my PAB  */
if envelope :list "from" "pab" { spamadjust "-100"; }
   /* But better check open-list postings -- that list gets
      postings with forged From addresses.  If the spam score
      if over 200 even after any adjustment for being
      sent by a recognized contact, discard the message. */
if allof (header :contains ["To","Cc","Bcc"] "open-list@domain.com",
          spamtest :value "ge" "200") {
     discard;
     stop;
     }
   /* File messages to or from my buddies in my "softball" PAB list
      or with softball in the subject, to my softball folder */
if anyof (envelope :list ["from","to"] "softball",
          header :contains "Subject" "softball") { fileinto "softball"; }
   /* Discard mildly spammy messages (mild after adjustment for known
      senders, above) that don't show me on a recipient header
      line */
if allof (not header :contains
            ["To","Cc","Bcc","Resent-to","Resent-Cc","Resent-Bcc"]
            "my-own-address",
          spamtest :value "ge" "50") {
      discard;
      stop;
      }
    /* Keep messages from known (in my PAB) correspondents */
if envelope :list "from" "pab" { keep; }
```

Comparing date with list of holidays

For another example, suppose that a site keeps a list of site-wide holiday days stored in the MTA's general database, in general database entries of the form:

```
HOLIDAY|yyyy-mm-dd       Yes
```

(where for purposes of this example, it is the mere existence of an entry that matters, not the details of what its right hand side translation value---here Yes---may be), and that the site wishes users to be able to perform "currentdate" and "date" tests against that list using the special list named "holiday". Then the site might use:

```
SIEVE_EXTLISTS

  currentdate|*|*|*|*|holiday|*   $N$C${HOLIDAY|$4}$Y$E
  date|*|*|*|*|holiday|*          $N$C${HOLIDAY|$4}$Y$E
```

This would then allow users to use tests such as

```
require "["date","extlists"];
if currentdate :list "date" "holiday" { redirect "mobile-address"; }
```

A more sophisticated use would be to store a label specifying the type of holiday (*e.g.*, "`National`", "`Municipal`", "`Religious`", "`Corporate`", *etc.*) as the right hand side of each general database entry. Then Sieve scripts could check that returned value as a property (using the Sieve variables extension and checking the returned property value via `${1}`) and perform additional decision making based on the type of holiday.

Sieve external list tests don't have to involve checking an actual list. In such cases a string test is typically used since no value actually comes from the message. For example, the mechanism can be used to implement a user attribute which, if present, is inserted into all messages delivered to the user as a header. The first step is to make the attribute, which we'll call *userAddHeader*, available to the external list machinery as a spare attribute:

```
# msconfig set ldap_spare_4 userAddHeader
```

The SIEVE_EXTLISTS mapping would then be:

```
SIEVE_EXTLISTS

    string|*||*|*|addheader|*    $N$*
    string|*|*|*|*|addheader|*   $Y$1$*
```

Note the use of $* to make this sieve recipient-specific.

And the sieve to perform the header addition would be:

```
require ["extlists", "editheader", "variables"];
if string :list "addheader" "addheader" {
  addheader "X-Added-Header" "${1}";}
```

This would probably best be implemented as a destination channel sieve, although any type of sieve would work.

5.1.2.11.1 Example Sieve external lists with properties

The MTA supports a private feature of Sieve external lists, whereby external lists can return properties associated with list entries. This can be a powerful additional tool. This section presents two examples below, both variants on "capturing" copies of particular messages passing through the MTA.

Capturing a user's "external" messages

Suppose that you wish to capture copies of certain users' Internet correspondence, without bothering to capture copies of those users' internal correspondence (meaning that direct use of an `ldap_capture` LDAP attribute would capture unneeded messages), and that you'd like to keep track of which users are in this category in LDAP, rather than hard-coding such a list directly into a Sieve script. One approach for doing this would be to use channel-level

source and destination Sieve scripts on the tcp_local channel (which is the channel handling messages coming in from, or going to, the Internet), where such Sieve scripts make use of an external list to check LDAP to determine which users' messages are eligible for capture. Using the properties feature of the MTA's Sieve external lists implementation, the external list will also return the capturer address to use (the address to which to send the captured message copies). The components of such an approach are:

1. Add some user-level LDAP attribute to the schema (or disable schema checking) and set that attribute on the users for whom you want capture, with a value which is the address to which to send the captured message copies. (Note that typically such an attribute should have ACIs so that users themselves can't even see the attribute, let alone change its value.) This example will assume there is an attribute named mailCaptureInternet for this purpose. (Note that if you already have ldap_capture defined and pointing to the name of some LDAP attribute used for unconditional capture, then you probably don't want to use the same attribute for this "conditional" capture, as that would merely result in an additional capture copy in the "conditional" cases. Instead you want a different LDAP attribute, which will only be consulted and have an effect in this special case.)

2. Set the ldap_spare_4 MTA option to the name of this "conditional capture" attribute; in unified configuration:

   ```
   msconfig> set mta.ldap_spare_4 "mailCaptureInternet"
   ```

   or in legacy MTA configuration mode, set in the option.dat file:

   ```
   LDAP_SPARE_4=mailCaptureInternet
   ```

   Pointing ldap_spare_4 at this attribute means that the attribute's value will be included in probes of the SIEVE_EXTLISTS mapping table, which will turn out to be convenient.

3. Define Sieve external lists named "capture-to" and "capture-from" via a SIEVE_EXTLISTS mapping table as follows. (In legacy configuration mode, this SIEVE_EXTLISTS mapping table should be placed in the MTA mappings file; in Unified Configuration mode, the mapping table can be created by editting from within the msconfig utility.)

```
SIEVE_EXTLISTS

! Define an external list named "capture-to" for use in "envelope" tests of
! the To address.  Because the LDAP_SPARE_4 field of the pattern has a
! match pattern of %*, a probe will match this entry only when the envelope
! To recipient being tested has a non-empty mailCaptureInternet value:
!
  envelope|*|%*|*|*|capture-to|*   $Y$*$1$2
  envelope|*|*|*|*|capture-to|*    $N
!
! When the probe matches, the test succeeds ($Y) and the entry returns
! <mailCaptureInternet-value> for the matched address as the first (indeed
! only) property, so it will be accessible via Sieve ${1} variable.
! Note that because this is a recipient-specific test, making use of the
! LDAP_SPARE_4 value, the entry includes $* in the template.
!
! Now define an external list named "capture-from" for use in "envelope" tests
! of the From address.  Because the Sieve language is oriented towards
! performing actions on behalf of message recipients, obtaining information
! from LDAP regarding the message sender (envelope From) requires some
! additional, explicit LDAP lookups (more than is required for the "capture-to"
! external list case).
! First, get the base DN for the user entries in the domain of the From
```

```
! address and rebuild a new probe:
!
  envelope|*|*|*|*|capture-from|*@*  $N$CBASEDN|FROM|$4@$5|$}$5,_base_dn_{
!
! If the envelope From was that of a user in one of "our" domains, then
! the $}<domain-name>,_base_dn_{ lookup should succeed, so the entry
! succeeded and the probe is now:
! BASEDN|FROM|<from-address>|<basedn-of-from-domain>
!
  BASEDN|FROM|*|*     \
$C$]ldap:///$1?mailCaptureInternet?sub?(&(|(mail=$=$0$_)(mailEquivalentAddress=$=$0$_))(mailCaptureInternet=$=*$_))[$Y
!
! When this probe matched and the LDAP lookup succeeds, then the test
! succeeds ($Y) and the entry returns <mailCaptureInternet-value>
! as a first property (so accessible via Sieve ${1} variable), thus the
! capture attribute value for that matched address is available.
```

4. On the `tcp_local` channel (and any other dedicated-to-Internet-correspondence channel(s)), use a `sourcefilter` Sieve along the lines of:

```
require ["envelope","extlists","variables"];
if envelope :list "to" "capture-to" { capture "${1}"; }
```

and a `destinationfilter` Sieve along the lines of:

```
require ["envelope","extlists","variables"];
if envelope :list "from" "capture-from" { capture "${1}"; }
```

Note that this example used the same LDAP attribute `mailCaptureInternet` to determine capture for both incoming and outgoing directions. (The incoming, "`capture-to`", list took advantage of setting `ldap_spare_4` to conveniently fetch the value of this attribute for the recipient; for the outgoing, "`capture-from`", list, two separate, explicitly configured LDAP lookups were required to first locate where in the directory to search, and second fetch the actual attribute value.) But separate attributes could be used, if different criteria were desired for incoming *vs*. outgoing. Also, in this example the Sieve external list itself simply checks the attribute value---and the fact that the capture is (intended) for Internet correspondence is incorporated by virtue of the Sieve filters being placed on the Internet correspondence channel (`tcp_local`). More complicated Sieve filter tests combined with this external list consultation could further refine which messages are captured; see for instance, the additional, "attachment type" testing shown in the example below. Or use of a Sieve filter consulting these external lists on different MTA channels could completely alter which messages get captured.

5.1.2.11.2 Testing Sieve external lists

As usual for Sieve filters, the `imsimta test -expression` utility is one way to do some checking and testing on Sieve external lists. And it may be worth making special note that use of the utility with the switch `-debug=3` will show some details of operation of the `SIEVE_EXTLISTS` mapping table lookup; this may be especially useful for debugging or confirming correct configuration of a `SIEVE_EXTLISTS` mapping table.

5.1.2.12 Sieve fileinto action

RFC 5228 (Sieve) defines the "`fileinto`" action as optional since though quite desirable, it may not be possible in some environments. In order to use "`fileinto`", a Sieve script must, per Sieve syntax, declare that it will use it via

```
require "fileinto";
```

Note that "fileinto" is not supported for domain Sieves. And the number of "fileinto" actions that may be performed by a Sieve script is limited (as of the 8.0 release, this limit only applies to user-level Sieves) by the max_fileintos MTA option (default value 10).

To implement a Sieve script's "fileinto" action, the MTA's behavior is controlled by the fileinto channel option: that channel option is normally configured to insert the folder-name specified by the Sieve script's "fileinto" argument into the recipient address in the form of a subaddress. Next, the MTA must pass along to the Message Store the decision of whether to "trust" the subaddress for folder delivery purposes; relevant channel options are deliveryflags and flagtransfer. Note that even if a Sieve script appears to perform a "fileinto" action, the actual delivery-into-a-folder requires that proper configuration have been performed to properly implement the transfer to the Message Store of the desired "fileinto" effect.

The copy extension adds a ":copy" tag to "fileinto" (so that the "fileinto" does not, as would be normal, cancel the Sieve "implicit keep"). The imap4flags extension adds, among other features, a ":flags" tagged argument (to specify IMAP flags to set on the message as it is delivered).

Note that users are permitted to "fileinto" their *own* folders; in contrast, delivery to another user (or to a desired folder belonging to another user) is *not* a "fileinto" effect but rather requires a "redirect" action. There is one exception to this, and that is the case (such as in cases of head of household Sieve filters) where the owner of a Sieve differs from the user on whose behalf the Sieve is being applied; the MTA's private ":owner" tag specifies that the folder named is that of the owner of the Sieve filter, rather than of the user for whom the Sieve is being applied.

5.1.2.13 Sieve ihave extension

As of Messaging Server 7.0, the MTA supports the Sieve ihave extension described in RFC 5463 (Sieve Email Filtering: Ihave Extension); the capability name is "ihave". This includes the "ihave" test and the "error" control structure.

The ihave test takes as argument a list of capability names and returns true if all the listed capabilities are available to the Sieve script. Thus this permits a Sieve script to be coded in such a way as to be flexible regarding what extensions it attempts to use, and also potentially to be portable (run in different environments). In particular, when a capability's availability has been confirmed via a successful ihave test, then that extension becomes available throughout the entire Sieve script, as if it had been listed in a require action. The error control structure may be used when it is desired to exit with a runtime error if an ihave test fails (a capability is not available).

5.1.2.14 Sieve imap4flags extension

As of MS 6.3p1, the MTA supports the Sieve imap4flags extension of RFC 5232; the capability name is "imap4flags". This includes the "addflag", "setflag", and "removeflag" actions, and the "hasflag" test, as well as the ":flags" argument for the "keep" and "fileinto" actions.

Note that as IMAP system flags always begin with a backslash character, \, and as backslash is the quoting character in Sieve, when specifying such an IMAP system flag, the backslash in the flag name must itself be quoted with another backslash, *e.g.*:

```
require "imap4flags";
keep :flags "\\Flagged";
```

An example of setting a user IMAP flag is:

```
require "imap4flags";
if header :contains "Disposition-Notification-To" "*@domain.com" {
  addflag "$MDNRequired";
  }
```

Note that as of Messaging Server 7p24 and 7.0.5, `imexpire` supports expiring messages based on user flags.

5.1.2.15 Sieve mime extension

As of Messaging Server 7.0u1, the MTA supports the Sieve `mime` extension of RFC 5703 (Sieve Email Filtering: MIME Part Tests, Iteration, Extraction, Replacement, and Enclosure); the capability name is "`mime`". (The MTA does not, however, support either "`replace`" or "`enclose`", also described in RFC 5703; for replacement sorts of effects, see instead the MTA's charset conversion facility or the conversion channel, and for enclosure sorts of effects, see instead the MTA's message capture facilities.)

New in the 8.0 release is support for the "`foreverypart`" Sieve extension (from RFC 5703); the capabability name is "`foreverypart`". In addition to the "`break`" control command, the MTA's implementation also supports the nonstandard "`continue`" control command:

```
continue [:name string]
```

"`continue`" has the expected semantics: control is passed to the bottom of the "`foreverypart`" loop.

Note that the MTA also supports a nonstandard "`loop`" extension, discussed under Sieve loop extension. It is wise to stick with use of "`foreverypart`" when it suffices for a purpose, but the "`loop`" construct does offer another alternative for more complex loop-based processing.

New in the 8.0 release is support for the "`extracttext`" Sieve extension (from RFC 5703). Note that since the MTA's Sieve support is implemented as an overlay on top of an underlying language interpreter, the use of "`extracttext`" outside of a "`foreverypart`" is not detected as an error at compile time. Additionally, "`extracttext`" is only supported on leaf parts: it cannot be used on multipart and message/rfc822 parts.

New in MS 8.1 is the ability to control whether or not the foreverypart Sieve control looks inside of nested messages or treats them as leaf parts. The `:processnestedmesssages` argument tells foreverypart to look inside and is the default. `:retainnestedmessages` causes nested messages to be treated as leaf parts.

As of the 8.0 release, the behavior of the Sieve "`size`" test inside of "`foreverypart`" loops has been changed. Previously "`size`" operated on the message as a whole no matter what the context; now it operates on the current part only. Note that only decoded part data is

considered; part headers are not included in the size calculation. Also note that the size of non-leaf (message and multipart) parts is currently zero; this may or may not be changed in the future.

This nonstandard extension to the Sieve "`size`" test is mainly intended to be used to implement attachment size checks. However, since the "`size`" test can also be used as function call (in which case it returns the size in octets), this can also be used in conjunction with "`foreverypart`" to build message manifests for insertion into header fields or logging with the "`transactionlog`" action.

For instance, one use of "`foreverypart`" would be to scan the parts of a message to build a so-called "manifest" of the message, where the `addprefix` extension could be used to add the manifest to the first text part of the message:

```
require ["variables","mime","foreverypart"];
addprefix "Manifest:";
foreverypart {
  if not anyof (header :mime :type :is "Content-type" "multipart",
                header :mime :type :is "Content-type" "message")
    {
    if header :mime :contenttype :matches "Content-type" "*" {
      addprefix "Part " + "${0}" + ", Size " + size + " characters of content";
    }
  }
}
addprefix "Total size: " + size + " characters including header";
addprefix "End of manifest.\r\n\r\n";
```

In a system-level Sieve (so that `addconversiontag` may be used), the following Sieve script will add a conversion tag incorporating the message's content size as part of the conversion tag:

```
require ["variables","foreverypart"];
counter = 0;
foreverypart { counter = counter + size; };
addconversiontag "size" . counter;
```

As of the 8.0 release, when user Sieves are allowed to use integer variables (system-level Sieves had already been allowed to do so), the following Sieve would work even at user-level to add a manifest to the first text part of the message:

```
require ["variables","mime","foreverypart"];
partnumber=0;
total=0;
addprefix "Manifest:";
foreverypart {
  if not anyof (header :mime :type :is "Content-type" "multipart",
                header :mime :type :is "Content-type" "message")
    {
    partnumber += 1;
    total = total + size;
    if header :mime :contenttype :matches "Content-type" "*" {
      addprefix "Part # " . partnumber . " of type " . "${0}" .
                " and size " . size . " characters";
```

```
      }
    }
  };
addprefix "Total size: " . size . " characters including header, with";
addprefix "            " . total . " characters of content.";
addprefix "End of manifest.\r\n\r\n";
```

5.1.2.16 Sieve notify extension

New in MS 7.0.5, the MTA supports RFC 5435 (Sieve Email Filtering: Extension for Notifications) and RFC 5436 (Sieve Notification Mechanism: mailto). As of MS 8.0, a private `nonotify` system-level action is also provided. And finally, as of MS 8.0.2.3, the File Carbon Copy (Fcc) described in the Internet-Draft draft-ietf-extra-sieve-fcc-02.txt is also supported.

5.1.2.16.1 The notify extension

The capability identifier for the notify extension defined in RFC 5435 is "`enotify`". This support extends, rather than replaces, the MTA's existing support (since MS 6.2) for a subset of the "`notify`" action defined in draft-martin-sieve-notify-01.txt.

The limitations on the implementation of draft-martin-sieve-notify-01.txt are:

1. The message parameter is not optional.
2. The "$...$" substitutions defined in section 3.1 are not supported. (Sieve variables may be used to provide this functionality.)
3. The "denotify" action is not supported.

Both forms of "`notify`" can be used simultaneously; *e.g.*:

```
require ["enotify","notify"];
# New, standard form -- the enotify capability
notify :message "subject-text" "mailto:a@b?body=body-text";
# Equivalent older form from the Martin draft -- the notify capability
notify :method "email" :options "a@b" "subject-text" "body-text";
```

If both "`notify`" extensions are enabled, the action arguments are examined to determine which extension is being used.

New in 7.0.5, "`notify`" actions in user-level Sieves are automatically cancelled when the overall Sieve verdict is "`jettison`", "`refuse`", "`reject`", or "`ereject`". "`notify`" in a system-level Sieve was treated the same, but no longer: such "`notify`" actions will now be honored, making it possible to use "`notify`" for some limited administrative auditing functions.

Note that by default, the "`notify`" action (both types) is disabled; to enable use of it, the `max_notifys` MTA option must be set to a positive value. Also note that as of 7.0.5, the MTA tracks uses of "`notify`" and limits successive (repeated) such actions within some time period; configuration of this is controlled by various autoresponse periodicity MTA options.

Normally, specifying a syntactically invalid recipient address, or syntactically invalid "`:from`" address, in a "`notify`" action results in the Sieve script aborting with an error. New in Messaging Server 7.0.5, the `notify_ignore_errors` MTA option may be enabled to cause such syntactic errors to be silently ignored.

5.1.2.16.2 The notify_method_capability and valid_notify_method tests

The `enotify` extension also adds two new tests, `valid_notify_method` and `notify_method_capability`. `valid_notify_method` takes an argument consisting of a list of notification methods and returns true if they are supported *and* syntactically valid, or false otherwise. `notify_method_capability` takes three arguments, a notification-uri, a notification-capability, and a list of keywords, and succeeds if a match occurs; this is intended to permit checking whether a desired form of notification can be performed as desired.

The `enotify` extension also adds a modifier `:encodeurl` to the `set` action of the `variables` extension. `:encodeurl` causes percent-encoding of any octet in the string that doesn't belong to the "unreserved" set for URIs, as described in RFC 3986 (Uniform Resource Identifier (URI): Generic Syntax).

5.1.2.16.3 The nonotify action

New in 8.0, the MTA supports a private action for system-level Sieves "`nonotify`", which suppresses all applications of either form of the "`notify`" action. (Technical note: "`nonotify`" affects those Sieves which are *both*: attached to the same recipient address, *and* evaluated later.)

5.1.2.16.4 The :mime nonpositional parameter

Both forms of the notify support support the nonpositional :mime parameter. If specified this parameter has the same semantics as with the vacation action: The causes the specified message body to be treated as a MIME entity as defined in RFC 2045 section 2.4, including both MIME headers and content.

5.1.2.16.5 The fcc extension

The `fcc` extension defines a new optional tagged argument ""fcc" that can be used with the notify and vacation actions to allow a copy of the vacation or notification message to be filed into a target mailbox belonging to the sieve owner. The mailbox argument to :fcc is analogous has the same semantics as the mailbox argument to the fileinto action; in effect it is as if a copy of the message was sent to the sieve owner with a user sieve specifying a fileinto action.

Support for the `fcc` extension was added in MS 8.0.2.3.

5.1.2.17 Sieve override extension

Multiple sieves can be and often are evaluated for a given message recipient. When this happens some actions, such as `addheader`, `capture`, or `addconversiontag`, are accumulated across all applicable sieves. But actions that determine the ultimate disposition of a message have to come from a single sieve.

The general rule is that the most specific sieve that sets a disposition wins. So if, say, a keep done by a system sieve would be overridden by a discard done by a user sieve.

A couple of nonstandard actions have previously been added to override this determination order. In particular, the most general sieve that performs a `jettison` or `refuse` action will determine the disposition of a message for a given recipient.

The use cases for `jettison` and `refuse` are obvious: If system policy has determined that a user cannot see a message, the user's own preferences need to be overridden. The jettison and refuse actions also have the advantage that they are incompatible with other disposition actions, making them easy to use.

In contrast, the other disposition actions (keep, discard, fileinto, redirect, etc.) are all compatible with each other, and in practice are used in a wide variety of combinations and permutations. So separate "override" variants of these actions don't make as much sense.

Even so, it may be useful for a system-level sieve to forcibly direct messages using redirect and possibly fileinto, while retaining their standard semantics in the context of the sieve where they are specified. For this to work correctly, such sieves need to be able to override disposition actions specified by more specific sieves. Accordingly, a nonstandard sieve override extension and corrresponding action has been added. A sieve that uses this action becomes the sieve determining the disposition of the message. If multiple sieves employ override, the most general one wins.

For example, suppose you have a system sieve:

```
redirect "foo@bar";
```

And the recipient has a user sieve:

```
keep;
```

The `keep` action wins and the message is filed into the recipient's INBOX folder. Now suppose the system sieve is changed:

```
require "override"; override; redirect "foo@bar":
```

Now the redirect action wins and the message is redirected.

5.1.2.18 Sieve redirect action

The Sieve "`redirect`" action performs a type of forwarding of a message. It cannot be combined with any of "`refuse`", "`reject`", or "`jettison`", whose semantics all imply no retention of the message (including no forwarding). The `max_redirects` MTA option imposes a limit on the maximum number of "`redirect`" actions that a user Sieve script is allowed to apply. As of 8.0, this limit applies only to user-level Sieves. Note that when the MTA performs a "`redirect`" action, it generates the new message (the redirected, that is, forwarded message) via enqueue to (prior to 8.0) the `reprocess` channel or (as of 8.0) the `process` channel.

A number of extensions can modify the effect of the standard Sieve "`redirect`" action.

The "`copy`" extension defined in RFC 3894 adds the "`:copy`" parameter to permit "`redirect`" to take effect without cancelling the default action of saving the message to the "INBOX".

Added in MS 6.3p1, the "`:resent`" and "`:noresent`" arguments are supported on the Sieve "`redirect`" action, for controlling whether Sieve "`redirect`" actions cause addition of Resent-* header lines. The `sieve_redirect_add_resent` MTA option may be used to control the MTA's default behavior. See also the `defer_header_addition` MTA option, which controls whether Sieve filters see added headers on redirected messages.

New in MS 6.3p1, the Sieve "`redirect`" action supports the "`:resetmailfrom`" and "`:keepmailfrom`" parameters, to control whether the envelope FROM for the redirected message is reset to match the Sieve owner, *vs.* the "original" envelope FROM address being

retained for use on the redirected message. Note that by DSN rules, "`:keepmailfrom`" cannot be used when "`:notify`" or "`:ret`" are also specified on a "`redirect`" action.

As of Messaging Server 7.0u2, the `redirect-dsn` extension (capability name "`redirect-dsn`") defined in RFC 6009 allows control over delivery status notification (DSN) parameters, adding two new parameters "`:notify`" and "`:ret`". (The "`:notify`" parameter support was actually added for MS 6.3p1, prior to standardization; standardization in RFC 6009 occurred in time for Messaging Server 7.0u2.)

The Sieve "`extlists`" extension may be used in conjunction with a "`redirect`" action, to redirect a message to (an externally stored) list of recipients. The `max_redirect_addresses` MTA option imposes a limit on how many such externally stored recipients will be used from the external list.

Note that when the Sieve environment extension is used, the "`vnd.oracle.last-verdict`" item is available, and one of its possible values is "`redirect`" -- which will be the case if and when the prior Sieve script that applied performed an explicit handling action of "`redirect`".

5.1.2.19 Sieve relational extension

RFC 5231 (Sieve Email Filtering: Relational Extension) adds relational operators to Sieve conditional tests such as "`address`", "`envelope`", and "`header`". The capability identifier is "`relational`":

```
require "relational";
```

Relational adds the "`:count`" match-type permitting counting the number of entities, and the "`:value`" match-type permitting numeric comparisons of the following forms:

```
:value "gt"
:value "ge"
:value "lt"
:value "le"
:value "eq"
:value "ne"
```

As of MS 8.0.1.3, the MTA allows :count to be combined with other match-types in header and address tests. When this is done the test performs the non-count match first, counting the number of matches. The resulting count is then compared with a third argument. An "i;ascii-numeric" comparator is always used for this second match.

For example, the following test checks to see if the domain "example.com" appears in more than five Received: fields and holds the message if it does:

```
if header :count "gt" :contains "received" "example.com" "5" {hold;}
```

Note that the address test counts addresses, not fields. For example, the following test checks to see if there are less than 10 addresses that have a subdomain of example.org as their domain in a recipient field:

```
if address :count "lt" :matches
```

```
:domain ["to", "cc", "bcc"] "*.example.org" "10" {...}
```

5.1.2.20 Sieve spamtest and virustest extensions

RFC 5235 defines Sieve filter extension tests "`spamtest`" and "`virustest`" intended to allow users to test whether a message is spam (unsolicited bulk e-mail) or contains a virus, with the Sieve test syntax itself being independent of the exact mechanism by which the message was determined to be spam or contain a virus. Typically the actual spam/virus determination might be made by a third-party spam/virus filter package returning a verdict; to convert the underlying spam/virus filter package verdict to a form usable (testable) with "`spamtest`" and "`virustest`", the MTA provides private extensions "`spamadjust`"" and "`virusset`". (The MTA also (7.0u2) supports setting a spam score via the `$,` flag in a `FROM_ACCESS` mapping table or recipient `*_ACCESS` mapping table, for cases where, say, a particular message source can be presumed to be emitting spam and/or virii.)

The capability identifiers for the tests from RFC 5235 are "`spamtest`" (or "`spamtestplus`" if the "`:percent`" argument to "`spamtest`" will be used) and "`virustest`". The MTA's private "`spamadjust`" and "`virusset`" actions are available without any special capability declaration; no "`require`" action is needed for their use.

Because the intended purpose of "`spamtest`" and "`virustest`" is to increase the portability and logical clarity of spam and virus handling in Sieve scripts, insulating the Sieve script from the details of the actual spam or virus detection/determination, understanding the interaction of multiple Sieve scripts may be of special relevance when setting up to enable use of such tests. For instance, a typical sort of use might be that when a spam/virus filter package returns a string verdict including some spam score, then the MTA is configured to convert that string into a spam score using the "`spamadjust`" action via a corresponding pair of MTA options `spamfilterN_verdict_M` and `spamfilterN_action_M`:

```
msconfig> exec get_path "config"
> "/opt/SUNWmsgsr/config"
msconfig> show spamfilter1_*
role.mta.spamfilter1_config_file = IMTA_TABLE:spamassassin.dat
role.mta.spamfilter1_library = IMTA_LIB:libspamass.so
role.mta.spamfilter1_name = SpamAssassin
msconfig> set spamfilter1_verdict_0 False*
msconfig# set spamfilter1_action_0 'require "addheader";virusset "0";addheader "Spam-test: $U";spamadjust "$U";'
msconfig# show spamfilter1_*_0
role.mta.spamfilter1_action_0 = require "addheader";virusset "0";addheader "Spam-test: $U";spamadjust "$U";
role.mta.spamfilter1_verdict_0 = False*
```

Then a user Sieve filter has a spam score available to test. And for instance, one user might choose to configure:

```
require ["fileinto", "spamtest","virustest","relational"];
if virustest :value "ge" "3" { discard; }
if spamtest :value "ge" "100"
  { if spamtest :value "ge" 200" { discard; }
    else {fileinto "spam"; }
  }
```

The MTA's support for Sieve external lists (7.0u1) includes supporting their use (supporting a "`:list`" argument) in "`spamtest`" and "`virustest`" tests. (For an entirely different in details and intention use of "`spamadjust`" and "`spamtest`" in conjunction with a Sieve external list,

see the example of "white-listing" Personal AddressBook addresses via a Sieve external list; in that example, the external list is a list of addresses, not a list of spam or virus levels.)

As of Messaging Server 7.0u3, the "`spamtest`" and "`virustest`" levels in effect for the active Sieve filter for a given recipient will be included in "`E`" (Enqueue) MTA message transaction log file entries when the `log_filter` MTA option is enabled. This will appear between the Sieve name and the applied action list, *e.g.*:

```
file:///file-spec, spamtest 26.000000, discard
```

5.1.2.21 Sieve subaddress extension

The MTA supports the Sieve subaddress extension specified in RFC 3598 (Sieve Email Filtering -- Subaddress Extension). The capability string is "`subaddress`":

```
require "subaddress";
```

The subaddress extension adds support for keywords "`:user`" (the local-part minus the subaddress) and "`:detail`" (the subaddress itself) to the address test and, if the envelope extension has also been enabled, to envelope tests.

Note that configuration of what character the MTA interprets as the separator between the username and their subaddress is controlled by the `subaddress_char` MTA option (by default, the plus character, `+`); background on other aspects of the MTA's subaddress handling can be found in the discussion of `subaddressexact` and related channel options.

Use of subaddresses on an email address, whether when subscribing to mailing lists, or for list moderator purposes, or for special purpose message forwarding, can make specialized handling of particular sorts of messages much more convenient. In reaction to the presence of a subaddress, a user's Sieve script might: deliver the message directly into a folder (use "`fileinto`"), generate an alert notification (use "`notify`"), perform particular forwarding (use "`redirect`"), *etc.* For instance, suppose a user has subscribed to a mailing list using the subaddress `game-list`. Then the following Sieve script:

```
require ["envelope","subaddress","fileinto"];
if envelope :detail "to" "game-list" { fileinto "games"; }
```

would cause messages addressed to the user due to their membership of that list to get filed into the folder named "`games`".

5.1.2.22 Sieve vacation extension

The MTA supports the standard Sieve extensions "`vacation`" and "`vacation-seconds`", defined in RFC 5230 and RFC 6131, respectively, in user-level Sieve filters. The respective capability names are "`vacation`" and "`vacation-seconds`", with "`vacation-seconds`" implying "`vacation`" which then need not be separately listed in a require clause; it suffices to list:

```
require "vacation-seconds";
```

In addition to the basic ":days" argument for "vacation", and the ":seconds" argument added by "vacation-seconds", the MTA also supports a private argument ":hours" (with the obvious meaning).

The max_vacations MTA option specifies the maximum number of Sieve "vacation" actions that may be performed by a Sieve script, with the default being 2. Exceeding this allowed number of vacation actions will result in an error "Too many vacations specified" during Sieve filter evaluation. (Though as of Messaging Server 7.0.5, if max_vacations=0 is set, then the "require" clause will fail and instead the error upon attempting to use "vacation" or "vacation :seconds" will be "Vacation not listed in require clause prior to use" or "Vacation-seconds not listed in require clause prior to use".)

The MTA supports a private action for system-level Sieves, "novacation", to disable user-level use of "vacation". Use of "vacation" may also be disabled via the FROM_ACCESS mapping table's$! flag; indeed, initial configuration of the MTA normally generates such a FROM_ACCESS mapping table to disable vacation message generation back to typical list "owner" addresses. (Technical note: New in 8.0, the effect of "novacation" has been refined a bit. In previous versions, "novacation" only took effect in Sieves evaluated after the one where "novacation" was invoked, and then "novacation" affected *all* subsequent use of "vacation". Since in practice "novacation" is used in the system Sieve to suppress any user Sieve use of vacation, and since the system Sieve is evaluated before any user Sieves, this aspect of "novacation" application had no significant effect. However, as of 8.0, "novacation" now affects those Sieves which are *both*: attached to the same recipient address, *and* evaluated later. This difference in effect is unlikely to matter for "novacation" -- but has been implemented for consistency with "nonotify".)

The MTA supports on "vacation" the private arguments ":reply", ":echo", and ":headers, controlling the format of the response message that the MTA generates. The default, if no such argument is specified, is to generate a Message Disposition Notification (MDN) as specified by RFC 5230. However, ":echo" will produce a "processed" message disposition notification (MDN) that contains the original message as returned content; or ":reply" will produce a pure reply containing only the reply text.

The MTA supports a private argument ":noaddresses" that suppresses the MTA's normal requirement (per the RFC 5230, Section 4.5 requirement) that the recipient address or one of its aliases (a mailAlternateAddress or mailEquivalentAddress value, or any alias address specified via the ":addresses" argument) *must* appear in a recipient header line in order for a vacation response message to be generated.

As of MS 8.0.2.3, the MTA supports a private argument ":noheadercheck" that suppresses the MTA's normal requirement (per the RFC 5230, Section 4.6 requirement) that various header fields, e.g., List-Id:, not be present for a vacation reply to the generated.

The MTA supports provisioning of users (and domains) with various LDAP attributes that the MTA will interpret as requesting vacation handling: the MTA will convert the values of such LDAP attributes into a pseudo-Sieve script (that is, a "vacation" action), that will be evaluated and applied *before* any explicit Sieve script of the user's. Such LDAP attributes typically have names of the form mailAutoReply* or vacation* -- for exact names in use, see the MTA options ldap_start_date, ldap_end_date, ldap_autoreply_mode, ldap_autoreply_subject, ldap_autoreply_text, ldap_autoreply_text_internal, ldap_autoreply_addresses, ldap_autoreply_timeout, and ldap_domain_attr_autoreply_timeout.

Previous response tracking, and suppression of additional vacation responses within some time period, is an essential part of "vacation" processing. For additional details on the MTA's implementation of such tracking, see the discussion of the Autoresponse periodicity MTA options.

As of MS 6.3, response message generation due to a "vacation" action will be included in MTA's message transaction log file Sieve filter field when the log_filter MTA option is enabled.

As of the 8.0 release, warnings that occur during Sieve evaluation such as issues with the vacation extension (or issues involving the memcache protocol or the duplicate extension), plus any specifically specified warning text specified via the Sieve "warn" action will result in a "warn" clause in the log_filter field of MTA message transaction log entries.

Support for the fcc extension was added in MS 8.0.2.3. The fcc extension defines a new optional tagged argument ":fcc" that can be used with the notify and vacation actions to allow a copy of the vacation or notification message to be filed into a target mailbox belonging to the sieve owner. The mailbox argument to :fcc is analogous has the same semantics as the mailbox argument to the fileinto action; in effect it is as if a copy of the message was sent to the sieve owner with a user sieve specifying a fileinto action.

5.1.2.22.1 Why a vacation message was not generated

The list of things that can go "wrong" with vacation messages is pretty much anything that can go wrong with a message in general, plus a lot more vacation-specific factors. For instance:

- the recipient domain isn't defined properly in LDAP, with the result that the recipient domain isn't found and matched as desired,
- the recipient address isn't defined properly in LDAP, with the result that (even once the recipient domain is found) the recipient address isn't found and matched as desired,
- the recipient domain or user *is* properly defined and found in LDAP, but currently has a domain or recipient status other than "active" (or a few active-with-special-handling variants such as "defer", "defer-submit", or "deliver"), that is, has a status such as "inactive" or "disabled" or "deleted" or "hold"; see the various domain and user or group status LDAP attributes including mailDomainStatus, mailUserStatus, and inetMailGroupStatus, (or more precisely, the LDAP attributes named, respectively, by the ldap_domain_attr_mail_status, ldap_user_mail_status, and ldap_group_mail_status MTA options),
- the sender didn't use an expected form of the recipient's address; recall that vacation messages very specifically, (in accordance with what's called for by the standards), don't get sent unless either: the recipient address is "found" in a recipient header line, or another alternate-but-expected address form is "found" in a recipient header line (with such alternate address matching being controlled by the vacation action's :addresses argument or the LDAP attribute named by the ldap_autoreply_addresses MTA option),
- the actual original message contains any of various vacation disabling (again, as called for by standards) header lines or notification envelope flags,
- the original message matches a FROM_ACCESS mapping table entry that sets the $! flag or has a system/channel Sieve script apply a "novacation" action,
- the original message came in when the user was not "on vacation" (as specified via the vacationStartDate and vacationEndDate LDAP attributes, or more precisely

whatever attributes are named by the `ldap_start_date` and `ldap_end_date` MTA options),

- within the relevant response timeout period, as called for by RFC 5230 (Sieve Vacation Extension) Section 4.2, the "same" vacation message was already sent to this sender; the length of the timeout period is controlled by the `vacation` action's `:days` parameter, or via LDAP attributes such as `mailAutoReplyTimeout` (or whatever attribute is named by the `ldap_autoreply_timeout` MTA option) as modified by the `vacation_minimum_timeout` MTA option,

- the MTA encountered problems accessing the vacation-response-database file, or (new in 8.0) problems communicating with Memcache if the vacation response data is being stored in Memcache,

- a Sieve script attempts to execute "too many" `vacation` actions, where "too many" is controlled by the `max_vacations` MTA option (default 2),

- attempting to use `vacation` from a system level Sieve script,

- attempting to use `vacation` combined with `reject`, `refuse`, or `jettison`,

- syntax errors in a Sieve `vacation` action,

- for vacation messages defined via LDAP attributes, suitable vacation response text is lacking: the user lacks a value for the `mailAutoreplyText` LDAP attribute, or in the case of an original message sender in the same domain as the user, lacks values for both the `mailAutoreplyText` LDAP attribute and the (preferentially used to respond to other "internal" users) `mailAutoreplyTextInternal` LDAP attribute, (or more precisely, lacks values for the attributes named by the `ldap_autoreply_text` and `ldap_autoreply_text_internal` MTA options),

- *etc.*

Overall, keep in mind that a vacation message is only supposed to be sent if everything, *absolutely everything*, about a particular message lines up just right as far as that particular message getting a vacation message generated back in response. The fallback in case of problems or doubt about whether a particular message meets all the criteria for sending back a vacation message is to *not* generate a vacation message. See RFC 3834 (Recommendations for Automatic Responses to Electronic Mail) for some of the principles that apply.

As of the 8.0 release, warnings that occur during Sieve evaluation such as issues accessing the vacation-prior-response database (whether that "database" is stored as an on-disk file, or stored in memcache), (as well as similar issues with the duplicate extension), plus any specifically specified warning text specified via the Sieve "`warn`" action will result in a "`warn`" clause in the `log_filter` field of MTA message transaction log entries. But most of the above reasons why a vacation message was not generated will *not* result in any such warning, as they are considered part of normal operation.

5.1.2.23 Sieve variables extension

As of MS 6.2, the MTA added initial support for the Sieve variables extension, modified in MS 6.3 as the initial variables draft changed, eventually to become RFC 5229 (Sieve Email Filtering: Variables Extension). Note that as part of allowing use of string variables, the variables extension also adds to the Sieve language a "`set`" action and a "`string`" test. Also,

when variables are enabled, the MTA's Sieve implementation allows the use of assignment statements of the forms:

```
var-name := string-expression;
var-name = string-expression;
```

That is, either "=" or ":=" is supported as the assignment operator. (Note that the semi-colon terminating the statement may be omitted if the statement is at the end of a block.)

The capability string is "variables":

```
require "variables";
```

Several items of note regarding variables:

- Variable substitutions are not allowed in body test arguments. If they are used, an error is likely to occur. For example, this Sieve script will fail:

  ```
  require ["variables", "body"];
  set "a" "testing"
  if body :contains "${a}" { discard; }
  ```

  This restriction exists so that a list of all arguments to body in all scripts can be computed in advance and searched for in a single pass. If this restriction were to be lifted, it would be easy to construct scripts that would require an arbitrary number of passes over the message, which is unacceptable in a server environment. As such, this should be considered to be a permanent restriction.

- The MTA has a private extension to the Sieve external lists extension, which is that the MTA also supports properties associated with list entries. When Sieve variables are enabled, properties may be returned in additional variables.

- The "set" action's ":quotewildcard" modifier was first implemented in MS 6.3. However, for MS 7.0.4 the name of the modifier was changed (in the mistaken expectation of a name change in the RFC) to ":quotewild". As of the 8.0 release, either modifier name, ":quotewild" or ":quotewildcard", will be accepted.

- When the Sieve notify extension of RFC 5435 (capability "enotify") is enabled also, it adds an ":encodeurl" modifier to the variables "set" action.

- When the Sieve regex extension is enabled also, it adds a ":quoteregex" modifier to the variables "set" action.

- Sieve :regex match type tests now set variables in the same way that :matches match type test do. Note that unlike glob-style matches (as when :matches is used), where the default is to store whatever matched any wildcard that appears in the pattern, in :regex match type tests only those regular expressions enclosed in parentheses are stored. If parentheses are needed but storage is not desired, then the (?:) form may be used.

- The maximum number of variables that the MTA will permit in a Sieve script is controlled by the max_variables MTA option, by default 128.

- The maximum length that the MTA will permit for a variable name is 128 characters; this is not configurable.

- The MTA does not currently support the use of variable namespaces, so variable names may not contain any periods.
-
-

Examples of using variables can be found in discussions of the Sieve editheader extension, Sieve body extension, Sieve external lists, Sieve mime extension, and Sieve custom tests via mappings.

5.1.2.24 Sieve conversiontag extensions

For system-level Sieve scripts, the MTA's private conversion tag manipulation Sieve actions "`addconversiontag`" and "`setconversiontag`" have been supported since MS 6.3, and the "`removeconversiontag`" action has been supported since Messaging Server 7.0u3. No capability name (no "`require`") clause need be used before using these actions. These actions take a single argument specifying either a string or list of conversion tags. "`addconversiontag`" adds the specified conversion tag(s) to the current list of conversion tags, while "`setconversiontag`" empties the existing list before adding the specified new conversion tags. Note that these actions are performed very "late in the game" of message processing, so "`setconversiontag`" can be used to undo all other converison tag setting mechanisms. "`removeconversiontag`" can be used to undo all or part of preceeding "`addconversiontag`" or "`setconversiontag`" operations.

Also, in system-level Sieves, as of MS 6.3, the "`envelope`" test accepts "`conversiontag`" as a field specifier value, checking the current list of conversion tags, one at a time. (This test only "sees" the set of conversion tags that were present prior to Sieve processing; the effects of "`setconversiontag`" and "`addconversiontag`" are not visible.)

For further discussion and examples of using Sieve conversion tag extensions, see Sieve filter manipulation of conversion tags.

5.1.2.24.1 Sieve filter manipulation of conversion tags

The MTA has a private mechanism of *conversion tags*, which may be set and used in a variety of ways and for a variety of purposes including special routing, or user-specific automatic document conversion. The MTA's Sieve implementation includes private Sieve extensions to inspect and set these conversion tags. These private Sieve extensions include an envelope test field `conversiontag` (new in MS 6.3, and supported only in system Sieves) which takes an optional `:count` modifier, as well as several actions supported only in system Sieve filters: the (new in MS 6.3) `addconversiontag` and `setconversiontag` actions, and the (new in Messaging Server 7.0u3) `removeconversiontag` action.

The actions `addconversiontag`, `setconversiontag`, and `removeconversiontag` actions take as argument either a Sieve string (containing a single conversion tag value) or Sieve list (consisting of a list of strings each of which is a single conversion tag value). `setconversiontag` clears whatever existing conversion tags might be present, and then adds the specified conversion tag(s). Note that these conversion tag actions are performed relatively late in message processing, so in particular `setconversiontag` can be used to undo all other conversion tag setting mechanisms (including LDAP attribute caused conversion tags).

Note that `removeconversiontag` operates only on conversion tags set via a `setconversiontag` or `addconversiontag` action. However, it is possible by combining

operations to have removeconversiontag remove a conversion tag present due to some other reason (such as due to a user LDAP attribute having previously set a conversion tag): obtain the current set of conversion tags via the envelope field conversiontag and put it into a Sieve variable, then do a setconversiontag to the value of that variable, then do a removeconversiontag. The reason why this is required (and why removeconversiontag operates the way it does) is to avoid triggering per-recipient message copy split-up: obtaining potentially recipient-specific envelope fields, such as envelope conversion tags, forces per-recipient sensitivity and evaluation of Sieve scripts, and hence potentially forces per-recipient message copy split-up.

For instance, in a channel Sieve filter, if one wanted to remove an "unprocessed" conversion tag (if present) and replace it with a "processed" conversion tag, while preserving any other existing conversion tags, one could use:

```
require ["envelope","variables"];
if envelope :matches "conversiontag" "*" {
  setconversiontag ${1};
  removeconversiontag "unprocessed";
  addconversiontag "processed";
  }
```

Another use of the "envelope" test of the "conversiontag" field is to count how many active conversion tags are present. For instance, if a "high" number of (distinct) conversion tags might as well be considered a request for "full" (do everything) processing, and if there is also a single conversion tag "full-processing" that has that meaning (requesting full processing), then consider:

```
require ["envelope","relational"];
if envelope :count "ge" "conversiontag" "3" {
 setconversiontag "full-processing"; }
```

5.1.2.25 Sieve addprefix and addsuffix extensions

The MTA's private addprefix and addsuffix actions have been supported since Messaging Server 7.0u3. No capability name (no "require") clause need be used before using these actions. These actions take a single string argument specifying text to be added at the beginning or end, respectively, of the first plain text part of a message. (Note that the Sieve language's text: syntax for entering long, multi-line strings, may be convenient for specifying prefix or suffix text.)

The effects of "addprefix" or "addsuffix" are similar to the effects of the mgrpMsgPrefixText or mgrpMsgSuffixText group LDAP attributes (more precisely, the attributes named by the ldap_prefix_text and ldap_suffix_text MTA options), or the alias_prefix_text and alias_suffix_text alias options, or the [PREFIX_TEXT] and [SUFFIX_TEXT]alias file named parameters. Note, however, that the Sieve actions work in any sort of Sieve, not just Sieves attached to groups.

If multiple Sieves are active and more than one prefix or suffix is specified, they are concatenated.

When logging of Sieve filter actions applied has been enabled via the log_filter MTA option, note that only the name of the action, *e.g.*, "addprefix" or "addsuffix", will be

included in the logged field; the actual text added to the message will *not* be logged (as it might be very long).

There is an example of use of "`addprefix`" in the discussion of the Sieve editheader extension.

5.1.2.26 Sieve addtag extension

The MTA's private Sieve extension `addtag` action has been supported since MS 6.0. `addtag` provides a convenient way to add a prefix string, that is, a "tag", to a Subject: header line. (The `replaceheader` action provides an alternate, though somewhat more complex, mechanism to get such an effect.) Note that the `addtag` effect is *not* visible to other Sieves being evaluated at the same time; this is unlike `addheader` (as of MS 6.1p1 and 6.2).

Adding multiple tags is supported, for instance, "`Re:`" and "`FWD:`". Prior to MS 6.3, `addtag` took a space-delimited list of arguments; as of MS 6.3, `addtag` takes a string argument consisting of vertical bar delimited tags. Each of the tags is searched for separately in the current Subject: line, and then added if not already present. (This means in particular that prior to MS 6.3, doing an `addtag` operation on a Subject: field that itself includes spaces, *e.g.*, `addtag $U` on a SpamAssassin verdict, was not a good idea: "weird" results were possible when part of the tag string was already present on the Subject: header line. This motivated the change to use of a vertical bar delimiter for MS 6.3.)

The `addtag` Sieve action effect is analogous to the effects of the `alias_tag` alias option, the `[TAG]` alias file named parameter, or the `mgrpListTag` group LDAP attribute (more precisely, the LDAP attribute named by the `ldap_add_tag` MTA option).

5.1.2.27 Sieve adjustcounter extension

New in 8.0, a set of eight signed, 64 bit counters has been added to the MTA's counters. The values of this set of counters can be adjusted from system Sieve scripts, and later be displayed or accessed via the usual counters display and access facilities. These counters have no predefined meanings; they can be used for any purpose.

A nonstandard Sieve action "`adjustcounter`" has been added to manipulate these counters, with syntax:

```
adjustcounter [:duplicate] [:channel channel-string] counter [value]
```

where "*`counter`*" specifies the counter to operate on (an integer in the range 1-8). "*`value`*" is the amount by which to adjust the counter; if omitted, it defaults to 1.

The counters associated with the current source channel are affected by default. The "`:channel`" nonpositional parameter can be used to switch to some other channel. Note that variable substitution can be used on the "*`channel-string`*" argument to select a channel computed by the script. Also note that the channel must be defined in the configuration; arbitrary channel names are not allowed.

The "`adjustcounter`" action can only be used in system-level Sieves; an error will occur if an attempt is made to use it from user-level sieves.

Sieve scripts may be reevaluated multiple times, *e.g.*, when a message is sent to multiple recipients and the script employs an envelope "to" test. When this happens it is normally not desirable for the counter operation to be repeated, so counter adjustments are suppressed

by default when scripts are reevaluated. This default can be overridden by specifying the "`:duplicate`" nonpositional parameter.

The counters show up in "`imsimta counters -show`" output as follows:

```
Sieve counter [1]               1
Sieve counter [2]               10
Sieve counter [3]               10
Sieve counter [8]               -15
```

Note that counters can have negative values. Also note that counters with a value of 0 are suppressed from the display.

These counters can also be retrieved through the `PMDFgetChannelCounters64` routine in the PMDF API.

As an example, the following script fragment, if implemented in a system Sieve on a system that has OpenDKIM set up as a milter, will keep track of DKIM verification operations:

```
require ["variables", "environment"];
if environment :matches "host" "*" {set "host" "${0}";}
if header :matches :index 1 "authentication-results" "*${host}*dkim*" {
  if header :contains :index 1 "authentication-results" "dkim=pass" {
    adjustcounter 1;
  } else {
    adjustcounter 2;
  }
  adjustcounter 3;
} else {
  adjustcounter 4;
}
```

Counter 1 will contain the number of successful verifications performed, counter 2 will contain the number of failed verifications, counter 3 will contain the total verifications, and counter 4 will count the number of messages without a local DKIM result.

5.1.2.28 Sieve capture extension

The MTA supports a private "`capture`" extension action (capability name "`capture`" -- but it may be used without explicitly listing it in a "`require`" clause) for capturing a message copy for legal intercept, or archival, or message replay, or similar purposes. "`monitor`" is a deprecated synonym for the "`capture`" action.

Two optional nonpositional parameters, "`:dsn`" and "`:message`", were added for MS 6.3; "`:journal`" (to generate Microsoft® Exchange "envelope journaling" format) was added for 7.0u2; "`:header`" (which can be used as a modifier with either `:dsn` or `:journal`) was added for 8.0.

See Format of captured message copies for examples of these formats.

See Example Sieve external lists with properties for complex examples using "`capture`".

5.1.2.29 Sieve hold extension

The MTA supports a private "hold" extension action for system Sieve filters; use of this action causes the message file to be side-lined as a .HELD file in the MTA queue area. Note that attempts to use the action in a non-system level Sieve script will be ignored without generating an error message.

As of MS 8.0.2.2, the "hold" action accepts an optional string argument. This argument is used to specify a reason string for the hold action; the value will appear in the log_filter field of MTA message transaction log entries.

5.1.2.30 Sieve comparators

In addition to the standard Sieve comparators "i;ascii-casemap" and "i;octet" described in RFC 5228, and "i;ascii-numeric" described in RFC 4790, the MTA also supports some additional, non-standard comparators.

Because the MTA's Sieve implementation supports negative integers in addition to the standard unsigned integers, the MTA supports a "i;ascii-integer" comparator to compare signed integers.

New in MS 8.0. The MTA's comparators "i;ascii-casemap-collapse" and "i;octet-collapse" are similar to the correspondingly named standard comparators, except that all folding white space characters (space, tab, carriage return, line feed) are removed from both the target and pattern strings prior to comparison. Use of these white-space-collapsing comparators is recommended for Sieve comparisons of header values including optional semantically meaningless white space, as many popular email clients exhibit various standards-incompliant behaviors regarding white space in header lines occurring next to MIME encoded-words, or around line folding; standards-compliant Sieve matching may thus not appear to match users' expectations, when client generation and display of white space diverges from standards.

New in MS 8.0.1.2. The MTA's comparators "i;ascii-casemap-compress" and "i;octet-compress" are similar to the correspondingly named standard comparators, except that all folding white space characters (space, tab, carriage return, line feed) are compressed into a single ASCII space and those at the begininng and end of the strings are removed. This is done to both the target and pattern strings prior to comparison. Use of these white-space-compressing comparators is recommended for Sieve comparisons of structured header values that include embedded white space.

5.1.2.31 Sieve importance extension

New in 7.0.5, the "importancetest" Sieve test and "importanceadjust" Sieve action have been implemented. These nonstandard extensions are provided so that multiple Sieve scripts can cooperate in making a determination of a message's importance, much like the "spamtest" and "spamadjust" extensions allow multiple Sieves to cooperate in determining whether or not a message is spam.

"importancetest" and "importanceadjust" work in the same way as "spamtest" and "spamadjust", except that:

- Importance values range from 0 to 100.
- The initial value of "importancetest", and the value if no "importanceadjust" actions have been performed, is 50.

- Fractional adjustments are allowed, but the importance value is rounded to an integer by the "importancetest" test.

5.1.2.32 Sieve loop extension

New in 7.0.5, the MTA supports a private "loop" construct in system-level Sieves, specifically in spamfilter, in alias file [FILTER], or alias_filter alias option defining a non-personal alias (*e.g.* a mailing list alias), destination channel, the FROM_ACCESS mapping table or a Recipient *_ACCESS mapping table, source channel, and system systemfilter (imta.filter) Sieves. (No "require" clause is needed.) The syntax is:

```
loop {
      ...
      exitif (expression);
      ...
      nextif (expression);
      ...
      }
```

A loop may contain zero or more "exitif" and/or "nextif statements. The loop terminates if the argument to exitif evaluates to true. New in 8.0.2.3, nextif can be used to cause the loop to restart if the associated condition evaluates to true.

Loops may be nested:

```
loop {
      ...
      loop {
            ...
            exitif (expression1); # Exit from inner loop #1
            }
      ...
      exitif (expression2); # Exit from outer loop
      ...
      loop {
            ...
            exitif (expression3); # Exit from inner loop #2
            }
      }
```

Loops should be used with extreme care because of the possibility of putting the MTA into a CPU loop. It tends to be wise to use more limited capabilities, for instance, the "foreverypart" extension, when such a more limited capability suffices.

5.1.2.33 Sieve memcache extension

As of the 8.0 release, the MTA supports a private "memcache" operator, which may be used to perform both actions and tests. (Configuration of MTA connections to memcache is required; see the Memcache MTA options and in particular see the memcache_host MTA option which requires an explicit, valid value.) This nonstandard extension is available without any special

capability declaration; no "`require`" action is needed for its use. By default, the "`memcache`" operator may be used in any Sieve script, but its availability may be selectively disabled via the `enable_sieve_memcache` MTA option. This extension is provided so that Sieve filters can access and manipulate data using the memcache protocol.

The various Sieve "`memcache`" operations share a set of common nonpositional parameters:

`:host host-string`	Specifies the host name(s) and port(s) for the memcached server to use in *`host`*`:`*`port`* format. The *`port`* part is optional and defaults to value given to the `memcache_port` MTA option. If "`:host`" isn't specified, the host and port are given by the `memcache_host` and `memcache_port` MTA options respectively.
`:host [host-string1, host-string2, ...]`	If a list of *`host`*`:`*`port`* pairs is specified, one will be chosen by applying a hash function to the key. This provides the means to distribute key-value pairs across multiple memcache servers. Note that the algorithm used is the same as for the memcache mapping callout.
`:tableprefix prefix-string`	Unlike MeterMaid, each memcache server provides a single storage area; in effect a single "table". Multiple tables can be implemented by adding a prefix to the key. "`:tableprefix`" provides a convenient way to specify such a prefix while making it clear that the string is a prefix and not logically part of the key. (Note that some servers that implement the memcache protocol impose additional structure on the key themselves; the "`:tableprefix`" parameter may be useful in specifying such structure.)
`:timeout timeout-number`	Specifies the timeout value in seconds for the entry being created or updated. The default timeout value is 0, which means the entry never times out.
`:quota quota-int`	Specifies the maximum number of counts to permit during the quota timeout period. This corresponds to MeterMaid throttle table `quota` setting.
`:quotatimeout quota-timeout-int`	Specifies the duration in seconds of the period over which counts are recorded. This corresponds to MeterMaid throttle table `quota_time` setting.
`:penalize`	Corresponds to MeterMaid throttle table option `penalize` setting.
`:limit`	(New in MS 8.0.2.3.) Normally :throttle operations update the throttle even when the throttle engages; this is appropriate when throttling an external activity that occurs outside the control of Messaging Server. The addition of :limit causes a :throttle test to only update when the throttle does not engage; this is appropriate when a throttle is being used to limit some internal activity that doesn't occur when the throttle engages. Any operation failure is also handled in a failsafe manner when :limit is specified

	- server down, network failure, wrong data type, etc. - to return TRUE rather than the usual FALSE.
`:duplicate`	It may be necessary to evaluate Sieves more than once, *e.g.*, when a message is sent to multiple recipients and the Sieve employs an envelope "to" test. Additionally, even if a particular Sieve script does not contain such a test, it may nevertheless be necessary to reevaluate it if a previous script was reevaluated and that action changed one or more of the inputs to the current script.
MATCH-TYPE and COMPARATOR	See RFC 5228 for information about MATCH-TYPE and COMPARATOR parameters.

The memcache Sieve extension provides the following operations:

```
memcache :add  [:host host-string] [:tableprefix prefix-string]
         [:duplicate] [:timeout timeout-number] key-string
         value-string
```

Add a new entry with the specified key, value and timeout. The operation only suceeds if the entry does not already exist. The operation returns TRUE if the entry is added successfully, FALSE if not. For example:

```
if not memcache :add "a" "b" { ... handle failure ... }
```

memcache "`:add`" operations are skipped and return success unconditionally on script reevaluations by default. "`:duplicate`" forces the operation to be performed on all reevaluations.

```
memcache :adjustdown adjustment-value [:host host-string]
         [:tableprefix prefix-string] [:duplicate] [MATCH-TYPE]
         [COMPARATOR] [:quotatimeout quotatimeout-numeric [:penalize]]
         [:timeout timeout-value] key-string [test-string]
```

Decrement the entry with the specified key by the specified adjustment value. The entry must contain an unsigned decimal string. The adjustment value can be either an integer or a string; if it is a string it must contain an optionally signed decimal value. Negative adjustment value are allowed and will be converted into an appropriate increment operation.

The specified entry will be created (with a value of 0) prior to adjustment if it doesn't already exist. The timeout value is only used if the entry has to be created.

memcache "`:adjustdown`" operations can be applied to throttle entries. If this is done, the appropriate quota parameters must be specified in case the entry needs to be created.

Note that memcache's increment and decrement operations do not support negative values. Attempts to decrement an entry to a value below 0 will result in a 0 value being stored.

The adjusted value is returned as an unsigned decimal string if neither MATCH-TYPE, COMPARATOR, nor test-string are specified. However, if any of these parameters are specified this operation functions as a test with updated value of the entry being the tested

value. MATCH-TYPE and COMPARATOR default to `:value "lt"` and `"i;ascii-numeric"` respectively. For example:

```
if memcache :adjustdown 1 "entry" "10" {
  ... handle entry less than 10 ... }
```

memcache "`:adjustdown`" operations are performed on reevaluations but the adjustment amount is changed to `0`. "`:duplicate`" causes the adjustment amount to be retained on reevaluations.

```
memcache :adjustup adjustment-value [:host host-string]
         [:tableprefix prefix-string] [:duplicate] [MATCH-TYPE]
         [COMPARATOR] [:quotatimeout quotatimeout-numeric [:penalize]]
         [:timeout timeout-value] key-string [test-string]
```

Increment the entry with the specified key by the specified adjustment value. The entry must contain an unsigned decimal string. The adjustment value can be either an integer or a string; if it is a string it must contain an optionally signed decimal value. Negative adjustments values are allowed and will be converted into an appropriate decrement operation.

The specified entry will be created (with a value of 0) prior to adjustment if it doesn't already exist. The timeout value is only used if the entry has to be created.

memcache "`:adjustup`" operations can be applied to throttle entries. If this is done, the appropriate quota parameters must be specified in case the entry needs to be created.

The adjusted value is returned as an unsigned decimal string if if neither MATCH-TYPE, COMPARATOR, nor test-string are specified. However, if any of these parameters are specified this operation functions as a test with updated value of the entry being the tested value. MATCH-TYPE and COMPARATOR default to `:value "gt"` and `"i;ascii-numeric"` respectively. For example:

```
if memcache :adjustup 1 "entry" "10" { ... handle entry greater than 10 ... }
```

memcache "`:adjustup`" operations are performed on reevaluations but the adjustment amount is changed to `0`. "`:duplicate`" causes the adjustment amount to be retained on reevaluations.

```
memcache :append [:host host-string] [:tableprefix prefix-string]
         [:duplicate] key-string value-string
```

Append the specified value to the entry with the specified key. The entry must already exist. Returns TRUE if the operation is successful, FALSE if it is not.

memcache "`:append`" operations are skipped and return success unconditionally on reevaluations by default. "`:duplicate`" forces the operation to be performed on all reevaluations.

```
memcache :fetch [:host host-string] [:tableprefix prefix-string]
```

```
[MATCH-TYPE] [COMPARATOR] key-string [test-string]
```

Fetches the value of the entry with the specified key.

The entry's value is simply returned as a string if neither MATCH-TYPE, COMPARATOR, nor test-string are specified. An empty string will be returned if the specified entry doesn't exist.

However, if any of the three parameters are specified this operation functions as a test with current value of the entry being the tested value. MATCH-TYPE and COMPARATOR default to `:is` and `"i;ascii-casemap"` respectively. The test always fails if the entry does not exist. This can be to test for the existence of an entry:

```
if memcache :fetch :matches "entry" "*" { ... entry exists ... }
```

memcache "`:fetch`" operations are simply repeated on reevaluations.

```
memcache :prepend [:host host-string] [:tableprefix prefix-string]
         [:duplicate] key-string value-string
```

Prepend the specified value to the entry with the specified key. The entry must already exist. Returns TRUE if the operation is successful, FALSE if it is not.

memcache "`:prepend`" operations are skipped and return success unconditionally on reevaluations by default. "`:duplicate`" forces the operation to be performed on all reevaluations.

```
memcache :release [:duplicate]
         [:host host-string] [:tableprefix prefix-string]
         [:timeout timeout-value]  key-string
```

Implements a generic reservation capability, where a specified key-string can be repeatedly reserved up to a specified quota. :release releases a reservation previously created by :reserve. The associated memcache entry contains a record of how many reservations are held by each process on the host. Outstanding reservations associated with nonexistent processes will be automatically deteled.

This operation always functions as a test, returning TRUE if the reservatation has been releaves succesfully, FALSE otherwise.

memcache reservation operations are performed on reevaluations.

```
memcache :remove [:host host-string] [:tableprefix prefix-string]
         [:duplicate] [:lockout lockout-numeric] key-string
```

Remove the entry with the specified key. A lockout value, if specified, is an unsigned integer specifying the amount of time to "lock" the key - during that time attempts to store an entry with that key will fail. A lockout default of 0 is the default and causes no lockout to occur. Returns TRUE if the operation is successful, FALSE if it is not.

memcache "`:remove`" operations are skipped and return success unconditionally on reevaluations by default. "`:duplicate`" forces the operation to be performed on all reevaluations.

```
memcache :replace [:host host-string] [:tableprefix prefix-string]
         [:timeout timeout-value] key-string value-string
```

Update the value and timeout of an entry. The entry must already exist. Returns TRUE if the operation is successful, FALSE if it is not.

memcache "`:replace`" operations are simply repeated on reevaluations.

```
memcache :reserve :quota quota-numeric [:duplicate]
         [:host host-string] [:tableprefix prefix-string]
         [:timeout timeout-value]  key-string
```

Implements a generic reservation capability, where a specified key-string can be repeatedly reserved up to a specified quota. Each reserve operation must be matched by a corresponding release. The associated memcache entry contains a record of how many reservations are held by each process on the host. Outstanding reservations associated with nonexistent processes will be automatically deteled.

Note that since there is no server-side awareness of entry semantics the quota parameter must be specified in every reserve call in case the entry needs to be created. If the entry already exists the quota parameter value will be checked against the corresponding value stored in the entry.

Each reserve operation increments the reservation count by 1, and should be matched by a corresponding release operation.

This operation always functions as a test, returning TRUE if the reservation is successful, FALSE otherwise.

memcache reservation operations are performed on reevaluations.

```
memcache :store [:host host-string] [:tableprefix prefix-string]
         [:timeout timeout-value] key-string value-string
```

Creates a new entry or updates an existing entry with the specified key, value and timeout. Returns TRUE if the operation is successful, FALSE if it is not.

memcache "`:store`" operations are simply repeated on reevaluations.

```
memcache :throttle :quota quota-numeric [:duplicate]
         :quotatimeout quotatimeout-numeric [:penalize] [:limit]
         [:host host-string] [:tableprefix prefix-string]
         [:timeout timeout-value] [MATCH-TYPE] [COMPARATOR]
         [:adjustup adjustment-value] [:adjustdown adjustment-value]
         key-string [test-string]
```

Implements the MeterMaid throttle capability. See the MeterMaid documentation for details of throttle semantics. Note that since there is no server-side awareness of entry semantics the quota and quotatimeout parameters must be specified in every throttle call in case the entry needs to be created. If the entry already exists the parameter values will be checked against the corresponding values stored in the entry.

The throttle value is incremented by default. Either "`:adjustup`" or "`:adjustdown`" can be used to specify an alternate adjustment value. (Note that in this case these nonpositional parameters function as modifiers, not operation specifiers.)

New in MS 8.0.2.3, "`:limit`" can be specified to prevent the throttle from being adjusted if it engages and to behave in a failsafe fashion.

This operation always functions as a test. If neither MATCH-TYPE, COMPARATOR, nor test-string are specified TRUE is returned if the throttle is engaged, FALSE if it is not engaged or an error occurs. If one of these three parameters is provided the throttle is adjusted and then Sieve tests are applied to the adjusted value. The default MATCH-TYPE is `:value "gt"` and the default COMPARATOR is `"i;ascii-numeric"`.

memcache "`:throttle`" operations are performed on reevaluations but the adjustment amount is changed to `0`. "`:duplicate`" causes the adjustment amount to be retained on script reevaluations.

5.1.2.34 Sieve metermaid extension

As of the 8.0 release, the MTA supports a private "`metermaid`" operator, to access and manipulate data stored in MeterMaid; the operator has uses both as an action and as a test. This nonstandard extension is available without any special capability declaration; no "`require`" action is needed for its use. By default, the "`metermaid`" operator may be used in any Sieve script, but its availability may be selectively disabled via the `enable_sieve_metermaid` MTA option.

The location of the MeterMaid server that Sieve scripts may query, as well as various other basics of MeterMaid communication, server are specified via MeterMaid MTA options, especially `metermaid_host`, `metermaid_port`, and `metermaid_secret`.

The various Sieve "`metermaid`" operations share a set of common nonpositional parameters:

`:host host-string`	Specifies the host name and port for the MeterMaid server to use in *`host`*`:`*`port`* format. The *`port`* part is optional and defaults to value given to the `metermaid_port` MTA option. If "`:host`" isn't specified, the host and port are given by the `metermaid_host` and `metermaid_port` MTA options respectively.
`:duplicate`	It may be necessary to evaluate Sieves more than once, *e.g.*, when a message is sent to multiple recipients and the Sieve employs an envelope "to" test. Additionally, even if a particular Sieve script does not contain such a test, it may nevertheless be necessary to reevaluate it if a previous script was reevaluated and that action changed one or more of the inputs to the current script.
MATCH-TYPE and COMPARATOR	See RFC 5228 for information about MATCH-TYPE and COMPARATOR parameters.

The following "`metermaid`" operations are available:

```
metermaid :adjustdown adjustment-value [:host host-string]
          [:duplicate] [MATCH-TYPE] [COMPARATOR]
```

table-string key-string [*test-string*]

The "`metermaid :adjustdown`" operation decrements the entry with the given key in the specified table by the adjustment value. This operation is only supported on simple tables configured for integer values and throttle tables.

The adjustment value can be either an integer or a string; if it is a string, it must contain an optionally signed decimal value. Negative adjustment value are allowed and will be converted into an appropriate increment operation.

The specified entry will be created (with a value of `0`) prior to adjustment if it doesn't already exist.

The adjusted value is returned as an unsigned decimal string if neither MATCH-TYPE, COMPARATOR, nor *`test-string`* are specified. However, if any of these parameters are specified, this operation functions as a test with updated value of the entry being the tested value. MATCH-TYPE and COMPARATOR default to `:value "lt"` and `"i;ascii-numeric"` respectively. For example:

```
if metermaid :adjustdown 1 "table" "entry" "10"
   { ... handle entry less than 10 ... }
```

"`:adjustdown`" operations are performed on reevaluations but the adjustment amount is changed to `0`. "`:duplicate`" causes the adjustment amount to be retained on reevaluations.

```
metermaid :adjustup adjustment-value [:host host-string]
          [:duplicate] [MATCH-TYPE] [COMPARATOR]
          table-string key-string [test-string]
```

The "`metermaid :adjustup`" operation increments the entry with the specified key in the given table by the adjustment value. This operation is only supported on simple tables configured for integer values and throttle tables.

The adjustment value can be either an integer or a string; if it is a string, it must contain an optionally signed decimal value. Negative adjustments values are allowed and will be converted into an appropriate decrement operation.

The specified entry will be created (with a value of `0`) prior to adjustment if it doesn't already exist.

The adjusted value is returned as an unsigned decimal string if neither MATCH-TYPE, COMPARATOR, nor *`test-string`* are specified. However, if any of these parameters are specified this operation functions as a test with updated value of the entry being the tested value. MATCH-TYPE and COMPARATOR default to `:value "gt"` and `"i;ascii-numeric"` respectively. For example:

```
if metermaid :adjustup 1 "table" "entry" "10"
   { ... handle entry greater than 10 ... }
```

"`:adjustup`" operations are performed on reevaluations but the adjustment amount is changed to `0`. "`:duplicate`" causes the adjustment amount to be retained on reevaluations.

```
metermaid :fetch [:host host-string] [MATCH-TYPE] [COMPARATOR]
          table-string key-string [test-string]
```

The "`metermaid :fetch`" operation fetches the value of the entry with the specified key from the given table. Fetch is supported on all types of tables, although in the case of throttle tables it is implemented by performing an adjust with an adjustment value of `0`.

The entry's value is simply returned as a string if neither MATCH-TYPE, COMPARATOR, nor *`test-string`* are specified. An empty string will be returned if the specified entry doesn't exist.

However, if any of the three parameters are specified, this operation functions as a test with current value of the entry being the tested value. MATCH-TYPE and COMPARATOR default to `:is` and `"i;ascii-casemap"` respectively. The test always fails if the entry does not exist. This can be used to test for the existence of an entry:

```
if metermaid :fetch :matches "table" "entry" "*" { ... entry exists ... }
```

"`:fetch`" operations are simply repeated on reevaluations.

```
metermaid :greylisting [:host host-string] [:duplicate]
          [MATCH-TYPE] [COMPARATOR]
          table-string key-string [test-string]
```

The "`metermaid :greylisting`" operation provides access to the MeterMaid greylisting capability. See the MeterMaid documentation for details of greylisting semantics. Of course this operation only works on greylisting tables.

This operation always functions as a test. If neither MATCH-TYPE, COMPARATOR, nor *`test-string`* are specified, then TRUE is returned if greylisting is engaged, while FALSE is returned if greylisting is not engaged or an error occurs.

If one of these three parameters is provided, the throttle is incremented and then Sieve tests are applied to the value. The default MATCH-TYPE is `:is` and the default COMPARATOR is `"i;ascii-casemap"`. Note that this is implemented as an adjust operation since the connect operation doesn't provide the throttle value as a result.

The test aspect of "`:greylisting`" operations is repeated on reevaluations, but the entry is not updated. "`:duplicate`" causes the entire operation to be performed on reevaluations.

```
metermaid :remove [:host host-string] [:duplicate]
                  table-string key-string
```

The "`metermaid :remove`" operation removes the entry with the specified key from the given table. Returns TRUE if the operation is successful, FALSE if it is not.

Remove is supported on all types of tables.

"`:remove`" operations are skipped and return success unconditionally on reevaluations by default. "`:duplicate`" forces the operation to be performed on all reevaluations.

```
metermaid :store [:host host-string]
                 table-string key-string value-string
```

The "metermaid :store" operation creates a new entry or updates an existing entry with the specified key in the given table. Returns TRUE if the operation is successful, FALSE if it is not.

Store is supported on all table types except throttle tables.

":store" operations are simply repeated on reevaluations.

```
metermaid :throttle [:host host-string] [:duplicate]
                    [MATCH-TYPE] [COMPARATOR]
                    table-string key-string
```

The "metermaid :throttle" operation provides access to the MeterMaid throttle capability. See the MeterMaid documentation for details of throttle semantics. Of course this operation only works on throttle tables.

This operation always functions as a test. If neither MATCH-TYPE, COMPARATOR, nor *test-string* are specified, then TRUE is returned if the throttle is engaged, while FALSE is returned if the throttle is not engaged or an error occurs.

If one of these three parameters is provided, the throttle is incremented and then Sieve tests are applied to the value. The default MATCH-TYPE is :value "gt" and the default COMPARATOR is "i;ascii-numeric". Note that this is implemented as an adjust operation since the connect operation doesn't provide the throttle value as a result.

The test aspect of ":throttle" operations is repeated on reevaluations but the entry is not updated. ":duplicate" causes the entire operation to be performed on reevaluations.

5.1.2.35 Sieve redis extension

As of the 8.0.2.3 release, the MTA supports a private "redis" operator, which may be used to perform both actions and tests. (Configuration of MTA connections to Redis is required.) This nonstandard extension is available without any special capability declaration; no "require" action is needed for its use. By default, the "redis" operator may be used in any Sieve script, but its availability may be selectively disabled via the enable_sieve_redis MTA option. This extension is provided so that Sieve filters can access and manipulate data using the redis protocol.

The various Sieve "redis" operations share a set of common nonpositional parameters:

:tableprefix prefix-string	Unlike MeterMaid, each redis server provides a single storage area; in effect a single "table". Multiple tables can be implemented by adding a prefix to the key. ":tableprefix" provides a convenient way to specify such a prefix while making it clear that the string is a prefix and not logically part of the key.
:timeout timeout-number	Specifies the timeout value in seconds for the entry being created or updated. The default timeout value is 0, which means the entry never times out.
:quota quota-int	Specifies the maximum number of counts to permit during the quota timeout period. This corresponds to MeterMaid throttle table quota setting.

`:quotatimeout quota-timeout-int`	Specifies the duration in seconds of the period over which counts are recorded. This corresponds to MeterMaid throttle table `quota_time` setting.
`:penalize`	Corresponds to MeterMaid throttle table option `penalize` setting.
`:limit`	Normally :throttle operations update the throttle even when the throttle engages; this is appropriate when throttling an external activity that occurs outside the control of Messaging Server. The addition of :limit causes a :throttle test to only update when the throttle does not engage; this is appropriate when a throttle is being used to limit some internal activity that doesn't occur when the throttle engages. Any operation failure is also handled in a failsafe manner when :limit is specified - server down, network failure, wrong data type, etc. - to return TRUE rather than the usual FALSE.
`:set`	New in MS 8.1.0.3. Specifies that the data associated with the key is a Redis set.
`:sortedset`	New in MS 8.1.0.3. Specifies that the data associated with the key is a Redis sorted set.
`:score score-number`	New in MS 8.1.0.3. Specifies the score for an entry in a Redis sorted set. The default score is 0.
`:duplicate`	It may be necessary to evaluate Sieves more than once, *e.g.*, when a message is sent to multiple recipients and the Sieve employs an envelope "to" test. Additionally, even if a particular Sieve script does not contain such a test, it may nevertheless be necessary to reevaluate it if a previous script was reevaluated and that action changed one or more of the inputs to the current script.
MATCH-TYPE and COMPARATOR	See RFC 5228 for information about MATCH-TYPE and COMPARATOR parameters.

The redis Sieve extension provides the following operations:

```
redis :add [:tableprefix prefix-string] [:duplicate]
      [:timeout timeout-number] [:set | :sortedset]
      [:score score] key-string value-string
```

Add a new entry with the specified key, value and timeout. The operation only suceeds if the entry does not already exist. The operation returns TRUE if the entry is added successfully, FALSE if not. If `:set` or `:sortedset` are specified add the specified value to the set. The set will be created if it doesn't already exist. A score of 0 is used for entries assed to sorted sets if no other value is specified.

For example:

```
if not redis :add "a" "b" { ... handle failure ... }
```

redis "`:add`" operations are skipped and return success unconditionally on script reevaluations by default. "`:duplicate`" forces the operation to be performed on all reevaluations.

```
redis :adjustdown adjustment-value [:tableprefix prefix-string]
      [:duplicate] [MATCH-TYPE] [COMPARATOR]
      [:quotatimeout quotatimeout-numeric [:penalize]]
      [:timeout timeout-value] [:sortedset] key-string [test-string]
```

Decrement the entry with the specified key by the specified adjustment value. The entry must contain an unsigned decimal string, The adjustment value can be either an integer or a string; if it is a string it must contain an optionally signed decimal value. Negative adjustment value are allowed.

The specified entry will be created (with a value of 0) prior to adjustment if it doesn't already exist. The timeout value is only used if the entry has to be created.

Redis "`:adjustdown`" operations can be applied to throttle entries. If this is done, the appropriate quota parameters must be specified in case the entry needs to be created.

New in MS 8.1.0.3, Redis "`:adjustdown`" operations can be applied to members of sorted sets by specifying the `:sortedset` parameter. If this is done `test-string` is interpreted as the name of the set member.

The adjusted value is returned as an unsigned decimal string if neither MATCH-TYPE, COMPARATOR, nor test-string are specified. However, if any of these parameters are specified this operation functions as a test with updated value of the entry being the tested value. MATCH-TYPE and COMPARATOR default to `:value "lt"` and `"i;ascii-numeric"` respectively. For example:

```
if redis :adjustdown 1 "entry" "10" {
  ... handle entry less than 10 ... }
```

redis "`:adjustdown`" operations are performed on reevaluations but the adjustment amount is changed to `0`. "`:duplicate`" causes the adjustment amount to be retained on reevaluations.

```
redis :adjustup adjustment-value [:tableprefix prefix-string]
      [:duplicate] [MATCH-TYPE] [COMPARATOR]
      [:quotatimeout quotatimeout-numeric [:penalize]]
      [:timeout timeout-value] [:sortedset] key-string [test-string]
```

Increment the entry with the specified key by the specified adjustment value. The entry must contain an unsigned decimal string. The adjustment value can be either an integer or a string; if it is a string it must contain an optionally signed decimal value. Negative adjustments values are allowed.

The specified entry will be created (with a value of 0) prior to adjustment if it doesn't already exist. The timeout value is only used if the entry has to be created.

Redis "`:adjustup`" operations can be applied to throttle entries. If this is done, the appropriate quota parameters must be specified in case the entry needs to be created.

New in MS 8.1.0.3, Redis "`:adjustup`" operations can be applied to members of sorted sets by specifying the `:sortedset` parameter. If this is done `test-string` is interpreted as the name of the set member.

The adjusted value is returned as an unsigned decimal string if if neither MATCH-TYPE, COMPARATOR, nor test-string are specified. However, if any of these parameters are specified this operation functions as a test with updated value of the entry being the tested value. MATCH-TYPE and COMPARATOR default to `:value "gt"` and `"i;ascii-numeric"` respectively. For example:

```
if redis :adjustup 1 "entry" "10" { ... handle entry greater than 10 ... }
```

Redis "`:adjustup`" operations are performed on reevaluations but the adjustment amount is changed to `0`. "`:duplicate`" causes the adjustment amount to be retained on reevaluations.

```
redis :append [:tableprefix prefix-string]
      [:duplicate] key-string value-string
```

Append the specified value to the entry with the specified key. The entry must already exist. Returns TRUE if the operation is successful, FALSE if it is not.

Redis "`:append`" operations are skipped and return success unconditionally on reevaluations by default. "`:duplicate`" forces the operation to be performed on all reevaluations.

```
redis :expire [:tableprefix prefix-string]
      [:duplicate] key-string
```

Sets the expiration time in seconds for the entry with the specified key. A time of 0 will cause the entry to be be deleted immediately. Negative values will cause the entry to be preserved indefinitely.Remove the entry with the specified key. Returns TRUE if the operation is successful, FALSE if it is not. Note that the expiration time for sets and sorted sets can be set without specifying any additional parameters.

Redis "`:expire`" operations are skipped and return success unconditionally on reevaluations by default. "`:duplicate`" forces the operation to be performed on all reevaluations.

```
redis :fetch [:tableprefix prefix-string]
      [MATCH-TYPE] [COMPARATOR] [:set | :sortedset]
      [:withscores] key-string [test-string]
```

Fetches the value of the entry with the specified key.

The entry's value is simply returned as a string if neither MATCH-TYPE, COMPARATOR, nor test-string are specified. An empty string will be returned if the specified entry doesn't exist.

However, if any of the three parameters are specified this operation functions as a test with current value of the entry being the tested value. MATCH-TYPE and COMPARATOR default to `:is` and `"i;ascii-casemap"` respectively. The test always fails if the entry does not exist. This can be to test for the existence of an entry:

```
if redis :fetch :matches "entry" "*" { ... entry exists ... }
```

The members of Redis sets and sorted sets may be fetched by specifying the corresponding parameter. Multiple members are returned as lists. If `:withscores` is specified member-score pairs are returned.

redis "`:fetch`" operations are simply repeated on reevaluations.

```
redis :release [:duplicate] [:tableprefix prefix-string]
      [:timeout timeout-value]  key-string
```

Implements a generic reservation capability, where a specified key-string can be repeatedly reserved up to a specified quota. :release releases a reservation previously created by :reserve. The associated Redis entry contains a record of how many reservations are held by each process on the host. Outstanding reservations associated with nonexistent processes will be automatically deteled.

This operation always functions as a test, returning TRUE if the reservatation has been releaves succesfully, FALSE otherwise.

Redis reservation operations are performed on reevaluations.

```
redis :remove [:tableprefix prefix-string]
      [:duplicate] key-string
```

Remove the entry with the specified key. Returns TRUE if the operation is successful, FALSE if it is not. Note that sets and sorted sets can be removed without specifying any additional parameters.

redis "`:remove`" operations are skipped and return success unconditionally on reevaluations by default. "`:duplicate`" forces the operation to be performed on all reevaluations.

```
redis :replace [:tableprefix prefix-string]
      [:timeout timeout-value] key-string value-string
```

Update the value and timeout of an entry. The entry must already exist. Returns TRUE if the operation is successful, FALSE if it is not.

redis "`:replace`" operations are simply repeated on reevaluations.

```
redis :reserve :quota quota-numeric [:duplicate]
      [:tableprefix prefix-string]
      [:timeout timeout-value]  key-string
```

Implements a generic reservation capability, where a specified key-string can be repeatedly reserved up to a specified quota. Each reserve operation must be matched by a corresponding release. The associated redis entry contains a record of how many reservations are held by each process on the host. Outstanding reservations associated with nonexistent processes will be automatically deteled.

Note that since there is no server-side awareness of entry semantics the quota parameter must be specified in every reserve call in case the entry needs to be created. If the entry already

exists the quota parameter value will be checked against the corresponding value stored in the entry.

Each reserve operation increments the reservation count by 1, and should be matched by a corresponding release operation.

This operation always functions as a test, returning TRUE if the reservation is successful, FALSE otherwise.

redis reservation operations are performed on reevaluations.

```
redis :store [:tableprefix prefix-string]
      [:timeout timeout-value] [:set | :sortedset]
      [:score score] key-string value-string
```

Creates a new entry or updates an existing entry with the specified key, value and timeout. Returns TRUE if the operation is successful, FALSE if it is not.

Store operations are identical to add operations for sets and sorted sets.

redis "`:store`" operations are simply repeated on reevaluations.

```
redis :throttle :quota quota-numeric [:duplicate]
      :quotatimeout quotatimeout-numeric [:penalize] [:limit]
      [:tableprefix prefix-string]
      [:timeout timeout-value] [MATCH-TYPE] [COMPARATOR]
      [:adjustup adjustment-value] [:adjustdown adjustment-value]
      key-string [test-string]
```

Implements the MeterMaid throttle capability. See the MeterMaid documentation for details of throttle semantics. Note that since there is no server-side awareness of entry semantics the quota and quotatimeout parameters must be specified in every throttle call in case the entry needs to be created. If the entry already exists the parameter values will be checked against the corresponding values stored in the entry.

The throttle value is incremented by default. Either "`:adjustup`" or "`:adjustdown`" can be used to specify an alternate adjustment value. (Note that in this case these nonpositional parameters function as modifiers, not operation specifiers.)

New in MS 8.0.2.3, "`:limit`" can be specified to prevent the throttle from being adjusted if it engages and to behave in a failsafe fashion.

This operation always functions as a test. If neither MATCH-TYPE, COMPARATOR, nor test-string are specified TRUE is returned if the throttle is engaged, FALSE if it is not engaged or an error occurs. If one of these three parameters is provided the throttle is adjusted and then Sieve tests are applied to the adjusted value. The default MATCH-TYPE is `:value "gt"` and the default COMPARATOR is `"i;ascii-numeric"`.

redis "`:throttle`" operations are performed on reevaluations but the adjustment amount is changed to `0`. "`:duplicate`" causes the adjustment amount to be retained on script reevaluations.

5.1.2.36 Sieve regex extension

As of MS 6.1, the MTA supports the proposed Sieve "regex" extension (see draft-murchison-sieve-regex-08), which adds a ":regex" match type to the Sieve language. The capability name is "regex":

```
require "regex";
```

Because evaluating arbitrary regex expressions is potentially computationally expensive, whether -- and which -- Sieves may use ":regex" may be controlled with the enable_sieve_regex MTA option; the default is 1, meaning that ":regex" is supported in all Sieves.

Restrictions on ":regex": Note that ":regex" is not supported with the "hasflag" test (from the "imap4flags" extension). Another restriction is that utf-8 comparator use with ":regex" is not supported. For performance reasons, the ":regex" match type is not supported for use with the Sieve "body" test.

New in 8.0, Sieve ":regex" match type tests now set variables in the same way that ":matches" match type tests do. Note that unlike glob-style matches (as when ":matches" is used) where the default is to store whatever matched any wildcard that appears in the pattern, in regex match type tests only those regular expressions enclosed in parentheses are stored. If parentheses are needed but storage is not desired, then the "(?:)" form may be used.

5.1.2.37 Sieve setenvelopefrom extension

New in MS 8.0, the MTA supports a private "setenvelopefrom" action in system level Sieve scripts. This nonstandard extension is available without any special capability declaration; no "require" action is needed for its use. "setenvelopefrom" accepts a single string argument specifying the new envelope From address.

For other Sieve actions especially relevant to notification messages, see also the Sieve "setnotify" and "setreturn" extensions.

5.1.2.38 Sieve setnotify and setreturn extensions

Introduced in Messaging Server 7.0u1, and available in system Sieves only, are the nonstandard Sieve actions "setnotify" and "setreturn". "setnotify" specifies a new value for the DSN NOTIFY parameter and "setreturn" specifies a new value for the DSN RET parameter. Both of these parameters are specified in RFC 3461, as are the possible values that can specified for each one.

The primary use of these actions is expected to be to adjust return policies for suspected spam. For example, if address validation cannot be performed, it may be prudent to disable nondelivery reports, return of content, or both for messages suspected of being spam:

```
setnotify "NEVER";
setreturn "HDRS";
```

For another Sieve action relevant to notification messages, see also the (new in MS 8.0) "setenvelopefrom" action which, by overriding a message's envelope From address, alters who will be informed if and when a notification message is later generated.

5.1.2.39 Sieve setoperation extension

As of the 8.0 release, the MTA supports a private "`setoperation`" action in system-level Sieves. This nonstandard extension is available without any special capability declaration; no "`require`" action is needed for its use. This extension is provided so that system-level Sieve filters can override the type of enqueue operation being performed. Note that this action can be performed on a per-recipient basis.

"`setoperation`" accepts a single string argument specifying the operation type. The possible operation types are:

```
"relay"
"submit"
"passthrough"
"default"
```

Note that since "`setoperation`" is a Sieve action, any effects it has only affect MTA behavior *after* Sieve evaluation. In particular, initial header fixups done on receipt of the header occur before Sieve evaluation and are therefore unaffected by this action. Only the `passthrough` channel option affects initial header fixups.

Note that for the Sieve "`environment`" extension, the MTA supports a private item `vnd.oracle.operation-type` to discover a message's existing operation mode.

5.1.2.40 Sieve setpriority and setmtpriority extensions

As of MS 7.0u4, the private "`setpriority`" action is available for system-level Sieves, to set an effective message processing priority. This nonstandard extension is available without any special capability declaration; no "`require`" action is needed for its use. "`setpriority`" takes a single string or integer argument which must be one of "`non-urgent`", "`normal`", or "`urgent`", or an integer in the range `0` to `4`; (note that non-urgent corresponds to `2`, normal to `3`, and urgent to `4`). Note that this priority is *not* stored in the message header and only affects processing at this particular stage of message transfer. If multiple "`setpriority`" actions are specified in different system-level Sieves, the one in the most specific Sieve wins.

New in MS 8.0, the "`setmtpriority`" action is available for system-level Sieves. This nonstandard extension is available without any special capability declaration; no "`require`" action is needed for its use. "`setmtpriority`" accepts a single integer or string argument and sets the current MT-PRIORITY to the argument value. This action is only allowed in system-level Sieves and the argument must be in the `-9` to `9` range of valid MT-PRIORITY values.

5.1.2.41 Sieve transactionlog extension

New in 8.0, for system-level Sieve scripts, the MTA's private "`transactionlog`" Sieve action can be used to annotate the transaction log. The action takes a single string argument specifying the annotation text.

All of the "`transactionlog`" actions in all of the applicable Sieves are concatenated into a single string, which is then available for inclusion in the MTA message transaction log file; see the `log_transactionlog` MTA option for details.

5.1.2.42 Sieve translate extension

New in MS 8.0.1, the MTA supports a private "translate" function, to translate a string (or a list) from one character set to another. No "require" clause is needed to use this private extension.

Note that RFC 5228 requires that Sieve filters represent strings in UTF-8. Even strings that (in original messages) were in some other charset are converted to UTF-8 for purposes of Sieve processing. So usually the entire issue of character sets can be ignored for Sieve processing: everything is represented in UTF-8. However, on occasion malformed messages may be encountered that contain incorrectly labelled, or incorrectly structured MIME encoded-words, where proper conversion to UTF-8 cannot be performed. Or special purpose generation of explicitly encoded-in-a-specific-charset strings may be desired. These are cases where the "translate" function may be of use.

"translate" takes three (positional) arguments: the original string, the character set of the original string, and the character set to which to translate the string. Note that the original string remains unchanged; the translated string is returned as a function result.

Either of the following two Sieve sequences of commands will request "fileinto" (folder delivery) to the folder named "nopNOP". The first example does this making use of a variable, plus the MTA Sieve implementation feature of allowing an assignment statement:

```
require ["variables","fileinto"];
set "string" "abcABC";
rotstring := translate "${string}" "US-ASCII" "ROT13";
fileinto "${rotstring}";
```

The second example does this by making use of the MTA Sieve implementation feature allowing expressions where arguments are normally expected, to perform the "translate" in-line, without use of any named variable:

```
require "fileinto";
fileinto (translate "abcABC" "US-ASCII" "ROT13");
```

5.1.2.43 Sieve warn extension

As of the 8.0 release, warnings that occur during Sieve evaluation (such as memcache protocol issues and issues with the duplicate or vacation extensions) will result in a "warn" clause in the log_filter field of MTA message transaction log entries.

Additionally, as of 8.0 the "warn" action, which takes either a string or list as an argument, is available for system-level Sieve scripts; its argument will be included in the "warn" clause in the log_filter field. This nonstandard extension is available without any special capability declaration; no "require" action is needed for its use.

New in MS 8.1.0.3, the private Sieve environment item, vnd.oracle.warnings, allows scripts to check and see if any Sieve warnings have occurred. The operation only succeeds if one or more warnings have occurred since the last check of vnd.oracle.warnings - or if no previous calls have been made, since the start of script processing. The item return value is the text of those warnings.

5.1.2.44 Sieve custom tests via mappings

As of updates to MS 6.2 and updates to MS 6.3, the MTA's Sieve implementation supports custom Sieve tests defined via MTA mapping tables. (This functionality also existed in an alternate, much less esthetic form, in earlier versions.)

Any mapping table with a name of the form `FILTER_`*`testname`* is presumed to define a new, custom Sieve test *`testname`*. The string result of the mapping will be returned in the "`${0}`" Sieve variable; the flag result of the mapping will be returned in the Sieve "`${1}`" variable.

For instance, a mapping table

```
FILTER_fruitcolor

  apple       red-or-yellow-or-green-or-pink$Y
  apricot     orange$Y
  avocado     green$Y
  banana      yellow$Y
  blackberry  purple$Y
  blueberry   blue-or-purple$Y
  grape       green-or-red-or-purple$Y
  kiwi        green$Y
  lemon       yellow$Y
  lime        green$Y
  mango       orange$Y
  orange      orange$Y
  peach       yellow-or-white$Y
  pineapple   yellow$Y
  raspberry   pink-or-yellow$Y
  strawberry  red-or-pink$Y
  watermelon  red-or-pink-or-yellow$Y
  *           $N
```

would allow use of a "`fruitcolor`" test in Sieve; *e.g.,*

```
require ["variables","fileinto"];
if header :matches "Fruit-of-the-day" "*" {set "todaysfruit" "${0}";}
if fruitcolor "${todaysfruit}"  {
  set "color" "${0}"; set "flags" "${1}";
  if "${flags}" :is "N" {fileinto "unknown-color-fruits";}
  else {
    if "${color}" :contains "red" {fileinto "red-fruits";}
    if "${color}" :contains "yellow" {fileinto "yellow-fruits";}
    if "${color}" :contains "green" {fileinto "green-fruits";}
  }
}
```

5.1.2.45 Sieve subroutines

(New in MS 8.0.) Support for user-defined routines has been added to the recipe language, and to system-level Sieves. Subroutine definitions have the general form:

```
sub routine-name {routine-body}
```

or if parameters are needed:

```
sub routine-name(parameter1, parameter2, ...) {routine-body}
```

The "`return`" control command can be used to return a specified result from the routine.

Parameters are passed by value and evaluation of parameters is lazy. If a parameter is never referenced it will never be evaluated. Note that evaluation of parameters in a particular order can be forced very easily:

```
sub f(p1,p2,p3) { p1; p2; p3; ... }
```

Local variables can be declared in a routine by specifying the "`my`" control command immediately preceeding the first use of the variable.

Autoincrement, autodecrement, and the various augmented assignment operators are all allowed on parameters and local variables. So is the exchange operator `:=:`. However, exchange cannot be used with a global variable on the right hand side and a local variable or parameter on the left hand side.

For example, a factorial function can be defined as follows:

```
sub f(n) {if n <= 1 {return 1;} else {return f(n-1)*n;}}
```

Recursion is limited to 20 levels. A routine can only call itself recursively since there is currently no forward declaration mechanism.

An example of the use of "`my`" would be:

```
sub fib(n) {my s = [1, 1];
            my a = 1;
            my b = 1;
            loop {exitif --n < 2;
                  my c = a + b;
                  s .= c;
                  a = b;
                  b = c;}
            return s;}
```

Note that use of user-defined routines in Sieves is restricted to system-level Sieves.

5.1.2.46 Sieve expressions

The MTA's Sieve implementation supports the use of expressions in places where the base Sieve specification expects values. Such expressions can make use of a number of arithmetic and string functions and operators.

Note that because Sieve syntax uses square brackets to denote lists, the MTA's usual support for using square brackets to index into strings is not supported within Sieve filters; within Sieve filters, parentheses must be used rather than square brackets to index into a string, *i.e.*, `a(1)` rather than `a[1]`.

Note that the `imsimta test -expression` utility can be used to test expression evaluation, and in particular Sieve filter expression evaluation.

5.2 Sieve hierarchy

Messaging Server's Sieve implementation has, as its most significant, major extension to Sieve, a nonstandard one: the ability for multiple scripts to apply to a single recipient. (The Sieve specifications assume a single Sieve script per user.) The MTA supports a number of types of Sieve scripts, whose specified effects are combined to result in an overall Sieve effect for each user.

Sieve scripts come in two general classes, system-level *vs.* user-level. Within these classes there are multiple different types of Sieve scripts. Such multiple Sieve scripts are combined in a logical order, as discussed in Sieve filters: semantics of multiple scripts. Then such multiple Sieve scripts are evaluated in a logical order, as discussed in Sieve filters: evaluation of multiple scripts.

5.2.1 Sieve filters: types of scripts

Messaging Server supports Sieve scripts of various types specified at multiple levels, whose specified effects will then be "combined" to yield an overall Sieve result for each user. The various types of Sieve scripts, in order from the most general to the most specific, are:

1. Spam filter Sieve scripts. Results produced by spam/virus filter package plugins are interpolated into Sieve scripts. Up to eight such spam/virus filter package plugins can be defined, hence up to eight such Sieve scripts can be produced. Among such spam/virus filter package Sieve scripts, package 1 is the most general proceeding through package 8 as the most specific. (*)

2. Source channel Sieve filters. The `sourcefilter` channel option is used to specify the location (via a URL) for a Sieve script applying for messages received via that source channel. (*)

3. System Sieve filter. A single system-wide (per MTA host) Sieve filter can be specified that applies to all recipients of all messages passing through this MTA. In Unified Configuration, the system Sieve filter is specified via the `systemfilter` MTA option; in legacy configuration, the normal location for this script is the file *`CONFIGROOT/`*`imta.filter`. (*)

4. Destination channel script. The `destinationfilter` channel option specifies the location (via a URL) for a Sieve script applying to messages enqueued to this destination channel. (*)

5. `ORIG_SEND_ACCESS`, `SEND_ACCESS`, `ORIG_MAIL_ACCESS`, and `MAIL_ACCESS` mapping table Sieve scripts (in the listed order; that is, the most general being `ORIG_SEND_ACCESS` through the most specific being `MAIL_ACCESS`). The `$S` sequence, when specified in any of these mapping tables, causes a Sieve URL to be read from the mapping result string.

6. Mailing list domain scripts. The domain entry associated with mailing lists defined in LDAP can use the `mailDomainSieveRuleSource` LDAP attribute (more technically, whatever

LDAP attribute is named by the ldap_domain_attr_filter MTA option) to specify a Sieve script. (*)

7. Mailing list scripts. Mailing lists defined in LDAP can use the mailSieveRuleSource LDAP attribute (more technically, whatever LDAP attribute is named by the ldap_filter MTA option) to specify a Sieve script. Lists defined via Unified Configuration alias options can use the alias_filter alias option to specify a Sieve script, just as in legacy configuration lists defined in the aliases file or database can use a [FILTER] nonpositional parameter to specify a Sieve URL. Also (and note that this is different from the user script case), any "head of household" script applied to a mailing list (specified by having on the group/list LDAP entry the LDAP attributes named by the ldap_filter_reference and ldap_hoh_filter MTA options) is also considered to be at this same level of generality as other mailing list scripts. The mailing list scripts are considered in the order in which they are encountered.

8. User domain scripts. The domain entry associated with users defined in LDAP can use the mailDomainSieveRuleSource attribute (more technically, whatever LDAP attribute is named by the ldap_domain_attr_filter MTA option) to specify a Sieve script. (*)

9. User scripts. Users defined in LDAP can use the mailSieveRuleSource LDAP attribute (more technically, whatever LDAP attribute is named by the ldap_filter MTA option) to specify a Sieve script. In Unified Configuration, users defined via alias options can use the alias_filter alias option to specify a Sieve script, just as in legacy configuration users defined in the aliases file or database can use a [FILTER] nonpositional parameter to specify a Sieve URL.

10. Head of household scripts. LDAP user entries can contain an attribute (specified by the ldap_filter_reference MTA option) that provides the distinguished name of the so-called "head of household", another LDAP user entry. This entry is read and any Sieve stored in the attribute specified by the ldap_hoh_filter MTA option (which defaults to mailSieveRuleSource) will be processed.

11. Finally, the filter channel option can applied to the destination channel; if used, it specifies a Sieve URL for a user Sieve (that is, it typically specifies a template including user-specific substitutions for how to locate user Sieve scripts).

The types marked with (*) are considered to be "system-level" scripts. Certain capabilities, most notably the "capture" action, are only available to system-level scripts. In the other direction, the vacation action is only available to user-level (non-system-level) scripts.

Many types of Sieve scripts may be specified or located via a URL; in particular, file:, ldap:, data:, and imap: URLs are supported, and a file: URL type is normally assumed so bare filenames (the name of a file containing a Sieve script) will also work as an argument in most places.

5.2.2 Sieve filters: semantics of multiple scripts

Since multiple Sieve scripts can apply to each recipient and different scripts can produce different results, there has to be a way to resolve conflicting results. The rules for determining the final result are:

1. The scripts associated with a particular recipient are scanned in order from most specific to most general. The result of the most specific script that executes an action which determines

the status of a message is used preferentially. The actions that determine the status of a message are:

- `discard`,
- `fileinto`,
- `keep`,
- `redirect`,
- `reject`, and
- (Messaging Server 7.0 or later) `ereject`.

2. A set of special, nonstandard actions are provided which, if used, work the other way around: the most general script that specifies them is used preferentially. These special actions are:
   - `jettison`(like discard) and
   - `refuse` (like reject)
3. A Sieve script marked with the (new in 8.0) `override` action becomes the Sieve determining the disposition of a message. If multiple Sieve scripts are marked `override`, then the most general Sieve script "wins". (Thus this is a generalization of the "`jettison`" and "`refuse`" sorts of effects -- but in addition to being able to combine "`override`" with "`discard`" to obtain a "`jettison`" effect, or "`override`" with "`reject`" to obtain a "`refuse`" effect, "`override`" may also be combined with actions such as "`fileinto`" or "`redirect`".)
4. "`capture`" actions in system-level Sieve scripts are executed unconditionally, regardless of whether or not the Sieve script that contains the "`capture`" action is selected as the one which determines message handling for this recipient.
5. Conversion tags set or added by the "`setconversiontag`" and "`addconversiontag`" actions, respectively, are processed unconditionally in a fashion similar to "`capture`" actions.
6. An error in any Sieve script forces a "`keep`" action and aborts further scanning. Additionally, a notification message is sent to the Sieve script owner reporting the problem.

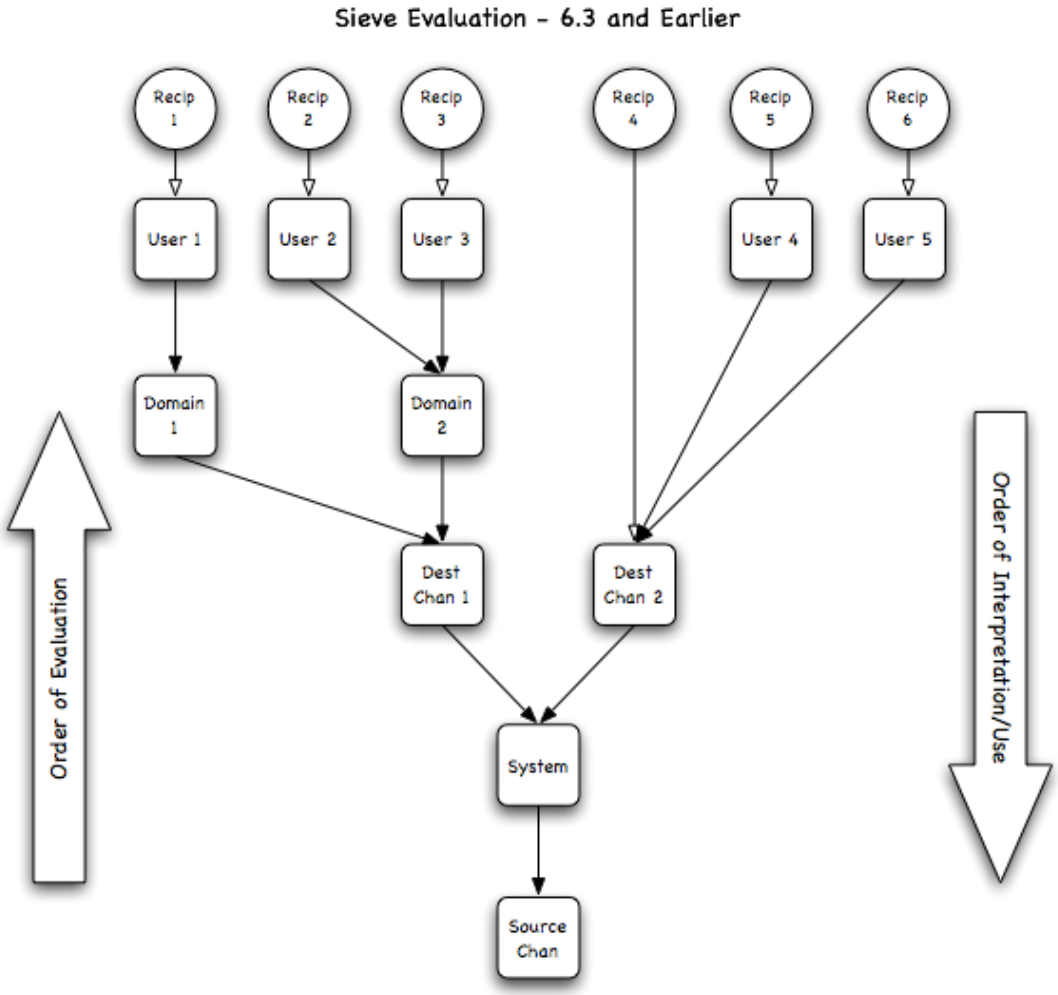
Prior to the 7.0 release, "`refuse`" actions were only available to system-level Sieve scripts, and "`refuse`", when used, forced the return of a 5yx response to the DATA command in SMTP. In 7.0 and later this is no longer the case: "`refuse`" now behaves like "`jettison`", making it possible for it to apply to only a subset of all recipients. However, the MTA checks and whenever possible will continue to use a 5yz response whenever it is possible to do so.

5.2.3 Sieve filters: evaluation of multiple scripts

The various different types of Sieve scripts are located, loaded, and associated with the appropriate recipient addresses as early as possible: Source channel scripts and the system Sieve script (`sourcefilter` and `systemfilter`) are dealt with during MAIL FROM processing and all others, with the exception of spam filter Sieves, are dealt with during

RCPT TO processing. Spam filter Sieves (see the `spamfilter*_action*` MTA options) are determined last: since they are derived from spam filter verdict processing, they can only be determined after message data is available.

Prior to Messaging Server 7.0, the internal linkage of Sieve script to recipients looked something like this:



Note that any given tier of the linkage tree can be omitted. As the arrows indicate, evaluation of Sieve scripts proceeded from the bottom to the top, while interpretation of Sieve script results proceeds from the recipients at the leaves down to the root (source channel Sieve filter).

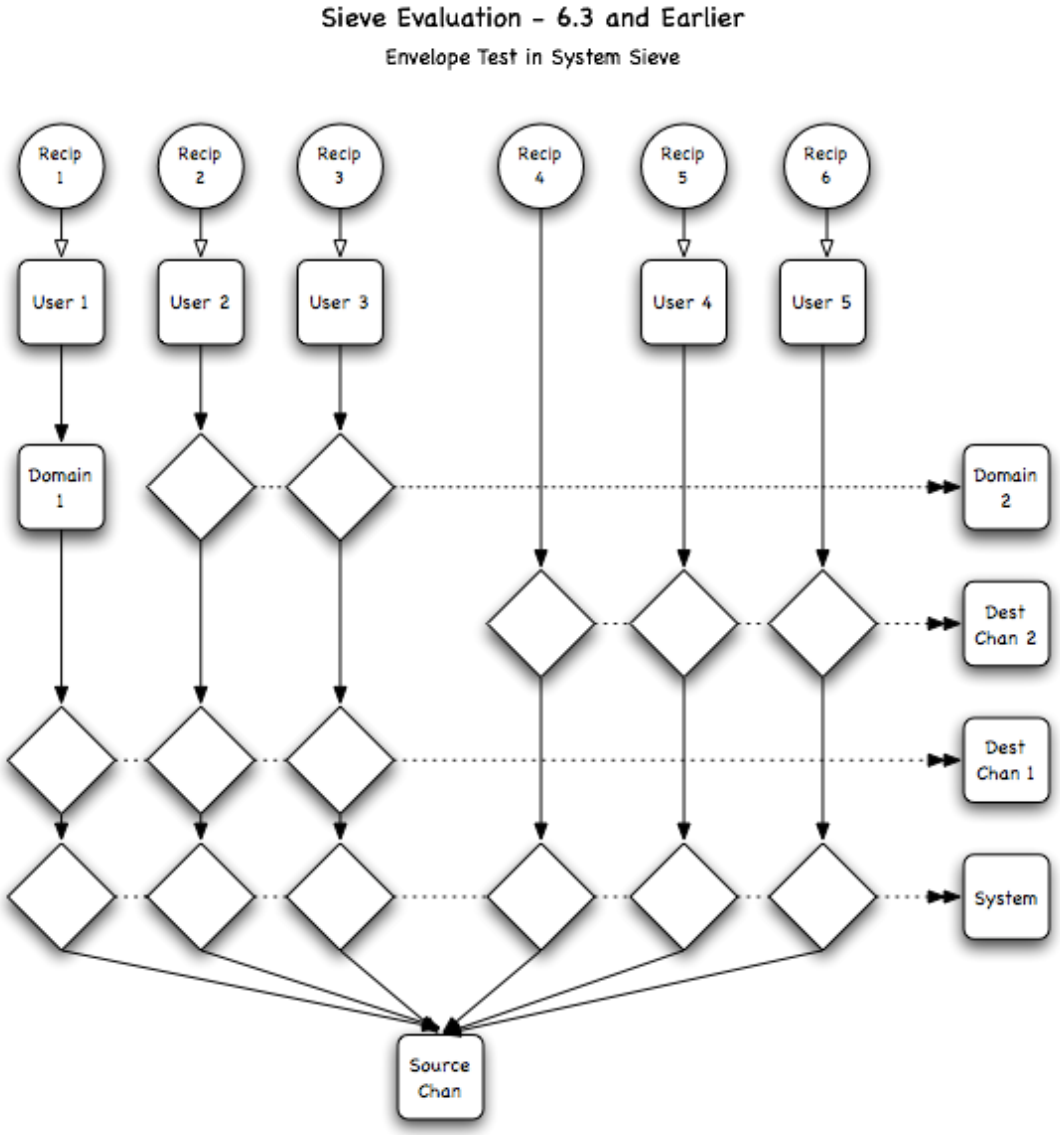
The prior-to-7.0 organization just described was fine in terms of Sieve script evaluation semantics. However, after it was implemented and various additional Sieve extensions were defined, a number of problems emerged:

- Information flow up the tree from the root (source channel Sieve filter) to the leaves (recipient Sieve filters) wasn't possible. This was a nonissue prior to the availability of the `"editheader"`, `"spamtest"`, and `"virustest"` extensions. But once these extensions entered the picture, it was only logical that the effects of more general scripts would be visible to more specific scripts. For example, a system Sieve that performs some test and decides a message is likely to be spam might want to indicate this fact either by adjusting

the spamtest score or by inserting a header. But this doesn't accomplish much when more specific scripts cannot see the results of these actions.

- In some situations, Sieve scripts were loaded but then the recipient addresses they were associated with ended up being dropped from the recipient list. When this happened there was no easy way to remove the scripts from the evaluation list and scripts were evaluated unnecessarily.

- Since the `envelope` test can examine recipient addresses, any Sieve script that employs such a test is necessarily recipient-specific and must be reevaluated for each recipient. Even worse, since this can change the result of the script, it has a cascade effect forcing all more specific scripts to be reevaluated as well. In order to get these semantics, the linkage tree had to be split and dummy nodes had to be inserted. For example, if the system Sieve script called for the "`envelope`" extension, the recipient tree shown above ended up looking like this:

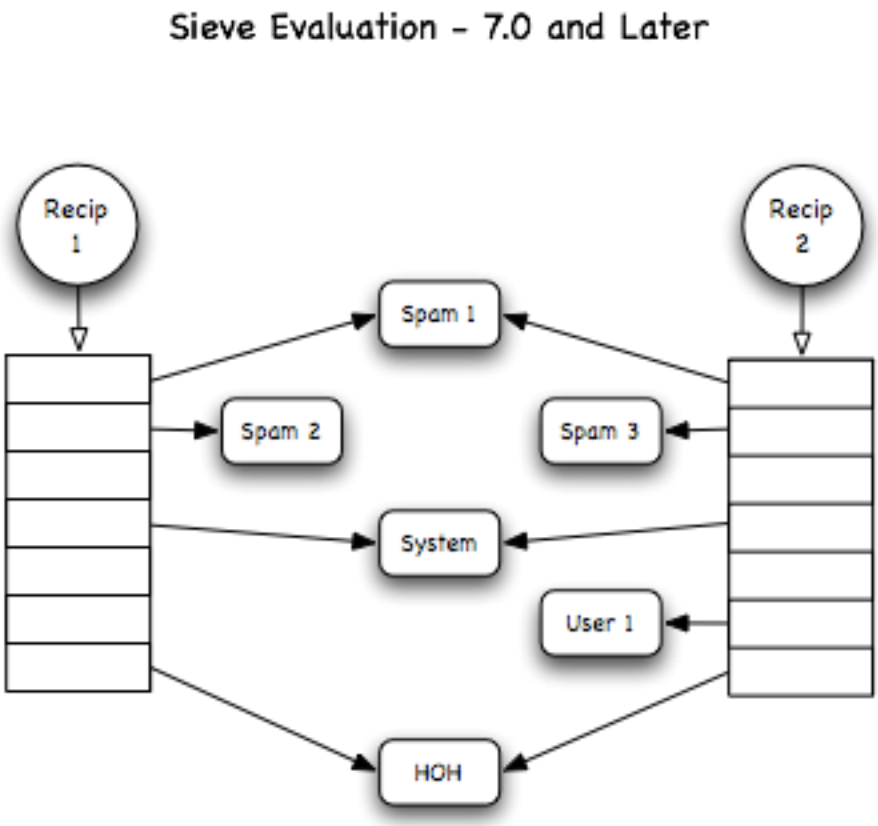


- All Sieve scripts must list all of the extensions they employ in an initial require clause. However, it is common for an extension to be listed but not actually used - and this is not necessarily a result of poor coding practice. For example, a script might perform a header or address test and depending on the result of that test only then perform an envelope test, as in the following example where the script is only recipient-specific given certain header values and it is unnecessary to reevaluate it for every recipient. But since the linkage tree has to be constructed prior to script evaluation the presence of the envelope extension in the require clause forces unnecessary reevaluations.

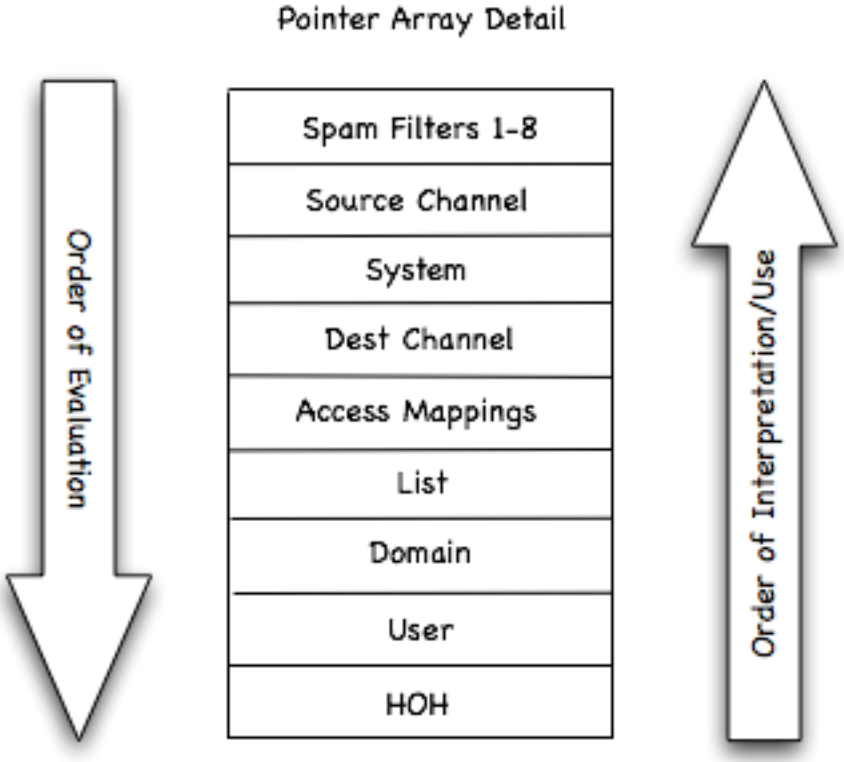
```
require ["envelope", "subaddress"];
if address :is "from" "user1@example.com" {
  if envelope :is :detail "to" "whatever" { ... }
}
```

- Sieve scripts often can be written to take advantage of a given extension if it is available but still function if it is not. The approach of enumerating of all extensions in the "`require`" clause does not allow the construction of such scripts. The "`ihave`" extension eliminates this restriction by adding a test that succeeds if the requested extension is available and fails if it is not. This would be extremely difficult to implement using the linkage tree approach since the extensions a given Sieve script uses can no longer be determined prior to Sieve script evaluation.

A new way of linking scripts to users was needed and has been implemented in 7.0. The linkage tree is gone, replaced with a per-recipient array:



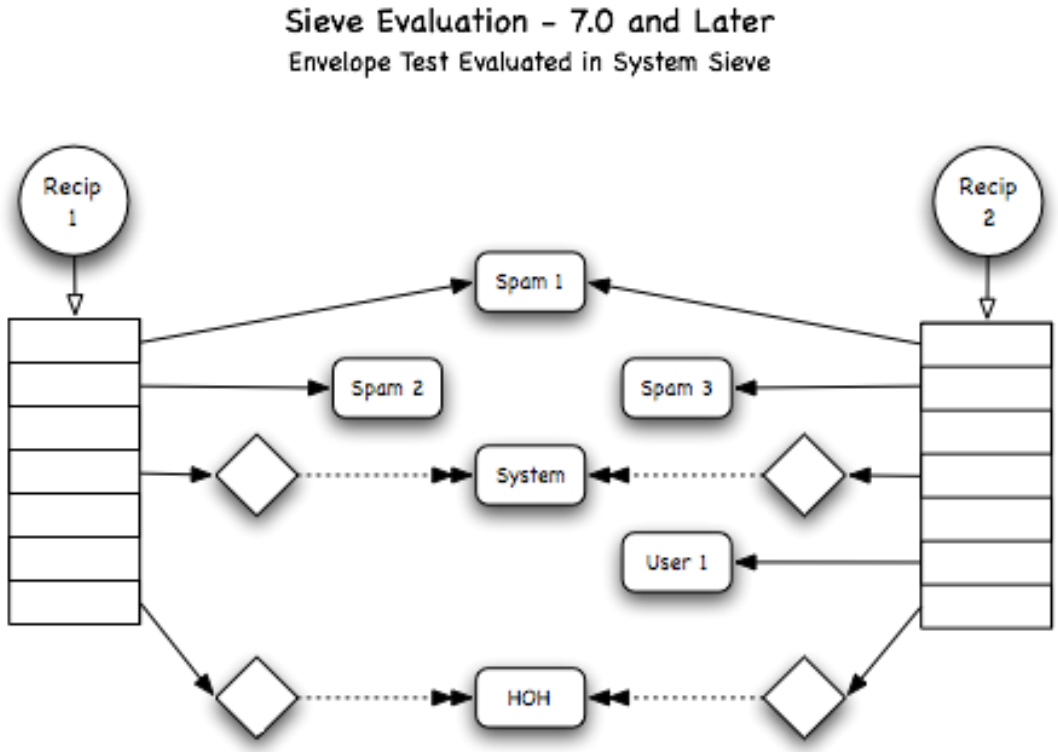
Sieve Evaluation - 7.0 and Later
Recip 1
Recip 2
Spam 1
Spam 2
Spam 3
System
User 1
HOH



Pointer Array Detail
Order of Evaluation
Spam Filters 1-8
Source Channel
System
Dest Channel
Access Mappings
List
Domain
User
HOH
Order of Interpretation/Use

This new structure eliminates all of the issues the linkage tree had. Scripts are now evaluated during final recipient address processing, eliminating unnecessary evaluation. Evaluation poceeds down the array, and if a particular script has already been evaluated on behalf of some other recipient the results can easily be checked for recipient specificity and reused if no dependency exists. Even better, information can be passed from more general scripts to more specific ones, and the additional checks for recipient-specific information inheritance are reasonably straightforward. And finally, when reevaluation is required the resulting "split" is much more straightforward.

For example, given the previous set of scripts, a recipient-specific system sieve results in the following augmented data structure:



5.3 Sieve filters: implementation internals

NOTE: This discussion is technical; while it may be of interest during debugging or in discussions with Oracle technical support, it is otherwise unlikely to be relevant or of interest for casual perusal.

Sieve parsing and evaluation is implemented using a generic parse/evaluation subsystem. In addition to Sieve, this system has also been used to implement other languages, most notably the language used by the PMDF-DIRSYNC product. Specific language details, in particular what "functions" can be called and what arguments they require, are specified through callbacks.

Parsed expressions are stored in two separate linked lists of arrays: One for instructions and the other for string data. The use of a series of array segments makes it possible to write parsed

expressions out to disk and read them back in later. This feature is used to store the system Sieve in the compiled configuration so it doesn't need to be reparsed.

This subsystem only understands basic script syntax; it knows nothing about specific Sieve semantics. Information about Sieve semantics is provided through callbacks passed to the parser and evaluator. The Sieve-specific callbacks are the routines `mm_check_function` and `mm_eval_function`.

5.4 Head of household Sieve filters

The MTA supports the concept of "head of household" (also referred to as "parental controls") filtering of incoming messages. This refers to cases where the MTA applies a "parent" or "head of household" Sieve filter to a user's incoming messages in addition to the user's own personal Sieve filter. This allows the "parent" or "head of household" user to exert some control over the receipt and handling of messages addressed to the "child" user.

Such "head of household" controls are enabled by marking a "child" user entry with:

- a site-chosen LDAP attribute enabling application of "head of household" control (see the `ldap_parental_controls` MTA option), and
- a site-chosen LDAP attribute (see the `ldap_filter_reference` MTA option) whose value will be the DN of the entry that contains the actual "head of household" Sieve filter (typically the DN of the "head of household" user).

By default, the "head of household" Sieve filter to be applied will simply be the "head of household" user's own Sieve filter as stored in `mailSieveRuleSource`; note that use of the Sieve "`envelope`" extension permits a Sieve filter to be sensitive to the recipient of a message, thus to distinguish between those messages addressed to the "head of household" user him/herself, *vs.* those messages having the "head of household" Sieve filter applied, but which were addressed to some other "child" user. However, see the `ldap_hoh_filter` MTA option which may be used to select use of a differently named LDAP attribute as the location of the "head of household" Sieve filter, if it is preferred to store the Sieve filter to be applied in a "head of household" capacity to "child" messages separately from the Sieve filter applying to the "head of household"'s own messages.

Sieve filter application requires a Sieve "owner" for certain purposes. By default, the "head of household" user's `mail` LDAP attribute is taken to be the Sieve "owner" when a Sieve filter is being applied in "head of household" capacity. However, see the `ldap_hoh_owner` MTA option which may be used to specify a different LDAP attribute whose value to consider as "owner" for such purposes.

Chapter 6 TCP wrappers

Access control for clients connecting to Message Store servers (or MMP or proxies) is implemented using the *TCP wrapper* concept. A TCP wrapper is a program that listens at the same port as the TCP daemon it serves. It uses access filters to verify client identity, and it gives the client access to the daemon if the client passes the filtering process. The design of the Messaging Server TCP wrapper is based on the Unix Tcpd access-control facility (created by Wietse Venema).

As part of its processing, the Messaging Server TCP client access-control system performs (when necessary) the following analyses of the socket end-point addresses:

- Reverse DNS lookups of both end points (to perform name-based access control)
- Forward DNS lookups of both end points (to detect DNS spoofing)

The system compares this information against access-control statements called *filters* to decide whether to grant or deny access. For each service, separate sets of Allow filters and Deny filters control access. Allow filters explicitly grant access. Deny filters explicitly forbid access.

When a client requests access to a service, the access-control system compares the client's address or name information to each of that service's filters, in order, by using these criteria:

- The search stops at the first match. Because Allow filters are processed before Deny filters, Allow filters take precedence.
- Access is granted if the client information matches an Allow filter for that service.
- Access is denied if the client information matches a Deny filter for that service.
- If no match with any Allow or Deny filter occurs, access is granted, except in the case where there are Allow filters but no Deny filters, in which case lack of a match means that access is denied.

The filter syntax described here is flexible enough that you should be able to implement many different kinds of access-control policies in a simple and straightforward manner. You can use both Allow filters and Deny filters in any combination, even though you can probably implement most policies by using almost exclusively Allows or almost exclusively Denies.

See TCP wrapper filter syntax for a discussion of TCP wrapper filter syntax. Note that MMP and the proxies use a general `tcpaccess` option to set any combination of Allow and Deny filters, whereas the IMAP and POP servers, the ENS server, and the eval_ldapd server, instead

use a domainallowed option and a domainnotallowed option to set, respectively, Allow and Deny filters.

There are also LDAP attributes at the user level, mailAllowedServiceAccess, and domain level, mailDomainAllowedServiceAccess, that are available to specify per-user or per-domain TCP wrapper access filters. (Note that the MMP and its proxies permit revectoring of exactly what LDAP attribute is used at the user level, via their tcpaccessattr option.) See the ldap_domain_timeout option for a discussion of the caching of domain level LDAP attributes such as mailDomainAllowedServiceAccess.

6.1 TCP wrapper filter syntax

TCP wrapper filter statements contain both service information and client information. The service information can include the name of the service, names of hosts, and addresses of hosts. The client information can include host names and host addresses. Both the server and client information can include wildcard names or patterns.

The general syntax of an access filter rule is:

```
< "+" | "-" > service-list: client-list
```

where multiple rules can be placed on the same line, separated by the $ character, and where

- + (allow filter)[1] means the services in the *service-list* are being granted to the *client-list*;
- - (deny filter)[1] means the services are being denied to the *client-list*;
- *service-list* is a comma separated list of services to which access is being granted or denied;
- *client-list* is a comma separated list of the clients to be allowed or denied access to the *service-list*.

In more detail, *service-list* is a comma or space separated list of *service-specification*s. A *service-specification* consists of simply a defined *service-name*, or *service-name@host-pattern*, or the special wildcard name ALL, or may make use of combinations of the above with the EXCEPT operator. Defined service names are imap, imaps, pop, pops, smtp, smtps, http, smime, and as of MS 7.0.5 mshttpd.[2]. See TCP wrapper filter wildcard patterns for more details on *host-pattern*s, and TCP wrapper filter EXCEPT operator for further details on the EXCEPT operator.

client-list is a comma or space separated list of *client-specification*s. A *client-specification* consists of any of a specific *host-name*, a *host-wildcard-pattern*, *username@host-wildcard-pattern*, or in the above forms may make use of the wildcard names described in Wildcard names for TCP wrapper service filters, and optionally the TCP wrapper filter EXCEPT operator.

The very simplest form of a filter is:

```
service: host-specification
```

where *service* is the name of the service (such as smtp, pop, imap, or http) and *host-specification* is the host name, IPv4 address, or wildcard name or wildcard pattern that

represents the client requesting access. When a TCP wrapper filter is processed, if the client seeking access matches *host-specification*, access is either allowed or denied (depending on which type of filter this is) to the service specified by *service*. Here are some examples:

```
imap: roberts.newyork.siroe.com
pop: ALL
http: ALL
```

If these are Allow filters, the first one grants the host roberts.newyork.siroe.com access to the IMAP service, and the second and third grant all clients access to the POP and HTTP services, respectively. If they are Deny filters, they deny those clients access to those services. (For descriptions of wildcard names such as ALL, see TCP wrapper filter wildcard names.)

Or for a more complex example, making use of a host name in a *service-specification* and a user name in a *client-specification*:

```
pop@mailserver1.siroe.com: ALL
imap: srashad@xyz.europe.siroe.com
```

If these are Deny filters, the first filter denies all clients access to the SMTP service on the host mailserver1.siroe.com. The second filter denies the user srashad at the host xyz.europe.siroe.com access to the IMAP service. (For more information on when to use these expanded server and client specifications, see TCP wrapper filter server-host specification and Client User-Name Specification.

When a TCP wrapper filter is processed, if the client seeking access matches *any* of the *client-specification* entries in *client-list*, then access is either allowed or denied (depending on which type of filter this is) to *all* the services specified in *service-list*. Here is an example:

```
pop, imap, http: .europe.siroe.com .newyork.siroe.com
```

If this is an Allow filter, it grants access to POP, IMAP, and HTTP services to all clients in either of the domains europe.siroe.com and newyork.siroe.com. For information on using a leading dot or other pattern to specify domains or subnet, see TCP wrapper filter wildcard patterns.

The following example enables multiple services on all clients.

```
+imap,pop,http:*
```

The following example shows multiple rules with the $ rule separator, but each rule is simplified to have only one service name and uses wildcards for the client list. (This is the most commonly used method of specifying access control in LDIF files.)

```
+imap:ALL$+pop:ALL$+http:ALL
```

An example of how to disallow all services for a user is:

```
-imap:*$-pop:*$-http:*
```

The following example shows how to restrict user access so that only SSL-encrypted POP and IMAP are permitted. Because back-end servers do not recognize the `imaps` and `pops` service names,[2] it is necessary to grant the MMP IP address(es) `pop` and `imap` service access; otherwise, connections between the MMP and the back-end servers will be rejected.

```
+imaps,pops:*$+imap,pop:MMP-IP-address(es)
```

[1] Note that use of "+" and "-" in access filters makes sense in values of LDAP attributes such as `mailAllowedServiceAccess` or for components such that MMP which set a general access filter via a `tcpaccess` option; but for components such as the IMAP and POP servers which separately specify Allow and Deny filters (`domainallowed` and `domainnotallowed` options), the explicit "+" and "-" are not needed.

[2] Note that the MMP supports service names `imap`, `imaps`, `pop`, `pops`, and `smtp`, and `smime`. The back-end (Message Store) system (with its servers such as IMAP and POP) supports `imap`, `pop`, `smtp`, `http`, and `smime`.

6.1.1 TCP wrapper filter wildcard names

Wildcard names for TCP wrapper service filters shows the TCP wrapper filter wildcard names that may be used to represent service names, host names, or user names.

Table 6.1 Wildcard names for TCP wrapper service filters

Wildcard name	Description
`ALL`, `*`	The universal wildcard. Matches all names.
`LOCAL`	Matches any local short-form host name (one whose name does not contain a dot character). Note that if your deployment uses only canonical names -- fully qualified domain names, hence including dots -- then even local short-form host names will contain dots and thus will not match this wildcard.
`UNKNOWN`	Matches any host whose name or address is unknown. Use this wildcard name carefully. Host names may be unavailable due to temporary DNS nameserver problems -- in which case all filters that use `UNKNOWN` will match all client hosts. A network address is unavailable when the software cannot identify the type of network with which it is communicating -- in which case all filters that use `UNKNOWN` will match all client hosts on that network.
`KNOWN`	Matches any host whose name *and* address are known. Use this wildcard name carefully. Host names may be unavailable due to temporary DNS nameserver problems -- in which case all filters that use `KNOWN` will fail for all client hosts. A network address is unavailable when the software cannot identify the type of network with which it is communicating -- in which case all filters that use `KNOWN` will fail for all client hosts on that network.
`DNSSPOOFER`	Matches any host whose DNS name does not match its own IP address.

6.1.2 TCP wrapper filter wildcard patterns

You can use the following patterns in service or client addresses:

- A string that begins with a dot character (`.`). A host name is matched if the last components of its name match the specified pattern. For example, the wildcard pattern .siroe.com matches all hosts in the domain siroe.com.
- A string of the form *n*`.`*n*`.`*n*`.`*n*`/`*m*`.`*m*`.`*m*`.`*m*. This wildcard pattern is interpreted as a *net*/*mask* pair. A host IP address is matched if *net* is equal to the bitwise AND of the IP address and *mask*. For example, the pattern `123.45.67.0/255.255.255.128` matches every address in the range `123.45.67.0` through `123.45.67.127`. Note that `255.255.255.255` is not permitted as a mask; use CIDR notation with `/32` instead.
- A string of the form *n*`.`*n*`.`*n*`.`*n*`/`*p*. This wildcard pattern is interpreted as being in CIDR notation, where *p* is the routing prefix. The corresponding subnet mask, *mask*, is *p* one bits followed by 32-*p* zero bits for a total of 32 bits. A host address is matched if the bitwise AND of *n*`.`*n*`.`*n*`.`*n* and *mask* is equal to the bitwise AND of the address and *mask*. For example, the pattern `123.45.67.0/25` matches every address in the range `123.45.67.0` through `123.45.67.127`.

6.1.3 TCP wrapper filter EXCEPT operator

The TCP wrapper access-control system supports a single operator. You can use the `EXCEPT` operator to create exceptions to matching names or patterns when you have multiple entries in either *service-list* or *client-list*. For example, the expression:

`list1` `EXCEPT` *`list2`*

means that anything that matches *list1* is matched, unless it also matches *list2*.

Here is an example:

```
ALL: ALL EXCEPT isserver.siroe.com
```

If this were a Deny filter, it would deny access to all services to all clients except those on the host machine isserver.siroe.com.

`EXCEPT` clauses can be nested. The expression:

`list1` `EXCEPT` *`list2`* `EXCEPT` *`list3`*

is evaluated as if it were:

`list1` `EXCEPT (`*`list2`* `EXCEPT` *`list3`*`)`

6.1.4 TCP wrapper filter server-host specification

You can further identify the specific service being requested in a TCP wrapper filter by including server host name or address information in the *service-specification* entry. In that case the entry has the form *service@host-specification*.

You might want to use this feature when your Messaging Server host machine is set up for multiple Internet addresses with different Internet host names. If you are a service provider, you can use this facility to host multiple domains, with different access-control rules, on a single server instance.

6.2 TCP wrapper filter examples

The examples in this section show a variety of approaches to controlling access using TCP wrapper access filters. In studying the examples, keep in mind that Allow filters are processed before Deny filters, the search terminates when a match is found, and access is granted when no match is found at all.

The examples listed here use host and domain names rather than IP addresses. Remember that you can include address and netmask information in TCP wrapper filters, which can improve reliability in the case of nameservice failure.

Example TCP wrapper filter: mostly denying

In this example, access is denied by default. Only explicitly authorized hosts are permitted access.

The default policy (no access) is implemented with a single, trivial deny rule via the `domainnotallowed` option:

```
ALL: ALL
```

This filter denies all service to all clients that have not been explicitly granted access by an Allow filter (set via the `domainallowed` option). The Allow filters, then might be something like these:

```
ALL: LOCAL @netgroup1
ALL: .siroe EXCEPT externalserver.siroe.com
```

The first rule permits access from all short-form host names in the local domain and from members of the group `netgroup1`. The second rule uses a leading-dot wildcard pattern to permit access from all hosts in the `siroe.com` domain, with the exception of the host `externalserver.siroe.com`.

Example TCP wrapper filter: mostly allowing

In this example, access is granted by default. Only explicitly specified hosts are denied access.

The default policy (access granted) makes explicit Allow filters unnecessary. The unwanted clients are listed explicitly in Deny filters (set via the `domainnotallowed` option) such as these:

```
ALL: externalserver.siroe1.com, .siroe.asia.com
ALL EXCEPT pop: contractor.siroe1.com, .siroe.com
```

The first filter denies all services to a particular host and to a specific domain. The second filter permits nothing but POP access from a particular host and from a specific domain.

Example TCP wrapper filter: Denying access from spoofed IPs or hosts

You can use the `DNSSPOOFER` wildcard name in a filter to detect host-name spoofing. When you specify `DNSSPOOFER`, the access-control system performs forward or reverse DNS lookups to verify that the client's presented host name matches its actual IP address. Here is an example for a Deny filter (which would be set via the `domainnotallowed` option):

```
ALL: DNSSPOOFER
```

This filter denies all services to all remote hosts whose IP addresses don't match their DNS host names.

Example TCP wrapper filter: Controlling access to Virtual Domains

If your messaging installation uses virtual domains, in which a single server instance is associated with multiple IP addresses and domain names, you can control access to each virtual domain through a combination of Allow and Deny filters. For example, you can use Allow filters like:

```
ALL@msgServer.siroe1.com: @.siroe1.com
ALL@msgServer.siroe2.com: @.siroe2.com
...
```

coupled with a Deny filter like:

```
ALL: ALL
```

Each Allow filter permits only hosts within domainN to connect to the service whose IP address corresponds to msgServer.siroeN.com. All other connections are denied.

Example TCP wrapper filter: Controlling IMAP access while permitting Webmail access

If you wish to allow users to access Webmail, but not access IMAP, create a filter like this:

```
+imap:access-server-host1,access-server-host2
```

This permits IMAP only from the access server hosts *access-server-host1* and and *access-server-host2*. You can set the access filter at the IMAP server level by using the option `imap.domainallowed`, or set the access filter at the user level via the `mailAllowedServiceAccess` LDAP attribute or at the domain level via the `mailDomainAllowedServiceAccess` LDAP attribute. (The MMP and its proxies will at the proxy level use the `tcpaccess` option, as well as at the user level whatever user LDAP attribute is named by the `tcpaccessattr` option, by default `mailAllowedServiceAccess`, and at the domain level the `mailDomainAllowedServiceAccess` LDAP attribute.)

6.3 TCP wrapper filter creation

The IMAP, POP, and HTTP services support Allow and Deny filters via options `domainallowed` and `domainnotallowed`; (such filters may also be created for SMTP services, but will only apply to authenticated SMTP sessions; instead see Mail filtering and access control for discussion of the MTA's approaches for controlling access). The MMP and its proxy services, the IMAP Proxy, POP Proxy, and vdomain for specifying Virtual Domain specific controls, instead support a `tcpaccess` option.

The `msconfig` utility is used to create or edit server level TCP wrapper filters in Unified Configuration; for example:

```
msconfig> set imap.domainallowed .siroe.com
msconfig> set pop.domainnotallowed imap.siroe.com
msconfig> set mmp.tcpaccess "+imap: siroe.com"
```

Note: Restart the relevant services after making changes to their access filters.

TCP wrapper access filters can also be set at the user level or domain level via LDAP attributes; see the user level `mailAllowedServiceAccess` LDAP attribute[1] and the domain level `mailDomainAllowedServiceAccess` LDAP attribute.

[1] The MMP and its proxy servers and virtual domains permit renaming of the user level LDAP attribute via their `tcpaccessattr` option. The IMAP, POP, and MSHTTP servers, however, do not support such renaming and expect use of the `mailAllowedServiceAccess` user level LDAP attribute.

6.4 Component domainallowed and domainnotallowed options

Various components allow setting allow or deny TCP access filters via *component*`.domainallowed` or *component*`.domainnotallowed` options. (However, the MMP and its subcomponents instead use a general `tcpaccess` option.)

6.4.1 `domainallowed` Option

The `domainallowed` option (available under `ens`, `eval_ldapd`, `http`, `imap`, `imapproxy`, `pop`, `popproxy`) specifies access filters specifying which domains and/or IP addresses are allowed access for the selected server.

6.4.1.1 Use with the IMAP proxy

The `domainallowed` IMAP Proxy/POP Proxy option (also available under `ens`, `eval_ldapd`, `http`, `imap`, and `pop`) specifies access filters specifying which domains and/or IP addresses are allowed access for the selected server.

6.4.1.2 Use with the POP proxy

The `domainallowed` IMAP Proxy/POP Proxy option (also available under `ens`, `eval_ldapd`, `http`, `imap`, and `pop`) specifies access filters specifying which domains and/or IP addresses are allowed access for the selected server.

6.4.1.3 Use with http

The `domainallowed` MSHTTP option specifies access filters specifying which domains and/or IP addresses are allowed HTTP access.

6.4.1.4 Use with imap

The `domainallowed` IMAP option specifies access filters specifying which domains and/or IP addresses are allowed IMAP access.

6.4.1.5 Use with pop

The domainallowed POP option specifies access filters specifying which domains and/or IP addresses are allowed POP access.

6.4.1.6 Use with ens

The domainallowed ENS option specifies access filters specifying which domains and/or IP addresses are allowed ENS access.

6.4.1.7 Use with eval_ldapd

The domainallowed option under eval_ldapd allows setting access filters specifying which domains and/or IP addresses are allowed evaluation ldapd access.

6.4.2 domainnotallowed Option

The domainnotallowed option specifies access filters specifying which domains and/or IP addresses are not allowed access for the selected server.

6.4.2.1 Use with the IMAP proxy

The domainnotallowed IMAP Proxy/POP Proxy option (also available at other levels) specifies access filters specifying which domains and/or IP addresses are not allowed access for the selected server.

6.4.2.2 Use with the POP proxy

subsubitem="domainnotallowed MMP/IMAP Proxy option"/>

The domainnotallowed IMAP Proxy/POP Proxy option (also available at other levels) specifies access filters specifying which domains and/or IP addresses are not allowed access for the selected server.

6.4.2.3 Use with eval_ldapd

The domainnotallowed option under eval_ldapd allows setting access filters specifying which domains and/or IP addresses are *not* allowed evaluation ldapd access.

6.4.2.4 Use with http

The domainnotallowed MSHTTP option specifies access filters specifying which domains and/or IP addresses are not allowed HTTP access.

6.4.2.5 Use with imap

The domainnotallowed IMAP option specifies access filters specifying which domains and/or IP addresses are not allowed IMAP access.

6.4.2.6 Use with pop

The domainnotallowed POP option specifies access filters specifying which domains and/or IP addresses are not allowed POP access.

6.4.2.7 Use with ens

The domainnotallowed ENS option specifies access filters specifying which domains and/or IP addresses are not allowed ENS access.

Part II Messaging Server command line utilities

Messaging Server comes with a collection of command line utilities. Utilities for the MTA are documented in the MTA command line utilties chapter.

Most Message Store utilities are documented in the "Message Store Command Reference" chapter of the System Administrator's Guide. This includes the following command line utilities: **configutil**, **counterutil**, **deliver**, **hashdir**, **imcheck**, **imdbverify**, **imexpire**, **iminitquota**, **immonitor-access**, **impurge**, **imquotacheck**, **imsasm**, **imsbackup**, **imsconnutil**, **imscripter**, **imsexport**, **imsimport**, **imsrestore**, **mboxutil**, **mkbackupdir**, **msprobe**, **msuserpurge**, **readership**, **reconstruct**, **rehostuser**, **relinker**, **stored**.

Utilities in the `bin` directory are considered public interfaces unless otherwise documented, and utilities in the `lib` directory are considered private interfaces unless they are documented. Output from command line interfaces is considered unstable (subject to change at any time) unless the documentation explicitly states otherwise.

A subset of the Mozilla Network Security Services tools are included in the `lib` directory as a convenience. These include: **certutil**, **modutil**, **pk12util**, **cmsutil**, **ssltap**. The included versions have no functional changes from the Mozilla versions; refer to the Mozilla NSS project for documentation of these utilities.

Chapter 7 configtoxml_utility

7.1 Syntax

```
configtoxml [switches]
```

7.1.1 Restrictions

This is implemented as a Perl script, so a reasonably modern version of Perl must be installed on the system to run this.

7.2 Description

The configtoxml utility converts a legacy configuration to a Unified Configuration.

7.3 Switches

7.3.1 -32|-64

Installation is a 32 bit (-32) or 64 bit (-64) Messaging Server. Default is 64 bit.

7.3.2 --force, -f

Ignore safety checks: allow running as non-root and permit overwriting of any pre-existing Unified Configuration files.

Caution: Using this option may result in a non-functioning configuration. The `restricted.cnf` file must be owned by `root` or the user listed in that file.

7.3.3 --help, -h

Print usage information.

7.3.4 --instance *INSTANCE*, -i *INSTANCE*

Instance name to insert in the generated configuration files. The default is **ims**.

7.3.5 --location *DIR*, -l *DIR*

Read the legacy configuration files from the specified directory DIR. The default is the normal configuration directory.

7.3.6 --noactive, -n

Do not generate an active configuration and do not move the legacy configuration files to *config-root*/legacy-config/. The generated Unified Configuration files will have the names config_.xml, xpass_.xml, and restricted_.cnf and will be written to *config-root*. This may not be used in conjuction with the --output or --undo switches.

7.3.7 --output *CONFIG-FILE PASSWORD-FILE RESTRICTED-FILE*, -o *CONFIG-FILE PASSWORD-FILE RESTRICTED-FILE*

Direct the Unified Configuration file output to the designated files. By default, the files config.xml, xpass.xml, and resricted.cnf are written to the *config-root* directory. This may not be used in conjunction with the --noactive or --undo switches.

7.3.8 --role *ROLE*, -r *ROLE*

Role name to insert in the generated configuration files. The default is to use **ims**.

7.3.9 --yes, -y

Pre-answer any confirmation questions with a "yes" response so that this script can be run without user intervention.

7.3.10 --undo, -u

Remove any active Unified Configuration files and restore any legacy configuration files.

7.4 Usage Notes

Usage Notes: Stop the Messaging Server before running the **configtoxml** command. Alternatively, use the --noactive switch to prevent writing out an active configuration.

When generating an active Unified Configuration, the **configtoxml** command moves all the processed legacy configuration files to the *config-root*/legacy-config directory.

The --undo switch removes the Unified Configuration and restores the legacy configuration files.

7.5 Example

```
# imsimta version
Oracle Communications Messaging Server 7u5-28.12 64bit (built Nov 5 2012)
libimta.so 7u5-28.12 64bit (built 15:58:11, May 23 2012)
Using /opt/sun/comms/messaging/config/imta.cnf (not compiled)
Linux host1.example.com 2.6.39-100.5.1.el5uek #1 SMP Tue Mar 6 20:25:25 EST 2012 x86_64 x86_64 x86_64 GNU/Lin

# configtoxml
WARNING: This procedure will produce an active Unified Configuration which
        will override any existing legacy configuration.

Continue anyway [no]? yes
Creating the directory /opt/sun/comms/messaging/config/legacy-config/
Moving the processed legacy configuration files to /opt/sun/comms/messaging/config/legacy-config/

# bin/imsimta version
Oracle Communications Messaging Server 7u5-28.12 64bit (built May Nov 5 2012)
libimta.so 7u5-28.12 64bit (built 15:58:11, Nov 5 2012)
Using /opt/sun/comms/messaging/config/config.xml (not compiled)
Linux host1.example.com 2.6.39-100.5.1.el5uek #1 SMP Tue Mar 6 20:25:25 EST 2012 x86_64 x86_64 x86_64 GNU/Lin
```

Chapter 8 configure_utility

The configure utility generates an initial product configuration. This is an alias for the init-config utility; see the documentation of that command for details.

Chapter 9 inetuser utility

The inetuser utility is a very limited LDAP provisioning utility for Messaging Server.

9.1 Syntax

```
inetuser --command-file=file
inetuser --help
inetuser --version
inetuser create [switches]user
inetuser show [switches]user
inetuser checkpw [switches]user
inetuser show-domain [switches]domain
inetuser check-dssetup
```

9.1.1 Restrictions

This command uses LDAP configuration settings by default. However, commands that update LDAP generally require Directory Manager credentials and it is a best practice to limit the

access rights available to the administrative account specified by base.ugldapbinddn and by base.ugldapbindcred. As a result, it's typically necessary to specify the `--bind-dn=binddn` and `--bind-pwfile=file` switches to specify a Directory Manager account when updating LDAP directly.

9.2 Parameters

The `create`, `show`, and `checkpw` subcommands take a user identity as a parameter. The user identity is typically the value of the `uid` LDAP attribute (possibly modified by the ldap_uid option) and may include `@domain` to refer to an LDAP domain.

The `show-domain` subcommand takes a domain provisioned in LDAP as a parameter.

No parameters are present when a top-level switch is used or other subcommands are used.

9.3 Description

The inetuser utility is a very limited LDAP provisioning utility for Messaging Server that supports LDAP schema 1 and LDAP schema 2. This tool has been present in Messaging Server for some time and is used by the init-config utility to provision an initial administrative user, group, and associated default domain.

The `create` subcommand is used to create users and domains.

The `show` subcommand is used to show a user's LDAP entry.

The `checkpw` subcommand is used to check a user's LDAP password against the directory. The `inetuser` utility will return a status of `0` if the password is correct.

The `show-domain` subcommand shows a domain's LDAP entry.

The `check-dssetup` subcommand shows information from the `comms_dsseetup` utility that is present in the LDAP directory.

9.4 Examples

The following command creates a user with common name "John Smith" and user identity 'jsmith'. With this command, the email address defaults to 'jsmith@*defaultdomain*' (this assumes the directory manager password is stored in the file *pwfile* in the current directory):

```
# inetuser create -D "cn=Directory Manager" -j pwfile -p "cn=John Smith" jsmith
password:
```

The following command creates a new domain with a new administrative user:

```
# inetuser create -D "cn=Directory Manager" -j pwfile -a all -c newadmin@newdomain.example.com
password:
```

9.5 Switches

9.5.1 --command-file=file, -f file

This top-level switch reads and executes inetuser subcommands from the specified file instead of executing one subcommand from the command line.

9.5.2 --help, -?

This top-level switch displays command usage summary.

9.5.3 --version, -V

This top-level switch displays command version information.

9.5.4 --admin=type, -a type

This create subcommand switch specifies the type of admin user to create. Supported values are `all` (store administrator) and `access` (administrative account used by Messaging Server to authenticate). If not specified, the user account will not have administrative privilege.

9.5.5 --attrlist=attrs, -A attrs

This show subcommand switch specifies a comma-separated list of attributes to show from the user entry, instead of showing all known attributes.

9.5.6 --autocreate, -c

This create subcommand switch will cause the domain to be created when creating a user if it doesn't already exist. Note that the tool requires the first user in a domain to be a store administrator so it's generally necessary to include the `--admin=all` switch with this one.

9.5.7 --bind-dn=binddn, -D binddn

This subcommand switch specifies the bind DN to use for LDAP server authentication. If not specified, the value of the base.ugldapbinddn option is used instead. The credentials specified by that option typically do not have permission to write to the LDAP directory so this switch is usually necessary with the `create` subcommand (as is the `--bind-pwfile` switch).

9.5.8 --bind-pwfile=file, -j file

This subcommand switch specifies a file containing the bind password to use for LDAP server authentication. If not specified, the value of the base.ugldapbindcred option is used as the bind password instead.

9.5.9 --default-domain=domain, -d domain

This subcommand switch specifies the default domain to use if a domain is not explicitly specified. When this switch is not specified, the value of the base.defaultdomain option is used.

9.5.10 --dry-run, -n

This subcommand switch prevents the tool from modifying the LDAP directory. It may be useful to combine this with the `--ldif` switch.

9.5.11 --hostlist=host, -h host

This subcommand switch specifies one or more LDAP server host names to use when connecting to the LDAP server. If not provided, the value of the base.ugldaphost option is used. This may be needed with the `create` subcommand if that option specifies a slave LDAP server rather than a master LDAP server.

9.5.12 --ldapattrval=avl, -p avl

This create subcommand switch specifies an LDAP attribute value list of additional known attributes to include when creating a user. The syntax of the list is *attr1=value1,attr2=value2*. Special characters may be escaped with backslash (\). Alternatively, the value can be base64-encoded by specifying a $ symbol before the equals (=) symbol. The set of known attributes is limited, so if the attribute name is not known by the utility, an error will result.

9.5.13 --ldif=file, -l file

This create subcommand switch specifies a file that will record a copy of the LDIF generated internally by this tool that is used to modify the LDAP directory. Combing this with the `--dry-run` switch is useful to review the changes the tool would make to LDAP. This may also be helpful to customers developing their own provisioning tools.

9.5.14 --logfile=file, -L file

This subcommand switch requests that any diagnostics are appended to the specified file.

9.5.15 --myhost=host, -H host

This subcommand switch specifies the name of the host used to provision store-related attributes such as `mailHost`. If this is not provided, the value of the base.hostname option is used.

9.5.16 --novalidate

Normally the tool will prompt and abort if a mismatch or error is detected. This subcommand switch suppresses that behavior.

9.5.17 --orgdn=dn, -O dn

This create subcommand switch specifies the LDAP DN to use when provisioning a schema 1 organization group in LDAP when creating a domain. This switch is primarily for use by the init-config utility.

9.5.18 --postmaster=mailaddr, -M mailaddr

This create subcommand switch specifies the mail address of the user to include in the postmaster group when creating a domain with a postmaster group. This switch is primarily for use by the init-config utility.

9.5.19 --port=port, -P port

This subcommand switch specifies the LDAP server port to use. If not specified, the value of the base.ugldapport option is used.

9.5.20 --preserveCritical

Normally the tool will prompt and default to overwrite certain critical attributes when performing a create operation and the specified user and/or domain already exists. The subcommand switch prevents the tool from overwriting such attributes.

9.5.21 --pwfile=file, -J file

This create subcommand switch specifies a file containing the password to use when creating a user. If this is not provided, the tool will prompt for a password.

9.5.22 --quiet, -q

This subcommand switch suppresses some prompts and diagnostics.

9.5.23 --require-ssl, -Z

This subcommand switch require use of SSL when communicating with the LDAP server.

9.5.24 --verbose, -v

This subcommand switch requests additional diagnostics from the utility. May be used more than once to increase the amount of diagnostic information.

Chapter 10 init-config utility

The init-config utility initializes the system for use by Messaging Server and generates an initial product configuration.

10.1 Syntax

```
init-config [switches]
```

10.1.1 Restrictions

Must have superuser privileges in order to use this utility. This is implemented as a Perl script, so a reasonably modern version of Perl must be installed on the system to run this. It is more convenient to use this tool if an LDAP server has been installed previously and the `comms_dssetup` tool has been used to initialize the LDAP server.

10.2 Parameters

None.

10.3 Description

The `init-config` tool prepares a system for use by Messaging Server and generates an initial configuration for the product. It can be run in an interactive mode or in a silent mode

(when a state file is provided). By default, the initial configuration generated is designed for product evaluation purposes and enables the primary product services (MTA & Message Store) including a number of common channels and mappings. Alternatively, the tool can be used to generate a limited configuration appropriate as a starting point for a deployment by using the `--recipes=` (or `-r`) switch with a list of initial config recipes (this is new in Messaging Server 8.1). Note that in initial config recipe mode, statefile variables are limited to 1024 characters in length.

The following list summarizes the functions performed by init-config:

1. Creates the Unix user and group for Messaging Server, if needed.
2. If in evaluation or `ldapinit` mode, it creates LDAP server entries (or LDIF) for the default domain, administrative user and postmaster, along with access control lists.
3. If in evaluation or `ldapinit` mode, it creates Directory Server entries (or LDIF) for an administrative group and user for the host where configure is run; this administrative group and user have limited write access to the directory. If in `useldap` mode, this account must already exist and be provided by prompt or state file.
4. Creates DataRoot and ConfigRoot directories with correct permissions.
5. Creates subdirectories of the DataRoot and ConfigRoot directories with correct permissions.
6. Generates a random secret for authentication to local-only services, such as the job_controller and watcher.
7. Prompts you with the minimum number of questions about your environment to create an initial Messaging Server configuration with correct permissions.
8. Attempts to disable mail servers that come with the operating system, for example, Postfix and Sendmail.
9. Prior to MS 8.0.2: runs the imsimta chbuild command to compile character set conversion tables. Starting with MS 8.0.2 a compiled table is bundled in the install package and used unless the customer overrides.
10. Creates convenience symlinks from the install directory to the *DataRoot*, *ConfigRoot*, and *log* directories. Prior to MS 8.0.2, these symlinks were required for correct product functionality.

The following table describes the state file variables used by init-config. State file variables starting with an "ic" prefix are ignored if unrecognized; other state file variables will generate a warning if unrecognized.

Table 10.1 State File variables for initial configuration

Variable Name	Related Configuration	Description
Fqdn.TextField	base.hostname	Fully qualified local hostname. Mandatory.
msg.DataPath	*N/A*	Use a non-default *DataRoot* (not recommended).
iMS.UserId	user in *restricted.cnf*	Specifies the Unix user identity for server processes. Mandatory.
iMS.GroupId	*N/A*	Specifies the primary Unix group of the Unix user if user creation is needed.
UGDIR_URL	*multiple*	An `ldap` or `ldaps` URL for the LDAP server.

UGDIR_BINDDN	*N/A*	Specifies the LDAP administrator user (required for evaluation or ldapinit modes).
UGDIR_BINDPW	*N/A*	Specifies the LDAP administrator password (required for evaluation or ldapinit modes). This password is obfuscated using a ROT-13 variant.
Postmaster.TextField	alias	MTAs require a postmaster for error reports. This option is used directly as an alais value by the mta initial config recipe, or to initialize a Postmaster group by evaluation or ldapinit modes.
admin.password	base.proxyadminpass, etc.	Password for the store administrative user primarily used for proxy login between servers. This password is base64-encoded for obfuscation.
EmailDomain.TextField	base.defaultdomain	Default email domain.
OrgName.TextField	*N/A*	Default organization DN, only used by evaluation or ldapinit modes.
InternalIPlist	INTERNAL_IP mapping table	Specifies IP address information, in comma-delimited form, for systems permitted to relay mail without authentication. Note: when used in initial config recipe mode, all statefile variables have a length limit of 1024 characters. As a result, additional statefile variables `ic.iplist2`, `ic.iplist3`, ... can be used to provide additional values for this setting.
ic.iplist2, ic.iplist*n*	INTERNAL_IP mapping table	In initial config recipe mode, this specifies IP addresses for systems permitted to relay in addition to the ones in the `InternalIPlist`. Each of these values is limited to 1024 characters. These are read in order, starting with InternalIPlist, then ic.iplist2, ic.iplist3, ic.iplist4, ... stopping when no value is found in the statefile. The values are sorted before producing the INTERNAL_IP mapping table.
XMLCONFIG	*N/A*	Starting in Messaging Server 8.1, this option is ignored and Unified Configuration is always used. For previous versions, when set to 1 this creates a Unified Configuration and when set to 0, creates a legacy configuration. The --xml and --noxml command options override what is specified in the statefile.
cassandra	store.dbtype, isc.enable	When set to 1, use a Cassandra message store rather than a classic message store. New in Messaging Server 8.0.2.
dssetup.ugsuffix	base.ugldapbasedn	Specifies the user/group suffix. Unless `--noldap` is specified, the default comes from LDAP `cn=CommsServers,o=comms-config`.
dssetup.dcsuffix	base.dcroot	Specifies the domain suffix. Unless `--noldap` is specified, the default comes from LDAP `cn=CommsServers,o=comms-config`.

dssetup.schematype	base.ldap_schemalevel	Specifies the schema type. Unless `--noldap` is specified, the default comes from LDAP `cn=CommsServers,o=comms-config`.
admin.user	store.admins, base.proxyadmin	Administrative user for proxy authentication and store administration. Defaults to "admin". New in Messaging Server 8.0.2.3.
ugldap.hostlist	base.ugldaphost	LDAP server (a space-delimited failover server is permitted). When present, this overrides UGDIR_URL. New in Messaging Server 8.0.2.3.
ugldap.port	base.ugldapport	LDAP server default port. When present, this overrides UGDIR_URL. New in Messaging Server 8.0.2.3.
ugldap.usessl	base.ugldapusessl	When to require SSL for LDAP. When present, this overrides UGDIR_URL. New in Messaging Server 8.0.2.3.
ugldap.binddn	base.ugldapbinddn	LDAP administrative user for server operations. This user should be able to read all user entries but should have limited write access to the directory. Such a user is created by evaluation or ldapinit modes. New in Messaging Server 8.0.2.3.
ugldap.bindcred	base.ugldapbindcred	Password for server operations. This password is base64-encoded for obfuscation. New in Messaging Server 8.0.2.3.
ic_lmtp_ipmask_list	LMTP_ACCESS mapping	Used only by `lmtpserver` initial config recipe. This specifies IP address information, in comma-delimited form, for systems permitted to deliver mail to the LMTP server without authentication. The LMTP_ACCESS mapping table works the same way as the INTERNAL_IP mapping table. New in Messaging Server 8.1.
icmmpimap_enable	mmp.enable, *etc.*	Used only by `proxy` initial config recipe. When set to 1, this enables the MMP and settings for an MMP IMAP proxy. New in Messaging Server 8.1.
icmmppop_enable	mmp.enable, *etc.*	Used only by `proxy` initial config recipe. When set to 1, this enables the MMP and settings for an MMP POP proxy. New in Messaging Server 8.1.
icmshttpd_enable	http.enable, *etc.*	Used only by `proxy` initial config recipe. When set to 1, this enables the Convergence mshttpd proxy and settings for submission proxy via mshttpd. New in Messaging Server 8.1.
icsubmithost	alarm.noticehost, http.smtphost	Required by the `proxy` initial config recipe. This specifies the hostname of a submission server used for mail from the alarm subsystem and Convergence mshttpd (if enabled). New in Messaging Server 8.1.
icsubmitport	http.smtpport	Used only by `proxy` initial config recipe. This specifies the port of a submission server used for mail from Convergence mshttpd (if enabled).

		This defaults to 587; however use of 465 for SSL-encrypted submission should be considered. New in Messaging Server 8.1.

10.4 Switches

10.4.1 --cassandra

Configure use of the Cassandra Message Store rather than classic Message Store.

10.4.2 --dataroot=*dataroot*

Specifies an alternate location for the data root directory where read/write product configuration and operational data will be stored. The default location for the data root directory is `/var/`*`server-root`* where *`server-root`* is the installation directory. Use of a non-default *`dataroot`* is not recommended.

10.4.3 --debug

Requests additional debugging information while generating initial configuration; this primarily impacts LDAP operations.

10.4.4 --help, -?

Display command usage summary.

10.4.5 --ignoreSendmail

Ignore the presence of Sendmail or Postfix on the system. By default, the initial configuration tool attempts to avoid port conflicts by disabling Sendmail or Postfix if those tools are enabled.

10.4.6 --ldapport=*ldapPort*

Use a non-default LDAP port to communicate with the LDAP server.

10.4.7 --ldif

Treat the LDAP directory as read-only and generate an LDIF file in a *DataRoot*/install/configure.ldif file for any desired changes to the directory. The administrator must apply the LDIF file to the directory after initial configuration but before starting the Messaging Server product. This is helpful if the person doing the Messaging Server installation does not have directory administrative rights.

10.4.8 --list-recipes

Displays the available initial configuration recipes and exits.

10.4.9 --noldap

Create a full evaluation installation without an LDAP server present. This is used in combination with the `--state=`*statefile* and `--ldif` switches to configure Messaging Server

when the LDAP server is not available at the time initial configuration is generated. Normally the answers provided to `comms_dssetup` questions are read from the LDAP server by this tool; but when this switch is used, those values should be provided in the state file. Note that it's possible to both configure and use a routing-only MTA without LDAP; use of the `--recipes` switch (new in Messaging Server 8.1) is the recommended way of doing that.

10.4.10 --novalidate

Skip most validation of user input and state file variables. This may result in a non-functional configuration. This is provided primarily as a mechanism to work around possible bugs in the init-config tool's validation logic.

10.4.11 --noxml

Generate an initial legacy configuration rather than an initial Unified Configuration (XML based). This option is not supported starting with Messaging Server 8.0.2, and no longer works starting with Messaging Server 8.1.

10.4.12 --preserveCritical

When initializing the LDAP server for use by Messaging Server, this prevents certain critical attributes from being overwritten with different values, even if new values are provided. See the installation guide for a more in-depth discussion of critical LDAP attributes.

10.4.13 --quiet, -q

Suppress most non-error console output (a logfile is still created containing necessary information to diagnose issues).

10.4.14 --recipes=*recipe-list*, -r *recipe-list*

Generate a minimal configuration for a particular deployment function as determined by a list of initial configuration recipes. LDAP will not be involved unless `ldapinit` or `useldap` is included in the recipe list.

10.4.15 --saveState=*statefile*

Specifies the location to save a state file. The default location is *DataRoot*`/setup/saveState`.

10.4.16 --ssl

Require SSL when communicating with the LDAP server. Any necessary SSL certificates and configuration must be manually set up prior to using this option.

10.4.17 --state=*statefile*

Use a silent installation file and do not prompt the administrator for information.

10.4.18 --version, -V

Displays the product version and exits.

10.4.19 --xml

Force use of Unified Configuration, even if the statefile specifies use of legacy configuration. Starting with Messaging Server 8.1, this is the default behavior so this switch has no effect.

10.5 Examples

To configure an evaluation installation of Messaging Server when an LDAP server is present (interactive).

```
# init-config
```

To initialize LDAP server and configure the first classic Message Store in a multi-system deployment (interactive).

```
# init-config -r ldapinit,store,lmtpserver
```

To configure an additional classic Message Store in a multi-system deployment (interactive).

```
# init-config -r useldap,store,lmtpserver
```

To add an MTA with submission service to a Messaging Server multi-system deployment (interactive).

```
# init-config -r useldap,mta,submit
```

To add an MMP and/or mshttpd service to a Messaging Server multi-system deployment (interactive).

```
# init-config -r useldap,proxy
```

To configurate a routing-only MTA without LDAP (interactive).

```
# init-config -r mta
```

To configurate using a state file (non-interactive).

```
# init-config --state=/path/to/statefile
```

To list available initial configuration recipes.

```
# init-config --list-recipes
Available Initial Configuration Recipes:
 ldapinit        Initialize LDAP directory for use by Messaging Server
 lmtpserver      LMTP server (used by initial configuration)
 mta             Configure an MTA (used by initial configuration)
 none            Minimal configuration with external services disabled
```

```
proxy           Proxy configuration (MMP, Convergence mshttpd)
store           Configure a message store (used by initial configuration)
submit          Add submission service to an MTA (initial configuration)
useldap         Enable support for LDAP users (doesn't initialize LDAP)
```

Chapter 11 msconfig utility

11.1 Syntax

```
msconfig [switches] [command] [\command]...
```

11.2 Parameters

The *msconfig* utility may be used interactively by invoking it without any commands:

```
msconfig
```

or noninteractively by specifying one or more commands as an argument, e.g.,

```
msconfig SET <option> <value>
```

11.2.1 Switches

The *msconfig* utility accepts a number of switches on the invocation line.

11.2.1.1 -directory=*config-directory*

Specifies an alternate location for Messaging Server configuration files. msconfig will read and write config.xml and xpass.xml from this alternate location. The directory where the files are located must be given as an argument.

11.2.1.2 -help

Prints basic information about using msconfig and enters the msconfig help system. msconfig exits after help system access is terminated.

11.2.1.3 -input=*input-file*

If specified, msconfig will read commands from a file instead of from the terminal. The input file name must be given as an argument. If -input is specified no msconfig commands can be given on the invocation line.

11.2.1.4 -multiple

If specified, the -multiple switch allows multipe commands to be specified on the command line separated by backslashes "\".

11.2.1.5 -novalidate

Read the configuration but do not validate it. Warning: This should only be used in extreme situations where a broken configuration needs to be analyzed. Such a configuration should NEVER be used in production.

11.2.1.6 -output=*output-file*

If specified, msconfig will direct its output to the specified file.

11.2.1.7 -page

Controls whether or not msconfig help system output stops and prompts after each page. -page is the default; use -nopage to disable output paging.

11.2.1.8 -prompt

Controls whether or not the help system prompts for additional topics after a topic has been output. -prompt is the default; use -noprompt to turn off help system prompting.

11.2.1.9 -readonly

Open configuration in readonly mode and without locking. This is useful when performing display operations that should not fail when someone is editing the configuration.

11.2.1.10 -remark=*remark-string*

Specifies a remark to attach to configuration as it is written. The remark string must be given as an argument.

The primary use of -remark is to specify a remark when a command is given on the invocation line, e.g.,

```
msconfig -remark "Enable enqueue debugging" set mm_debug 5
```

11.2.1.11 -require=*conditions*

The -require switch specifies a list of conditions that must be met for "successful" operation. msconfig will exit with a nonzero status if these conditions are not met. The available conditions are:

- write - One or more configuration writes must have been performed.

11.2.2 Commands

List of *msconfig* utility commands:

11.2.2.1 DEFAULT

Reset the location where options are set to default location.

11.2.2.2 DEPLOYMAP operation

Manipulate deployment maps. The supported operations are ADD, DELETE, DUMP, LIST, CREATE, RENAME, SET, READ, and WRITE.

11.2.2.3 DIRECTORY [filter]

Displays the recipes whose names match the specified <filter>.

11.2.2.4 DIFFERENCES [m [n]]

Compare configurations.

11.2.2.5 EDIT object

Places the specified object in a file and invokes the editor to enable editing.

11.2.2.6 EXECUTE string

Execute the specified string as if it were a one-line recipe. The final value computed by the recipe is printed at the end of execution.

11.2.2.7 EXIT

Exit msconfig utility with a prompt to write if configuration was modified.

11.2.2.8 HELP [topic[subtopic...]]

Display help.

11.2.2.9 HISTORY

Display previous saved configurations.

11.2.2.10 INSTANCE

Store options in instance.

11.2.2.11 IMPORT config

Read configuration from alternate file(s).

11.2.2.12 LOG

Display previous saved configurations. Synonym for `HISTORY`

11.2.2.13 QUIT

Exit *msconfig* utility discarding changes.

11.2.2.14 REVERT [n]

Discard modifications and reload configuration.

11.2.2.15 ROLE

Store options in role.

11.2.2.16 RUN recipe [arg1 [arg2....]]

Run the specified recipe file with the specified arguments. If no file path is given as part of "recipe" the command will look for the file in <configroot>/recipes, and if not found there, it will look in <serverroot>/lib/recipes.

The arguments specified in the run command can be accessed in the recipe with the argc and argv functions.

11.2.2.17 SET option [value1 [value2....]]

Set option to the specified value(s).

11.2.2.18 SHOW option [namefilter [valuefilter]]

Show value of option.

11.2.2.19 UNSET option

Delete option setting.

11.2.2.20 WRITE

Write out configuration changes.

11.3 Description

The *msconfig* utility is used to examine and modify Messaging Server configuration. See Configuration syntax for more information on the Messaging Server configuration.

The utility performs type checking on configuration settings it makes. See Option value syntax for further details.

11.4 Prompts

When run interactively, msconfig's default prompt is:

```
msconfig>
```

When modifications have been made to the configuration the prompt will change to:

```
msconfig#
```

The DEFAULT, INSTANCE, and ROLE commands also affect the prompt:

- Default mode:

```
msconfig>
```

- Instance mode:

```
msconfig.instance>
```

- Role mode:

```
msconfig.role>
```

11.5 Return status

msconfig returns a status of 0 if the last command executed successfully, 1 if the last command generated an error, and 2 if the last command could not be performed because the configuration was locked.

msconfig will also return a status of 1 if the conditions specified as arguments to the -require switch are not met.

11.6 Some Useful Commands

11.6.1 Help Command

The *msconfig* utility is a comprehensive help utility and its help command can be used to get help not only on the utility and its commands but also on various topics pertaining to the Messaging Server.

```
msconfig help
```

This lists all the Topics on which help is available. Choose a specific Topic which gives some information and then one can enter additional sub-topics for more in depth information.

Help on specific msconfig commands can be accessed in interactive mode by entering:

```
help commands            <- List of available commands
help commands <command>  <- Information about command <command>
```

Help on the options msconfig can manipulate can be accessed by entering:

```
help option <option>     <- Information about option <option>
```

Note that options in the help system should be specified without any associated scope.

Use the `-search` switch along with list of strings to display ALL articles that contain the specified strings.

```
help -search string1 [string2...]
```

Use the `-keyword` switch along with list of keywords to display ALL articles marked with any of the specified keywords.

To disable the prompts when additional information is available, use the `-noprompt` switch.

Help output by default is paged. Use `<space>` to display additional pages. `<return>` displays an additional line. `a` displays remaining information without paging and `q` stops the output. Use `-nopage` switch to disable paging.

11.6.2 Show Command

Use the *msconfig show* command to display current settings.

For example, to show all currently enabled options:

```
msconfig show *enable
```

11.6.3 Set Command

Use the *msconfig set option [value1 [value2]]* command to set option values.

Use the *-prompt* switch for entering passwords since it causes the utility to prompt for the value without echoing it.

Values must be quoted if they contain spaces. In non-interactive mode, each special character must be prefixed with the escape character "\". For example, to set the value of the *auth.searchfilter* option to *(|(uid=%U)(mail=%o)):*

```
msconfig set auth.searchfilter \"\(\|\(uid\=\%U\)\(mail\=\%o\)\)\"
```

11.6.4 Edit Command

Use the *msconfig editobject* command to edit the specified object in a file in an appropriate textual form. The *msconfig edit* command invokes the editor specified by the EDITOR shell variable. You can then make the change, save it, exit, and your configuration is updated.

For example, suppose you want to set the master_debug option on the tcp_local channel:

```
msconfig set channel:tcp_local.master_debug
```

Even if you did not know the preceding command, you could still use the msconfig command to perform this operation by invoking it in edit mode:

```
msconfig edit channels
```

You can also edit a single channel block by itself by running the following command:

```
msconfig edit channel tcp_local
```

Channel-specific option files are mapped into the Unified Configuration as sub-elements of a general "options" channel option. These options appear at the bottom of each channel block when you run edit channels. The following example illustrates this point:

```
tcp_local identnonenumeric inner loopcheck maysaslserver maytlsserver mx \
 pool SMTP_POOL remotehost saslswitchchannel tcp_auth smtp sourcespamfilter1 \
 switchchannel
tcp_local-daemon
==
trace_level=2
```

The *msconfig* command provides the same editing capability for MTA rewrite rules *(edit rewrites)*, mappings *(edit mappings)*, MTA conversion channel control entries *(edit conversions)*, Sieve filters *(edit filter)*, options *(edit option)* and MTA aliases *(edit aliases)*

All objects placed in the file for editing are deleted prior to reloading the file's contents. Use `-noreplace` to treat the resulting file contents as configuration additions.

All configuration changes are normalized and validated by default. Use `-novalidate` to disable validation.

11.6.5 List and Compare Configurations Commands

The repository of previous configurations, known as the graveyard, is stored in the *ConfigRoot/old-configs/* directory. The move from current configuration to the graveyard is performed when a new configuration is written to disk. The graveyard maintains the most recent 100 configurations. With the graveyard, you can restore an old configuration by reverting to a previous configuration. Furthermore, you can compare differences between any two configurations, for example, between the active configuration and a previous configuration, or two old configurations.

```
msconfig history         <- List of configurations in the graveyard

msconfig differences     <- Compare configurations
```

Chapter 12 refresh utility

The refresh utility refreshes the configuration of running Messaging Server components.

12.1 Syntax

```
refresh [components ...]
```

12.1.1 Restrictions

Must have superuser privileges or use the Solaris RBAC feature in order to use this utility.

12.2 Parameters

12.2.1 *component*

One or more *component* parameters may be supplied to refresh specific running components. See start-msg utility for a list of the valid values for *component*.

12.3 Description

This triggers a configuration refresh of one or more running Messaging Server processes. The actual configuration refresh by each process happens asynchronously.

Note: The MTA's design makes it easy to restart a dispatcher server process without service impact. In general, therefore, MTA options are not refreshable (with mappings being a notable exception). For example, `imsimta restart smtp` causes the dispatcher to start new SMTP server processes for future incoming connections, reading a new configuration. This happens without service interruption. The Message Store, ENS, and MMP design makes restarting a process a service outage, so it is important for refresh logic to be built for most options in these servers. Most of these options are therefore refreshable.

Having msconfig print a restart required warning would generate a lot of pointless warnings for MTA options which is undesirable behavior for Unified Configuration. Because of this, the msconfig utility does not issue a warning when an option that requires a restart is modified. The legacy configutil tool does issue such a warning.

12.4 Example

The following command refreshes the IMAP server:

```
# refresh imap
```

Chapter 13 start-msg utility

The start-msg utility starts enabled Messaging Server components.

13.1 Syntax

```
start-msg [-m] [-l] [-L] [components ...]
```

13.1.1 Restrictions

Must have superuser privileges or use the Solaris RBAC feature in order to use this utility. Only one start-msg or stop-msg process may run at a time on the system.

13.2 Parameters

13.2.1 ha

The `ha` parameter starts the server in high-availability mode and is normally only used by a cluster agent control script.

13.2.2 *component*

One or more *component* parameters may be supplied to start a specific enabled component. Valid values for *component* include:

- `watcher` - watches for process failure and triggers restart of appropriate components.
- `ens` - event notification server (enpd); required for IMAP IDLE.
- `metermaid` - legacy RAM-based storage facility similar to memcache or Redis; see MeterMaid documentation.
- `store` - stored message store maintenance process.
- `purge` - impurge message store daemon.

- `imap` - IMAP server.
- `pop` - POP3 server.
- `isc` - Indexed search converter service (required by Elasticsearch feature).
- `cert` - Certificate validation daemon used by Convergence S/MIME feature.
- `http` - Convergence mshttpd proxy.
- `sched` - Scheduler daemon for period tasks.
- `deploymap` - feature in development.
- `dispatcher` - Multi-process service controller used by the MTA and LMTP server (starts other processes).
- `job_controller` - MTA's outbound delivery controller (starts other processes).
- `snmp` - SNMP monitoring sub-agent.
- `sms` - SMS gateway service.
- `mmp` - Messaging Multiplexor (POP and IMAP proxy).
- `rollovermanager` - Time-based log-file rollover service.
- `mta` - an alias for the dispatcher and job_controller.

13.3 Description

This starts one or more enabled Messaging Server components. Which components are started can be controlled by using the appropriate enable option, e.g., `store.enable` to enable the store, or the appropriate enablesslport option the appropriate component's scope., e.g., `imap.enablesslport` for IMAP's SSL port. If a specified component is already running, the component will continue running unchanged. If a specified component is not enabled, an error will be displayed for that component.

13.4 Switches

13.4.1 `-l`

List active servers and exit.

13.4.2 `-L`

List enabled servers and exit.

13.4.3 `-m`

Start the message stored process as the preferred replication master when using classic Message Store with automatic failover and DB replication enabled. This should be used once when setting up a replication affinity group.

13.5 Examples

The following command starts all enabled Messaging Server components:

```
# start-msg
```

The following command starts the **imap** server process(es):

```
# start-msg imap
```

Chapter 14 stop-msg utility

The stop-msg utility stops running Messaging Server components.

14.1 Syntax

```
stop-msg [-f] [components ...]
```

14.1.1 Restrictions

Must have superuser privileges or use the Solaris RBAC feature in order to use this utility. Only one start-msg or stop-msg process may run at a time on the system.

14.2 Parameters

14.2.1 ha

The ha parameter stops the server in high-availability mode and is normally only used by a cluster agent control script.

14.2.2 *component*

One or more *component* parameters may be supplied to stop a specific running component. See start-msg utility for a list of the valid values for *component*.

14.3 Description

This stops one or more running Messaging Server components. Stopping components generally results in a service outage for that component. If the goal is to activate changes in refreshable product options, see the refresh utility and the imsimta reload utility.

14.4 Switches

14.4.1 -f

Force stop using SIGKILL (may result in metadata corruption in the classic Message Store).

14.5 Examples

The following command stops all running Messaging Server components:

```
# stop-msg
```

The following command stops the **impurge** server process:

```
# start-msg purge
```

Part III Infrastructure

Core infrastructure of Message Server includes the Scheduler and Watcher, with the Watcher's associated msprobe facility and Alarm facility, and the Deployment Map facility.

Fundamentals of configuration affecting Messaging Server as a whole, or at least many components, tend to be set as Base options, or for authentication-specific settings, as Auth options. (A few special, security-related options establishing the main Messaging Server user id, *etc.*, are not set as `config.xml` options, but instead are stored in the `restricted.cnf` file.)

Chapter 15 `restricted.cnf` file

As of MS 7.0.5, certain special, security-related "options" -- defining fundamental Messaging Server Unix accounts -- are stored in the `restricted.cnf` file (for both Unified Configuration and legacy configuration). (Note that these few "options" are not settable using `msconfig`; instead edit the `restricted.cnf` file.) These "options" include:

1. `user`, replacing as of MS 7.0.5 the former `imta_user` MTA Tailor option (specifying the UNIX user id of the MTA user) and the former `serveruid` Message Store option (specifying the UNIX user id of the Message Store user).

2. `group`, replacing as of MS 7.0.5 the former `imta_world_group` MTA Tailor option (specifying the UNIX group id of the MTA user). Note that the `servergid` Message Store option (specifying the UNIX group id of the Message Store user) was deleted in MS 7.0.4; the Message Store now always uses the primary group of the user specified via the `serveruid` Message Store option.

3. `pipeuser`, as of MS 8.0 preferred to the deprecated use of the `user` channel option on the pipe channel (specifying the username under which the channel runs).

4. `allow_pipe_setuid`, new in MS 8.0; when set to `0` (the default), the pipe channel is only allowed to run as the specified `pipeuser`; if set to `1`, then the pipe channel is allowed to run as other users.

5. `noprivuser`, replacing as of MS 7.0.5 the former `imta_user_username` MTA Tailor option (specifying the UNIX user id for certain untrusted operations such as MTA mapping table sequence number file access, or untrusted pipe channel operations).

Chapter 16 Base options

Options set at base level tend to be those that either affect overall Messaging Server operation, or else that set a default which may then be overridden for particular services.

Underneath base are also the groups of options domainmap (which only has the option debug), as well as autorestart options, certmap options.

See also the umask Message Store option, which affects more than only Message Store files.

16.1 accounturl Option

The accounturl base option specifies the location of the server administration resource for end users (obsolete).

16.2 authcachesize Option

The authcachesize base option specifies the maximum number of concurrent users/entries in the user/authentication cache.

The Messaging Server can cache the results of LDAP user lookups and successful authentication (*e.g.*, when logging into IMAP, POP or SMTP). The authcachesize option defines the number of authentication user cache entries. A higher setting for authcachesize improves performance while using more memory. A lower setting reduces performance and reduces the amount of memory used.

16.3 authcachettl Option Under base

The authcachettl base option specifies the length of time in seconds an authentication cache entry will remain valid. Set to 0 to disable authentication caching.

Note that setting ldapcachettl smaller than authcachettl causes the entire user entry to expire, thereby also expiring the user authentication information in the user entry.

16.4 bgmax Option

The bgmax option (available under base, imap, pop, mmp, imapproxy, and popproxy) specifies the maximum number of IP addresses associated with authentication failures to keep track of simultaneously. See bgpenalty for more information.

16.5 bgpenalty Option

When an authentication failure occurs from a particular client IP address, subsequent authentication attempts from that IP address are treated as "BadGuys" and are delayed. If an authentication failure is followed by a successful authentication, the successful authentication is delayed, but the IP address ceases to be treated as a "BadGuy" for subsequent attempts.

The bgpenalty option (available under base, imap, pop, mmp, imapproxy, and popproxy) specifies the length of time in seconds added to the authentication delay after each failed authentication.

16.6 bgmaxbadness Option

The bgmaxbadness option (available under base, imap, pop, mmp, imapproxy, and popproxy) specifies the maximum length of time in seconds for the authentication delay which occurs after a series of failed authentication attempts. See bgpenalty for more information.

16.7 bgdecay Option

The bgdecay option (available under base, imap, pop, mmp, imapproxy, and popproxy) represents the time in seconds it takes for a BadGuy's penalty to be forgiven. See bgpenalty for more information.

16.8 bglinear Option

The bglinear option (available under base, imap, pop, mmp, imapproxy, and popproxy) defines whether a BadGuy's penalty decays linearly over time (1), or is a step function on expiration (0). See bgpenalty for more information.

16.9 bgexcluded Option

The bgexcluded option (available under base, imap, pop, mmp, imapproxy, and popproxy) represents a list of excluded IP/mask pairs, or the name of a file to read for these pairs. These client addresses will not be penalized for authentication failure (there is no default value).

16.10 dblockcount Option

The dblockcount base option sets the maximum number of BDB locks. The minimum allowed value is 5000; the maximum is 500000.

16.11 dbtxnsync Option

The dbtxnsync base option sets the database transaction synchronization level. A value of 0 or 1 selects none while a value of 2 requests that all writes be synchronously flushed to the log on every transaction commit.

16.12 dcroot Option

The dcroot base option specifies the root of the DC tree in Directory Server. Normally initial configuration sets this option to an appropriate value.

The MTA has a "twin" option, ldap_domain_root, which may be set to specify an MTA-specific override for this option.

16.13 debugkeys Option Under base

The debugkeys base option specifies a space-separated list of keywords used to enable various optional debugging facilities; see Keywords That May Be Included in debugkeys Option Value.

Note that the SMTP server's AUTH_DEBUG TCP/IP-channel-specific option can override debugkeys for SMTP server authentication purposes.

For Message Store and other non-MTA processes, setting a relevant debugkey will enable NOTICE-level logging in the logfile for that process. The MTA has a different logging model and requires two additional settings to see debugging associated with a debugkey. First, MTA debug log files must be enabled (via master_debug, slave_debug, or the equivalent finer-grained mechanism). Second, it's necessary to set mta.mm_debug to a value of at least 3 for the DKIM-related debugkeys or to set mta.os_debug to 1 for the LDAP and authentication-related debugkeys.

16.14 defaultdomain Option Under base

The defaultdomain base option specifies the Messaging Server default domain. This is used to determine whether a domain is the default domain or a hosted domain.

Normally the defaultdomain base option is set to an appropriate value during initial configuration.

The MTA has a "twin" option, ldap_default_domain, that can override the defaultdomain base option for MTA purposes. See the description of ldap_default_domain for details on how the MTA uses the defaultdomain value (if ldap_default_domain is not set).

16.15 dnsresolveclient Option

The dnsresolveclient base option forces servers -- the IMAP server, POP server, and MSHTTP server -- to perform a DNS reverse lookup on client connections to attempt to determine a corresponding host name. Note that if TCP wrappers are enabled -- see the tcpaccess server option -- then such DNS reverse lookups will be performed regardless of the setting of dnsresolveclient.

For the MTA's SMTP server and DNS reverse lookups, see the ident* channel options.

16.16 enablelastaccess Option

The enablelastaccess base option enables last access time tracking. Access time data is used by imsconnutil and mboxutil -o -t.

16.17 filterurl Option

The filterurl base option specifies the URL for incoming mail (server side) filter (obsolete).

16.18 folderurl Option

The folderurl base option specifies the URL for personal folder management (obsolete).

16.19 hostname Option Under base

The hostname base option specifies the fully qualified DNS hostname of this mail server. Normally this option is set to an appropriate value during initial configuration.

The MTA has a "twin" option, ldap_local_host, that may be set to override this base option for MTA-specific purposes.

16.20 installedlanguages Option

The installedlanguages base option takes a comma separated list of language codes: alphabetic characters only, comma separated list (e.g. "en, fr"). This is identical to RFC 2068's Accept-Language: field definition, but with no q-value.

16.21 ipv6in Option

When set to a value of 1, the ipv6in option instructs Messaging Server to accept inbound IPv6 connections for all services provided that the host has at least one network interface configured for IPv6. Services specifically configured to listen on only IPv4 interfaces cannot also accept inbound IPv6 connections. When set to a value of 0, inbound IPv6 connections are not allowed.

Inbound IPv4 connections will always be permitted.

16.22 ipv6out Option

When set to a value of 1, the ipv6out option instructs Messaging Server to attempt outbound IPv6 connections for all services provided that the host has at least one network interface configured for IPv6. Services specifically configured to bind their source IP address only to IPv4 interfaces cannot attempt IPv6 outbound connections. For example, an SMTP client bound to a specific IPv4 interface cannot then establish an outbound IPv6 connection. When set to a value of 0, outbound IPv6 connections are not allowed.

When set to a value of 1, outbound services will attempt DNS lookups of both A and AAAA records. Connection attempts will then be made in the order dictated by the ipv6sortorder option. Note the DNS lookups will always request A records. This option only controls whether or not AAAA records are also requested.

16.23 ipv6usegethostbyname Option

By setting the ipv6usegethostbyname option to the value "1", Messaging Server will use gethostbyname() for all host name to IP address lookups. This has the immediate effect of forcing the use of IPv4 for all outbound connections and host name to IP address lookups. Usage of this option is restricted.

16.24 ipv6sortorder Option

The ipv6sortorder option controls the order in which IPv4 (A) and IPv6 (AAAA) DNS address records are used when attempting connections to other named systems.

Table 16.1 ipv6sortorder Option Values

Value	Behavior
default	Process A and AAAA records in the order returned by the operating system.
a	Process only A records; ignore AAAA records.
aaaa	Process only AAAA records; ignore A records.
a-aaaa	Process A records, then AAAA records.
aaaa-a	Process AAAA records, then A records

16.25 LDAP bind and connect options: ldap_schemalevel (1 or 2)

The ldap_schemalevel base option specifies the schema level in use. This option is also available at MTA level. Supported values are 1 or 2. If this option is not set, schema level 1 is assumed to be in use.

16.26 LDAP lookup cache MTA options: ldap_domain_timeout (integer)

The ldap_domain_timeout option (available at both base and MTA levels) controls the retention time (in seconds) for entries in the domain map cache. The default is -900; as the value used is the absolute value of the ldap_domain_timeout setting, this corresponds to 15 minutes. If setting ldap_domain_timeout explicitly, set it to a positive value so that the MTA can detect that it has indeed been intentionally set.

16.27 ldap_domain_known_attributes Option

The ldap_domain_known_attributes MTA (and base) option controls whether the MTA's domain lookup LDAP queries request all domain attributes, *vs.* building and requesting a list of "known" domain attributes. The default of 0 means to request all domain attributes; setting this option to 1 causes the MTA to request its hard-coded list of "known" domain attributes.

It has been claimed that the ldap_domain_known_attributes setting can have a performance impact in some LDAP server environments.

The "known" attribute list consists of all attributes specified in the various ldap_domain_attr_* and similar MTA options, as well as any attributes specified in any LDAP domain map attribute substitutions. This should cover all the cases where the MTA requests domain attributes via its internal domain lookup facilities. However, in the unlikely event that other calls are made to the domain map facility, a site that has added additional

domain attributes may be forced to use the default setting of 0 so that LDAP domain queries will return those additional, custom LDAP attribute values.

16.28 Direct LDAP attribute name MTA options: ldap_domain_attr_basedn (LDAP attribute name)

The ldap_domain_attr_basedn MTA (and base) option names the domain LDAP attribute, by default inetDomainBaseDn, used to store the base DN for the domain's users and groups.

The presence in a domain entry of the attribute named by ldap_domain_attr_basedn is not always obligatory with Schema 2, as with Schema 2 in the domain attribute's absence user and group entries will be assumed to reside directly under the domain entry.

Note that the mapping table domain map attribute substitution ${domain,_base_dn_{ returns either the value of the LDAP attribute named by the ldap_domain_attr_basedn MTA option (so normally the value of the inetDomainBaseDN LDAP attribute), or if no such LDAP attribute is set as can be the case in Schema 2 mode, returns a constructed DN corresponding to the DN for the domain entry.

16.29 Direct LDAP attribute name MTA options: ldap_domain_attr_alias (LDAP attribute name)

The ldap_domain_attr_alias MTA (and base) option specifies the name of an LDAP attribute (by default aliasedObjectName) used to identify domain alias entries in the directory. The attribute is present only on a domain alias entry, not on the canonical domain entry; it contains the DN of the entry for which it is an alias. It is used only in Schema 1 or in Schema 2 compatibility mode (with a DC Tree), not in Schema 2 native mode (no DC Tree).

16.30 Direct LDAP attribute name MTA options: ldap_domain_attr_uid_separator (LDAP attribute name)

The ldap_domain_attr_uid_separator MTA (and base) option names the domain LDAP attribute, by default domainUidSeparator, used to store what the separator character is between UIDs and domains for addresses in this domain. This option is used both by the MTA, and by the authentication code; the authentication code looks first for the option to be set at base level, but if not set there, the authentication code will use the MTA level option setting.

16.31 Direct LDAP attribute name MTA options: ldap_domain_attr_status (LDAP attribute name)

The ldap_domain_attr_status MTA (and base) option names the domain LDAP attribute, by default inetDomainStatus, whose value specifies the current status of the domain. (The analogous user level attribute is inetUserStatus or whatever user LDAP attribute is named by the ldap_user_status MTA option; an analogous group attribute can be defined via the ldap_group_status MTA option. Compare also with the ldap_domain_attr_mail_status MTA option naming the domain LDAP attribute specifying the current mail status of the domain.) Valid values for the attribute named by the ldap_domain_attr_status option are active, inactive, or deleted. If no such attribute is present, or is present but with no value, a value of active is assumed.

16.32 Direct LDAP attribute name MTA options: ldap_domain_attr_mail_status (LDAP attribute name)

The ldap_domain_attr_mail_status MTA (and base) option names the domain LDAP attribute, by default mailDomainStatus, whose value specifies the current mail status of the domain. (The analogous user level attribute is mailUserStatus or whatever user LDAP attribute is named by the ldap_user_mail_status MTA option; the analogous group attribute is inetMailGroupStatus or whatever group LDAP attribute is named by the ldap_group_mail_status MTA option. Compare also with the ldap_domain_attr_status MTA option naming the domain LDAP attribute specifying the current general status of the domain.) Valid values for the attribute named by the ldap_domain_attr_mail_status option are: active, inactive, deleted, hold, disabled, overquota, and (new in MS 6.0) unused and removed and (new in 8.0) nonlocal; other values are interpreted as inactive. Note that the imquotacheck utility is what updates mailDomainStatus to set it to overquota.

(Note that the acceptalladdresses channel option, if used, modifies the timing and form of the rejection.)

16.33 Direct LDAP schema MTA options: ldap_basedn_filter_schema1 (LDAP URL filter), ldap_basedn_filter_schema2 (LDAP URL filter elements)

(New in MS 6.3-0.15.) The ldap_basedn_filter_schema1 MTA option specifies the filter used to identify schema 1 domains when performing baseDN searches. The ldap_basedn_filter_schema2 MTA option specifies additional filter elements used to identify schema 2 domains when performing baseDN searches. The default is that neither the ldap_basedn_filter_schema1 MTA option nor ldap_basedn_filter_schema2 MTA option is set. When these options are not set, then the values of ldap_domain_filter_schema1 and ldap_domain_filter_schema2, respectively, are used if those options are set. But if none of these options are set, then the default for ldap_basedn_filter_schema1 is "(objectclass=inetDomain)", while the default for ldap_basedn_filter_schema2 is the empty string.

16.34 Direct LDAP schema MTA options: ldap_domain_filter_schema1 (LDAP URL filter), ldap_domain_filter_schema2 (LDAP URL filter)

The default is that neither the ldap_domain_filter_schema1 nor ldap_domain_filter_schema2 option is set, neither at the MTA level nor at the base level. When these options are not set, then internal defaults in the domain map code are used, equivalent to:

```
ldap_domain_filter_schema1=(|(objectclass=inetDomain)(objectclass=inetdomainalias))
ldap_domain_filter_schema2=(objectclass=sunManagedOrganization)
```

16.35 ldap_host_alias_list Option Under base

The ldap_host_alias_list Base option allows setting a list of host names that will be recognized as synonyms for the host name. It corresponds to the configutil parameter local.imta.hostnamealiases in legacy configuration. The value takes a comma-separated list of up to 40 host aliases; each host alias may be at most 256 characters long; the total length of the entire list is limited to 1024 characters. (In iMS 5.2, the limits were smaller: at most 20 host aliases and each host alias at most 252 characters long.)

In Unified Configuration, this value is used by the Message Store when interpreting the mailHost attribute to determine whether a user's mailboxes can be accessed locally. In legacy configuration, the local.imta.hostnamealiases must be used for this purpose.

Unless mta.local_host_alias_list has been set (thereby overriding the base.local_host_alias_list), the local_host_alias_list base option also affects MTA operation. The ldap_host_alias_list value(s) are used by the MTA when deciding whether a domain's mailRoutingHosts value(s) or a user's mailHost value is "local" (this MTA itself). That is, once an LDAP lookup of a domain or user occurs, this option's value(s) affect the interpretation of the result of the LDAP lookup.

16.36 ldapconnecttimeout Option

The ldapconnecttimeout base option specifies the time in seconds to wait for a new LDAP connection to complete.

16.37 ldapmodifytimeout Option

The ldapmodifytimeout base option specifies the time in seconds to wait for LDAP modify operations to complete.

16.38 ldappoolrefreshinterval Option

The ldappoolrefreshinterval base option specifies the length of time in minutes before LDAP connections are automatically closed then re-established to the LDAP server. Also, length of elapsed time in minutes until the failover directory server reverts back to the primary directory server. If set to -1, use the code default which is 35 minutes.

16.39 ldaprequiretls Option

If SSL is not already being used on a given LDAP connection (*e.g.*, due to ugldapusessl or an ldaps: URL), enabling the ldaprequiretls base option will require successful negotiation of TLS (using LDAP StartTLS) before proceeding with the connection.

16.40 ldapsearchtimeout Option

The ldapsearchtimeout base option specifies how many seconds the server will wait for an LDAP search to complete (unless there is a more specific timeout option for that LDAP search), before the search will failover to a backup LDAP server or the operation will fail.

Note that the MTA has its own configuration setting, ldap_timeout.

16.41 ldaptrace Option

The ldaptrace base option enables LDAP trace (debug) logging. Deprecated in favor of debugkeys (Unified Configuration) or local.debugkeys 'ldap' key.

16.42 listenaddr Option Under base

The listenaddr base option specifies the IPv4 address to listen on when accepting connections, or to bind to when making connections. The allowed values for the listenaddr option include an IPv4 address in dotted decimal form (e.g., 127.0.0.1), or a short form or fully-qualified DNS host name which will be resolved to an IPv4 address by obtaining the DNS A record for the name. To explicitly specify the default value of binding to all available interfaces, the string "INADDR_ANY" may be used. To bind to the loopback device, 127.0.0.1, the string "localhost" may be specified.

If base.listenaddr is not explicitly set, then the default for accepting connections is the string "INADDR_ANY", while the default for making connections is the loopback address.

Note that one of the (several) implications of listenaddr is that it sets the host IP for most servers in the product, including the ENS server. Versions prior to 7 Update 4 instead used a legacy syntax in the local.ens.port option for the ENS server host IP address.

16.43 listurl Option

The listurl base option specifies the URL for mailing list management (obsolete).

16.44 lockdir Option

The lockdir base option specifies the full pathname of server lock directory. Defaults to /tmp/.ENCODED_SERVERROOT/lock/ on Solaris and /dev/shm/.ENCODED_SERVERROOT/lock/ on Linux, where ENCODED_SERVERROOT is

composed of mail server user plus the $SERVERROOT with / replaced by _ .*e.g.*, /tmp/.mailsrv_opt_sun_comms_messaging64/lock/

If the directory does not exist, it will be created.

On Linux, it is a better choice to locate the directory under /dev/shm rather than under /tmp.

IMPORTANT: Stop and restart all Message Store processes immediately after changing this value. New processes will use the new value and be unable to communicate with a stored using the old value.

16.45 loginseparator Option

The loginseparator base option specifies the character(s) to be used as login separator (between userid and domain).

16.46 obsoleteimap Option

The obsoleteimap base option allows use of old IMAP2bis and IMAP4 commands.

16.47 preferpoll Option

To improve performance, the IMAP and MMP servers use Solaris Event Completion Ports on Solaris instead of the poll system call starting with the Messaging Server 7.0.5 release. Since the Messaging Server 8.0.1 release, the servers use epoll on Linux instead of the poll system call. Setting the preferpoll option (available at base and MMP level) to 1 will revert to use of the standard Posix poll API instead. When preferpoll is set to 1, then the polldelay option also applies.

16.48 projectid Option Under base

The projectid option specifies the numeric identifier Messaging Server uses when obtaining shared memory segments. This identifier is used in ftok() calls to generate a shared memory segment key. By default, a value of 7 is used. Only the lowest eight bits of the value are significant.

16.49 properties Option

The properties base option and rolename option are used only during initial configuration by a Deployment Map client to convey information to a remote Deployment Map server.

16.50 proxyadmin Option

The proxyadmin base option specifies the default store admin login name. It may be overridden for any particular backend host using the imapadminproxy option.

16.51 proxyadminpass Option

The proxyadminpass base option specifies the default store admin password corresponding to the proxyadmin account. It may be overridden for each particular backend host using the imapadminpassproxy option.

16.52 proxyimapport Option

The proxyimapport base option specifies the default IMAP port number for connections to backend store servers. It may be overridden for particular backend hosts by setting the imapport proxy option for that backend host, proxy.*hostname*.imapport, (where note that any periods in the hostname must be quoted at the msconfig command line using the backslash character).

16.53 proxyimapssl Option

The proxyimapssl base option enables SSL access to backend store servers. Defaults to 1 if the backend store IMAP port is 993, and 0 otherwise.

16.54 proxyserverlist Option

The proxyserverlist base option specifies a Message Store server list from which to list shared folders. Takes a space-separated string. Not configured by default.

Note that if the proxytrustmailhost Base option is enabled, then a user's mailHost LDAP attribute value will be "trusted" for proxying purposes as if it had been specified in the proxyserverlist.

16.55 proxytrustmailhost Option

The proxytrustmailhost base option controls whether to proxy commands such as URLFETCH to the user's LDAP mailHost, if that server is not listed in proxyserverlist.

16.56 pwchangeurl Option

The pwchangeurl base option specifies the URL a user visits to change his/her password. If specified, this will be sent with password expiration warnings (*e.g.*, IMAP ALERT). (If this option is not set, the IMAP server will also check the accounturl base option.)

Note that a trailing "/" is required on the URL, e.g.,

```
msconfig set base.pwchangeurl http://webmail.example.com/
```

See also the IMAP password expiration alert options.

16.57 rbac Option

The rbac base option enables use of Role-Based Access Controls on Solaris (don't require root access).

16.58 rfc822headerallow8bit Option

The rfc822headerallow8bit base option, if set to 1, allows 8-bit characters in message headers in Messenger Express. If this parameter is set to 0 (in legacy configuration, a value of "no" for the local.rfc822header.allow8bit configutil parameter), or if the 8-bit character is invalid, then the character will be displayed as "?".

16.59 secret Option Under base

The secret Base option specifies a default to be used by the Watcher, if the Watcher's own watcher.secret option has not been specified. The value should match that of the Job Controller's secret, job_controller.secret.

16.60 serveruid Option

The serveruid base option specifies the UNIX user id of Messaging Server. This is deprecated in favor of the user option in restricted.cnf which is used preferentially. In Messaging Server 8, this option is always ignored and configutil -o local.serveruid returns the value of the user option in restricted.cnf.

16.61 sitelanguage Option

The sitelanguage base option specifies the default language tag for use by the Message Store (and its command line utilities), and the MSHTTP server.

16.62 softtokendir Option

When using both Sun Cluster and Solaris libpkcs11 soft token, the Sun Cluster agent will clear the environment so the normal SOFTTOKEN_DIR environment variable can't be used. The softtokendir Base option will be used by the ims_svc_* utilities to set the SOFTTOKEN_DIR environment variable.

16.63 ssladjustciphersuites Option

The ssladjustciphersuites option allows adjusting which SSL cipher suites are enabled or disabled. (This option is available under base, mmp, imapproxy, popproxy, and vdomain.) SSL cipher suites control the level of protection required between SSL client and server. Different cipher suites have different properties and use different cryptographic algorithms. At any time a specific crytographic algorithm might be weakened or compromised by new research in cryptography. The ability to change the default cipher suites allows the software to adapt as security technology changes. In addition as CPUs get faster, the key size necessary to provide several years of comfortable protection increases, even if the algorithm is considered state-of-the-art.

The default set of SSL cipher suites used will change over time as more secure ones are introduced and weaker ones are deprecated. It is expected most deployments will be happy with the default set of cipher suites and it is generally not a good idea to adjust the available cipher suites without reason. However, here are some scenarios where it may be helpful to adjust cipher suites:

1. A site with specific security policies may wish to provide a fixed list of cipher suites to use that is set by site policy rather than simply using state-of-the-art suites provided by the NSS library. Such a site would typically configure this setting to '-ALL,...' where '...' contains the cipher suite names.

2. A site which is experimenting cipher suites that require installation of special server certificate types, for example the DSS cipher suites. Such a site would enable these additional suites once installation was complete.

3. If a site is forced to continue supporting a particularly old client that only supports old cipher suites, they can be explicitly enabled (for example '+RC4' enables the RC4 cipher suites).

4. A site that chooses to disable an older cipher or hash function pro-actively despite potential interoperability issues may choose to do so. For example, to disable all ciphers using the '3DES' or 'SHA1' algorithms, simply set '-3DES,-SHA1'. Be aware that this sort of pro-active action may generate support calls from end users running older mail clients.

5. In the event the cryptographic research community discovers a vulnerability in one or more of the ciphers enabled by default, this provides a mechanism to immediately disable those ciphers. For example, to disable all ciphers using the '3DES' algorithm, simply set '-3DES'.

As of NSS 3.28 (2017), the following cipher suites are enabled by default in the NSS library: TLS_AES_128_GCM_SHA256, TLS_CHACHA20_POLY1305_SHA256, TLS_AES_256_GCM_SHA384, TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256, TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256, TLS_ECDHE_ECDSA_WITH_CHACHA20_POLY1305_SHA256, TLS_ECDHE_RSA_WITH_CHACHA20_POLY1305_SHA256, TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384, TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA, TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA, TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA, TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256, TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256, TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA, TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384, TLS_DHE_RSA_WITH_AES_128_GCM_SHA256, TLS_DHE_RSA_WITH_CHACHA20_POLY1305_SHA256, TLS_DHE_RSA_WITH_AES_256_GCM_SHA384, TLS_DHE_RSA_WITH_AES_128_CBC_SHA, TLS_DHE_DSS_WITH_AES_128_CBC_SHA, TLS_DHE_RSA_WITH_AES_128_CBC_SHA256, TLS_DHE_RSA_WITH_AES_256_CBC_SHA, TLS_DHE_DSS_WITH_AES_256_CBC_SHA, TLS_DHE_RSA_WITH_AES_256_CBC_SHA256, TLS_DHE_RSA_WITH_3DES_EDE_CBC_SHA, TLS_DHE_DSS_WITH_3DES_EDE_CBC_SHA, TLS_ECDH_RSA_WITH_AES_128_CBC_SHA, TLS_ECDH_RSA_WITH_AES_256_CBC_SHA, TLS_RSA_WITH_AES_128_GCM_SHA256, TLS_RSA_WITH_AES_256_GCM_SHA384, TLS_RSA_WITH_AES_128_CBC_SHA, TLS_RSA_WITH_AES_128_CBC_SHA256, TLS_RSA_WITH_AES_256_CBC_SHA, TLS_RSA_WITH_AES_256_CBC_SHA256, TLS_RSA_WITH_3DES_EDE_CBC_SHA.

The complete list of cipher suites present in NSS 3.28 (2017) follows: SSL_DHE_DSS_WITH_3DES_EDE_CBC_SHA, SSL_DHE_DSS_WITH_DES_CBC_SHA, SSL_DHE_RSA_WITH_3DES_EDE_CBC_SHA, SSL_DHE_RSA_WITH_DES_CBC_SHA, SSL_RSA_EXPORT_WITH_RC2_CBC_40_MD5, SSL_RSA_EXPORT_WITH_RC4_40_MD5, SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA, SSL_RSA_FIPS_WITH_DES_CBC_SHA, SSL_RSA_WITH_3DES_EDE_CBC_SHA, SSL_RSA_WITH_DES_CBC_SHA, SSL_RSA_WITH_NULL_MD5, SSL_RSA_WITH_NULL_SHA, SSL_RSA_WITH_RC4_128_MD5, SSL_RSA_WITH_RC4_128_SHA, TLS_AES_128_GCM_SHA256, TLS_AES_256_GCM_SHA384, TLS_CHACHA20_POLY1305_SHA256, TLS_DHE_DSS_WITH_3DES_EDE_CBC_SHA, TLS_DHE_DSS_WITH_AES_128_CBC_SHA, TLS_DHE_DSS_WITH_AES_256_CBC_SHA, TLS_DHE_DSS_WITH_RC4_128_SHA, TLS_DHE_RSA_WITH_3DES_EDE_CBC_SHA, TLS_DHE_RSA_WITH_AES_128_CBC_SHA, TLS_DHE_RSA_WITH_AES_128_CBC_SHA256, TLS_DHE_RSA_WITH_AES_128_GCM_SHA256,

TLS_DHE_RSA_WITH_AES_256_CBC_SHA, TLS_DHE_RSA_WITH_AES_256_CBC_SHA256,

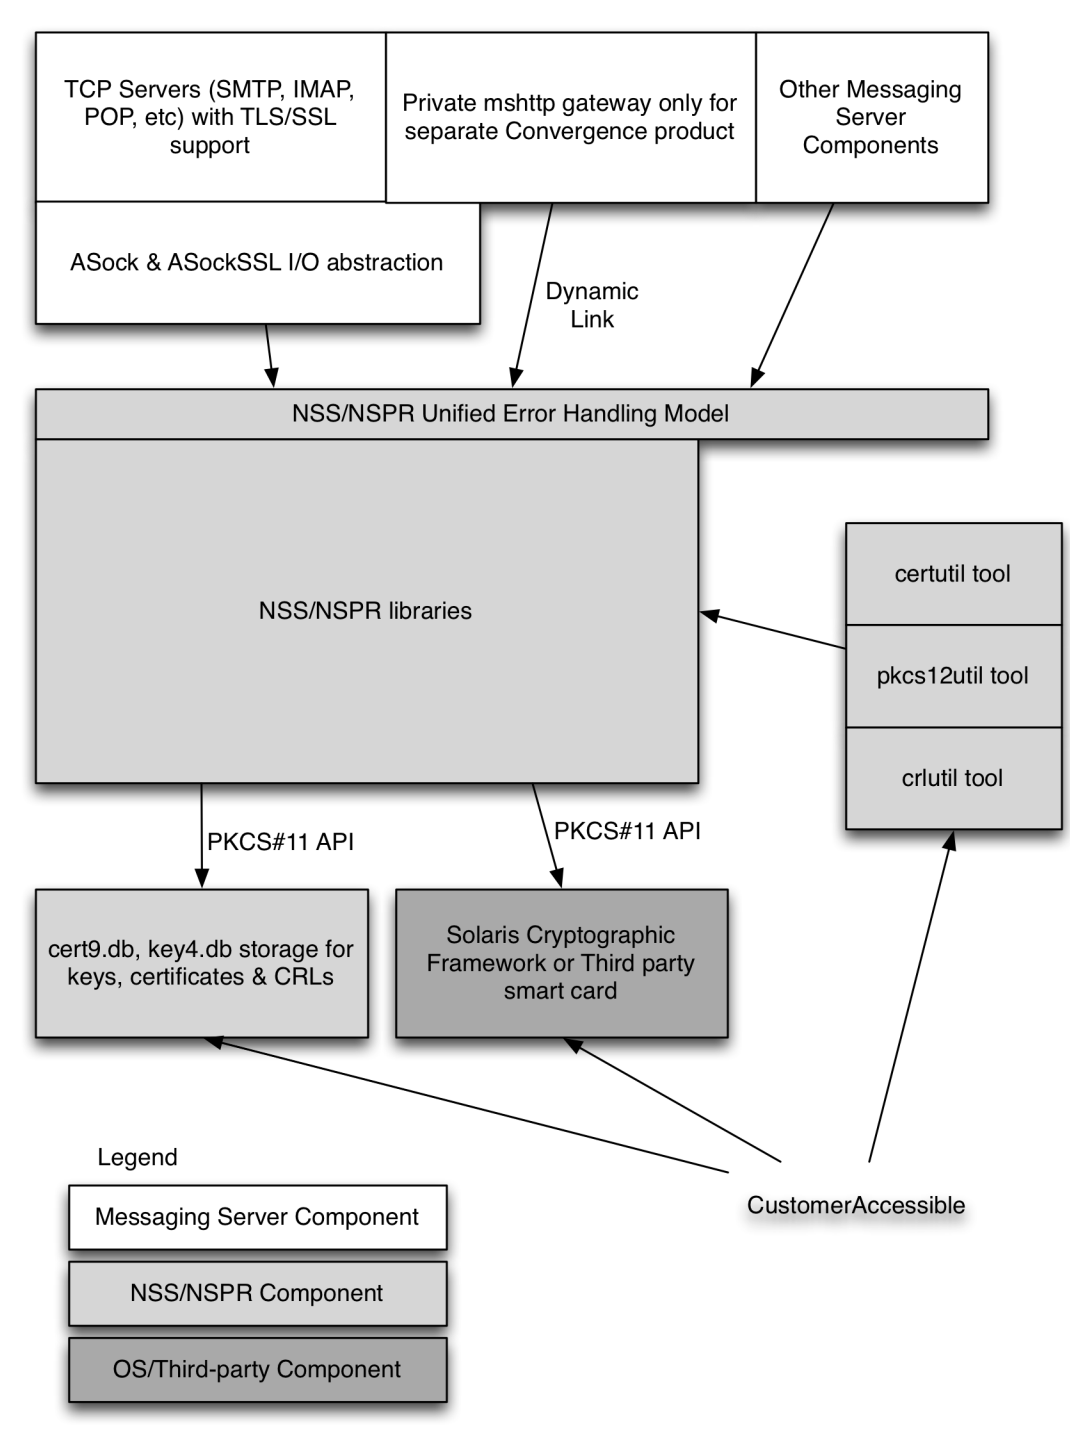
TLS 1.3 (NSS 3.39+) has its own cipher suites separate from previous TLS versions. These include: TLS_AES_128_GCM_SHA256, TLS_CHACHA20_POLY1305_SHA256, TLS_AES_256_GCM_SHA384.

Always keep in mind that adjusting the available ciphersuites can impact multiple protocols; NSS is tightly integrated into Messaging Server, as the following diagram illustrates:



16.64 sslcachedir Option

The sslcachedir option, (available under base, mmp, imapproxy, and popproxy), specifies the SSL session cache directory used to track SSL sessions across multiple connections by the MMP. Prior to 7.0.5.31.0, this also controlled the location of the SSL database files and

defaulted to the config directory. As of the 7.0.5.31.0 release, the ssldbpath base option takes precedence over this option for specifying the location of SSL database files.

NOTE: In order for results to predictable, this option must be the same for the IMAP Proxy and POP Proxy -- any settings of this option for the proxies must match. (Or better yet, don't set it explicitly for any of the proxies; instead set it at MMP level.)

16.65 ssldbpath Option

The ssldbpath base option specifies the location of certificate and key files. This defaults to the product configuration directory; see the CONFIGROOT environment variable.

Additional base options impacting the certificate and key file names and format are ssldbprefix and (prior to MS 8.0) ssldblegacy. Prior to MS 7.0.5.31.0, see also the sslcachedir option.

16.66 ssldblegacy Option

When set, the ssldblegacy base option requires SSL/TLS server certificates, CAs and CRLs to be stored in the legacy cert8.db and key3.db formats supported by our SSL/TLS library. When this is not set, both the legacy cert8.db/key3.db and the modern cert9.db/key4.db formats are supported. The legacy format requires servers to be shut down when updating the database for any reason. The modern format allows updates to be performed while the servers are running. The default was changed from 1 to 0 in the 7.0.5 release. Starting with the 8.0 release, this setting is ignored, the modern format is preferred and the legacy format will be migrated to the modern format on upgrade.

Additional base options impacting the certificate and key file location and names are ssldbpath and ssldbprefix.

16.67 ssldbprefix Option

The ssldbprefix base option specifies the prefixes of the certificate and key files.

Additional base options impacting the certificate and key file location and format are ssldbpath and (prior to MS 8.0) ssldblegacy.

16.68 sslcompress Option

The sslcompress base option determines whether support for the SSL/TLS Compression option (RFC 3749) is enabled. Enabling this is not recommended.

16.69 sslnicknames Option Under base

The sslnicknames Base option specifies a list of the nicknames of the certificates in the SSL certificate database to offer as the server certificate if SSL/TLS is enabled. Only one nickname of each certificate type is permitted (*e.g.*, one RSA certificate, one DSS certificate) so normally only one will be specified. The default is "Server-Cert". This base level list may be overridden for particular services.

16.70 sslpkix Option

The sslpkix base option enables use of PKIX verification for SSL/TLS client certificates (RFC 3280). Full PKIX validation can involve network connections to validate certificates via OCSP or check CRLs. We have not tested these scenarios for correct operation when the system is under load and to verify that network timeouts and server shut down operate correctly when such verifications are in progress.

16.71 sslrequiresafenegotiate Option

Setting the sslrequiresafenegotiate base option requires all SSL/TLS peers to implement safe SSL re-negotiation as specified in RFC 5746. In late 2009, an attack against the SSL/TLS protocol was discovered that makes any client that does not require secure re-negotiation insecure when talking to almost any SSL/TLS server that implements pre-5746 re-negotiation. While our servers are safe from the attack once the NSS 3.12.5 or later patch is installed, this option causes the server to refuse to talk to SSL/TLS clients unless those clients have also been upgraded to be safe from the attack. This feature can be helpful at a security-sensitive site to detect clients that need to be upgraded to improve site security.

16.72 sslrenegotiate Option

The SSL/TLS protocol includes a re-negotiation feature that is primarily used by classic HTTP for client certificate authentication. This feature is not needed by Messaging Server and is disabled by default as of the 7.0.5.31.0 release. Setting this option will enable this feature.

16.73 sslconnlimit Option

The sslconnlimit boolean option determines when SSL connections will be rejected if a connection limit specified by connlimits or a DNS RBL blocklist specified by dnsrbl is encountered. By default, the connection is rejected after SSL is negotiated using an application-level protocol error describing the rejection. If this is set, the connection is rejected prior to SSL negotiation by sending a fatal SSL user_canceled alert at the SSL protocol layer.

16.74 stressperiod Option

When a process such as the MMP becomes stressed due to high load or a denial of service attack, the stressperiod option controls how long (in seconds) the Watcher will consider that process stressed as well as how often that process will send a new stress notification to the Watcher. This allows msprobe to tell the difference between a wedged server (which should be restarted to improve the system) and a stressed process that is making forward progress but may have a response time larger than the msprobe timeout. Restarting such a process may reduce overall system performance as any disconnected clients are likely to reconnect to the system thus increasing the load. If a stressed process becomes wedged, then msprobe will be able to restart that process after the stressperiod expires.

This is presently only implemented by the MMP.

16.75 stressfdwait Option

When a process is running out of available file descriptors and the `stressfdwait` Base option is set, then the process is permitted to stop accepting new connections until the file descriptor shortage goes away. If this is turned off, the process will continue trying to accept connections until it fails. This is presently only implemented for the MMP and is on by default. As stress fd wait is a new feature, it may be helpful to disable the feature temporarily if it is causing an unexpected problem.

16.76 supportedlanguages Option

The `supportedlanguages` base option specifies the languages supported by server code.

16.77 threadholddelay Option

The `threadholddelay` base option sets a thread hold delay time (in milliseconds) for IMAP and POP connections. This is the amount of time that asynchronous read and write operations will try to keep a worker thread around.

16.78 tlsminversion Option

16.78.1 Use with base

The `tlsminversion` base option determines the minimum acceptable version of TLS (the modern version of the SSL protocol). This presently takes a value of `TLS1.0`, `TLS1.1`, `TLS1.2`, and new in Messaging Server 8.1: `TLS1.3`. This option defaults to `TLS1.2` (disabling TLS 1.0 & 1.1 by default). Prior to the 8.1 release, TLS 1.1 was the default and prior to the 8.0.1 release, TLS 1.0 was the default. If this is set to `TLS1.2` (the current default), the setting of the `tlsv12enable` option is ignored. If this is set to `TLS1.3`, the setting of the `tlsv13enable` option is ignored.

16.78.2 Use with channel

When placed on a channel, the `tlsminversion` option overrides the base default for the minimum TLS version for all messages dequeued from the channel.

16.79 tlsv12enable Option

The `tlsv12enable` base option determines whether TLS version 1.2 (the recommended version of the SSL protocol) is enabled. For releases prior to 8.0 this defaulted to 0; starting with 8.0 this defaults to 1. As of MS 8.0.1, if `tlsminversion` is set to `TLS1.2` or `TLS1.3`, this option is ignored and TLS 1.2 is enabled.

16.80 tlsv13enable Option

The `tlsv13enable` base option determines whether TLS version 1.3 (the modern version of the SSL protocol) is enabled. For releases prior to 8.0 this defaulted to 0; starting with 8.0 this defaults to 1. If `tlsminversion` is set to `TLS1.3`, this option is ignored and TLS 1.3 is enabled.

16.81 tmpdir Option Under base

The tmpdir base option specifies the temporary file directory; defaults to $DATAROOT/tmp/.

On Linux, this option should instead be set to /dev/shm/.

16.82 ugldapbasedn Option

The ugldapbasedn base option specifies the root of the user/group configuration tree in the Directory Server. Normally this option is set to an appropriate value during initial configuration.

The MTA has a "twin" option, ldap_user_root, which may be used to override this base option for MTA-specific purposes.

16.83 ugldapbindcred Option

The ugldapbindcred base option specifies the password for the user/group administrator.

The MTA has a "twin" option, ldap_password, which may be used to override this base option for MTA-specific purposes.

16.84 ugldapbinddn Option

The ugldapbinddn base option specifies the DN of the user/group administrator. Normally initial configuration sets this option to a value of the form:

```
uid=msg-admin-<msg.ServerHostName>-<msg.product.InstallationTimestamp>, ou=People, <deforgdn>
```

The MTA has a "twin" option, ldap_username, which may be used to override this base option for MTA-specific purposes.

16.85 ugldaphost Option

The ugldaphost base option specifies the LDAP server list for user/group lookup. Takes a space-separated string. A port may be specified by appending ":port" to a host name in the list. If empty or not set, the loopback interface is used.

Normally this option is set to an appropriate value during initial configuration.

The MTA has a "twin" option, ldap_host, which may be set to specify an MTA-specific override of this option's value.

16.86 ugldapport Option

The ugldapport base option specifies the LDAP port for user/group lookup if a port is not specified in the ugldaphost list. The default is 389, though initial configuration may set it to a different value. As of the 7.0.5 release, if this is set to 636, then SSL will be used regardless of ugldapusessl setting.

The MTA has a "twin" option, ldap_port, which may be set to specify an MTA-specific override of this option's value.

16.87 ugldapusessl Option

The ugldapusessl base option if enabled says to use SSL to connect to the user/group LDAP server. Note that as of 7.0.5, if ugldapport is set to 636, then SSL will be used regardless of the value of ugldapusessl.

16.88 welcomemsg Option Under base

The welcomemsg Base option specifies a default welcome message for new users of the Message Store. The maximum size is 1 MB.

Syntax: "$" line separators, with headers.

Note that the base value can be localized using the welcomemsg option set under named message_language groups.

This default welcome message message specified at base level is only used if there is no domain-specific welcome message in a preferred language (no mailDomainWelcomeMessage tagged with a preferred language) set on the LDAP entry of the domain in which the new user resides.

16.89 logfile options

There are a number of options relating to nslog log files, set under a logfile group, under the appropriate component. logfile options may be set under base, http, imap, metermaid, mmp, mta, imapproxy, popproxy, messagetrace, pop, snmp, rollovermanager, tcp_lmtp_server, transactlog, msadmin, ens, job_controller, or dispatcher.

For additional debugging, see also the debugkeys option available for a number of Messaging Server components.

Certain components support automatic log file rollover; see the rollovermanager options.

16.89.1 expirytime Option

The expirytime logfile option, *component*.logfile.expirytime, specifies the maximum time in seconds a log file is kept. The default is 604800 seconds (corresponding to one week).

16.89.2 flushinterval Option

The flushinterval logfile option, *component*.logfile.flushinterval, specifies the time interval in seconds between logfile buffer flushes.

16.89.3 filemode Option

The `filemode logfile` option, *`component`*`.logfile.filemode`, specifies the file mode in octal used to create log files for the specified component. The value will be masked with octal 0666 and the process umask to set actual log file permissions. If you want a process with a different userid but in the same group as the Messaging Server user to have read access to log files, use `0640`. The store.umask option can be used to modify the process umask to allow this.

Note that the `filemode` option does not apply to MTA debug logs or MTA transaction log files.

For the 8.0 release and later, it is no longer necessary to modify the umask.

16.89.4 `logmillisecond` Option

When the `logmillisecond logfile` option, *`component`*`.logfile.logmillisecond`, is turned on (that is, set to `1`), then milliseconds will be shown in nslog log files.

16.89.5 `loglevel` Option Under logfile

The `loglevel logfile` option specifies the logging level for the whatever component's logfile it is set under. *E.g.*, `imap.logfile.loglevel` specifies the logging level for the IMAP server's log file.

Valid values for the `loglevel` option are: `nolog`, `emergency`, `alert`, `critical`, `error`, `warning`, `notice`, `information`, or `debug`. The default is `notice`.

The `loglevel logfile` option for the MTA specifies an MTA log level used for the `imta` log file (primarily used by `ims_master` and the LMTP server).

16.89.6 `maxlogfiles` Option

The `maxlogfiles logfile` option, *`component`*`.logfile.maxlogfiles`, specifies the maximum number of log files to retain.

16.89.6.1 Use with mmp Under logfile

For the MMP, the `maxlogfiles logfile` option, `mmp.logfile.maxlogfiles`, was new for Messaging Server 7u1.

16.89.7 `maxlogfilesize` Option

When an nslog log file for a component reaches the *`component`*`.logfile.maxlogfilesize` size, a log rollover operation will be triggered; logging may continue to the log file while the rollover operation is in progress. In the Messaging Server 7.0.5 release, the default value was increased to keep more historical data. In previous versions, the default value was 2097152 (2MB).

16.89.7.1 Use with mmp Under logfile

For the MMP, the `maxlogfilesize logfile` option, `mmp.logfile.maxlogfilesize`, was new for Messaging Server 7u1.

16.89.8 maxlogsize Option

When an nslog log file rollover operation occurs, if the maximum total size in bytes of all log files for this service exceeds the *component*.logfile.maxlogsize value, then the older log files will be removed as part of the rollover process until the sum of the file sizes observed at the start of the rollover operation falls below this threshold. In the Messaging Server 7.0.5 release, the default value was increased to keep more historical data. In previous versions, the default value was 20971520 (20MB).

16.89.8.1 Use with mmp Under logfile

For the MMP, the maxlogsize logfile option, mmp.logfile.maxlogsize, was new for Messaging Server 7u1.

16.89.9 rollovertime Option

The rollovertime logfile option, *component*.logfile.rollovertime, specifies the length of time in seconds to keep a log file active. That is, the maximum period of time to record data to a single log file. The default is 86400 seconds (corresponding to one day).

16.89.9.1 Use with mmp Under logfile

For the MMP, the rollovertime logfile option, mmp.logfile.rollovertime, was new for Messaging Server 7u1.

16.89.10 rolloverpolicy Option

The rolloverpolicy logfile option, *component*.logfile.rolloverpolicy, specifies the policy of rolling over an active log file.

Starting with Messaging Server 8.0.2, this option is deleted. Rollover based on size is always performed, and rollover based on time is performed if the rollover manager process is enabled. DELETED: simplify rollover model.

- 0: disabled;
- 1: rollover based on time specified by rollovertime logfile option;
- 2: rollover based on log file size specified by maxlogfilesize logfile option;
- 3: rollover based on both time and log file size.

16.89.11 syslogfacility Option

The syslogfacility logfile option, *component*.logfile.syslogfacility, specifies whether or not logging for that *component* is directed to the syslog service. The value of such an option can be none, user, mail, daemon, or local0 to local7. If the value is set, messages are logged to the syslog facility corresponding to the set value and all other log file service options are ignored. The special value of none (which is the default) disables use of the syslog service.

16.89.11.1 Use with mmp Under logfile

For the MMP, the syslogfacility logfile option, mmp.logfile.syslogfacility, was new for Messaging Server 7u1.

16.90 Base autorestart options

Under the `base` group is the `autorestart` group, with merely two options available, `base.autorestart.enable` and `base.autorestart.timeout` (which may also be set and referred to simply as `autorestart.enable` and `autorestart.timeout`). Enabling autorestart means that Messaging Server can attempt to restart components that seem to be in trouble.

Autorestart of Messaging Server components is triggered if/when `msprobe` detects a "problem" with a component of Messaging Server, at which point `msprobe` requests that the Watcher attempt a restart of that "troubled" component of Messaging Server.

16.90.1 `enable` Option Under autorestart

The `enable` Autorestart option (`base.autorestart.enable` or more simply `autorestart.enable` in Unified Configuration, or `local.autorestart` in legacy configuration) enables automatic restart of failed or frozen (unresponsive) servers including IMAP, POP, MSHTTP, Job Controller, Dispatcher, and MMP servers.

16.90.2 `timeout` Option Under autorestart

The `timeout` Autorestart option, (`autorestart.timeout` in Unified Configuration, or `local.autorestart.timeout` in legacy configuration), specifies a failure retry time-out, in seconds. The default is `600` seconds. If a server fails more than once during this designated period of time, then the system will stop trying to restart this server. If this happens in an HA system, Messaging Server is shutdown and a failover to the other system occurs. The value (set in seconds) should be set to a period value longer than the msprobe interval. (See the `schedule.task:msprobe.crontab` option setting for msprobe's schedule).

16.91 Base certmap options

Several options affect certificate map operation. These options are grouped under `base.certmap`, but may be referred to and set more simply as merely under `certmap`.

For debugging of certificate map operations, see also the `certmap` keyword of the `debugkeys` option.

16.91.1 `dncomps` Option

The `dncomps` certmap option determines how to search for a client certificate in the directory. If this is not supplied, the server will expect the client certificate subject to contain the exact DN of the user in LDAP. If this is set to the empty string, a search will be performed under the ugldapbasedn based on a search filter from the filtercomps. If this is set to a space-separated list of components, then a DN will be constructed by extracting the values of those components from the certificate subject in the order listed. If the component in the certificate subject is different from the component that will be used in the LDAP DN, then a translation is specified by using *`subject-component=ldap-component`* in the space separated list. For backwards compatibility, "`mail`" and "`e`" are treated as synonyms.

16.91.2 `filtercomps` Option

The filtercomps certmap option determines the search filter to use when locating the user entry in LDAP associated with a client certificate subject. If this is not provided or empty, then a search filter of (objectclass=*) will be used. If this is set to a space separated list of components, then a search filter will be formed by extracting values from components in the certificate subject in the order listed and combining them with a logical and. If the component in the certificate subject is different from the attribute name that will be used in the LDAP search filter, then a translation is specified by using *subject-component=ldap-component* in the space separated list. For backwards compatibility, "mail" and "e" are treated as synonyms.

Typically, filtercomps is not used unless dncomps is set to the empty string.

16.91.3 verifycert Option

If the verifycert certmap option is set to 1, then when a user record in LDAP is found for a given client certificate, the binary DER form of that certificate will be compared to the userCertificate;binary attribute in LDAP. Authentication will succeed only if there is an exact match.

16.91.4 cmapldapattr Option

The cmapldapattr certmap option specifies the name of an LDAP attribute that will contain the certificate subjects for valid client certificates. There is no standard LDAP attribute defined for this purpose so it will be necessary to extend your LDAP schema. The attribute name certSubjectDN is suggested. If this is specified, the server will perform a subtree search under ugldapbasedn to locate a user. This is performed before the server attempts to use dncomps or filtercomps to find the user entry.

16.92 Base domainmap options

The only domainmap option is debug.

See also the usedomainmap Auth option.

The imsimta test -domain_map utility may be used to verify domain definitions.

16.92.1 debug Option Under domainmap

The base.domainmap.debug option sets the level of debugging messages for the domain map library code.

Chapter 17 Scheduler options

The Messaging Server Scheduler schedules and initiates execution of various periodic jobs for Messaging Server. These jobs may include the following named `task`s:

1. `return_job`, the MTA's message return job (message bouncer job), that returns (bounces) excessively old, undelivered messages,

2. `expire`, the Message Store's message expiration job, that deletes *from disk* messages that users have deleted from their mailboxes,

3. `msprobe`, checking whether Messaging Server components such as server processes are available ("up") and responsive,

4. `purge`, the MTA's log file purge job, that purges "older" MTA log files,

5. `snapshot`, the Message Store's database "snapshot" job, that captures a current-moment "snapshot" of the messages in the Message Store,

6. `snapshotverify`, the Message Store's database "snapshot verification" job, that verifies whether snapshots are sound.

The only options for the Scheduler itself are `enable` (to enable the Scheduler's own operation) and `enablelog`. The settings of more interest are those under named `task` groups under the Scheduler, configuring behavior of each named task.

The Scheduler does not have its own `logfile` option group. This means that in unified configuration Scheduler debugging is controlled by the `base.logfile` option group. For example, Scheduler debug output to the default log can be enabled by setting:

```
msconfig> set base.logfile.loglevel debug
```

Note that this enables debug output for other utilities, e.g., msprobe, as well.

17.1 `enable` Option Under schedule

The `enable` Scheduler option, `schedule.enable` (Unified Configuration) or `local.sched.enable` (legacy configuration), enables the Scheduler service on `start-msg` startup. This option defaults to `0` if not set, but initial configuration normally enables the option.

17.2 enablelog Option

To enable output from the Scheduler's tasks to go to separate log files in the *DATAROOT*/log directory, set enablelog to 1. This creates logfiles named <task-name>.log.<unix-timestamp> each time a scheduler task is executed. These log files are not removed automatically, so customers using this option will need to configure their own mechanism to remove older log files of this format.

This option is not refreshable; the scheduler must be stopped and restarted if this option is changed.

17.3 Scheduler task options

When the Scheduler is enabled, each named task known to the Scheduler *may* be explicitly enabled or disabled via the task's own enable option (but typically the task's enable value defaults appropriately based on which Messaging Server components are enabled), and if enabled (whether implicitly or explicitly) will be executed at the schedule set via the crontab option for that task; *e.g.*,

```
msconfig> show schedule.enable
role.schedule.enable = 1
msconfig> show mta.enable
role.mta.enable = 1
msconfig> show schedule.task:return_job.*
role.schedule.task:return_job.crontab = 30 0 * * * lib/return_job
```

The Scheduler supports the following named tasks in particular:

1. expire, the Message Store's message expiration job, that deletes *from disk* messages that users have deleted from their mailboxes, and purges messages from users' mailboxes according to administrative criteria,

2. msprobe, checking whether Messaging Server components such as server processes are available ("up") and responsive,

3. purge, the MTA's log file purge job, that purges older MTA log files,

4. return_job, the MTA's message return job (message bouncer job), that returns (bounces) excessively old, undelivered messages,

5. snapshot, the Message Store's database "snapshot" job, that captures a current-moment "snapshot" of the messages in the Message Store,

6. snapshotverify, the Message Store's database "snapshot verification" job, that verifies whether snapshots are sound.

Individual Scheduler tasks can themselves be enabled or disabled through the use of the enable task option. For example, the following commands disable msprobe and explicitly enable imexpire:

```
msconfig> set schedule.task:msprobe.enable 0
msconfig# set schedule.task:expire.enable 1
```

Almost all Scheduler settings are refreshable: New tasks can be added, task parameters can be changed, disabled tasks can be enabled, and as of Messaging Server 8.0.1.2, enabled tasks can be enabled. In all of these cases a `refresh imsched` will cause the changes to take effect.

At present only the outright deletion of a task requires a Scheduler restart:

```
stop-msg sched
start-msg sched
```

Other tasks can be executed by the Scheduler. For instance, rather than executing the Message Store's `impurge` job as a daemon as normally configured when `store.enable` is enabled, a site can disable that daemon via `store.purge.enable=0` and instead configure the Scheduler to run the `impurge` command periodically.

17.3.1 enable Option Under task

The `enable` Scheduler task option, `schedule.task:`*`name`*`.enable` (Unified Configuration) or `local.schedule.`*`name`*`.enable` (legacy configuration), controls whether a task should be scheduled.

If the Scheduler has been enabled, `schedule.enable=1`, all tasks default to being scheduled, unless explicitly disabled via `schedule.task:`*`task-name`*`.enable=0`. That is, the purpose of the task-level `enable` option is to provide a way to *disable* tasks.

17.3.2 expire task options

The `expire` Scheduler task has a few options: `enable` to enable automatic scheduling of execution of `imexpire` and `crontab` to control that schedule.

Note that configuration of what `imexpire` actually does when it runs involves additional other, potentially complex, configuration. See Message Store expire options, Message Store expirerule options, the `expiresieve` Message Store option, and the discussion of `imexpire` invoking spamfilter packages for discussions of configuration of what `imexpire` actually does when it executes.

17.3.2.1 enable Option Use With expire Under task

The `enable` Scheduler `task` option for the `expire` task controls whether the expire task should be scheduled. It defaults to the setting of the `store.enable` option (Unified Configuration) or `local.store.enable configutil` parameter (legacy configuration).

17.3.2.2 crontab Option Use With expire Under task

The `crontab` Scheduler `task` option for the `expire` task controls the interval for running `imexpire`, enabled with `schedule.task:expire.enable` (Unified Configuration) which defaults to the setting of the `store.enable` setting, (or in legacy configuration, `local.schedule.expire.enable` which defaults to the setting of `local.store.enable`).

`schedule.task:expire.crontab` uses UNIX `crontab` format: minute hour day-of-month month-of-year day-of-week command arguments.

Initial configuration normally sets this to:

```
msconfig> show schedule.task:expire.crontab
role.schedule.task:expire.crontab = 0 23 * * * bin/imexpire
```

17.3.3 msprobe task options

The `msprobe` Scheduler task, which runs `msprobe` to check on the status of various services, has a couple of options.

Note the distinction between these options set under the Scheduler task `msprobe`, `schedule.task:msprobe.`*`option-name`*, which control the *scheduling of execution* of `msprobe`, compared to the separate set of msprobe options controlling the actual *operation* of `msprobe`, set as `msprobe.`*`option-name`* or under specific service probes as `msprobe.probe:`*`specific-service-name.option-name`*.

17.3.3.1 `enable` Option Use With msprobe Under task

The `enable` Scheduler `task` option for the `msprobe` task controls whether the msprobe task should be scheduled.

17.3.3.2 `crontab` Option Use With msprobe Under task

The `crontab` Scheduler `task` option for the `msprobe` task controls the `msprobe` run schedule, enabled with `schedule.task:msprobe.enable` (Unified Configuration) or `local.schedule.msprobe.enable` (legacy configuration). `msprobe` is a daemon that probes servers to see if they respond to service requests. `schedule.task:msprobe.crontab` uses UNIX `crontab` format: minute hour day-of-month month-of-year day-of-week command arguments.

Initial configuration sets this to:

```
msconfig> show schedule.task:msprobe.crontab
role.schedule.task:msprobe.crontab = 5,15,25,35,45,55 * * * * lib/msprobe
```

17.3.4 purge task options

The `purge` Scheduler task, which purges "old" versions of MTA log files, has a couple of options.

(Note the distinction between this MTA log file purge job, *vs*. the similarly named `impurge` job/daemon which purges old Message Store messages.)

17.3.4.1 `enable` Option Use With purge Under task

The `enable` Scheduler `task` option for the `purge` task controls whether the MTA's log file purge task should be scheduled. Defaults to the setting of the `mta.enable` option (Unified Configuration) or `local.imta.enable configutil` parameter (legacy configuration). Starting with the 8.0 release, this instead defaults to 1 if any of the following are set:

dispatcher.enable option (Unified Configuration), the local.dispatcher.enable configutil parameter (legacy configuration), the job_controller.enable option (Unified Configuration), the local.job_controller.enable configutil parameter (legacy configuration); and otherwise will default to 0. As the new dispatcher and job_controller enable options default to the mta.enable setting, upgrading customers should see no behavior change.

17.3.4.2 crontab Option Use With purge Under task

The crontab Scheduler task option for the purge task controls the interval for running imsimta purge, enabled with schedule.task:purge.enable (Unified Configuration) which defaults to the value of mta.enable, (or in legacy configuration local.schedule.purge.enable which defaults to the value of local.imta.enable). imsimta purge removes older MTA log files. schedule.task:purge.crontab uses UNIX crontab format: minute hour day-of-month month-of-year day-of-week command arguments.

Initial configuration sets this to:

```
msconfig> show schedule.task:purge.crontab
role.schedule.task:purge.crontab = 0 0,4,8,12,16,20 * * * bin/imsimta purge -num=5
```

17.3.5 return_job options

The return_job Scheduler task has a couple of options. The return_job checks for messages in the MTA queue area that have not yet been delivered, and then generates delay warning messages, or bounces the messages, as appropriate and configured via the *notices channel options and return_units MTA option.

A number of MTA options modify operation of the return_job. In particular the return_split_period and return_cleanup_period MTA options affect the return_job's management of MTA transaction log files, while for debugging the return_job, see the return_debug and return_verify MTA options.

17.3.5.1 enable Option Use With return_job Under task

The enable Scheduler task option for the return_job task controls whether the return_job task should be scheduled. Defaults to the setting of the mta.enable option (Unified Configuration) or local.imta.enable configutil parameter (legacy configuration). Starting with the 8.0 release, the mta.enable option is deprecated so this instead defaults to the value of the job_controller.enable option (Unified Configuration) or the local.job_controller.enable configutil parameter (legacy configuration). As the job_controller.enable option defaults to the value of the mta.enable option, upgrading customers should see no behavior change.

17.3.5.2 crontab Option Use With return_job Under task

The crontab Scheduler task option for the return_job task controls the interval for running the MTA return_job, enabled with schedule.task:return_job.enable (Unified Configuration) which defaults to the setting of mta.enable (or in legacy configuration local.schedule.return_job.enable which defaults to the setting of local.imta.enable).

`schedule.task:return_job.crontab` uses UNIX `crontab` format: minute hour day-of-month month-of-year day-of-week command arguments.

Initial configuration sets this to:

```
msconfig> show schedule.task:return_job.crontab
role.schedule.task:return_job.crontab = 30 0 * * * lib/return_job
```

17.3.6 snapshot task options

See also the Scheduler's `snapshotverify` task options. See also the `snapshotdirs` and `snapshotpath` Message Store options.

17.3.6.1 `enable` Option Use With snapshot Under task

The `enable` Scheduler `task` option for the `snapshot` task controls whether the snapshot / verify task should be scheduled. Defaults to the setting of the `store.enable` option (Unified Configuration) or `local.store.enable configutil` parameter (legacy configuration).

17.3.6.2 `crontab` Option Use With snapshot Under task

The `imdbverify` snapshot and verify option, enabled with `schedule.task:snapshot.enable` (Unified Configuration) which defaults to `store.enable` (or in legacy configuration `local.schedule.snapshot.enable` which defaults to `local.store.enable`). `imdbverify` will take a snapshot backup copy of the database and verify it for use during automatic recovery.

Initial configuration sets this to:

```
msconfig> show schedule.task:snapshot.crontab
role.schedule.task:snapshot.crontab = 0 2 * * * bin/imdbverify -s -m
```

17.3.7 snapshotverify task options

See also the Scheduler `snapshot` task options.

17.3.7.1 `enable` Option Use With snapshotverify Under task

The `enable` Scheduler `task` option for the `expire` task controls whether the process log verify task for rolling backups should be scheduled. Defaults to the setting of the `store.enable` option (Unified Configuration) or `local.store.enable configutil` parameter.

17.3.7.2 `crontab` Option Use With snapshotverify Under task

The `imdbverify` utility updates snapshots of the mboxlist database incrementally. The snapshots can be used during automatic recovery. The `imdbverify` utility is enabled with `schedule.task:snapshotverify.enable` (Unified Configuration) or `local.schedule.snapshotverify.enable` (legacy configuration).

Initial configuration sets this to:

```
msconfig> show schedule.task:snapshotverify.crontab
role.schedule.task:snapshotverify.crontab = 5,15,25,35,45,55 * * * * bin/imdbverify
```

Chapter 18 Watcher options

The Watcher has just a few options.

See also `msprobe` options and Base autorestart options.

18.1 `enable` Option Under watcher

The `enable` Watcher option, `watcher.enable` (Unified Configuration) or `local.watcher.enable` (legacy configuration), enables the Watcher service on `start-msg` startup. The Watcher service is a daemon that monitors Messaging Server and restarts services that fail. Refer to `autorestart.enable` (`local.autorestart` in legacy configuration) and the Administration Guide for details.

This option defaults to `0` if not set, but initial configuration normally enables the option.

18.2 `port` Option Under watcher

The `port` Watcher option specifies the `watcher` listen port. The default is `49994`.

18.3 `secret` Option Under watcher

The `secret` Watcher option specifies the shared secret used by the Watcher when communicating with watched processes. If `watcher.secret` is not specified, it will default to the value of the `secret` Base option, `base.secret`. The value should match that of the Job Controller's `secret`, `job_controller.secret`.

Chapter 19 msprobe options

There are a few options affecting msprobe operation. msprobe's service-specific probes can also individually override some of the general msprobe values.

Note the distinction between these options controlling *operation* of `msprobe`, set as `msprobe.option-name`, compared to the separate set of `msprobe` Scheduler task options which control the *timing of execution* of `msprobe`, and which are set as `schedule.task:msprobe.option-name`.

When msprobe detects a possible problem, it can, depending upon other configuration, potentially let the Watcher know (at which point the Watcher can attempt to restart a troubled component) and/or generate an alarm message; see the Base autorestart options especially `base.autorestart.enable`) and Watcher options, and Alarm options, respectively.

See also the `stressperiod` and `stressfdwait` base options (which currently affect only the MMP).

19.1 queuedir Option

The `queuedir` msprobe option specifies the full pathname of spool directory or local queue directory to be monitored by `msprobe`. On an MTA system, to have `msprobe` monitor the MTA queue area, set this option to `DATAROOT/queue/`; since this option has no default value, leaving it unset means that `msprobe` will not monitor the MTA queue area.

19.2 timeout Option Under msprobe

The `msprobe.timeout` msprobe option specifies the time in seconds that msprobe waits after sending a request that goes unfulfilled before restarting a service. This is a general default for msprobe's probes; a service-specific probe can set its own, override timeout via the `msprobe.probe:service-name.timeout` option.

Attempting to set a value of 0 will result in the value 30 (the default) getting used as the msprobe default.

19.3 warningthreshold Option Under msprobe

The `msprobe.warningthreshold` option sets a default warning threshold for any msprobe probe that does not have its own, more explicit, warning threshold set (via a `msprobe.probe:name.warningthreshold` option).

19.4 Probe options

msprobe's service-specific probes can set their own `warningthreshold` and `timeout` values, overriding msprobe's general default such values. Such probe values are set within a named probe group, where the name may (currently) be one of:

- `cert`
- `deploymap`
- `ens`
- `http`
- `imap`
- `job_controller`
- `lmtp`
- `metermaid`
- `pop`
- `smtp`
- `submit`

So for instance:

```
msconfig> set msprobe.probe:submit.timeout 120
```

Chapter 20 Alarm options

msprobe can generate warning messages (so-called "alarms") if it detects possible problems such as server non-responsiveness, or disk unavailability. Several options control such warning ("alarm") messages. The options relating to the submission and format of such messages are set directly under the top-level `alarm` group. Options relating to the triggering of generation of such warning ("alarm") messages are set under a named `alarm.system` group.

20.1 `noticehost` Option

The `noticehost` alarm option specifies the SMTP host to which msprobe should submit warning messages. If `noticehost` is not set, it will default (as of Messaging Server 7 update 2) to the value of `http.smtphost` (in legacy configuration, `service.http.smtphost`), or the loopback address. Do not use the SMTP server being monitored (the local instance) as the `noticehost`. To disable alarm message, set `noticeport` to 0.

20.2 `noticeport` Option

The `noticeport` alarm option specifies the SMTP port to which msprobe will connect when submitting alarm messages. A value of 0 will disable alarm message submission.

20.3 `noticercpt` Option

The `noticercpt` alarm option specifies the recipient of msprobe alarm messages. If not set, "`Postmaster@`*`local-hostname`*" will be used, where *`local-hostname`* is the value of the `hostname` Base option.

20.4 `noticesender` Option

The `noticesender` Alarm option specifies the address used in From: header (and envelope From) of msprobe alarm messages. If not set, "`Postmaster@`*`local-hostname`*" will be used, where *`local-hostname`* is the value of the `hostname` Base option.

20.5 noticetemplate Option

The noticetemplate alarm option specifies the msprobe alarm message template. %s in the template is replaced with the following in order: sender, recipient, alarm description, alarm instance, alarm current value and alarm summary text. DELETED: Too prone to format errors; support dropped in 6.3 release; use of the former default value is now hard-coded.

As of MS 6.3, and the removal of this option, the msprobe alarm messages are always constructed as:

```
From: <noticesender>
To: <noticercpt>
Subject: ALARM: <description> of "<instance>" is <current-value>

<summary-text>
```

(corresponding to the former default template).

20.6 smtpauthpassword Option Under alarm

The smtpauthpassword alarm option specifies the password that will be used when msprobe submits mail to the MTA. See also smtpauthuser.

20.7 smtpauthuser Option Under alarm

When msprobe submits, SMTP authentication will be used if both smtpauthuser and smtpauthpassword are set. These two Alarm options specify the administrative user name and password that are used to submit alarm.

20.8 Alarm system options

Options regarding the triggering of msprobe warning ("alarm") messages regarding various components or "systems" are set under alarm.system:*system-name*, where *system-name* is either diskavail or serverreponse.

20.8.1 description Option Use With diskavail Under system

The alarm.system:diskavail.description option specifies the description for the diskavail alarm.

20.8.2 description Option Use With serverresponse Under system

The alarm.system:serverresponse.description option specifies the description for the serverresponse alarm.

20.8.3 statinterval Option

The statinterval option under a named alarm.system group, so either alarm.system:diskavail.statinterval or alarm.system:serverresponse.statinterval, specifies the interval in seconds between checks on the named system. Set to 0 to disable checks.

20.8.3.1 Use with diskavail Under system

The alarm.system:diskavail.statinterval option specifies the interval in seconds between disk availability checks. The default is 3600 seconds. Set to 0 to disable checks of disk usage.

20.8.3.2 Use with serverresponse Under system

The alarm.system:serverresponse.statinterval option specifies the interval in seconds between checks on server responsiveness. The default is 600 seconds. Set to 0 to disable checking of server response.

20.8.4 threshold Option

The threshold option, available under the alarm system named groups diskavail and serverresponse, specifies the threshold measurement for triggering an alarm.

20.8.4.1 Use with diskavail Under system

The alarm.system:diskavail.threshold option specifies the percentage of disk space availability below which an alarm is sent. The default is 10 percent.

20.8.4.2 Use with serverresponse Under system

The alarm.system:serverresponse.threshold option specifies the server response time, in seconds, triggering an alarm. The default is 10 seconds.

20.8.5 thresholddirection Option

Specifies whether an alarm is issued when the measurement is greater than (1) or less than (-1) the specified threshold.

20.8.5.1 Use with diskavail Under system

The alarm.system:serverresponse.thresholddirection option specifies whether the alarm is issued when disk space availability is below threshold (-1) or above it (1). The default is -1.

20.8.5.2 Use with serverresponse Under system

The alarm.system:serverresponse.theshlddirection option specifies whether an alarm is issued when server response time is greater than (1) or less than (-1) the threshold. The default is 1.

20.8.6 warninginterval Option

The warninginterval Alarm system option specifies, for a named system, the interval in hours between subsequent issuances of the alarm.

20.8.6.1 Use with diskavail Under system

msprobe can generate warning messages if it detects possible disk availability problems. The alarm.system:diskavail.warninginterval option specifies the interval in hours between subsequent repetition of disk availability alarms. The default is 24 hours.

20.8.6.2 Use with serverresponse Under system

msprobe can generate warning messages if it detects possible server problems (*i.e.*, server non-responsiveness). The alarm.system:serverresponse.warninginterval option specifies the interval in hours between subsequent repetition of server response alarm. The default is 24 hours.

20.9 smtptls Option Under alarm

The smtptls Alarm options specifies whether to use TLS for SMTP connections; that is, whether alarm uses the SMTP extension STARTTLS and negotiates TLS use.

Chapter 21 Auth options

A number of options may be set under the auth group to affect authentication in general.

For debugging of authentication, see also the debugkeys option. For the format for addresses used in authentication, see also the ldap_domain_attr_uid_separator and loginseparator Base options and defaultdomain IMAP, POP, and MMP *et al.* option.

Caching of authentication results is controlled by the authcachesize and authcachettl Base options.

Regarding client certificate based authentication, see also the Base certmap options.

For configuration of authentication use for SMTP message submission, see TLS and SASL channel options and Password and TLS MTA options and the AUTH_ACCESS mapping table.

For tracking and penalization of "bad guy" failed authentication attempts, see the bg* options such as bgpenalty, settable at Base, IMAP, POP, and IMAP Proxy and POP Proxy levels. Or for monitoring or penalizing failed SMTP AUTH attempts, see various example uses of the LOG_ACTION mapping table.

See also the allowanonymouslogin option available under imap, pop, and http.

21.1 authenticationldapattributes Option

The authenticationldapattributes Auth option specifies a space-separated list of additional LDAP user attributes to look up and pass to the third-party authentication server. This option is also available at imapproxy, popproxy, and vdomain level (to override, for the respective lookups, the general Auth option). To enable support for a third-party authentication server, set the authenticationserver option. For developer instructions and SDK see the directory msg_svr_base/examples/tpauth.

21.2 authenticationserver Option

The authenticationserver Auth option specifies the hostname and port for a third-party authentication service to use for authentication. This option is also available at imapproxy and popproxy level (to override, for the respective server, the general Auth option). The recommended value is :56 when a third-party authentication service is available on the loopback interface of the server process performing authentication. For developer instructions and SDK see the directory msg_svr_base/examples/tpauth.

When not set, the servers will authenticate via LDAP.

21.3 auto_transition Option

When the auto_transition Auth option is set to 1 and a user provides a plain text password, the password storage format will be transitioned to the default password storage method for the directory server. This can be used to migrate from plaintext passwords to APOP or CRAM-MD5.

21.4 broken_client_login_charset Option

Some mail clients violate the IMAP and POP standards that require usernames and passwords to be in US-ASCII for the LOGIN and USER/PASS commands. These broken clients may instead use another charset, such as UTF-8 or ISO-8859-1 for usernames and passwords. Note that standards compliant clients may use the SASL PLAIN mechanism for IMAP, POP and SMTP submission. SASL PLAIN requires use of the UTF-8 charset and thus supports multiple languages with interoperable codepoints.

When the broken_client_login_charset Auth option has the default value of UTF-8, clients that incorrectly send UTF-8 for the LOGIN or USER/PASS commands will be allowed to authenticate and will interoperate with clients that use standards-compliant SASL PLAIN usernames and passwords.

When this option is set to the ISO-8859-1 value, then a three step workaround is enabled to attempt to achieve partially interoperable behavior:

1. First, the usernames and passwords are converted from ISO-8859-1 to UTF-8 and a standards-compliant search and bind to the LDAP directory is attempted. If this succeeds, the user is authenticated and everything works fine. If the search fails, then the username does not exist in the directory and the authentication fails.

2. If the standard bind fails, Messaging Server will attempt to use the ISO-8859-1 password in an LDAP simple bind operation (this step is compliant with the 1997 version of LDAP, but not the 2006 version of LDAP). Directory Server Enterprise Edition does not enforce the UTF-8 password restriction for simple bind and is thus compatible with this second step of the workaround. If this succeeds, the user is considered authenticated.

3. After a successful non-standard LDAP bind, Messaging Server will attempt to correct the incompliant password entry in the LDAP directory by writing the UTF-8 version of the password to the user's userPassword attribute. If this succeeds, subsequent authentications for that user will be faster and standards compliant and the user will be compatible with standard authentication mechanisms such as SASL PLAIN. When this step occurs a message is written to the log at notice log level.

Before setting this to a non-default value, customers should verify they have no other systems that perform LDAP simple bind operations with a charset other than UTF-8 to the LDAP server used by Messaging Server. LDAP clients that violate RFC 4511 in that way will not interoperate with standard use of SASL PLAIN or this workaround.

For step 3 to operate correctly, the Messaging Server End User administrator (as specified in the ugldapbinddn option) must have write access to the userPassword attribute. The LDAP Access Control Instructions (ACI) set up by Messaging Server's configure utility do not include this write access, so the LDAP ACI titled Messaging Server End User

Adminstrator Write Access Rights on the user/group tree must be updated to add userPassword to the attribute list. See the Directory Server documentation for instructions on editing Directory Server Access Control.

21.5 canonicalsearchfilter Option

The canonicalsearchfilter Auth option value is used when locating a user in an LDAP domain using the user's canonical identity. When a user authenticates, a translation is done from authentication identity to canonical identity. With default settings there is no difference between these two identities and the search filters are the same. However, if a site wishes to have users authenticate using an attribute other than uid, then these identities can be different and thus different search filters are needed for authentication user lookup and canonical user lookup. The syntax is the same as inetDomainSearchFilter (see schema guide).

For Messaging Server 8.0.2, the default was changed to use %P as the attribute name instead of 'uid'. The %P substitution refers to the LDAP attribute name specified by the ldap_permid option. This means it is only necessary to change the ldap_permid option to control the canonical user identity.

21.6 has_plain_passwords Option

The has_plain_passwords Auth option is a boolean to indicate that the directory stores plaintext passwords, which enables APOP and CRAM-MD5.

21.7 requireauthenticationserver Option

The requireauthenticationserver option is available under auth and under imapproxy and popproxy.

When an authentication server is configured using the authenticationserver option, and requireauthenticationserver is 1 (the default), that server must be running and responding to requests or authentication will not succeed. If requireauthenticationserver is set to 0, then built-in authentication mechanisms will be permitted even if the authentication server ceases to respond to requests.

21.8 searchfilter Option

The searchfilter Auth option specifies the default search filter used to look up users for basic authentication and identity purposes when one is not specified in the inetDomainSearchFilter for the domain. The syntax is the same as inetDomainSearchFilter (see schema guide).

21.9 searchfordomain Option

By default, the authentication system looks up the domain in LDAP following the rules for domain lookup, and then looks up the user. However, if the searchfordomain Auth option is set to "0" rather than the default value of "1", then the domain lookup does not happen and a search for the user (using the searchfilter option's value) occurs directly under the LDAP tree specified by the ugldapbasedn option. This is provided for compatibility with legacy single-domain schemas, but use is not recommended for new deployments as even a

small company may go through a merger or name change which requires support for multiple domains.

21.10 usedomainmap Option

The `usedomainmap` Auth option controls whether to look up domains prior to locating users when performing authentication. If disabled, then search the entire user/group subtree when authenticating a user.

Note that the `imsimta test -domain_map` utility can perform certain basic checks of domain layout validity.

Chapter 22 sectoken options

The only security token option is `tokenpass`, which may be set inside a named `sectoken` group, taking the place in Unified Configuration of settings made in the `sslpassword.conf` file in legacy configuration.

22.1 `tokenpass` Option

The `tokenpass` option is set inside a named `sectoken` group; this Unified Configuration setting takes the place of what in legacy configuration would be set as a *`token-name`*`:`*`password`* pair inside the `sslpassword.conf` file.

When configuring Secure Sockets Layer (SSL) or Transport Layer Security (TLS), the private keys are stored in a configuration private key file (presently `key8.db`) or a physical hardware device. These storage locations are collectively referred to as tokens. The private keys are typically encrypted with a password that the server requires to accept an SSL or TLS connection. The password for a given token is stored in the `tokenpass` option in a `sectoken` group whose name is the name of the token. The default software token's name is "`Internal (Software) Token`".

For instance, the legacy configuration setting in the `sslpassword.conf` file of:

```
Internal (Software) Token:whatever
```

would be set using Unified Configuration as:

```
msconfig> set "sectoken:Internal (Software) Token.tokenpass" whatever
```

Chapter 23 Deployment Map options

Several options relate to the Deployment Map service.

See also the `properties` Base option.

Note that msprobe can probe for whether the Deployment Map server is running; see msprobe's probe options.

23.1 `enable` Option Under deploymap

The `enable` Deployment Map option, `deploymap.enable`, enables use of the Deployment Map service. Whether to run as a client or server is specified with the `run_as_server` option. The default is to run as a client.

23.2 `capability_starttls` Option Under deploymap

The `capability_starttls` deploymap option, when set to `1` (the default), causes the Deployment Map server to enable the STARTTLS extension. Advertising TLS (SSL) support does not mandate its use. Requiring use of TLS (SSL) is accomplished with the `deploymap.sslusessl` option.

23.3 `debug` Option Under deploymap

The `debug` Deployment Map option, `deploymap.debug`, enables the generation of debug output in the Deployment Map server or client's log file.

23.4 `heartbeat` Option

Deployment Map clients keep their TCP connection open indefinitely to the Deployment Map server. Typically, there is only traffic over the connection when a client connects or disconnects or a change is made to the deployment map. Consequently, the TCP connection can remain silent for hours if not days. To prevent network hardware from closing the connection due to inactivity, the client periodically sends a simple heartbeat to the server. By default, this heartbeat is sent every 30 minutes plus or minus a random number of seconds. The period of this heartbeat is controlled with this option. To disable heartbeats entirely, specify a value of 0.

23.5 port Option Under deploymap

The port Deployment Map option, deploymap.port, specifies the TCP port on which the Deployment Map service listens for incoming TCP connections. The default is 4570.

23.6 properties Option

The properties base option and rolename option are used only during initial configuration by a Deployment Map client to convey information to a remote Deployment Map server.

23.7 run_as_server Option

The Deployment Map service consists of a single server running on one Messaging Server host, and all other Messaging Server hosts running Deployment Map clients. When the Deployment Map service is enabled, the host runs a Deployment Map client by default. To instead run a Deployment Map server, set this option to the value 1. The other hosts -- the clients -- should either not specify this option or, if they do specify it, set it to the value 0. Further, clients must specify the server_host Deployment Map option (local.deploymap.serverhost for legacy config). That option specifies the hostname or IP address of the host running the Deployment Map server.

23.8 server_host Option Under deploymap

The server_host Deployment Map option specifies the fully qualified hostname or IP address of the remote Deployment Map server. This option is only used when the run_as_server option is set to 0 (false) or not specified. Use the port option to specify the TCP port which the remote Deployment Map server listens on.

23.9 sslusessl Option Under deploymap

Setting sslusessl to 1 instructs Deployment Map clients and servers to require the use of SSL (also known as TLS). When enabled on the server, the server will not allow clients to authenticate without first having successfully negotiated SSL. When enabled on the client, the client will negotiate SSL before attempting to authenticate. If the server does not advertise the TLS capability, then the client will not authenticate.

A server with this option enabled must also have the deploymap.capability_starttls option enabled (local.deploymap.capability.starttls in a legacy configuration).

23.10 userid and passwd Options

The userid and passwd Deployment Map options (local.deploymap.userid and local.deploymap.passwd for legacy config) are the shared secret pair used by Deployment Map clients to authenticate with the Deployment Map server. They will be sent in the clear unless the use of SSL has been enabled with the deploymap.sslusessl Deployment Map option (local.deploymap.sslusessl in legacy configuration).

A password and userid pair must be used in order for a client to connect to the Deployment Map server and be recognized by the server as being online. Without the authentication pair,

a client may only request the current deployment map file and list of online hosts. This shared secret pair must also be used to add or remove a host from the deployment map file.

Chapter 24 rollovermanager options

The Messaging Server's `rollovermanager` process performs time-based roll over for nslog-style log files. Criteria for log file "roll over" for these components is configured via the usual `logfile` options for the respective service.

The `rollovermanager` log file is controlled by `rollovermanager.logfile.*` options and the process is controlled by `rollovermanager.enable`.

For 8.0, the rollover manager only performed time-based rollover for three log files (imap, pop, transactlog). This was expanded to cover all log files with the 8.0.2 release.

24.1 `enable` Option Under rollovermanager

The `enable` rollovermanager option enables its operation.

Chapter 25 Messaging Server Ports

The Messaging Server uses different TCP (and UDP) Ports for different services. Some of these are intended for use by end-users, some for use by the deployment, and some for use only by the local host. This table lists the ports used by the product and their typical values. It's important to appropriately configure firewalls to only expose the intended ports.

Table 25.1 Table of TCP/IP Ports used by Messaging Server

Service	Port	Usage	Option	Description
Cassandra client	9042	product deployment	`store.casconnectpoints`	Cassandra Query Protocol used by Cassandra Message Store.
Certificate Port	55443	product deployment	`http.cert_port`	Private certificate validation protocol for Convergence S/MIME client.
ClamAV Port	3310	product deployment	PORT ClamAV plugin option	Used to talk to ClamAV via libclamav.so spam filter plugin.
dbreplicate server & client	55000	product deployment	`store.dbreplicate.port`	Berkeley DB replication for classic store automatic failover.
DNS client	53 (UDP & TCP)	nameserver in `/etc/resolv.conf`	N/A	DNS client used for MTA MX lookups, DNS RBL lookups, etc.
Elasticsearch client	9200	product deployment	`elasticsearch.port`	Port used to communicate with Elasticsearch.
ens	7997	product deployment	`ens.port`	Non-SSL product internal event notification service. Client port is specified via the `ensport` notifytarget option with `ensusessl` determining if SSL is used.
ens ssl	8997	product deployment	`ens.sslport`	SSL product internal event notification service.
icap client	1344	product deployment	PORT ICAP plugin option	Typically used to talk to Nortan AV via libicap.so spam filter plugin; RFC 3507.
imap	143	end-user (or product deployment with MMP)	`imap.port`	Non-SSL Internet Message Access Protocol (IMAP) RFC 3501.
imaps	993	end-user (or product deployment with MMP)	`imap.sslport`	SSL Internet Message Access Protocol (IMAP) RFC 8314, RFC 3501.
isc client	8070	product deployment	`isc_client.server_port`	Indexed search converter service used to support Elastic Search and Cassandra store search. Use `isc_client.sslusessl` to control SSL
isc server	8070	product deployment	`isc.server_port`	Indexed search converter service used to support Elastic Search and Cassandra store search. Use `isc.sslusessl` to control SSL
job controller	27442	host internal	`job_controller.tcp_ports`	Internal service used to notify job controller of message enqueues.
LDAP client	389 or 636	product deployment	`base.ugldapport`	Lightweight Directory Access Protocol (LDAPv3) RFC 4511 used for domain, user, and group lookups and authentication. Use 636 for SSL.
LMTP client	225	product deployment	`channel:tcp_lmtpcs.port`	Local Mail Transfer Protocol product interface based on RFC 2033.
LMTP server	225	product deployment	`dispatcher.service:LMTPSS.tcp_ports`	Local Mail Transfer Protocol product interface based on RFC 2033.
ManageSieve server	4190	end-user	`dispatcher.service:MANAGESIEVE.tcp_ports`	Protocol for managing Sieve scripts in RFC 5804.
memcache client	11211	product deployment	`mta.memcache_port`	A de-facto standard protocol used to talk to a fast key/value database typically used for deployment-wide tracking, metering, and rate-limiting.
metermaid client	63837	product deployment	`metermaid_client.server_port`	Product private RAM database similar to memcached. Use of memcached/Redis is recommended instead of metermaid for newer deployments.
metermaid server	63837	product deployment	`metermaid.port`	Product private RAM database similar to memcached. Use of memcached/Redis is recommended instead of metermaid for newer deployments.
mmp-imap	143	end-user	`imapproxy.tcp_listen:imapproxy1.tcp_ports`	Non-SSL MMP IMAP proxy RFC 3501.
mmp-imaps	995	end-user	`imapproxy.tcp_listen:imapproxy1.ssl_ports`	SSL MMP IMAP proxy RFC 8314, RFC 3501.

mmp-pop3	110	end-user	`popproxy.tcp_listen:popproxy1.tcp_ports`	Non-SSL MMP POP3 proxy RFC 1939.
mmp-pop3s	993	end-user	`popproxy.tcp_listen:popproxy1.ssl_ports`	SSL MMP POP3 proxy RFC 8314, RFC 1939.
mtqp client	1038	product deployment or intranet deployments	`mta.mtqp_port`	Message Tracking Query Protocol (RFC 3887) with private extensions for message recall.
mtqp server	1038	product deployment or external tracking/recall clients	`dispatcher.service:MTQP.tcp_ports`	Message Tracking Query Protocol (RFC 3887) with private extensions for message recall.
pop3	110	end-user (or product deployment with MMP)	`pop.port`	Non-SSL Post Office Protocol version 3 (POP3) RFC 1939.
pop3s	993	end-user (or product deployment with MMP)	`pop.sslport`	SSL Post Office Protocol version 3 (POP3) RFC 8314, RFC 1939.
Redis client	6379	product deployment	`redis.port`	Protocol used to talk to a Redis server key/value database typically used for deployment-wide tracking, metering, and rate-limiting.
Redis sentinel client	26379	product deployment	TBD	Protocol used to talk to a Redis sentinel server to determine the active Redis master host for a named Redis master/slave pool.
smpp client	none	product deployment	`sms_gateway.smpp_relay.server_port`	Relay port for SMS gateway via Short Message Peer-to-Peer (SMPP) service.
snmp server	161 (UDP)	product deployment	`snmp.port`	SNMP monitoring port (RFC 2789, RFC 3411-3418).
smtp server	25	Internet MTAs	`dispatcher.service:SMTP.tcp_ports`	Simple Mail Transfer Protocol Relay Service (SMTP relay) RFC 5321.
Socks client	1080	product deployment	`socksport` channel option	Used to traverse a SOCKS 5 firewall (RFC 1928, RFC 1929).
Solr client	8983	product deployment	`store.solrconnectpoints`	Used by Cassandra store to bootstrap Datastax Solr search indexing. No longer used starting with Messaging Server 8.1.
Spamd client	783	product deployment	PORT Spam Assassin plugin option	Used to talk to Spam Assassin via libspamass.so spam filter plugin.
submission client	25	product deployment	`http.smtpport`, `alarm.noticeport`	Webmail & alarm SMTP Message Submission RFC 6409.
submission server	587	end-user	`dispatcher.service:SMTP_SUBMIT.tcp_ports`	Non-SSL Message Submission (SMTP submission) RFC 6409.
submissions server	465	end-user	`dispatcher.service:SMTP_SUBMIT.ssl_ports`	SSL Message Submission (SMTP submission) RFC 8314, RFC 6409.
watcher	49994	host internal	`watcher.port`	Private service to detect stressed and crashed processes for self-repair.
wmap / mshttpd	8990	product deployment	`http.port`	Non-SSL private webmail proxy layer between Convergence and IMAP, based on HTTP.
wmaps / mshttpd	8991	product deployment	`http.sslport`	SSL private webmail proxy layer between Convergence and IMAP, based on HTTP.

Part IV The Message Store

Messaging Server provides a Message Store for storing users' email, and provides servers that support email client access to user mail.

There are a great many options for controlling and modifying Message Store operation; besides general Base options, see specifically the Message Store options and Partition options. A few options relating to localization of automatically generated messages may be found under message_language_options.

For configuration of the servers that support email client access to user mail in the Message Store, see IMAP options, POP options, and MSHTTP options.

For configuration of some automatic maintenance jobs relating to the Message Store, see Scheduler task options.

Chapter 26 Message Store options

Many options for the Message Store are set directly under the store group, *e.g.*:

```
msconfig> set store.option-name option-value
```

Under the store group are also other named groups with their own additional options:

- archive
- checkpoint
- dbreplicate
- deadlock
- expire
- expirerule
- folderquota
- messagetype
- msghash
- privatesharedfolders
- publicsharedfolders
- purge
- relinker
- typequota

Options under a store subgroup may be set with a command of the form:

```
msconfig> set store.subgroup.option-name option-value
```

For example:

```
msconfig> set store.deadlock.checkinterval 12
```

A number of Message Store options from previous versions are now obsolete and have been deleted.

Note that options specifically about Message Store partition setup are grouped under the (top-level) partition group; they are not grouped under store.

Of course base level options, as they affect Messaging Server as a whole, can be significant for Message Store operation. But there are a couple of base level options that are particularly oriented towards the Message Store:

- dbtxnsync
- enablelastaccess
- dblockcount
- welcomemsg

26.1 enable Option Under store

The enable Message Store option, store.enable (Unified Configuration) or local.store.enable (legacy configuration), enables the Message Store when starting services. This option defaults to 0 if not set, but initial configuration normally enables the option.

26.2 admins Option

The admins Message Store option takes a space separated list of user ids with message store administrator privileges. The default is the user id admin. If single-valued or not set, the MMP will use this as the default value for its storeadmin option.

26.3 allowbadmailbox Option

The allowbadmailbox Message Store restricted option will disable certain mailbox validity checks in the message store. A value of 1 will disable Unicode normalization and a value of 2 will disable validity checks of the IMAP international naming convention. Use of this can have unpredictable results, including breaking ISS synchronization, causing backup problems and breaking IMAP clients. It exists primarily for testing purposes and as a contingency in case there are unexpected problems with ICU normalization. This option may be removed in a future release.

This option is ignored if Cassandra store is used or if an IMAP client negotiates UTF8=ACCEPT -- in both cases bad mailbox names are unconditionally forbidden.

Customers using ISS should never set this option on a production system; ISS requires all mailbox names to be RFC 5198 compliant.

26.4 autounsubscribe Option

Cassandra store only. The autounsubscribe Message Store option controls whether folders are unsubscribed by imapd automatically when they are deleted. The default is 1, meaning that folders are unsubscribed automatically. This option has no effect in classic store. Classic store does not unsubscribe folders automatically.

26.5 autorepair Option

The autorepair Message Store option may be set to repair damaged mailboxes automatically.

26.6 autorepairdebug Option

The autorepairdebug Message Store option enables the backup of mailbox index files, before repair, to the /storedebug subdirectory under the Messaging Server temporary file directory specified by base.tmpdir in Unified Configuration (local.tmpdir in legacy configuration). The maximum number of backup mailboxes is 10.

Note: Sites should remove the files and directories under /storedebug manually when they are not needed.

26.7 backupdir Option

The backupdir Message Store option specifies the directory for backup image of Message Store data.

26.8 backupexclude Option

The backupexclude Message Store option specifies mailboxes to be excluded from a backup operation. You can specify a single mailbox or a list of mailboxes separated by the "%" character.

See also the backup_group options.

26.9 cachepreviewlen Option

The cachepreviewlen Message Store option specifies the message preview cache record length. Save the first chunk of the message body in the cache file for fast preview access.

26.10 cachesynclevel Option

The cachesynclevel Message Store option controls the synchronization level for the store cache file, overriding the general synclevel value. 0: no sync, 1: data sync only, 2: data sync and metadata sync (that is, all file attributes, including access time and modification time).

If synclevel is at its default value (-1), then cachesynclevel defaults to 1. However, if synclevel has been set to a non-default value, then that value also becomes the default for cachesynclevel.

26.11 casconnectpoints Option

The casconnectpoints Message Store option specifies a space-separated list of Cassandra Cluster connect points (ip addresses). If not specified, this option defaults to the IPv4 loopback address (127.0.0.1). specified, this option defaults to the local host (127.0.0.1).

26.12 solrconnectpoints Option

The solrconnectpoints Message Store option specifies a space-separated list of Cassandra Cluster connect points (ip addresses) for IMAP solr search. If not specified, casconnectpoints is used.

26.13 msgconnectpoints Option

The msgconnectpoints Message Store option specifies a space-separated list of Cassandra Cluster connect points (ip addresses) for msg keyspace access. If not specified, casconnectpoints is used.

26.14 cacheconnectpoints Option

The cacheconnectpoints Message Store option specifies a space-separated list of Cassandra Cluster connect points (ip addresses) for cache keyspace access. If not specified, casconnectpoints is used.

26.15 casusername Option

The casusername Message Store option specifies the username for cassandra cluster authentication.

26.16 caspassword Option

The caspassword Message Store option specifies the password for cassandra cluster authentication.

26.17 casmetarf Option

The casmetarf Message Store option specifies the replication factor for the store meta keyspace. If not specified, this option defaults to 1.

26.18 casmsgrf Option

The casmsgrf Message Store option specifies the teplication factor for the store msg keyspace. If not specified, this option defaults to 1.

26.19 cassolrrf Option

The cassolrrf Message Store option specifies the replication factor for the store solr keyspace. If not specified, this option defaults to 1.

26.20 cascacherf Option

The cascacherf Message Store option specifies the replication factor for the store cache keyspace. If not specified, this option defaults to 1.

26.21 casmaxconnectionsperhost Option

RESTRICTED: The casmaxconnectionsperhost Message Store option specifies the maximum number of connections per host. If not specified, this option defaults to 500.

26.22 casnumthreadsio Option

RESTRICTED: The casnumthreadsio Message Store option specifies the number of IO threads that will handle Cassandra query requests. If not specified, this option defaults to 5.

26.23 cascasopretrycount Option

RESTRICTED: The cascasopretrycount Message Store option specifies the cassandra CAS operation retry count upon write timeout. If not specified, this option defaults to 3.

26.24 cascasopretryintervalinms Option

RESTRICTED: The `cascasopretryintervalinms` Message Store option specifies the cassandra CAS operation retry interval (in milliseconds) upon write timeout. If not specified, this option defaults to `10`.

26.25 caskeyspaceprefix Option

The `caskeyspaceprefix` Message Store option specifies a prefix to all Cassandra keyspace names used by the Message Store. This can be used to have multiple message stores in the same Cassandra ring. This should not be changed on an operational server. This option defaults to "ms_".

26.26 cascachedc Option

The `cascacheadc` Message Store option specifies the datacenter of the cache keyspace. This option defaults to "`DC1`".

26.27 casmetadc Option

The `casmetadc` Message Store option specifies the datacenter of the meta keyspace. This option defaults to "DC1".

26.28 casmsgdc Option

The `casmsgdc` Message Store option specifies the datacenter of the msg keyspace. This option defaults to "DC1".

26.29 cassolrdc Option

The `cassolrdc` Message Store option specifies the datacenter of the solr keyspace. This option defaults to "`DC1`".

26.30 checkdiskusage Option

The `checkdiskusage` Message Store option enables stopping messages from being delivered to a Message Store partition when the partition fills more than a specified percentage of available disk space. If disk usage goes higher than the specified threshold, the store daemon locks the partition and logs a message to the default log files. When disk usage falls below the threshold, the partition is unlocked, and messages are again delivered to the store.

See also the `alarm.system:diskavail.threshold` option which sets a threshold for disk availability below which an alarm message will be sent to the postmaster.

26.31 checkmailhost Option

The `checkmailhost` Message Store option enables checking that the user `mailhost` attribute matches this server.

26.32 cleanupage Option

The cleanupage Message Store option specifies the age (in hours) of an expired or expunged message before purge will permanently remove it. The minimum allowed value is 1; the maximum is 2400 (100 days).

26.33 cleanupsize Option

The cleanupsize Message Store option specifies the minimum number of expunged messages before purge will permanently remove them.

26.34 dbcachesize Option Under store

The dbcachesize Message Store option specifies the mailbox list database cache size. Setting the optimal cache size can make a big difference in overall Message Store performance. Cache efficiency can be determined by running *msg-svr-base*/imcheck -s.

As of Messaging Server 7.0.5, the default for the Message Store option dbcachesize is 67108864 (previously the default had been 16777216). Only values in the range 1048576-1073741824 (from 1024*1024 to 1024*1024*1024) will be used, with smaller values being silently adjusted up, while attempting to set a larger value will result in only this maximum being used (and a warning message, if warning level logging is enabled for the Message Store).

Note that there is also a separate dbcachesize option available at the Message Store msghash level, store.msghash.dbcachesize.

26.35 dblogregionmax Option

The dblogregionmax Message Store option sets the size of the underlying logging area of the mboxlist environment, in bytes. The log region is used to store filenames and commit records. The log region size should be at least (600 * number of message store processes) + (100 * max commit records) + 32000. Values in the range 131072-2097152 (from 128*1024 to 2*1024*1024) are permitted; the default is 655360 (640*1024).

26.36 dbnumcaches Option

The dbnumcaches Message Store option controls the number of mboxlist db caches. If dbnumcaches is 0 or 1, the cache will be allocated contiguously in memory. If it is *n* greater than 1, the cache will be broken up into *n* equally sized, separate pieces of memory. The maximum value permitted is 32.

26.37 dbregionmax Option

The dbregionmax Message Store option sets the maximum amount of memory to be used by shared structures in the mboxlist environment region. These are the structures used to coordinate access to the environment other than mutexes and those in the page cache. Values in the range 33554432-536870912 (from 32*1024*1024 to 512*1024*1024) are allowed, with the default being 33554432.

26.38 dbsync Option

The dbsync Message Store option affects flushing of store database data to disk. If this is set to 1, cached database information will be flushed to disk before the database file is closed.

26.39 dbtmpdir Option

The dbtmpdir Message Store option specifies the mailbox list database temporary directory. Defaults to /tmp/.ENCODED_SERVERROOT/store/, where ENCODED_SERVERROOT is composed of mail server user plus the $SERVERROOT with / replaced by _. *e.g.* /tmp/.mailsrv_opt_sun_comms_messaging64/store/

This is a directory which is very heavily accessed. If the disks that house the mboxlist database temporary directory are not fast enough at very large sites, performance problems might occur. As part of their performance and tuning steps, sites should take a note of this and define a value for this parameter which either points to a memory mapped file system, or which points to a location on a fast file system.

26.40 dbtype Option

The dbtype Message Store option specifies the Message Store type. Use 'bdb' for the classic message store based on files and Oracle Berkeley DB or 'cassandra' for the Cassandra message store. The Cassandra Message Store was introduced in Messaging Server 8.0.2 and presently requires Unified Config. See the installation guide for additional requirements to run Cassandra Mesage Store.

26.41 deadlockaggressive Option

A non zero integer *N* value for the deadlockaggressive Message Store option indicates aggressive deadlock resolution, combined by delaying transaction retries by *N* seconds.

26.42 defaultmailboxquota Option

The defaultmailboxquota Message Store option specifies the default mailbox quota in bytes, kilobytes, megabytes, or gigabytes, *i.e.*, 3221225472, or 3145728K, or 3072M, or 3G.

Note that the maximum value that will be handled properly is 4294967292K.

Note that there is a user level LDAP attribute for setting per-user mailbox quota (overriding for that user this Message Store defaultmailboxquota default quota). The user level LDAP attribute is normally named mailQuota, but see the ldap_disk_quota MTA option; and see also the ldap_domain_attr_disk_quota MTA option for defining a domain level LDAP attribute.

26.43 defaultmessagequota Option

The defaultmessagequota Message Store option specifies the default message quota (in number of messages).

Note that the maximum value that will be handled properly is 4294967292.

Note that there is a user level LDAP attribute for setting per-user message quota (overriding for that user this Message Store defaultmessagequota default quota). The user level

LDAP attribute is normally named mailMsgQuota, but see the ldap_message_quota MTA option; and see also the ldap_domain_attr_message_quota MTA option for defining a domain level LDAP attribute.

26.44 defaultpartition Option

The defaultpartition Message Store option specifies the default partition. The default is "primary". Only applicable on INBOX. Subfolders will be created in the partition of the parent folder.

For further configuration of partitions, see the Partition options.

26.45 diskusagethreshold Option

Specifies the disk-usage threshold for the partition-monitoring feature. (For details about this feature, see the checkdiskusage option in Unified Configuration, or the local.store.checkdiskusage parameter in legacy configuration). The value of diskusagethreshold is a percentage from 1 to 99.

26.46 encryptnew Option

RESTRICTED: The encryptnew Message Store option enables encrypting new messages.

26.47 ensureownerrights Option

By default, the Message Store grants list and administer rights to a folder's owner. If the ensureownerrights Message Store option is set to "0", however, then these owner rights can be removed in order to create hidden folders.

26.48 expiresieve Option

The expiresieve Message Store option enables use of Sieve scripts in store.expirerule file rule sets; it particular, it enables application of sieve attributes in such files.

26.49 expungesynclevel Option

The expungesynclevel Message Store option specifies the synchronization level for the store expunge file, overriding the general synclevel value. 0: no sync, 1: data sync only, 2: data sync and metadata sync (that is, all file attributes, including access time and modification time).

If synclevel is at its default value (-1), then expungesynclevel defaults to 1. However, if synclevel has been set to a non-default value, then that value also becomes the default for expungesynclevel.

26.50 finalcheckpoint Option

If the finalcheckpoint Message Store option is set to 1, then the Message Store performs a final checkpoint of the transaction log before closing the mailbox list database.

26.51 folderlockcount Option

The folderlockcount Message Store option sets the maximum number of folder locks. The minimum allowed value is 1000; the maximum is 100000.

26.52 indexeradmins Option

The indexeradmins Message Store option takes a space separated list of user ids with Message Store indexer administrator privileges. The last access timestamp will not be updated when authenticating with a user id in this list.

26.53 indexmapreadonly Option

The indexmapreadonly Message Store option is a potential optimization for NFS on some operating systems. Normally Messaging Server opens the index file for read/write access and maps that file for read-only use. When this option is set, Messaging Server will open the index file twice, once in read/write and once in read-only mode and memory map the read-only file descriptor. This may reduce performance on some filesystems (due to the extra file open operation), but may be helpful if you're seeing high system CPU usage in munmap on NFS.

26.54 indexsynclevel Option

The indexsynclevel Message Store option specifies the synchronization level for store index file, overriding the general synclevel value. 0: no sync, 1: data sync only, 2: data sync and metadata sync (that is, all file attributes, including access time and modification time).

If synclevel is at its default value (-1), then indexsynclevel defaults to 1. However, if synclevel has been set to a non-default value, then that value also becomes the default for indexsynclevel.

26.55 keypass Option

RESTRICTED: Keystore password.

26.56 keylabel Option

RESTRICTED: The keylabel Message Store option specifies the label of the Message Store key in the keystore.

26.57 listimplicit Option

When the listimplicit Message Store option is set to "1", implicitly shared folders will appear in lists performed by store admins.

26.58 logexpungedetails Option

The logexpungedetails Message Store option controls whether details of expunge operation will be logged. If set to "1", expunge details will be logged. Starting with Messaging

Server 8.0.1, expunge details are logged to the transactlog if it is enabled. Starting with Messaging Server 8.0.2, when the transactlog is enabled, this option is ignored and the actions option controls whether expunge events are logged.

26.59 mailboxpurgedelay Option

The mailboxpurgedelay Message Store option When a mailbox is deleted by the end user, expunge all the messages and purge the data after store.cleanupage has expired. Expunged messages can be restored with 'mboxutil -R'. Expunged messages are moved to the new location when a mailbox is renamed.

26.60 maxcachefilesize Option

The maxcachefilesize Message Store option specifies the maximum cache file size (in bytes). A new cache file is created when the current cache file size has exceeded this limit. Minimum value is 1048576.

26.61 maxfolders Option

The maxfolders Message Store option specifies a maximum number of folders per user. Set to 0 (the default) for infinite.

26.62 maxlog Option

The maxlog Message Store option specifies the maximum number of allowable accumulated database transaction log files before the server is deemed unhealthy, after which msprobe will trigger a restart of stored.

26.63 maxmessages Option

The maxmessages Message Store option specifies a maximum number of messages per folder.

26.64 messagesynclevel Option

The messagesynclevel Message Store option specifies the synchronization level for store message file, overriding the general synclevel value. 0: no sync, 1: data sync only, 2: data sync and metadata sync (that is, all file attributes, including access time and modification time).

If synclevel is at its default value (-1), then messagesynclevel defaults to 1. However, if synclevel has been set to a non-default value, then that value also becomes the default for messagesynclevel.

26.65 overquotastatus Option

The overquotastatus Message Store option enables tracking of user quota status, thus enabling quota enforcement before messages are enqueued in the MTA and thereby reducing the potential for MTA queues to fill up. When set, and a user is not yet over quota, but an incoming message pushes the user over quota, then the message is delivered, but the

mailUserStatus LDAP attribute is set (by the Message Store) to overquota so no more messages will be accepted by the MTA.

Note that enbling the overquotastatus Message Store option causes the quotaoverdraft Message Store option to be enabled automatically.

26.66 perusersynclevel Option

The perusersynclevel Message Store option specifies the synchronization level for the store peruser file, overriding the general synclevel value. 0: no sync, 1: data sync only, 2: data sync and metadata sync (that is, all file attributes, including access time and modification time).

If synclevel is at its default value (-1), then perusersynclevel defaults to 1. However, if synclevel has been set to a non-default value, then that value also becomes the default for perusersynclevel.

26.67 pin Option

The pin Message Store option specifies a list of IMAP mailbox names -- in common terminology, folder names -- to protect from deletion or modification except by the Message Store Administrator. The format is as follows: "*mailbox1%mailbox2%mailbox3*", where *mailbox1*, *mailbox2* and *mailbox3* are the IMAP mailboxes to be protected (note that spaces can be used in mailbox names), and % is the separator between each mailbox.

For instance, if a Messaging Server administrator has used

```
# mboxutil -r mboxname mboxname partition
```

to move certain folders to a specified partition and wishes to ensure that the folders *stay* on that specified partition, rather than getting deleted and recreated on another partition, (for instance, has moved "Trash" and "Spam" folders to less expensive storage), then the administrator will also want to "pin" the folders in question, *e.g.*:

```
msconfig> set store.pin Trash%Spam
```

26.68 quotaenforcement Option

The quotaenforcement Message Store option enables quota enforcement. When off, the quota database is still updated, but messages are always delivered.

26.69 quotaexceededmsg Option Under store

The quotaexceededmsg Message Store option specifies the warning message to be sent to a user when a user's quota exceeds the warning threshold. In default operation (quotaoverdraft not enabled), the warning threshold is determined by the quotawarn Message Store option (legacy configuration, store.quotawarn). But when quotaoverdraft has been enabled, either explicitly or implicitly via overquotastatus, then instead the warning is generated only when a user actually exceeds their quota.

There is support for the following variable substitutions:

[ID]	userid
[DISKUSAGE]	disk usage
[DOMAIN]	user's domain (new in 8.0.1.3)
[NUMMSG]	number of messages
[PERCENT]	`store.quotawarn`percentage
[POSTMASTER]	postmaster address for user's domain (new in 8.0.1.3)
[QUOTA]	mailquota attribute value
[MSGQUOTA]	mailmsgquota attribute value

The message must contain a header (with at least a subject line), followed by `$$`, then the message body. The `$` represents a new line.

Note that the From: header line on the notification message will be:

```
From: Mail Administrator <Postmaster@base.hostname>
```

substituting in the value of `base.hostname` (or `local.hostname` in legacy configuration).

26.70 quotaexceededmsginterval Option

The `quotaexceededmsginterval` Message Store option specifies the interval (in days) to wait before sending another quota exceeded message.

26.71 quotagraceperiod Option

The `quotagraceperiod` Message Store option specifies the time (in hours) a mailbox must be over quota before messages to the mailbox will bounce back to the sender.

26.72 quotanotification Option

The `quotanotification` Message Store option enables quota notification for the Message Store. Such notification may include both an actual e-mail message, generated at a frequency controlled by the `quotaexceededmsginterval` Message Store option, and (if the user's e-mail client supports IMAP ALERT) also a notification pop-up on the user's e-mail client screen every time the user selects a mailbox.

Note that the `quotanotification` option must be disabled (at least temporarily) when using the `imquotacheck` utility to generate quota warning messages, so that the quota database's last-warn-time can be properly updated.

26.73 quotaoverdraft Option

The `quotaoverdraft` Message Store option is used to provide compatibility with systems that migrated from the Netscape Messaging Server. When set to `1`, the Message Store allows delivery of one additional message that puts disk usage over quota. After the user is over

quota, any additional messages are deferred or bounced, the quota warning message is sent, and the quota grace period timer starts. The option is treated as being enabled if the overquotastatus option is set.

Note that enabling quotaoverdraft means that quota enforcement does not start until *after* a user goes over quota, and in particular, means that the quotawarn Message Store option (used to warn users that they are nearing their quota limit when strict, no-overdraft, quota limits are in effect) does not take effect.

26.74 quotawarn Option

The quotawarn Message Store option specifies the percentage of quota that must be exceeded before clients are sent an over quota warning.

Note that such quota warning messages are only generated automatically when strict quota enforcement is in effect: that is, when the quotaoverdraft Message Store option is *not* enabled (whether explicitly or implicitly due to overquotastatus having being enabled). To generate quota warning messages before a user has exceeded their quota when quotaoverdraft is permitted, instead see the imquotacheck utility.

26.75 rollingdbbackup Option

The rollingdbbackup Message Store option controls whether rolling store database backups are made. The default is 1, meaning that such database backups are made.

26.76 searchengine Option

The searchengine Message Store option specifies the Message search engine type. Use 'iss' for the ISS search engine on Classic store (bdb); 'dse' for the DSE/Solr search engine on DSE Cassandra message store; Or, 'elastic' for the Elasticsearch engine on Classic message store and Cassandra store. The DSE Cassandra Message Store with Solr search engine was introduced in Messaging Server 8.0.2 and is no longer supported starting with Messaging Server 8.1. The Classic Store with Elasticsearch engine was introduced in Messaging Server 8.0.2.2. The Cassandra Message Store with Elasticsearch engine was introduced in Messaging Server 8.0.2.3. Both Open Source Cassandra and DSE Cassandra are supported. See the Index and Search section for additional requirements to run Elasticsearch. When searchengine isn't set, the messaging Server uses DSE/Solr on Cassandra store, ISS if ISS is enabled or brute force on Classic store.

26.77 seenckpinterval Option

The seenckpinterval Message Store option sets the peruser db archive interval (in number of hours). The default is 6. Set to 0 to disable peruser archiving.

26.78 seenckpstart Option

The seenckpstart Message Store option sets the initial hour of the peruser db archive after stored starts running. Allowed values are 0 (midnight) - 23 (11PM). The default is 0.

26.79 serviceadmingroupdn Option

The serviceadmingroupdn Message Store option specifies the DN of the service administrator group.

Normally initial configuration sets this option to a value of the form:

```
cn=Service Administrators,ou=Groups, <local.ugldapbasedn>
```

26.80 sharedfolders Option

The sharedfolders Message Store option enables shared folder listing and namespaces. SELECT and LSUB are not affected by this option. Users can SELECT their shared folders and use LSUB to list subscribed shared folders when this option is disabled.

26.81 snapshotdirs Option

The snapshotdirs Message Store option specifies the number of separate snapshots to store on disk. Minimum is 2. Recommend enough to be sure you have a good database back by the time you figure out the current one is beyond repair.

26.82 snapshotpath Option

The snapshotpath Message Store option specifies the path in which to copy the mboxlist directory. Permissions must be set for the message store owner. Snapshots will be placed in subdirectories.

26.83 subscribesynclevel Option

The subscribesynclevel Message Store option controls the synchronization level for store subscribe file, overriding the general synclevel value. 0: no sync, 1: data sync only, 2: data sync and metadata sync (that is, all file attributes, including access time and modification time).

If synclevel is at its default value (-1), then subscribesynclevel defaults to 1. However, if synclevel has been set to a non-default value, then that value also becomes the default for subscribesynclevel.

26.84 synclevel Option

The synclevel Message Store option specifies the default sync level for store files. -1: no default, 0: no sync, 1: data sync only, 2: data sync and metadata sync (that is, all file attributes, including access time and modification time).

The synchronization level may be set more specifically for particular types of Message Store files, overriding this general synclevel setting, via the more specific options messagesynclevel, cachesynclevel, indexsynclevel, expungesynclevel, perusersynclevel, and subscribesynclevel.

26.85 undeleteflag Option

When the undeleteflag Message Store boolean option is set, it causes imapd to set an explicit $undeleted message flag when the \Deleted flag is removed. This feature allows clients to detect when a previously deleted message is no longer deleted, which can be helpful when providing a gateway to a protocol that has to treat this scenario as if a new message arrived. The $undeleted message flag has no additional special semantics and may be set or cleared by clients if the IMAP ACL on the mailbox permits flag changes.

26.86 umask Option

The umask Message Store option specifies the file mode creation mask (in octal) for many files created by Messaging Server, including the MTA as well as the Message Store. By default, store file access by other users or users in the same group is forbidden by file permissions. Setting umask to '027' will allow users in the same primary group as the Messaging Server user to read subsequently created message store files. A more restrictive '037' setting may be appropriate for log file access. See also the filemode logfile option.

26.87 Message Store archive options

There are a number of options relating to the Message Store's facility for performing compliance archiving. (Note that if configured to perform archiving, the Message Store generates archive message copies when users perform IMAP APPEND operations. Message Store archiving is enabled by setting store.archive.compliance or See also use of the archive value of the action attribute in imexpire's store.expirerule files to perform archiving, rather than expiration, of messages meeting expiration rule set criteria. See also Archiving messages for discussion of configuring the MTA to generate archive message copies while messages are transitting the MTA.) Note that a list of such options and related topics may be obtained using the command:

```
msconfig> apropos archive
```

A Message Store archive option may be set using a command such as

```
msconfig> set store.archive.option-name option-value
```

See also the store.msghash.enable and store.msghash.nummsgs options.

See also the general discussion of Archiving messages.

New in MS 8.0.1, the Message Store supports generating archive message copies in Microsoft Exchange "envelope journaling" format, directed to some archival address; see the style, destination, and source_channel Archive options in particular.

New in MS 8.0.1, the Message Store no longer supports the operational archiving option. DELETED: operational.

For debugging of archiving operations, see also the archive keyword of the debugkeys option.

26.87.1 tmpdir Option Under archive

The tmpdir Message Store archive option specifies the temporary directory for archived message retrieval. If not set, the tmpdir Base option value (local.tmpdir in legacy configuration) is used.

On Linux, this option should instead be set to /dev/shm/.

26.87.2 compliance Option

The compliance Message Store archive option enables compliance archive.

26.87.3 operational Option

The operational Message Store archive option enables operational archive. DELETED: Removed in MS 8.0.2.

26.87.4 source_channel Option

The store.archive.source_channel option specifies the name of the MTA channel used to submit Microsoft Exchange Journal format messages. This option must be set (to the name of a valid MTA channel) when Message Store archive journal format is set (store.archive.style=3). It is recommended that a distinct MTA channel be created for this Message Store journal archive purpose, so that such submissions are clearly identifiable in the MTA message transaction logs.

26.87.5 destination Option

If set, the store.archive.destination option specifies the address where Exchange Journal format archive messages generated by message store compliance archiving are to be sent. If the option is not set, archive messages are sent to the addresses specified in the domain capture and user capture LDAP attributes associated with the user performing the IMAP APPEND operation.

26.87.6 style Option

The store.archive.style option controls the archive format that is created by store compliance archiving. Currently the supported values are:

1. AXS:One
2. it.com format
3. Microsoft Exchange Journal format

The default value is 1, meaning AXS:One archiving is the default.

26.87.7 reportdir Option

Archive confirm report directory.

26.87.8 intext Option

The intext Message Store archive option controls whether or not address reversal processing is done while archiving to determine whether addresses are internal or external.

26.87.9 posteddatemode Option

The posteddatemode Message Store archive option controls how the Axs:One PostedDate field is populated. A setting of 0 uses the header Date: field. A positive value N that's less than 100 uses the date information from the Nth header Received: field counting from the top of the header. A negative value N greater than -100 uses the date information from the (-N)th header Date: field counting from the bottom of the header. A value of 100, the default, uses the IMAP message internal date.

26.87.10 useheaderrecipients Option

The useheaderrecipients Message Store archive option controls whether header recipient addresses (To:, Cc:, and Bcc: fields) are treated as specifying actual message recipients. In operational mode no envelope information is available, so header information is the only source of possible message recipients.

26.87.11 retrieveport Option

The retrieveport Message Store archive option specifies the archive retrieve server port.

26.87.12 retrieveserver Option

Archive retrieve server.

26.87.13 retrievetimeout Option

The retrievetimeout Message Store archive option specifies the archive retrieve timeout in seconds.

26.87.14 path Option Under archive

The path Message Store archive option specifies the archive injection directory.

26.88 Message Store checkpoint options

There are a few options relating to the Message Store's facility for checkpointing.

26.88.1 stresslimit Option

The stresslimit Message Store checkpoint option specifies the maximum stored checkpoint duration in seconds. Throttling starts when checkpoint duration exceeds this limit.

26.88.2 debug Option Under checkpoint

The debug Message Store checkpoint option (*i.e.*, store.checkpoint.debug), if set, enables stored checkpoint debug.

26.89 Message Store dbreplicate options

There are a number of options relating to the Message Store's facility for performing replication of its database. Note that a list of such options and related topics may be obtained using the command:

```
msconfig> apropos dbreplicate
```

A Message Store dbreplicate option may be set using a command such as

```
msconfig> set store.dbreplicate.option-name option-value
```

26.89.1 enable Option Under dbreplicate

Tne enable Message Store dbreplicate option enables the mboxlist database replication feature.

26.89.2 port Option Under dbreplicate

The port Message Store dbreplicate option specifies the mailbox list database replication TCP port number. The default is 55000. This will be used to listen for incoming connections.

26.89.3 dbremotehost Option

The dbremotehost Message Store dbreplicate option specifies a space separated list of remote hosts in the replication group. Host format is *host*[:*port*]. If *port* is not specified, default port number 55000 is used. If this is not set, but a storehostlist value is set for a proxy group including the current server, then this will default to the value of that storehostlist setting.

26.89.4 dbpriority Option

The dbpriority Message Store dbreplicate options specifies the replication site priority in group elections. A special value of 0 indicates that this site cannot be a replication group master.

26.89.5 twosites Option

The twosites Message Store dbreplicate option enables two sites replication. When this option is disabled, the Message Store cannot take over as master if the original master fails in a replication group with only two sites. In the event this happens, the Message Store cluster will be unavailable for write access. A two-site replication group is vulnerable to duplicate masters when there is a disruption to communications between the sites. You should strongly consider having three or more electable sites in your replication group. All sites in the group must have the same value for this option.

26.89.6 queuemax Option

The queuemax Message Store dbreplicate options specifies the replication manager incoming queue size limit.

26.89.7 ackpolicy Option

The ackpolicy Message Store dbreplicate option controls the replication manager transaction commit acknowledgment policy. All nodes in a cluster must have the same policy. Valid values are:

- 0 = Do not wait for any client replication message acknowledgments.
- 1 = Wait until at least one client site has acknowledged.
- 2 = Wait until at least one electable peer has acknowledged.
- 3 = Wait until it has received acknowledgements from the majority of electable peers.
- 4 = Wait until all electable peers have acknowledged.
- 5 = Wait until all connected clients have acknowledged.
- 6 = Wait until all replicaton clients have acknowledged.

26.89.8 acktimeout Option

The acktimeout Message Store dbreplicate options specifies the amount of time, in seconds, the replication manager waits to collect enough acknowledgments from replication group clients, before giving up and returning a failure indication.

26.90 Message Store deadlock options

Under the deadlock group are a few Message Store options relating to deadlocks. See also the Message Store option (directly under store, rather than under store.deadlock) deadlockaggressive.

26.90.1 autodetect Option

The autodetect Message Store deadlock option sets whether all or just one thread resolves deadlock.

26.90.2 checkinterval Option

The checkinterval Message Store deadlock option specifies the sleep length in milliseconds between deadlock detections. Note that previous versions of the documentation for this option (such as provided by configutil -H) incorrectly stated the units as microseconds, but the implementation has always interpreted this as milliseconds.

26.91 Message Store expire options

The exploglevel option is presently the only Message Store option specifically set under the expire group.

Several former expire Message Store options have been deleted.

Additional Unified Configuration Message Store options relating to message expiry (but which are not specifically store.expire options) include:

- schedule.task:expire.crontab
- store.expiresieve
- store.expirerule.* options
- store.cleanupage
- store.mailboxpurgedelay

Also see the Scheduler options for the expire task:

- schedule.task:expire.enable
- schedule.task:expire.crontab

26.91.1 exploglevel Option

The exploglevel Message Store expire option specifies an expire log level.

- 0: no log.
- 1: log summary for the entire expire session.
- 2: log one message per mailbox expired.
- 3: log one message per message expired.

26.92 Message Store expirerule options

There are two separate ways to configure the Message Store's rules for expiring (purging) old (or otherwise undesired) messages. Global expiration rules *can* be defined via Message Store expirerule options (or the corresponding configutil parameters in legacy configuration), as discussed below; however, the preferred (more flexible, and more performant) approach is to define expiration rules using store.expirerule files. See the discussion of such files, as they allow more flexible, targetted rule sets (such as different per-user or per-partition rules), and they support additional criteria, and their use is more efficient for larger numbers of rules.

There are a number of options relating to the Message Store's rules for expiring (purging) old (or otherwise undesired) messages. Note that a list of such expiration rule options and related topics may be obtained using the command:

```
msconfig> apropos expirerule
```

A Message Store expirerule option may be set using a command such as

```
msconfig> set store.expirerule.option-name option-value
```

See also Message Store expire options for a list of additional Message Store options relating to message expiry (but which are not expirerule options), and see the expiresieve Message Store option which can enable use of Sieve filter tests in expire rules, and the discussion of imexpire invoking spamfilter packages. For the scheduling of automatic execution of imexpire, see the Scheduler expire task.

26.92.1 deleted Option

Syntax: "and"|"or".

When the deleted Message Store expirerule option is set to "or", expire messages if the '\Deleted' IMAP system flag is set *or* other criteria in the expire rule are met. When set to "and", expire messages if the '\Deleted' IMAP system flag is set *and* other criteria in the expire rule are met.

26.92.2 exclusive Option

When the exclusive Message Store expirerule option is set to "1", it is the only rule applied even if other rules match the given criteria.

26.92.3 folderpattern Option

The folderpattern Message Store expirerule option specifies the folders for which the rule apply. The value must start with a "user/", which represents the directory *store-root*/partition/*/.

Syntax: POSIX regular expression. For examples, refer to imexpire folder patterns.

26.92.4 foldersizebytes Option

The foldersizebytes Message Store expirerule option specifies the maximum number of bytes in folder. Older messages will be expunged if this limit is exceeded.

26.92.5 messagecount Option

The messagecount Message Store expirerule option specifies the upper limit on number of messages to be kept in the specified folders. Older messages will be expunged if this limit is exceeded.

26.92.6 messagedays Option

The messagedays Message Store expirerule option specifies the upper limit on the age of messages in the specified folder(s), using for message age the time when a message was originally deposited into the Message Store; messages "old" in terms of original delivery to the Message Store can thus be deleted even if such a message has only recently been moved to the current folder. Compare with the expire rule file setting "savedays", which uses the time since a message was placed into the current folder.

26.92.7 messagesize Option

The messagesize Message Store expirerule option specifies the size of an over-sized message.

26.92.8 messagesizedays Option

The messagesizedays Message Store expirerule option specifies the days an over-sized message should remain in a folder.

26.92.9 seen Option

Syntax: "and"|"or".

When the seen Message Store expirerule option is set to "or", expire messages if the '\Seen' system flag is set *or* other criteria in the expire rule are met. When set to "and", expire messages if the '\Seen' system flag is set *and* other criteria in the expire rule are met.

26.93 Message Store folderquota options

Currently, the only Message Store folderquota option is enable.

26.93.1 enable Option Under folderquota

The enable Message Store folderquota option enables quota by folder.

26.94 Message Store messagetype and typequota options

The Message Store messagetype option enable enables Message Store message typing; by default, the standard MIME Content-type: header field is inspected, but optionally the messagetype option header may be set, for sites that wish to inspect an alternate header field (the Message-context: header field, defined in RFC 3458 (Message Context for Internet Mail) can be a good choice); then under messagetype the further integer-indexed mtindex groups of options contenttype and flagname specify the actual message types, and optionally a corresponding quotaroot may be set for purposes of type-specific quotas. That is, with the header Message Store messagetype option specifying what header field to inspect, then integer-indexed sets of mtindex options define the types themselves, where an integer-indexed mtindex contenttype option defines a value to recognize in that header field, and then the correspondingly indexed flagname Message Store messagetype mtindex option specifies the Message Store name to use for such messages; *e.g.*:

```
msconfig> set store.messagetype.enable 1
msconfig# set store.messagetype.header Message-context
msconfig# set store.messagetype.mtindex:1.contenttype voice-message
msconfig# set mtindex:1.flagname Voice
msconfig# set mtindex:2.contenttype fax-message
msconfig# set mtindex:2.flagname Fax
msconfig# set mtindex:3.contenttype pager-message
msconfig# set mtindex:3.flagname Pager
msconfig# set mtindex:4.contenttype multimedia-message
msconfig# set mtindex:4.flagname Multimedia
msconfig# set mtindex:5.contenttype text-message
msconfig# set mtindex:5.flagname Text
```

Sites that wish to perform Message Store message typing that find they are receiving messages lacking the header line which the site wishes to use as a basis for message typing decisions, (*e.g.*, receiving messages lacking Message-context:), may wish to consider configuring an MTA system level Sieve filter to add an appropriate header line based upon other message characteristics (*e.g.*, an addheader action based upon the message's outermost MIME Content-type: header line) to provide a basis for the Message Store's message typing.

Sites that wish to enforce per-message-type quotas would also set the enable Message Store typequota option, and define per-message-type quotas using the quotaroot option under Message Store messagetype with mtindex appropriately indexed for each type. For instance, continuing the above example (that is, assuming that five message types have already been defined as above), enabling use of user per-message-type quotas would involve:

```
msconfig# set store.typequota.enable 1
msconfig# set store.messagetype.mtindex:1.quotaroot Voice
```

```
msconfig# set mtindex:2.quotaroot Fax
msconfig# set mtindex:3.quotaroot Pager
msconfig# set mtindex:4.quotaroot Multimedia
msconfig# set mtindex:5.quotaroot Text
```

and then setting a user's actual quotas would mean setting the user's `MailQuota` LDAP attribute (quota on space) and/or `mailMsgQuota` LDAP attribute (quota on number of messages) with per-message-type value syntax; *e.g.*:

```
mailQuota: 80M;#Voice%40M;#Fax%10M;#Pager%5M;#Multimedia%20M;#Text%10M
mailMsgQuota: 10000;#Voice%300;#Fax%40;#Pager%300;#Multimedia%300;#Text%9000
```

26.94.1 enable Option Under messagetype

The `enable` Message Store `messagetype` option enables the Message Store's message typing feature.

26.94.2 enable Option Under typequota

The `enable` Message Store `typequota` option is checked only if Message Store message typing has been enabled (`store.messagetype.enable` is `1`). When Message Store message typing has been enabled, then setting `store.typequota.enable` enables quota by message type. To set different quotas for different message types, see the `quotaroot` Message Store `messagetype mtindex` option.

26.94.3 header Option

By default, Message Store message typing (if enabled -- see the `store.messagetype.enable` option) determines message type from the MIME Content-type: header field. The `header` Message Store `messagetype` option allows a site to inspect an alternate header field for Message Store message typing purposes.

26.94.4 contenttype Option

The `contenttype` Message Store `messagetypemtindex` option defines a message type. More specifically, each integer-indexed `mtindexcontenttype` value defines a string to recognize on the `store.messagetype.header` field, whereas the correspondingly integer-indexed `flagname` Message Store `messagetype mtindex` option specifies the Message Store name to use for such messages.

26.94.5 flagname Option

The `flagname` Message Store `messagetype mtindex` option specifies the flag name of a message type. The `flagname` option would always be used in conjunction with a (correspondingly indexed `mtindex`) `contenttype` option.

26.94.6 quotaroot Option

The `quotaroot` Message Store `messagetype mtindex` option specifies the quota root suffix for a message type. (See the IMAP QUOTA extension, RFC 2087.) The `quotaroot`

option would always be used in conjunction with a (correspondingly indexed `mtindex`) `contenttype` and `flagname` options.

Note that enforcement of different quotas for different message types will not occur unless the `enable` Message Store `typequota` option has been set (and of course also the user's LDAP entry must define different quotas in its `mailQuota` and/or `mailMsgQuota` LDAP attributes).

26.95 Message Store msghash options

A Message Store `msghash` option may be set using a command such as

```
msconfig> set store.msghash.option-name option-value
```

26.95.1 enable Option Under msghash

The `enable` Message Store `msghash` option enables message hash database.

26.95.2 dbcachesize Option Under msghash

The `dbcachesize` Message Store `msghash` option, `store.msghash.dbcachesize`, specifies the message hash database cache size. Only values in the range 524288-536870912 (from 512*1024 to 512*1024*1024) will be used (other values will be silently adjusted into that range), with the default being 8388608 (8*1024*1024).

Note that this `store.msghash.dbcachesize` option is separate from the `store.dbcachesize` option, which controls a different cache size.

26.95.3 nummsgs Option

The `nummsgs` Message Store `msghash` option specifies the message hash database size.

26.96 Message Store purge options

The Message Store has several options under the `purge` group:

- `count`
- `enable`
- `maxthreads`
- `percentage`

A Message Store `purge` option may be set using a command such as

```
msconfig> set store.purge.option-name option-value
```

Additional Message Store options that relate to purging of messages but which are *not* under `purge` include:

- `store.cleanupage`
- `store.cleanupsize`
- `store.mailboxpurgedelay`

- store.relinker.maxage
- store.relinker.purgecycle

Also see the Scheduler expire task options

- schedule.task:expire.enable
- schedule.task:expire.crontab

26.96.1 enable Option Under purge

The enable Message Store purge option, store.purge.enable (Unified Configuration) or local.purge.enable (legacy configuration), enables the purge server on start-msg startup. Initial configuration normally sets this option based on the setting of the enable Message Store option, store.enable (Unified Configuration) or local.store.enable (legacy configuration).

If store.enable is 0, the value of this option is ignored and the impurge daemon is not started. If store.enable is 1, the impurge daemon will run unless this option is explicitly set to 0.

Note that a setting of store.purge.enable=1 (whether set explicitly, or in effect due to store.enable=1) enables the Message Store impurge process to run as a daemon (server) process. Alternatively, it is possible to instead disable such a daemon process, store.purge.enable=0, and instead configure the Scheduler to execute an impurge command periodically, using a Scheduler task. impurge cannot be executed manually by an administrator, nor run by the Scheduler, if it is already running as a daemon process; attempting to run it again will result in an error in the Messaging Server default log file along the lines of:

```
[24/Feb/2009:14:47:15 +1100] hostname impurge[17986]: General Error: Could not get purge session lock. Possibly another impurge is running
```

26.96.2 count Option

The count Message Store purge option specifies the minimum number of expunged cache records (for a folder) before purge will permanently remove them. The minimum allowed value is 1; maximum is 1000000.

26.96.3 maxthreads Option Under purge

The maxthreads Message Store purge option specifies the maximum number of threads. The default is 64; the maximum value that will be used is 100; attempts to set a higher value will result in a value of 100 getting used.

26.96.4 percentage Option

The percentage Message Store purge option specifies the percentage of expunged cache records (for a folder) before purge will permanently remove them.

26.96.5 crontab Option Use With purge Under task

The crontab Scheduler task option for the purge task controls the interval for running imsimta purge, enabled with schedule.task:purge.enable (Unified

Configuration) which defaults to the value of `mta.enable`, (or in legacy configuration `local.schedule.purge.enable` which defaults to the value of `local.imta.enable`). `imsimta purge` removes older MTA log files. `schedule.task:purge.crontab` uses UNIX `crontab` format: minute hour day-of-month month-of-year day-of-week command arguments.

Initial configuration sets this to:

```
msconfig> show schedule.task:purge.crontab
role.schedule.task:purge.crontab = 0 0,4,8,12,16,20 * * * bin/imsimta purge -num=5
```

26.97 Message Store relinker options

A Message Store `relinker` option may be set using a command such as

```
msconfig> set store.relinker.option-name option-value
```

26.97.1 `enable` Option Under relinker

The `enable` Message Store `relinker` option enables real-time re-linking of messages in the append code, and `stored` purge. The `relinker` command-line tool may be run even if this option is off, however since `stored` will not purge the repository, `relinker -d` must be used for this task. Turning this option on affects message delivery performance in exchange for the disk space savings.

26.97.2 `maxage` Option

The `maxage` Message Store `relinker` option specifies the maximum age in hours for messages to be kept in the repository, or considered by the `relinker` command-line. `-1` means no age limit, that is, only purge orphaned messages from the repository. For `relinker` it means process existing messages regardless of age. Shorter values keep the repository smaller thus allow `relinker` or `stored` purge to run faster and reclaim disk space faster, while longer values allow duplicate message re-linking over a longer period of time, for example, when users copy the same message to the store several days apart, or when running a migration over several days or weeks.

26.97.3 `minsize` Option

The `minsize` Message Store `relinker` option specifies the minimum size in kilobytes for messages to be considered by run-time or command-line `relinker`. Setting a non-zero value gives up the `relinker` benefits for smaller messages in exchange for a smaller repository.

26.97.4 `purgecycle` Option

The `purgecycle` Message Store `relinker` option specifies the approximate duration in hours of an entire `stored` purge cycle. The actual duration depends on the time it takes to scan each directory in the repository. Smaller values will use more I/O and larger values will not reclaim disk space as fast. `0` means run purge continuously without any pause between directories. `-1` means don't run purge in `stored` (then purge must be performed using the `relinker -d` command).

26.98 Message Store shared folder options

Message Store `privatesharedfolders` options include:

- `restrictanyone`
- `restrictdomain`
- `shareflags`

Message Store `publicsharedfolders` options include:

- `user`

Other Message Store options relating to shared folders include:

- `store.listimplicit`
- `store.sharedfolders`

Other components with options relating to shared folders include:

- `proxyserverlist` base option
- `imap.immediateflagupdate`

26.98.1 `restrictanyone` Option

The `restrictanyone` Message Store `privatesharedfolders` option disallows regular users sharing private folders to anyone.

26.98.2 `restrictdomain` Option

Classic store only. The `restrictdomain` Message Store `privatesharedfolders` option disallow regular users sharing private folders to users in another domain. This option has no effect in cassandra store. Regular users cannot share private folders to users in another domain in cassandra store.

26.98.3 `shareflags` Option

The `shareflags` Message Store `privatesharedfolders` option controls whether private shared folders share `\Seen` and `\Deleted` flags across users.

26.98.4 `user` Option Under publicsharedfolders

The `user` Message Store `publicsharedfolders` option specifies the public shared folder owner's store user identity. For non-ASCII users or domains, this should use the Net-Unicode (RFC 5198) form of the user and domain (IDN A-labels should not be used).

Chapter 27 message_language options

There are a few options available for localizing certain automatically generated messages. These options may be set under named `message_language` groups, *e.g.*, `message_language:`*`language-name.option-name`*.

27.1 `quotaexceededmsg` Option Under message_language

The `quotaexceededmsg` option under a named `message_language` group specifies a localized message to be sent to user when quota exceeds the warning threshold. In default operation (`quotaoverdraft` not enabled), the warning threshold is determined by the `quotawarn` Message Store option (legacy configuration, `store.quotawarn`). But when `quotaoverdraft` has been enabled, either explicitly or implicitly via `overquotastatus`, then instead the warning is generated only when a user actually exceeds their quota.

There is support for the following variables:

[ID]	userid
[DISKUSAGE]	disk usage
[DOMAIN]	user's domain (new in 8.0.1.3)
[NUMMSG]	number of messages
[PERCENT]	`store.quotawarn`percentage
[POSTMASTER]	postmaster address for user's domain (new in 8.0.1.3)
[QUOTA]	mailquota attribute value
[MSGQUOTA]	mailmsgquota attribute value

The message must contain a header (with at least a subject line), followed by $$, then the message body. The $ represents a new line.

27.2 `welcomemsg` Option Under message_language

The `welcomemsg` option specified under a named `message_language` specifies a localized welcome message for new Message Store users. The maximum size is 1 MB.

Syntax: "$" line separators, with headers.

Chapter 28 Partition options

There are several options specifically concerning Message Store partitions. A `partition` option may be set using a command such as:

```
msconfig> set partition:primary.path partition1
```

For other, general Message Store configuration, see the Message Store options, such as `checkdiskusage` and `defaultpartition`.

28.1 `messagepath` Option

The `messagepath` partition option specifies the path name of a store partition containing the message files. If this is not a full path, this is relative to the `/store/partition` subdirectory of the DATAROOT data directory. If not specified, the value for the `partition:`*`partition-name`*`.path` option (in legacy configuration, the `store.partition.*.path` configutil parameter) is used.

28.2 `cachepath` Option

The `cachepath` partition option specifies the path name of a store partition containing the mailbox cache files. If this is not a full path, this is relative to the `store/partition` subdirectory of the data directory (DATAROOT). If not specified, the value for the `partition:`*`partition-name`*`.path` option (in legacy configuration, the `store.partition.*.path` configutil parameter) is used.

28.3 `path` Option Under partition

The `path` partition option specifies the path name of a Message Store partition. If this is not a full path, this is relative to the `store/partition` subdirectory of the data directory (DATAROOT).

The `partition:`*`partition-name`*`.path` value is also used as the default for the `messagepath` and `cachepath` partition options, if they are not set explicitly.

Note that message expiration rules for this partition may be stored in files located in this directory; see `store.expirerule` files.

28.4 `path` Option Use With primary Under partition

The `partition:primary.path` option specifies the path name of the primary partition; (if not a full path, this is relative to the `store/partition` subdirectory of the data directory).

Note that the `defaultpartition` Message Store option defaults to "`primary`" -- so the definition of the partition named "`primary`" normally defines the partition that the Message Store uses by default.

Chapter 29 backup_group options

Under backup_group, there is a single option, re_pattern.

See also the backupexclude Message Store option.

29.1 re_pattern Option

The re_pattern option under backup_group specifies the regular expression pattern used to select a group of user mailboxes for backup. If no patterns are specified for any backup groups, the backup group 'user' can be used (defined with the pattern '%') which matches all users.

Chapter 30 Store Transaction Log Format

Message store XML transaction logging is enabled by setting the `messagetrace.activate` option to `transactlog`. Both the MTA and store have legacy transaction log formats that are deprecated in favor of the XML format. For a discussion of the MTA XML logging format, see the log_format MTA option.

Each log entry is a self-closing XML entity with a two-letter entity name that contains attributes (also with two-letter names). New attributes may be added and the attributes may be re-ordered in any patch release, so use of an XML-aware parser is recommended. The content of the log is intended to be extended in a backwards-compatible format (with possible exceptions for a major release), unlike the legacy store messagetrace and server log formats which are unstable. Due to the size of transaction log files on busy systems, use of a SAX-style parser is recommended.

To control what actions are logged, use the actions option (unified configuration only). To control what attributes are logged, use the actionattributes option. Note that the MTA uses a different mechanism to control what is logged; see the Transaction logging MTA options section.

30.1 XML Log Attributes Always Present in Store Transaction log

The following attributes appear on all Store Transaction Log entries and are thus not mentioned in the event-specific descriptions below:

- `pi` - Process id (integer). Note that the MTA uses a different format for this attribute documented in the log_process option.
- `sn` - service name (e.g., imap, pop, imquotacheck)
- `ts` - time stamp. Both MTA & store use ISO 8601 format as of 8.0.2; but in 8.0 the store used a legacy timestamp format.

30.2 XML Log Common Attributes

The following attributes may appear on several XML log entry event types with largely consistent meaning. When these are mentioned in the 'Common' attribute list for an event type, they will be included unless disabled by the actionattributes option.

- `ma` - IMAP Mailbox name (internal form)
- `mi` - Message id

- `om` - Source mailbox for copy/rename (`ma` is destination mailbox)
- `si` - session id (IMAP & POP): a unique integer identifier for a client session/connection.
- `tr` - transport information (MTA & store). Prior to 8.0.2, the store only included the client's address and port in this field.
- `us` - User name: the canonial authorization user identity (the permanent identity of the primary mail account being accessed). For more information on user identifiers see User Identifiers. Can also be [unauthenticated] when appropriate. For the `ac` action, the string "Admin" is used when this can't be determined (typically for mboxutil).

30.3 XML Log Entity Names and Specific Attributes:

`ac` - Access Control Change (IMAP only). Attributes include:

- Common: `ma`, `si`, `us`
- `ao` - Old ACL using permanent user identifiers. New in 8.0.2.
- `an` - New ACL using permanent user identifiers. New in 8.0.2.
- `nt` - Old and new ACL with ':' delimiter (Messaging Server prior to 8.0.2 only).

`bm` - Big Memory Allocation Event (new in MS 8.0.2.2). Attributes include:

- `nt` - Big memory function (malloc, calloc, realloc)
- `sz` - Bytes allocated
- `fn` - Source filename of allocation
- `ln` - Source line number of allocation

`cp` - Copy Message Event (new in MS 8.0.2.2). Attributes include:

- Common: `ma`, `om`, `si`
- `mc` - number of copied messages
- `sz` - total size of copied messages
- `su` - source IMAP UID set for copy operation
- `uc` - destination IMAP UID set for copy operation
- `uv` - IMAP UIDVALIDITY for destination
- `nt` - Error message on copy failure (omitted on success, new in MS 8.1.0.5.0)

`co` - Socket Connection (open/close). Attributes include:

- Common: `si`, `tr`
- `ac` - Action code. First letter is 'O' for connection open and 'C' for connection close. Subsequent letters are extensible flags. See MTA transaction log entry format for the

meaning of the subsequent flags for the MTA. Subcodes that can be used by the MMP and store include:

- `D` - Closed due to DNS RBL
- `I` - Closed due to internal/config error
- `L` - Closed due to connection limit
- `P` - Closed due to broken pipe
- `R` - Closed due to connection reset
- `S` - Closed due to socket error
- `T` - Closed due to timeout
- `W` - Closed due to TCP Access wrap filter
- `F` - Closed due to force kill, imsconnutil -k

- `at` - Store only: will be 'ssl' if SSL was used at connection open time or empty string if SSL was not used.
- `br` - bytes received during connection (new in MS 8.0.2).
- `bs` - bytes sent during connection (new in MS 8.0.2).
- `fu` - flag update page scan count (new in MS 8.0.2.2). A large number indicates potentially significant server CPU consumed by this user's client.
- `nm` - number of mailboxes selected during session (new in MS 8.0.2, imap/pop only).
- `nt` - In 8.0, contains unstructured information about the connection at connection close. Removed in MS 8.0.2 in favor of separate attributes.
- `rr` - Reason connection was rejected (new in 8.0.2.1, MMP only)
- `sb` - Search body count (new in MS 8.0.2.2). This counts the number of messages mapped for searching purposes by this user. This does not count searches performed by ISS, DSE or elastic search.
- `sd` - Session duration with HHH:MM:SS format (new in MS 8.0.2).
- `td` - Time spent on DNS RBL lookups in milliseconds (new in MS 8.0.2.1, MMP only).

`ex` - Expunge Action (store IMAP expunge/expire). Attributes include:

- Common: `ma`, `mi`, `si`
- `mc` - Messages in mailbox (post-expunge). Prior to MS 8.0.2 this attribute combined `me` with the pre-expunge message count using a '/' delimiter.
- `me` - Messages changed (for `ex` action, messages expunged). New in MS 8.0.2.
- `mi` - Message Id. Note that when this attribute is enabled, a separate expunge log entry is created for each message. If this attribute is not enabled, then only one expunge entry is created for each expunge operation.

- `no` - Node name (local host name or remote client IP & port).

`fc` - Flag Change Action (store +/-flags). New in MS 8.0.2.2.

- Common: `ma`, `si`
- `ac` - Action code; one of "S" for set, "C" for clear or "R" for replace.
- `fl` - Flag list (space delimited)
- `me` - Number of messages changed
- `sq` - IMAP modification sequence for this change
- `uc` - UIDs changed in IMAP uid set format
- `uv` - IMAP UIDVALIDITY for mailbox

`fe` - Fetch Message Action (POP & IMAP only). Attributes include:

- Common: `ma`, `mi`, `si`, `us`
- `fd` - Fetch decoding (b64, qp or omitted) (8.0.2 IMAP only)
- `fo` - Offset to message part in stored message (8.0.2 IMAP only)
- `fp` - Fetch offset into message part (8.0.2 IMAP only)
- `om` - Alternate for `ma` code (8.0.1 POP only)
- `sz` - Actual bytes fetched. For 8.0.2 this is a number. For earlier 8.0 versions, this instead contains a string combining: fetch start offset ":" fetch data size or "Binary:" followed by the offset into the message, the offset into the decoded data and the fetch data size (IMAP only).
- `ui` - IMAP UID for message (8.0.2 IMAP only)

`li` - Login/Authenticate Action (store/MMP). Attributes include:

- Common: `si`, `tr`, `us`
- `ae` - Integer authentication error code; see `nt` for description. Omitted if not known (MMP only, new in MS 8.0.2.1)
- `at` - Authentication Type (SASL mechanism name, ssl-port-cert, anonymous or plaintext)
- `bd` - badness delay (seconds) before next authentication attempt (MMP only, new in MS 8.0.2.1)
- `cs` - Ciphersuite used followed by TLS version. If SSL/TLS is not used, this will be 'noSSL'.
- `nt` - Authentication Error or Reply
- `ph` - Proxy host name from mailHost or affinity config (MMP only, new in MS 8.0.2.1).
- `pt` - Proxy transport information (MMP only, new in MS 8.0.2.1)
- `ua` - User authentication identity. This is the user whose password is used to authenticate; which differs from `us` when administrative proxy authentication is used (new in MS 8.0.2).

- `uo` - Original user identity. This is the identity originally specified by the client prior to canonicalization (MMP only, new in MS 8.0.2.1)

`lo` - Logout action; (POP-only, only if poplogmboxstat is set). Attributes include:

- Common: `si`, `tr`, `us`
- `ct` - Unix timestamp of POP login.
- `mc` - Number of messages not marked for deletion.
- `sz` - Total bytes in messages not marked for deletion.

`ma` - Message Append Action. Attributes include:

- Common: `ma`, `mi`, `si`, `us`
- `cx` - alternate name for session identifier (MS 8.0.1 only).
- `sz` - Total bytes in the appended message.
- `ui` - IMAP UID for message
- `uv` - IMAP UIDVALIDITY for message

`is` - ISC Convertion Action. Attributes include:

- Common: `us`
- `ma` - The user-folderId information .
- `ui` - IMAP UID for message
- `sz` - Total bytes in the message.
- `ez` - Total bytes sent to ElasticSearch
- `it` - Indexing of document in Elasticsearch response time in microseconds

`mc`, `md`, `mr` - Mailbox Create, Delete, Rename Actions (IMAP only). Attributes include:

- Common: `ma`, `om`, `si`, `us`
- `fi` - partition name (classic store only)
- `rt` - Mailbox Rename duration (introduced in 8.1.0.1)

`ms`, `mu` - Mailbox Subscribe, Unsubscribe Actions (IMAP only). Attributes include:

- Common: `ma`, `si`, `us`
- `fi` - namespace (IMAP2bis only)

`qc` - Quota Change (IMAP only). Attributes include:

- Common: `si`, `us`
- `ur` - Quota Root

- dq - Disk storage quota (number in KB)

qe - Quota Exceeded Action (quotacheck tool only). Attributes include:

- Common: us
- dq - Disk storage quota (number in KB)
- du - Disk storage usage (number in KB)
- mq - Message count quota (number)
- mc - Message count used (number)
- qt - Overquota Trigger (numeric percentage)
- qr - Quota Rule Name ('General' if not using a rule file)

se - Search, Sort or Thread Mailbox (IMAP only). Attributes include: (new in 8.0.2.2)

- Common: ma, si
- mc - Number of matching messages
- nm - Number of mailboxes searched (only counts local mailboxes when remote shared folders are present).
- nt - Error message on search failure (omitted on success)
- sb - Search body count. This counts the number of messages mapped for searching purposes for this search. This does not count searches performed by ISS, DSE or Elasticsearch.
- sf - Search flags (Q=Message sequence search, U=Uid search, I=iss, D=dse, E=elastic, C=classic, T=Thread, X=Context, S=Sort, M=multi-mailbox search)
- td - Time passed during search in milliseconds (omitted if 0)

sl - Select Mailbox (IMAP only). Attributes include:

- Common: ma, si, tr, us

Chapter 31 Message expiration

Message expiration automatically removes messages from the Message Store based on configured criteria. For example, automatic expiration can selectively remove old messages, overly large messages, seen or deleted messages, messages with specific Subject: lines, messages of a certain type, *etc.*.

Note: Oracle Communications Messaging Server removes messages without giving a warning, so it is important to **inform users about message expiration policies**! Unexpected message removal can be a source of consternation for users and administrators.

Message expiration is performed by the `imexpire` utility. This utility may be run manually, and/or be configured to run automatically on a schedule as configured for the Scheduler's expire task.

The rules for what the `imexpire` utility (the expire task) does -- which messages it checks, for which expiration criteria -- may be controlled in two distinct ways. An older, and nowadays less preferred, method is to define global rules (applying to all messages and users) via Message Store expirerule options (corresponding to legacy configuration configutil parameters). The preferred method is to define the expiration rule via `store.expirerule` files.

For use of `imexpire` post-message-delivery to scan messages for spam or viruses, see `imexpire` invoking spamfilter pacakges.

31.1 `store.expirerule` files

The use of `store.expirerule` files (rather than Message Store `expirerule` options) is the preferred way to configure message expiration rules for the Message Store.

Multiple `store.expirerule` files may be configured, each located in the directory that pertains to the scope of the expiration rules. That is, rules that apply globally to the entire Message Store are located in one directory, rules that apply to a particular partition are located in a directory for that partition, while rules that apply to specific users are located in user-specific directories, which may be further scoped as applying only to a particular folder of that user. (This feature of scoped expiration rules is one of the benefits of using `store.expirerule` files, rather than Message Store `expirerule` options, as such options are inherently global and apply to the whole Message Store.)

1. The global message expiration rules are stored in the *`CONFIGROOT`*`/store.expirerule` file. (Note that each global rule will be checked against *every* user's *every* folder, potentially resulting in noticeable processing overhead depending upon the number of global rules and the number of users and folders. Therefore, in general, avoid putting any more expiration rules than necessary in this file; in particular, do not put partition, user, or folder rules in this global rules file.)

2. Partition message expiration rules are stored in the directory location specified by the corresponding partition's `partition:`*`partition-name`*`.path` value, so typically

DATAROOT/store/partition/*partition-name*/store.expirerule

3. User message expiration rules are stored as a:

   DATAROOT/store/partition/*partition-name/userid*/store.expirerule file.

   Alternatively, user message expiration rules may be stored in a partition store.expirerule file, but defined to apply to a user via the file's setting of a ruleset folderpattern attribute to a value user/*userid*.*

4. Folder-specific message expiration rules are stored as a:

   DATAROOT/store/partition/*partition-name/userid/folder*/store.expirerule

   file. Alternatively, user message expiration rules may be stored in a partition store.expirerule file, but defined to apply only to a folder via the file's setting of a ruleset folderpattern attribute to a value user/*userid/folder-name*

It is also possible to exclude specified users from the expiration rules via use of a expire_exclude_list file, located in the *CONFIGROOT* directory. (For instance, an administrator, postmaster, or archival address might be exempted from message expiration via this mechanism.) The format of the file is line oriented; the user ID of each user to be exempted from message expiration should be listed, one user ID per line of the file.

When imexpire runs, it will create one thread per partition; each partition thread will go through the list of user folders under its assigned partition, loading the relevantly scoped store.expirerule files as it goes. It checks each folder against the expiration rules applicable to that folder, and expunge messages as needed.

31.1.1 store.expirerule file rulesets

As of MS 6.2p4, the rules in a store.expirerule file can be grouped into *rule sets* by prefixing the attribute names with a textual *rule name*. For instance:

```
Rule1.regexp: 1
Rule1.folderpattern: user/.*
Rule1.messagedays: 30
Rule2.folderpattern: user/.*@example.org/.*
Rule2.messagedays: 15
```

The attributes which may be specified in a rule set are listed in imexpire Ruleset Attributes.

Table 31.1 imexpire Ruleset Attributes

Attribute	expirerule Option	Description (Attribute Value)
action	*None; expirerule options always operate as discard rule*	Specifies an action to perform on the messages matching the expiration rules. The possible values are: • discard -- discards the message. This is the default. • report -- prints the mailbox name, uid-validity, and uid to stdout. The message is not changed by this action. • archive -- archives the message with the Compliance and Content Management System. The message is not changed by this action. This is a form of operational archiving, and is no longer supported as of MS 8.0.2. • fileinto: *folder-name* -- files the message into the specified folder. The shared folder prefix can be specified to file messages to folders owned by another user. The original message is discarded if the fileinto operation is successful.

exclusive	exclusive	Specifies whether or not this is an exclusive rule. The default is 0 (this rule is not exclusive) If specified as exclusive, then only this rule applies to the specified mailbox(es) and all other rules are ignored. If more than one exclusive rule exists, the last exclusive rule loaded will be used. For example, if a global and a local exclusive rule are specified, the local rule will be used. If there is more than one global exclusive rule, the last global rule listed by configutil is used. (1 or 0)
expires		imexpire will select the message if the date value specified by an Expires: header field value is older than the expiration date based on the messagedays attribute value. If multiple expiration header fields are specified, the earliest expiration date will be used. (string)
expiry-date		imexpire will select the message if the date value specified by an Expiry-date: header field value is older than the expiration date based on the messagedays attribute value. If multiple expiration header fields are specified, the earliest expiration date will be used. (string)
folderpattern	folderpattern	Specifies the folders affected by this rule. The format must start with user/, which represents the directory *DATAROOT*/store/partition/*/. See imexpire folder patterns. (POXIX regular expression)
messagecount	messagecount	Maximum number of messages in a folder. Oldest messages are expunged as additional messages are delivered. (integer)
foldersizebytes	foldersizebytes	Maximum size of folder, in bytes, before the oldest messages are expunged when additional messages are delivered. (integer in bytes)
messagedays	messagedays	Number of days in the Message Store before message is expunged. (integer)
messagesize	messagesize	Maximum size of message, in bytes, before it is marked to be expunged. (integer in bytes)
messagesizedays	messagesizedays	Grace period: days an over-sized message should remain in a folder. (integer)
messageheader.*field-name*		Specifies a header field name and header field value string. The header field name and header field values are not case-sensitive, and regular expressions are not recognized. Example: Rule1.messageheader.Subject: Get Rich Now! Headers other than Subject: can be used. (string)
regexp		Enable UNIX regular expression in rules creation. If not set, IMAP expressions will be used. See imexpire folder patterns for further details. (0 or 1)
savedays		Number of days a message is saved in a folder until being expunged. (integer)
seen	seen	\Seen is an IMAP system flag set by the Message Store when the user opens a message. If the store.expirerule file rule set attribute seen is set to and, then the message must be seen *and* another rule criterion must be met before the rule is fulfilled. If the attribute seen is set to or, then a message only needs to be seen *or* another rule criterion be met before the rule is fulfilled. The default is and. (and or or)
sieve		A Sieve test specifying message selection criteria. Example: Rule17.sieve: header :contains "Subject" "Make money fast" In order for sieve attribute values to take effect, the expiresieve Message Store option must be enabled; they will be ignored otherwise. Note that by also using a rule set action of fileinto: *folder-name* in a rule set with a sieve test, an effect of performing a Sieve "fileinto" based on a Sieve test can be obtained; that is, the rule set's sieve value supplies the Sieve test and the rule set's action: fileinto: supplies the fileinto folder name. (string)
deleted	deleted	\Deleted is an IMAP system flag set by the Message Store when the user deletes a message. If the store.expirerule file rule set attribute deleted is set to and, then the message must be deleted *and* another rule criterion must be met before the rule is fulfilled. If the attribute deleted is set to or, then a message only needs to be deleted *or* another rule criterion be met before the rule is fulfilled. The default is and. (and or or)
join		(New in MS 7.0.4) join may only be specified(set 1) when exclusive rule is set . The default is 0. Specifying join: 1 means all rule criterias are combined as single rule. (0 or 1)
userflag.*flag-name*		(New in MS 7.0.5, as well as MS 7.0.4.24) Valid values are 'and' and 'or'; the default is 'and'. Specify user IMAP flags in expiration rules. For instance, the following rule expires those messages with the 'junk' flag set, and which are older than 30 days: messagedays: 30 userflag.junk: and
channel		(New in MS 7.0.5) Specify the name of an MTA channel as which to "run" for purposes of spam/virus filtering. In order for a channel attribute value to take effect, the expiresieve Message Store option must be enabled. (string)
rescanhours		(New in MS 7.0.5) When using imexpire to perform post-delivery spam/virus filtering, the rescanhours tells imexpire to rescan those message that have not been scanned for the specified number of hours. The default is 10. In order for any rescanhours attribute value to take effect, the expiresieve Message Store option must be enabled. (integer)

Note that discarded messages are only expunged at the end of the imexpire run, that is, only one expunge operation is performed on each folder.

31.2 imexpire folder patterns

Folder patterns can be specified using POSIX regular expressions, if the imexpire attribute regexp is set to 1. If the regexp attribute is not set (the default), IMAP expressions will

be used. The format is that the folder pattern must start with `user/`, followed by a pattern. imexpire folder pattern examples shows the both formats of folder pattern for various folders.

Table 31.2 imexpire folder pattern examples

Scope	Folder patterns (regexp: 0)	Folder patterns (regexp: 1)
Apply rule to all message in all folders of *userid*.	user/*userid*/*	user/*userid*.*
Apply to messages of *userid* in folder Sent.	user/*userid*/Sent	user/*userid*/Sent
Apply rule to entire Message Store.	user/*	user/.*
Apply rule to any folder named Trash, anywhere in any user's hierarchy.	user/*/Trash	user/.*/Trash
Apply rule to folders of users in hosted domain example.org.	user/*@example.org/*	user/.*@example.org/.*
Apply rule to folders of users in the default domain.	*Not applicable*	user/[^@]*/.*

31.3 imexpire and localized mailbox names

The IMAP protocol specifies that mailbox names use modified UTF-7 encoding. Messaging Server supports localized character sets on external interfaces so that mailbox names can be localized. Internally, however, the system converts the localized name to MUTF-7. Thus, a folder that has a localized mailbox name on a client will have a corresponding mailbox file name in MUTF-7. (Note that IMAP error messages will output mailbox names in MUTF-7 and not the localized character set.)

In general, most Message Store utilities that require mailbox names expect the names in the localized character set, although they may have an option flag that allows a different character set to be used. These utilities include `reconstruct`, `mboxutil`, `imsbackup`, `imsrestore`, and `hashdir`. However, `imexpire` requires that the mailbox name, specified as the attribute `folderpattern`, be in MUTF-7. Using a localized name will not work.

To obtain the appropriate `folderpattern` value for use with `imexpire`, it may be necessary to convert a localized mailbox name to the modified UTF-7 equivalent. This can be done using the `mboxutil -E` command as follows:

```
$ mboxutil -l -p user/han/*

  msgs  Kbytes last msg         partition   quotaroot mailbox

    57     100 2010/04/29 11:18 primary       5242880 user/han/INBOX
     1       1 2010/04/30 12:56 primary             -
user/han/multibyte-mailbox-name

$ mboxutil -l -E MUTF-7 -p user/han/*

    57     100 2010/04/29 11:18 primary       5242880 user/han/INBOX
     1       1 2010/04/30 12:56 primary             -
user/han/&kAFP4W4IMH8wojCkMMYw4A-
```

The output of the first `mboxutil` command shows the localized mailbox name. The output of the second `mboxutil` command shows the mailbox name in MUTF-7. The MUTF-7 mailbox name is identical to that shown in response to an IMAP LIST command:

```
x list "" *
```

```
* LIST (\NoInferiors) "/" INBOX
* LIST (\HasNoChildren) "/" &kAFP4W4IMH8wojCkMMYw4A-
```

To convert the local charset to modified UTF-7 encoding, use the mboxutil command's -E option:

```
$ mboxutil -l -E MUTF-7 -P user/han/multibyte-mailbox-name

  msgs  Kbytes last msg         partition   quotaroot mailbox

     1       1 2010/04/30 12:56 primary             -
user/han/&kAFP4W4IMH8wojCkMMYw4A-
```

Such a mboxutil -E command can be used in preparation for use of any utility that requires the use of an MUTF-7 mailbox name, including as discussed here in preparation to use imexpire.

Chapter 32 Store Index and search

The message store supports three index and search services: ISS, DSE Solr, and Elasticsearch. Note that DSE Solr is no longer available starting with the Messaging Server 8.1 release. Classic store supports ISS and Elasticsearch. DSE Cassandra store supports Solr and Elasticsearch. Open source Cassandra store supports Elasticsearch. The classic message store does not enable any index and search services by default. When index and search service is not enabled, IMAP uses brute force for body search. Brute force message body search is very I/O intensive. Consider using an index and search service when search performance is crucial.

When either Elasticsearch or DSE Solr is enabled, the message store uses ISC to convert binary message content to text before indexing. Therefore, ISC must be configured on when either Elasticsearch or DSE Solr is enabled. ISS has built-in content conversion, so ISC is not required.

ISC

Indexed Search Converter (ISC) is a Java and http-based server that converts message content to text for index and search purposes. ISC is included in the Messaging Server package and uses Apache Tika to detect and extract text content from email messages. The converted texts are cached. On indexing, the message store looks up the text content in the cache. If the text is found, the message store reads it from the cache. Otherwise, the message store sends the meta data to ISC. ISC reads the message content, converts it to text, and writes the text to the cache.

In classic store, ISC uses the file system to cache the text content. In Cassandra store, ISC uses Cassandra to store the cache content.

ISC requires read access to the message store in order to convert the content of a message. When used with classic store, ISC can be co-located with other message store processes or can run on a separate server with shared filesystem access to message store data.

Review the ISC Options for more information about configuring ISC.

Elasticsearch

Elasticsearch is a distributed search engine based on Lucene. It provides full text search services with built-in high availability, replication, horizontal scaling, and automatic load balancing. When Elasticsearch is enabled, the message store sends the message content to Elasticsearch for indexing when messages are appended to the mailboxes; the IMAP server sends search queries to Elasticsearch to perform textual searches.

To enable elasticsearch:

- set `store.searchengine` to `elastic`
- set `elasticsearch.hostlist` to a list of Elasticsearch hosts
- set `elasticsearch.numshards` to the number of shareds
- set `elasticsearch.numreplicas` to the number of replicas

- set `elasticsearch.storesource` to false if storage space is limited

Review the Elasticsearch options for more information about configuring use of Elasticsearch.

DSE Solr

Datastax Enterprise (DSE) Solr is an index and search component provided by Datastax. DSE Solr index and search is enabled by default when Cassandra message store is enabled prior to Messaging Server 8.1. Messaging Server provides the FIT plugin to prepare the message content for indexing. FIT must be installed on all the Solr nodes.

ISS

Oracle Communications Indexing and Search Service (ISS) is a separate index and search service developed by Oracle. The message store uses Glassfish MQ event notification services to send data for indexing to ISS and ISS re-synchronizes with the Message Store over IMAP. Starting with Messaging Server 8.0.2.2, ISS is deprecated and support for ISS may be removed in a future release of Messaging Server. Starting with Messaging Server 8.1, ISS is no longer included with Messaging Server and use of a previous version of ISS is only supported for the purpose of migrating from ISS to Elasticsearch.

Review the Indexer Options for more information about configuring use of ISS.

32.1 Migrating from ISS to Elasticsearch

The message store supports the following migration strategies:

Side by side migration

- Install a new message store.
- Enable Elasticsearch and ISC on the new message store.
- Migrate users from the old store to the new store with rehostuser.
- Decommission the old store when all the users are migrated to the new store.

In-place migration

- Upgrade the messaging server to 8.0.2.2.
- Enable Elasticsearch and ISC.
- Enable impurge if it is not enabled.
- Restart the server.
- Folders are scheduled for migration automatically when they are accessed.
- Run 'imcheck -H' to migrate all the folders.
- Remove ISS event notification target and ISS client configuration on the message store.

32.2 Migrating from DSE SOLR to Elasticsearch

The message store supports the following migration strategies:

Side by side migration

- Install an Elasticsearch cluster.
- Install a Cassandra cluster.
- Install a new message store.
- Enable Elasticsearch, Cassandra and ISC on the new message store.
- Migrate users from the old store to the new store with rehostuser.
- Decommission the old store when all the users are migrated to the new store.

In-place migration

- Install an Elasticsearch cluster.
- Upgrade the messaging server to the latest version.
- Enable Elasticsearch.
- Enable ISC and impurge if it is not enabled.
- Configure `store.solrconnectpoints` if it is not configured
- Restart the server.
- Folders are scheduled for migration automatically when they are accessed.
- Run 'imcheck -H' to migrate all the folders.
- Remove Solr configuration on the message store.
- Disable Solr in DSE cluster, or remove the Solr DC and update the mbox keyspace accordingly

32.3 Search Technology Comparison

Comparisons can be made based on various different criteria. The following sections cover some of the possibilities.

32.3.1 Substring vs. Indexed Search

The classic search technology built-in to imapd performs a substring search (a search term matches any word containing that substring). The indexed search technologies (Elasticsearch, DSE Solr, and ISS) use a word-based search where a search term must match an entire word (or root word). Wildcard options for indexed search are available, but add significant overhead so searches take longer and require more resources. It may be desirable to configure wildcard use for address headers. In order to strictly comply with the IMAP standard for searching, all textual searches must be configured as substring searches (using the `imap.indexer.substring_search` option). However, modern web searches tend to be

word-based so our product defaults to word-based searches for message text as we believe that behavior will be faster and familiar to end-users.

32.3.2 Search Complexity

Elasticsearch supports all searches that IMAP supports (flag and annotation terms in an IMAP search command are converted to UID lists by imapd). DSE Solr supports all searches; however the ANNOTATE extension (RFC 5257) is not implemented on Cassandra Store. ISS only supports a subset of search operations; see the `imap.indexer.enable` option for a description of ISS limitations.

32.3.3 Index Storage

Elasticsearch can store indexes on Elasticsearch local disk without the need for a storage array. Use of local SSD will reduce the number of nodes required in the Elasticsearch cluster for a given workload. Use of local SSD is recommended for DSE Solr search. Use of a storage array with fast iSCSI support is recommended for ISS.

32.3.4 Search Host Failures

The imapd Elasticsearch client will round-robin between hosts listed in the `elasticsearch.hostlist` option; it will periodically retry Elasticsearch hosts that were previously down. The message store ISC client will failover to a backup host if more than one host is listed in the `isc_client.ischosts` option; otherwise conversion will be deferred and performed by `impurge` later. The DSE Solr client will use the `store.solrconnectpoints` option to bootstrap a list of available DSE Solr servers; and DSE Solr uses the Cassandra Gossip protocol to stay current on the list of available Cassandra/Solr nodes as long as at least one of the nodes listed in `solrconnectpoints` is online when the server process starts. When the ISS host is unavailable, search will be performed by classic search. With ISS, it is important to keep your JMQ broker running reliably.

32.3.5 High Availability

Elasticsearch has built-in high availability; a minimum cluster size of three nodes is recommended. DSE Solr search uses Cassandra's high availability mechanism. A minimum cluster of three Cassandra-only and two Cassandra/Solr nodes is recommend for the msgindex table. ISS has no HA mechanism; a reliable filesystem is recommended and fallback to classic search occurs when ISS fails.

32.3.6 Data Growth

Elasticsearch and DSE Solr scale horizontally; as your data size grows you will need to add servers to your Elasticsearch or Cassandra clusters. For ISS, once the capacity of a message store or ISS server is exceeded; you must use the `rehostuser` tool to move users to a new message store with a new ISS server.

32.3.7 Reindexing

Elasticsearch will require a reindex when a classic store userid is renamed. However, rehostuser and renaming mailboxes will not require a reindex with Elasticsearch as long as source and target hosts share the same Elasticsearch cluster. Cassandra store supports separate

external and persistent userids so DSE Solr will not require a reindex when the external userid is changed. ISS requires a reindex of impacted content when a userid is renamed, rehostuser is used, or a mailbox is renamed.

32.3.8 Stop Words

In order to reduce the size of the index, English stop words are not included in the index by default for Elasticsearch and DSE Solr search. Stop words in a search query will match no messages if they are part of a single search key or are in a boolean OR clause. For Elasticsearch, stop words in an AND clause will match all messages. Stop words used in a wildcard search will only match text containing a word that contains the stop word as a substring.

32.3.9 Whitespace

The classic search ignores whitespace, so search terms will match across whitespace breaks. Whitespace is significant to indexed search technologies.

32.3.10 Punctuation

The classic search is punctuation sensitive. The indexed search technologies treat most punctuation as whitespace equivalent.

32.3.11 Diacritical Sensitivity

The classic search is case and diacritical insensitive by default. The `diacritical_sensitive_languages` option can be used to make classic search diacritical sensitive for certain languages. The indexed search technologies are diacritical sensitive by default.

32.3.12 Convergence/ISS Attachment Search

The attachment search feature is only available with ISS which is deprecated. If your deployment depends on this feature please contact Oracle support and explain how you use it to assist Oracle's determination on whether to implement an equivalent feature with Elasticsearch.

32.3.13 Non-IMAP Search API

ISS supports a non-IMAP search API via an HTTP-based protocol. At this time, Oracle reserves the right to make incompatible changes to the elasticsearch and DSE/Solr indexing models if that is necessary to improve the product (the odds of such changes will decrease over time). If you have a business use case that requires an HTTP-based search API please contact Oracle support for consideration of such a request.

32.4 Elasticsearch options

Elasticsearch options control IMAP search operations when the `searchengine` is set to `elastic`. See also the ISC Options and Indexer Options.

32.4.1 `hostlist` Option Under elasticsearch

The hostlist elasticsearch option specifies a space separated list of elasticsearch hosts. Host format is *host*[:*port*]. If *port* is not specified, the port number is determined based on the setting of the elasticsearch.port option.

32.4.2 port Option Under elasticsearch

The port elasticsearch option specifies the default elasticsearch server TCP port number. This is used if no port is specified in the elasticsearch.hostlist option. The default is 9200.

32.4.3 authusername Option Under elasticsearch

The authusername Elasticsearch option sets the username that will be used for HTTP basic authentication when communicating with Elasticsearch. The elasticsearch.authpassword option must also be set. This option is only used when the store.searchengine option is set to elastic.

32.4.4 authpassword Option Under elasticsearch

The authpassword Elasticsearch option sets the password that will be used for HTTP basic authentication when communicating with Elasticsearch. The elasticsearch.authusername option must also be set. This option is only used when the store.searchengine option is set to elastic.

32.4.5 sslusessl Option Under elasticsearch

The sslusessl Elasticsearch option will require use of SSL when communicating with Elasticsearch. This option is only used when the store.searchengine option is set to elastic.

32.4.6 storesource Option

The _source field in Elasticsearch contains the document body that was passed at index time. If elasticsearch.storesource is enabled, the message store will create the elasticsearch store/msg index mapping with the _source field enabled; IMAP copy will use the _source field from Elasticsearch to index the message on the destination folder. The _source field data consumes a lot of disk space. You might want to disable the _source field if storage space is limited. Disabling the _source field will disable the ability to reindex, upgrade or repair index from Elasticsearch. See https://www.elastic.co/guide/en/elasticsearch/reference/current/mapping-source-field.html before disabling this option.

32.4.7 numshards Option

The numshards field in Elasticsearch specifies the number of shards in the Elasticsearch message store index. The elasticsearch.numshards is used by stored to create the message store index in Elasticsearch. The number of shards cannot be changed after the index is created.

32.4.8 numreplicas Option

The numreplicas field in Elasticsearch specifies the number of replicas in the Elasticsearch message store index. The elasticsearch.numreplicas is used by stored to create the

elasticsearch message store index. The message store does not update the number of replicas after the index is created. The number can be updated in Elasticsearch manually.

32.5 Indexer options

Enabling the Messaging Server's ISS client (via `imap.indexer.enable=1` and a valid setting for the `imap.indexer.server_host` option) causes certain IMAP search and sort commands to be sent to ISS (the Indexing and Search Service). See the `imap.indexer.enable` description for more details.

There are several Indexer options further affecting Messaging Server's consultations of ISS. Also see the `indexeradmins` Message Store option, `store.indexeradmins`.

32.5.1 `enable` Option Under indexer

The `enable` Indexer option, if set to `1`, causes sending some IMAP search and sort commands to ISS, the Indexing and Search Service. The server_host Indexer option must also be set for this to function correctly. The ISS processes search operations based on words rather than substrings so results may not be IMAP standards compliant and may differ from a search performed by the IMAP server.

If the ESEARCH RETURN (ALL) result option is present in the search command, then ISS is used. For all other ESEARCH extension features, the ISS is not used. The ISS is not used if KEYWORD, HEADER, OLDER, YOUNGER, MODSEQ, ANNOTATION, or RECENT appear. At least one of the following search terms: SUBJECT, FROM, TO, CC, BCC, TEXT or BODY must be present for the ISS to be used. If an error occurs from the ISS, then the search may fall back to processing by the IMAP server. See the ISS documentation for details on what searches it supports as it may not support all combinations of AND, OR and NOT operators that IMAP supports. The specific rules of what is sent to the ISS and what is processed locally on the IMAP server may change in future releases.

The `bodytextonly` option modifies the above rules so that TEXT or BODY must be present or the search will not be sent to the ISS.

As of Messaging Server 7.0.5.30.0, the ISS is used to process IMAP ESEARCH commands with RETURN (ALL) result option. For all other ESEARCH extension features, the ISS is not used.

Also see the debugkeys option's `search` key to enable IMAP search and sort command related debug.

32.5.2 `port` Option Under indexer

The `port` Indexer option specifies the TCP port on which ISS listens for incoming TCP connections, *i.e.*, the TCP port to which Messaging Server should connect to communicate with ISS. The default is `8070`.

If the `indexer.sslusessl` option (`service.imap.indexer.sslusessl` option in legacy configuration) is set, the IMAP server uses SSL to authenticate to ISS on this port.

32.5.3 `server_host` Option Under indexer

The `server_host` Indexer option specifies the fully qualified host name or IP address where the Indexing and Search Server runs. This `indexer.server_host` option must

be set, to tell Messaging Server where ISS is running, if the IMAP server has been told via imap.indexer.enable=1 to consult ISS.

32.5.4 timeout Option Under indexer

The timeout Indexer option specifies the timeout in seconds for read and write operations between the IMAP server and ISS.

32.5.5 connecttimeout Option Under indexer

The connecttimeout indexer option , (indexer.connecttimeout in Unified Configuration, or service.imap.indexer.connectwait in legacy configuration), specifies how long in seconds the IMAP server should wait for a connection to be established to the Indexing and Search Service (ISS). Attempting to set this option to a value greater than 30 will result in a value of 10 being used.

32.5.6 bodytextonly Option

If the bodytextonly Indexer option is set to 1, then send IMAP search queries to ISS, the Indexing and Search Server, if the query contains BODY or TEXT terms and the query does not contain any search terms that ISS does not support.

32.5.7 substring_search Option

The substring_search Indexer option specifies which, if any, search parameters sent to an external searchengine, should be preceded and followed by a "*", so that a search for subject ear would match "searches" as well as "ear". The search parameter will not be preceded and followed by the '*' character, if it contains a space character or a double quote character or a opening parentheses in the beginning or a closing parenthesis at the end. The value given should be one or more of subject text body from to cc bcc separated by one or more spaces. Use with caution as this imposes a significant load on the search engine.

When the internal search engine is used, a substring match is always performed and this option is ignored.

32.5.8 suffix_search Option

The suffix_search Indexer option specifies which, if any, search parameters sent to an external searchengine should be followed by a "*", so that a search for subject book would match "bookmark" as well as "book". The search parameter will not be followed by the '*' character, if it contains a space character or a double quote character or a opening parentheses in the beginning or a closing parenthesis at the end. The value given should be one or more of subject text body from to cc bcc header separated by one or more spaces. The default is the empty string.

(Note that the meanings of suffix_search and prefix_search could be considered reversed; read carefully before setting.)

When the internal search engine is used, a substring match is always performed and this option is ignored.

32.5.9 prefix_search Option

The prefix_search Indexer option specifies which, if any, search parameters sent to an external search engine should be preceded by a "*", so that a search for subject mine would match "determine" as well as "mine". The search parameter will not be preceded by the '*' character, if it contains a space character or a double quote character or a opening parentheses in the beginning or a closing parenthesis at the end. The value given should be one or more of subject text body from to cc bcc header separated by one or more spaces. Use with caution as this imposes a significant load on the search engine. The default is the empty string.

(Note that the meanings of suffix_search and prefix_search could be considered reversed; read carefully before setting.)

When the internal search engine is used, a substring match is always performed and this option is ignored.

32.5.10 sslusessl Option Under indexer

If the sslusessl Indexer option is set to 1, then the IMAP server uses SSL to authenticate to the ISS, connecting to the port specified by the port Indexer option (service.imap.indexer.port option in legacy configuration).

32.6 ISC options

ISC Options control the Indexed Search Converter process. The ISC process is used to extract text from messages for use by an indexed search engine. It is presently required when your searchengine is set to dse or elastic.

32.6.1 enable Option Under isc

The enable ISC option, (isc.enable in Unified Configuration, not available in legacy configuration), enables the ISC service on start-msg startup.

This option defaults to 0 if not set, but initial configuration may enable the option as appropriate.

32.6.2 authpassword Option Under isc

The authpassword ISC option sets the password that will be used by the Message Store to communicate with the ISC server and will be used by the ISC server for server-to-server authentication. This option is only applicable when use of the Indexed Search Converter is enabled.

32.6.3 basicjavaswitches Option

The basicjavaswitches ISC option specifies a space-separated list of JVM options (heap settings, GC options, etc) to use when starting the java isc process. The default settings for this option are the recommended JVM switches for running ISC, described below. The recommended JVM switches may change between releases as Oracle gains tuning experience with ISC. Unless the customer determines one of the recommended JVM switches is inappropriate for their environment changes to this option are discouraged as an explicit setting means future changes to the recommended defaults will not be applied.

The extrajavaswitches option can be used to append customer preferred JVM switches without replacing the recommended default settings.

```
## Heap options
# Sets the initial size (in bytes) of the heap.
-Xms8g

# Specifies the maximum size (in bytes) of the heap.
-Xmx32g

# Specifies the recommended garbage collector for ISC
-XX:+UseG1GC

# Specifies the maximum pause for garbage collection
-XX:MaxGCPauseMillis=200
```

Changes to this option do not take effect until ISC is restarted.

32.6.4 cachettl Option Under isc

The cachettl option specifies the time-to-live, measured in seconds, for the converted text in the conversion cache. The converted contents expire after this time, and ISC will have to re-convert any new document with the same content. The default is 30 days. The minimum is one hour.

32.6.5 extrajavaswitches Option

The extrajavaswitches ISC option specifies a space-separated list of JVM options that are used in addition to the recommended Java switches present in the basicjavaswitches ISC option. This option is for customer-provided JVM modifications while basicjavaswitches should only be used to override the recommended JVM switches. For a full list of available JVM options, please refer to the Java official documentation at http://docs.oracle.com.

Changes to this option do not take effect until ISC is restarted.

32.6.6 sslusessl Option Under isc

Flag to enable SSL for ISC server connections. SSL is disabled by default. If this option is set to 1, then the corresponding isc_client.sslusessl option must also be set to 1 on the LMTP host(s), and the fit.sslusessl option must be set to 1 on the Cassandra host(s) that connect to this ISC server.

If this option is set to 1, then the base.ssljkspath and base.ssljkspassword options must be set to the Java SSL keystore path and the Java keystore password respectively.

32.6.7 authusername Option Under isc

The authusername ISC option sets the username that will be used by the Message Store to communicate with the ISC server and will be used by the ISC server for server-to-server authentication. This option is only applicable when use of the Indexed Search Converter is enabled.

32.6.8 server_port Option Under isc

The server_port isc option specifies the Http port for the ISC process. If empty or not set, the default is 8070.

If isc.sslusessl is set to 1, this will be setup as an https port.

32.6.9 maxthreads Option Under isc

The maxthreads isc option specifies the maximum number of parallel requests that the isc http server can process. Default is 10000. Cannot exceed 60000.

Starting with 8.0.2.2, this has no effect and may be removed in a future release.

32.6.10 logdir Option Under isc

The logdir isc option specifies the log files location for ISC.

The user that owns the ISC process must have write permissions to this location.

32.6.11 authusername Option Under isc_client

The authusername isc_client option sets the username that will be used by the LMTP server to communicate with the ISC server and will be used by the ISC server for server-to-server authentication. This option is only applicable when use of the Indexed Search Converter is enabled.

32.6.12 authpassword Option Under isc_client

The authpassword ISC_CLIENT option sets the password that will be used by the LMTP server to communicate with the ISC server for authentication. This option is only applicable when use of the Indexed Search Converter is enabled.

32.6.13 ischosts Option Under isc_client

The ischosts isc_client option specifies a space-separated list of hosts (with optional :port) for the isc server. List multiple hosts to avoid a single point of failure.

32.6.14 max_conns Option Under isc_client

The max_conns isc_client option specifies the maximum number of connections that are permitted from a single LMTP process to the ISC server. Starting with 8.0.2.2, this option is preferred over the isc_client.connlimits option.

32.6.15 sslusessl Option Under isc_client

Flag to enable SSL for ISC server connections. SSL is disabled by default. If this option is set to 1, then the corresponding isc.sslusessl option must also be set to 1 on the host(s) specified by isc_client.ischosts.

32.6.16 server_port Option Under isc_client

The `server_port isc_client` option specifies the ISC server port number. If empty or not set, the default is `8070`.

The value for this option must match the isc.server_port on the host(s) specified by isc_client.ischosts.

32.7 FIT options

32.7.1 `logdir` Option Under fit

The `logdir` fit option specifies the log files location for FIT.

The user that owns the DSE (Cassandra) process must have write permissions to this location.

32.7.2 `jloglevel` Option Under fit

The `jloglevel` stats option specifies the FIT log level. Default is INFO. Available options (in increasing order of importance) are FINEST, FINER, FINE, INFO, WARNING and SEVERE.

Chapter 33 Client access to Message Store servers

The TCP client access control mechanism used by Message Store servers such as the POP and IMAP servers, and proxy servers such as the MMP and MSHTTP, uses TCP wrappers. The ENS server also uses this mechanism.

Note that the MMP behaves a bit differently with respect to access control than do the other services, in that the MMP "`imap`" service controls both IMAP and IMAP+SSL services; that is, it controls both ports 143 and 993. In contrast, other Messaging Server services treat IMAP and IMAP+SSL as separate services, each with their own separate access control.

See also the `connlimits` option, which may be used to limit the number of connections, (rather than outright blocking). And see the `bg*` options, such as `bgpenalty`, which may be configured to penalize failed authentication attempts.

For allowing inspection of (rather than controlling/limiting) when a user last accessed the Message Store, see the `enablelastaccess` base option. For allowing inspection of what users are currently connected via the IMAP server or via the MSHTTP server, see the `imap.enableuserlist` and `http.enableuserlist` options. And see the `imsconnutil` utility for displaying such information.

For access control on the MTA's SMTP server and other Dispatcher services, see instead Mail filtering and access control and in particular the `PORT_ACCESS` mapping table.

Chapter 34 IMAP options

There are many options affecting IMAP operation.

See also the following options which are described rather generically under Base options, but which may also be set specifically under imap (as for instance if one wishes to have IMAP use a different value than the general base value): the logfile options, the various bg* options, and defaultdomain.

See also the Indexer options; though they are set under imap.indexer, they are documented separately.

Of notable relevance to IMAP operation, see also the base.obsoleteimap, base.threadholddelay, base.dnsresolveclient, base.pwchangeurl options, and on Solaris, see also the base.preferpoll option.

Note that msprobe can probe for whether the IMAP server is running; see msprobe's msprobe.probe:imap. options.

34.1 enable Option Under imap

The enable IMAP option, (imap.enable in Unified Configuration, or service.imap.enable in legacy configuration), enables the IMAP service on start-msg startup. Note: IMAP over SSL service is enabled/disabled separately using imap.enablesslport in Unified Configuration, or service.imap.enablesslport in legacy configuration.

This option defaults to 0 if not set, but initial configuration may enable the option as appropriate.

34.2 actions Option

The actions option (available for imap, pop, and messagetrace) specifies the actions enabled in Message Store transaction logging. This can take the value of "all" to enable logging of all actions, or "+(a1 a2 a3)" to enable only attributes listed, or "-(a1 a2 a3)" to enable all attributes except those listed. See the Store Transaction Log Format section for permitted attribute codes.

For 8.0.1 this is "all" by default and for 8.0.2 this is "-(fe)" (log everything except the fetch action) by default.

34.3 actionattributes Option

The actionattributes option (available for imap, pop, and messagetrace) specifies the action attributes enabled in Message Store transaction logging. This can take the value of "all" to enable logging of all actions, or "+(e1 e2 e3)" to enable only event codes listed, or "-(e1 e2 e3)" to enable all events except those listed. See the Store Transaction Log Format section for permitted event codes.

For 8.0.1 this is "all" by default and for 8.0.2 this is "-(mi)" (log all attributes except the message id attribute) by default. Note that the message id is expensive to extract from message headers and requires per-message logging of expunge events.

34.4 adminbypassquota Option

Enabling the adminbypassquota IMAP option allows admin users to bypass quota enforcement when they append messages to mailboxes with the IMAP APPEND command.

34.5 allowanonymouslogin Option Under imap

The allowanonymouslogin IMAP option enables the SASL ANONYMOUS mechanism for use by IMAP.

34.6 authfaildelay Option

The authfaildelay option (available under IMAP and POP) determines how long the server delays before reporting an authentication failure. This option is present only for the back-end POP3 and IMAP servers. The MMP uses a more sophisticated badguyslist facility (see bgpenalty). Decreasing the authfaildelay option below the default value (3) is not recommended.

34.7 banner Option Under imap

The banner IMAP option specifies the IMAP protocol welcome banner. The value is a one line string, with virtual parameters: %h=*hostname*, %p=*protocol* (ESMTP, POP or IMAP), %P=*product-name*, %v and %V=*version* (short or long).

34.8 bgmax Option

The bgmax option (available under base, imap, pop, mmp, imapproxy, and popproxy) specifies the maximum number of IP addresses associated with authentication failures to keep track of simultaneously. See bgpenalty for more information.

34.9 bgpenalty Option

When an authentication failure occurs from a particular client IP address, subsequent authentication attempts from that IP address are treated as "BadGuys" and are delayed. If an authentication failure is followed by a successful authentication, the successful authentication is delayed, but the IP address ceases to be treated as a "BadGuy" for subsequent attempts.

The bgpenalty option (available under base, imap, pop, mmp, imapproxy, and popproxy) specifies the length of time in seconds added to the authentication delay after each failed authentication.

34.10 bgmaxbadness Option

The bgmaxbadness option (available under base, imap, pop, mmp, imapproxy, and popproxy) specifies the maximum length of time in seconds for the authentication delay

which occurs after a series of failed authentication attempts. See bgpenalty for more information.

34.11 bgdecay Option

The bgdecay option (available under base, imap, pop, mmp, imapproxy, and popproxy) represents the time in seconds it takes for a BadGuy's penalty to be forgiven. See bgpenalty for more information.

34.12 bglinear Option

The bglinear option (available under base, imap, pop, mmp, imapproxy, and popproxy) defines whether a BadGuy's penalty decays linearly over time (1), or is a step function on expiration (0). See bgpenalty for more information.

34.13 bgexcluded Option

The bgexcluded option (available under base, imap, pop, mmp, imapproxy, and popproxy) represents a list of excluded IP/mask pairs, or the name of a file to read for these pairs. These client addresses will not be penalized for authentication failure (there is no default value).

34.14 broken_client_defer_exists Option

Starting in Messaging Server 8.0, the IMAP server notifies the client as soon as new mail arrives regardless of whether the IDLE command is in use. The IMAP specification requires clients to support this behavior (RFC 3501 section 2.2.2). Some clients fail to comply with the standard and lose state information about new messages. This option can be set to workaround clients that are broken in this way. It causes IMAP EXISTS and RECENT responses to be deferred unless a command is in progress.

34.15 capability_acl Option

The capability_acl IMAP option, when set to 1 (the default), causes the IMAP server to enable the ACL IMAP extension. (See RFC 4314 (IMAP4 Access Control List (ACL) Extension).)

34.16 capability_annotate Option

The capability_annotate IMAP option, when set to 1 (the default), causes the IMAP server to enable the ANNOTATE-EXPERIMENT-1 IMAP extension. (See RFC 5257 (IMAP ANNOTATE Extension).)

34.17 capability_binary Option

The capability_binary IMAP option, when set to 1 (the default), causes the IMAP server to enable the BINARY IMAP extension. (See RFC 3516 (IMAP4 Binary Content Extension).)

34.18 capability_catenate Option

The capability_catenate IMAP option, when set to 1 (the default), causes the IMAP server to enable the CATENATE IMAP extension. (See RFC 4469 (IMAP CATENATE Extension).)

34.19 capability_children Option

The capability_children IMAP option, when set to 1 (the default), causes the IMAP server to enable the CHILDREN IMAP extension (See RFC 3348 (IMAP4 Child Mailbox Extension).)

34.20 capability_condstore Option

The capability_condstore IMAP option, when set to 1 (the default), causes the IMAP server to enable the CONDSTORE IMAP extension. (See RFC 4551 (IMAP Extension for Conditional STORE Operation or Quick Flag Changes Resynchronization).)

Note that the QRESYNC extension subsumes all of CONDSTORE. So if capability_qresync is enabled, CONDSTORE is effectively enabled regardless of whether or not it is enabled due to capability_condstore.

34.21 capability_context_search Option

The capability_context_search IMAP option, when set to 1 (the default), causes the IMAP server to enable the CONTEXT=SEARCH IMAP extension. (See RFC 5267 (Contexts for IMAP4).)

34.22 capability_context_sort Option

The capability_context_sort IMAP option, when set to 1 (the default), causes the IMAP server to enable the CONTEXT=SORT IMAP extension. (See RFC 5267 (Contexts for IMAP4).)

34.23 capability_create_special_use Option

The capability_create_special_use IMAP option, when set to 1 (the default), causes the IMAP server to enable the CREATE-SPECIAL-USE IMAP extension. This was introduced in the 8.0 release of Messaging Server and is described in RFC 6154 (IMAP LIST Extension for Special-Use Mailboxes).

34.24 capability_enable Option

The capability_enable IMAP option, when set to 1 (the default), causes the IMAP server to enable the ENABLE IMAP extension. (See RFC 5161 (The IMAP ENABLE Extension).)

34.25 capability_esearch Option

The capability_esearch IMAP option, when set to 1 (the default), causes the IMAP server to enable the ESEARCH IMAP extension. (See RFC 4731 (IMAP4 Extension to SEARCH Command for Controlling What Kind of Information Is Returned).)

See also the capability_multisearch and maxsearchmailboxes IMAP options.

34.26 capability_esort Option

The capability_esort IMAP option, when set to 1 (the default), causes the IMAP server to enable the ESORT IMAP extension. (See RFC 5267 (Contexts for IMAP4).)

34.27 capability_id Option

The capability_id IMAP option, when set to 1 (the default), causes the IMAP server to enable the IMAP ID extension. (See RFC 2971 (IMAP4 ID extension).)

34.28 capability_idle Option

Setting the capability_idle IMAP option to 1 (the default) causes the IMAP server to enable the IDLE IMAP extension, if ENS is also enabled. (See RFC 2177 (IMAP4 IDLE command).)

34.29 capability_imap4 Option

Enable the IMAP4 capability. The default is normally 0 (false), but the default is 1 (true) if obsoleteimap (in legacy configuration, local.obsoleteimap) is set. Compare with capability_imap4rev1, which enables the modern IMAP protocol. (For the definition of IMAP4, see RFC 1730 (INTERNET MESSAGE ACCESS PROTOCOL - VERSION 4). The more modern version of IMAP is IMAPv4rev1, initially defined in RFC 2060 (INTERNET MESSAGE ACCESS PROTOCOL - VERSION 4rev1), since updated by RFC 3501 (INTERNET MESSAGE ACCESS PROTOCOL - VERSION 4rev1).)

34.30 capability_imap4rev1 Option

The capability_imap4rev1 IMAP option, when set to 1 (the default), causes the IMAP server to enable the IMAP4rev1 capability. (See RFC 3501 (INTERNET MESSAGE ACCESS PROTOCOL - VERSION 4rev1).)

34.31 capability_language Option

The capability_language IMAP option, when set to 1 (the default), causes the IMAP server to enable the LANGUAGE IMAP extension. (See RFC 5255 (Internet Message Access Protocol Internationalization).)

34.32 capability_list_status Option

The capability_list_status IMAP option, when set to 1 (the default), causes the IMAP server to enable the LIST-STATUS IMAP extension. This extension was initially introduced

in the 8.0 release of Messaging Server and is described in RFC 5258 (IMAPv4 LIST Command Extensions).

34.33 capability_literal Option

The capability_literal IMAP option, when set to 1 (the default), causes the IMAP server to enable the LITERAL+ IMAP extension. (See RFC 2088 (IMAP4 non-synchronizing literals).)

34.34 capability_login_referrals Option

The capability_login_referrals IMAP option, when set to 1 (the default), causes the back-end IMAP server to enable the LOGIN-REFERRALS IMAP extension. LOGIN OK referrals are generated when the user connects to a mailstore that is not that user's primary read-write mailstore. Presently only OK referrals are generated because the client may be connecting to access shared folders owned by another user who is local to that server. The MMP does not generate login referrals but will follow them as part of the store failover feature. (See RFC 2221 (IMAP4 Login Referrals).)

34.35 capability_metadata Option

The capability_metadata IMAP option, when set to 1 (the default), causes the IMAP server to enable the METADATA IMAP extension. (See RFC 5464 (The IMAP METADATA Extension).)

34.36 capability_multisearch Option

For 7.0.5.31.0 and later, the capability_multisearch IMAP option is disabled by default and if enabled will enable the experimental XMSEARCH IMAP extension that is a subset of the functionality described in RFC 6237 (IMAP4 Multimailbox SEARCH Extension). The ESEARCH command will be disabled unless this is set to 1.

For the 8.0 release and later, this is enabled by default and controls visibility of the MULTISEARCH capability as described in RFC 7377 (IMAP4 Multimailbox SEARCH Extension).

See also the capability_esearch and maxsearchmailboxes IMAP options.

34.37 capability_namespace Option

The capability_namespace IMAP option, when set to 1 (the default), causes the IMAP server to enable the NAMESPACE IMAP extension. (See RFC 2342 (IMAP4 Namespace).)

34.38 capability_notify Option

The capability_notify IMAP option, when set to 1, causes the IMAP server to enable the NOTIFY IMAP extension. The default is 0. (See RFC 5465 (The IMAP NOTIFY Extension).)

34.39 capability_qresync Option

The capability_qresync IMAP option, when set to 1 (the default), causes the IMAP server to enable the QRESYNC IMAP extension. (See RFC 7162 (IMAP Extensions: CONDSTORE and QRESYNC).)

Note that the QRESYNC extension subsumes all of the CONDSTORE extension. So if capability_qresync is enabled, CONDSTORE is effectively enabled regardless of whether or not it is enabled due to capability_condstore.

34.40 capability_quota Option

The capability_quota IMAP option, when set to 1 (the default), causes the IMAP server to enable the QUOTA IMAP extension. (See RFC 2087 (IMAP4 QUOTA extension).)

34.41 capability_savedate Option

The capability_savedate IMAP option, when set to 1 (the default), causes the IMAP server to enable the SAVEDATE IMAP extension. (See RFC 8514.)

34.42 capability_sasl_ir Option

The capability_sasl_ir IMAP option, when set to 1 (the default), causes the IMAP server to enable the SASL-IR IMAP extension. (See RFC 4959 (IMAP Extension for Simple Authentication and Security Layer (SASL) Initial Client Response).)

34.43 capability_searchres Option

The capability_searchres IMAP option, when set to 1 (the default), causes the IMAP server to enable the SEARCHRES IMAP extension. (See RFC 5182 (IMAP Extension for Referencing the Last SEARCH Result).)

34.44 capability_sort Option

The capability_sort IMAP option, when set to 1 (the default), causes the IMAP server to enable the SORT IMAP extension (RFC 5256 (Internet Message Access Protocol - SORT and THREAD Extensions)).

34.45 capability_sort_display Option

The capability_sort_display IMAP option, when set to 1 (the default), causes the IMAP server to enable the SORT=DISPLAY IMAP extension (RFC 5957).

34.46 capability_special_use Option

The capability_special_use IMAP option, when set to 1 (the default), causes the IMAP server to enable the SPECIAL-USE IMAP extension. This was introduced in the 8.0 release of Messaging Server and is described in RFC 6154 (IMAP LIST Extension for Special-Use Mailboxes).

34.47 capability_starttls Option Under imap

The capability_starttls IMAP option, when set to 1 (the default), causes the IMAP server to enable the STARTTLS IMAP extension. (See RFC 2595 (Using TLS with IMAP, POP3, and ACAP) and RFC 3501 (IMAP4rev1).)

34.48 capability_status_size Option

The capability_status_size IMAP option, when set to 1 (the default), allows an IMAP client to ask the IMAP server for the size of all messages in a mailbox. For more information, see RFC 8438 IMAP Extension for STATUS=SIZE.

34.49 capability_thread_references Option

The capability_thread_references IMAP option, when set to 1 (the default), causes the IMAP server to enable the THREAD=REFERENCES IMAP extension. (See RFC 5256 (Internet Message Acces Protocol - SORT and THREAD Extensions).)

34.50 capability_thread_subject Option

The capability_thread_subject IMAP option, when set to 1 (the default), causes the IMAP server to enable the THREAD=ORDEREDSUBJECT IMAP extension. (See RFC 5256 (Internet Message Acces Protocol - SORT and THREAD Extensions).)

34.51 capability_uidplus Option

The capability_uidplus IMAP option, when set to 1 (the default), causes the IMAP server to enable the UIDPLUS IMAP extension. (See RFC 2359 (IMAP4 UIDPLUS extension).)

34.52 capability_unselect Option

The capability_unselect IMAP option, when set to 1 (the default), causes the IMAP server to enable the UNSELECT IMAP extension. (See RFC 3691 (Internet Message Access Protocol (IMAP) UNSELECT command).)

34.53 capability_url_partial Option

The capability_url_partial IMAP option, when set to 1 (the default), tells the IMAP client that it can use partial references in an IMAP URL. See RFC 5550 section 5.7 for more information.

34.54 capability_urlauth Option

The capability_urlauth IMAP option, when set to 1 (the default), causes the IMAP server to enable the URLAUTH IMAP extension. (See RFC 4467 (Internet Message Access Protocol (IMAP) - URLAUTH Extension).)

34.55 capability_utf8_accept Option

The capability_utf8_accept IMAP option, when set to 1 (the default), allows an IMAP client to enable use of UTF-8 mailbox names, quoted strings, and messages. See RFC 6855 IMAP Support for UTF-8 for more details.

Note that whether or not this is explicitly enabled by a client, the message store is presently liberal about allowing UTF-8 in the protocol and email messages with UTF-8 headers into the message store. The primary behavior difference when a client ENABLEs this extension is to disallow use of the modified-UTF-7 mailbox naming convention in the IMAP session and convert all mailboxes to UTF-8 when performing IMAP LIST operations.

34.56 capability_within Option

The capability_within IMAP option, when set to 1 (the default), causes the IMAP server to enable the WITHIN IMAP extension. (See RFC 5032 (WITHIN Search Extension to the IMAP Protocol).)

34.57 capability_x_netscape Option

The capability_x_netscape IMAP option, if set to 1, (the default being 0), causes the IMAP server to enable the X-NETSCAPE IMAP extension.

34.58 capability_x_orcl_as Option

The capability_x_orcl_as IMAP option, when set to 1 (the default), causes the IMAP server to enable the X-ORCL-AS IMAP capability. This capability was added in the 8.0 release of Messaging Server and refers to protocol extensions that may be useful for ActiveSync gateways.

34.59 capability_x_sun_imap Option

The capability_x_sun_imap IMAP option, when set to 1 (the default), causes the IMAP server to enable the X-SUN-IMAP IMAP extension.

34.60 capability_x_sun_sort Option

The capability_x_sun_sort IMAP option, when set to 1 (the default), causes the IMAP server to enable the X-SUN-SORT IMAP extension.

34.61 capability_x_unauthenticate Option

The capability_x_unauthenticate IMAP option, when set to 1, causes the IMAP server to advertise the X-UNAUTHENTICATE IMAP extension. Starting with Messaging Server 8.1,

this has been replaced by the imap.capability_unauthenticate option. The default is 0. This should only be turned on when imap.capability_unauthenticate has been set to 1 and there is a need for backwards compatibility with a client that only recognizes X-UNAUTHENTICATE.

34.62 capability_unauthenticate Option

The capability_unauthenticate IMAP option, when set to 1, causes the IMAP server to advertise the UNAUTHENTICATE IMAP extension from RFC 8437. This is off by default (0).

34.63 capability_xrefresh Option

The capability_xrefresh IMAP option, when set to 1 (the default), causes the IMAP server to Enable the XREFRESH IMAP extension.

34.64 capability_xsender Option

The capability_xsender IMAP option, when set to 1 (the default), causes the IMAP server to advertise the XSENDER IMAP extension. In version 8.0 and later, the XSENDER feature was removed from imapd and this option has been deleted. DELETED: simplify message store by removing non-standard feature.

Important note: If the MMP imapproxy.capability option is explicitly configured, it is critical that XSENDER not be included in the value for MS 8.0 and later, as this can lead to clients trying to use the capability and failing. Similar considerations apply to third-party IMAP proxies that advertise a fixed set of capabilities.

34.65 capability_xserverinfo Option

The capability_xserverinfo IMAP option, if set to 1 (the default being 0), causes the IMAP server to enable the XSERVERINFO IMAP extension.

34.66 capability_xsnippet Option

The capability_xsnippet IMAP option, when set to 1 (the default), causes the IMAP server to enable the XSNIPPET IMAP extension (draft). This extension is experimental and subject to change in the event equivalent functionality is standardized.

34.67 capability_xum1 Option

The capability_xum1 IMAP option, when set to 1 (the default), causes the IMAP server to enable the XUM1 IMAP extension.

34.68 connlimits Option

The connlimits option (available under http, imap, pop, mmp, imapproxy, popproxy, specifies the maximum number of connections per IP address for the selected server. The syntax is: "*realm1*,*realm2*,..." where a realm has the form of address ranges and maximum number of connections expressed as any of the following four forms:

Table 34.1 `connlimits` Option Value Forms

a.b.c.d|e.f.g.h:m		IPv4 address, netmask, connection max
	a.b.c.d	IPv4 address
	e.f.g.h	network mask
	m	maximum connection count
a.b.c.d/p:m		IPv4 address, routing prefix, connection max
	a.b.c.d	IPv4 address
	p	routing prefix
	m	maximum connection count
a.b.c.d|e.f.g.h:m		IPv4 address, netmask, connection max
	a.b.c.d	IPv4 address
	e.f.g.h	network mask
	m	maximum connection count
[a/p]:m		IPv6 address, routing prefix, connection max
	a	IPv6 address; compressed "::" format allowed
	p	routing prefix
	m	maximum connection count
a.b.c.d|e.f.g.h:m		IPv4 address, netmask, connection max
	a.b.c.d	IPv4 address
	e.f.g.h	network mask
	m	maximum connection count
:m		Match any address
	m	maximum connection count

There should be at least one realm of the form ":m" to cover the default case by matching any IPv4 or IPv6 address. To match only IPv4 addresses, use "0.0.0.0/0:m" or "0.0.0.0|0.0.0.0:m". And to match only IPv6 addresses, use "[::0/0]:m".

The option has no default value; however, initial configuration normally sets a value of `:20` for the IMAP Proxy, and POP Proxy:

```
msconfig> show connlimits
role.imapproxy.connlimits = :20
role.popproxy.connlimits = :20
```

For backwards compatibility reasons, this option may instead specify the full path to a configuration file name that contains one realm per line. Such a file name must begin with '/'. This usage is deprecated and may be removed in a future release.

34.68.1 Use with isc_client

The `connlimits` isc_client option specifies the maximum number of connections that are permitted from a single LMTP process to the ISC server. Starting with 8.0.2.2, this isc_client option is deprecated; the `isc_client.max_conns` option should be used instead.

34.69 diacritical_sensitive_languages Option

By default, IMAP search is diacritical insensitive (meaning diacritical marks are ignored when searching for a string) while ISS search (as is used when imap.indexer.enable and imap.indexer.server_host are set) is diacriticial sensitive (meaning only exact diacritical matches are returned). This option can be used to make IMAP search diacritical sensitive for specific languages. The value is a space separated list of language tags (RFC 5646). If the IMAP LANGUAGE extension (RFC 5255) is used to negotiate a language in this list or a user's preferredLanguage LDAP attribute includes one of the languages in this list, then IMAP searches that are not sent to ISS will be diacritical sensitive instead of the default diacritical insensitive. If the language 'i-default' is included in this option then IMAP searches will be diacritical sensitive if the LANGUAGE extension is not used or the default language is explicitly selected.

34.70 domainallowed Option Under imap

The domainallowed IMAP option specifies access filters specifying which domains and/or IP addresses are allowed IMAP access.

34.71 domainnotallowed Option Under imap

The domainnotallowed IMAP option specifies access filters specifying which domains and/or IP addresses are not allowed IMAP access.

34.72 enablesslport Option Under imap

The enablesslport IMAP option sets whether or not IMAP over SSL service is started; if enabled, this service uses the port set in the sslport IMAP option. For the 7.0.5 release, the sslusessl IMAP option must also be explicitly set to enable the separate SSL port. For the 8.0 release, setting this option enables the separate SSL port and it is no longer necessary to explicitly set the sslusessl IMAP option.

34.73 enableuserlist Option Under imap

The enableuserlist IMAP option enables imsconnutil connected user listing for IMAP service.

34.74 extra_capabilities Option

If the extra_capabilities IMAP option is set, the string specified is included in the IMAP server capability list. The use of capability names that do not begin with 'X' will often break IMAP standards compliance and manifest as client compatibility problems that may result in support calls. As a result, use of this option is not recommended. Including ']' in this value will also violate the standard and break client compatibility.

34.75 fixinternaldate Option

The fixinternaldate IMAP option specifies whether to fix the IMAP internaldate for appended messages when the client fails to pass a valid date argument. With the default value of 1, this will read the date from the most recent received header in the message content and use that as the default internal date. When this is 0, the server's current time will be used as the default internal date. Set this to 0 if strict compliance with the IMAP standard is required. The default setting of 1 is more likely to behave as end-users expect when an IMAP client moves mail to the IMAP server.

34.76 forcetelemetry Option Under imap

Setting the forcetelemetry IMAP option to 1 forces telemetry for all users. Warning: this generates a lot of data and should not be used on a production system.

See also the logcommands IMAP option.

34.77 idletimeout Option Under imap

The idletimeout IMAP option specifies a maximum idle time, in minutes, for IMAP connections.

If an IMAP client has no activity for longer than the idletimeout value, then the IMAP server will close the connection with a message:

```
* BYE timeout surpassed
```

The default is 30 minutes, which RFC 3501 (IMAP v4rev1) specifies as the minimum such timeout. Attempting to set this option to a smaller value will result in a value of 30 being used (and an nslog Warning level message); attempting to set this option to a value larger than two days (larger than 2880=48*60) will result in a value of 48*60 being used (with no nslog message).

If using the MMP, see also its mmp.timeout option, where client IMAP connections can be affected by the setting under mmp as well as imapproxy.

34.78 immediateflagupdate Option

When the immediateflagupdate IMAP option is set to 1, then \Seen and \Deleted flags for users other than the mailbox owner are updated in the database on disk immediately, instead of being buffered and updated once in a while. This is needed for IMAP IDLE to show flag changes correctly with shared folders.

The default was changed to 1 for the 7.0.5 release.

34.79 legacy_proxyauth Option

The legacy_proxyauth IMAP option enables the legacy proxy authorization IMAP PROXYAUTH command; this command was useful prior to 1999 when the standards-based replacement mechanism was published. This non-standard command, provides a mechanism that is similar but inferior to the standard SASL authorization identity that can be provided with the SASL PLAIN mechanism, as documented in RFC 2595. This option is available for

customers who have not yet adapted their systems to use the standard mechanism. Note that the PROXYAUTH command is not compatible with the MMP (it may or may not work).

34.80 logauthsessionid Option

Set the logauthsessionid IMAP option to include a numeric session id in square brackets at the end of protocol authentication responses. This can be used to correlate authentication errors in the log with authentication errors sent over the network.

34.81 logcommands Option

If the logcommands IMAP option is enabled, this will record information about IMAP client commands in a file called imapcmd in the log directory. Each line will have a session identifier followed by command information. This differs from the telemetry facility in that user-specific information is omitted to protect privacy, server responses are omitted, there is no timing information, it is controlled globally for all users and commands prior to authentication are logged. This option is refreshable (via a refresh imapd command) and is intended to gather a sample of client behavior rather than to be used continuously. The present version does not have the ability to size limit or rollover this log file.

34.82 logprotocolerrors Option Under imap

If the logprotocolerrors IMAP option is greater than zero, protocol errors are logged as debug messages for IMAP.

34.83 logunauthsession Option Under imap

The logunauthsession IMAP option enables log messages from unauthenticated client IMAP sessions. Prior to turning this on, consider verifying that your logging filesystem can handle the amount of I/O possible from unauthenticated clients connecting frequently.

34.84 maxmessagesize Option Under imap

The maxmessagesize IMAP option specifies the maximum message size (in bytes) that IMAP clients are allowed to save via the append command. A legacy configutil option, service.imap.maxmessagesize is introduced in 8.0.2.1.

34.85 maxnoops Option

The maxnoops IMAP option specifies the maximum number of NOOP commands accepted before connection is forcibly closed.

34.86 maxprotocolerrors Option Under imap

The maxprotocolerrors IMAP option specifies the maximum number of protocol errors allowed before the IMAP connection is forcibly closed.

34.87 maxsearchmailboxes Option

The maxsearchmailboxes IMAP option specifies the maximum number of mailboxes that may be searched by one IMAP ESEARCH command. If this limit is exceeded, the search command will return an error. Setting this to 0 results in no limit.

34.88 maxsearchnest Option

The maxsearchnest IMAP option specifies the maximum nesting depth in an IMAP SEARCH command. If this limit is exceeded, the search command will return an error. Nesting of at least 20 levels is always permitted regardless of this setting.

34.89 maxsessions Option Under imap

The maxsessions IMAP option specifies the maximum number of sessions per IMAP server process.

34.90 maxthreads Option Under imap

The maxthreads IMAP option specifies the maximum number of threads per IMAP server process.

34.91 numprocesses Option Under imap

the numprocesses IMAP option specifies the number of IMAP server processes.

Note that the Watcher must be enabled for stop-msg to correctly shut down all processes if this is set to a value larger than one.

34.92 plaintextmincipher Option Under imap

If the imap.plaintextmincipher option is > 0, then disable use of plaintext passwords unless a security layer (SSL or TLS) is activated. This forces users to enable SSL or TLS on their client to login which prevents exposure of their passwords on the network.

34.93 polldelay Option

Solaris-only. The polldelay (IMAP and MMP) option specifies the wait time before calling poll() in milliseconds. Workaround for poll performance bug on Solaris (6438988, 6379476). Setting this to -1 activates a different workaround as of 7 update 4 patch 24. The alternate code tries to keep the size of the poll array relatively constant and instead uses -1 in the poll array for inactive descriptors. The poll array will be larger, but change size less frequently. To date this appears to noticably improve performance under stress.

The default has changed from 1 to -1 in the Messaging Server 7.0.5 release. In addition, poll is no longer used in the Messaging Server 7.0.5 release (and thus this option is ignored) unless preferpoll is set.

34.94 port Option Under imap

The port IMAP option specifies the IMAP server port number. The default is 143.

34.95 sslcachesize Option Under imap

The sslcachesize IMAP option specifies the number of SSL sessions to be cached by the IMAP server. If this is set to 0 or not set, this will use a default provided by the Mozilla NSS library which was 10000 last time this was checked (March 2016).

34.96 sslnicknames Option Under imap

The sslnicknames IMAP option specifies a list of SSL/TLS server certificate nicknames (only one per certificate type) for IMAP to offer clients if SSL/TLS enabled. Overrides for IMAP the base level sslnicknames option (corresponding to the legacy configuration encryption.rsa.nssslpersonalityssl configutil parameter).

34.97 sslport Option Under imap

The sslport IMAP option specifies the port number for the IMAP over SSL service. The default is 993. Note that to enable the IMAP+SSL service, the enablesslport IMAP option must be set also. (In MS 7.0.5, it was also necessary to set the sslusessl IMAP option *explicitly* to 1 even though the default was 1; but as of MS 8.0, setting sslusessl is not necessary for the IMAP server.)

When using the MMP (IMAP Proxy), see its sslbacksideport option to tell the IMAP Proxy to attempt to connect with SSL to the IMAP sslport.

34.98 sslusessl Option Under imap

If a server certificate is installed and the sslusessl IMAP option is not set to 0, then STARTTLS is enabled on the IMAP server (listening at its regular port).

As regards listening at a separate sslport, note that for the 7.0.5 release, the sslusessl option must be *explicitly* set to 1 (even though the default was 1) as well as setting imap.enablesslport to enable SSL connections on a separate sslport. For the 8.0 release, it is no longer necessary to explicitly set this option in order to enable SSL connections on a separate port.

34.99 submituser Option

The submituser IMAP option specifies the Message Store userid used by the MTA when resolving submit IMAP URLs in BURL commands.

34.100 withinresolution Option

The withinresolution IMAP option specifies the interval (in minutes) between recalculations of Contexts involving the search options YOUNGER or OLDER.

34.101 IMAP password expiration alert options

A few pwexpirealert options under imap control the sending of IMAP ALERT notifications to IMAP users to warn that the user's password will expire.

See also the pwchangeurl Base option.

34.101.1 firstwarn Option

Setting the firstwarn IMAP password expiration alert option, imap.pwexpirealert.firstwarn, causes sending an IMAP ALERT to notify a user that their password will expire soon. The value specifies the number of seconds of remaining password validity before a warning is sent. For example, specify 259200 (3*24*60*60) to begin sending warnings 3 days before expiration.

34.101.2 viametermaid Option

By default the IMAP server limits password expirations to once per day on a per-process basis. Set the viametermaid IMAP password expiration alert option, imap.pwexpirealert.viametermaid, to use MeterMaid to get per-metermaid instance limits instead. If this is set, then is is also necessary to set at least the MeterMaid secret option (metermaid.config.secret in legacy configuration, or in Unified Configuration metermaid.secret or alternatively mta.metermaid_secret), as well as other relevant MeterMaid client settings.

34.101.3 metermaidtable Option

The metermaidtable IMAP password expiration alert option, imap.pwexpirealert.metermaidtable, specifies the name of the MeterMaid table to use for password expiration alerts in IMAP.

Chapter 35 POP options

The POP server has a number of options.

See also the following options which are described rather generically under Base options, but which may also be set specifically under `pop` (as for instance if one wishes to have POP use a different value than the general base value): the `logfile` options, the various `bg*` options, and `defaultdomain`.

Of notable relevance to POP operation, see also the `base.threadholddelay` and `base.dnsresolveclient` options.

Note that msprobe can probe for whether the POP server is running; see msprobe's `msprobe.probe:pop.` options.

The MSHTTP server can optionally be configured to perform collection of messages from remote POP servers; see the allowcollect, maxcollectmsglen, and popbindaddr MSHTTP options.

35.1 enable Option Under pop

The enable POP option, (pop.enable in Unified Configuration, or service.pop.enable in legacy configuration), enables the POP service on start-msg startup. Note: POP over SSL service is enabled/disabled separately using pop.enablesslport in Unified Configuration, or service.pop.enablesslport in legacy configuration.

This option defaults to 0 if not set, but initial configuration may enable the option as appropriate.

35.2 actions Option

The actions option (available for imap, pop, and messagetrace) specifies the actions enabled in Message Store transaction logging. This can take the value of "all" to enable logging of all actions, or "+(a1 a2 a3)" to enable only attributes listed, or "-(a1 a2 a3)" to enable all attributes except those listed. See the Store Transaction Log Format section for permitted attribute codes.

For 8.0.1 this is "all" by default and for 8.0.2 this is "-(fe)" (log everything except the fetch action) by default.

35.3 actionattributes Option

The actionattributes option (available for imap, pop, and messagetrace) specifies the action attributes enabled in Message Store transaction logging. This can take the value of "all" to enable logging of all actions, or "+(e1 e2 e3)" to enable only event codes listed, or "-(e1 e2 e3)" to enable all events except those listed. See the Store Transaction Log Format section for permitted event codes.

For 8.0.1 this is "all" by default and for 8.0.2 this is "-(mi)" (log all attributes except the message id attribute) by default. Note that the message id is expensive to extract from message headers and requires per-message logging of expunge events.

35.4 allowanonymouslogin Option Under pop

The allowanonymouslogin POP option sets whether or not anonymous login is allowed by POP.

35.5 authfaildelay Option

The authfaildelay option (available under IMAP and POP) determines how long the server delays before reporting an authentication failure. This option is present only for the back-end POP3 and IMAP servers. The MMP uses a more sophisticated badguyslist facility (see bgpenalty). Decreasing the authfaildelay option below the default value (3) is not recommended.

35.6 banner Option Under pop

The banner POP option specifies the POP protocol welcome banner. One line string, with virtual parameters: %h=*hostname*, %p=*protocol* (ESMTP,POP or IMAP), %P=*product-name*, %v and %V=*version* (short or long).

35.7 bgmax Option

The bgmax option (available under base, imap, pop, mmp, imapproxy, and popproxy) specifies the maximum number of IP addresses associated with authentication failures to keep track of simultaneously. See bgpenalty for more information.

35.8 bgpenalty Option

When an authentication failure occurs from a particular client IP address, subsequent authentication attempts from that IP address are treated as "BadGuys" and are delayed. If an authentication failure is followed by a successful authentication, the successful authentication is delayed, but the IP address ceases to be treated as a "BadGuy" for subsequent attempts.

The bgpenalty option (available under base, imap, pop, mmp, imapproxy, and popproxy) specifies the length of time in seconds added to the authentication delay after each failed authentication.

35.9 bgmaxbadness Option

The bgmaxbadness option (available under base, imap, pop, mmp, imapproxy, and popproxy) specifies the maximum length of time in seconds for the authentication delay which occurs after a series of failed authentication attempts. See bgpenalty for more information.

35.10 bgdecay Option

The bgdecay option (available under base, imap, pop, mmp, imapproxy, and popproxy) represents the time in seconds it takes for a BadGuy's penalty to be forgiven. See bgpenalty for more information.

35.11 bglinear Option

The bglinear option (available under base, imap, pop, mmp, imapproxy, and popproxy) defines whether a BadGuy's penalty decays linearly over time (1), or is a step function on expiration (0). See bgpenalty for more information.

35.12 bgexcluded Option

The bgexcluded option (available under base, imap, pop, mmp, imapproxy, and popproxy) represents a list of excluded IP/mask pairs, or the name of a file to read for these pairs. These client addresses will not be penalized for authentication failure (there is no default value).

35.13 connlimits Option

The connlimits option (available under http, imap, pop, mmp, imapproxy, popproxy, specifies the maximum number of connections per IP address for the selected server. The syntax is: "*realm1*,*realm2*,..." where a realm has the form of address ranges and maximum number of connections expressed as any of the following four forms:

Table 35.1 connlimits Option Value Forms

a.b.c.d|e.f.g.h:m		IPv4 address, netmask, connection max
	a.b.c.d	IPv4 address
	e.f.g.h	network mask
	m	maximum connection count
a.b.c.d/p:m		IPv4 address, routing prefix, connection max
	a.b.c.d	IPv4 address
	p	routing prefix
	m	maximum connection count
a.b.c.d|e.f.g.h:m		IPv4 address, netmask, connection max
	a.b.c.d	IPv4 address
	e.f.g.h	network mask
	m	maximum connection count
[a/p]:m		IPv6 address, routing prefix, connection max
	a	IPv6 address; compressed "::" format allowed
	p	routing prefix
	m	maximum connection count
a.b.c.d|e.f.g.h:m		IPv4 address, netmask, connection max
	a.b.c.d	IPv4 address
	e.f.g.h	network mask
	m	maximum connection count
:m		Match any address
	m	maximum connection count

There should be at least one realm of the form ":m" to cover the default case by matching any IPv4 or IPv6 address. To match only IPv4 addresses, use "0.0.0.0/0:m" or "0.0.0.0|0.0.0.0:m". And to match only IPv6 addresses, use "[::0/0]:m".

The option has no default value; however, initial configuration normally sets a value of :20 for the IMAP Proxy, and POP Proxy:

```
msconfig> show connlimits
role.imapproxy.connlimits = :20
role.popproxy.connlimits = :20
```

For backwards compatibility reasons, this option may instead specify the full path to a configuration file name that contains one realm per line. Such a file name must begin with '/'. This usage is deprecated and may be removed in a future release.

35.13.1 connlimits Option Under isc_client

The connlimits isc_client option specifies the maximum number of connections that are permitted from a single LMTP process to the ISC server. Starting with 8.0.2.2, this isc_client option is deprecated; the isc_client.max_conns option should be used instead.

35.14 domainallowed Option Under pop

The domainallowed POP option specifies access filters specifying which domains and/or IP addresses are allowed POP access.

35.15 domainnotallowed Option Under pop

The domainnotallowed POP option specifies access filters specifying which domains and/or IP addresses are not allowed POP access.

35.16 emulateqpopper Option

Hack.

35.17 enablesslport Option Under pop

The enablesslport POP option sets whether or not POP over SSL service is started; if enabled, this service uses the port set in the sslport POP option. For the 7.0.5 release, the sslusessl POP option must also be explicitly set to enable the separate SSL port. For the 8.0 release, setting this option enables the separate SSL port and it is no longer necessary to explicitly set the sslusessl POP option.

35.18 forcetelemetry Option Under pop

Setting the forcetelemetry POP option to 1 forces telemetry for all users. Warning: this generates a lot of data and should not be used on a production system.

35.19 idletimeout Option Under pop

The idletimeout POP option specifies a maximum idle time, in minutes, for POP connections. After this timeout, an idle POP connection will be disconnected. The default is 10 minutes. Only values between 10 and 1440 (24*60) will be used; attempting to set a value outside this range will result in the nearest permissible value being used.

If using the MMP, see also its mmp.timeout option, where client POP connections can be affected by the setting under mmp as well as popproxy.

35.20 lockmailbox Option

When set to 1 (on), the lockmailbox POP option limits the number of POP sessions allowed to access a mailbox at a time to one. When set to 0 (off), POP users can access mailboxes in multiple sessions concurrently.

35.21 logprotocolerrors Option Under pop

If the logprotocolerrors POP option is greater than zero, protocol errors are logged as debug messages for POP.

35.22 logunauthsession Option Under pop

The logunauthsession POP option enables log messages from unauthenticated client POP sessions. Prior to turning this on, consider verifying that your logging filesystem can handle the amount of I/O possible from unauthenticated clients connecting frequently.

35.23 maxprotocolerrors Option Under pop

The maxprotocolerrors POP option specifies the maximum number of protocol errors allowed before the POP connection is forcibly closed.

35.24 maxsessions Option Under pop

The maxsessions POP option specifies the maximum number of sessions per server process.

35.25 maxthreads Option Under pop

The maxthreads POP option specifies the maximum number of threads per POP server process.

35.26 numprocesses Option Under pop

The numprocesses POP option specifies the number of POP server processes.

Note that the Watcher must be enabled for stop-msg to correctly shut down all processes if this is set to a value larger than one.

35.27 plaintextmincipher Option Under pop

If the pop.plaintextmincipher option is > 0, then disable use of plaintext passwords unless a security layer (SSL or TLS) is activated. This forces users to enable SSL or TLS on their client to login which prevents exposure of their passwords on the network.

35.28 poplogmboxstat Option

The poplogmboxstat POP option, if set to 1 (the default being 0), causes the POP log to show mailbox statistics on login and logout.

35.29 popstatuskludge Option

RESTRICTED: The popstatuskludge POP option, if set to 1 (the default of this restricted option being 0), enables the POP server to generate a message Status: header line on the fly

indicating messages as unread or read based upon saving the highest message read by the client.

35.30 port Option Under pop

The port POP option specifies the POP server port number. The default is 110.

35.31 sslcachesize Option Under pop

The sslcachesize POP option specifies the number of SSL sessions to be cached by the POP server. If this is set to 0 or not set, this will use a default provided by the Mozilla NSS library which was 10000 last time this was checked (March 2016).

35.32 sslnicknames Option Under pop

The sslnicknames POP option specifies a list of SSL/TLS server certificate nicknames (only one per certificate type) for POP to offer clients if SSL/TLS enabled. Overrides for POP the base level sslnicknames option (corresponding to the legacy configuration encryption.rsa.nssslpersonalityssl configutil parameter).

35.33 sslport Option Under pop

The sslport POP option specifies the port number for the POP over SSL port. The default is 995. Note that to enable the POP+SSL service, the enablesslport POP option must also be set. (In MS 7.0.5 it was also necessary to set the sslusessl POP option *explicitly* to 1 even though the default was 1; but as of MS 8.0, the POP server does not require that option.)

When using the MMP (POP Proxy), see its sslbacksideport option to tell the POP Proxy to attempt to connect with SSL to the POP sslport.

35.34 sslusessl Option Under pop

If a server certificate is installed and the sslusessl POP option is not set to 0, then STARTTLS is enabled on the POP server (listening at its regular port).

As regards listening at a separate sslport, note that for the 7.0.5 release, the sslusessl option must be *explicitly* set to 1 (even though the default was 1) as well as setting pop.enablesslport to enable SSL connections on a separate sslport. For the 8.0 release, it is no longer necessary to explicitly set this option in order to enable SSL connections on a separate port.

Chapter 36 Message Trace options

Message Trace can be enabled by setting the `messagetrace.activate` option to `transactlog` (recommended), `yes` (deprecated), or `messagetrace` (deprecated). The `actions` and `actionattributes` options may be used to further control the detail included in message tracing. The only other Message Trace options are logfile options set as `transactlog.logfile.*` (for `transactlog` log file) or `messagetrace.logfile.*` (for `messagetrace` log file).

36.1 `activate` Option

The `activate` Message Trace option, `messagetrace.activate` (or in legacy configuration the `configutil` parameter `local.msgtrace.active`), enables message tracing. Permitted values are `no`, `yes`, `msgtrace`, and `transactlog`. Specifying `msgtrace` causes message tracing to be written in traditional format, to a file named `msgtrace`. Specifying `transactlog` causes message trace entries to be written in an easy-to-parse XML format, similar to the MTA's XML format message transaction entries, to a file named `transactlog`. As of MS 8.0.1, the Message Store `msgtrace` log format (selected via `msgtrace`) is deprecated in favor of the Message Store action log format (selected via `transactlog`) which uses an easy-to-parse format (XML) described in the Store Transaction Log Format section.

Note that the default values for the actions and actionattributes have changed in 8.0.2; they both need to be set to "all" explicitly to get functionality that is a superset of the old `msgtrace` or `yes` settings.

Starting with the Messaging Server 8.1 release, the legacy `msgtrace` format has been removed so both `msgtrace` and `yes` values are treated as synonyms for `transactlog`.

36.2 `actions` Option

The `actions` option (available for `imap`, `pop`, and `messagetrace`) specifies the actions enabled in Message Store transaction logging. This can take the value of "all" to enable logging of all actions, or "+(a1 a2 a3)" to enable only attributes listed, or "-(a1 a2 a3)" to enable all attributes except those listed. See the Store Transaction Log Format section for permitted attribute codes.

For 8.0.1 this is "all" by default and for 8.0.2 this is "-(fe)" (log everything except the fetch action) by default.

36.3 `actionattributes` Option

The `actionattributes` option (available for `imap`, `pop`, and `messagetrace`) specifies the action attributes enabled in Message Store transaction logging. This can take the value of "all" to enable logging of all actions, or "+(e1 e2 e3)" to enable only event codes listed, or "-(e1 e2

e3)" to enable all events except those listed. See the Store Transaction Log Format section for permitted event codes.

For 8.0.1 this is "all" by default and for 8.0.2 this is "-(mi)" (log all attributes except the message id attribute) by default. Note that the message id is expensive to extract from message headers and requires per-message logging of expunge events.

36.4 loglevel Option Under messagetrace

Legacy Message Trace data is inherently `information` level. So setting the `messagetrace.loglevel` option to a higher value than `information` will suppress the recording of Message Trace data. Data in the `transactlog` is inherently `critical` level.

Chapter 37 `notifytarget` options

Named `notifytarget` groups are used to control the operation of sending notifications to an ENS server or JMQ broker. Such `notifytarget` groups replace the legacy configuration `local.store.notifyplugin.*.* configutil` options.

For instance, to configure notifications to an ENS server (whose basic options are shown in the example below), one makes a named `notifytarget` group, in this example `ens1`, and sets any necessary options below that:

```
msconfig> show ens.*
```

```
role.ens.enable = 1
msconfig> show -default base.listenaddr
base.listenaddr: <no-default>
msconfig> show -default ens.port
ens.port: 7997
msconfig> set notifytarget:ens1.enable 1
msconfig# set notifytarget:ens1.enshost 127.0.0.1
msconfig# set notifytarget:ens1.ensport 7997
```

37.1 enable Option Under notifytarget

The enable option under notifytarget, notifytarget:*target-name*.enable, specifies whether to generate notifications for this destination. This defaults to 1. This can also be used to disable the default destination for a JMQ plugin, so notifications are only sent to destinations specified in the ldapdestination attribute in users' directory entries.

37.2 notifytype Option

The notifytype option under notifytarget specifies the type of this notification target. Presently the value can be either ens (the default) or jmq. Note that support for jmq is deprecated and will be removed in a future release. For XML mode this setting is used in each notifytarget instead of having one "local.store.notifyplugin" string that lists all the plugins.

Starting with the Messaging Server 8.1 release, the JMQ notifytargets feature is deprecated. This feature is only supported for customers migrating from ISS to Elasticsearch.

37.3 enseventkey Option Under notifytarget

The enseventkey option under notifytarget, notifytarget:*target-name*.enseventkey, specifies the event key to use for ENS notifications. The default is "enp://127.0.0.1/store/%M" where %M is replaced at runtime with the mailbox name for mailbox-related events. The value of the enseventkey option must not contain any question mark "?" characters.

37.4 enshost Option Under notifytarget

The enshost option under notifytarget, notifytarget:*target-name*.enshost, specifies the IP address or hostname of the ENS server. If unset, defaults to the value of the listenaddr base option (service.listenaddr in legacy configuration) or the loopback address.

37.5 ensport Option Under notifytarget

The ensport option under notifytarget, notifytarget:*target-name*.ensport, specifies the TCP port number of the ENS server. This will generally correspond to the setting of the ens.port option (local.ens.port in legacy configuration).

Prior to MS 8.0, this option defaulted to a value of 7997. As of MS 8.0, if ens.enablesslport (local.ens.enablesslport in legacy configuration) is set,

then this option defaults to the value of ens.sslport (local.ens.sslport in legacy configuration) if it is set or 8997 if the sslport is not explicitly set; otherwise, this option defaults to the value of ens.port (local.ens.port in legacy configuration) if it is set to a valid value, or 7997 if ens.port does not have a valid value.

37.6 enspwd Option

The enspwd option under notifytarget, notifytarget:*target-name*.enspwd, specifies the ENS Broker user password that is used to authenticate to the ENS broker. The default value of the option will be the value of the option ens.secret, if the *target-name* of the notifytarget is ms-internal or the notifytarget:*target-name*.enshost is not set or the notifytarget:*target-name*.enshost is same as the value of the listenaddr Base option (service.listenaddr in legacy configuration) or the notifytarget:*target-name*.enshost is 127.0.0.1 or the notifytarget:*target-name*.enshost is ::1.

37.7 ensuser Option

The ensuser option under notifytarget, notifytarget:*target-name*.ensuser, specifies the ENS username. The default is "guest".

37.8 ensusessl Option

The ensusessl option is available for notifytargets. The defaulting is special for notifytarget:ms-internal.

37.8.1 Use with notifytarget

The ensusessl option under notifytarget, notifytarget:*target-name*.ensusessl, specifies whether the connection to the ENS broker for this notification target should use TLS/SSL or not. This works only if the notifytype of the notifytarget is equal to "ens". Setting ensusessl to 1 directs the notifytarget to connects to the specified ENS enshost using TLS/SSL.

Arbitrary, remote targets of notifytarget default to an ensusessl value of 0. But if the *target-name* of the notifytarget is ms-internal, the default value will be equal to value of the enablesslport ENS option.

37.8.2 Use with ms-internal Under notifytarget

The ensusessl option under notifytarget:ms-internal, notifytarget:ms-internal.ensusessl, specifies whether the connection to the ENS broker for this notification target should use TLS/SSL or not. This works only if the notifytype of notifytarget:*target-name* is equal to "ens". Setting ensusessl to 1 directs the notifytarget to connect to the specified ENS enshost using TLS/SSL.

While arbitrary, remote targets of notifytarget default to 0, for ms-internal, the default value will be equal to value of the enablesslport ENS option.

37.9 jmqhost Option Under notifytarget

The jmqhost option under notifytarget, notifytarget:*target-name*.jmqhost, specifies the hostname of the JMQ broker.

Starting with the Messaging Server 8.1 release, the JMQ notifytargets feature is deprecated. This feature is only supported for customers migrating from ISS to Elasticsearch.

37.10 jmqport Option Under notifytarget

The jmqport option under notifytarget, notifytarget:*target-name*.jmqport, specifies the port number of the JMQ broker. The default is 7676.

Starting with the Messaging Server 8.1 release, the JMQ notifytargets feature is deprecated. This feature is only supported for customers migrating from ISS to Elasticsearch.

37.11 jmqpwd Option Under notifytarget

The jmqpwd option under notifytarget, notifytarget:*target-name*.jmqpwd, specifies the Glassfish MQ (formerly called Java MQ or JMQ) user password that is used to authenticate to the Glassfish MQ broker. The default value was removed in the 8.0 release. For security reasons, this should not be set to an easy-to-guess value such as guest. Starting with the Messaging Server 8.1 release, the JMQ notifytargets feature is deprecated. This feature is only supported for customers migrating from ISS to Elasticsearch.

37.12 jmqtopic Option Under notifytarget

The jmqtopic option under notifytarget, notifytarget:*target-name*.jmqtopic, specifies the name of the topic or queue to which JMQ will publish events. The default is JES-MS. Note that if notifytarget:*target-name*.jmqqueue is set, it will override the jmqtopic value.

Note that the corresponding *target-name* setting of notifytarget:*target-name*.destinationtype is what controls whether in fact a topic *vs*. queue is used.

Starting with the Messaging Server 8.1 release, the JMQ notifytargets feature is deprecated. This feature is only supported for customers migrating from ISS to Elasticsearch.

37.13 jmquser Option Under notifytarget

The jmquser option under notifytarget, notifytarget:*target-name*.jmquser, specifies the JMQ username. The default is "guest".

Starting with the Messaging Server 8.1 release, the JMQ notifytargets feature is deprecated. This feature is only supported for customers migrating from ISS to Elasticsearch.

37.14 jmqqueue Option

The jmqqueue option under notifytarget, notifytarget:*target-name*.jmqqueue, specifies the name of the topic or queue to which JMQ will

publish events; (if set, this overrides jmqtopic, or in legacy configuration local.store.notifyplugin.*.jmqtopic).

Note that the corresponding *target-name* setting of notifytarget:*target-name*.destinationtype is what controls whether in fact a topic *vs*. queue is used.

Starting with the Messaging Server 8.1 release, the JMQ notifytargets feature is deprecated. This feature is only supported for customers migrating from ISS to Elasticsearch.

37.15 maxbodysize Option Under notifytarget

The maxbodysize option under notifytarget, notifytarget:*target-name*.maxbodysize, specifies the maximum size (in bytes) of the body that will be transmitted with the notification. If the body is longer than this, it will be truncated.

37.16 maxheadersize Option Under notifytarget

The maxheadersize option under notifytarget, notifytarget:*target-name*.maxheadersize, specifies the maximum size (in bytes) of the header that will be transmitted with the notification. If the header is longer than this, it will be truncated and padded with a blank line.

37.17 msgflags Option Under notifytarget

The msgflags option under notifytarget, notifytarget:*target-name*.msgflags, enables the msgflag notification mechanism.

37.18 destinationtype Option

The destinationtype option under notifytarget, notifytarget:*target-name*.destinationtype, specifies the JMQ destination type, queue or topic (the default).

Starting with the Messaging Server 8.1 release, the JMQ notifytargets feature is deprecated. This feature is only supported for customers migrating from ISS to Elasticsearch.

37.19 ldapdestination Option

The ldapdestination option under notifytarget, notifytarget:*target-name*.ldapdestination, specifies what LDAP attribute is to be used to look up a JMQ notification destination. If this is not specified, or the user lacks this attribute, or the value of this attribute is zero length, the library id is used as the destination. Although any attribute can be used, the mailEventNotificationDestination attribute has been defined for this purpose.

Starting with the Messaging Server 8.1 release, the JMQ notifytargets feature is deprecated. This feature is only supported for customers migrating from ISS to Elasticsearch.

37.20 persistent Option

The persistent option under notifytarget, notifytarget:*target-name*.persistent, specifies whether persistent JMQ messages are to be used. The default of 0 means that non-persistent JMQ messages are used.

Starting with the Messaging Server 8.1 release, the JMQ notifytargets feature is deprecated. This feature is only supported for customers migrating from ISS to Elasticsearch.

37.21 priority Option

The priority option under notifytarget, notifytarget:*target-name*.priority, specifies the priority to be used for JMQ notification messages.

Starting with the Messaging Server 8.1 release, the JMQ notifytargets feature is deprecated. This feature is only supported for customers migrating from ISS to Elasticsearch.

37.22 ttl Option

The ttl option under notifytarget, notifytarget:*target-name*.ttl, specifies the time-to-live (in milliseconds) for JMQ messages. 0, the default, means no timeout.

Starting with the Messaging Server 8.1 release, the JMQ notifytargets feature is deprecated. This feature is only supported for customers migrating from ISS to Elasticsearch.

37.23 deletemsg Option Under notifytarget

The deletemsg option under notifytarget, notifytarget:*target-name*.deletemsg, specifies whether DeleteMsg events will generate a notification.

37.24 loguser Option Under notifytarget

The loguser option under notifytarget, notifytarget:*target-name*.loguser, specifies whether LogUser events will generate a notification. For JMQ notifications (notifytarget:*target-name*.notifytype=jmq), the default is 0. For ENS notifications (notifytarget:*target-name*.notifytype=ens), the default is 1 for the ms-internal target, but 0 for other *target-name* targets.

37.25 newmsg Option Under notifytarget

The newmsg option under notifytarget, notifytarget:*target-name*.newmsg, specifies whether NewMsg events will generate a notification.

37.26 overquota Option Under notifytarget

The overquota option under notifytarget, notifytarget:*target-name*.overquota, specifies whether OverQuota events will generate a notification.

37.27 underquota Option Under notifytarget

The underquota option under notifytarget, notifytarget:*target-name*.underquota, specifies whether UnderQuota events will generate a notification.

37.28 setacl Option

The setacl option under notifytarget, notifytarget:*target-name*.setacl, specifies whether SetAcl events will generate a notification.

37.29 noninbox Option Under notifytarget

The noninbox option under notifytarget, notifytarget:*target-name*.noninbox, determines whether all folders generate notifications or if only the INBOX generates notifications: 0: only INBOX, 1: all folders. As of 7 Update 4, this defaults to 1 for ENS and 0 for JMQ. As of Messaging Server 7.0.5, this defaults to 1 for both ENS and JMQ.

37.30 msgtypes Option

For JMQ notifications (notifytarget:*target-name*.notifytype=jmq), the msgtypes option under notifytarget, notifytarget:*target-name*.msgtypes, determines whether to include message type counts in PurgeMsg, DeleteMsg, CopyMsg, NewMsg, and UpdateMsg messages.

37.31 purgemsg Option Under notifytarget

The purgemsg option under notifytarget, notifytarget:*target-name*.purgemsg, specifies whether PurgeMsg events will generate a notification.

37.32 readmsg Option Under notifytarget

The readmsg option under notifytarget, notifytarget:*target-name*.readmsg, specifies whether ReadMsg events will generate a notification.

37.33 updatemsg Option Under notifytarget

The updatemsg option under notifytarget, notifytarget:*target-name*.updatemsg, specifies whether UpdateMsg events will generate a notification.

37.34 expungemsg Option

The expungemsg option under notifytarget, notifytarget:*target-name*.expungemsg, specifies whether ExpungeMsg events will generate a notification.

37.35 annotatemsg Option

The annotatemsg option under notifytarget, notifytarget:*target-name*.annotatemsg, specifies whether AnnotateMsg events will generate a notification.

37.36 changeflag Option

The changeflag option under notifytarget, notifytarget:*target-name*.changeflag, specifies whether ChangeFlag events will generate a notification. For JMQ notifications (notifytarget:*target-name*.notifytype=jmq), the default is 0. For ENS notifications (notifytarget:*target-name*.notifytype=ens), the default is 1.

37.37 copymsg Option

The copymsg option under notifytarget, notifytarget:*target-name*.copymsg, specifies whether IMAP COPY operations will generate Copy events or UpdateMsg events.

Chapter 38 IMAP error statuses

When users attempt to access or manipulate their mailboxes or messages via an IMAP client or POP client may, various Message Store errors may occur and be reported or logged; these errors are referred to as *IMAP errors*, since the Message Store is a fundamentally IMAP-oriented repository of messages. Utilities operating on the Message Store may also encounter such IMAP errors. And MTA channels attempting to deliver to the Message Store, *i.e.*, `ims-ms` channels or `tcp_lmtpcs*` channels, can also encounter a subset of such IMAP errors (discussed further in ims-ms channel error messages).

Additional details on the underlying Message Store issue that gave rise to an IMAP error status may be available in the Message Store NSLOG logging for the component which encountered the issue; in the case of the `ims-ms` channel or LMTP server, see the `imta` NSLOG file discussed in ims-ms channel debugging and error logging.

Table 38.1 IMAP error statuses

Name	Type	RFC 5530 code	Text+	Meaning
IMAP_IOERROR	MTA-temp	[CONTACTADMIN]	System I/O error. Administrator, check server log for details.	The Message Store may be corrupted, or otherwise inaccessible (*e.g.*, disk not mounted); or the Message Store `store.idx` file may have reached its 2 gigabyte size limit.
IMAP_CONFIG_ERROR	MTA-perm	[CONTACTADMIN]	Configuration error	For the MTA Message Store delivery channels, returned if either LDAP pool code, or the domain map code, cannot be initialized. For Message Store servers and Message Store utilities, returned if the Message Store or library code cannot be initialized.
IMAP_PERMISSION_DENIED	MTA-perm	[NOPERM]	Permission denied	Typically, this error relates to an attempt to create or delete a mailbox (*i.e.*, folder), where either there was a (semantic) problem with the folder name, or a problem with IMAP ACLs on the folder. (Note that for privacy reasons, IMAP ACL problems may instead be reported with the less informative IMAP_MAILBOX_NONEXISTENT error.) This error may also be reported in cases of ACL problems attempting to read or modify an IMAP flag on a message.
IMAP_QUOTA_EXCEEDED	MTA-temp	[OVERQUOTA]	Over quota	The recipient has exceeded their configured quota, but for less than the configured grace period.
IMAP_QUOTA_EXCEEDED_PERSISTENT	MTA-perm	[OVERQUOTA]	Over quota	The user has exceeded their configured quota for more than the configured grace period.
IMAP_MESSAGE_TOO_LARGE	MTA-perm	[LIMIT]	Message too large	Message is larger than the user's entire quota.
IMAP_USERFLAG_EXHAUSTED		[LIMIT]	Too many keywords in mailbox	
IMAP_MAILBOX_BADFORMAT	MTA-temp	[CORRUPTION]	Mailbox has an invalid format	The mailbox may be corrupted.
IMAP_MAILBOX_NOTSUPPORTED	MTA-temp		Operation is not supported on mailbox	The mailbox may be corrupted.
IMAP_MAILBOX_NONEXISTENT	MTA-perm	[NONEXISTENT]	Mailbox does not exist	(Recall that these error messages are general IMAP error messages, that may occur in other contexts besides `ims-ms` channel or LMTP channel delivery.) When this error occurs in the context of an `ims-ms` or LMTP channel delivery, the meaning is as follows. Normally, the `ims-ms` channel and LMTP server `tcp_lmtpss*` channel will create a mailbox, if it does not exist. And when delivery to a specific folder is being attempted due to a Sieve `"fileinto"` action, and the folder does not exist, the channel will attempt to create the folder. (If the folder part of the address was not generated by the user's Sieve filter nor world writeable, then the channel will log a General facility, Information level notice to the `imta` file saying "`append_setup` *`path`* `failed, trying INBOX:`" followed by the IMAP_MAILBOX_NONEXISTENT error text. If the folder part was due to the user's Sieve filter but the folder could not be created, then the channel will log a General facility, Error level notice to the `imta` file saying "`mboxlist_createmailbox` *`path`* `failed, trying INBOX:`" with the specific IMAP error text.) But if the partition is bogus, then this error will be returned.
IMAP_WRONG_MAILHOST	MTA-perm		Mailbox is on a different server	Arises when attempting to create a mailbox (folder). For the MTA's delivery channels, this suggests that either

				the user's LDAP entry is missing a `mailHost` attribute entirely, or their `mailHost` has been changed (their mailbox has been moved) while old messages were awaiting delivery in the `ims-ms` channel queue area, or that there is an error in the MTA configuration (causing it to attempt to deliver a message on the wrong `mailHost`), or operator error whereby messages have been manually moved (incorrectly) from one host to another.
IMAP_MAILBOX_EXISTS		[ALREADYEXISTS]	Mailbox already exists	When attempting to create a folder, this is a success status
IMAP_MAILBOX_BADNAME	MTA-perm	[CANNOT]	Invalid mailbox name	
	Delivery temporary errors			
IMAP_MAILBOX_LOCKED	MTA-temp	[INUSE]	Mailbox is busy	The mailbox was locked. When this status is encountered, the MTA delivery channel (`ims-ms` or `tcp_lmtpcs*`) first retries 10 times at 100 millisecond intervals (before this error is ever even reported back from the channel). Prior to 8.0, lock attempts were nonblocking; a 1 second time is used in 8.0 or later. If the mailbox remains locked, then the channel gives up on this delivery attempt, generating a "`Q`" record with the "`Mailbox is busy`" reason if `logging` is enabled. And then there is special code in the `ims-ms` channel (and as of MS 7.0 in the LMTP client channel; see the MAILBOX_BUSY_FAST_RETRY TCP/IP-channel-specific option) to ask the Job Controller to retry delivery again very, very soon---with a randomly generated backoff of between one second and two minutes---overriding the normal `*backoff` values. Occasional occurrences of such a temporary error are normal, as for instance if a user is logged in and performing extensive, time-consuming operations on a mailbox; indeed, it is because an occasional such occurrence is "normal" that the delivery channels have special code to handle this (usually transient) error condition by retrying delivery very soon. However, persistent occurrences for the same user might suggest a problem with that user's mailbox. Or, if such errors suddenly start occurring at around the same time for all (or many) users, that could be a suggestion of some more widespread and general problem with the Message Store.
IMAP_MAILBOXLIST_NONEXISTENT		[NONEXISTENT]	Mailbox list does not exist	
IMAP_MAILBOX_EXHAUSTED		[LIMIT]	Too many mailboxes	IMAP client attempt to perform an IMAP search on more than `maxsearchmailboxes`.
IMAP_MAILBOX_PINNED		[NOPERM]	Mailbox is pinned	Attempt to deleted a "pinned" mailbox (that is, folder); see the `pin` Message Store option.
IMAP_PARTITION_UNKNOWN	Temporary		Unknown/invalid partition	The user's `mailMessageStore` LDAP attribute does not correspond to a *`partition-name`* defined via a `path` partition option in Unified Configuration (a `store.partition.`*`partition-name`*`.path` configutil parameter in legacy configuration), or the value of that option or configutil parameter does not point to a valid location, or contains invalid characters (only alphanumeric characters are allowed). (If a user does not have a `mailMessageStore` set at all, then the Message Store's default partition, `defaultpartition` Message Store option in Unified Configuration or `store.defaultpartition` configutil parameter in legacy configuration, is assumed, which defaults to `primary`. When the absence of an explicit `mailMessageStore` is causing use of the default partition, then whatever the default partition is, it must then have a valid path specified in the `path` option for that named partition in Unified Configuration (`partititon:`*`whatever`*`.path`) or the `store.partition.`*`whatever`*`.path` configutil parameter; in particular, when `store.defaultpartition` has its default value of `primary`, then the primary partition must have a valid path specified in `partition:primary.path` in Unified Configuration or `store.partition.primary.path` in legacy configuration.)
IMAP_INVALID_IDENTIFIER		[CANNOT]	Invalid identifier	May occur when attempting to set an ACL on a folder
IMAP_INVALID_MSGNO			Invalid message number	
IMAP_MESSAGE_CONTAINSNULL	MTA-perm	[UNKNOWN-CTE]	Message contains NUL characters	(A message that has gone through the MTA will not normally cause such an error, as the MTA will normally legalize message content.)
IMAP_MESSAGE_BADHEADER	MTA-perm		Message contains invalid header	
IMAP_MESSAGE_NOBLANKLINE	MTA-perm		Message has no header/body separator	(A message that has gone through the MTA will not normally cause such an error, as the MTA will

				normally legalize messages one way or another; see the `*headertermination` channel options.)
IMAP_MESSAGE_EXHAUSTED		[LIMIT]	Too many messages	
IMAP_QUOTAROOT_NONEXISTENT			Quota root does not exist	
IMAP_MAILBOX_TOO_LARGE		[LIMIT]	Mailbox too large	
IMAP_ANNOTATEMORE_TOOBIG		[LIMIT]	Data too big	
IMAP_UIDVALIDITY_INCORRECT			Mailbox has been replaced by a newer version	
IMAP_UNRECOGNIZED_CHARSET		[BADCHARSET]	Unrecognized character set	
IMAP_UNRECOGNIZED_LANGUAGE			Unrecognized language	
IMAP_INVALID_USER	MTA-perm		Invalid user	The recipient address did not parse into syntactically valid uid, channel part, and optionally domain and/or folder portions
IMAP_INVALID_LOGIN		[AUTHENTICATIONFAILED]	Login incorrect	
IMAP_ANONYMOUS_NOT_PERMITTED	IMAP-only		Anonymous login is not permitted	Returned by the IMAP server to any attempt to login as "`anonymous`" when `imap.allowanonymouslogin` has *not* been set.
IMAP_USER_NOT_PERMITTED		[AUTHORIZATIONFAILED]	User not permitted	
IMAP_TEMP_AUTH_FAILURE		[UNAVAILABLE]	Authentication server temporarily unavailable	
IMAP_UNSUPPORTED_QUOTA			Unsupported quota resource	
IMAP_UNRECOGNIZED_COMPARATOR		[BADCOMPARATOR]	Unrecognized comparator	
IMAP_BADURLPART			nonexistant message section	
IMAP_BADURL			Invalid or inappropriate URL	
IMAP_JUNK_AT_END			Junk at end of command	
IMAP_NO_OVERQUOTA		[OVERQUOTA]	Mailbox is over quota	
IMAP_NO_CLOSEQUOTA		[ALERT]	Mailbox is at <x>% of quota	
IMAP_NO_MSGGONE			Message no longer exists	
IMAP_NO_MSGTMPFAIL		[UNAVAILABLE]	Message temporarily unavailable	
IMAP_NO_DECODE		[UNKNOWN-CTE]	Unable to decode message	
IMAP_NO_CHECKPERUSER			Unable to checkpoint per-user flags	
IMAP_NO_CHECKPRESERVE			Unable to preserve per-user flags	
IMAP_PROXY_UNAVAILABLE		[UNAVAILABLE]	Server hosting this mailbox is not available	
IMAP_PROXY_ERROR		[CONTACTADMIN]	Error parsing backend IMAP server response	
IMAP_PROXY_DISCONNECTED		[UNAVAILABLE]	The backend IMAP server has disconnected	
IMAP_PROXY_CONDSTORE_ERROR			The backend IMAP server does not support CONDSTORE	
IMAP_PARTITION_FULL	MTA-temp	[CONTACTADMIN]	Store partition is full	See also the (new in MS 6.2) configutil parameters `local.store.checkdiskusage` and `local.store.diskusagethreshold` (initially instead named `local.store.diskthreshold` in MS 6.2), or in Unified Configuration the `checkdiskusage` and `diskusagethreshold` Message Store options, which control whether---and when---the store performs checks on its disk space usage. With such checks enabled, the store will "lock" a partition (at which point the IMAP_PARTITION_FULL error will be returned) slightly before the partition is actually filled up. This is a safety measure, to ensure that expunge operations (which need to rewrite the index files) have disk room in which to operate.

IMAP_PROXY_ONLY	MTA-perm		Server is not configured for local users	
IMAP_REPLACEMENT_STRING_TOO_LONG			unknown-character-replacement value is too long	
IMAP_CANNOT_CONVERT_FROM_CHARSET			Charset of original body unrecognised	
IMAP_CANNOT_CONVERT_TO_CHARSET			Destination charset unrecognized	
IMAP_CONVERT_ERROR			Conversion failed	
IMAP_BAD_CONVERT_PARAMETERS			Bad convert parameter specified	
IMAP_MISSING_CONVERT_PARAMETER			Required convert parameter missing	
IMAP_UNKNOWN_CHARACTER_FOUND			unknown character found. try specifying unknown-character-replacement	
IMAP_NO_CONVERTER			No converter defined for this pair of body types	
IMAP_CONVERT_MULTIPART			Cannot convert whole message or multipart parts	
IMAP_URLERR_SCHEME			Invalid URL scheme found in URL	
IMAP_URLERR_RELPATH			Relative path found in URL	
IMAP_URLERR_USER			Invalid user name found in URL	
IMAP_URLERR_PASS			Invalid password found in URL	
IMAP_URLERR_HOST			Invalid host found in URL	
IMAP_URLERR_PORT			Invalid port found in URL	
IMAP_INVALID_ACCESS		[NOPERM]	Access denied	
IMAP_ANNOTATE_TOOBIG		[ANNOTATE TOOBIG]	Annotation too large.	
IMAP_ANNOTATE_TOOMANY		[ANNOTATE TOOMANY]	Too many annotations.	
IMAP_INVALID_USEATTR		[USEATTR]	Use attribute not supported.	
IMAP_MESSAGE_CONTAINSNL	Permanent		Message contains bare newlines	(A message that has gone through the MTA will not normally cause such an error, as the MTA will normally canonicalize message content resulting in proper use of CRLF for line breaks, and encoded newlines in binary content; see the discussion of the `lmtp*` and `smtp*` channel options.)
Untagged BYE responses				
IMAP_BYE_LOGOUT			LOGOUT received	
IMAP_BYE_SHUTDOWN			System shutting down	
IMAP_ACCOUNT_TEMP_UNAVAILABLE		[UNAVAILABLE]	Account temporarily unavailable for system maintenance	
Tagged OK responses				
IMAP_OK_COMPLETED			Completed	
Password expiration warnings				
IMAP_PWEXPIRE_LESS1DAY		[ALERT]	Your password will expire in less than one day.	See the IMAP password expiration alert options.
IMAP_PWEXPIRE_1DAY		[ALERT]	Your password will expire in one day.	See the IMAP password expiration alert options.
IMAP_PWEXPIRE_NDAYS		[ALERT]	Your password will expire in <n> days.	See the IMAP password expiration alert options.
IMAP_PWCHANGE_URL			You may change your password by directing your web browser to <url>.	Additional text added to above password expiration warnings, if the pwchangeurl base option is set (or if it is not set, if the `accounturl` base option is set).
Used when archiving causes APPEND to fail				

IMAP_ARCHIVE_FAILAPPEND		[CONTACTADMIN]	Mailbox append disabled due to archiving failure.	If the `compliance` Message Store archive option is set, but the archiving could not be performed during an attempted IMAP APPEND operation, this is the error returned.
Additional IMAP errors				
IMAP_FSCORRUPT			File system error. Administrator, check server log for details.	Typically means that the cache file or index file is corrupted.
IMAP_SYS_ERROR			System error. Administrator, check server log for details (new in 8.0.2).	
IMAP_SERVER_TEMP_BUSY			Server temporary busy. Administrator, check server log for details (new in 8.0.2).	
IMAP_REFER_USER			Follow referral to access INBOX and personal folders.	IMAP server referral attempt.
IMAP_REFER_MASTER			This is a read-only replica, follow referral for read-write master.	IMAP server referral attempt.
IMAP reporting underlying authentication (HULA) errors				
HULA_TRANS		[TRANSITION-NEEDED]	A transition is needed to use the specified mechanism	
HULA_EXPIRED		[EXPIRED]	Password expired	
HULA_NOMEM		[UNAVAILABLE]	Not enough memory available	
HULA_TRYAGAIN		[UNAVAILABLE]	Transient failure -- try authentication again	
HULA_UNAVAIL		[UNAVAILABLE]	Service temporarily unavailable	
HULA_NOAUTHZ		[AUTHORIZATIONFAILED]	Not authorized to login as specified user	
HULA_DISABLED		[AUTHORIZATIONFAILED]	Account disabled	Domain status, or user status, is "`disabled`"
HULA_ENCRYPT		[PRIVACYREQUIRED]	Encryption required	
HULA_*all-other-errors*		[AUTHENTICATIONFAILED]	*error-detail-text*	All other authentication (HULA) errors.

[+] The IMAP error text is localizable. The text shown in this table is merely the default text (which happens to be English).

Chapter 39 User identifiers

A user in a mail store can have multiple user identifiers for different purposes; this section provides a summary of some of the possible identifiers for a user:

Canonical Identifier

The canonical identifier for a user is typically derived from an LDAP lookup. In a default configuration, this is the value of the LDAP entry's uid followed by "@" and the domain name containing the user. The ldap_permid option (or if that's not set, the ldap_uid option) determine which LDAP attribute is used to construct this identifier. The `domainUidSeparator` domain LDAP attribute also alters how this attribute is constructed. This is also the value used for `%s` in the canonicalsearchfilter option.

External Identifier

For Cassandra store, this is the identifier used in IMAP ACL commands and when referencing shared folders through IMAP. Both ACL identifiers and shared folder names are internally stored using the store user identifer, but that is converted to and from the external identifier (if one exists) when IMAP is used. The ldap_extid option must be set to specify the LDAP attribute containing the external identifier, otherwise the store user identifier will be used.

LDAP Distinguished Name (DN)

The LDAP distinguished name provides a unique reference to a user entry in LDAP. Messaging Server does not have any specific requirements on which attributes are present in a user LDAP DN, although it is recommended that a subtree is created in LDAP for each set of users associated with one or more domain names. Messaging Server does not support multi-valued RDNs.

Original Login Identifier

The original login identifier is the identifier the user sends over the wire when performing a login or authentication operation. It may or may not be qualified by a domain name. There can be multiple valid login identifiers for the same user, but a given login identifier should uniquely match an LDAP entry. For LDAP search filter template options such as searchformat and replayformat, this identifier is referred to with the %o substitution. The `inetDomainSearchFilter` LDAP domain attribute typically determines how this is translated into a specific user's LDAP entry.

Permanent or Persistent User Identifier

Another name for the store user identifier, but explicitly noting that the identifier should be permanent and/or persistent. The ldap_permid option controls the LDAP attribute that contains this identifier for a given user.

Pre-Lookup Login Identifier

The pre-lookup login identifier is derived from the original login identifier by making sure it is qualified by the appropriate domain name. This includes converting any non-default domain delimiter (specified by the

loginseparator option) into the canonical delimiter (typically '@' or the first character listed in that option). This is determined prior to performing LDAP lookups for authentication purposes.

Store User Identifier

The store user identifier is the same as the canonical identifier, except that if the domain name is the default domain, then the domain portion of the identifier is omitted. Message store command line tools use this identifier when referring to users. For the classic message store, mboxutil can be used to migrate the content of a store user identifier's account to a new user identifier (due to IMAP ACLs and shared folder subscriptions, the process is not fast and will cause problems when the user being renamed is logged in). For Cassandra store, this identifier can not be changed; instead an external identifier should be used as that can be changed easily.

Part V Proxies and the MMP

Proxies and the MMP, for accessing the Message Store have a number of configuration options.

Chapter 40 Proxy options

Various options may be set under a named `proxy` group to control aspects of proxy connection authentication and port and hosts. Note that since such options are set under a named proxy group, where the group name is a host name, such options are set using syntax such as:

```
msconfig> set proxy:host\.domain\.com.proxy-option-name option-value
```

(In particular, note that when a group name has embedded period characters, as is routine for hostnames, each such embedded period in the name requires backslash quoting on the command line.)

See also the base options with names beginning `proxy*` as they set defaults if the proxy options are not set.

40.1 `httpadmin` Option

DEPRECATED: See the `proxyadmin` Base option instead.

Store admin login name for a specific host if different from `local.service.http.proxy.admin`. Not configured by default.

40.2 `httpadminpass` Option

DEPRECATED: See the `proxyadminpass` Base option instead.

The `httpadminpass` Proxy option specifies the store admin password for a specific host if different from `local.service.http.proxy.adminpass`. Not configured by default.

40.3 `imapadmin` Option

The `imapadmin` proxy option specifies the store admin login name for a specific host if different from `proxyadmin` base option (`local.service.proxy.admin` in legacy configuration). Not configured by default.

40.4 `imapadminpass` Option

The `imapadminpass` proxy option specifies a store admin password for a specific host if different from `proxyadminpass` (`local.service.proxy.adminpass` in legacy configuration). Not configured by default.

40.5 imapport Option

The imapport proxy option (legacy configuration local.service.proxy.imapport.hostname) specifies the IMAP port number used when connecting to the backend mail store hostname specified by the Unified Configuration group name for the proxy group. Thus a setting of imapport could appear along the lines of:

```
msconfig> set proxy:host\.domain\.com.imapport 143
```

where each period character in the backend host name host.domain.com must be quoted with a backslash character in the msconfig command. If imapport is set, then it overrides for connections to that backend mail store the base.proxyimapport option's value (default 143).

40.6 storehostlist Option

The storehostlist Proxy option specifies a list of server hostnames that have access to the same message store data. For classic store, the first hostname in the list should be the default master for the message store while the other hosts in the list should be configured to act as failover hosts for the master. For Cassandra store, the hosts are considered equivalent but connections are attempted in order.

When a mailHost attribute is found in LDAP, it is first resolved via this configuration. This allows MMP, mshttpd, imapd and MTA clients (with affinitylist) to try connecting to the mail store via an alternative host. The hostnames used in this option must match the hostnames in the mailHost attributes exactly (although ASCII case variations are permitted).

The value of the base.hostname option must be present in the storehostlist if you want the current host to participate in that replication group.

40.7 hostselect Option

The hostselect Proxy option specifies how the back-end server is selected from a list of possible hosts in the storehostlist option when a front-end service such as the MMP, mshttpd or LMTP client connects to a back-end service. The failover value routes all connections to the first host in the list or the host that was most recently successful for this affinity group. This value is recommended when using the automatic failover feature of the classic message store. The roundrobin value uses each host in the list in sequence to provide limited load balancing between the hosts and is recommended for use with the Cassandra message store.

Chapter 41 MMP and IMAP Proxy and POP Proxy and vdomain options

There are many options affecting MMP operation, or operation of its subcomponents the IMAP Proxy, or the POP Proxy, plus additional options modifying the support for "virtual domains". These options are often available for setting at more than one scope; they are listed, with their defaults, in MMP and its subcomponents, available options and their defaults.

Table 41.1 MMP and its subcomponents, available options and their defaults

Option	MMP	IMAP Proxy	POP Proxy	SUBMIT Proxy	vdomain

See also the logfile options, which are available at many levels, including for the MMP and its components.

Note that many Base options are relevant to the MMP, including stressperiod and stressfdwait.

41.1 enable Option Under the MMP

The enable MMP option enables the MMP service on start-msg startup. The default if this option is not set is 0, but initial configuration may set the option to enable the MMP, as appropriate.

To actually run a proxy server, note that the proxy server must have a tcp_listen block defined with at least one non-zero port specified within that block; see in particular the tcp_ports and ssl_ports tcp_listen block options.

41.2 adminpolicy Option

The adminpolicy MMP option specifies the algorithm used to determine which users have administrative proxy privilege when authenticating to the MMP. The default simple setting means there is only one administrator specified by the storeadmin option. The group setting causes the MMP to ignore the storeadmin option when determining who is and administrator and instead use the group-based admin policy used by the MTA and message store. In particular, proxy admins can be specified by the store.admins option, the store.indexeradmins option, the service administrators group as determined by the serviceadmingroupdn option, or a domain administrator group (a group within the domain with the inetMailAdministrator objectclass).

41.3 memcached_enable Option

The memcached_enable MMP option specifies whether badguy information is stored in memcached server or in process memory. The default is 0. If set to 1, stored in memcached.

41.4 memcached_host Option

The memcached_host MMP option specifies the memcached server host name. The default is local host.

41.5 memcached_port Option

The memcached_port MMP option specifies the port Number memcached listens to. The default port is 11211.

41.6 authcachettl Option Under the MMP

The Messaging Server can cache the results of successful LDAP authentication (*e.g.*, when logging into IMAP, or POP, or when the MMP has preauth enabled). The authcachettl

option (available at base, MMP, IMAP Proxy, POP Proxy, and vdomain levels) defines the length of time that authentication cache entries are preserved in seconds. Lower values will reduce performance, but result in faster recognition of server password changes. Higher values will increase performance, but result in delayed recognition of server password changes. Changes made to a `userPassword` value in a user's LDAP entry are not seen until the cache entry's time-to-live (TTL) has expired. If you wish to have password changes seen at least every 15 minutes, then set the `authcachettl` value to 900.

41.7 `authenticationldapattributes` Option

The `authenticationldapattributes` Auth option specifies a space-separated list of additional LDAP user attributes to look up and pass to the third-party authentication server. This option is also available at `imapproxy`, `popproxy`, and `vdomain` level (to override, for the respective lookups, the general Auth option). To enable support for a third-party authentication server, set the `authenticationserver` option. For developer instructions and SDK see the directory `msg_svr_base/examples/tpauth`.

41.8 `authenticationserver` Option

The `authenticationserver` Auth option specifies the hostname and port for a third-party authentication service to use for authentication. This option is also available at `imapproxy` and `popproxy` level (to override, for the respective server, the general Auth option). The recommended value is `:56` when a third-party authentication service is available on the loopback interface of the server process performing authentication. For developer instructions and SDK see the directory `msg_svr_base/examples/tpauth`.

When not set, the servers will authenticate via LDAP.

41.9 `authservice` Option

If `authservice` is set to 1 and `authservicettl` is positive, the MMP will allow queries about who is currently logged into the MMP, for the purpose of POP before SMTP relay authentication. This option is available at the `popproxy` and `vdomain` levels. This option should almost never be turned on globally; you should configure this by virtual domain. Setting the `authservice` parameter to 1 permits probing of the authservice cache with the xqueryauth ip-address command over the POP protocol.

41.10 `authservicettl` Option

The MMP can be configured to remember from which IP address a particular user has authenticated for a period of time. `authservicettl` controls that period of time; it may be set at the `popproxy` or `vdomain` level. This is primarily used for POP before SMTP service, in which case this should be a value greater than 0. A setting of -1 will disable this feature.

41.11 `backsideport` Option

The `backsideport` option, available for the IMAP Proxy and POP Proxy, specifies the port the MMP will use when connecting to a message store server. This option lets you run a multiplexor and a store server on the same machine, with the store server on a different port. If

the value of backsideport option is same as sslbacksideport then the MMP will use SSL to connect to the message store server.

41.12 banner Option Under the MMP

The banner MMP option specifies a banner replacement string. The MMP will use the string you specify for its greeting line. The default banner string contains the software name and version information:

```
Messaging Multiplexor (product-name version numberbit (built build-date))
```

41.13 banner Option Under the IMAP proxy

The banner IMAP Proxy option specifies a banner replacement string. The IMAP Proxy will use the string you specify for its greeting line. The default banner string contains the software name and version information.

41.14 banner Option Under the POP proxy

The banner POP Proxy option specifies a banner replacement string. The POP Proxy will use the string you specify for its greeting line. The default banner string contains the software name and version information.

41.15 bethegroup Option

Group ID of for the MMP AService process. DELETED: As of 7u4 (7.4-18.01), the MMP uses the primary group of the user specified by betheuser; or in Unified Configuration, the user option in restricted.cnf is preferred.

41.16 betheuser Option

This specifies the Unix user ID that will be used as the owner of the MMP's AService process (the process group owner will be the primary group of that user). This is deprecated in favor of the user option in restricted.cnf which will be used preferentially. If this is not set and restricted.cnf is not present, the MMP will attempt to use the imta_user option from imta_tailor instead. For the 7.0.5 release, the MMP will attempt to use local.serveruid before checking imta_tailor. The value of this option must match the values of the imta_user and local.serveruid options.

Note that this option is not migrated into the Unified configuration, but is checked to ensure that it is the same as the user option in restricted.cnf.

41.17 bgmax Option

The bgmax option (available under base, imap, pop, mmp, imapproxy, and popproxy) specifies the maximum number of IP addresses associated with authentication failures to keep track of simultaneously. See bgpenalty for more information.

41.18 bgpenalty Option

When an authentication failure occurs from a particular client IP address, subsequent authentication attempts from that IP address are treated as "BadGuys" and are delayed. If an authentication failure is followed by a successful authentication, the successful authentication is delayed, but the IP address ceases to be treated as a "BadGuy" for subsequent attempts.

The bgpenalty option (available under base, imap, pop, mmp, imapproxy, and popproxy) specifies the length of time in seconds added to the authentication delay after each failed authentication.

41.19 bgmaxbadness Option

The bgmaxbadness option (available under base, imap, pop, mmp, imapproxy, and popproxy) specifies the maximum length of time in seconds for the authentication delay which occurs after a series of failed authentication attempts. See bgpenalty for more information.

41.20 bgdecay Option

The bgdecay option (available under base, imap, pop, mmp, imapproxy, and popproxy) represents the time in seconds it takes for a BadGuy's penalty to be forgiven. See bgpenalty for more information.

41.21 bglinear Option

The bglinear option (available under base, imap, pop, mmp, imapproxy, and popproxy) defines whether a BadGuy's penalty decays linearly over time (1), or is a step function on expiration (0). See bgpenalty for more information.

41.22 bgexcluded Option

The bgexcluded option (available under base, imap, pop, mmp, imapproxy, and popproxy) represents a list of excluded IP/mask pairs, or the name of a file to read for these pairs. These client addresses will not be penalized for authentication failure (there is no default value).

41.23 binddn Option

DEPRECATED: Consider using the ugldapbinddn option instead.

The binddn option specifies the Distinguished Name used by the MMP to authenticate to the Directory Server. For schema 1, the binddn must have privileges to access the domain tree as specified by the ldapurl option as well as any users referenced from that domain tree. For schema 2, the binddn must have privileges to access the usergroupdn tree.

The Messaging Server default directory ACIs require a bind to authenticate users against the Directory Server.

41.24 bindpass Option

Password the MMP uses in conjunction with the binddn option. DEPRECATED: Consider using ugldapbinddn and ugldapbindcred instead.

41.25 canonicalvirtualdomaindelim Option

The canonicalvirtualdomaindelim option (available for mmp, imapproxy, and popproxy) specifies the canonical virtual domain delimiter: that is, the character used by the POP and IMAP proxy to separate the user ID from the appended virtual domain when replaying the user name to the Message Store server. The default is the at-sign character, @, so user IDs passed to the Message Store servers have the form userid@virtual.domain.

41.26 capability Option

The capability IMAP Proxy option specifies the capability replacement string. The MMP will use the string you specify for capability instead of its default (own) capability to tell IMAP clients what it (or the servers behind it) can do. This variable has no effect in POP3. There is no need to include STARTTLS and AUTH= extensions as they are added automatically based on the other relevant MMP configuration settings.

There is no need to adjust this string if the backend IMAP servers are entirely from the same version of the Messaging Server installer. Otherwise, it is important to specify a capability list that includes only the features supported by all the backend IMAP servers. The appropriate string can be determined by telnetting to port 143 on each kind of backend server and entering the command c capability. Then list only the capabilities present on all backend IMAP servers.

41.27 certmapdn Option

The legacy configuration certmapdn has been replaced in Unified Configuration by use of the more general usergroupdn option.

41.28 certmapfile Option

Legacy config only: The name of the certmap file (for SSL client-cert-based authentications). It may be a full path, but the product's configuration directory will be searched if only a file name is provided.

When this is not set, there is no certmap file and thus the MMP will not request client certificates from the client.

The recommended setting is certmap.conf.

This points to the certmap file that will be migrated into the relevant part of the MMP's Unified configuration.

41.29 connecttimeout Option Under the MMP

The connecttimeout MMP option specifies how long the MMP should wait for a connection to be established to a back-end mailstore (seconds).

41.30 connecttimeout Option Under the IMAP proxy

The connecttimeout IMAP Proxy option specifies how long the MMP IMAP proxy should wait for a connection to be established to a back-end mailstore (seconds).

41.31 connecttimeout Option Under the POP proxy

The connecttimeout POP Proxy option specifies how long the MMP POP proxy should wait for a connection to be established to a back-end mailstore (seconds).

41.32 connlimits Option

The connlimits option (available under http, imap, pop, mmp, imapproxy, popproxy, specifies the maximum number of connections per IP address for the selected server. The syntax is: "*realm1*,*realm2*,..." where a realm has the form of address ranges and maximum number of connections expressed as any of the following four forms:

Table 41.2 connlimits Option Value Forms

a.b.c.d|e.f.g.h:m		IPv4 address, netmask, connection max
	a.b.c.d	IPv4 address
	e.f.g.h	network mask
	m	maximum connection count
a.b.c.d/p:m		IPv4 address, routing prefix, connection max
	a.b.c.d	IPv4 address
	p	routing prefix
	m	maximum connection count
a.b.c.d|e.f.g.h:m		IPv4 address, netmask, connection max
	a.b.c.d	IPv4 address
	e.f.g.h	network mask
	m	maximum connection count
[a/p]:m		IPv6 address, routing prefix, connection max
	a	IPv6 address; compressed "::" format allowed
	p	routing prefix
	m	maximum connection count
a.b.c.d|e.f.g.h:m		IPv4 address, netmask, connection max
	a.b.c.d	IPv4 address
	e.f.g.h	network mask
	m	maximum connection count
:m		Match any address

m	maximum connection count

There should be at least one realm of the form ":m" to cover the default case by matching any IPv4 or IPv6 address. To match only IPv4 addresses, use "0.0.0.0/0:m" or "0.0.0.0|0.0.0.0:m". And to match only IPv6 addresses, use "[::0/0]:m".

The option has no default value; however, initial configuration normally sets a value of `:20` for the IMAP Proxy, and POP Proxy:

```
msconfig> show connlimits
role.imapproxy.connlimits = :20
role.popproxy.connlimits = :20
```

For backwards compatibility reasons, this option may instead specify the full path to a configuration file name that contains one realm per line. Such a file name must begin with '/'. This usage is deprecated and may be removed in a future release.

41.32.1 connlimits Option Under isc_client

The `connlimits` isc_client option specifies the maximum number of connections that are permitted from a single LMTP process to the ISC server. Starting with 8.0.2.2, this isc_client option is deprecated; the `isc_client.max_conns` option should be used instead.

41.33 connrejectthreshold Option

The `connrejectthreshold` MMP option specifies the number of connections to accept before rejecting client connections with a soft error at connection time. The default value is computed based on the operating system file descriptor limits for the MMP server process, or 2000 if such file descriptor limits can not be determined. If this is set too high, connections can fail with a '`Too many open files`' error.

The default calculation is the file descriptor limit minus 64 (to leave space for log files, LDAP connection pools, internal pipes, etc) divided by 2.

41.34 crams Option

The `crams` option (available under `mmp`, `imapproxy`, `popproxy`, and `vdomain`) is a boolean indicating whether or not to enable the legacy Challenge-Response Authentication Mechanisms (CRAMs) including APOP and CRAM-MD5. For this to work, passwords must be stored in LDAP in plain text format and the `BindDN` must have read access to the `userPassword` attribute -- or in more modern configurations `ugldapbinddn` must have read access to `ugldapbindcred`. If `crams` is not set, the has_plain_passwords option will be used instead.

Use of this option in new deployments is strongly discouraged as these authentication mechanisms provide poor security characteristics for the modern Internet.

41.35 debugkeys Option

The `debugkeys` option (available under `base`, `mmp`, `imapproxy`, `popproxy`, and `vdomain`) specifies a space-separated list of keywords used to enable various optional debugging facilities. Currently recognized keywords are listed in the table below.

Table 41.3 Keywords for debugkeys option value

Keyword	Function
archive	log diagnostics for imapd archiving interface
authserv	log auth server protocol communications (new in 7.0.5)
bind	log additional details about some TCP socket bind attempts
certmap	log debug-level details about certificate mapping operations used for client certificate authentication (new in 7.0.5)
connect	log additional details about some TCP connection attempts (more coverage in 7.0.5)
dkim	diagnostics for built-in DKIM signing (new in 8.1.0.1)
dkimsig	perform an extra sanity check for built-in DKIM signing (new in 8.1.0.1) that is slower but may produce better diagnostics.
dkhash	log information about exactly how the DKIM hash is computed, including message content (may have privacy concerns).
dkimkey	log parsed DKIM private keys used for signing (may have privacy concerns).
dnsrbl	diagnostics for MMP DNS RBL function in main MMP log file (new in 8.0.2.3)
enssub	enable logging of ENS subscribe/unsubscribe events at notice level (new in 8.0)
gdisp	help diagnose generic dispatcher API issues
gdwork	GDisp worker thread information
gdcvar	GDisp condition variables (not presently used by the MMP).
eventloop	Log GDisp event loop statistics. May be helpful to diagnose performance problems (new in 8.0.2.2).
http	Log http transcripts related to Elasticsearch and ISC. (new in 8.0.2.2).
hula	log state changes in HULA (user lookup / authentication, new in 7.0.5)
ldap	log an LDAP directory protocol trace (replaces the now deprecated ldaptrace base option)
lpool	log ldap connection activity (mostly INFO & DEBUG level, new in 7.0.5); for MTA output, see also the os_debug MTA option
maparse	Diagnostics for IMAP mail access parser (new in 8.0). The set of IMAP commands this covers presently includes APPEND, STORE, SETMETADATA, SEARCH, ESEARCH, SORT, THREAD. Additional commands will be added over time. This is refreshable.
metermaid	log transcript of metermaid client used to limit IMAP password expiration alerts (new in 7.0.5)
perf	log performance-related timestamps particularly with respect to MMP authentication
search	log IMAP search and sort command processing at DEBUG level (new in 7.0.5)
tls	enable additional SSL/TLS debugging (presently just lists active cipher suites in the MMP log)

`unicodembox`	enable debugging for unicode normalization of mailbox names (new in MS 8.0.2)

41.35.1 Use with base

The `debugkeys` base option specifies a space-separated list of keywords used to enable various optional debugging facilities; see Keywords That May Be Included in debugkeys Option Value.

Note that the SMTP server's `AUTH_DEBUG` TCP/IP-channel-specific option can override `debugkeys` for SMTP server authentication purposes.

For Message Store and other non-MTA processes, setting a relevant debugkey will enable NOTICE-level logging in the logfile for that process. The MTA has a different logging model and requires two additional settings to see debugging associated with a debugkey. First, MTA debug log files must be enabled (via `master_debug`, `slave_debug`, or the equivalent finer-grained mechanism). Second, it's necessary to set `mta.mm_debug` to a value of at least 3 for the DKIM-related debugkeys or to set `mta.os_debug` to 1 for the LDAP and authentication-related debugkeys.

41.36 `defaultdomain` Option

When POP, IMAP and SMTP users authenticate, they typically provide an unqualified user ID (a user ID without a domain portion). The value of the `defaultdomain` option is appended to unqualified user IDs. When used as an MMP virtual domain option, this allows a single MMP server with multiple IP addresses to support unqualified user IDs for multiple hosted domains. This may also be set as a service-wide option.

41.36.1 Use with base

The `defaultdomain` base option specifies the Messaging Server default domain. This is used to determine whether a domain is the default domain or a hosted domain.

Normally the `defaultdomain` base option is set to an appropriate value during initial configuration.

The MTA has a "twin" option, `ldap_default_domain`, that can override the `defaultdomain` base option for MTA purposes. See the description of `ldap_default_domain` for details on how the MTA uses the `defaultdomain` value (if `ldap_default_domain` is not set).

41.37 `dnsrbl` Option

The `dnsrbl` MMP option provides a list of domain names used to perform a DNS Realtime Blackhole List check for incoming POP and IMAP connections. The checks are performed in serial and may significantly impact the time it takes for clients to connect to the proxy. When a connection is rejected, a protocol-appropriate access denied error will be provided unless the connection is over SSL and the `sslconnlimit` option is also set, in which case an SSL `user_canceled` alert will be sent. If the `messagetrace.activate` option is set to `transactlog`, then the rejection will be noted in a `co` log entry in the store transaction log.

41.38 domainallowed Option Under the IMAP proxy

The domainallowed IMAP Proxy/POP Proxy option (also available under ens, eval_ldapd, http, imap, and pop) specifies access filters specifying which domains and/or IP addresses are allowed access for the selected server.

41.39 domainnotallowed Option Under the IMAP proxy

The domainnotallowed IMAP Proxy/POP Proxy option (also available at other levels) specifies access filters specifying which domains and/or IP addresses are not allowed access for the selected server.

41.40 domainsearchformat Option

The domainsearchformat option (available under mmp, imapproxy, popproxy, and vdomain) specifies a printf-style format string with which to construct Users/Groups LDAP queries for the user's mailhost when hosteddomains is enabled. If domainsearchformat is not set, then the searchfilter option will be used (regardless of whether hosteddomains is set). Valid escape sequences are:

```
%s (userid+virtualdomain)
%U (userid only)
%V (virtual domain only)
%C (client IP address)
%S (server IP address)
%D (client cert subject DN)
%o (original user as passed from client)
```

41.41 hosteddomains Option

The hosteddomains option (available under mmp, imapproxy, popproxy, and vdomain) specifies whether the MMP should use Hosted Domains. The default is 1, meaning that Hosted Domains are supported. If hosteddomains is set to 0, then the value of the searchfordomain authentication option controls the behavior during user authentication lookups.

If you are using the Messaging Server directory schema (LDAP Schema, v1 or LDAP Schema, v2), hosteddomains should be set to the default value of 1

If set to 0, then the MMP assumes the server supports only one domain and the ugldapbasedn option points to a directory subtree containing all users supported by the server, each user with a unique UID. Setting hosteddomains to "0" is not recommended as even a small company is likely to eventually go through a name change or acquisition where support for multiple domains would be helpful.

When set to 1, the MMP honors the following additional options (for legacy configuration, these appear in the MTA's option.dat configuration file):

ldap_schemalevel
ldap_domain_filter_schema1
ldap_domain_filter_schema2
ldap_attr_domain1_schema2
ldap_attr_domain2_schema2
ldap_global_config_templates
ldap_attr_domain_search_filter
ldap_domain_attr_basedn
ldap_domain_attr_canonical
ldap_domain_attr_alias

These settings may be used to enable LDAP Schema, v2 with the MMP.

41.42 ipv6in Option

When set to a value of 1, the ipv6in option instructs Messaging Server to accept inbound IPv6 connections for all services provided that the host has at least one network interface configured for IPv6. Services specifically configured to listen on only IPv4 interfaces cannot also accept inbound IPv6 connections. When set to a value of 0, inbound IPv6 connections are not allowed.

Inbound IPv4 connections will always be permitted.

41.43 ipv6out Option

When set to a value of 1, the ipv6out option instructs Messaging Server to attempt outbound IPv6 connections for all services provided that the host has at least one network interface configured for IPv6. Services specifically configured to bind their source IP address only to IPv4 interfaces cannot attempt IPv6 outbound connections. For example, an SMTP client bound to a specific IPv4 interface cannot then establish an outbound IPv6 connection. When set to a value of 0, outbound IPv6 connections are not allowed.

When set to a value of 1, outbound services will attempt DNS lookups of both A and AAAA records. Connection attempts will then be made in the order dictated by the ipv6sortorder option. Note the DNS lookups will always request A records. This option only controls whether or not AAAA records are also requested.

41.44 langlist Option

The langlist option (under mmp or imapproxy) controls the list of supported languages returned by the IMAP LANGUAGE extension when issued to the MMP prior to authentication.

41.45 ldapcachesize Option

The MMP can cache results of user searches. The ldapcachesize option (available under mmp, imapproxy, popproxy, and vdomain) defines the number of cache entries; ldapcachettl defines the length of time the entries are preserved in seconds. Lower values will reduce performance, but result in faster recognition of LDAP user entry changes. Higher values will increase performance, but result in delayed recognition of LDAP user

entry changes. If this is not set, then the authcachesize option's value will be used instead. If ldapcachesize is set, it will override authcachesize for MMP purposes only.

41.46 ldapcachettl Option

The MMP can cache results of user searches. The ldapcachesize option defines the number of cache entries; ldapcachettl (available under mmp, imapproxy, popproxy, and vdomain) defines the length of time the entries are preserved in seconds. Lower values will reduce performance, but result in faster recognition of LDAP user entry changes. Higher values will increase performance, but result in delayed recognition of LDAP user entry changes.

Note that setting ldapcachettl smaller than authcachettl causes the entire user entry to expire, thereby also expiring the user authentication information in that user entry.

41.47 ldappendingoplimit Option

The ldappendingoplimit option (available under mmp, imapproxy, and popproxy) specifies the number of in-progress LDAP connections the MMP will allow before it will delay incoming connections to wait for previous LDAP operations to complete. This prevents a denial-of-service attack on the MMP from impacting the LDAP server.

The default has changed from 20 to 128 in the 7.0.5 release.

41.48 ldaprefreshinterval Option

The ldaprefreshinterval option (available under mmp, imapproxy, and popproxy) specifies the seconds that the MMP will keep a connection open to the LDAP server. When the MMP notices that the refresh interval has passed, the MMP will close the LDAP connection and open a new one.

41.49 ldaptimeout Option

The ldaptimeout option specifies the number of seconds the MMP will wait for an LDAP operation to complete before it will attempt a failover to a backup LDAP server or fail the operation. DEPRECATED: Consider using the ldapsearchtimeout and ldapmodifytimeout options instead.

41.50 ldapurl Option

DEPRECATED as of 7.0.5: consider using ugldaphost, ugldapusessl, dcroot and ugldapbasedn instead.

The ldapurl option, available for the MMP, IMAP Proxy, and POP Proxy specifies an LDAP URL pointing to the top of the site's DC directory tree (used by schema 1), if hosteddomains is set to yes (default). If hosteddomains is set to no, then ldapurl points to a directory subtree containing all users supported by the server. Prior to 7.0.5, this option was needed for the MMP to operate correctly. For schema 2 support, the usergroupdn option must be set and is used instead of the path portion of this URL.

SSL (LDAPS) is supported, but the SSL configuration must also be correct, and SSL-enabled.

To enable failover, the host part of the URL may be a space-separated list of hosts. Be sure to enclose the entire URL in double-quotes if it contains a space. For example:

```
"ldap://ldap1.example.com ldap2.example.com/o=internet"
```

41.51 logdir Option

The logdir logfile option, *component*.logfile.logdir, specifies the directory path for log files. If this is not specified, log files will be placed in the DATAROOT/log directory.

For the MTA, the mta.logfile.logdir option is only used by Message Store insertion tasks. It specifies the directory path to the imta log file used for Message Store insertion (ims_master, LMTP). It is not used by other parts of the MTA which always log to the default location. The default location is DATAROOT/log. Changing that path to a soft-link is supported.

41.51.1 Use with isc

The logdir isc option specifies the log files location for ISC.

The user that owns the ISC process must have write permissions to this location.

41.51.2 Use with fit

The logdir fit option specifies the log files location for FIT.

The user that owns the DSE (Cassandra) process must have write permissions to this location.

41.52 loglevel Option Under the MMP

The MMP's loglevel option can be: nolog, emergency, alert, critical, error, warning, notice, information or debug. Note that loglevel will be ignored by the MMP if use_nslog is set to 0.

The MMP will not generate messages with priority higher than 'error'. For backwards compatibility, MMP configuration files may use integer settings from 3 to 7 for 'error' to 'debug' respectively, or 0 for 'nolog'.

41.53 loglevel Option Under the IMAP proxy

The IMAP Proxy loglevel option can be: nolog, emergency, alert, crticial, error, warning, notice, information or debug. The MMP will not generate messages with priority higher than 'error'.

41.54 loglevel Option Under the POP proxy

The POP Proxy loglevel option can be: nolog, emergency, alert, crticial, error, warning, notice, information or debug. The MMP will not generate messages with priority higher than 'error'.

41.55 mailhostattrs Option

The mailhostattrs option (available under mmp, imapproxy, popproxy, and vdomain) specifies a space-separated list of LDAP attributes identifying the user's mail host; the default is simply mailHost. The multiplexor tries each attribute returned by the search in the order specified by the list to identify the mail store where that user's mail lives.

This is rather analogous to the MTA's ldap_mailhost option.

41.56 maxconcurrentconnectionattempts Option

The maxconcurrentconnectionattempts option (available under mmp, imapproxy, and popproxy) specifies the number of outstanding connection attempts permitted to the same backend mailstore. If this is exceeded, users on that mailstore will have their connections rejected with a temporary service outage error. This limit prevents a DNS or mailstore outage of one server from consuming all the MMP worker threads.

The default has changed from 10 to 32 in the Messaging Server 7.0.5 release.

41.57 maxthreads Option Under the MMP

The maxthreads MMP option specifies the maximum number of threads allowed per server process for the selected server. The MMP does not count worker threads attempting to lookup or connect to a back-end server against this limit; see the separate maxconcurrentconnectionattempts option to limit such connections.

41.58 numprocesses Option Under the MMP

The numprocesses MMP option specifies the number of MMP AService processes.

Note that the Watcher must be enabled for stop-msg to correctly shut down all processes if this is set to a value larger than one.

41.59 numthreads Option

The numthreads MMP option had specified the maximum number of worker threads to permit for the MMP.

DELETED: This MMP AService.cfg option was removed in favor of the maxthreads option.

41.60 plaintextmincipher Option Under the IMAP proxy

If the plaintextmincipher option under imapproxy or popproxy is > 0, then disable use of plaintext passwords over the respective service unless a security layer (SSL or TLS) is activated for the selected service. This forces users to enable SSL or TLS on their client to login which prevents exposure of their passwords on the network.

41.61 polldelay Option

Solaris-only. The polldelay (IMAP and MMP) option specifies the wait time before calling poll() in milliseconds. Workaround for poll performance bug on Solaris (6438988, 6379476). Setting this to -1 activates a different workaround as of 7 update 4 patch 24. The alternate code tries to keep the size of the poll array relatively constant and instead uses -1 in the poll array for inactive descriptors. The poll array will be larger, but change size less frequently. To date this appears to noticably improve performance under stress.

The default has changed from 1 to -1 in the Messaging Server 7.0.5 release. In addition, poll is no longer used in the Messaging Server 7.0.5 release (and thus this option is ignored) unless preferpoll is set.

41.62 preauth Option

The preauth option (available under mmp, imapproxy, popproxy, and vdomain) enables pre-authentication by the MMP. When preauth is set to 1 (yes in legacy configuration), a user is authenticated against the LDAP server before a connection is made to the backend mailstore server. When preauth is set to 0 (no in legacy configuration), the MMP connects to the backend mailstore server and simply replays the authentication information. Because of the additional authentication step, preauth reduces the overall performance, but protects the backend mailstore servers from denial-of-service attacks by unapproved users. preauth is mandatory for the POP-before-SMTP feature of the MMP.

When using hosteddomains, the mailAccessProxyPreAuth attribute in the domain node in the LDAP server overrides this option.

41.63 preauthtimeout Option

The preauthtimeout option (available for the IMAP Proxy, POP Proxy) specifies the MMP session timeout prior to authentication.

41.64 preferpoll Option

To improve performance, the IMAP and MMP servers use Solaris Event Completion Ports on Solaris instead of the poll system call starting with the Messaging Server 7.0.5 release. Since the Messaging Server 8.0.1 release, the servers use epoll on Linux instead of the poll system call. Setting the preferpoll option (available at base and MMP level) to 1 will revert to use of the standard Posix poll API instead. When preferpoll is set to 1, then the polldelay option also applies.

41.65 replayformat Option Under the MMP

The replayformat MMP/IMAP Proxy/POP Proxy/vdomain option takes an argument of a printf-style format string that says how to construct the user ID for replay to the Message Store server. Valid escape sequences are:

```
%s (user@domain where '@' is the canonical domain delimiter)
%o (original user as sent by the client)
```

```
%U (userid only, prior to LDAP lookup)
%V (virtual domain only)
%A[attr] (value of user's attribute "attr")
```

For example, %A[uid]@%V for a user with joe as the value of the UID LDAP attribute and domain=siroe.com would yield:

```
joe@siroe.com
```

For the MMP, when using hosteddomains, the mailAccessProxyReplay attribute in the domain node in the LDAP server overrides this option.

41.66 replaypass Option

The replaypass option (available under mmp, imapproxy, and popproxy) is a boolean indicating whether to replay the end-user's password to the back-end IMAP or POP server. If this is set to 0, then the password is not replayed and administrative proxy authentication is used, so the storeadminpass option must also be set.

41.67 requireauthenticationserver Option

The requireauthenticationserver option is available under auth and under imapproxy and popproxy.

When an authentication server is configured using the authenticationserver option, and requireauthenticationserver is 1 (the default), that server must be running and responding to requests or authentication will not succeed. If requireauthenticationserver is set to 0, then built-in authentication mechanisms will be permitted even if the authentication server ceases to respond to requests.

41.68 restrictplainpasswords Option

When the restrictplainpasswords option (available under mmp, imapproxy, popproxy, and vdomain) is set to 1, this will forbid use of plaintext passwords unless an SSL/TLS security layer is active. If this is not set, the plaintextmincipher option will be used.

41.69 searchformat Option

The searchformat option (available under mmp, imapproxy, popproxy, and vdomain) specifies a printf-style format string with which to construct Users/Groups LDAP queries to locate a user in the directory (and in particular to determine the user's mailhost) when hosteddomains is disabled -- or if hosteddomains is enabled but domainsearchformat is not set. Valid escape sequences are:

```
%s (userid+virtualdomain)
%U (userid only)
%V (virtual domain only)
%C (client IP address)
%S (server IP address)
```

```
%D (client cert subject DN)
%o (original user as passed from client)
```

41.70 serverdownalert Option

The serverdownalert IMAP Proxy option specifies the string returned to client in an IMAP ALERT message when the MMP cannot connect to a user's store server.

41.71 servicelist Option

For legacy MMP config only: The servicelist MMP option pecifies which services to start and the ports/interfaces on which the MMP will listen for those services. Services are listed all on a single line in the following format:

SERVICENAME @ *HOSTPORT* [| *HOSTPORT*]

where *SERVICENAME* is popproxyaservice, imapproxyaservice or smtpproxyaservice; (any prefix to these names is ignored for backwards compatibility).

This option must be set for the MMP to function correctly. The initial configuration (as of release 7 Update 3) will set this to:

```
ImapProxyAService@143 PopProxyAService@110
```

Note that this option is not migrated directly to the Unified configuration. Equivalent settings appear in the tcp_listen sections of the popproxy, and imapproxy sections.

41.72 spoofemptymailbox Option

If the spoofemptymailbox POP Proxy option is set to 1 (default is 0) and the user's POP server is unavailable, the MMP will simply return an empty mailbox listing. Turning this option on will override the spoofmessagefile option. We have received reports that this will cause certain clients (including Microsoft® Outlook) to re-download the mailbox when the back-end server comes back online.

41.73 spooftempfail Option

If the spooftempfail POP Proxy option is set to 1 (default is 0) and a temporary authentication error occurs subsequent to locating the user in LDAP, the MMP will simply return an empty mailbox listing or if spoofemptymailbox is 0 and spoofmessagefile is set, then the spoof message file will be used. We have received reports that this will cause certain clients (including Microsoft Outlook) to re-download the mailbox when the temporary condition is resolved.

A temporary authentication error can occur as a result of defer (or as of Messaging Server 7.5 defer-submit) or hold mail user status (mailUserStatus) or as a result of hold mail domain status (mailDomainStatus) prior to connecting to the back-end POP server, and can also occur if the back-end server returns a [SYS/TEMP] authentication failure. In the former case, the MMP's LDAP cache settings apply.

41.74 spoofmessagefile Option

The spoofmessagefile POP Proxy option specifies the file to use for POP3 inbox spoofing. The MMP can imitate a base-functionality POP3 server in case it can't connect to a client's store machine. In such a situation, the MMP creates an inbox for the user and places this one message into it. The format of the message contained in this file should conform to dot-stuffed RFC 822 (including the final '.').

By default, there is no spoof message file.

41.75 ssladjustciphersuites Option

The ssladjustciphersuites option allows adjusting which SSL cipher suites are enabled or disabled. (This option is available under base, mmp, imapproxy, popproxy, and vdomain.) SSL cipher suites control the level of protection required between SSL client and server. Different cipher suites have different properties and use different cryptographic algorithms. At any time a specific crytographic algorithm might be weakened or compromised by new research in cryptography. The ability to change the default cipher suites allows the software to adapt as security technology changes. In addition as CPUs get faster, the key size necessary to provide several years of comfortable protection increases, even if the algorithm is considered state-of-the-art.

The default set of SSL cipher suites used will change over time as more secure ones are introduced and weaker ones are deprecated. It is expected most deployments will be happy with the default set of cipher suites and it is generally not a good idea to adjust the available cipher suites without reason. However, here are some scenarios where it may be helpful to adjust cipher suites:

1. A site with specific security policies may wish to provide a fixed list of cipher suites to use that is set by site policy rather than simply using state-of-the-art suites provided by the NSS library. Such a site would typically configure this setting to '-ALL,...' where '...' contains the cipher suite names.

2. A site which is experimenting cipher suites that require installation of special server certificate types, for example the DSS cipher suites. Such a site would enable these additional suites once installation was complete.

3. If a site is forced to continue supporting a particularly old client that only supports old cipher suites, they can be explicitly enabled (for example '+RC4' enables the RC4 cipher suites).

4. A site that chooses to disable an older cipher or hash function pro-actively despite potential interoperability issues may choose to do so. For example, to disable all ciphers using the '3DES' or 'SHA1' algorithms, simply set '-3DES,-SHA1'. Be aware that this sort of pro-active action may generate support calls from end users running older mail clients.

5. In the event the cryptographic research community discovers a vulnerability in one or more of the ciphers enabled by default, this provides a mechanism to immediately disable those ciphers. For example, to disable all ciphers using the '3DES' algorithm, simply set '-3DES'.

As of NSS 3.28 (2017), the following cipher suites are enabled by default in the NSS library: TLS_AES_128_GCM_SHA256, TLS_CHACHA20_POLY1305_SHA256, TLS_AES_256_GCM_SHA384, TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256, TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256, TLS_ECDHE_ECDSA_WITH_CHACHA20_POLY1305_SHA256, TLS_ECDHE_RSA_WITH_CHACHA20_POLY1305_SHA256,

TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384,
TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA,
TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA,
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA,
TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256,
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256,
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA,
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384,
TLS_DHE_RSA_WITH_AES_128_GCM_SHA256,
TLS_DHE_RSA_WITH_CHACHA20_POLY1305_SHA256,
TLS_DHE_RSA_WITH_AES_256_GCM_SHA384,
TLS_DHE_RSA_WITH_AES_128_CBC_SHA, TLS_DHE_DSS_WITH_AES_128_CBC_SHA,
TLS_DHE_RSA_WITH_AES_128_CBC_SHA256, TLS_DHE_RSA_WITH_AES_256_CBC_SHA,
TLS_DHE_DSS_WITH_AES_256_CBC_SHA, TLS_DHE_RSA_WITH_AES_256_CBC_SHA256,
TLS_DHE_RSA_WITH_3DES_EDE_CBC_SHA,
TLS_DHE_DSS_WITH_3DES_EDE_CBC_SHA, TLS_ECDH_RSA_WITH_AES_128_CBC_SHA,
TLS_ECDH_RSA_WITH_AES_256_CBC_SHA, TLS_RSA_WITH_AES_128_GCM_SHA256,
TLS_RSA_WITH_AES_256_GCM_SHA384, TLS_RSA_WITH_AES_128_CBC_SHA,
TLS_RSA_WITH_AES_128_CBC_SHA256, TLS_RSA_WITH_AES_256_CBC_SHA,
TLS_RSA_WITH_AES_256_CBC_SHA256, TLS_RSA_WITH_3DES_EDE_CBC_SHA.

The complete list of cipher suites present in NSS 3.28 (2017) follows:
SSL_DHE_DSS_WITH_3DES_EDE_CBC_SHA, SSL_DHE_DSS_WITH_DES_CBC_SHA,
SSL_DHE_RSA_WITH_3DES_EDE_CBC_SHA, SSL_DHE_RSA_WITH_DES_CBC_SHA,
SSL_RSA_EXPORT_WITH_RC2_CBC_40_MD5, SSL_RSA_EXPORT_WITH_RC4_40_MD5,
SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA, SSL_RSA_FIPS_WITH_DES_CBC_SHA,
SSL_RSA_WITH_3DES_EDE_CBC_SHA, SSL_RSA_WITH_DES_CBC_SHA,
SSL_RSA_WITH_NULL_MD5, SSL_RSA_WITH_NULL_SHA,
SSL_RSA_WITH_RC4_128_MD5, SSL_RSA_WITH_RC4_128_SHA,
TLS_AES_128_GCM_SHA256, TLS_AES_256_GCM_SHA384,
TLS_CHACHA20_POLY1305_SHA256, TLS_DHE_DSS_WITH_3DES_EDE_CBC_SHA,
TLS_DHE_DSS_WITH_AES_128_CBC_SHA, TLS_DHE_DSS_WITH_AES_256_CBC_SHA,
TLS_DHE_DSS_WITH_RC4_128_SHA, TLS_DHE_RSA_WITH_3DES_EDE_CBC_SHA,
TLS_DHE_RSA_WITH_AES_128_CBC_SHA, TLS_DHE_RSA_WITH_AES_128_CBC_SHA256,
TLS_DHE_RSA_WITH_AES_128_GCM_SHA256,
TLS_DHE_RSA_WITH_AES_256_CBC_SHA, TLS_DHE_RSA_WITH_AES_256_CBC_SHA256,
TLS_DHE_RSA_WITH_AES_256_GCM_SHA384,
TLS_DHE_RSA_WITH_CHACHA20_POLY1305_SHA256,

TLS_ECDHE_RSA_WITH_3DES_EDE_CBC_SHA,
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA,
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256,
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA,
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384,
TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384,
TLS_ECDHE_RSA_WITH_CHACHA20_POLY1305_SHA256,
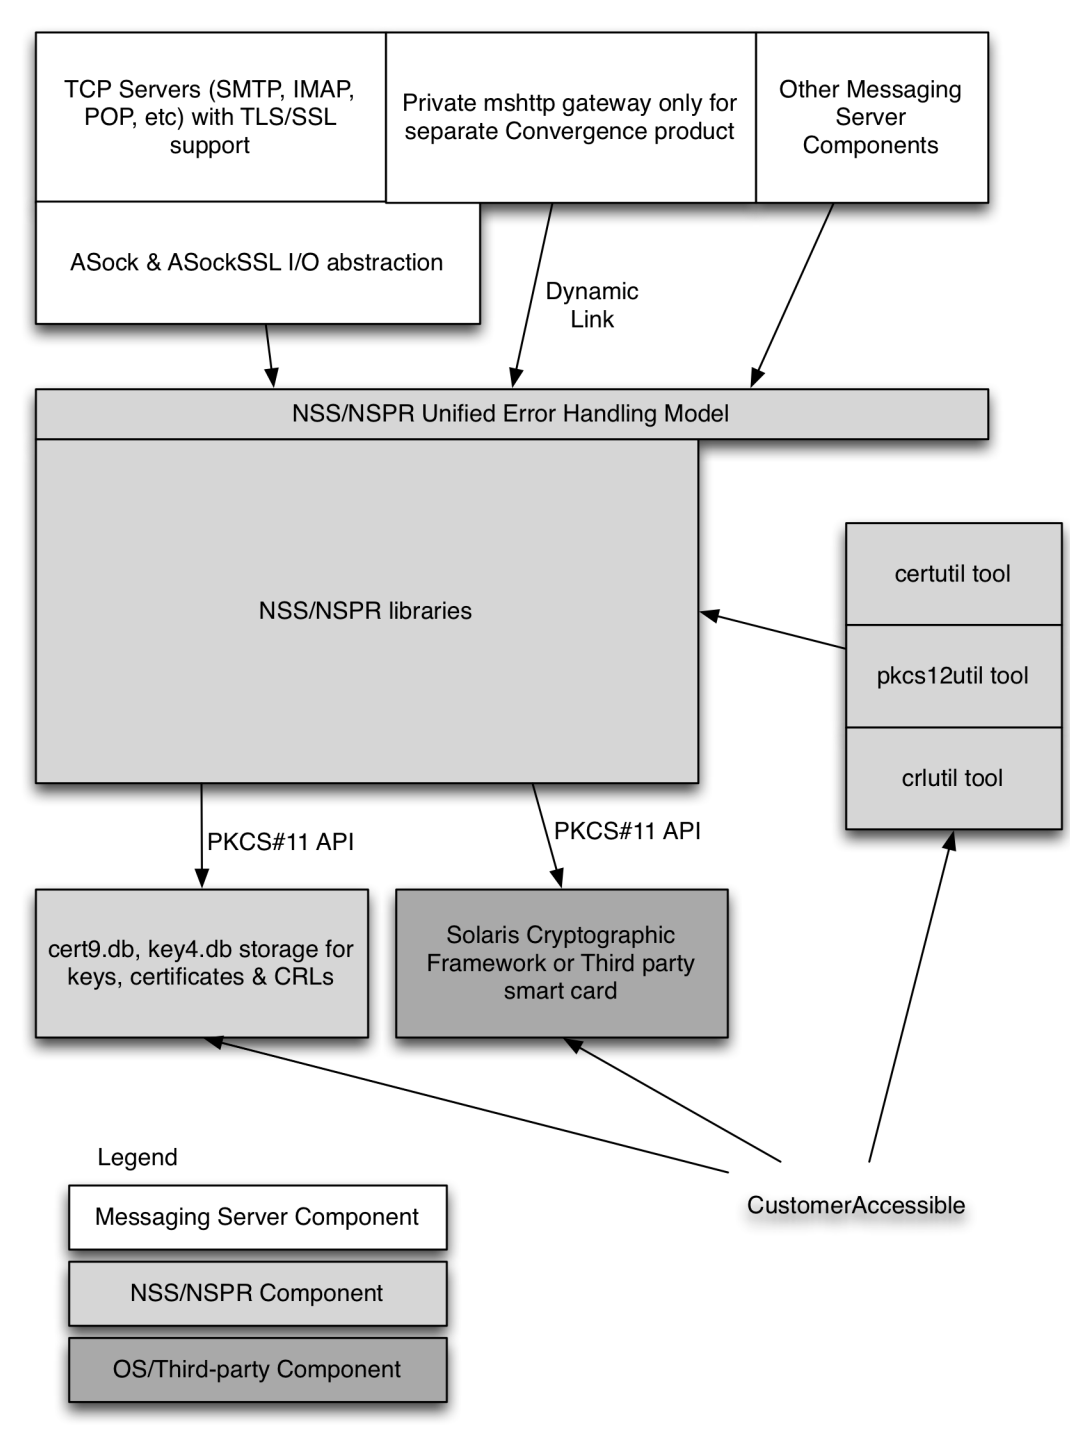
TLS_ECDHE_RSA_WITH_RC4_128_SHA,
TLS_ECDH_ECDSA_WITH_3DES_EDE_CBC_SHA,
TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA,
TLS_ECDH_ECDSA_WITH_AES_256_CBC_SHA,
TLS_ECDH_ECDSA_WITH_RC4_128_SHA, TLS_ECDH_RSA_WITH_3DES_EDE_CBC_SHA,
TLS_ECDH_RSA_WITH_AES_128_CBC_SHA, TLS_ECDH_RSA_WITH_AES_256_CBC_SHA,
TLS_ECDH_RSA_WITH_RC4_128_SHA, TLS_RSA_WITH_3DES_EDE_CBC_SHA,

TLS_RSA_WITH_AES_128_CBC_SHA, TLS_RSA_WITH_AES_128_CBC_SHA256, TLS_RSA_WITH_AES_128_GCM_SHA256, TLS_RSA_WITH_AES_256_CBC_SHA, TLS_RSA_WITH_AES_256_CBC_SHA256, TLS_RSA_WITH_AES_256_GCM_SHA384, TLS_RSA_WITH_CAMELLIA_128_CBC_SHA, TLS_RSA_WITH_CAMELLIA_256_CBC_SHA, TLS_RSA_WITH_RC4_128_MD5, TLS_RSA_WITH_RC4_128_SHA, TLS_RSA_WITH_SEED_CBC_SHA.

TLS 1.3 (NSS 3.39+) has its own cipher suites separate from previous TLS versions. These include: TLS_AES_128_GCM_SHA256, TLS_CHACHA20_POLY1305_SHA256, TLS_AES_256_GCM_SHA384.

Always keep in mind that adjusting the available ciphersuites can impact multiple protocols; NSS is tightly integrated into Messaging Server, as the following diagram illustrates:



41.76 sslbacksideport Option

The sslbacksideport IMAP Proxy and POP proxy option specifies the port number to which the MMP will try to connect on the store servers using SSL if an SSL connection was made to the MMP. If this parameter is not set, the MMP will not use SSL when connecting to the store. There are no default values, but ports 993 and 995 are recommended for IMAP and

POP, respectively. (On the relevant back end Message Store systems, see the sslport option for IMAP and POP, respectively, to see on what ports the backend Message Store is actually listening for such incoming SSL connections.)

41.77 sslcachedir Option

The sslcachedir option, (available under base, mmp, imapproxy, and popproxy), specifies the SSL session cache directory used to track SSL sessions across multiple connections by the MMP. Prior to 7.0.5.31.0, this also controlled the location of the SSL database files and defaulted to the config directory. As of the 7.0.5.31.0 release, the ssldbpath base option takes precedence over this option for specifying the location of SSL database files.

NOTE: In order for results to predictable, this option must be the same for the IMAP Proxy and POP Proxy -- any settings of this option for the proxies must match. (Or better yet, don't set it explicitly for any of the proxies; instead set it at MMP level.)

41.78 sslcertprefix Option

The sslcertprefix option (available under mmp, imapproxy, and popproxy) specifies the filename prefix to the SSL certificate database file. The certificate database file must be in the directory specified by the ssldbpath setting. No prefix will be used by default. DEPRECATED: The ssldbprefix option should be used instead.

NOTE: In order for results to predictable, this option must be the same for the IMAP and POP proxies.

41.79 sslenable Option

The sslenable option, available for the MMP, IMAP Proxy, and POP Proxy, specifies whether SSL is enabled for the specified proxy service (via the STARTTLS command).

41.80 sslkeypasswdfile Option

DELETED as of MS 7.0.5.

File location for the passwords that protect access to the private key file. Passwords may be null if the key is not password-protected. This option is deprecated, and will go away. Use is not recommended as all product components except the MMP: simply use the default sslpassword.conf name. If multiple SSL configurations are required, use ssldbpath to relocate these files instead.

NOTE: In order for results to predictable, this option must be the same for the IMAP, POP,and SMTP proxies -- that is, in legacy configuration it must be the same in the files ImapProxyAService.cfg, PopProxyAService.cfg and SmtpProxyAService.cfg, or in Unified Configuration any settings of this option for the various proxies must match.

41.81 sslkeyprefix Option

Filename prefix to the SSL key database file. The key database file must be in the directory specified by the ssldbpath setting. No prefix will be used by default. DEPRECATED: The ssldbprefix option should be used instead.

NOTE: In order for results to predictable, this option must be the same for the IMAP, POP,and SMTP proxies -- that is, in legacy configuration it must be the same in the files ImapProxyAService.cfg, PopProxyAService.cfg and SmtpProxyAService.cfg, or in Unified Configuration any settings of this option for the various proxies must match.

41.82 sslnicknames Option Under the MMP

The sslnicknames option (available at MMP, IMAP Proxy, POP Proxy, and vdomain level, as well as at Base and other levels) specifies a list of the nicknames of the certificates in the SSL certificate database to offer as the server certificate. Only one nickname of each certificate type is permitted (*e.g.*, one RSA certificate, one DSS certificate) so normally only one will be specified.

41.83 sslsecmodfile Option

Security module database file name. If you have hardware accelerators for SSL ciphers, this file describes them to the Messaging Server. DELETED: Support removed in 7.0.5 as customized module file name feature in NSS goes away with new cert9.db/key4.db/pkcs11.txt format.

41.84 storeadmin Option

The storeadmin option (available under mmp, imapproxy, popproxy, and vdomain) is set to the user name of the store administrator for proxy authentication and is necessary to support SSL client certificates and RFC 2595-style proxy authentication. If this is not set and the admins Message Store option is single-valued, the value of the admins option will be used instead. Otherwise MMP features requiring store admin credentials will be disabled.

41.85 storeadminpass Option

The storeadminpass option (available under mmp, imapproxy, popproxy, and vdomain) specifies the password for the store administrator used by MMP proxy authentication necessary to support SSL client certificates and RFC 2595-style proxy authentication. If not set, this defaults to the value of proxyadminpass.

41.86 syncldap Option

The syncldap option (available under imapproxy and popproxy) causes the IMAP Proxy or POP Proxy to do synchronous LDAP lookups instead of async LDAP lookups. This may improve performance under high load conditions by reducing the number of round-trips through the main poll dispatch loop. Make sure the ldappendingoplimit option is set to a value below maxthreads if this is enabled. Set this to 0 to get the pre-7.0.5 async LDAP behavior. The async LDAP behavior is deprecated and may be removed in a future release.

41.87 tcp_listen options

Named tcp_listen groups can appear under the imapproxy, and popproxy groups. Several options may be set under tcp_listen.

41.87.1 tcp_ports Option Under tcp_listen

Under a top level imapproxy or popproxy component, inside a named tcp_listen group, the tcp_ports option specifies the TCP port(s) on which that proxy server listens; *e.g.*:

```
msconfig> set imapproxy.tcp_listen:imap-proxy-1.tcp_ports 143
```

41.87.2 ssl_ports Option Under tcp_listen

Under a top level imapproxy or popproxy component, inside a named tcp_listen group, the ssl_ports option specifies the TCP port(s) on which that proxy server listens for SSL connections; *e.g.*:

```
msconfig> set imapproxy.tcp_listen:imap-proxy-1.ssl_ports 993
```

41.87.3 listen_addresses Option Under tcp_listen

Under a top level imapproxy or popproxy component, inside a named tcp_listen group, the listen_addresses option specifies the list of interface addresses on which that proxy server listens; *e.g.*:

```
msconfig> set imapproxy.tcp_listen:imap-proxy-1.listen_addresses "192.168.1.0 190.168.1.1"
```

The list of interface address values may include hostnames, IPv4 address literals, or the string "INADDR_ANY" (which is the default).

41.87.4 backlog Option Under tcp_listen

RESTRICTED: Under a top level imapproxy or popproxy component, inside a named tcp_listen group, the backlog option is intended to control the depth of the TCP backlog queue for the socket for that proxy server. However, currently this option's value is not used when set in a tcp_listen block, and instead the hard-coded value 1024 is used.

41.88 tcpaccess Option

The tcpaccess option (available under mmp, imapproxy, popproxy, and vdomain) specifies wrap-style filters that describes TCP access control for the MMP (globally). If this is not set, then the domainallowed and domainnotallowed options for the service will be used instead.

See "Configuring Client Access to POP, IMAP, and HTTP Services" in the "Configuring Security and Access Control" chapter of the Messaging Server Administrator's Guide for background on TCP wrapper filter syntax.

41.89 tcpaccessattr Option

The tcpaccessattr option -- available for the MMP, IMAP proxy, POP proxy, and virtual domains -- specifies the name of a per-user LDAP attribute that contains a wrap-style filter describing the TCP access control for the user.

41.90 timeout Option Under the MMP

The timeout MMP option specifies the session timeout in seconds. To be standards-compliant, the value of this option must not be set lower than 1800 seconds (30 minutes) for IMAP, 600 seconds (10 minutes) for POP or SMTP.

See also the options for the IMAP server, POP server, and SMTP SUBMIT server: imap.idletimeout, pop.idletimeout, and the SMTP SUBMIT server's various *_TIME channel-specific options.

41.91 timeout Option Under the IMAP proxy

The timeout IMAP Proxy option specifies the session timeout in seconds. To be standards-compliant, the value of this option must not be set lower than 1800 seconds (30 minutes) for IMAP.

See also the IMAP server's own idletimeout option.

41.92 timeout Option Under the POP proxy

The timeout POP Proxy option specifies the session timeout in seconds. To be standards-compliant, the value of this option must not be set lower than 600 seconds (10 minutes) for POP.

See also the POP server's own idletimeout option.

41.93 use_nslog Option Under the MMP

DEPRECATED for the MMP and its components as of MS 8.0: The use_nslog option (available at levels including mmp, imapproxy, and popproxy) may be set to 1 to enable use of nslog() for debugging output. This then enables the use of the logfile options, *component*.logfile.*option-name*, (or logfile.*component*.* in legacy configuration) for controlling logfile creation and rollover.

41.94 usenslog Option

The legacy configuration usenslog has been replaced in Unified Configuration by use_nslog.

41.95 usergroupdn Option

The usergroupdn option (available for the MMP, IMAP Proxy, POP Proxy, and Submit Proxy) specifies the baseDN for user, group and domain searches by the MMP in LDAP Schema, v2 mode. It is also used for client certificate mapping lookups in LDAP Schema, v1 mode. If this is not set, it defaults to the value of the ugldapbasedn option.

41.96 virtualdomaindelim Option

The virtualdomaindelim option (available under mmp, popproxy, imapproxy, and vdomain) takes a string value specifying the acceptable virtual domain delimiters. Any character in this string will be treated as a domain delimiter in a user ID received by the MMP. (The MMP searches user IDs from the end.) If this is not set, then the loginseparator option's value will be used instead.

41.97 virtualdomainfile Option

For legacy MMP config only: The name of the file containing your virtual domain mapping (a full path may be provided, but the product's configuration directory is used if no path is provided).

The recommended setting is vdmap.cfg. Uncomment this line in the configuration file to enable support for virtual domains.

This option is deleted during Unified Configuration migration and its contents are included in vdomain option groups.

Part VI Convergence webmail

Messaging Server includes a specialized HTTP server, MSHTTPD, that provides webmail client access to the Message Store.

The Oracle Communications Convergence webmail client supports S/MIME (Secure/Multipurpose Internet Mail Extension). This support has a number of configuration options.

New in MS 8.0.1, MSHTTP may call out to ICAP to perform HTML sanitization; this support has a number of icapservice configuration options.

For Messenger Express, see also the `rfc822headerallow8bit` base option.

Chapter 42 MSHTTP options

The http.enable and/or http.enablesslport options are the fundamental options for enabling operation of the MSHTTP server. Many other options are available to further modify and tune its operation.

Under http, there are additional groupings of options under feedback, httpcharset and mailcharset, and sieve.

42.1 enable Option Under http

The enable MSHTTP option (service.http.enable in legacy configuration) enables the HTTP service on start-msg startup. Note: HTTP over SSL service is enabled/disabled separately using http.enablesslport in Unified Configuration, or service.http.enablesslport in legacy configuration.

42.2 enablesslport Option Under http

Sets whether or not the HTTP over SSL service for Convergence is started. If enabled, the HTTP+SSL service listens on the port specified by the sslport MSHTTP option. For the 7.0.5 release, the sslusessl MSHTTP option must also be explicitly set to enable the separate SSL port. For the 8.0 release, setting this option enables the separate SSL port and it is no longer necessary to explicitly set the sslusessl MSHTTP option.

Note that if both http.enable and http.enablesslport (Unified Configuration) or service.http.enable and service.http.enablesslport (legacy configuration) are turned off, then msprobe does not try to monitor http.

42.3 allowanonymouslogin Option Under http

The allowanonymouslogin MSHTTP option enables the SASL ANONYMOUS mechanism for mshttpd.

42.4 allowcollect Option

Set the allowcollect MSHTTP option to 0 to prevent the server from performing remote POP mailbox collection.

Note that the maxcollectmsglen MSHTTP option specifies a maximum on the message size that may be collect, while the popbindaddr MSHTTP option specifies the IP address to which to bind outgoing POP connections when collecting external mail.

42.5 allowldapaddresssearch Option

The allowldapaddresssearch MSHTTP option controls whether legacy webmail client users (*i.e.*, users of Messenger Express & Communications Express) can search the directory for addresses.

42.6 altservice Option

The mshttpd daemon (webmail proxy) normally checks the mailAllowedServiceAccess and related LDAP attributes to see if the 'http' service is enabled for that user. If the altservice MSHTTP option is set to 1, it will instead use 'mshttpd' as the service name for such checks. This is useful if different access control settings are needed for the mshttpd daemon than for a front-end http server such as the one used by Convergence.

42.7 cert_enable Option

The cert_enable MSHTTP option controls whether to verify certificates against a CRL. When this is set, ensure that the crlenable S/MIME option (in legacy configuration, the crlenable parameter in the smime.conf file) is set to 1.

42.8 cert_port Option

The cert_port MSHTTP option specifies a port number on the machine where the Messaging Server runs to use for CRL communication. This port is used locally for that machine only. The value must be greater than 1024; the default is 55443.

42.9 charsetvalidation Option

Set the charsetvalidation MSHTTP option to "0" to disable charset validation on data sent to webmail client (not recommended). Setting this to "0" is a workaround to view messages

in webmail that are not labelled with the correct charset (the charset would be set then in the browser), but this will also likely generate Javascript errors and so cannot be recommended.

42.10 connlimits Option

The connlimits option (available under http, imap, pop, mmp, imapproxy, popproxy, specifies the maximum number of connections per IP address for the selected server. The syntax is: "*realm1,realm2,...*" where a realm has the form of address ranges and maximum number of connections expressed as any of the following four forms:

Table 42.1 connlimits Option Value Forms

a.b.c.d|e.f.g.h:m		IPv4 address, netmask, connection max
	a.b.c.d	IPv4 address
	e.f.g.h	network mask
	m	maximum connection count
a.b.c.d/p:m		IPv4 address, routing prefix, connection max
	a.b.c.d	IPv4 address
	p	routing prefix
	m	maximum connection count
a.b.c.d|e.f.g.h:m		IPv4 address, netmask, connection max
	a.b.c.d	IPv4 address
	e.f.g.h	network mask
	m	maximum connection count
[a/p]:m		IPv6 address, routing prefix, connection max
	a	IPv6 address; compressed "::" format allowed
	p	routing prefix
	m	maximum connection count
a.b.c.d|e.f.g.h:m		IPv4 address, netmask, connection max
	a.b.c.d	IPv4 address
	e.f.g.h	network mask
	m	maximum connection count
:m		Match any address
	m	maximum connection count

There should be at least one realm of the form ":m" to cover the default case by matching any IPv4 or IPv6 address. To match only IPv4 addresses, use "0.0.0.0/0:m" or "0.0.0.0|0.0.0.0:m". And to match only IPv6 addresses, use "[::0/0]:m".

The option has no default value; however, initial configuration normally sets a value of :20 for the IMAP Proxy, and POP Proxy:

```
msconfig> show connlimits
role.imapproxy.connlimits = :20
role.popproxy.connlimits = :20
```

For backwards compatibility reasons, this option may instead specify the full path to a configuration file name that contains one realm per line. Such a file name must begin with '/'. This usage is deprecated and may be removed in a future release.

42.10.1 connlimits Option Under isc_client

The connlimits isc_client option specifies the maximum number of connections that are permitted from a single LMTP process to the ISC server. Starting with 8.0.2.2, this isc_client option is deprecated; the isc_client.max_conns option should be used instead.

42.11 convergencefilterenabled Option

Starting with MS 8.0.2, mshttpd disables the built-in security filter for HTML and only has a filter to process URLs. As a result, use of Convergence version 3.0.1.1.0 or later with the modern whitelist HTML filter it provides is recommended. Once you have verified your Convergence version is compatible, and you have verified that the Convergence option mail.htmlsanitizer.enable is on, then you may set this option to 1. If you set this option to 1 without first verifying correct Convergence version and configuration, your Convergence end-users will be vulnerable to a number of security attacks.

42.12 cookiedomain Option

The cookiedomain MSHTTP option is a trusted circle SSO (legacy) parameter. The string value of this option is used to set the cookie domain value of all SSO cookies set by the Messenger Express HTTP server. This domain must match the DNS domain used by the Messenger Express browser to access the server. It is not the hosted domain name. This value must start with a period.

42.13 cookiename Option

The cookiename MSHTTP option specifies the cookie name to use to pass the HTTP session ID rather than including it as part of the URL. cookiename defaults to webmailsid if the uwcenabled MSHTTP option (local.webmail.sso.uwcenabled in legacy configuration) is enabled, and is unset if uwcenabled (local.webmail.sso.uwcenabled in legacy configuration) is not enabled.

42.14 da_host Option

The da_host MSHTTP option specifies the Delegated Administrator 1.x hostname. Initially set to value of the hostname Base option (in legacy configuration, local.hostname). This option is available for backwards compatibility only, and should no longer be used.

42.15 da_port Option

The da_port MSHTTP option specifies the Delegated Administrator 1.x port, by default 8080. This option is available for backwards compatibility only, and should no longer be used.

42.16 detectcharset Option

The detectcharset option for mshttpd enables automatic character set detection for unlabeled text parts supplied by Convergence.

42.17 domainallowed Option Under http

The domainallowed MSHTTP option specifies access filters specifying which domains and/or IP addresses are allowed HTTP access.

42.18 domainnotallowed Option Under http

The domainnotallowed MSHTTP option specifies access filters specifying which domains and/or IP addresses are not allowed HTTP access.

42.19 enableblacklistfilter Option

Starting with MS 8.0.2, mshttpd disables the built-in blacklist HTML filter by default and only has a filter to process URLs. Use of the modern whitelist HTML sanitizer available in Convergence 3.0.1.1.0 or later is recommended. This option can be set to 1 if the Convergence mail.htmlsanitizer.enable option is set. This can also be used if a deployment is unable to upgrade Convergence and is comfortable with the legacy blacklist filter.

42.20 enableuserlist Option Under http

The enableuserlist MSHTTP option enables imsconnutil connected user listing for HTTP service.

42.21 extrauserldapattrs Option

The extrauserldapattrs MSHTTP option, http.extrauserldapattrs, specifies the names of extra LDAP attributes returned to client (for customization). Syntax: attrname[:w] [,attrname]... (:w if read-write attribute).

42.22 filterhiddenmailinglists Option

The filterhiddenmailinglists MSHTTP option excludes the mgmanhidden LDAP attribute from the search filter when set to 0.

42.23 forcenbsptospace Option

Enabling forcenbsptospace will cause mshttpd to scan the incoming text and html parts of submitted messages for UTF-8 non-breaking spaces (0xC2A0) and replace them with ASCII spaces (0x20).

Note that this option will only function when the incoming content is UTF-8 encoded. Also note that this replacement is done blindly and may have a negative impact on space-sensitive content.

42.24 forcetelemetry Option Under http

Setting the forcetelemetry MSHTTP option to 1 forces telemetry for all users. Warning: this generates a lot of data and should not be used on a production system.

42.25 fullfromheader Option

If the fullfromheader MSHTTP option is set, then use the cn attribute (as well as the mail attribute) from the user's LDAP entry to build the "From:" header for outgoing messages; that is, include the cn value, if there is one.

42.26 generatereceivedheader Option

If the generatereceivedheader MSHTTP option is set to "0", webmail will not generate a Received: header, which normally contains the IP address of the sender.

42.27 gzipattach Option

The gzipattach MSHTTP option enables (when set to 1) or disables attachment download gzip by default for Internet Explorer clients.

42.28 gzipdynamic Option

The gzipdynamic MSHTTP option enables or disables compression of dynamic content (for example: request to *.msc files) delivered to Messenger Express or Communications Express mail clients. This can be disabled if Messenger Express or Communications Express users are getting corrupted content and cannot open their mail pages.

42.29 gzipstatic Option

The gzipstatic MSHTTP option enables or disables compression of static content (for example: HTML files) delivered to Messenger Express or Communications Express mail clients. This can be disabled if Messenger Express or Communications Express users are getting corrupted content and cannot open their mail pages.

42.30 htmlprocessor Option

The htmlprocessor MSHTTP option controls how html mail is sanitized prior to display by the Convergence webmail client. The mshttpd built-in blacklist processor is used when the value is set to 0 or 1. In MS 8.0.1, setting this option to 2 enables use of the ICAP service for HTML sanitization.

Use of the white-list sanitizer available in Convergence 3.0.1.1.0 or later is recommended. That filter is enabled by setting the Convergence option mail.htmlsanitizer.enable.

Starting with MS 8.0.2, mshttpd disables the built-in blacklist filter by default and only has a filter to process URLs. As a result, Convergence 3.0.1.1.0 or later is strongly recommended

with MS 8.0.2 and the Convergence option `mail.htmlsanitizer.enable` should be on. See the `http.convergencefilterenabled` option.

42.31 `httpproxyadmin` Option

The `httpproxyadmin` MSHTTP option specifies a back-end store admin login name. DEPRECATED: Consider using `proxyadmin` instead; `httpproxyadmin` will be ignored if `proxyadmin` has a value.

42.32 `httpproxyadminpass` Option

The `httpproxyadminpass` MSHTTP option specifies a back-end store admin password. DEPRECATED: Consider using `proxyadminpass` instead; `httpproxyadminpass` will be ignored if `proxyadminpass` has been set.

42.33 `idletimeout` Option Under http

The `idletimeout` MSHTTP option specifies a timeout, in minutes, for the low-level HTTP connection (which is different from the webmail session). Lower values will use fewer socket handles and higher values cause less overhead when the client needs to recreate the connection.

42.34 `ims5compat` Option

Set the `ims5compat` MSHTTP option to 1 on the MEMs and the backend servers to use 5.2 Messaging Express with a 6.x MEM.

42.35 `ipsecurity` Option

The `ipsecurity` MSHTTP option sets whether or not to restrict session access to login IP addresses. If set to `1`, then when the user logs in, the server remembers which IP address the user used to log in. Then it only allows that IP address to use the session cookie it issues to the user.

42.36 `ldapaddresssearchattrs` Option

The `ldapaddresssearchattrs` MSHTTP option specifies a string containing a comma-delineated list of LDAP attributes returned to legacy webmail client users (*i.e.*, users of Messenger Express or Communications Express) in a directory search.

42.37 `logunauthsession` Option Under http

The `logunauthsession` MSHTTP option enables log messages from unauthenticated client sessions. Prior to turning this on, consider verifying that your logging filesystem can handle the amount of I/O possible from unauthenticated clients connecting frequently.

42.38 `maxcollectmsglen` Option

The maxcollectmsglen MSHTTP option specifies the maximum message size the server collects from a remote POP mailbox. If any message in the mailbox to be collect exceeds this size, the collection will halt when that message is encountered.

Note that the allowcollect MSHTTP option controls whether or not such external collection is permitted, while the popbindaddr MSHTTP option specifies the IP address to which to bind outgoing POP connections when collecting external mail.

42.39 maxldaplimit Option

The maxldaplimit MSHTTP option sets the maximum LDAP lookup limit.

42.40 maxmessagesize Option Under http

The maxmessagesize MSHTTP option specifies the maximum message size (in bytes) client is allowed to send through MSHTTP. Note that the SMTP server to which the message is submitted may also impose its own, separate size limit.

See also the maxpostsize MSHTTP option.

42.41 maxpostsize Option

The maxpostsize MSHTTP option specifies the maximum HTTP post content length, in bytes. If not specified, the default is max(5*1024*1024, http.maxmessagesize). In legacy configuration this would be max(5*1024*1024, service.http.maxmessagesize).

42.42 maxsessions Option Under http

The maxsessions MSHTTP option specifies the maximum number of sessions per MSHTTP server process.

42.43 maxthreads Option Under http

The maxthreads MSHTTP option specifies the maximum number of threads per MSHTTP server process.

42.44 nofilecache Option

The nofilecache MSHTTP option disables html files caching; used for debugging.

42.45 numprocesses Option Under http

The numprocesses MSHTTP option specifies the number of HTTP server processes.

Note that the Watcher must be enabled for stop-msg to correctly shut down all processes if this is set to a value larger than one.

42.46 plaintextconvspace Option

If the plaintextconvspace MSHTTP option is set to "1", spaces in text messages will be converted to non-breaking spaces in webmail.

42.47 plaintextmincipher Option Under http

If the http.plaintextmincipher option is > 0, then disable use of plaintext passwords unless a security layer (SSL or TLS) is activated. This forces users to enable SSL or TLS on their client to login which prevents exposure of their passwords on the network.

42.48 plaintexttabsize Option

The plaintexttabsize MSHTTP option sets the tabsize for text message display in webmail.

42.49 popbindaddr Option

The popbindaddr MSHTTP option specifies the IP address to which to bind outgoing POP connections when collecting external mail. If unset, defaults to the value of listenaddr.

Note that the allowcollect MSHTTP option controls whether or not such external collection is permitted, and the maxcollectmsglen MSHTTP option specifies a maximum on the message size that may be collected.

42.50 port Option Under http

The port MSHTTP option specifies the Messenger Express HTTP port. The default is 8990.

42.51 proxyport Option

The proxyport MSHTTP option configures the port number of the back-end Messenger Express (HTTP) server with the Messaging Multiplexor.

42.52 replayformat Option Under http

The replayformat MSHTTPD option, http.replayformat, specifies the format for authentication replay from mshttpd to IMAP and MTA backends. Supports:

- %o for original userid as sent by the client,
- %s for *user@domain*,
- %U for userid only (prior to LDAP lookup),
- %V for virtual domain,
- %A[*attr*] for value of specified user's attribute.

42.53 resourcetimeout Option

The resourcetimeout MSHTTP option specifies the time, in seconds, after which mshttpd flushes cached session data from memory. Lower values will use less memory and higher values incur less overhead from resynchronizing from the session database. For correct session expiration this timeout is never higher than half the session timeout (and mshttpd enforces this). The default is min (900, sessiontimeout/2), thus normally 900, (corresponding to 15 minutes), unless sessiontimeout has been set to an unusually low value.

42.54 rfc2231compliant Option

The rfc2231compliant MSHTTP option enables webmail's RFC 2231 encoder so that the attachment filename will be encoded in the method defined by RFC 2231.

For the MTA's handling of RFC 2231 encoded material, see the parameterformat* channel options.

42.55 sessiontimeout Option

The sessiontimeout MSHTTP option specifies the Webmail client session timeout in seconds. The default is 7200 (corresponding to 2 hours); setting sessiontimeout to 0 will result in a timeout value of 30*24*3600 (corresponding to 30 days); attempting to set sessiontimeout to a positive value less than 10 will result in a value of 10 (10 seconds) being used.

42.56 showunreadcounts Option

The showunreadcounts MSHTTP option controls showing the unread message count in parentheses after the folder name. This option is only applicable for the Messenger Express and Communications Express web clients. For the Convergence web client this setting is always enabled.

42.57 singlesignoff Option

The singlesignoff MSHTTP option is used by trusted circle SSO (legacy). When this option is set, the server will remove all single sign-on cookies for the user matching the value of sso_prefix (in legacy configuration, local.webmail.sso.prefix). If set to 0 in this context, the server removes only its single sign-on user cookie.

42.58 smtpauthpassword Option Under http

The smtpauthpassword MSHTTP option specifies the password that will be used when mshttpd submits mail to the MTA. See also smtpauthuser.

Although this option has no default, initial configuration usually sets this option to have the value of the admin user's password.

42.59 smtpauthuser Option Under http

When mshttpd submits mail to the MTA, SMTP authentication will be used if both smtpauthuser and smtpauthpassword are set. These two MSHTTP options specify the administrative user name and password that are used to submit mail on behalf of end users.

42.60 smtphost Option

The smtphost MSHTTP option specifies a space-separated list of SMTP server hostnames. If smtphost is not specified, it will default to the value of the listenaddr base option (in legacy configuration, service.listenaddr) and if that's not set it will default to the value of the hostname base option (in legacy configuration, local.hostname). If none of the servers respond, a last resort attempt will be made to connect to the user's mailHost (as determined from the mailHost LDAP attribute in the user's LDAP entry).

Normally the SMTP server or SMTP SUBMIT server to which MSHTTP submits would be a Messaging Server SMTP server or SMTP SUBMIT server; see TCP/IP channels for a starting point discussion on configuration of Messaging Server SMTP and SMTP SUBMIT servers.

42.61 smtpport Option

The smtpport MSHTTP option specifies the SMTP or SMTP SUBMIT port to which MSHTTP will connect when submitting messages. The host(s) to which MSHTTP connects are set via the smtphost MSHTTP option.

Normally the SMTP server or SMTP SUBMIT server to which MSHTTP submits would be a Messaging Server SMTP server or SMTP SUBMIT server -- see TCP/IP channels for a starting point discussion on configuration of Messaging Server SMTP and SMTP SUBMIT servers. So in particular, for the port(s) on which such a Messaging Server SMTP server or SMTP SUBMIT server listens, see the tcp_ports Dispatcher service option, *e.g.*, dispatcher.service:SMTP.tcp_ports or dispatcher.service:SMTP_SUBMIT.tcp_ports.

The default for smtpport is 25. To have MSHTTP submit to an SMTP SUBMIT server instead, note that smtpauthuser and smtpauthpassword must be set properly, and then set http.smtpport to 587.

42.62 smtptls Option Under http

The smtptls MSHTTP option specifies whether to use TLS for SMTP connections; that is, whether MSHTTP uses the SMTP extension STARTTLS and negotiates TLS use.

42.63 sourceurl Option

The sourceurl MSHTTP option specifies the URL of the webmail server.

42.64 spooldir Option

The spooldir MSHTTP option specifies the attachment spool directory for client outgoing mail; if unspecified, uses the directory specified in the tmpdir Base option (in legacy configuration, local.tmpdir).

42.65 sslcachesize Option Under http

The sslcachesize MSHTTP option specifies the number of SSL sessions to be cached by the MSHTTP server. If this is set to 0 or not set, this will use a default provided by the Mozilla NSS library which was 10000 last time this was checked (March 2016).

42.66 sslnicknames Option Under http

The sslnicknames MSHTTP option specifies a list of SSL/TLS server certificate nicknames (only one per certificate type) for HTTP to offer clients if SSL/TLS enabled. Overrides for HTTP the base level sslnicknames option (corresponding to the legacy configuration encryption.rsa.nssslpersonalityssl configutil parameter).

42.67 sslport Option Under http

The sslport MSHTTP option, http.sslport, specifies the port number for the HTTP over SSL service. The default is 8891. Note that to enable the HTTP+SSL service, the enablesslport MSHTTP option must also be set. (In MS 7.0.5, the sslusessl MSHTTP option has to be explicitly set to 1 as well, even though the default was 1; as of MS 8.0, the sslusessl option is not needed, and indeed is ignored, by MSHTTP.)

42.68 sslsourceurl Option

The sslsourceurl MSHTTP option specifies the URL of the webmail server when SSL is enabled. (For enabling SSL, see the enablesslport MSHTTP option; note that in order for the sslsourceurl URL to be used, not only must enablesslport be enabled, but the SSL initialization must indeed have succeeded.)

42.69 sslusessl Option Under http

Starting with the 8.0 release, this option has no effect on the mshttpd server.

As regards listening at a separate sslport, note that for the 7.0.5 release, the sslusessl option must be *explicitly* set to 1 (even though the default was 1) as well as setting http.enablesslport to enable SSL connections on a separate sslport.

42.70 sso_enable Option

The sso_enable MSHTTP option enables (legacy) trusted circle single sign on functions, including accepting and verifying SSO cookies presented by the client when the login page is fetched. It returns an SSO cookie to the client for a successful login and responds to requests from other SSO partners to verify its own cookies. Setting this option to 0 (the default) disables trusted circle SSO.

42.71 sso_id Option

The sso_id MSHTTP option is a trusted circle SSO (legacy) parameter. The string value of this option is used as the application ID value when formatting SSO cookies set by the Messenger

Express HTTP server. The default value is null. This is an arbitrary string. Its value must match what you specify for the Delegated Administrator in its `resource.properties` file. The corresponding entry in `resource.properties` would be: `Verificationurl-XXX-YYY = http://webmailhost:webmailport/VerifySSO?` Where `XXX` is the `ssl_prefix` (in legacy configuration, `local.webmail.sso.prefix`) value set above, and `YYY` is the value of `sso_id` (in legacy configuration, `local.webmail.sso.id`) set here.

42.72 sso_prefix Option

The `sso_prefix` MSHTTP option is a trusted circle SSO (legacy) parameter. It specifies the prefix value when formatting SSO cookies set by the webmail server. Only SSO cookies with this prefix value are recognized by the server; all other SSO cookies are ignored.

42.73 usesentdate Option

If the `usesentdate` MSHTTP option is set to "1", webmail will use a message's Date: header for the date the message was received. If set to "0", webmail will use the date the message arrived in the user's mailbox, which is considered more accurate.

42.74 uwcenabled Option

The `uwcenabled` MSHTTP option enables (when set to 1) or disables (when set to 0) Communications Express access to Messenger Express. When enabled, the session ID will be passed in a cookie with the name of the value of the `cookiename` MSHTTP option (Unified Configuration) or `local.service.http.cookiename configutil` parameter (legacy configuration) if such an option is set, or with the name `webmailsid` if `cookiename` (`local.service.http.cookiename` in legacy configuration) is not set. Both `uwcenabled` and `cookiename` (`local.webmail.sso.uwcenabled` and `local.service.http.cookiename` in legacy configuration) must match on the front and back ends.

42.75 uwccontexturi Option

The `uwccontexturi` MSHTTP option specifies the path in which Communications Express is deployed. Specify this parameter only when Communications Express is not deployed under `/`. For example, if Communications Express is deployed in `/uwc`, `local.webmail.sso.uwccontexturi=uwc`.

42.76 uwchome Option

The `uwchome` MSHTTP option specifies the URL required to access the home link.

42.77 uwclogouturl Option

The `uwclogouturl` MSHTTP option specifies the URL Messenger Express uses to invalidate the Communications Express session.

42.78 uwcport Option

The uwcport MSHTTP option specifies the Communications Express port.

42.79 uwcsslport Option

The uwcsslport MSHTTP option specifies the Communications Express SSL port.

42.80 xmailer Option

The xmailer MSHTTP option may be set to override the X-Mailer: header field value with the specified string.

42.81 MSHTTP errors

To localize/customize MSHTTP error messages:

1. Copy the files *SERVERROOT*/lib/bundles/http_err_*.properties to a site-private (not a Messaging Server) directory.
2. Modify the files as desired.
3. Use the genrb utility to generate a new .res file.
4. Copy the site-generated .res file back to the *SERVERROOT*/lib/bundles/http_err_*.properties

Note that the lib/bundles directory can be rewritten by patches; check for changes to the files with any patches and version updates, so that you can reinstantiate the site-specific changes.

42.82 MSHTTP feedback options

The http.feedback.spam and http.feedback.notspam specify the e-mail addresses to which reports of spam/not-spam are to be directed.

42.82.1 spam Option

The spam MSHTTP feedback option, http.feedback.spam (Unified Configuration) or service.feedback.spam (legacy configuration), specifies an email address to which to send reports of spam mail.

42.82.2 notspam Option

The notspam MSHTTP feedback option, http.feedback.notspam (Unified Configuration) or service.feedback.notspam (legacy configuration), specifies an email address where to send reports of not-spam mail.

42.83 MSHTTP httpcharset and mailcharset options

Under http are httpcharset and mailcharset options to set the (default) character set for various languages.

42.83.1 af Option

The af option (available under http.httpcharset and http.mailcharset) sets the character set used for Afrikaans.

42.83.1.1 Use with httpcharset

Default http character set for Afrikaans.

42.83.1.2 Use with mailcharset

Default mail character set for Afrikaans.

42.83.2 ar Option

42.83.2.1 Use with httpcharset

Default http character set for Arabic.

42.83.2.2 Use with mailcharset

Default mail character set for Arabic.

42.83.3 be Option

42.83.3.1 Use with httpcharset

Default http character set for Byelorussian.

42.83.3.2 Use with mailcharset

Default mail character set for Byelorussian.

42.83.4 bg Option

42.83.4.1 Use with httpcharset

Default http character set for Bulgarian.

42.83.4.2 Use with mailcharset

Default mail character set for Bulgarian.

42.83.5 ca Option

42.83.5.1 Use with httpcharset

Default http character set for Catalan.

42.83.5.2 Use with mailcharset

Default mail character set for Catalan.

42.83.6 cs Option

42.83.6.1 Use with httpcharset

Default http character set for Czech.

42.83.6.2 Use with mailcharset

Default mail character set for Czech.

42.83.7 da Option

42.83.7.1 Use with httpcharset

Default http character set for Danish.

42.83.7.2 Use with mailcharset

Default mail character set for Danish.

42.83.8 de Option

42.83.8.1 Use with httpcharset

Default http character set for German.

42.83.8.2 Use with mailcharset

Default mail character set for German.

42.83.9 el Option

42.83.9.1 Use with httpcharset

Default http character set for Greek.

42.83.9.2 Use with mailcharset

Default mail character set for Greek.

42.83.10 en Option

42.83.10.1 Use with httpcharset

Default http character set for English.

42.83.10.2 Use with mailcharset

Default mail character set for English.

42.83.11 es Option

42.83.11.1 Use with httpcharset

Default http character set for Spanish.

42.83.11.2 Use with mailcharset

Default mail character set for Spanish.

42.83.12 et Option

42.83.12.1 Use with httpcharset

Default http character set for Estonian.

42.83.12.2 Use with mailcharset

Default mail character set for Estonian.

42.83.13 eu Option

42.83.13.1 Use with httpcharset

Default http character set for Basque.

42.83.13.2 Use with mailcharset

Default mail character set for Basque.

42.83.14 fi Option

42.83.14.1 Use with httpcharset

Default http character set for Finnish.

42.83.14.2 Use with mailcharset

Default mail character set for Finnish.

42.83.15 fr Option

42.83.15.1 Use with httpcharset

Default http character set for French.

42.83.15.2 Use with mailcharset

Default mail character set for French.

42.83.16 ga Option

42.83.16.1 Use with httpcharset

Default http character set for Irish.

42.83.16.2 Use with mailcharset

Default mail character set for Irish.

42.83.17 gl Option

42.83.17.1 Use with httpcharset

Default http character set for Galician.

42.83.17.2 Use with mailcharset

Default mail character set for Galician.

42.83.18 he Option

42.83.18.1 Use with httpcharset

Default http character set for Hebrew.

42.83.18.2 Use with mailcharset

Default mail character set for Hebrew.

42.83.19 hr Option

42.83.19.1 Use with httpcharset

Default http character set for Croatian.

42.83.19.2 Use with mailcharset

Default mail character set for Croatian.

42.83.20 hu Option

42.83.20.1 Use with httpcharset

Default http character set for Hungarian.

42.83.20.2 Use with mailcharset

Default mail character set for Hungarian.

42.83.21 is Option

42.83.21.1 Use with httpcharset

Default http character set for Icelandic.

42.83.21.2 Use with mailcharset

Default mail character set for Icelandic.

42.83.22 it Option

42.83.22.1 Use with httpcharset

Default http character set for Italian.

42.83.22.2 Use with mailcharset

Default mail character set for Italian.

42.83.23 ja Option

42.83.23.1 Use with httpcharset

Default http character set for Japanese.

42.83.23.2 Use with mailcharset

Default mail character set for Japanese.

42.83.24 ko Option

42.83.24.1 Use with httpcharset

Default http character set for Korean.

42.83.24.2 Use with mailcharset

Default mail character set for Korean.

42.83.25 lt Option

42.83.25.1 Use with httpcharset

Default http character set for Lithuanian.

42.83.25.2 Use with mailcharset

Default mail character set for Lithuanian.

42.83.26 lv Option

42.83.26.1 Use with httpcharset

Default http character set for Latvian.

42.83.26.2 Use with mailcharset

Default mail character set for Latvian.

42.83.27 mk Option

42.83.27.1 Use with httpcharset

Default http character set for Macedonian.

42.83.27.2 Use with mailcharset

Default mail character set for Macedonian.

42.83.28 nl Option

42.83.28.1 Use with httpcharset

Default http character set for Dutch.

42.83.28.2 Use with mailcharset

Default mail character set for Dutch.

42.83.29 no Option

42.83.29.1 Use with httpcharset

Default http character set for Norwegian.

42.83.29.2 Use with mailcharset

Default mail character set for Norwegian.

42.83.30 pl Option

42.83.30.1 Use with httpcharset

Default http character set for Polish.

42.83.30.2 Use with mailcharset

Default mail character set for Polish.

42.83.31 pt Option

42.83.31.1 Use with httpcharset

Default http character set for Portuguese.

42.83.31.2 Use with mailcharset

Default mail character set for Portuguese.

42.83.32 ro Option

42.83.32.1 Use with httpcharset

Default http character set for Romanian.

42.83.32.2 Use with mailcharset

Default mail character set for Romanian.

42.83.33 ru Option

42.83.33.1 Use with httpcharset

Default http character set for Russian.

42.83.33.2 Use with mailcharset

Default mail character set for Russian.

42.83.34 sk Option

42.83.34.1 Use with httpcharset

Default http character set for Slovak.

42.83.34.2 Use with mailcharset

Default mail character set for Slovak.

42.83.35 sl Option

42.83.35.1 Use with httpcharset

Default http character set for Slovenian.

42.83.35.2 Use with mailcharset

Default mail character set for Slovenian.

42.83.36 sq Option

42.83.36.1 Use with httpcharset

Default http character set for Albanian.

42.83.36.2 Use with mailcharset

Default mail character set for Albanian.

42.83.37 sr Option

42.83.37.1 Use with httpcharset

Default http character set for Serbian.

42.83.37.2 Use with mailcharset

Default mail character set for Serbian.

42.83.38 sv Option

42.83.38.1 Use with httpcharset

Default http character set for Swedish.

42.83.38.2 Use with mailcharset

Default mail character set for Swedish.

42.83.39 th Option

42.83.39.1 Use with httpcharset

Default http character set for Thai.

42.83.39.2 Use with mailcharset

Default mail character set for Thai.

42.83.40 tr Option

42.83.40.1 Use with httpcharset

Default http character set for Turkish.

42.83.40.2 Use with mailcharset

Default mail character set for Turkish.

42.83.41 uk Option

42.83.41.1 Use with httpcharset

Default http character set for Ukrainian.

42.83.41.2 Use with mailcharset

Default mail character set for Ukrainian.

42.83.42 yi Option

42.83.42.1 Use with httpcharset

Default http character set for Yiddish.

42.83.42.2 Use with mailcharset

Default mail character set for Yiddish.

42.83.43 zh-cn Option

42.83.43.1 Use with httpcharset

Default http character set for Simplified Chinese.

42.83.43.2 Use with mailcharset

Default mail character set for Simplified Chinese.

42.83.44 zh-tw Option

42.83.44.1 Use with httpcharset

Default http character set for Traditional Chinese.

42.83.44.2 Use with mailcharset

Default mail character set for Traditional Chinese.

42.84 MSHTTP sieve options

The port of the web container where the Mail Filter has been deployed may be specified via an option under `http.sieve`, either `http.sieve.port` or `http.sieve.sslport`.

42.84.1 port Option Under sieve

The port MSHTTP sieve option, http.sieve.port, specifies the port of the web container where the Mail Filter has been deployed.

42.84.2 sslport Option Under sieve

The sslport MSHTTP sieve option, http.sieve.sslport (Unified Configuration) or local.webmail.sieve.sslport (legacy configuration), specifies the the SSL port of the web container where the Mail Filter has been deployed.

Chapter 43 SMIME options

Several options affect S/MIME operation.

In addition to the options set under `smime`, a few MSHTTP options (set under `http`) are also relevant when using S/MIME, including `cert_enable` and `cert_port`.

43.1 `enable` Option Under smime

The `enable` S/MIME option controls whether the S/MIME features are available to Web Client Mail users who have permission to use them.

43.2 `usercertfilter` Option

The `usercertfilter` SMIME option specifies the URL filter string used to search for certificates by attributes of directory objects. It is used in conjunction with the `certurl` option. It is required when S/MIME features are enabled. Use any combination of these three email address attributes (but at least one). Example:

```
(|(mail=%e)(mailAlternateAddress=%e)(mailEquivalentAddress=%e))
```

43.3 trustedurl Option

The trustedurl S/MIME option specifies the URL used to search for trusted certificates used to verify user certificates. It is required when S/MIME features are enabled. Optional logindn/loginpw credentials for use when accessing this url can be appended in the form: |*logindn*|*loginpw* Both or neither must appear.

Note: the administrator must create the ldap entry for "SMIME Admin". Example:

```
ldap://mail.siroe.com:389/cn=SMIME Admin, ou=people, o=mail.siroe.com,
o=mailUsers?cacertificate;binary?sub?(objectclass=certificationauthority)
```

43.4 certurl Option

The certurl SMIME option specifies the URL used to search for user certificates. The filter in usercertfilter is appended to this URL with the "%e" specifiers replaced by the email address of the user for whom certificates are being searched. It is required when S/MIME features are enabled. Optional logindn/loginpw credentials for use when accessing this url can be appended in the form: |logindn|loginpw Both or neither must appear. Example:

```
ldap://mail.siroe.com:389/ou=people, o=mail.siroe.com, o=mailUsers?userCertificate;binary?sub?
```

43.5 sslrootcacertsurl Option

The sslrootcacertsurl S/MIME option specifies the URL used to locate the Root certificates used for secure HTTP protocol It is required when S/MIME features are enabled and SSL protocols are enabled. Optional logindn/loginpw credentials for use when accessing this url can be appended in the form: |logindn|loginpw Both or neither must appear. Note: the administrator must create the ldap entry for "SSL Root CA Certs". Example:

```
ldap://mail.siroe.com:389/cn=SSL Root CA Certs, ou=people, o=mail.siroe.com,
o=mailQA?cacertificate;binary?base?(objectclass=certificationauthority)
```

43.6 logindn Option

The logindn S/MIME option specifies the Root UID for LDAP access to all the URLs specified for SMIME (options certurl, crlmappingurl, sslrootcacertsurl, trustedurl). It is optional; if not specified, the credentials of the Messaging Server are used. If specified, loginpw must also be specified. Note: any local credentials appended to a URL are used instead of this specification.

Example: cn=Directory Manager

43.7 loginpw Option

The loginpw S/MIME option specifies the password for LDAP access to all the URLs specified for SMIME (options certurl, crlmappingurl, sslrootcacertsurl, trustedurl). It is optional; if not specified, the credentials of the Messaging Server are used. If specified, logindn must also be specified. The value may be obfuscated with base64 by using $== instead of == as the smime.conf delimiter (this feature might appear in a future release). Note: any local credentials appended to a URL are used instead of this specification.

43.8 platformwin Option

The platformwin S/MIME option specifies one or more library names needed by smart cards or local key store on the Windows platform. The example below is the default; you need to specify this option only if your library settings differ. This option is required if any Communications Express Mail users use the Windows platform. Example:

```
CAPI:library=capibridge.dll;
```

43.9 platformmac Option

The platformmac S/MIME option specifies one or more library names needed by smart cards or local key store on the Macintosh platform. The example below is the default; you need to specify this option only if your library settings differ. This option is required if any Communications Express Mail users use the Macintosh platform. Example:

```
MOZILLA:library=libsoftokn3.dylib;
```

43.10 platformlinuxx86 Option

The platformlinuxx86 S/MIME option specifies one or more library names needed by smart cards or local key store on the Linux platform. The example below is the default; you need to specify this option only if your library settings differ. This option is required if any Communications Express Mail users use the Linux platform. Example:

```
MOZILLA:library=libsoftokn3.so;
```

43.11 platformhpux Option

The platformhpux S/MIME option specifies one or more library names needed by smart cards or local key store on the HPUX platform. The example below is the default; you need to specify this option only if your library settings differ. This option is required if any Communications Express Mail users use the HPUX platform. Example:

```
MOZILLA:library=libsoftokn3.sl;
```

43.12 platformsolarissparc Option

The platformsolarissparc S/MIME option specifies one or more library names needed by smart cards or local key store on the Sparc Solaris platform. The example below is the default; you need to specify this option only if your library settings differ. This option is required if any Communications Express Mail users use the Sparc Solaris platform. Example:

```
MOZILLA:library=libsoftokn3.so;
```

43.13 alwaysencrypt Option

The alwaysencrypt S/MIME option controls the initial setting for whether all outgoing messages are automatically encrypted for all Communications Express Mail users with permission to use S/MIME. Choose one of these values:

Table 43.1 Possible alwaysencrypt option values

Value	Meaning
0	Do not encrypt messages. The encryption checkboxes within Communications Express Mail are displayed as unchecked. This is the default.
1	Always encrypt messages.The encryption checkboxes within Communications Express Mail are displayed as checked.

43.14 alwayssign Option

The alwayssign S/MIME option controls the initial setting for whether all outgoing messages are automatically signed for all Communications Express Mail users with permission to use S/MIME. Choose one of these values:

Table 43.2 Possible alwayssign option values

Value	Meaning
0	do not sign messages. The signature checkboxes within Communications Express Mail are displayed as unchecked. This is the default.
1	always sign messages. The signature checkboxes within Communications Express Mail are displayed as checked.

43.15 crlenable Option

The crlenable S/MIME option controls whether certificates are checked against CRLs. If there is a match, a certificate is considered revoked. The values of the send*revoked options (sendencryptcertrevoked and sendsigncertrevoked) determine whether a revoked certificate is rejected or used by Communications Express Mail. Choose one of these values:

Table 43.3 Possible crlenable option values

Value	Meaning
0	each certificate is not checked against a CRL.
1	each certificate is checked against a CRL. This is the default.

43.16 crldir Option

The crldir S/MIME option specifies the directory path information to locate the database where CRL information is stored. The default value is DATAROOT/store/mboxlist.

43.17 crlurllogindn Option

The crlurllogindn S/MIME option specifies the Root UID for LDAP access to all the URLs specified in the CRL Mapping table. It is optional; if not specified, the credentials of the Messaging Server are used. If specified, crlurlloginpw must also be specified. Note: any local credentials appended to a URL in the CRL Mapping table are used instead of this specification. Example: cn=Directory Manager

43.18 crlurlloginpw Option

Specifies the password for LDAP access to all the URLs specified in the CRL Mapping table. It is optional; if not specified, the credentials of the Messaging Server are used. If specified, crlurllogindn must also be specified. The value may be obfuscated with base64 by using $== instead of == as the smime.conf delimiter (this feature might appear in a future release). Note: any local credentials appended to a URL in the CRL Mapping table are used instead of this specification.

43.19 crlmappingurl Option

The crlmappingurl S/MIME option specifies the URL used to locate the CRL mapping. Optional logindn/loginpw credentials for use when accessing this url can be appended in the form "|logindn|loginpw". Both or neither must appear. Note: the administrator must create the ldap entry for "SMIME Admin". Example: ldap://mail.siroe.com:389/cn=SMIME Admin, ou=people, o=mail.siroe.com, o=mailQA?msgCRLMappingRecord?sub?(objectclass=msgCRLMappingTable)

43.20 timestampdelta Option

The timestampdelta S/MIME option specifies the time interval in seconds before the received time on messages.

43.21 crlaccessfail Option

The crlaccessfail S/MIME option specifies the time interval to wait after multiple CRL attempts, in the form: "#fails:#mins:#minswait" where:

Table 43.4 crlaccessfail fields

Field	Meaning
#fails	number of CRL URL failures before triggering wait
#mins	number of minutes during which the #fails must occur
#minswait	number of minutes to wait until another CRL URL attempt will be allowed If crlaccessfail is used, no fields are optional, and all values must be greater than 0.

Example: 2:20:10.

43.22 checkoverssl Option

The checkoverssl S/MIME option controls whether an SSL communications link is used when checking a certificate against a CRL. Choose one of these values:

Table 43.5 checkoverssl S/MIME option values

Value	Meaning
0	do not use an SSL communications link.
1	use an SSL communications link. This is the default.

43.23 readsigncert Option

The readsigncert S/MIME option controls whether the certificate used to sign a message is checked against a CRL when the message is read. Choose one of these values:

Table 43.6 readsigncert fields

Value	Meaning
0	do not check the certificate against a CRL.
1	check the certificate against a CRL. This is the default.

43.24 revocationunknown Option

The revocationunknown S/MIME option determines the action to take when an ambiguous status is returned when checking a certificate against a CRL. In this case, it is not certain if the certificate is valid or has a revoked status. Choose one of these values:

Table 43.7 revocationunknown S/MIME option Values

Value	Meaning
ok	treat the certificate as valid.
revoked	treat the certificate as revoked. This is the default.

43.25 sendencryptcert Option

The sendencryptcert S/MIME option controls whether a certificate used to encrypt an outgoing message is checked against a CRL before using it. Choose one of these values:

Table 43.8 sendencryptcert fields

Value	Meaning
0	do not check the certificate against a CRL.
1	check the certificate against a CRL. This is the default.

43.26 sendencryptcertrevoked Option

The sendencryptcertrevoked S/MIME option determines the action to take if a certificate used to encrypt an outgoing message has been revoked. Choose one of these values:

Table 43.9 sendencryptedcertrevoked fields

Value	Meaning
allow	use the certificate.
disallow	do not use the certificate. This is the default.

43.27 sendsigncert Option

The sendsigncert S/MIME option controls whether a certificate used for signing an outgoing message is checked against a CRL before using it. Choose one of these values:

Table 43.10 sendsigncert fields

Value	Meaning
0	do not check the certificate against a CRL.
1	check the certificate against a CRL. This is the default.

43.28 sendsigncertrevoked Option

The sendsigncertrevoked S/MIME option determines the action to take if the certificate used to sign an outgoing message has been revoked. Choose one of these values:

Table 43.11 sendsigncertrevoked fields

Value	Meaning
allow	use the certificate.
disallow	do not use the certificate. This is the default.

43.29 crlusepastnextupdate Option

The crlusepastnextupdate S/MIME option specifies whether to continue to use a CRL after its next update date (in case a new CRL is not available or accessible). Choose one of these values:

Table 43.12 crlusepastnextupdate fields

Value	Meaning
0	do not use a CRL after its next update date.
1	continue to use a CRL after its next update date. This is the default.

43.30 appletlogging Option

The appletlogging S/MIME option specifies whether to enable logging on the applet. Choose one of these values:

Table 43.13 appletlogging fields

Value	Meaning
0	do not log applet output. This is the default.
1	log applet output.

Chapter 44 SSO options

The `verifyurl` option is the only option under the `sso` group. See also various MSHTTP options relating to SSO, especially the `sso_*` MSHTTP options.

44.1 `verifyurl` Option

The `verifyurl` option specifies a trusted circle SSO (legacy) parameter. It sets the verify URL values for peer SSO applications. The standard form of the value of the verify URL is:

`http://[peer_hostname]:[port]/VerifySSO?`

This value should be set for the application ID of a peer SSO application whose SSO cookies are to be honored.

Chapter 45 icapservice options

New in MS 8.0.1, if the `htmlprocessor` MSHTTP option is set to `2`, then the ICAP service will be used to perform HTML sanitization. There are a few options that configure this use of the ICAP service.

45.1 `forcetelemetry` Option Under icapservice

Setting the `forcetelemetry` icapservice option to `1` forces telemetry for all users. Warning: this generates a lot of data and should not be used on a production system.

45.2 `service_name` Option

The `service_name` option sets the name used by the ICAP client when performing HTML sanitization. The default is "`email`" and there's no need to change this.

45.3 `server_host` Option Under icapservice

The `server_host icapservice` option specifies the ICAP server host name. If empty or not set, the loopback interface is used.

45.4 `server_port` Option Under icapservice

The `server_port icapservice` option specifies the ICAP server port. The default is `1344`.

Part VII The MTA

The Messaging Server MTA is a general-purpose, store-and-forward system for distributing computer-based mail. The term *store-and-forward* means that the Messaging Server MTA automatically handles the requeuing and retransmission of mail messages necessitated when network links or services are temporarily unavailable. In contrast to *mail user agents* (MUAs) such as Messenger Express or Communications Express (UWC) which are used to create and read electronic mail messages, the Messaging Server MTA is a *mail transport agent* (MTA) responsible for directing messages to the appropriate network transport and ensuring reliable delivery over that transport.

The MTA provides a uniform distribution environment that can be interfaced to multiple user interfaces (MUAs), networks, protocols, and transport mechanisms. As this interfacing, from the user's point of view, is accomplished transparently, the MTA presents to the user a homogeneous mail network; *i.e.,* the MTA seamlessly blends heterogeneous mail networks into a single, coherent mail system.

There are many components to the MTA.

Chapter 46 Channels

The MTA consists of a large number of components, but the central unifying construct in the MTA is the *channel*. A channel represents an e-mail connection with another computer system or group of systems. The actual hardware connection or software transport or both may vary widely from one channel to the next. Only the MTA administrator need know anything about the MTA's channels; users are never aware of the existence of channels and only see a single, uniform interface regardless of how messages reach their destination.

Each channel consists of one or more channel programs and an outgoing message queue for storing messages that are destined to be sent to one or more of the systems associated with the channel. Channel programs perform two functions: (1) they transmit messages to remote

systems, deleting them from their queue after they are sent, and (2) they accept messages from remote systems, placing them in the channel queues. Note that while a channel program only removes messages from its own queue it can enqueue messages on any queue whatsoever, including its own.

A channel program which initiates a transfer to a remote system on its own is called a "master" program, while a program which accepts transfers initiated by a remote system is called a "slave" program. A channel may be served by a master program, a slave program, or both. Either type of program may or may not be bidirectional; the direction in which a message is travelling may have nothing to do with the type of program that handles it. Very often, however, a master program transmits messages, while a slave program receives messages. An SMTP channel, for instance, has a master program that only transmits messages (the SMTP client) and a slave program that only receives messages (the SMTP server).

The execution of channel programs is primarily triggered and controlled by the two major "control" processes of the MTA: the Dispatcher listens on TCP ports and triggers execution of appropriate "slave" channel programs (such as the SMTP server and LMTP server "slave" programs), while the Job Controller maintains a database of what messages are awaiting delivery attempts, and schedules and triggers execution of channel programs (primarily channel "master" programs) to attempt deliveries. However, channel programs can be run via other mechanisms; see, for instance, the `imsimta run` utility, used for manual triggering of channel program execution.

46.1 Available channels

Every MTA channel has a unique name containing up to 32 characters. Only lowercase letters, numbers, underscores, and dollar signs should be used in channel names.

Certain channel names are reserved for particular uses. Moreover, the MTA (especially the Job Controller) recognizes certain families of channel names, (channel name prefixes), and will make internal assumptions about such channels. There are both hard-coded expectations of certain special channel name usage, plus in particular some historical but now wide-spread "conventions" regarding use of certain `tcp_*` channel names. Using channel names in a conflicting manner can lead to serious problems. MTA administrators are encouraged to use these channels for the stated purposes and in general to pick channel names of their own that do not conflict with these usage conventions.

Table 46.1 Modern reserved channel names

Name	Reserved For
`bitbucket`	Bit bucket channel (deletes all messages queued to it)
`bsin_*`	BSMTP inbound channels
`bsout_*`	BSMTP outbound channels
`circuitcheck`	Message circuit checking channel
`conversion`	Message body part conversion channel
`defragment`	Message defragmentation channel
`filter_discard`	Channel for delayed deletion of message discarded or jettisoned due to Sieve actions (or analogous `*_ACCESS` mapping table flag effects)
`hold`	Channel where messages are temporarily detained for administrative purposes such as user migration

ims-ms	Channel delivering to the Message Store (without use of LMTP; see also the tcp_lmtpss channel when LMTP is used instead).
ims-ms_*	Additional channels delivering to the Message Store.
l	The local channel; in modern Messaging Server configurations, a "placeholder" channel that performs no delivery but rather performs alias processing only.
native	Delivery to UNIX /var/mail mailboxes.
pipe	Pipe channel
pipe_*	Additional pipe channels
process	Processing channel
process_*	Additional processing channels
reprocess	Reprocessing channel
reprocess_	Additional reprocessing channels
sms*	SMS channels
tcp_auth	By convention, the SMTP-over-TCP/IP channel handling incoming authenticated messages.
tcp_intranet	By convention, the SMTP-over-TCP/IP channel communicating with other internal hosts.
tcp_lmtpcs*	By convention, LMTP client channels.
tcp_lmtpss	By convention, the LMTP server delivering to the Message Store on an LMTP back end system.
tcp_local	By convention, the SMTP-over-TCP/IP channel communicating with the Internet.
tcp_submit	By convention, the SMTP SUBMIT server channel.
tcp_tas	By convention, the SMTP-over-TCP/IP channel receiving telephony messages that need so-called "Guaranteed Message Deposit" (quota bypass for message delivery).
tcp_*	Additional TCP/IP SMTP (or LMTP) channels
test_smtp_*	Test (sample code) channels
uucp_	UUCP channel (UNIX, or DEC/Shell UUCP)

In addition to the above modern channel names, there are various obsolete or historical channels where use of those old channel names may cause confusion:

Table 46.2 Outdated reserved channel names

Name or prefix	Reserved For
address	Extract addressing information from the body of a message
address_*	Additional addressing channels
aoce_	Apple AOCE channels
anje_	ANJE (BITNET)
bit_	Jnet (BITNET)
bull_	BULLETIN channels

cc_	cc:Mail channels
cn_	Internal usage by the national Australian network
ctcp_	Carnegie Mellon University TCP/IP channels; obsolete
d	The DECnet MAIL channel; used to deliver messages across DECnet via VMS MAIL
d_	Additional MAIL-11 over DECnet channels
data_to_bitmap	Raw FAX data to bitmap channel
data_to_bitmap_	Additional data to bitmap channels
directory	Directory alias expansion channel
directory_	Directory alias expansion channels
dn_	PhoneNet over DECnet
dsmtp_	SMTP over DECnet
era_	ERA channels
etcp_	Excelan TCP/IP channels; obsolete
faxsr_	Fax Sr. channels
fax_to_data	Inbound FAX to raw data channel
fax_to_data_	Inbound FAX to raw data channel
ff_	Microsoft® Mail channels
ftcp_	Network Research Corporation FUSION TCP/IP channels; obsolete
g3_to_fax	Group 3 to FAX modem spooler
g3_to_fax_	Group 3 to FAX modem channels
ker_	Kermit protocol
ln_	Lotus Notes channels
mail_	General VMS MAIL delivery
mailserv	Mail and list server channel
mhs_	Novell MHS channels
mime_to_x400	MIME to X.400 conversion channel
mime_to_x400_	MIME to X.400 conversion channels
mime_to_x40084_	MIME to X.400-1984 conversion channels; obsolete
mint	MINT user agent from Wesleyan University
mr_	PMDF-MR gateway
mrif_	PMDF-MR as Message Router TS replacement channels
msgstore	PMDF Message Store delivery channel
msgstore_	PMDF MessageStore channel
mtcp_	Process Software MultiNet (formerly Cisco MultiNet, formerly TGV MultiNet) TCP/IP channels; obsolete
netdata_	Netdata (PROFS) channels
notes_	VAX NOTES channels

osfl_	UNIX local channels
ovvm_	OV/VM (PROFS) channels
p	Generic PhoneNet channel; used to communicate with a central PhoneNet host
p_	PhoneNet channels
pager	E-mail to pager channel
pager_	Pager channels
popstore	PMDF popstore delivery channel; a msgstore channel can be---and typically is -- used instead
profs_	PROFS channels
printer	e-mail to spooled printer
printer_*	Additional e-mail to spooled printer channels
ps_to_g3	PostScript to Group 3 FAX interpreter
ps_to_g3_	PostScript to Group 3 FAX channels
ptcp_	Process Software TCPware
px25_	PhoneNet over X.25; obsolete
qm_	QuickMail channels
snads_	SNADS channels
subject	Channel to extract information from Subject: lines
sync_db_	Database synchronization channels
sync_dirbot_	Directory synchronization robot (DIRBOT) channels
sync_ldap_	LDAP directory synchronization channels
sync_ldif_	LDIF directory agent channels
sync_ln_	Lotus Notes directory agent channels
text_to_ps	Text to PostScript converter
text_to_ps_	Additional text to PostScript channels
utcp_	ULTRIX (UCX) Connection TCP/IP channels; obsolete
vn_	UUCP channel (DECUS UUCP)
wpo_	GroupWise (WordPerfect Office) channels
wtcp_	Wollongong TCP/IP (WIN/TCP) channels; obsolete
x400_	X.400 channels
x40084_	X.400-1984 channels; obsolete
x400_to_mime	X.400 to MIME conversion channel
x400_local	X.400 transport channel
xapi_	MAILbus 400 channels
xsmtp_	SMTP over X.25; obsolete

46.2 Channel configuration

In Unified Configuration, each MTA channel is configured as a named set of options under a channel group. For instance, configuration of the tcp_local channel (the typical channel used to communicate with the Internet) could be along the lines of:

```
msconfig> show channel:tcp_local
role.channel:tcp_local.official_host_name = tcp-daemon
role.channel:tcp_local.identnonenumeric (novalue)
role.channel:tcp_local.inner (novalue)
role.channel:tcp_local.loopcheck (novalue)
role.channel:tcp_local.maysaslserver (novalue)
role.channel:tcp_local.maytlsserver (novalue)
role.channel:tcp_local.defaultmx (novalue)
role.channel:tcp_local.pool = SMTP_POOL
role.channel:tcp_local.remotehost (novalue)
role.channel:tcp_local.saslswitchchannel = tcp_auth
role.channel:tcp_local.single_sys (novalue)
role.channel:tcp_local.smtp (novalue)
role.channel:tcp_local.switchchannel (novalue)
```

In legacy configuration, each MTA channel was configured in the imta.cnf file, with blank lines separating distinct channel definitions. For instance, a tcp_local channel definition in imta.cnf might appear as (with a blank line before and after these lines):

```
tcp_local smtp mx single_sys identnonenumeric pool SMTP_POOL \
  switchchannel maysaslserver saslswitchchannel tcp_auth maytlsserver \
  inner loopcheck remotehost
tcp-daemon
```

Note that in Unified Configuration, the edit channels command may be used to edit channel definitions "as if" they were in the familiar, legacy configuration file form:

```
msconfig> edit channels
```

Note that the channel-specific options -- those set in legacy configuration in channel option files, rather than as legacy configuration channel keywords -- in Unified Configuration are set under the options named group, *e.g.*,

```
msconfig> set channel:tcp_local.options.ALLOW_ETRNS_PER_SESSION 2
```

Since channel-specific options are specific to the type of channel in question -- different types of channels tend to have completely different channel-specific options -- look under the discussions of the specific channel type to find out details of what channel-specific options are available for a particular channel type, as channel-specific options do not appear under the general list of options.

46.2.1 defaults and nodefaults pseudo-channels

Many configurations involve repetition of various channel options on all or nearly all channels. Maintaining such a configuration is both tedious and error-prone. The MTA offers a simple way to change what options are set by default on various channels. This mechanism can be used to greatly simplify some configurations.

Note that in Unified Configuration channel neither multiple defaults channel nor the relative ordering of channels in the configuration are preserved. However, care is taken when the configuration is read to process the defaults channel first. As such, unified configuration is limited to having a single defaults channel that affects all subsequent channels.

If a line of the form:

```
defaults option1 option2 option3 ...
```

is inserted into the configuration, all channel blocks following this line will inherit the options specified on the line. The `defaults` line can be thought of as a special channel block that changes the option defaults without actually specifying a channel. The `defaults` line, or pseudo-channel definition, also does not require any additional lines of channel block information (if any are specified they will be ignored); in Unified Configuration terms, the `defaults` pseudo-channel does not need (and will ignore) any `official_host_name`, `local_host_alias`, or `additional_host_names` option settings.

There is no limit on the number of `defaults` lines that can be specified in a legacy configuration --- the effects of multiple `defaults` lines are cumulative with the most recently encountered (reading from top to bottom) line having precedence. Unified configurations are limited to a single defaults channel.

It may be useful to unconditionally eliminate the effects of any `defaults` lines starting at some point in a legacy configuration file (at the start of a standalone section of channel blocks in an external file, for example). The `nodefaults` line is provided for this purpose. It takes the form:

```
nodefaults
```

and has the obvious effect --- it nullifies all settings established by any previous `defaults` channel and returns the configuration to the state that would apply if no `defaults` had been specified. This functionality is not available in unified configurations.

Like regular channel blocks, a blank line must separate each `defaults` or `nodefaults` channel block from other channel blocks. The `defaults` and `nodefaults` channel blocks are the only channel blocks which may appear before the local channel in the configuration file. However, like any other channel block, they must appear after the last rewrite rule.

Initial configuration generates a `defaults` pseudo-channel located prior to any other channel definition (so applying to all other initially configured channels):

```
msconfig> show channel:defaults.*
role.channel:defaults.defaulthost = &/IMTA_DEFAULTDOMAIN/ &/IMTA_DEFAULTDOMAIN/
role.channel:defaults.maxjobs = 7
role.channel:defaults.noswitchchannel (novalue)
role.channel:defaults.notices = 1 2 4 7
```

46.3 Channel options

Channel options are available to adjust many attributes and aspects of channel operation. Unified Configuration channel options subsume the *channel keywords* of legacy configuration, as well as the second and optional additional lines of legacy configuration channel definitions; and the Unified Configuration `options` group allows setting the channel-specific options

of legacy configuration (those set in legacy configuration in a channel option file). That is, in legacy configuration, channel keywords would appear after the channel name on the first line of the channel definition in `imta.cnf`, and then the second and optional additional lines of a channel definition in `imta.cnf` would set the `official_host_name` for a channel and optionally the `local_host_alias` and `additional_host_names`; while channel-specific options would be set in the *`channel-name`*`_option` channel option file.

In Unified Configuration, any desired channel options are set under a named `channel` group; *e.g.*, for options that merely need to be turned on:

```
msconfig> set channel:channel-name.option-name
```

or for channel options that take an argument:

```
msconfig> set channel:channel-name.option-name option-value
```

Some channel options take arguments; each option argument is limited in general to 40 characters, though some special options allow arguments of 256 characters (252 characters in iMS 5.2 and earlier), and a few options (as of 7.0.5 including `sourcefilter` and `destinationfilter`) allow arguments up to 1024 characters.

In Unified Configuration, option argument case is preserved even if not quoted. Quoting is not necessary for most option arguments; but options that take multiple "arguments" (in legacy configuration terms), must in Unified Configuration be set by specifying a single, quoted argument. For instance:

```
msconfig> set channel:tcp_local.saslswitchchannel tcp_auth
role.channel:tcp_local.saslswitchchannel = tcp_auth
msconfig# set channel:tcp_local.backoff "PT30M PT1H PT1H PT2H PT4H PT8H"
role.channel:tcp_local.backoff = PT30M PT1H PT1H PT2H PT4H PT8H
```

In legacy configuration, option arguments are normally forced to lowercase, but case will be preserved if the option argument is quoted. Also, while legacy configuration options are normally limited to taking at most five arguments, when the arguments themselves are quoted that restriction is lifted; (see for instance, the `backoff` channel option).

Note that the channel-specific options -- those set in legacy configuration in channel option files, rather than as legacy configuration channel keywords -- in Unified Configuration are set under the `options` group, *e.g.*,

```
msconfig> set channel:tcp_local.options.ALLOW_ETRNS_PER_SESSION 2
```

Since channel-specific options are specific to the type of channel in question -- different types of channels tend to have completely different channel-specific options -- look under the discussions of the specific channel types to find out details of what channel-specific options are available, as channel-specific options do not appear under the general list of options, nor as channel options.

46.3.1 Alphabetic list of channel options

Channel options listed alphabetically below lists channel keywords alphabetically. Channel options shown in **`bold face type`** are defaults.

Table 46.3 Channel options listed alphabetically

Option	Usage
`_733`	Use % routing in the envelope; synonymous with `percents`
`_822`	Use source routes in the envelope; synonymous with `sourceroute`
`acceptalladdresses`	(New in MS 6.1) Accept messages despite certain errors that would normally cause message rejection
`accepttemporaryfailures`	(New in 8.0.1.1.0) Accept messages despite recipient address temporary error conditions (*e.g.*, over quota, LDAP server unavailable, Spam/virus filter unavailable, *etc.*).
`acceptvalidaddresses`	(New in MS 6.1) Perform normal rejection checks on incoming messages
`additional_host_names`	Additional hosts the channel can reach
`addlineaddrs`	RESTRICTED: Attempt to extract additional envelope recipient addresses from X-VMS-To: and X-VMS-Cc: header lines
`addresssrs`	(New in MS 6.3p1) Addresses matching this channel are eligible for SRS encoding
`addreturnpath`	Add a Return-Path: header line
`addrsperfile`	Number of addresses per message file
`addrsperjob`	Number of addresses to be processed by a single job
`addrtypescan`	(New in MS 7.0.5) Store recipient address "type" in an envelope flag
`addrtypescanbccdefault`	(New in MS 7.0.5) Store recipient address "type" in an envelope flag, assuming unmatched recipient addresses are Bcc: addresses
`affinitylist`	(New in MS 8.0) Enable affinity lookups, disable MX lookups
`after`	Specify time delay before master channel programs run
`aliasdetourhost`	Specify an "override" `mailHost` for any user found in LDAP; effect is to "detour" messages for such a user to the specified host
`aliaslocal`	Look up aliases; *e.g.*, query alias file and alias database, and perform `alias_url*` lookups
`aliasmagic`	(New in MS 6.0) RESTRICTED: Destination channel override of the `alias_magic` MTA option, controlling the order of the different types of alias lookups
`aliasoptindetourhost`	(New in MS 6.2p4) Specify an "override" `mailHost` for any user who is opted-in via whatever LDAP attribute is named by the `ldap_detourhost_optin` MTA option; the effect is to "detour" messages for such a user to the specified host
`aliaspostmaster`	Redirect postmaster messages to the local channel postmaster
`aliaswild`	Do an * lookup if no exact alias match is found
`allowetrn`	Honor SMTP client ETRN commands
`allowswitchchannel`	Allow switching to this channel from a `switchchannel` channel
`alternateblocklimit`	Divert messages that exceed the specified number of blocks to the `alternatechannel`
`alternatechannel`	Messages that exceed a channel's `alternateblocklimit`, `alternatelinelimit`, or `alternaterecipientlimit` will be diverted to the channel's specified `alternatechannel`
`alternatelinelimit`	Divert messages that exceed the specified number of lines to the `alternatechannel`
`alternaterecipientlimit`	Divert messages that exceed the specified number of recipients to the `alternatechannel`
`authhost`	(New in 8.0.2.1) Use the domain of the authenticated user's primary address complete addresses
`authpassword`	(New in MS 7.0.5) Password for SMTP channel's client use of SMTP AUTH PLAIN
`authrewrite`	Use SMTP AUTH information in header
`authusername`	(New in MS 7.0.5) Username for SMTP channel's client use of SMTP AUTH PLAIN
`autosecretary`	RESTRICTED: Not yet implemented
`backoff`	Channel delivery retry backoff intervals
`bangonly`	Source channel: disable interpretation of % host-routing
`bangoverpercent`	Group A!B%C as A!(B%C)
`bangstyle`	Use UUCP ! routing in the envelope; synonymous with `uucp`
`bccserver`	(New in MS 8.0.2.3) XBCC extension is enabled
`bidirectional`	Channel is served by both a master and slave program
`binaryclient`	(New in MS 6.3.) RESTRICTED: Not yet fully implemented. Enable BINARYMIME support in the SMTP client
`binaryserver`	(Introduced in MS 6.3 but at that time RESTRICTED as not yet fully implemented; actual implementation new in MS 8.0) Enable BINARYMIME support in the SMTP server
`blocketrn`	Do not honor SMTP client ETRN commands
`blocklimit`	Maximum number of MTA blocks allowed per message
`cacheeverything`	Cache all connection information
`cachefailures`	Cache only connection failure information
`cachesuccesses`	Cache only connection success information
`caption`	(New in MS 6.3) Channel caption: a short description, suitable as the caption for a column of a table
`channelfilter`	Specify the location of channel filter file; synonym for `destinationfilter`
`charset7`	Default character set to associate with 7-bit text messages
`charset8`	Default character set to associate with 8-bit text messages

charsetesc	Default character set to associate with text containing the escape character
checkehlo	Check the SMTP greeting banner for whether to use EHLO
chunkingclient	(New in MS 6.3) Enable CHUNKING support in the SMTP client
chunkingserver	(New in MS 6.3) Enable CHUNKING support in the SMTP server
commentinc	Leave comments in message header lines intact
commentmap	Apply COMMENT_STRINGS mapping to comments in message header lines
commentomit	Remove comments from message header lines
commentstrip	Remove problematic characters from comment field in message header lines
commenttotal	Strip comments (material in parentheses) everywhere
conditionalpassthrough	"Pass-through" mode, if any Received: header lines are present
conditionalrelay	"Relay" mode, if any Received: header lines are present
conditionalsecuritymultiparts	Process inside security multiparts, retaining preamble material
connectalias	Do not rewrite addresses upon message dequeue
connectcanonical	Rewrite addresses upon message dequeue
contchar	DEPRECATED: Specify batch SMTP continuation line character
contposition	DEPRECTED: Specify folding point in batch SMTP lines
convertoctetstream	Convert application/octet-stream material as appropriate
copysendpost	Send copies of failures to the postmaster unless the originator address is blank
copywarnpost	Send copies of warnings to the postmaster unless the originator address is blank
daemon	Specify name of a gateway daemon (host) to route to
datefour	Convert date/time specifications to four digit years
datetwo	Convert date/time specifications to two digit years
dayofweek	Include day of week in date/time specifications
defaulthost	Specify a domain name to use to complete addresses
defaultmx	Channel determines whether or not to do MX lookups from network
defaultnameservers	Consult TCP/IP stack's choice of nameservers
deferralrejectlimit	New in MS 6.2. Limit the number of bad (failing) recipient addresses
deferred	Honor deferred delivery dates in Deferred-delivery: header lines; as of MS 7.0, deprecated in favor of deferreddestination
deferreddestination	(New in MS 7.0) Honor deferred delivery dates in Deferred-delivery: header lines; synonym for deferred
deferredsource	(New in MS 7.0) Honor deferred delivery dates in Deferred-delivery: header lines
defertemporaryfailures	(New in 8.0.1.1.0) Defer, with SMTP temporary rejection, recipient addresses with temporary error conditions (*e.g.*, over quota, LDAP server unavailable, Spam/virus filter unavailable, *etc.*).
defragment	Reassemble any MIME-compliant message/partial parts queued to this channel
deletemessagehash	(New in MS 6.3) Delete message hash
deliveryflags	Set flags controlling certain delivery behaviors
dequeue_removeroute	Alias for dequeueremoveroute; in legacy configuration, strip source route (@source-route:address) when dequeuing message
dequeueremoveroute	(Unified Configuration only) Strip source route (@source-route:address) when dequeuing message
description	Channel description
destinationbrightmail	DEPRECATED: Alias for destinationspamfilter1
destinationbrightmailoptin	DEPRECATED: Alias for destinationspamfilter1optin
destinationconversiontag	(New in MS 7.0.5.) Conversion tags to add to outgoing recipients
destinationdkimignore	(New in MS 8.0.) Take no special action in regards to DKIM-Signature: header fields
destinationdkimpreserve	(New in MS 8.0) Don't rewrite DKIM-signed messages for specified domains
destinationdkimremove	(New in MS 8.0) Remove DKIM signatures
destinationfilter	Specify the location of channel Sieve filter to apply to outgoing messages
destinationnosolicit	New in MS 6.2. List of solicitation types not accepted
destinationspamfilter	Alias for destinationspamfilter1
destinationspamfilter1	(New in MS 6.2) Enable spam/virus filtering (by spam/filter package 1) for messages enqueued to this destination channel
destinationspamfilter1optin	(New in MS 6.2) Enable spam/virus filtering (by spam/filter package 1) for messages enqueued to this destination channel, with the optin value provided as argument
destinationspamfilter2	(New in MS 6.2) Enable spam/virus filtering (by spam/filter package 2) for messages enqueued to this destination channel
destinationspamfilter2optin	(New in MS 6.2) Enable spam/virus filtering (by spam/filter package 2) for messages enqueued to this destination channel, with the optin value provided as argument
destinationspamfilter3	(New in MS 6.2) Enable spam/virus filtering (by spam/filter package 3) for messages enqueued to this destination channel
destinationspamfilter3optin	(New in MS 6.2) Enable spam/virus filtering (by spam/filter package 3) for messages enqueued to this destination channel, with the optin value provided as argument

destinationspamfilter4	(New in MS 6.2) Enable spam/virus filtering (by spam/filter package 4) for messages enqueued to this destination channel
destinationspamfilter4optin	(New in MS 6.2) Enable spam/virus filtering (by spam/filter package 4) for messages enqueued to this destination channel, with the optin value provided as argument
destinationspamfilter5	(New in MS 6.3) Enable spam/virus filtering (by spam/filter package 5) for messages enqueued to this destination channel
destinationspamfilter5optin	(New in MS 6.3) Enable spam/virus filtering (by spam/filter package 5) for messages enqueued to this destination channel, with the optin value provided as argument
destinationspamfilter6	(New in MS 6.3) Enable spam/virus filtering (by spam/filter package 6) for messages enqueued to this destination channel
destinationspamfilter6optin	(New in MS 6.3) Enable spam/virus filtering (by spam/filter package 6) for messages enqueued to this destination channel, with the optin value provided as argument
destinationspamfilter7	(New in MS 6.3) Enable spam/virus filtering (by spam/filter package 7) for messages enqueued to this destination channel
destinationspamfilter7optin	(New in MS 6.3) Enable spam/virus filtering (by spam/filter package 7) for messages enqueued to this destination channel, with the optin value provided as argument
destinationspamfilter8	(New in MS 6.3) Enable spam/virus filtering (by spam/filter package 8) for messages enqueued to this destination channel
destinationspamfilter8optin	(New in MS 6.3) Enable spam/virus filtering (by spam/filter package 8) for messages enqueued to this destination channel, with the optin value provided as argument
destinationspamfilteroptin	Synynom for destinationspamfilter1optin
destinationsrs	(New in MS 6.3p1) Messages destined out this channel are eligible for SRS encoding
disabledestinationbrightmail	DEPRECATED: Alias for disabledestinationspamfilter1
disabledestinationfilter	(New in MS 7.0u3) Disable evaluation and application of specified Sieve filters
disabledestinationspamfilter	Alias for disabledestinationspamfilter1
disabledestinationspamfilter1	(New in MS 6.2) Disable spam/virus filtering (via spam/filter package 1) for messages enqueued to this channel
disabledestinationspamfilter2	(New in MS 6.2) Disable spam/virus filtering (via spam/filter package 2) for messages enqueued to this channel
disabledestinationspamfilter3	(New in MS 6.2) Disable spam/virus filtering (via spam/filter package 3) for messages enqueued to this channel
disabledestinationspamfilter4	(New in MS 6.2) Disable spam/virus filtering (via spam/filter package 4) for messages enqueued to this channel
disabledestinationspamfilter5	(New in MS 6.3) Disable spam/virus filtering (via spam/filter package 5) for messages enqueued to this channel
disabledestinationspamfilter6	(New in MS 6.3) Disable spam/virus filtering (via spam/filter package 6) for messages enqueued to this channel
disabledestinationspamfilter7	(New in MS 6.3) Disable spam/virus filtering (via spam/filter package 7) for messages enqueued to this channel
disabledestinationspamfilter8	(New in MS 6.3) Disable spam/virus filtering (via spam/filter package 8) for messages enqueued to this channel
disableetrn	Disable support for the ETRN SMTP command
disablesourcebrightmail	DEPRECATED: Alias for disablesourcespamfilter1
disablesourcefilter	(New in MS 7.0u3) Disable evaluation and application of specified Sieve filters
disablesourcespamfilter	(New in MS 6.1) Synynom for disablesourcespamfilter1
disablesourcespamfilter1	(New in MS 6.2) Disable spam/virus filtering (via spam/virus filter package 1) for messages enqueued by this channel
disablesourcespamfilter2	(New in MS 6.2) Disable spam/virus filtering (via spam/virus filter package 2) for messages enqueued by this channel
disablesourcespamfilter3	(New in MS 6.2) Disable spam/virus filtering (via spam/virus filter package 3) for messages enqueued by this channel
disablesourcespamfilter4	(New in MS 6.2) Disable spam/virus filtering (via spam/virus filter package 4) for messages enqueued by this channel
disablesourcespamfilter5	(New in MS 6.3) Disable spam/virus filtering (via spam/virus filter package 5) for messages enqueued by this channel
disablesourcespamfilter6	(New in MS 6.3) Disable spam/virus filtering (via spam/virus filter package 6) for messages enqueued by this channel
disablesourcespamfilter7	(New in MS 6.3) Disable spam/virus filtering (via spam/virus filter package 7) for messages enqueued by this channel
disablesourcespamfilter8	(New in MS 6.3) Disable spam/virus filtering (via spam/virus filter package 8) for messages enqueued by this channel
disconnectbadauthlimit	(New in MS 6.2) Force SMTP session disconnect after a specified number of failed SMTP AUTH attempts
disconnectbadburllimit	(New in MS 7.0u4) Force SMTP SUBMIT session disconnect after a specified number of invalid BURL commands is exceeded
disconnectbadcommandlimit	New in MS 6.2. Force SMTP session disconnect after a specified number of bad (unrecognized) SMTP commands is exceeded
disconnectcommandlimit	New in MS 7.0u1. Force SMTP session disconnect after a specified number of SMTP commands is exceeded
disconnectrecipientlimit	New in MS 6.2. Force SMTP session disconnect after a specified number of recipients is exceeded
disconnectrejectlimit	New in MS 6.2. Force SMTP session disconnect after a specified number of bad recipients (rejected recipients) is exceeded
disconnecttransactionlimit	(New in MS 6.2) Force SMTP session disconnect after a specified transaction limit is exceeded
dispositionchannel	New in MS 6.2. Channel to use when generating message disposition notifications
dkimignore	(New in MS 7.0.5) Take no special action in regards to DKIM-Signature: header fields
dkimpreserve	(New in MS 7.0.5) Don't rewrite DKIM-signed messages for specified domains
dkimremove	(New in MS 7.0.5) Remove DKIM signatures
dnsforcetemporary	Treat host not found and no address lookup errors as temporary failures. This option is new in 8.0.1.3.
domainetrn	Honor only those SMTP client ETRN commands that specify a domain
domainvrfy	Issue SMTP VRFY commands using full address
dropblank	Strip blank To:, Resent-To:, Cc:, or Resent-Cc: headers
ehlo	Use EHLO on all initial SMTP connections

eightbit	Channel supports eight bit characters
eightnegotiate	Channel should negotiate use of eight bit transmission if possible
eightstrict	Channel should reject messages that contain unnegotiated eight bit data
enqueue_removeroute	Strip source route (@source-route:address) when enqueuing message
envelopetunnel	(New in 8.0.1) Tunnel envelope fields via header lines
errsendpost	Send copies of failures to the postmaster if the originator address is illegal
errwarnpost	Send copies of warnings to the postmaster if the originator address is illegal
expandchannel	Channel in which to perform deferred expansion due to application of expandlimit
expandlimit	Process an incoming message "off-line" when the number of addressees exceeds this limit
expirysource	(New in MS 7.0) Source channel supports Expiry-date: header value
explicitsaslexternal	(New in MS 8.0) Disable automatic use of AUTH EXTERNAL at MAIL FROM
expnallow	(New in MS 6.1) Explicitly enable support of the SMTP command EXPN
expndefault	(New in MS 6.1) Default handling of the SMTP command EXPN
expndisable	(New in MS 6.1) Disable support of the SMTP command EXPN
exproute	Explicit routing for this channel's addresses
externalidentity	(New in MS 7.0.5) Identity for SMTP channel's client use of SMTP AUTH EXTERNAL
fileinto	Specify effect on address when a Sieve filter fileinto action is applied
filesperjob	Number of queue entries to be processed by a single job
filter	Specify the location of user Sieve filter files
fixsyntaxerrors	(New in MS 8.0) Correct syntax errors in header fields
flagtransfer	Support private XDFLG/XAFLG SMTP/LMTP extensions and (new in MS 8.0.2.3) XCONVTAG SMTP extension; pass along delivery flags, such as trusting a subaddress, IMAP flags, and conversion tags.
forcedreceivedfrom	(New in MS 8.0.1) When constructing a Received: header line, force use of the specified string in the "from ..." clause
foreign	DEPRECATED: Use VMS MAIL's foreign message format as needed with VMS MAIL
forwardcheckdelete	If a reverse DNS lookup has been performed, next perform a forward lookup on the returned name to check that the returned IP number matches the original; if not, delete the name and use the IP address
forwardchecknone	Do not perform a forward lookup after a DNS reverse lookup
forwardchecktag	If a reverse DNS lookup has been performed, next perform a forward lookup on the returned name to check that the returned IP number matches the original; if not, tag the name with *
futurerelease	(New in MS 7.0) Enable source channel support for the future release SMTP extension
generatemessagehash	(New in MS 6.3) Generate a hash of specified message header fields
header_733	Use % routing in the message header
header_822	Use source routes in the message header
header_uucp	Use ! routing in the header
headerbottom	DEPRECATED: Place the message header at the bottom of the message (usage discouraged; use with caution)
headerdecodesrs	Decode SRS encoding of addresses in header lines
headerfoldpreserve	Attempt to preserve original header line fold points
headerfoldremove	Re-do header line folding
headerinc	Place the message header at the top of the message
headerkeeporder	(New in MS 6.3) Preserve ordering of header lines
headerlabelalignment	Align headers
headerlimit	Truncate message header at specified size
headerlineincrement	Increment used when attempting to fold header lines
headerlinelength	Fold long headers
headeromit	DEPRECATED: Omit the message header from the message (usage discouraged; use with caution)
headerread	Apply source channel header trimming rules from a header option file to the message headers before headers are processed (use with caution)
headerset7	RESTRICTED: Decode the specified charset in headers when dequeuing
headerset8	RESTRICTED: Decode the specified charset in headers when dequeuing
headersetesc	RESTRICTED: Decode the specified charset in headers when dequeuing
headertrailingpreserve	Preserve trailing spaces (including before fold points) in header lines
headertrailingremove	Remove trailing spaces (including before fold points) in header lines
headertrim	Apply destination channel header trimming rules from a header option file to the message headers after headers are processed (use with caution)
holdlimit	.HELD an incoming message when the number of addressees exceeds this limit
identnone	Do not perform IDENT lookups; do perform IP to hostname translation; include both hostname and IP address in Received: header

identnonelimited	Do not perform IDENT lookups; do perform IP to hostname translation, but do not use the hostname during channel switching; include both hostname and IP address in Received: header
identnonenumeric	Do not perform IDENT lookups or IP to hostname translation
identnonesymbolic	Do not perform IDENT lookups; do perform IP to hostname translation; include only the hostname in Received: header
identtcp	Perform IDENT lookups on incoming SMTP connections and IP to hostname translation; include both hostname and IP address in Received: header
identtcplimited	Do perform IDENT lookups; do perform IP to hostname translation, but do not use the hostname during channel switching; include both hostname and IP address in Received: header
identtcpnumeric	Perform IDENT lookups on incoming SMTP connections, but do not perform IP to hostname translation
identtcpsymbolic	Perform IDENT lookups on incoming SMTP connections and IP to hostname translation; include only hostname in Received: header
ignoreencoding	Ignore Encoding: header on incoming messages
ignoremessageencoding	(New MS 6.3.) Ignore any Content-transfer-encoding: header line present on incoming MIME message parts
ignoremultipartencoding	(New in MS 6.3.) Ignore any Content-transfer-encoding: header line present on incoming MIME multipart parts
implicitsaslexternal	(New in MS 8.0) Enable automatic use of AUTH EXTERNAL at MAIL FROM after successful negotiation of TLS
improute	Implicit routing for this channel's addresses
includefinal	Include final form of address in delivery notifications
includereceivedip	(New in 8.0.1.2) Include IP address information in the from clauses of generated Received: lines.
inner	Rewrite inner message headers on messages queued to this channel
innertrim	Apply header trimming rules from an options file to inner message headers (use with caution)
interfaceaddress	Bind to the specified TCP/IP interface address
interpretencoding	Interpret Encoding: header on incoming messages
interpretmessageencoding	(New in MS 6.3.) Interpret any Content-transfer-encoding: header line present on incoming MIME message parts
interpretmultipartencoding	(New in MS 6.3.) Interpret any Content-transfer-encoding: header line present on incoming MIME multipart parts
ipbackoff	(New in MS 8.0.2.3) Channel delivery retry backoff intervals for messages in IP backoff mode
ipbackofftimeout	(New in MS 8.0.2.3) Timeout for IP backoff entries made in memcache or Redis.
keepmessagehash	(New in MS 6.3) Keep message hash
language	Specify a preferred language for messages that have none
lastresort	Specify a last resort host
limitheadertermination	(New in MS 7.0.5) Only CRLFCRLF terminates message header
linelength	Message lines exceeding this length limit will be wrapped
linelimit	Maximum number of lines allowed per message
lmtp	Channel uses LMTP
lmtp_cr	Accept CR as an LMTP line terminator
lmtp_crlf	Require CRLF as the LMTP line terminator
lmtp_crorlf	Allow any of CR, LF, or CRLF as the LMTP line terminator
lmtp_lf	Accept LF as an LMTP line terminator
localbehavior	RESTRICTED: Control some local-channel-like behaviors
localvrfy	Issue SMTP VRFY command using local address
logging	Log message enqueues and dequeues into the MTA message transaction log file
logheader	Include message headers in the MTA message transaction log entries
loopcheck	Enable support for the XLOOP SMTP extension (used to detect a type of message loop)
mailfromdnsverify	Verify that the domain specified on MAIL FROM: line is in the DNS
master	Channel is served only by a master program
master_debug	Generate debugging output in the channel's master program output
maxblocks	Maximum number of MTA blocks per message; longer messages are broken into multiple messages
maxconnectionrateperdomain	Implements a limit on the rate of connections made to a domain using the smartsend plugin
maxconnectionsperdomain	Implements limits on the number of simultaneous connections to a domain using the smartsend plugin
maxheaderaddrs	Maximum number of addresses per message header line; longer header lines are broken into multiple header lines
maxheaderchars	Maximum number of characters per message header line; longer header lines are broken into multiple header lines
maxjobs	Maximum number of jobs which can be created at once
maxlines	Maximum number of message lines per message; longer messages are broken into multiple messages
maxmessagerateperdomain	Implements a limit on the rate of messages sent to a domain using the smartsend plugin
maxperiodicnonurgent	Specify that periodic jobs should only process messages of non-urgent or lower priority
maxperiodicnormal	Specify that periodic jobs should only process messages of normal or lower priority
maxperiodicurgent	Specify that periodic jobs should process messages of urgent or lower priority

maxprocchars	Specify maximum length of headers to process
maysasl	Allow SMTP server and client SASL authentication
maysaslclient	SMTP client attempts to use SASL authentication
maysaslserver	SMTP server offers SASL authentication
maytls	SMTP client and server allow TLS use
maytlsclient	SMTP client will attempt TLS use
maytlsserver	SMTP server allows TLS use
minperiodicnonurgent	Specify that periodic jobs should only process messages of non-urgent or higher priority
minperiodicnormal	Specify that periodic jobs should only process messages of normal or higher priority
minperiodicurgent	Specify that periodic jobs should only process messages of urgent priority
missingrecipientpolicy	Set policy for how to legalize (which header to add) messages that are lacking any recipient headers
mlslabel	(New in MS 7.0) RESTRICTED: Not yet fully implemented
mlsrange	(New in MS 7.0) RESTRICTED: Not yet fully implemented
msexchange	Channel serves MS Exchange gateways
mtprioritiesallowed	(New in MS 8.0) Range of SMTP MT-PRIORITY values accepted during enqueue; other values adjusted to be within range
mtprioritiesrequired	(New in MS 8.0) Range of SMTP MT-PRIORITY values accepted during enqueue; messages with other values will be rejected.
multigate	Channel serves multiple BITNET gateways, or LMTP back ends
multiple	Accepts multiple destination hosts in a single message copy
mustsasl	Must use SASL authentication
mustsaslclient	SMTP client insists upon SASL authentication
mustsaslserver	SMTP server insists upon SASL authentication
musttls	SMTP client and server insist upon TLS use and will not transfer messages with remote sides that do not support TLS
musttlsclient	SMTP client insists upon TLS use and will not send messages to any remote SMTP server that does not support TLS use
musttlsserver	SMTP server insists upon TLS use and will not accept messages from any remote SMTP client that does not support TLS use
mx	TCP/IP network and software supports MX record lookups
nameparameterlengthlimit	Maximum length to allow for NAME parameter of MIME Content-type: header line
nameservers	Consult specified nameservers rather than TCP/IP stack's choice (only for MX records as of MS 7.0)
noaddlineaddrs	Do not attempt the (risky) extraction of recipient addresses from VMS MAIL header lines
noaddresssrs	(New in MS 6.3p1) Addresses matching this channel will not be SRS encoded.
noaddreturnpath	Do not add a Return-Path: header line
noaddrtypescan	(New in MS 7.0.5) Do not store recipient address "type" in an envelope flag
noauthhost	(New in 8.0.2.1) Disable use the domain of the authenticated user's primary address to complete addresses
nobangoverpercent	Group A!B%C as (A!B)%C (default)
nobccserver	(New in MS 8.0.2.3) XBCC extension is disabled
nobinaryclient	(New in MS 6.3.) Disable BINARYMIME support in the SMTP client
nobinaryserver	(New in MS 6.3.) Disable BINARYMIME support in the SMTP server
noblocklimit	No limit specified for the number of MTA blocks allowed per message
nocache	Do not cache any connection information
nochannelfilter	Do not perform channel filtering for outgoing messages; synonym for nodestinationfilter
nochunkingclient	(New in MS 6.3) Disable CHUNKING support in the SMTP client
nochunkingserver	(New in MS 6.3) Disable CHUNKING support in the SMTP server
noconvert_octet_stream	Alias for noconvertoctetstream; in legacy configuration, do not convert application/octet-stream material
noconvertoctetstream	(Unified Configuration only) Do not convert application/octet-stream material
nodayofweek	Remove day of week from date/time specifications
nodefaulthost	Do not specify a domain name to use to complete addresses
nodeferred	Alias for nodeferreddestination (do not honor deferred delivery dates)
nodeferreddestination	(New in MS 7.0u4) Do not honor deferred delivery dates
nodeferredsource	(New in MS 7.0u4) Do not honor deferred delivery dates
nodefragment	Do not perform special processing for message/partial messages
nodestinationfilter	Do not perform channel filtering for outgoing messages
nodestinationsrs	(New in MS 6.3p1) Messages matching this destination channel will not have addresses SRS encoded.
nodns	TCP/IP network does not support DNS (nameserver) lookups; on UNIX, merely disables MX lookups since on UNIX it is nsswitch.conf that controls consultation of nameservers
nodnsforcetemporary	Treat host not found and no address lookup errors as permanent failures. This option is new in 8.0.1.3.
nodropblank	Do not strip blank To:, Resent-To:, Cc:, or Resent-Cc: headers

noehlo	Never use the SMTP EHLO command
noexpirysource	(New in MS 7.0) Source channel ignores Expiry-date: header value
noexproute	No explicit routing for this channel's addresses
nofileinto	Sieve filter fileinto action has no effect
nofilter	No external-to-LDAP user Sieve filters
noflagtransfer	Disable private XDFLG/XAFLG SMTP/LMTP extensions and (new in MS 8.0.2.3) XCONVTAG SMTP extension; do not pass along delivery flags, IMAP flags, and conversion tags.
noheaderdecodesrs	Do not decode SRS encoding of addresses in header lines (default)
noheaderread	Do not apply header trimming rules from header option file upon message enqueue
noheadertrim	Do not apply header trimming rules from header option file
noimproute	No implicit routing for this channel's addresses
noinner	Do not rewrite inner message headers on messages queued to this channel
noinnertrim	Do not apply header trimming to inner message headers
nolinelimit	No limit specified for the number of lines allowed per message
nolocalbehavior	No special local-channel-like behavior requested
nologging	Do not log message enqueues and dequeues into the MTA message transaction log file
noloopcheck	Disable support for the XLOOP SMTP extension (used to detect a type of message loop)
nomailfromdnsverify	Do not perform DNS domain verification on the MAIL FROM: address
nomaster_debug	Do not generate debugging output in the channel's master program output
nomsexchange	Channel does not serve MS Exchange gateways
nomultigate	Channel does not serve multiple BITNET gateways or LMTP back ends
nomx	TCP/IP network does not support MX lookups
nonotary	RESTRICTED: Disable DSN extension use by SMTP/LMTP client
nonrandommx	Do MX lookups; do not randomize returned entries with equal precedence
nonurgentafter	Specify time delay before master channel programs run for non-urgent priority messages
nonurgentbackoff	Channel delivery retry backoff intervals for non-urgent priority messages
nonurgentblocklimit	Force messages above this size to wait unconditionally for a periodic job
nonurgentnotices	Specify the amount of time which may elapse before notices are sent and messages returned for messages of non-urgent priority
noproxyprotocol	(New in MS 8.1.0.1) Proxy protocol support is disabled
noreceivedfor	Do not include envelope To address in Received: header
noreceivedfrom	Do not include the envelope From address when constructing Received: header
noremotehost	Use local host's domain name as the default domain name to complete addresses
norestricted	Do not apply RFC 1137 restricted encoding to addresses
noreturnaddress	Use the value of the return_address MTA option
noreturnpersonal	Use the value of the return_personal MTA option
noreverse	Do not apply address reversal to addresses
normalafter	Specify time delay before master channel programs run for normal priority messages
normalbackoff	Channel delivery retry backoff intervals for normal priority messages
normalblocklimit	Force messages above this size to nonurgent priority
normalnotices	Specify the amount of time which may elapse before notices are sent and messages returned for messages of normal priority
norules	Do not do channel-specific rewrite rule checks
nosasl	SASL authentication not attempted or permitted
nosaslclient	SMTP client does not attempt SASL authentication
nosaslpassauth	Do not pass along a MAIL FROM AUTH parameter
nosaslserver	SMTP server does not permit SASL authentication
nosaslswitchchannel	Do not switch channel upon successful SASL authentication
nosasltrustauth	(New in MS 7.0u3) Do not promote a MAIL FROM AUTH parameter to the MTA's authenticated originator address envelope field
nosendetrn	Do not send SMTP ETRN command
nosendpost	Do not send copies of failures to the postmaster
noserviceconversion	(New in MS 7.0.3) Service conversions for messages coming in this channel must be enabled via the CHARSET-CONVERSION mapping table
noslave_debug	Do not generate debugging output in the channel's slave program output
nosmtp	Channel does not use SMTP
nosocks	Do not do SOCKS connections

nosourcefilter	Source channel does not have an associated Sieve filter
nosourceinner	(New in MS 8.1.0.1) Do not rewrite inner message headers on message sent from this channel
nosourcesrs	(New in MS 6.3p1) Messages matching this source channel will not have addresses SRS encoded.
noswitchchannel	Stay with the server channel; do not switch to the channel associated with the originating host; do not permit being switched to
notary	Normal NOTARY support
nothurman	Do not perform thurman format conversion
notices	Specify the amount of time which may elapse before notices are sent and messages returned
notick	RESTRICTED: Do not put a ticket in the BSMTP stream
notificationchannel	(New in MS 6.2.) Channel to use when generating notifications
notls	SMTP client and server neither attempt nor allow TLS use
notlsclient	SMTP client does not attempt TLS use when sending messages
notlsserver	SMTP server does not offer or allow TLS use when receiving messages
notrackingclient	(New in MS 8.0) Disable SMTP client support of message tracking
notrackingserver	(New in MS 8.0) Disable SMTP server support of message tracking
noturn	Disable the SMTP TURN command
nouma	Do not perform "thurman on demand" format conversion
novrfy	Do not issue SMTP VRFY commands
nowarnpost	Do not send copies of warnings to the postmaster
nox_env_to	Do not add X-Envelope-to: header lines while enqueuing
noxclient	(New in MS 8.0) XCLIENT SMTP extension is disabled
parameterformatdefault	(New in MS 7.0.5) Normal handling of MIME parameters, using RFC 2231 encoding when appropriate
parameterformatminimizeencoded	(New in MS 7.0.5) Remove unnecessary, redundant RFC 2231 encoding from MIME parameters
parameterformatstripencoded	(New in MS 7.0.5) Strip any characters requiring RFC 2231 encoding from MIME parameters, so that RFC 2231 encoding may be removed
parameterlengthlimit	Maximum length to allow for parameters of MIME Content-type: header line
passsyntaxerrors	(New in MS 8.0) Disable certain header field syntax error fixup
passthrough	Do no message processing
percentonly	Interpret percent character in an address local-part
percents	Use % routing in the envelope; (legacy configuration's 733 is an alias for `percents`)
personalinc	Leave personal names in message header lines intact
personalmap	Apply `PERSONAL_NAMES` mapping to personal names in message header lines
personalomit	Remove personal name fields from message header lines
personalstrip	Strip problematic characters from personal name fields in message header lines
pool	Specify Job Controller pool in which channel programs run
port	Send to the specified TCP/IP port
postheadbody	Both the message's header and body are copied to the postmaster when a delivery failure occurs
postheadonly	Only the message's header is copied to the postmaster when a delivery failure occurs
presence	RESTRICTED: Not yet implemented
processsecuritymultiparts	Process inside security multiparts
proxyprotocol	(New in MS 8.1.0.1) Proxy protocol support is enabled
randommx	Do MX lookups; randomize returned entries with equal precedence
receivedfor	Include envelope to address in Received: header
receivedfrom	Include the envelope From address when constructing Received: header
receivedstate	(New in MS 8.0) Include a state indicator when constructing Received: header
recipientcutoff	Set a limit for the number of recipients-per-message-copy accepted on a channel; attempts to submit a message with more than this number of recipients will cause *all* recipients to be rejected
recipientlimit	Set a limit for the number of recipients-per-message-copy accepted on a channel; additional recipients will get a temporary rejection error
refuseehlo	RESTRICTED: Disable EHLO support in SMTP server
refusenotary	(New in MS 8.0.1) RESTRICTED: Disable DSN extension support in SMTP server
rejectsmtplonglines	Reject incoming SMTP messages with illegally long lines
relaxheadertermination	Allow lines containing white space characters to terminate the header of a message
relay	Mark the channel as a relay channel
remotehost	Use remote host's name as the default domain name to complete addresses
reportboth	Generate both header and NOTARY delivery receipt requests from "foreign" delivery receipt requests

reportheader	Generate only header delivery receipt requests from "foreign" delivery receipt requests
reportnotary	Generate only NOTARY delivery receipt requests from "foreign" delivery receipt requests
reportsuppress	Suppress delivery receipt requests from "foreign" delivery receipt requests
restricted	Apply RFC 1137 restricted encoding to addresses
retainsecuritymultiparts	Do not process inside security multiparts
returnaddress	Set the return address for the local Postmaster
returnenvelope	Control use of blank envelope return addresses
returnpersonal	Set the personal name for the local Postmaster
reverse	Apply address reversal to addresses; that is, apply reverse_url LDAP-based address reversal, the reverse database, and the REVERSE mapping to addresses
routelocal	Rewriting should shortcircuit routing addresses
rules	Do channel-specific rewrite rule checks
saslpassauth	Pass along a MAIL FROM AUTH parameter
saslruleset	Specify the security configuration rule set to use for SASL transactions
saslswitchchannel	Switch to another channel when SASL authentication is successful
sasltrustauth	(New in MS 7.0u3) Promote any MAIL FROM AUTH parameter to the MTA's authenticated originator address envelope field
secondclassafter	Specify time delay before channel runs for secondclass priority messages
secondclassblocklimit	Force messages above this size to third class priority
secondclassqueue	RESTRICTED: Not implemented for Messaging Server MTA; (for PMDF, specified the queue for master channel program processing of second class messages)
sendetrn	Send SMTP ETRN command
sendpost	Send copies of failures to the postmaster
sensitivitycompanyconfidential	Allow messages of any sensitivity
sensitivitynormal	Reject messages whose sensitivity is higher than normal
sensitivitypersonal	Reject messages whose sensitivity is higher than personal
sensitivityprivate	Reject messages whose sensitivity is higher than private
serviceconversion	(New in MS 7.3) Perform service conversions for messages coming in this channel regardless of CHARSET-CONVERSION
sevenbit	Channel does not support eight bit characters; eight bit characters must be encoded
silentetrn	Honor SMTP client ETRN commands, without echoing channel information
single	Only one envelope To address per message copy
single_sys	Each message copy must be for a single destination system
slave	Channel is serviced only by a slave program
slave_debug	Generate debugging output in the channel's slave program output
smtp	Channel uses SMTP
smtp_cr	Accept CR as an SMTP line terminator
smtp_crlf	Require CRLF as the SMTP line terminator
smtp_crorlf	Allow any of CR, LF, or CRLF as the SMTP line terminator; default on TCP/IP channels
smtp_lf	Accept LF as an SMTP line terminator
sourceblocklimit	Maximum number of MTA blocks allowed per incoming message
sourcebrightmail	DEPRECATED: Alias for sourcespamfilter1
sourcebrightmailoptin	DEPRECATED: Alias for sourcespamfilter1optin
sourcecommentinc	Leave comments in incoming message header lines intact
sourcecommentmap	Apply COMMENT_STRINGS mapping to comments in incoming message header lines
sourcecommentomit	Remove comments from incoming message header lines
sourcecommentstrip	Remove problematic characters from comment field in incoming message header lines
sourcecommenttotal	Strip comments (material in parentheses) everywhere in incoming messages
sourceconversiontag	(New in MS 7.0.5) Conversion tags to add to message
sourcefilter	Specify the location of the channel's Sieve filter for incoming messages
sourceinner	(New in MS 8.1.0.1) Rewrite inner message headers on message sent from this channel
sourcenosolicit	(New in MS 6.2.) List of solicitation types not accepted
sourcepersonalinc	Leave personal names in incoming message header lines intact
sourcepersonalmap	Apply PERSONAL_NAMES mapping to personal names in incoming message header lines
sourcepersonalomit	Remove personal name fields from incoming message header lines
sourcepersonalstrip	Strip problematic characters from personal name fields in incoming message header lines
sourceroute	Use source routes in the message envelope; (_822 is an alias for sourceroute, synonymous with legacy configuration's 822)

sourcespamfilter	Alias for sourcespamfilter1
sourcespamfilter1	(New in MS 6.2) Enable spam/virus filtering (by spam/virus filter package 1) for messages enqueued by this source channel
sourcespamfilter1optin	(New in MS 6.2) Enable spam/virus filtering (by spam/virus filter package 1) for messages enqueued by this source channel, with the optin value provided as argument
sourcespamfilter2	(New in MS 6.2) Enable spam/virus filtering (by spam/virus filter package 2) for messages enqueued by this source channel
sourcespamfilter2optin	(New in MS 6.2) Enable spam/virus filtering (by spam/virus filter package 2) for messages enqueued by this source channel, with the optin value provided as argument
sourcespamfilter3	(New in MS 6.2) Enable spam/virus filtering (by spam/virus filter package 3) for messages enqueued by this source channel
sourcespamfilter3optin	(New in MS 6.2) Enable spam/virus filtering (by spam/virus filter package 3) for messages enqueued by this source channel, with the optin value provided as argument
sourcespamfilter4	(New in MS 6.2) Enable spam/virus filtering (by spam/virus filter package 4) for messages enqueued by this source channel
sourcespamfilter4optin	(New in MS 6.2) Enable spam/virus filtering (by spam/virus filter package 4) for messages enqueued by this source channel, with the optin value provided as argument
sourcespamfilter5	(New in MS 6.3) Enable spam/virus filtering (by spam/virus filter package 5) for messages enqueued by this source channel
sourcespamfilter5optin	(New in MS 6.3) Enable spam/virus filtering (by spam/virus filter package 5) for messages enqueued by this source channel, with the optin value provided as argument
sourcespamfilter6	(New in MS 6.3) Enable spam/virus filtering (by spam/virus filter package 6) for messages enqueued by this source channel
sourcespamfilter6optin	(New in MS 6.3) Enable spam/virus filtering (by spam/virus filter package 6) for messages enqueued by this source channel, with the optin value provided as argument
sourcespamfilter7	(New in MS 6.3) Enable spam/virus filtering (by spam/virus filter package 7) for messages enqueued by this source channel
sourcespamfilter7optin	(New in MS 6.3) Enable spam/virus filtering (by spam/virus filter package 7) for messages enqueued by this source channel, with the optin value provided as argument
sourcespamfilter8	(New in MS 6.3) Enable spam/virus filtering (by spam/virus filter package 8) for messages enqueued by this source channel
sourcespamfilter8optin	(New in MS 6.3) Enable spam/virus filtering (by spam/virus filter package 8) for messages enqueued by this source channel, with the optin value provided as argument
sourcespamfilteroptin	Alias for sourcespamfilter1optin
sourcesrs	(New in MS 6.3p1) Messages from this source channel are eligible for SRS encoding
spareN	(New in 8.0.2.2) Fill in the corresponding spare value slot with the specified value
spfhelo	(New in MS 6.3) Perform an SPF lookup at the HELO/EHLO command
spfmailfrom	(New in MS 6.3) Perform an SPF lookup at the MAIL FROM command
spfnone	(New in MS 6.3) Do not perform any SPF lookups
spfrcptto	(New in MS 6.3) Perform an SPF lookup at the RCPT TO command
streaming	Specify degree of protocol streaming for channel to use
subaddressexact	Alias must match exactly, including exact subaddress match
subaddressrelaxed	Alias without subaddress may match
subaddresswild	Alias with subaddress wildcard may match
subdirs	Use multiple subdirectories for messages queued to channel
submit	Mark the channel as a submit-only channel
suppressfinal	Include only original form of address in notification messages
suppressreceivedip	(New in 8.0.1.2) Do not include IP address information in the from clauses of generated Received: lines.
switchchannel	Switch effective source channel to the channel associated with the originating host's source IP
threaddepth	Number of messages triggering new thread with SMTP client
tick	RESTRICTED: Put a ticket in the BSMTP stream
tlsswitchchannel	Switch to specified source channel upon successful TLS negotiation
trackingclient	(New in MS 8.0.) Enable SMTP client support of message tracking
trackingdelivered	(New in MS 8.0.) Treat messages dequeued from this channel as delivered
trackingfirst	(New in MS 8.0.) Tracking information goes to first alias expansion result
trackinggenerate	(New in MS 8.0.) Enable SMTP client support of message tracking
trackinginternal	(New in MS 8.0.) This channel transfers internally
trackingmultiple	(New in MS 8.0.) Tracking information passes through aliases
trackingrelayed	(New in MS 8.0.) Treat messages dequeued from this channel as relayed
trackingserver	(New in MS 8.0.) Enable SMTP server support of message tracking
trackingsingle	(New in MS 8.0.) Only pass tracking info through single recipient alias
trackingtimeoutdefault	(New in MS 8.0.) Default timeout (s) for tracking requests
trackingtimeoutmax	(New in MS 8.0.) Maximum timeout (s) for tracking requests
trackingtimeoutmin	(New in MS 8.0.) Minimum timeout (s) for tracking requests
transactionlimit	(New in MS 6.1) Limit the number of transactions per SMTP session (messages per SMTP connection) accepted

truncatesmtplonglines	Truncate incoming SMTP messages with illegally long lines
turn	RESTRICTED: Enable the SMTP TURN command
turn_in	RESTRICTED: Enable the SMTP TURN command for incoming connections; that is, the SMTP server will accept SMTP TURN commands
turn_out	RESTRICTED
uma	Perform thurman conversion if would be MIME-ifying the message anyway for other reasons
unrestricted	Do not apply RFC 1137 restricted encoding to addresses
urgentafter	Specify time delay before master channel programs run for urgent priority messages
urgentbackoff	Channel delivery retry backoff intervals for urgent priority messages
urgentblocklimit	Force messages above this size to normal priority
urgentnotices	Specify the amount of time which may elapse before notices are sent and messages returned for messages of urgent priority
useintermediate	Include the "intermediate" form of recipient address, that form previously presented as active from the MTA's point of view, in delivery status notification messages
usepermanenterror	(New in MS 8.0) Override use_permanent_error MTA option on a per-source-channel basis
user	DEPRECATED as of MS 8.0; instead use the pipeuser option in restricted.cnf. Specify account under which to run the pipe channel
usereplyto	Specify mapping of Reply-to: header
useresent	Specify mapping of Resent- headers for non RFC 822 environments
userswitchchannel	(New in MS 6.3) Enable switching from this source channel to a channel selected via a per-user or per-domain LDAP attribute
usetemporaryerror	(New in MS 8.0) Override use_temporary_error MTA option on a per-source-channel basis
utf8header	(New in MS 8.0.2) Enable unconditional EAI support
utf8negotiate	(New in MS 8.0.2) Enable EAI support
utf8strict	(New in MS 8.0.2) Enable EAI support with strict enforcement
uucp	Alias for bangstyle; (use UUCP ! routing in the envelope)
validatelocalnone	Enqueuing channels perform no validation check on the local part of addresses they enqueue to this channel
validatelocalsystem	Enqueuing channels check that the local part of addresses they enqueue to this channel matches an account on the system
verb_never	RESTRICTED: Ignore VERB commands in the BSMTP stream
verb_none	RESTRICTED: Accept VERB commands in the BSMTP stream
verb_off	RESTRICTED: Insert a VERB OFF command into the BSMTP stream
verb_on	RESTRICTED: Insert a VERB ON command into the BSMTP stream
viaaliasoptional	Alias match not required
viaaliasrequired	Alias match required
vrfyallow	Provide informative responses to SMTP VRFY command
vrfydefault	Default responses to SMTP VRFY command, according to channel's TCP/IP-channel-specific HIDE_VERIFY option setting
vrfyhide	Provide obfuscatory responses to SMTP VRFY command
warnpost	Send copies of warnings to the postmaster
wrapsmtplonglines	Wrap incoming SMTP messages with illegally long lines
x_env_to	Add X-Envelope-to: header lines while enqueuing
xclient	(New in MS 8.0) XCLIENT SMTP extension is enabled, only one group of XCLIENT commands permitted
xclientrepeat	(New in MS 8.0) XCLIENT SMTP extension is enabled, and groups of XCLIENT commands are permitted
xclientsasl	(New in MS 8.0) XCLIENT SMTP extension is enabled, and LOGIN attribute is allowed
xclientsaslrepeat	(New in MS 8.0) XCLIENT SMTP extension is enabled, LOGIN attribute is permitted, and groups of XCLIENT commands are permitted

46.3.2 Functional group list of channel options

There are a great many channel options available for configuring channel behavior. The channel options may be viewed in an alphabetic list; alternatively, they may also be viewed grouped by functionality for convenience in considering inter-related options.

In Unified Configuration, channel options are configured directly under the channel name:

`channel:`*`channel-name.channel-option`*

In legacy configuration, channel options were set as keywords on the channel definition in the MTA configuration file, `imta.cnf`; channel options appeared on the first line of a channel definition, after the channel name.

Note that there are also many MTA options affecting MTA operation in general (rather than affecting specific channels); in general such MTA level options are distinct from channel options (not merely global defaults for channels) as MTA options may alter more fundamental aspects of MTA operation, but in some cases an MTA level option does establish a default for all channels which may then be overridden via a channel option analogue.

Note also that besides the normal channel options under discussion here, some channels also support some channel-specific options. These are channel-specific options which are *only* supported and available for that specific type of channel: for historical (and functional) reasons they are implemented differently from the usual channel options. Such channel-specific options were, in legacy configuration, configured in channel option files; in Unified Configuration they are configured under the `options` channel option:

`channel:`*`channel-name`*`.options.`*`channel-specific-option-name`*

See the specific type of channel for a list of that channel's valid channel-specific options.

Channel options listed alphabetically lists channel options alphabetically; Channel options grouped by functionality below lists channel options by functional group:

- Addresses
- Attachments and MIME processing
- BSMTP-specific
- Character sets and eight bit data
- Conversion tag and service conversion
- Display labels
- DKIM
- Error interpretation
- File creation in the MTA queue area
- Gateway/firewall/mailhub/Message Router channel connection
- Headers
- Host names
- Incoming channel matching and switching
- Logging and debugging
- Long address lists or headers
- Message hash
- Message tracking
- MLS
- Notification messages and postmaster messages
- Processing control and job submission
- Sensitivity limits
- Sieve filters and delivery flags
- Size limits on messages
- Spam/virus filter package use
- SMTP and LMTP protocol
- TCP/IP connections, DNS lookups, and SOCKS connections
- TLS and SASL

Channel options shown in **bold face type** are defaults; channel options marked with + are only supported under OpenVMS.

Table 46.4 Channel options grouped by functionality

Option	Usage
Addresses	
_733	Use % routing in the envelope; alias for percents
_822	Use source routes in the envelope; alias for sourceroute
acceptalladdresses	(New in MS 6.1) Accept messages despite certain errors that would normally cause message rejection
accepttemporaryfailures	(New in 8.0.1.1.0) Accept messages despite recipient address temporary error conditions (*e.g.*, over quota, LDAP server unavailable, Spam/virus filter unavailable, *etc.*).
acceptvalidaddresses	(New in MS 6.1) Perform normal rejection checks on incoming messages
addlineaddrs	RESTRICTED: Attempt to extract additional envelope recipient addresses from X-VMS-To: and X-VMS-Cc: header lines
addresssrs	(New in MS 6.3p1) Addresses matching this channel are eligible for SRS encoding
addreturnpath	Add a Return-Path: header line
addrtypescan	(New in MS 7.0.5) Store recipient address "type" in an envelope flag
addrtypescanbccdefault	(New in MS 7.0.5) Store recipient address "type" in an envelope flag, assuming unmatched recipient addresses are Bcc: addresses
aliasdetourhost	Specify an "override" mailHost for any user found in LDAP; effect is to "detour" messages for such a user to the specified host
aliaslocal	Look up aliases; *i.e.*, query alias file and alias database and alias options and perform alias_url* lookups
aliasmagic	(New in MS 6.0) RESTRICTED: Destination channel override of the alias_magic MTA option, controlling the order of the different types of alias lookups
aliasoptindetourhost	(New in MS 6.2p4) Specify an "override" mailHost for any user who is opted-in via whatever LDAP attribute is named by the ldap_detourhost_optin MTA option; the effect is to "detour" messages for such a user to the specified host
aliaswild	Do an * lookup if no exact alias match is found
authhost	(New in 8.0.2.1) Use the domain of the authenticated user's primary address to complete addresses
authrewrite	Use SMTP AUTH information in header
bangonly	Source channel: disable interpretation of % host-routing
bangoverpercent	Group A!B%C as A!(B%C)
bangstyle	Use UUCP ! routing in the envelope; (uucp from legacy configuration is an alias for bangstyle)
defaulthost	Specify a domain name to use to complete addresses
defertemporaryfailures	(New in 8.0.1.1.0) Defer, with SMTP temporary rejection, recipient addresses with temporary error conditions (*e.g.*, over quota, LDAP server unavailable, Spam/virus filter unavailable, *etc.*).
dequeue_removeroute	Alias for dequeueremoveroute; in legacy configuration, strip source route (@source-route:address) when dequeuing message
dequeueremoveroute	(Unified Configuration only) Strip source route (@source-route:address) when dequeuing message
destinationsrs	(New in MS 6.3p1) Messages destined out this channel are eligible for SRS encoding
enqueue_removeroute	Alias for enqueueremoveroute; in legacy configuration, strip source route (@source-route:address) when enqueuing message
enqueueremoveroute	(Unified Configuration only) Strip source route (@source-route:address) when enqueuing message
exproute	Explicit routing for this channel's addresses
headerdecodesrs	Decode SRS encoding of addresses in header lines
holdlimit	.HELD an incoming message when the number of addressees exceeds this limit
improute	Implicit routing for this channel's addresses
localbehavior	RESTRICTED: Control some local-channel-like behavior
missingrecipientpolicy	Set policy for how to legalize (which header to add) messages that are lacking any recipient headers
noaddlineaddrs	Do not attempt the (risky) extraction of recipient addresses from VMS MAIL header lines
noaddresssrs	(New in MS 6.3p1) Addresses matching this channel will not be SRS encoded.
noaddreturnpath	Do not add a Return-Path: header line
noaddrtypescan	Do not store recipient address "type" in an envelope flag
noauthhost	(New in 8.0.2.1) Disable use the domain of the authenticated user's primary address to complete addresses
nobangoverpercent	Group A!B%C as (A!B)%C (default)
nodefaulthost	Do not specify a domain name to use to complete addresses
nodestinationsrs	(New in MS 6.3p1) Messages matching this destination channel will not have addresses SRS encoded.
noexproute	No explicit routing for this channel's addresses
noheaderdecodesrs	Do not decode SRS encoding of addresses in header lines (default)
noimproute	No implicit routing for this channel's addresses
nolocalbehavior	No special local-channel-like behavior requested

noremotehost	Use local host's domain name as the default domain name to complete addresses
norestricted	Do not apply RFC 1137 restricted encoding to addresses
noreverse	Do not apply address reversal to addresses
norules	Do not do channel-specific rewrite rule checks
nosourcesrs	(New in MS 6.3p1) Messages matching this source channel will not have addresses SRS encoded.
percents	Use % routing in the envelope; (legacy configuration's 733 is an alias for percents)
recipientcutoff	Set a limit for the number of recipients-per-message-copy accepted on a channel; attempts to submit a message with more than this number of recipients will cause *all* recipients to be rejected
recipientlimit	Set a limit for the number of recipients-per-message-copy accepted on a channel; additional recipients will get a temporary rejection error
remotehost	Use remote host's name as the default domain name to complete addresses
restricted	Apply RFC 1137 restricted encoding to addresses
reverse	Apply address reversal to addresses in messages destined to this channel; *i.e.*, apply reverse_url LDAP-provisioned address reversal, the reverse database, and the REVERSE mapping table to addresses
routelocal	Rewriting should shortcircuit routing addresses
rules	Do channel-specific rewrite rule checks
sourceroute	Use source routes in the message envelope; (_822 is an alias for sourceroute, synonymous with legacy configuration's 822)
sourcesrs	(New in MS 6.3p1) Messages from this source channel are eligible for SRS encoding
spareN	(New in 8.0.2.2) Fill in the corresponding spare value slot with the specified value
subaddressexact	Alias must match exactly, including exact subaddress match
subaddressrelaxed	Alias without subaddress may match
subaddresswild	Alias with subaddress wildcard may match
unrestricted	Do not apply RFC 1137 restricted encoding to addresses
uucp	Alias for bangstyle
utf8header	(New in MS 8.0.2) Enable unconditional EAI support
utf8negotiate	(New in MS 8.0.2) Enable EAI support
utf8strict	(New in MS 8.0.2) Enable EAI support with strict enforcement
validatelocalnone	Enqueuing channels perform no validation check on the local part of addresses they enqueue to this channel
validatelocalsystem	Enqueuing channels check that the local part of addresses they enqueue to this channel matches an account on the system
viaaliasoptional	Alias match not required
viaaliasrequired	Alias match required
Attachments and MIME processing	
conditionalsecuritymultiparts	Process inside security multiparts, retaining preamble material
convert_octet_stream	Alias for convertoctetstream; in legacy configuration, convert application/octet-stream material as appropriate
convertoctetstream	(Unified Configuration only) Convert application/octet-stream material as appropriate
defragment	Reassemble any MIME-compliant message/partial parts queued to this channel
ignoreencoding	Ignore Encoding: header on incoming messages
ignoremessageencoding	(New in MS 6.3.) Ignore any Content-transfer-encoding: header line present (illegally) on incoming MIME message parts
ignoremultipartencoding	(New in MS 6.3.) Ignore any Content-transfer-encoding: header line present on incoming MIME multipart parts
interpretencoding	Interpret Encoding: header on incoming messages
interpretmessageencoding	(New in MS 6.3.) Interpret any Content-transfer-encoding: header line present (illegally) on incoming MIME message parts
interpretmultipartencoding	(New in MS 6.3.) Interpret any Content-transfer-encoding: header line present on incoming MIME multipart parts
linelength	Message lines exceeding this length limit will be wrapped
maxblocks	Maximum number of MTA blocks per message; longer messages are broken into multiple messages
maxlines	Maximum number of message lines per message; longer messages are broken into multiple messages
nameparameterlengthlimit	Maximum length to allow for NAME parameter of MIME Content-type: header line
noconvert_octet_stream	Alias for noconvertoctetstream; in legacy configuration, do not convert application/octet-stream material
noconvertoctetstream	(Unified Configuration only) Do not convert application/octet-stream material
nodefragment	Do not perform special processing for message/partial messages
nolinelimit	No limit specified for the number of lines allowed per message
nothurman	Do not perform thurman format conversion
nouma	Do not perform "thurman on demand" format conversion
parameterformatdefault	(New in MS 7.0.5) Normal handling of MIME parameters, using RFC 2231 encoding when appropriate
parameterformatminimizeencoded	(New in MS 7.0.5) Remove unnecessary, redundant RFC 2231 encoding from MIME parameters
parameterformatstripencoded	(New in MS 7.0.5) Strip any characters requiring RFC 2231 encoding from MIME parameters, so that RFC 2231 encoding may be removed

parameterlengthlimit	Maximum length to allow for parameters of MIME Content-type: header line
passthrough	Do no message processing
processsecuritymultiparts	Process inside security multiparts
retainsecuritymultiparts	Do not process inside security multiparts
thurman	Convert uuencoded and Binhex "blobs" to MIME format
uma	Perform thurman conversion if would be MIME-ifying the message anyway for other reasons
BSMTP and Bitnet	
contchar	DEPRECATED: Specify batch SMTP continuation line character
contposition	DEPRECATED: Specify folding point in batch SMTP lines
notick	RESTRICTED: Do not put a ticket in the BSMTP stream
tick	RESTRICTED: Put a ticket in the BSMTP stream
verb_never	RESTRICTED: Ignore VERB commands in the BSMTP stream
verb_none	RESTRICTED: Accept VERB commands in the BSMTP stream
verb_off	RESTRICTED: Insert a VERB OFF command into the BSMTP stream
verb_on	RESTRICTED: Insert a VERB ON command into the BSMTP stream
Character sets and eight bit data and EAI	
charset7	Default character set to associate with 7-bit text messages
charset8	Default character set to associate with 8-bit text messages
charsetesc	Default character set to associate with text containing the escape character
eightbit	Channel supports eight bit characters
eightnegotiate	Channel should negotiate use of eight bit transmission if possible
eightstrict	Channel should reject messages that contain unnegotiated eight bit data
headerset7	RESTRICTED: Decode the specified charset in headers when dequeuing
headerset8	RESTRICTED: Decode the specified charset in headers when dequeuing
headersetesc	RESTRICTED: Decode the specified charset in headers when dequeuing
parameterformatdefault	(New in MS 7.0.5) Normal handling of MIME parameters, using RFC 2231 encoding when appropriate
parameterformatminimizeencoded	(New in MS 7.0.5) Remove unnecessary, redundant RFC 2231 encoding from MIME parameters
parameterformatstripencoded	(New in MS 7.0.5) Strip any characters requiring RFC 2231 encoding from MIME parameters, so that RFC 2231 encoding may be removed
sevenbit	Channel does not support eight bit characters; eight bit characters must be encoded
utf8header	(New in MS 8.0.2) Enable unconditional EAI support
utf8negotiate	(New in MS 8.0.2) Enable EAI support
utf8strict	(New in MS 8.0.2) Enable EAI support with strict enforcement
Conversion tags and service conversions	
destinationconversiontag	(New in MS 7.0.5) Conversion tags to add to outgoing recipients
noserviceconversion	(New in MS 7.0.3) Service conversions for messages coming in this channel must be enabled via the CHARSET-CONVERSION mapping table
serviceconversion	(New in MS 7.0.3) Perform service conversions for messages coming in this channel regardless of CHARSET-CONVERSION
sourceconversiontag	(New in MS 7.0.5) Conversion tags to add to message
Display labels	
caption	(New in MS 6.3) Channel caption: a short description, suitable as the caption for a column of a table
description	Channel description
DKIM	
dkimignore	(New in MS 7.0.5) Take no special action in regards to DKIM-Signature: header fields
dkimpreserve	(New in MS 7.0.5) Don't rewrite DKIM-signed messages for specified domains
dkimremove	(New in MS 7.0.5) Remove DKIM signatures
Error interpretation	
usepermanenterror	(New in MS 8.0) Override use_permanent_error MTA option on a per-source-channel basis
usetemporaryerror	(New in MS 8.0) Override use_temporary_error MTA option on a per-source-channel basis
File creation in the MTA queue area	
addrsperfile	Number of addresses per message file
expandchannel	Channel in which to perform deferred expansion due to application of expandlimit
expandlimit	Process an incoming message "off-line" when the number of addressees exceeds this limit
multiple	Accepts multiple destination hosts in a single message copy
single	Only one envelope To address per message copy

single_sys	Each message copy must be for a single destination system
subdirs	Use multiple subdirectories for messages queued to channel
Gateway/firewall/mailhub/Message Router channel connection	
aliasdetourhost	Specify an "override" mailHost for any user found in LDAP; effect is to "detour" messages for such a user to the specified host
aliasoptindetourhost	(New in MS 6.2p4) Specify an "override" mailHost for any user who is opted-in via whatever LDAP attribute is named by the ldap_detourhost_optin MTA option; the effect is to "detour" messages for such a user to the specified host
daemon	Specify name of a gateway daemon (host) to route to
lastresort	Specify a last resort host
multigate	Channel serves multiple BITNET gateways, or multiple LMTP back ends
nomultigate	Channel does not serve multiple BITNET gateways, or multiple LMTP back ends
user	DEPRECATED as of MS 8.0; instead use the pipeuser option in restricted.cnf. Specify account under which to run the pipe channel
Headers	
addreturnpath	Add a Return-Path: header line
authhost	(New in 8.0.2.1) Use the domain of the authenticated user's primary address to complete addresses
authrewrite	Use SMTP AUTH information in header
commentinc	Leave comments in message header lines intact
commentmap	Apply COMMENT_STRINGS mapping to comments in message header lines
commentomit	Remove comments from message header lines
commentstrip	Remove problematic characters from comment field in message header lines
commenttotal	Strip comments (material in parentheses) everywhere
datefour	Convert date/time specifications to four digit years
datetwo	Convert date/time specifications to two digit years
dayofweek	Include day of week in date/time specifications
defaulthost	Specify a domain name to use to complete addresses
dropblank	Strip blank To:, Resent-To:, Cc:, or Resent-Cc: headers
envelopetunnel	(New in Cayenne) Tunnel envelope fields via header lines
fixsyntaxerrors	(New in MS 8.0) Correct syntax errors in header fields
forcedreceivedfrom	(New in MS 8.0.1) When constructing a Received: header line, force use of the specifed string in the "from ..." clause
header_733	Use % routing in the message header
header_822	Use source routes in the message header
header_uucp	Use ! routing in the header
headerbottom+	(OpenVMS only) Place the message header at the bottom of the message (usage discouraged; use with caution)
headerdecodesrs	Decode SRS encoding of addresses in header lines
headerfoldpreserve	Attempt to preserve original header line fold points
headerfoldremove	Re-do header line folding
headerinc	Place the message header at the top of the message; *i.e.*, normal handling
headerkeeporder	(New in MS 6.3) Preserve ordering of header lines
headerlabelalignment	Align headers
headerlimit	Truncate message header at specified size
headerlineincrement	Increment used when attempting to fold header lines
headerlinelength	Fold long headers
headeromit+	(OpenVMS only) Omit the message header from the message (usage discouraged; use with caution)
headerread	Apply source channel header trimming rules from a header option file to the message headers before headers are processed (use with caution)
headerset7	RESTRICTED: Decode the specified charset in headers when dequeuing
headerset8	RESTRICTED: Decode the specified charset in headers when dequeuing
headersetesc	RESTRICTED: Decode the specified charset in headers when dequeuing
headertrim	Apply destination channel header trimming rules from an header option file to the message headers after headers are processed (use with caution)
includereceivedip	(New in 8.0.1.2) Include IP address information in the from clauses of generated Received: lines.
inner	Rewrite inner message headers on message queued to this channel
innertrim	Apply header trimming rules from a header option file to inner message headers (use with caution)
limitheadertermination	(New in MS 7.0.5) Only CRLFCRLF terminates message header
maxheaderaddrs	Maximum number of addresses per message header line; longer header lines are broken into multiple header lines
maxheaderchars	Maximum number of characters per message header line; longer header lines are broken into multiple header lines

missingrecipientpolicy	Set policy for how to legalize (which header to add) messages that are lacking any recipient headers
noaddreturnpath	Do not add a Return-Path: header line
noauthhost	(New in 8.0.2.1) Disable use the domain of the authenticated user's primary address to complete addresses
nodayofweek	Remove day of week from date/time specifications
nodefaulthost	Do not specify a domain name to use to complete addresses
nodropblank	Do not strip blank To:, Resent-To:, Cc:, or Resent-Cc: headers
noheaderdecodesrs	Do not decode SRS encoding of addresses in header lines (default)
noheaderread	Do not apply header trimming rules from any header option file upon message enqueue
noheadertrim	Do not apply header trimming rules from any header option file
noinner	Do not rewrite inner message headers on messages queued to this channel
noinnertrim	Do not apply header trimming to inner message headers
noreceivedfor	Do not include envelope To address in Received: header
noreceivedfrom	Do not include the envelope From address when constructing Received: header
noremotehost	Use local host's domain name as the default domain name to complete addresses
norestricted	Do not apply RFC 1137 restricted encoding to addresses
noreverse	Do not apply address reversal to addresses
norules	Do not do channel-specific rewrite rule checks
nosourceinner	(New in MS 8.1.0.1) Do not rewrite inner message headers on message sent from this channel
nox_env_to	Do not add X-Envelope-to: header lines while enqueuing
passsyntaxerrors	(New in MS 8.0) Disable certain header file syntax error fixup
passthrough	Do no message processing
personalinc	Leave personal names in message header lines intact
personalmap	Apply PERSONAL_NAMES mapping to personal names in message header lines
personalomit	Remove personal name fields from message header lines
personalstrip	Strip problematic characters from personal name fields in message header lines
receivedfor	Include envelope to address in Received: header
receivedfrom	Include the envelope From address when constructing Received: header
receivedstate	(New in MS 8.0) Include a state indicator when constructing Received: header
relaxheadertermination	Allow lines containing white space characters to terminate the header of a message
remotehost	Use remote host's name as the default domain name to complete addresses
restricted	Apply RFC 1137 restricted encoding to addresses
reverse	Apply address reversal to addresses; that is, apply reverse_url LDAP-based address reversal, the reverse database, and the REVERSE mapping to addresses
rules	Do channel-specific rewrite rule checks
sensitivitycompanyconfidential	Allow messages of any sensitivity
sensitivitynormal	Reject messages whose sensitivity is higher than normal
sensitivitypersonal	Reject messages whose sensitivity is higher than personal
sensitivityprivate	Reject messages whose sensitivity is higher than private
sourcecommentinc	Leave comments in incoming message header lines intact
sourcecommentmap	Apply COMMENT_STRINGS mapping to comments in incoming message header lines
sourcecommentomit	Remove comments from incoming message header lines
sourcecommentstrip	Remove problematic characters from comment field in incoming message header lines
sourcecommenttotal	Strip comments (material in parentheses) everywhere in incoming messages
sourceinner	(New in MS 8.1.0.1) Rewrite inner message headers on message sent from this channel
sourcepersonalinc	Leave personal names in incoming message header lines intact
sourcepersonalmap	Apply PERSONAL_NAMES mapping to personal names in incoming message header lines
sourcepersonalomit	Remove personal name fields from incoming message header lines
sourcepersonalstrip	Strip problematic characters from personal name fields in incoming message header lines
suppressreceivedip	(New in 8.0.1.2) Do not include IP address information in the from clauses of generated Received: lines.
unrestricted	Do not apply RFC 1137 restricted encoding to addresses
usereplyto	Specify mapping of Reply-to: header
useresent	Specify mapping of Resent- headers for non RFC 822 environments
x_env_to	Add X-Envelope-to: header lines while enqueuing
Host names	
additional_host_names	(Unified Configuration only) Additional hosts the channel can reach

daemon	Specify name of a gateway daemon to route to
defaulthost	Specify a domain name to use to complete addresses
lastresort	Specify a last resort host
local_host_alias	(Unified Configuration only) Override official_host_name on outgoing messages
nodefaulthost	Do not specify a domain name to use to complete addresses
noremotehost	Use local host's domain name as the default domain name to complete addresses
official_host_name	(Unified Configuration only) Official host name for the channel
remotehost	Use remote host's name as the default domain name to complete addresses
Incoming channel matching and switching	
allowswitchchannel	Allow switching to this channel from a switchchannel channel
nosaslswitchchannel	Do not switch channel upon successful SASL authentication
noswitchchannel	Stay with the server channel; do not switch to the channel associated with the originating host; do not permit being switched to
saslswitchchannel	Switch to another channel when SASL authentication is successful; the channel to switch to is specified via the value of the user's mailSMTPSubmitChannel LDAP attribute (or as of MS 8.0, whatever LDAP attribute is named by the ldap_auth_attr_submit_channel MTA option
switchchannel	Switch effective source channel to the channel associated with the originating host's source IP
tlsswitchchannel	Switch to specified source channel upon successful TLS negotiation
userswitchchannel	(New in MS 6.3) Enable switching from this source channel to a channel selected via a per-user or per-domain LDAP attribute
Logging and debugging	
logging	Log message enqueues and dequeues into the MTA message transaction log file
logheader	Include message header records in the MTA message transaction log file
master_debug	Generate debugging output in the channel's master program output
nologging	Do not log message enqueues and dequeues into the MTA message transaction log file
nomaster_debug	Do not generate debugging output in the channel's master program output
noslave_debug	Do not generate debugging output in the channel's slave program output
slave_debug	Generate debugging output in the channel's slave program output
Long address lists or headers	
alternatechannel	Messages that exceed a channel's alternateblocklimit, alternatelinelimit, or alternaterecipientlimit will be diverted to the channel's specified alternatechannel
alternaterecipientlimit	Divert messages that exceed the specified number of recipients to the alternatechannel
deferralrejectlimit	(New in MS 6.2) Limit the number of bad (failing) recipient addresses
disconnectrecipientlimit	(New in MS 6.2) Force SMTP session disconnect after the specified number of recipients is exceeded
disconnectrejectlimit	(New in MS 6.2) Force SMTP session disconnect after the specified number of bad recipients (rejected recipients) is exceeded
expandchannel	Channel in which to perform deferred expansion due to application of expandlimit
expandlimit	Process an incoming message "off-line" when the number of addressees exceeds this limit
holdlimit	.HELD an incoming message when the number of addressees exceeds this limit
maxprocchars	Specify maximum length of headers to process
recipientcutoff	Set a limit for the number of recipients-per-message-copy accepted on a channel; attempts to submit a message with more than this number of recipients will cause *all* recipients to be rejected
recipientlimit	Set a limit for the number of recipients-per-message-copy accepted on a channel; additional recipients will get a temporary rejection error
Message hashes	
deletemessagehash	(New in MS 6.3) Delete message hash
generatemessagehash	(New in MS 6.3) Generate a hash of specified message header fields
keepmessagehash	(New in MS 6.3) Keep message hash
Message tracking	
notrackingclient	(New in MS 8.0.) Disable SMTP client support of message tracking
notrackingserver	(New in MS 8.0.) Disable SMTP server support of message tracking
trackingclient	(New in MS 8.0.) Enable SMTP client support of message tracking
trackingdelivered	(New in MS 8.0.) Treat messages dequeued from this channel as delivered
trackingfirst	(New in MS 8.0.) Tracking information goes to first alias expansion result
trackinggenerate	(New in MS 8.0.) Enable SMTP client support of message tracking
trackinginternal	(New in MS 8.0.) This channel transfers internally
trackingmultiple	(New in MS 8.0.) Tracking information passes through aliases
trackingrelayed	(New in MS 8.0.) Treat messages dequeued from this channel as relayed
trackingserver	(New in MS 8.0.) Enable SMTP server support of message tracking

trackingsingle	(New in MS 8.0.) Only pass tracking info through single recipient alias
trackingtimeoutdefault	(New in MS 8.0.) Default timeout (s) for tracking requests
trackingtimeoutmax	(New in MS 8.0.) Maximum timeout (s) for tracking requests
trackingtimeoutmin	(New in MS 8.0.) Minimum timeout (s) for tracking requests
Multi Level Security	
mlslabel	(New in MS 7.0) RESTRICTED: Not yet fully implemented
mlsrange	(New in MS 7.0) RESTRICTED: Not yet fully implemented
Notification messages and postmaster messages	
aliaspostmaster	Redirect postmaster messages to the local channel postmaster
copysendpost	Send copies of failures to the postmaster unless the originator address is blank
copywarnpost	Send copies of warnings to the postmaster unless the originator address is blank
dispositionchannel	(New in MS 6.2) Channel to use when generating dispositions
errsendpost	Send copies of failures to the postmaster if the originator address is illegal
errwarnpost	Send copies of warnings to the postmaster if the originator address is illegal
expirysource	(New in MS 7.0) Source channel supports Expiry-date: header value
includefinal	Include final form of address in delivery notifications
language	Specify a preferred language for messages that have none
noexpirysource	(New in MS 7.0) Source channel ignores Expiry-date: header value
nonotary	RESTRICTED: Disable DSN extension use by SMTP/LMTP client
nonurgentnotices	Specify the amount of time which may elapse before notices are sent and messages returned for messages of non-urgent priority
noreturnaddress	Use the value of the return_address MTA option
noreturnpersonal	Use the value of the return_personal MTA option
normalnotices	Specify the amount of time which may elapse before notices are sent and messages returned for messages of normal priority
nosendpost	Do not send copies of failures to the postmaster
notary	Support SMTP DSN extensions
notices	Specify the amount of time which may elapse before notices are sent and messages returned
notificationchannel	(New in MS 6.2) Channel to use when generating notifications
nowarnpost	Do not send copies of warnings to the postmaster
postheadbody	Both the message's header and body are sent to the postmaster when a delivery failure occurs
postheadonly	Only the message's header is sent to the postmaster when a delivery failure occurs
processsecuritymultiparts	Process inside security multiparts
reportboth	Generate both header and NOTARY delivery receipt requests from "foreign" delivery receipt requests
reportheader	Generate only header delivery receipt requests from "foreign" delivery receipt requests
reportnotary	Generate only NOTARY delivery receipt requests from "foreign" delivery receipt requests
reportsuppress	Suppress delivery receipt requests from "foreign" delivery receipt requests
retainsecuritymultiparts	Do not process inside security multiparts
returnaddress	Set the return address for the local Postmaster
returnenvelope	Control use of blank envelope return addresses
returnpersonal	Set the personal name for the local Postmaster
sendpost	Send copies of failures to the postmaster
suppressfinal	Include only original form of address in notification messages
urgentnotices	Specify the amount of time which may elapse before notices are sent and messages returned for messages of urgent priority
useintermediate	Include the "intermediate" form of recipient address, that form previously presented as active from the MTA's point of view, in delivery status notification messages
warnpost	Send copies of warnings to the postmaster
Processing control and job submission	
addrsperjob	Number of addresses to be processed by a single job
after	Specify time delay before master channel programs run
backoff	Channel delivery retry backoff intervals
bidirectional	Channel is served by both a master and slave program
deferred	DEPRECATED as of MS 7.0, in favor of deferreddestination, which it is an alias for in Unified Configuration; honor deferred delivery dates in Deferred-delivery: header lines;
deferreddestination	(New in MS 7.0) Honor deferred delivery dates in Deferred-delivery: header lines; (deferred is an alias for deferreddestination)
deferredsource	(New in MS 7.0) Honor deferred delivery dates in Deferred-delivery: header lines

expandchannel	Channel in which to perform deferred expansion due to application of expandlimit
expandlimit	Process an incoming message "off-line" when the number of addressees exceeds this limit
filesperjob	Number of queue entries to be processed by a single job
futurerelease	(New in MS 7.0) Enable source channel support for the future release SMTP extension
ipbackoff	(New in MS 8.0.2.3) Channel delivery retry backoff intervals for messages in IP backoff mode
ipbackofftimeout	(New in MS 8.0.2.3) Timeout for IP backoff entries made in memcache or Redis.
master	Channel is served only by a master program
maxjobs	Maximum number of jobs which can be created at once
maxperiodicnonurgent	OBSOLETE: Job Controller behavior is unaffected by this option; (used to specify that periodic jobs should only process messages of non-urgent or lower priority); see instead Job Controller priority-based processing
maxperiodicnormal	OBSOLETE: Job Controller behavior is unaffected by this option; (used to specify that periodic jobs should only process messages of normal or lower priority); see instead Job Controller priority-based processing
maxperiodicurgent	OBSOLETE: Job Controller behavior is unaffected by this option; (used to specify that periodic jobs should process messages of urgent or lower priority); see instead Job Controller priority-based processing
minperiodicnonurgent	OBSOLETE: Job Controller behavior is unaffected by this option; (used to specify that periodic jobs should only process messages of non-urgent or higher priority); see instead Job Controller priority-based processing
minperiodicnormal	OBSOLETE: Job Controller behavior is unaffected by this option; (used to pecify that periodic jobs should only process messages of normal or higher priority); see instead Job Controller priority-based processing
minperiodicurgent	OBSOLETE: Job Controller behavior is unaffected by this option; (used to specify that periodic jobs should only process messages of urgent priority); see instead Job Controller priority-based processing
mtprioritiesallowed	(New inMS 8.0) Range of SMTP MT-PRIORITY values accepted during enqueue; other values adjusted to be within range
mtprioritiesrequired	(New in MS 8.0) Range of SMTP MT-PRIORITY values accepted during enqueue; messages with other values will be rejected.
nodeferred	Do not honor deferred delivery dates
nodeferreddestination	(New in MS 7.0u4) Do not honor deferred delivery dates
nodeferredsource	(New in MS 7.0u4) Do not honor deferred delivery dates
nonurgentafter	Specify time delay before master channel programs run for non-urgent priority messages
nonurgentbackoff	Channel delivery retry backoff intervals for non-urgent priority messages
nonurgentblocklimit	Force messages above this size to wait unconditionally for a periodic job
normalafter	Specify time delay before master channel programs run for normal priority messages
normalbackoff	Channel delivery retry backoff intervals for normal priority messages
normalblocklimit	Force messages above this size to non-urgent priority
pool	Specify Job Controller pool in which channel programs run
secondclassafter	Specify time delay before channel runs for secondclass priority messages
secondclassblocklimit	Force messages above this size to third class priority
slave	Channel is serviced only by a slave program
threaddepth	Number of messages triggering new thread with SMTP client
urgentafter	Specify time delay before master channel programs run for urgent priority messages
urgentbackoff	Channel delivery retry backoff intervals for urgent priority messages
urgentblocklimit	Force messages above this size to normal priority
user	DEPRECATED as of MS 8.0; instead use the pipeuser option in restricted.cnf. Specify account under which to run the pipe channel
Sensitivity limits	
sensitivitycompanyconfidential	Allow messages of any sensitivity
sensitivitynormal	Reject messages whose sensitivity is higher than normal
sensitivitypersonal	Reject messages whose sensitivity is higher than personal
sensitivityprivate	Reject messages whose sensitivity is higher than private
Sieve filters and delivery flags	
addrtypescan	(New in MS 7.0.5) Store recipient address "type" in an envelope flag
addrtypescanbccdefault	(New in MS 7.0.5) Store recipient address "type" in an envelope flag, assuming unmatched recipient addresses are Bcc: addresses
channelfilter	Alias for destinationfilter
deliveryflags	Set flags controlling certain delivery behaviors
destinationfilter	Specify the location of channel filter file for outgoing messages; (channelfilter is an alias for destinationfilter)
fileinto	Specify effect on address when a Sieve "fileinto" action is applied
filter	Specify the location of user filter files
flagtransfer	Support private XDFLG/XAFLG SMTP/LMTP extensions and (new in MS 8.0.2.3) XCONVTAG SMTP extension; pass along delivery flags, such as trusting a subaddress, IMAP flags, and conversion tags.
noaddrtypescan	(New in MS 7.0.5) Do not store recipient address "type" in an envelope flag

nochannelfilter	Alias for nodestinationfilter
nodestinationfilter	Do not perform channel filtering on outgoing messages; (nochannelfilter is an alias for nodestinationfilter)
nofileinto	Sieve "fileinto" action has no effect
nofilter	No external-to-LDAP user Sieve filters
noflagtransfer	Disable private XDFLG/XAFLG SMTP/LMTP extensions and (new in MS 8.0.2.3) XCONVTAG SMTP extension; do not pass along delivery flags, IMAP flags, and conversion tags.
nosourcefilter	Source channel does not have an associated Sieve filter
scriptlimit	(New in MS 8.0) Maximum number of Sieve scripts a user can have
sievelimit	(New in MS 8.0) Maximum size of a user Sieve script
sizelimit	(New in MS 8.0) Maximum combined size of a user's Sieve scripts
sourcefilter	Specify the location of the channel's Sieve filter for incoming messages
Size limits on messages	
alternateblocklimit	Divert messages that exceed the specified number of blocks to the alternatechannel
alternatechannel	Messages that exceed a channel's alternateblocklimit, alternatelinelimit, or alternaterecipientlimit will be diverted to the channel's specified alternatechannel
alternatelinelimit	Divert messages that exceed the specified number of lines to the alternatechannel
alternaterecipientlimit	Divert messages that exceed the specified number of recipients to the alternatechannel
blocklimit	Maximum number of MTA blocks allowed per message
holdlimit	.HELD an incoming message when the number of addressees exceeds this limit
linelimit	Maximum number of lines allowed per message
noblocklimit	No limit specified for the number of MTA blocks allowed per message
nonurgentblocklimit	Force messages above this size to wait unconditionally for a periodic job
normalblocklimit	Force messages above this size to non-urgent priority
sourceblocklimit	Maximum number of MTA blocks allowed per incoming message
urgentblocklimit	Force messages above this size to normal priority
Spam/virus filter package use	
destinationbrightmail	DEPRECATED: Alias for destinationspamfilter1
destinationbrightmailoptin	DEPRECATED: Alias for destinationspamfilter1optin
destinationspamfilter	Alias for destinationspamfilter1
destinationspamfilter1	(New in MS 6.2) Enable spam/virus filtering (by spam/virus filter package 1) for messages enqueued to this destination channel

SMTP and LMTP protocol	
allowetrn	Honor SMTP client ETRN commands
bccserver	(New in MS 8.0.2.3) XBCC extension is enabled
binaryclient	(New in MS 6.3.) RESTRICTED: Not yet fully implemented. Enable BINARYMIME support in the SMTP client
binaryserver	(New in MS 6.3 but at that time RESTRICTED: Not yet fully implemented; actual implementation new in MS 8.0) Enable BINARYMIME support in the SMTP server
blocketrn	Do not honor SMTP client ETRN commands
checkehlo	Check the SMTP greeting banner for whether to use EHLO
chunkingclient	(New in MS 6.3-0.15) Enable CHUNKING support in the SMTP client
chunkingserver	(New in MS 6.3-0.15) Enable CHUNKING support in the SMTP server
conditionalpassthrough	"Pass-through" mode, if any Received: header lines are present
conditionalrelay	"Relay" mode, if any Received: header lines are present
deferralrejectlimit	(New in MS 6.2) Limit the number of bad (failing) recipient addresses
destinationnosolicit	(New in MS 6.2) List of solicitation types not accepted

disableetrn	Disable support for the ETRN SMTP command
disconnectbadburllimit	(New in MS 7.0u4) Force SMTP SUBMIT session disconnect after a specified number of invalid BURL commands is exceeded
disconnectbadcommandlimit	New in (MS 6.2) Force SMTP session disconnect after a specified number of bad (unrecognized) SMTP commands is exceeded
disconnectcommandlimit	(New in MS 7.0u1) Force SMTP session disconnect after a specified number of SMTP commands is exceeded
disconnectrecipientlimit	(New in MS 6.2) Force SMTP session disconnect after a specified number of recipients is exceeded
disconnectrejectlimit	(New in MS 6.2) Force SMTP session disconnect after a specified number of bad recipients (rejected recipients) is exceeded
disconnecttransactionlimit	(New in MS 6.2) Force SMTP session disconnect after a specified transaction limit is exceeded
domainetrn	Honor only those SMTP client ETRN commands that specify a domain
domainvrfy	Issue SMTP VRFY commands using full address
ehlo	Use EHLO on all initial SMTP connections
eightbit	Channel supports eight bit characters
eightnegotiate	Channel should negotiate use of eight bit transmission if possible
eightstrict	Channel should reject messages that contain unnegotiated eight bit data
expnallow	(New in MS 6.1) Explicitly enable support of the SMTP command EXPN
expndefault	(New in MS 6.1) Default handling of the SMTP command EXPN
expndisable	(New in MS 6.1) Disable support of the SMTP command EXPN
flagtransfer	Support private XDFLG/XAFLG SMTP/LMTP extensions and (new in MS 8.0.2.3) XCONVTAG SMTP extension; pass along delivery flags, such as trusting a subaddress, IMAP flags, and conversion tags.
futurerelease	(New in MS 7.0) Enable source channel support for the future release SMTP extension
lmtp	Channel uses LMTP
lmtp_cr	Accept CR as an LMTP line terminator
lmtp_crlf	Require CRLF as the LMTP line terminator
lmtp_crorlf	Allow any of CR, LF, or CRLF as the LMTP line terminator
lmtp_lf	Accept LF as an LMTP line terminator
localvrfy	Issue SMTP VRFY command using local address
loopcheck	Enable support for the XLOOP SMTP extension (used to detect a type of message loop)
mailfromdnsverify	Verify that the domain specified on MAIL FROM: line is in the DNS
maxconnectionrateperdomain	Implements a limit on the rate of connections made to a domain using the smartsend plugin
maxconnectionsperdomain	Implements limits on the number of simultaneous connections to a domain using the smartsend plugin
maxmessagerateperdomain	Implements a limit on the rate of messages sent to a domain using the smartsend plugin
mtprioritiesallowed	(New in MS 8.0) Range of SMTP MT-PRIORITY values accepted during enqueue; other values adjusted to be within range
mtprioritiesrequired	(New in MS 8.0) Range of SMTP MT-PRIORITY values accepted during enqueue; messages with other values will be rejected.
nobccserver	(New in MS 8.0.2.3) XBCC extension is disabled
nobinaryclient	(New in MS 6.3.) Disable BINARYMIME support in the SMTP client
nobinaryserver	(New in MS 6.3.) Disable BINARYMIME support in the SMTP server
nochunkingclient	(New in MS 6.3.) Disable CHUNKING support in the SMTP client
nochunkingserver	(New in MS 6.3.) Disable CHUNKING support in the SMTP server
noehlo	Never use the SMTP EHLO command
noflagtransfer	Disable private XDFLG/XAFLG SMTP/LMTP extensions and (new in MS 8.0.2.3) XCONVTAG SMTP extension; do not pass along delivery flags, IMAP flags, and conversion tags.
noloopcheck	Disable support for the XLOOP SMTP extension (used to detect a type of message loop)
nomailfromdnsverify	Do not perform DNS domain verification on the MAIL FROM: address
noproxyprotocol	(New in MS 8.1.0.1) Proxy protocol support is disabled
nosendetrn	Do not send SMTP ETRN command
nosmtp	Channel does not use SMTP
notary	Normal NOTARY support
noturn	Disable the SMTP TURN command
novrfy	Do not issue SMTP VRFY commands
noxclient	(New in MS 8.0) XCLIENT SMTP extension is disabled
passthrough	Do no message processing
proxyprotocol	(New in MS 8.1.0.1) Proxy protocol support is enabled
recipientcutoff	Set a limit for the number of recipients-per-message-copy accepted on a channel; attempts to submit a message with more than this number of recipients will cause *all* recipients to be rejected
recipientlimit	Set a limit for the number of recipients-per-message-copy accepted on a channel; additional recipients will get a temporary rejection error
refuseehlo	RESTRICTED: Disable EHLO support in SMTP server

refusenotary	(New in MS 8.0.1) RESTRICTED: Disable DSN extension support in SMTP server
rejectsmtplonglines	Reject incoming SMTP messages with illegally long lines
relay	Mark the channel as a relay channel
sendetrn	Send SMTP ETRN command
sevenbit	Channel does not support eight bit characters; eight bit characters must be encoded
silentetrn	Honor SMTP client ETRN commands, without echoing channel information
smtp	Channel uses SMTP
smtp_cr	Accept CR as an SMTP line terminator
smtp_crlf	Require CRLF as the SMTP line terminator
smtp_crorlf	Allow any of CR, LF, or CRLF as the SMTP line terminator; default on TCP/IP channels
smtp_lf	Accept LF as an SMTP line terminator
sourcenosolicit	(New in MS 6.2) List of solicitation types not accepted
streaming	Specify degree of protocol streaming for channel to use
submit	Mark the channel as a submit-only channel
transactionlimit	(New in MS 6.1) Limit the number of transactions per SMTP session (messages per SMTP connection) accepted
truncatesmtplonglines	Truncate incoming SMTP messages with illegally long lines
turn	RESTRICTED: Enable the SMTP TURN command
turn_in	RESTRICTED: Enable the SMTP TURN command for incoming connections; that is, the SMTP server will accept SMTP TURN commands
turn_out	RESTRICTED
vrfyallow	Provide informative responses to SMTP VRFY command
vrfydefault	Default responses to SMTP VRFY command, according to channel's TCP/IP-channel-specific HIDE_VERIFY option setting
vrfyhide	Provide obfuscatory responses to SMTP VRFY command
wrapsmtplonglines	Wrap incoming SMTP messages with illegally long lines
xclient	(New in MS 8.0) XCLIENT SMTP extension is enabled, only one group of XCLIENT commands permitted
xclientrepeat	(New in MS 8.0) XCLIENT SMTP extension is enabled, and groups of XCLIENT commands are permitted
xclientsasl	(New in MS 8.0) XCLIENT SMTP extension is enabled, and LOGIN attribute is allowed
xclientsaslrepeat	(New in MS 8.0) XCLIENT SMTP extension is enabled, LOGIN attribute is permitted, and groups of XCLIENT commands are permitted
TCP/IP connections, DNS lookups, and SOCKS connections	
affinitylist	(New in MS 8.0) Enable affinity lookups, disable MX lookups
cacheeverything	Cache all connection information
cachefailures	Cache only connection failure information
cachesuccesses	Cache only connection success information
connectalias	Do not rewrite addresses upon message dequeue
connectcanonical	Rewrite addresses upon message dequeue
daemon	Specify name of a gateway daemon to route to
defaultmx	Channel determines whether or not to do MX lookups from network
defaultnameservers	Consult TCP/IP stack's choice of nameservers
dnsforcetemporary	Treat host not found and no address lookup errors as temporary failures. This option is new in 8.0.1.3.
forwardcheckdelete	If a reverse DNS lookup has been performed, next perform a forward lookup on the returned name to check that the returned IP number matches the original; if not, delete the name and use the IP address
forwardchecknone	Do not perform a forward lookup after a DNS reverse lookup
forwardchecktag	If a reverse DNS lookup has been performed, next perform a forward lookup on the returned name to check that the returned IP number matches the original; if not, tag the name with *
identnone	Do not perform IDENT lookups; do perform IP to hostname translation; include both hostname and IP address in Received: header
identnonelimited	Do not perform IDENT lookups; do perform IP to hostname translation, but do not use the hostname during channel switching; include both hostname and IP address in Received: header
identnonenumeric	Do not perform IDENT lookups or IP to hostname translation
identnonesymbolic	Do not perform IDENT lookups; do perform IP to hostname translation; include only the hostname in Received: header
identtcp	Perform IDENT lookups on incoming SMTP connections and IP to hostname translation; include both hostname and IP address in Received: header
identtcplimited	Do perform IDENT lookups; do perform IP to hostname translation, but do not use the hostname during channel switching; include both hostname and IP address in Received: header
identtcpnumeric	Perform IDENT lookups on incoming SMTP connections, but do not perform IP to hostname translation
identtcpsymbolic	Perform IDENT lookups on incoming SMTP connections and IP to hostname translation; include only hostname in Received: header

interfaceaddress	Bind to the specified TCP/IP interface address
lastresort	Specify a last resort host
mailfromdnsverify	Verify that the domain specified on MAIL FROM: line is in the DNS
mx	TCP/IP network and software supports MX record lookups
nameservers	Consult specified nameservers rather than TCP/IP stack's choice (only for MX records as of MS 7.0)
nocache	Do not cache any connection information
nodns+	On OpenVMS, TCP/IP network does not support DNS (nameserver) lookups; on UNIX, merely disables MX lookups since on UNIX it is `nsswitch.conf` that controls consultation of nameservers
nodnsforcetemporary	Treat host not found and no address lookup errors as permanent failures. This option is new in 8.0.1.3.
nomailfromdnsverify	Do not perform DNS domain verification on the MAIL FROM: address
nomx	TCP/IP network does not support MX lookups
nonrandommx	Do MX lookups; do not randomize returned entries with equal precedence
nosocks	Do not do SOCKS connections
port	Send to the specified TCP/IP port
randommx	Do MX lookups; randomize returned entries with equal precedence
spfhelo	(New in MS 6.3) Perform an SPF lookup at the HELO/EHLO command
spfmailfrom	(New in MS 6.3) Perform an SPF lookup at the MAIL FROM command
spfnone	(New in MS 6.3) Do not perform any SPF lookups
spfrcptto	(New in MS 6.3) Perform an SPF lookup at the RCPT TO command
threaddepth	Number of messages triggering new thread with multithreaded SMTP client
TLS and SASL	
authpassword	(New in MS 7.0.5) Password for SMTP channel's client use of SMTP AUTH PLAIN
authrewrite	Use SMTP AUTH information in header
authusername	(New in MS 7.0.5) Username for SMTP channel's client use of SMTP AUTH PLAIN
disconnectbadauthlimit	(New in MS 6.2) Force SMTP session disconnect after a specified number of failed SMTP AUTH attempts
explicitsaslexternal	(New in MS 8.0) Disable automatic use of AUTH EXTERNAL at MAIL FROM
externalidentity	(New in MS 7.0.5) Identity for SMTP channel client use of SMTP AUTH EXTERNAL
implicitsaslexternal	(New in MS 8.0) Enable automatic use of AUTH EXTERNAL at MAIL FROM after successful negotiation of TLS
maysasl	Allow SMTP server and client SASL authentication
maysaslclient	(Effective as of MS 7.0-3.01) SMTP client attempts to use SASL authentication
maysaslserver	SMTP server offers SASL authentication
maytls	SMTP client and server allow TLS use
maytlsclient	SMTP client will attempt TLS use
maytlsserver	SMTP server allows TLS use
msexchange	Channel serves MS Exchange gateways
mustsasl	Must use SASL authentication
mustsaslclient	(Effective as of MS 7.0-3.01) SMTP client insists upon SASL authentication
mustsaslserver	SMTP server insists upon SASL authentication
musttls	SMTP client and server insist upon TLS use and will not transfer messages with remote sides that do not support TLS
musttlsclient	SMTP client insists upon TLS use and will not send messages to any remote SMTP server that does not support TLS use
musttlsserver	SMTP server insists upon TLS use and will not accept messages from any remote SMTP client that does not support TLS use
nomsexchange	Channel does not serve MS Exchange gateways
nosasl	SASL authentication not attempted or permitted
nosaslclient	SMTP client does not attempt SASL authentication
nosaslpassauth	Do not pass along a MAIL FROM AUTH parameter
nosaslserver	SMTP server does not permit SASL authentication
nosaslswitchchannel	Do not switch channel upon successful SASL authentication
nosasltrustauth	(New in MS 7.0u3) Do not promote a MAIL FROM AUTH parameter to the MTA's authenticated originator address envelope field
notls	SMTP client and server neither attempt nor allow TLS use
notlsclient	SMTP client does not attempt TLS use when sending messages
notlsserver	SMTP server does not offer or allow TLS use when receiving messages
saslpassauth	Pass along a MAIL FROM AUTH parameter
saslruleset	Specify the security configuration rule set to use for SASL transactions
saslswitchchannel	Switch to another channel when SASL authentication is successful

sasltrustauth	(New in MS 7.0u3) Promote any MAIL FROM AUTH parameter to the MTA's authenticated originator address envelope field
tlsswitchchannel	Switch to specified channel upon successful TLS negotiation

+Supported only on OpenVMS.

46.3.3 Addresses channel options

There are many channel options relating to address handling. These are some of those most directly relating to address handling. See also the Long address lists or headers channel options for special handling of large numbers (long lists) of addresses, and the Headers channel options as a number of channel options relate to insertion or propagation of addresses in header lines.

46.3.3.1 _733 Option

The legacy configuration 733 channel option has been replaced in Unified Configuration by percents.

46.3.3.2 _822 Option

The legacy configuration 822 channel option has been replaced in Unified Configuration by sourceroute.

46.3.3.3 Envelope recipient validity checks (acceptalladdresses, acceptvalidaddresses)

When specified on a source channel, the acceptalladdresses option causes all envelope recipient addresses to be accepted unconditionally. Rather than returning errors during the SMTP session, a delivery status notification, or DSN, will be returned later if the message cannot be delivered to the specified recipient. With acceptalladdresses, various sorts of normally "invalid: recipient addresses will be accepted: syntactically invalid addresses, addresses of local users with problematic status (such as being "over quota" or "disabled" -- see the ldap_user_mail_status, ldap_group_mail_status, and ldap_domain_attr_mail_status MTA options), and recipients of messages that fail message acceptability checks. Relevant message acceptability checks include checking on whether a message: exceeds a configured sensitivity limit, or contains unnegotiated eight bit data (on a source channel marked eightstrict or utf8strict), or contains too-long-for-SMTP lines (on a source channel marked rejectsmtplonglines), or exceeds a configured message size limit (such as blocklimit, sourceblocklimit, block_limit, ldap_blocklimit, ldap_sourceblocklimit, ldap_maximum_message_size, ldap_domain_attr_blocklimit, ldap_domain_attr_sourceblocklimit, alias_blocklimit, or [BLOCKLIMIT]) or message line limit (such as linelimit, line_limit, alias_linelimit, or [LINELIMIT]) when the excessive size is detected after the DATA stage, or is entirely lacking in recipient header lines (on a source channel marked missingrecipientpolicy 6, or if the MTA option missing_recipient_policy=6 is set), or is rejected via the AUTH_REWRITE mapping table. Setting acceptalladdresses will also disable the SMTP protocol level rejection feature of the Sieve "refuse" action; with acceptalladdresses, addresses to be rejected due to application of a "reject" action will be accepted during the SMTP dialogue, and instead a subsequent non-delivery DSN generated.

In contrast, setting the acceptvalidaddresses option on a source channel causes all envelope recipient addresses to be validated prior to being accepted by the MTA. If an address

fails to validate, an appropriate error will be returned to the client during the SMTP dialogue. `acceptvalidaddresses` is the default.

Note that the MTA's default, `acceptvalidaddresses`, behavior is normally far preferable to `acceptalladdresses`: rejecting invalid addresses and messages "up front" rather than accepting them initially only to have to generate and send back a non-delivery notification later has advantages that should hardly need to be pointed out, including:

- Less work for the MTA. The reductions in work are in several areas, including: less processing required on incoming messages (in cases where a recipient address can be detected as invalid), less work generating non-delivery notification messages, less work attempting to deliver non-delivery notification messages, *etc.*
- Less network bandwidth required.
- Due to the above two points, less potential impact on throughput of other, valid, messages.
- Immediate (via an SMTP error) notification to e-mail clients of the error in their message, rather than a delayed notification via DSN.
- Avoiding "blow-back" spam, in cases of so-called "joe-job" (forged envelope From) spam.

However, `acceptalladdresses` can sometimes be useful in certain limited cases, such as when attempting to support poorly designed e-mail clients that fail to report SMTP errors correctly to the user. In such cases a DSN, while providing only a delayed indication rather than an immediate indication of an address or message problem, may be the only way to convey the MTA's accurate error information to the user. So appropriate use of `acceptalladdresses` tends to be restricted to cases of special incoming TCP/IP channels dedicated for submission of messages by applications or user e-mail clients with known limitations; `*switchchannel` effects, or else channels associated with special Dispatcher services listening on special ports or interface addresses, are features typically used for setting up such special channels.

Unconditional address acceptance (`acceptalladdresses`) should be used with extreme care; in particular, it should never be used on a source channel that accepts unauthenticated transactions from the Internet. The problem with such usage is that spammers will attempt to send mail to invalid addresses, which will be accepted and later result in a DSN being returned. Since envelope From addresses on spam are commonly forged, this will turn the system into a major source of blowback spam and is likely to result in blacklisting and other operational issues.

These options were first added in MS 6.1.

Compare with the (new in 8.0.1.1.0) `accepttemporaryfailures` and `defertemporaryfailures` channel options.

46.3.3.4 Envelope recipient error handling (`accepttemporaryfailures`, `defertemporaryfailures`)

(New in MS 8.0.1.1.0.) The `accepttemporaryfailures` and `defertemporaryfailures` source channel options control how recipient address temporary errors such as user over quota, spam filter temporarily unavailable, LDAP server unavailable, and so on are handled by the SMTP server. `defertemporaryfailures` is the default, and causes such errors to return an immediate 4yz error in the SMTP session. Setting `accepttemporaryfailures` causes

the address to be accepted, but the message will be placed in the reprocess queue and retried until it either times out and is returned or the error clears.

These channel options are only intended for use on SMTP channels. Placing them on an internal channel may have unexpected results.

Compare with the `acceptalladdresses` and `acceptvalidaddresses` channel options.

46.3.3.5 Filling in missing header addresses (`addlineaddrs`, `noaddlineaddrs`)

Situations can arise where messages are submitted to the MTA without proper originator and recipient address information in the message header. In such cases there may be additional information available in a nonstandard form, either in the header or elsewhere, that can be used to reconstruct the missing header information. When the `addlineaddrs` option is placed on a source channel it instructs submission agents to use whatever additional information is available to reconstruct the missing information. `noaddlineaddrs` is the default and prevents this from happening.

Currrently the only submission agent that supports `addlineaddrs` is the VMS MAIL interface in PMDF. This option has no effect on any Messaging Server channel.

46.3.3.6 Controlling Sender Rewriting Scheme (SRS) rewriting (`addresssrs`, `noaddresssrs`, `destinationsrs`, `nodestinationsrs`, `sourcesrs`, `nosourcesrs`)

(New in MS 6.3p1.) Sender Rewriting Scheme (SRS) rewriting is used by sites providing autoforwarding services to encapsulate MAIL FROM addresses so as to avoid running afoul of Sender Permitted From (SPF) checks. In order for an address to undergo SRS rewriting, SRS support must be configured and the following three conditions must be met: (1) The current source channel must be marked with the `sourcesrs` option, (2) The current destination channel must be marked with the `destinationsrs` option, and (3) Rewriting the MAIL FROM address must have matched a channel marked with the `addresssrs` option. `noaddresssrs`, `nodestinationsrs` and `nosourcesrs` are the default for all channels.

See also the `headerdecodesrs` and `noheaderdecodesrs` channel options.

46.3.3.7 Address type flags (`addrtypescan`, `addrtypescanbccdefault`, `noaddrtypescan`)

(New in 7.0.5.) If the `addrtypescan` channel option is set, then RCPT TO addresses (that is, envelope recipients) are compared with header recipient fields (To:, Cc:, Bcc:, Resent-To:, Resent-Cc:, and Resent-Bcc:). When a match is found, that fact is recorded in the delivery flags associated with that envelope recipient. Those flags are then used when generating the report part of Microsoft® Exchange 2007 envelope journaling archive messages, distinguishing between various types of envelope recipient addresses.

`addrtypescanbccdefault` operates in the same way as `addrtypescan`, except that when no matches are found for a given address, that address is assumed to be a blind carbon (Bcc:) recipient. This option should only be used when it is certain the messages have come directly from a client that implements Bcc: by simply omitting the blind carbon recipient from the header and which doesn't support any form of local mailing lists. Use in any other context is *guaranteed* to result in incorrect types being attached!

noaddrtypescan is the default.

Also note that since the MTA's delivery flags are used to store this informtion, the MTA's delivery flag transfer facilities may be used to transport this information between MTAs; see the deliveryflags channel option.

46.3.3.8 Force "detour" routing of hosted users (aliasdetourhost, aliasoptindetourhost)

The (new in iMS 5.2p2, and MS 6.1) aliasdetourhost channel option allows source-channel-specific overriding of hosted users' mailHost attribute value. In particular, aliasdetourhost is commonly used to achieve a "detour" in the routing of messages destined for local (hosted on this system) users. It allows better configuration and use of "intermediate filtering" sorts of channels and third party filtering hosts.

The aliasdetourhost channel option takes a single host/domain name as an argument. When specified on a source channel, this channel option causes alias expansion of addresses stored in LDAP to stop (short-circuit) just prior to the point where mailHost (more precisely, the attribute named by the ldap_mailhost MTA option) information is checked. The host specified by the aliasdetourhost channel option is used as the (assumed to be non-local) mailHost. That is, a source route containing the specified host is added to the address (just as if a non-local mailHost had been found) and processing continues onward from that point. Note that in particular, this forced use of the aliasdetourhost specified host as a non-local mailHost stops further expansion of the alias for purposes of things such as application of user forwarding and Sieve filter application (which normally would occur subsequently during alias expansion when a user's real mailHost is this MTA).

Thus use of aliasdetourhost on an incoming channel lets the MTA do address validation (check that an incoming address corresponds to a valid user entry), while "delaying" complete expansion and processing (in particular, forwarding and Sieve evaluation) of the valid local recipient addresses. This combination of effects is potentially very useful.

A typical application of this channel option is for purposes of "detouring" messages through a special channel or host, most often for purposes of spam/virus filtering. It is often used in conjunction with use of an "alternate" conversion channel for such "detour" purposes, where the "alternate" conversion channel approach is used to handle cases of non-local recipient addresses, while aliasdetourhost is used to handle cases of local-to-this-mailHost recipient addresses. (Use of an "alternate" conversion channel approach for a routing "detour" on local-to-this-mailHost recipient addresses incurs various problems, in particular in the areas of forwarding and Sieve filter evaluation timing. It is desirable to delay Sieve filter evaluation until after the "detour" - for instance, so that Sieve filters can look for headers added by the "detour" host. It is also desirable to delay application of user forwarding until after the "detour", to avoid potential duplication of the forwarding. Such a delay in the final parts of user alias expansion is exactly what aliasdetourhost can be used to achieve.)

The (new in MS 6.2p4) aliasoptindetourhost option has the same function as aliasdetourhost, except that it only applies for users in LDAP who have "opted-in" via whatever user attribute is named by the ldap_detourhost_optin MTA option, or whatever domain attribute is named by the ldap_domain_attr_detourhostoptin MTA option. The argument of the aliasoptindetourhost channel option specifies a list of detour hosts separated by commas. The value(s) of the optin attribute are compared with the list; the first match will be used as the "override" mailHost for any users who are "opted-in". However, any attribute that doesn't contain at least one period (which would be necessary to match a

legitimate mail host) is treated as an effective wildcard; the first host from the list will be used in this case.

Finally, if the option value matches the special value specified by the `aliasdetourhost_null_optin` MTA option it will simply be ignored. This mechanism is provided to accomodate provisioning systems that insist on every known attribute having a value. Omitting the attribute value entirely is the preferred method for disabling detour processing, however.

One disadvantage of using `aliasoptindetourhost` is that all alias expansion is deferred, including expansions that result in mail being discarded. This can lead to messages sent to the bitbucket wasting processing resources.

One way to work around this problem is to use a `$*` rewrite rule and an associated mapping to direct such addresses to the bitbucket channel, bypassing any use of aliasdetourhost. For example:

```
$*              $E$F${bitbucket_check,$U$@$H}

BITBUCKET_CHECK

  noreply@example.com     $Y$$U%$$H@bitbucket-daemon
  unattended@example.net  $Y$$U%$$H@bitbucket-daemon
```

This will caused any mail sent to noreply@example.com and unattended@example.net to be discarded before any other lookups or redirection.

46.3.3.9 Local address processing control (`aliaslocal`)

Normally only addresses rewritten to the local channel undergo alias processing. The `aliaslocal` channel option may be associated with a channel to cause addresses rewritten to that channel to undergo alias expansion.

46.3.3.10 Sources of alias information (`aliasmagic`)

Alias expansion is performed by consulting various sources of alias information one after another until a match is found. The `aliasmagic` channel option provides a means to control what sources are consulted and in what order. The argument to `aliasmagic` is an unsigned decimal value. Each decimal digit value specifies a different source of alias information. Possible values are:

Table 46.5 Alias_magic digits

Value	Meaning
0	No operation
1	Personal alias database
2	Local name table aliases
3	System alias database
4	System alias file
5	Special aliases

6	alias_url0
7	alias_url1
8	alias_url2
9	alias_url3

The digits of aliasmagic are processed from left to right. Processing stops when a match occurs. The default value for aliasmagic is given by the alias_magic MTA option.

46.3.3.11 Wildcard alias lookups (aliaswild)

Setting the aliaswild option on a destination channel causes an address of the form *@domain to be checked in the alias file and alias database if the regular lookup for localpart@domain fails. This lookup is performed before checking in the alias file and alias database for local parts without domains.

The effect of this setting is the same as if bit 2 (value 4) of the alias_domains MTA option is set; the only difference is that aliaswild only applies to a specific destination channel.

46.3.3.12 Authenticated originator information processing (authrewrite)

The authrewrite option may be used on a source channel to have the MTA propagate authenticated originator information, if available, into the headers. Normally the SMTP AUTH information is used (specifically, the user's canonical e-mail address, that is, the value of the mail attribute or new in MS 8.0 the value of whatever attribute is named by the ldap_auth_attr_sender MTA option, found when looking up the user for authentication), though this may be overridden via the FROM_ACCESS mapping. authrewrite takes a required bit-encoded integer value as an argument, according to the following table:

Table 46.6 authrewrite option values

Bit	Value	Usage
0-3	1	Add a Sender: header line, or a Resent-sender: header line if a Resent-from: or Resent-sender: was already present, containing the AUTH originator
0-3	2	Add a Sender: header line containing the AUTH originator
0-3	3	Use the AUTH_REWRITE mapping table, probing with any Resent-Sender: and Resent-From: info if present, and otherwise probing with Sender: and From: info
0-3	4	Use the AUTH_REWRITE mapping table, probing with Sender: and From: info
0-3	5	Add a From: header line, or a Resent-From: header line if a Resent-From: or Resent-Sender: was already present, containing the AUTH originator. This is **NOT RECOMMENDED** and **CONTRARY TO INTERNET STANDARDS**, and likely to **HARM** the security of your users. This option should almost **NEVER** be used: **THIS MEANS YOU!**.
0-3	6	Add a From: header line containing the AUTH originator. This is **NOT RECOMMENDED** and **CONTRARY TO INTERNET STANDARDS**, and likely to **HARM** the security of your users. This option should almost **NEVER** be used: **THIS MEANS YOU!**.
4	16	(New in 6.2) If set, apply the AUTH_REWRITE mapping table, even if SMTP AUTH has not been used
5	32	(New in 6.2) If set, probes to AUTH_REWRITE include the source-channel as a prefix field, separated by a vertical bar character from the rest of the probe string; that is, when this bit is set then probes take the form: *src-chan|env-from|[resent-]sender|[resent-]from|auth-originator*
6	64	(New in 7.2-7.02.) If set, use the rewritten version of the envelope from address in constructing the AUTH_REWRITE probe.
7	128	(New in 7.2-7.02.) If set, use the canonical version of the envelope from address in constructing the AUTH_REWRITE probe. Bit 6 (value 64) is a no-op if this bit is set.

8	256	(New in 7.3-11.01.) If set, add the value of the AUTH parameter from the SMTP MAIL FROM command to the AUTH_REWRITE probe, appearing just after the authorized originator address; that is, when this bit is set then probes take the form *env-from|[resent-]sender|[resent-]from|auth-originator|auth-param*
9	512	(New in MS 7.0.5) If set, the final tag set via $T in the *_ACCESS mappings will be prefixed to the AUTH_REWRITE mapping probe; that is, when this bit is set then probes take the form: *ACCESS-tag|env-from|[resent-]sender|[resent-]from|auth-originator*

46.3.3.13 Interpretation of local parts (bangoverpercent, nobangoverpercent, bangonly, percentonly, nobangorpercent)

The local parts of addresses are interpreted in accordance with the rules specified in RFC 5322 and RFC 976. However, there may be occasions when interpretation of embedded routing information is inappropriate. Additionally, ambiguities in the treatment of certain composite addresses that are not addressed by these standards. In particular, the interpretation of exclamation points and percent signs appearing in the local parts of addresses in domains the MTA has administrative authority over are not specified in any standard. These characters are sometimes used to provide a form of explicit multihop routing comparable to source routes.

Several source channel options are provided to control the interpretation of these characters. `nobangorpercent` disables special interpretation of both characters completely. `bangonly` treats local parts of the form A!B as a route from routing host A to user B; percent signs have no special meaning. `percentonly` treats local parts of the form A%B as a route from routing host B to user A; exclamation points have no special meaning.

If both characters are used to specify routing a question arises as to which one has precedence. In particular, an address of the form A!B%C can be interpreted as either A as the routing host and C as the final destination host, or C as the routing host and A as the final destination host.

While RFC 976 implies that it is all right for mailers to interpret addresses using the latter set of conventions, it does not say that such an interpretation is required. In fact, some situations may be better served by the former interpretation.

In any case, the `bangoverpercent` channe; option forces the former A!(B%C) interpretation. `nobangoverpercent` forces the latter (A!B)%C interpretation. `nobangoverpercent` is the default for all channels.

46.3.3.14 Address types and conventions (sourceroute, percents, bangstyle, header_822, header_733, header_uucp)

This group of destination channel options controls what types of addresses will be used in messages queued to the channel. A distinction is made between the addresses used in the transport layer (the message envelope) and those used in message headers.

The `sourceroute` option is the default and specifies that source routed envelope addresses should be used. This channel supports full RFC 5322 format envelope addressing conventions including source routes. The keyword `822` was a supported synonym for `sourceroute` in old configuration files but is not supported in XML-based configurations.

`percents` specifies that percent sign addressing conventions should be used in the envelope. The channel supports full RFC 5322 format envelope addressing with the exception of source routes; source routes will be rewritten using percent sign conventions instead. The channel

keyword `733` was a supported synonym for `percents` in old configuration files but is not supported in XML-based configurations.

Use of percent sign addresses on an SMTP channel will result in these conventions being carried over to the transport layer addresses in the SMTP envelope. This may violate RFC 5321. Only use percent sign addressing conventions when you are sure they are necessary.

The `bangstyle` channel option specifies that this channel uses addresses that conform to RFC 976 bang-style address conventions in the envelope (*i.e.,* this is a UUCP channel). The keyword `uucp` was a supported synonym for `bangstyle` in legacy configuration files but is not supported in unified configurations.

The `header_822` channel option specifies that source routes should be used in header addresses. This channel supports full RFC 5322 format header addressing conventions including source routes. This is the default if no other header address type option is specified.

The `header_733` channel option specifies that percent sign addresses should be used in the header. This channel supports RFC 5322 format header addressing with the exception of source routes; source routes should be rewritten using percent sign conventions instead.

Note that the use of 733 address conventions in message headers may violate RFC 5322 and RFC 976. Only use this option if messages are known to contain source route addresses in the header and you are sure that the channel connects to a system that simply cannot deal with source route addresses.

`header_uucp` specifies that bang-style addresses should be used in the header. The use of this option is *not* recommended. Such usage grossly violates RFC 976.

46.3.3.15 Recipient validity date check (`checkrrvs`, `ignorerrvs`)

The `checkrrvs` and `ignorerrvs` source channel options, for support of RFC 7293, are new in MS 8.0. `ignorerrvs` is the default.

`ignorerrvs` means that the SMTP server will not offer or support the RRVS SMTP extension. In particular, client attempts to use an RRVS parameter in a RCPT TO command will cause an error, and the MTA will ignore any Require-Recipient-Valid-Since: header line.

`checkrrvs` when set on an SMTP source channel means that the SMTP server offers and supports use of the SMTP RRVS extension. In particular, the MTA will check for a valid date for recipient mailbox ownership, whether specified (preferentially) in a RRVS parameter in the RCPT TO command, or in a Require-Recipient-Valid-Since: header field, and check for a valid date for the domain in the recipient address.

If the `checkrrvs` check fails on the recipient mailbox address, the recipient will be rejected with the SMTP error:

```
550 5.7.15 account information on file is older than actual user account
```

or alternate text as controlled by the `error_text_wrong_account` MTA option; if the `checkrrvs` check fails due to the domain creation date, the recipient will be rejected with the SMTP error:

```
550 5.7.18 domain owner has changed
```

or alternate text as controlled by the `error_text_wrong_domain` MTA option.

46.3.3.16 Clone messages to alternate destination (`clonehosts`)

(New in MS 8.0) A commonly requested capability is to "clone" all messages that meet some criteria and send them to an alternate destination. This can be accomplished in a variety of ways, including the Sieve "`capture`" action, the `MESSAGE-SAVE-COPY` mapping, the `FORWARD` mapping, and various sorts of address rewriting tricks, and all of these mechanisms have different characteristics as well as different advantages and disadvantages.

In the specific case when the desire is to clone all messages sent to a particular channel to another channel while preserving the initial address that expanded to that channel, none of the previously mentioned methods provide that specific result. (A `capture` action in a destination channel Sieve script can capture the message, but not the initial address. `MESSAGE-SAVE-COPY` has similar limitations and also requires playing queue management games.)

The `clonehosts` channel option provides this result. It accepts a single argument: A space-separated list of host names. When given a `clonehosts` setting of "*`host1 host2 host3`*" and a message sent to the addresses *`initial1`* and *`initial2`*, both of which expanded to one or more final recipient addresses destined to that channel, this setting will add the recipient addresses:

```
@host1:initial1
@host2:initial1
@host1:initial2
@host2:initial2
```

46.3.3.17 Host name to use when correcting incomplete addresses (`authhost`, `noauthhost`,`defaulthost`, `nodefaulthost`, `remotehost`, `noremotehost`)

The MTA often receives addresses consisting of a bare local-part and no "@domain" from misconfigured or incompliant mailers and SMTP clients. (Note that the standards do in fact require acceptance of one special address - "postmaster" in SMTP, but do not state how such an address is to be represented in a message header.) This happens often enough that simply disallowing such addresses is rarely an acceptable strategy.

The MTA, showing at least some respect for standards, must attempt to make such addresses legal before passing the message along. The MTA does this by appending a domain name to the address (*e.g.*, appends "@acme.com" to "mrochek", producing "mrochek@acme.com").

The set of options described here control how this domain name is selected. In this process the MTA makes a distinction between envelope To (RCPT TO) addresses versus addresses appearing in all other contexts (header, MAIL FROM), as well as distinguishing SUBMIT from SMTP.

In the following table showing what domain is used when various options or protocols are used, *o.org* is the domain attached to the local channel, *a.com* is the domain associated with the current authenticated user's primary email address, *l.com* is the first argument of the `defaulthost` option setting on the current source channel, *r.com* is the second argument of the `defaulthost` option setting on the current source channel, and *r.edu* is the domain associated with the remote SUBMIT/SMTP client.

Table 46.7 Options controlling missing domain fixups

Option	Protocol	Header/ MAIL FROM	RCPT TO
`authhost` (and authenticated)	SUBMIT/SMTP	@a.com	@a.com
`defaulthost`	SUBMIT/SMTP	@o.org	@o.org
`defaulthost` *l.com*	SUBMIT	@l.com	@l.com
`defaulthost` *l.com*	SMTP	@l.com	@o.org
`defaulthost` *l.com r.com*	SUBMIT	@l.com	@l.com
`defaulthost` *l.com r.com*	SMTP	@l.com	@r.com
`nodefaulthost` (MS 8.0.2.1 or later)	SUBMIT/SMTP	<no fixup>	<no fixup>
`remotehost`	SUBMIT	@r.edu	@r.edu
`remotethost`	SMTP	@r.edu	@o.org
<no options>	SUBMIT/SMTP	@o.org	@o.org

Note: The option in the preceding table are shown in precedence order, that is, a given option setting will override option settings further down the table.

The usual configuration is to have both arguments to `defaulthost` set to the `defaultdomain` on the defaults channel, overriding any use of the local channel host. It may be appropriate in multitenant configurations to set `authhost` on all channels that are marked with the `submit` channel option

Use of the `remotehost` channel option may be considered in rare cases where remote SMTP client exist in another administrative domain which partial addresses to refer to their own users.

Note that rewrite rules can make use of whatever default has been selected via the the `$G` and `$`*`n`*`G` substitutions.

Note that the `switchchannel`, `saslswitchchannel`, `tlsswitchchannel` and various other options can be used to associated incoming SMTP connections with a particular channel, and thus control what set of options are used.

46.3.3.18 `dequeue_removeroute` Option

The legacy configuration `dequeue_removeroute` channel option has been replaced in Unified Configuration by `dequeueremoveroute`.

46.3.3.19 Removing source routes (`dequeueremoveroute`, `enqueueremoveroute`)

The `dequeueremoveroute` channel option, when placed on a destination channel, causes source routes to be stripped from envelope recipient addresses when the channel dequeues messages (but after the channel has determined how to route the message). For instance, on a `dequeueremoveroute` TCP/IP channel that is not a `daemon` channel, the source route host is used to determine to what remote host to connect, but is stripped from the envelope

To addresses before they are presented to that remote host. In particular, this channel option may be useful at sites that use the `mailHost` LDAP attribute (more precisely, whatever LDAP attribute is named by the `ldap_mailhost` MTA option) to direct messages (via source routes, *`@mailhost:orig-address`*), to NMS systems or other systems that do not support source routes; the `dequeueremoveroute` channel option would be placed on a special TCP/IP channel set up to send to such an NMS system. But this channel option should not be used on a general channel where source routing in addresses may need to be preserved.

The `enqueueremoveroute` option, when placed on a destination channel, causes source routes to be stripped from recipient addresses enqueued to that channel *after* the regular address rewriting has been performed. Thus the `enqueueremoveroute` channel option may be useful in cases where a `mailHost` or `mailRoutingSmartHost` LDAP attribute (more precisely, whatever LDAP attribute is named by the `ldap_mailhost` or `ldap_domain_attr_smarthost` MTA option) has been set for a user or domain merely in order to force a particular channel match to some special channel during rewriting, but where the host specified in such an attribute is not relevant for actual mail delivery.

The obsolete `dequeue_removeroute` and `enqueue_removeroute` options are aliases for `dequeueremoveroute` and `enqueueremoveroute`, respectively. These obsolete options are not supported in unified configuration mode.

46.3.3.20 enqueue_removeroute Option

The legacy configuration `enqueue_removeroute` channel option has been replaced in Unified Configuration by `enqueueremoveroute`.

46.3.3.21 Routing information in addresses (exproute, noexproute, improute, noimproute)

The ideal addressing model that the MTA deals with assumes that all systems are aware of the addresses of all other systems and how to get to them. Unfortunately, this ideal is not attainable in many cases. The usual exception occurs when a channel connects to one or more systems that are not known to the rest of the world (*e.g.*, internal machines on a private network). Addresses for systems on this channel may not be legal on remote systems outside of the site. If such addresses are to be made repliable, they must contain a source route that tells remote systems to route messages through the local machine. The local machine can then (automatically) route the messages to these machines.

The `exproute` channel option (short for "explicit routing") tells the MTA that the associated channel requires explicit routing when its addresses are passed on to remote systems. If this option is specified on a channel, the MTA will add routing information containing the name of the local system (`channel:l.official_host_name`) (or the current alias for the local system, the current channel's `local_host_alias`) to all header addresses and all envelope From addresses that match the channel. `noexproute`, the default, specifies that no routing information should be added.

The MTA option `exproute_forward` can be used to restrict the action of `exproute` to backward-pointing addresses if desired.

Another scenario occurs when the MTA connects to a system via a channel that cannot perform proper routing for itself. In this case all addresses associated with other channels need to have routing inserted into them when they are used in mail sent to the channel that connects to the incapable system.

Implicit routing and the `improute` channel option are used to handle this situation. The MTA knows that all addresses matching other channels need routing when they are used in mail sent to a channel marked `improute`. `noimproute`, the default, specifies that no routing information should be added to addresses in messages going out on the specified channel.

The `improute_forward` MTA option can be used to restrict the action of `improute` to backward-pointing addresses if desired.

The `exproute` and `improute` channel options should be used sparingly. It makes addresses longer, more complex, and may defeat intelligent routing schemes used by other systems.

Explicit and implicit routing should not be confused with specified routes. Specified routes are used to insert routing information from rewrite rules into addresses. This is activated by the special A@B@C rewrite rule template. Specified routes, when activated, apply to all addresses, both in the header and the envelope. Specified routes are activated by particular rewrite rules and as such are usually independent of the channel currently in use. Explicit and implicit routing, on the other hand, are controlled on a per-channel basis and the route address inserted is always the local system.

46.3.3.22 Controlling Sender Rewriting Scheme (SRS) rewriting in header lines (`headerdecodesrs`, `noheaderdecodesrs`)

New in 8.0.1.3. The `headerdecodesrs` channel option, if set on the current source or destination channel, causes any SRS-encoded addresses found in any address header fields to be decoded. The decoding in this case does not enforce password or timeout checks; it is sufficient that the SRS domain match for decoding to occur.

The default is `noheaderdecodesrs`.

46.3.3.23 Local-channel-like behavior (`localbehavior`, `nolocalbehavior`)

Use of `localbehavior` or `nolocalbehavior` is RESTRICTED: do not use unless explicitly instructed to do so by Oracle.

The `localbehavior` channel option enables certain local-channel-like behaviors, including subsuming `aliaslocal` and `routelocal` effects. Explicit setting of `localbehavior` or `nolocalbehavior` is not usually appropriate; instead, channel defaults, optionally modified in specific ways via options such as `aliaslocal` or `routelocal`, should be used.

46.3.3.24 Handling messages that lack any recipient headers (`missingrecipientpolicy`)

RFC 822, the original Internet message format standard, had a requirement that all messages contain at least one recipient header field: a To:, Cc:, or Bcc:.

As of RFC 2822, the original update to RFC 822, relaxed the RFC 822 requirement and allowed submitted messages to be lacking in any recipient header line. This change was carried forward to the current message format standard, RFC 5322.

However, there are still MTAs around that operate according to RFC 822, and in particular may try to be helpful by adding a To: field containing all of the envelope recipients when no recipient fields are present. As such, it may be unwise to emit a message lacking all recipient

header lines, since the behavior of an RFC 822-compliant MTA or mail user agent may be undesirable when encountering a message that is, from its point of view, illegal---results may include rejection of such a message, potentially undesired exposure of recipient information such as recipients intended as Bcc: recipients, *etc*.

The `missingrecipientpolicy` channel option provides various capabilities that may be useful in addressing this issue. It takes an integer value specifying what approach to use to "fix" messages with no recipient field; the default value, if the channel option is not explicitly present, is to use the MTA option `missing_recipient_policy` value (which itself defaults to 0, if not set, which as of MS 6.2 is equivalent to a value of 1 meaning that messages are passed through unchanged---in MS 6.0 and MS 6.1 the default value of 0 had been equivalent to a value of 2 meaning that envelope To addresses are placed in a To: header).

Table 46.8 `missingrecipientpolicy` MTA option values

Value	Action
0	Use current best practices to resolve the situation. Prior to 6.2 this was the same as 2, in 6.2 and later it is the same as 1.
1	Pass the illegal-per-RFC 822 (though legal per RFC 5322) message through unchanged.
2	Place envelope To recipients in a To: header.
3	Place all envelope To recipients in a single Bcc: header.
4	Generate an empty group construct (*i.e.*, ;) To: header line. The phrase used in the group construct is controlled by the `missing_recipient_group_text` MTA option, so for instance "`To: Recipients not specified: ;`".
5	Generate a blank Bcc: header.
6	Reject the message (with a "`554 5.6.0 Error writing message - message is missing required recipient header fields`" error). (Note that the `acceptalladdresses` channel option, if used, modifies the timing and form of the rejection.)

Note that the `missing_recipient_policy` MTA option can be used to set an MTA system default for this behavior.

46.3.3.25 Restricted mailbox encoding (`restricted`, `unrestricted`, `norestricted`)

Some mail systems have great difficulty dealing with the full spectrum of addresses allowed by RFC 822. A particularly common example of this is sendmail-based mailers with incorrect configuration files. Quoted local-parts (or mailbox specifications) are a frequent source of trouble:

```
"freed, ned"@ymir.claremont.edu
```

This is such a major source of difficulty that a methodology was laid out in RFC 1137 to work around the problem. The basic approach is to remove quoting from the address and then apply a translation that maps the characters requiring quoting into characters allowed in an atom (see RFC 822 for a definition of an atom as it is used here). For example, the preceding address would become:

```
freed#m#_ned@ymir.claremont.edu
```

The `restricted` channel option tells the MTA that the channel connects to mail systems that require this encoding. The MTA then encodes quoted local-parts in both header and envelope addresses as messages are written to the channel. Incoming addresses on the channel are decoded automatically. The `unrestricted` channel option tells the MTA that this channel wants to see quoted addresses and that any restricted encodings should be decoded.

The `norestricted` channel option tells the MTA not to perform RFC 1137 encoding and decoding. `norestricted` is the default.

IMPORTANT NOTE: The `restricted` and `unrestricted` channel options should be applied to the channels that connects to systems unable to accept quoted or restricted local-parts respectively. They should *not* be applied to the channels that actually generate the quoted or restricted local-parts! (It is assumed that a channel capable of generating such an address is also capable of handling such an address.)

46.3.3.26 Channel-specific use of address reversal (`reverse`, `noreverse`)

The `reverse` channel option tells the MTA that addresses in messages enqueued to the channel should be checked against and possibly modified by address reversal (that is, modified by `reverse_url` controlled LDAP lookups, or the address reversal database, or the `REVERSE` mapping). `noreverse` exempts addresses in messages queued to the channel from address reversal processing. The `reverse` channel option is the default.

Note that, due to intended critical side-effects of `reverse_url` LDAP lookups, side-effects that will not occur if the `noreverse` channel option is used, typical Messaging Server sites **should not** use the `noreverse` channel option.

46.3.3.27 Channel-specific rewrite rules (`rules`, `norules`

The `rules` channel option tells the MTA to enforce channel-specific rewrite rule checks, and can be placed on source channels and on destination channels. When placed on a source channel, `rules` allows source channel-specific effects from `$N` or `$M` control sequences in a rewrite rule template to take effect when that source channel is enqueueing a message and rewriting addresses. When placed on a destination channel, `rules` allows destination channel-specific effects from `$C` or `$Q` control sequences in a rewrite rule template to take effect for addresses in messages being enqueued to that destination channel. `rules` is the default. `norules` tells the MTA not to check. These two channel options are usually used for debugging and are rarely used in actual applications.

46.3.3.28 Personal names in address message headers (`personalinc`, `personalmap`, `personalomit`, `personalstrip`, `sourcepersonalinc`, `sourcepersonalmap`, `sourcepersonalomit`, `sourcepersonalstrip`)

The MTA only interprets the contents of header lines when necessary. However, all registered headers containing addresses must be parsed in order to rewrite and eliminate shortform addresses and otherwise convert them to legal addresses. During this process personal names

(strings preceding angle-bracket-delimited addresses) are extracted and may optionally be modified or excluded when the header line is rebuilt.

On destination channels, this behavior is controlled by the use of the `personalinc`, `personalmap`, `personalomit`, and `personalstrip` channel options. `personalinc` tells the MTA to retain personal names in the headers. It is the default. `personalmap` tells the MTA to apply the PERSONAL_NAMES mapping table to personal names appearing in addressing header lines if such a mapping table exists, while if no such mapping table exists then `personalmap` is equivalent to `personalstrip`. `personalomit` tells the MTA to remove all personal names. And finally, `personalstrip` tells the MTA to strip any nonatomic characters from all personal name fields.

On source channels, this behavior is controlled by the use of a `sourcepersonalinc`, `sourcepersonalmap`, `sourcepersonalomit`, or `sourcepersonalstrip` channel option. `sourcepersonalinc` tells the MTA to retain personal names in the headers. It is the default. `sourcepersonalmap` tells the MTA to apply the `PERSONAL_NAMES` mapping table to personal names appearing in addressing header lines if such a mapping table exists, while if no such mapping table exists then `sourcepersonalmap` is equivalent to `sourcepersonalstrip`. `sourcepersonalomit` tells the MTA to remove all personal names. And finally, `sourcepersonalstrip` tells the MTA to strip any nonatomic characters from all personal name fields.

These options can be applied to any channel.

46.3.3.29 Short circuiting rewriting of routing addresses (`routelocal`)

The `routelocal` channel option causes the MTA, when rewriting an address to the channel, to attempt to "short circuit" any explicit routing in the address. Explicitly routed addresses (using !, %, or @ characters, or with an address embedded within quotes as the local-part of the address) will be simplified. (The "l" channel defaults to `routelocal` behavior.)

For instance, if domain.com is a domain that rewrites to a channel marked with the `routelocal` channel option, then any of the addresses

```
somewhere.else.com!user@domain.com
user%somewhere.else.com@domain.com
@domain.com:user@somewhere.else.com
"user@somewhere.else.com"@domain.com
```

will be rewritten to simply `user@somewhere.else.com`.

Use of this keyword on "internal" channels, such as internal TCP/IP channels, can potentially allow simpler configuration of SMTP relay blocking.

However, note that this option should not be used on channels that may require explicit *`@mailhost`* source routing or other routing, such as typical Oracle Messaging Server MTA internal TCP/IP channels.

46.3.3.30 Extra value channel options: `spare*` (string)

The `spare`*`N`* source channel options provide functionality (*`N`* = 1,...,18) are analogous to the attributes named by the `ldap_spare_`*`N`* MTA options, except with these options the corresponding spare slot is filled in when the source channel is selected.

The spare value slots are intended for site-customizable purposes, to be made known to the MTA (and hence be more easily accessible in MTA LDAP URLs and certain MTA mapping tables, *etc.*).

46.3.3.31 Subaddresses and alias matching (`subaddressexact`, `subaddressrelaxed`, `subaddresswild`)

A *subaddress* consists of extra detail information in the RFC 5322 "local-part" of an address (the portion to the left of the "@" sign); the subaddress is typically encoded into the local-part by using a separator character such as the plus character, `+`, and is subject to site-specific interpretation. (See for instance the discussion in the introduction of RFC 5233, Sieve: Subaddress Extension.) Use of subaddresses can be a convenient way to, *e.g.*:

- Request delivery directly to a named folder.
- Indicate that a message is being received due to membership of some mailing list.
- Request other special delivery handling, such as delivery to a voice mailbox.

In regard to subaddresses, the Messaging Server `ims-ms` and `tcp_lmtps*` channels interpret a `+` character in the local portion of an address (the mailbox portion) specially: in an address of the form `name+subaddress@domain` the Messaging Server Message Store delivery code considers the portion of the mailbox after the plus character a *subaddress*; *if* either the subaddress is "trusted" (as in the case of a subaddress added due to a Sieve filter "`fileinto`" action and confirmed for the channel via the `fileinto` channel option), or the folder has the IMAP post ACL set, *then* such channels may treat a subaddress as a request to deliver directly into the correspondingly named folder.

Subaddresses also affect the lookup of aliases by the local channel and the lookup of aliases by any channel marked with the `aliaslocal` channel option, and the lookup of mailboxes by the directory channel. The exact handling of subaddresses for such matching is configurable: when comparing an address against an entry, the MTA always first checks the entire mailbox including the subaddress for an exact match; whether or not the MTA performs additional checks after that is configurable. As of MS 6.1, the subaddress support in aliases includes `alias_urlN` alias lookups; that is, as of MS 6.1, the `subaddress*` channel options apply for `alias_urlN` lookups.

The `subaddressexact` channel option instructs the MTA to perform no special subaddress handling during entry matching; the entire mailbox, including the subaddress, must match an entry in order for the alias to be considered to match. No additional comparisons (in particular, no wildcarded comparisons or comparisons with the subaddress removed) will be performed. The `subaddresswild` channel option instructs the MTA that after looking for an exact match including the entire subaddress, the MTA should next look for an entry of the form `name+*`. (For wildcarding the entire localpart, not just the subaddress, see the `alias_domains` MTA option.) The `subaddressrelaxed` channel option instructs the MTA that after looking for an exact match and then a match of the form `name+*`, that the MTA should make one additional check for a match on just the `name` portion. With `subaddressrelaxed`, an alias entry of the form

```
name:    newname+*
```

will match either name or name+*subaddress*, transforming a plain name to newname, and transforming name+*subaddress* to newname+*subaddress*. The LDAP entry equivalent with

`subaddressrelaxed` set, to get the "transfer" of the subaddress to the forwarded-to address, would be to set:

```
mailDeliveryOption: forward
mailForwardingAddress: newname+*@newdomain
```

The default is `subaddressrelaxed`.

Thus the `subaddresswild` channel option or the `subaddressrelaxed` channel option may be useful when aliases or a directory channel are in use yet users wish to receive mail addressed using arbitrary subaddresses. These channel options obviate the need for a separate entry for every single subaddress variant on an address.

For the Messaging Server MTA, these channel options make sense on the L channel as a destination (or rather, as an alias application) channel.

New in 7.0.5, a `subaddress*` channel option setting on a source channel will affect address reversal performed on messages coming in that source channel. Previously, the presence of a subaddress would prevent address reversal from occurring. (This long-standing behavior was a remnant of the past when if a user was sophisticated enough to put on a subaddress, one might presume that the user was sophisticated enough to have already specified the exact address that they wanted to send from -- so altering such an address wouldn't be necessary and indeed would be dubious. However, nowadays many other behaviors and side-effects are triggered via address reversal so matching regardless of subaddress is typically desirable; the old assumption that reversal was not desirable in such cases is outdated.) As of 7.0.5, the default behavior is to attempt to match the address with or without the subaddress. If there's a match, then the subaddress will be transferred to any rewritten address. This behavior may be explicitly specified by setting the `subaddressrelaxed` channel option (the default) on the source channel. `subaddresswild`, if set, will match against subaddresses but disables transfer of the subaddress to the rewritten address. Finally, `subaddressexact` disables special subaddress handling during the reversal process.

46.3.3.32 Alias and address channel options: `usereversedatabase` (bitmask)

As of MS 8.0.1.3, the `usereversedatabase` source channel option provides a way to override the setting of the `use_reverse_database` MTA option on a channel by channel basis. All bits have identical meaning in both options.

46.3.3.33 uucp Option

The legacy configuration `uucp` channel option has been replaced in Unified Configuration by `bangstyle`.

46.3.3.34 Validating local part of address (`validatelocalnone`, `validatelocalsystem`, `validatelocalexternal`, `validatelocalpopstore`, `validatelocalmsgstore`, `validatelocalprofile`)

The `validatelocal*` channel options control whether any validity check on the local part (username) of an address is performed when messages are enqueued to the

channel. Different sorts of channels have different defaults; most channels default to `validatelocalnone`, meaning that no validation of the local part of the address is performed by the channel doing the enqueuing to the channel in question, but the local channel defaults to `validatelocalsystem`, meaning that the local part (username) of an address must be a valid, e-mail receiving account on the system. More specifically, `validatelocalsystem` means that on UNIX platforms, the local part (username) must have an account on the system, or on OpenVMS platforms that the local part (username) must have an account or VMS MAIL profile entry.

When `validatelocalnone` is placed on a channel, messages matching that channel are enqueued to the channel with no validation by the enqueuing channel; it will be up to the destination channel itself to validate the address. So for instance if `validatelocalnone` were placed on the local channel, then incoming SMTP messages apparently matching the local channel would be accepted by the SMTP server and enqueued to the local channel; if the local part turned out not to be a valid account, that would not be discovered until the local channel itself actually ran and checked the local part. (Note that the local channel isn't normally used for actual enqueues in Messaging Server.)

Conversely, if the name space for some other destination channel, say a MRIF_A1 channel, happened to exactly match the name space for the accounts on the local channel, then placing `validatelocalsystem` on the MRIF_A1 channel would cause enqueuing PMDF agents such as the SMTP server to reject messages destined for the MRIF_A1 channel for which the local part (username) could not be validated as if it were a VMS MAIL account.

The `validatelocalexternal`, `validatelocalpopstore`, `validatelocalmsgstore`, `validatelocalprofile` channel options are all currently unimplemented; their behavior is the same as `validatelocalnone`.

46.3.3.35 Require use of aliases (`viaaliasrequired`, `viaaliasoptional`)

The default is `viaaliasoptional`, meaning that an alias match and resulting expansion are not required to be part of address processing prior to enqueing to this channel. If `viaaliasrequired` is specified on a channel, then only addresses whose processing involved expansion of some sort of alias (LDAP entry, alias file entry, alias database entry, *etc.*) are allowed to be enqueued to the channel.

Note that `viaaliasrequired` must be used on the local channel for direct LDAP configuration to work properly.

46.3.4 Attachments and MIME processing channel options

A number of channel options affect the processing of so-called attachments and MIME parts. (Note that these are channel options which can generally be set on *any*type of channel. See also Message conversions for optional, more complex, processing of attachments and MIME parts, sometimes involving a "hop" through the specialized Conversion channel.)

See also the `conditionalpassthrough` and `conditionalrelay` channel options which, by setting operation type, have implications regarding "fixup" of MIME structure in messages, and also the `inner`, `noinner`, `sourceinner`, and `nosourceinner` channel options which, by controlling whether the MTA's processing looks "inside" messages, among other things affects "fixup" of the MIME header lines on encapsulated parts of messages. See also the

limitheadertermination and relaxheadertermination channel options which, by controlling what is interpreted as the division between the message header and the message body, thereby affects detection of a message's MIME structure.

46.3.4.1 Processing within security multiparts (conditionalsecuritymultiparts, processsecuritymultiparts, retainsecuritymultiparts)

The conditionalsecuritymultiparts, processsecuritymultiparts, and retainsecuritymultiparts channel options control the handling of security multiparts, (that is, multipart/signed and multipart/encrypted parts), by the MTA's message structure parsing code. They are particularly relevant for the conversion channel, as they control whether the conversion channel processes "inside" such multiparts. retainsecuritymultiparts is the default: multipart/signed and multipart/encrypted are treated as monolithic and not "looked inside" by MIME message structure parsing. For instance, by default (returnsecuritymultiparts) the conversion channel won't process any parts inside such parts. With processsecuritymultiparts, the conversion channel sees the parts inside the security multipart; note that enabling this breaks all signatures, since the MTA redoes all the boundary markers during its MIME structure parsing. conditionalsecuritymultiparts processes the multiparts similarly to processsecuritymultiparts, but retaining any "preamble" material inside the multipart.

46.3.4.2 convert_octet_stream Option

The legacy configuration convert_octet_stream channel option has been replaced in Unified Configuration by convertoctetstream.

46.3.4.3 Conversion of application/octet-stream material (convertoctetstream, noconvertoctetstream)

MIME provides a general-purpose type for exchange of pure untyped binary data. Such data may or may not be usable in any given circumstance; no other information about the data is available. Various MTA channels provide mechanisms for dealing with such data that may or may not be appropriate. The convertoctetstream and noconvertoctetstream options control these mechanisms; if the former is specified on a source channel conversions are performed and if the latter is specified no conversions are performed. The latter option is the default for all channels.

convertoctetstream is not relevant for any currently available Oracle Messaging Server channels.

46.3.4.4 Automatic defragmentation of message/partial messages (defragment, nodefragment)

The MIME standard provides the message/partial content type for breaking up messages into smaller parts. This is useful when messages have to traverse networks with size limits. Information is included in each part so that the message can be automatically reassembled once it arrives at its destination.

The defragment channel option and the defragmentation channel provide the means to reassemble messages in the MTA. When a channel is marked defragment any message/

partial messages queued to the channel will be placed in the defragmentation channel queue instead. Once all the parts have arrived the message is rebuilt and sent on its way.

The `nodefragment` disables this special processing. `nodefragment` is the default.

A `defragment` channel must be present in the configuration in order for the `defragment` channel option to have any effect. Initial configuration normally includes a `defragment` channel in the MTA configuration.

46.3.4.5 Encoding header interpretation (`ignorencoding`, `ignoremessageencoding`, `ignoremultipartencoding`, `interpretencoding`, `interpretmessageencoding`, `interpretmultipartencoding`)

The MTA has the ability to convert various non-standard message formats to MIME via the `Yes CHARSET-CONVERSION`. In particular, the RFC 1154 format uses a non-standard Encoding: header line. However, some gateways emit incorrect information on this header line, with the result that sometimes it is desirable to ignore this header. The `ignoreencoding` source channel option instructs the MTA to ignore any Encoding: header. (Note that unless the MTA has a `CHARSET-CONVERSION` enabled, such headers will be ignored in any case.) The `interpretencoding` source channel option instructs the MTA to pay attention to any Encoding: header line, if otherwise configured to do so, and is the default.

New in 6.3 are the `ignoremessageencoding`, `interpretmessageencoding`, `ignoremultipartencoding`, and `interpretmultipartencoding` source channel options. The MIME standards, RFC 2045 (which updates RFC 1521) and RFC 2046, restrict the set of allowed content-transfer-encodings permitted on MIME multipart or message parts to 7BIT, 8BIT, or BINARY in general, with the particular message subtypes message/partial and message/external-body being further restricted to allow only 7BIT. Nevertheless, buggy/incompliant software may sometimes emit messages that illegally label multipart or message parts as having another content-transfer-encoding. Now when such an illegal encoding label is seen, the question is whether the material is in fact encoded (illegally) as claimed, or whether the material is not in fact encoded and the claim is simply false.

Prior to 7.0.5, the MTA's default handling (and the only handling available prior to 6.3) is to believe the Content-transfer-encoding: label---and the MTA can (and will) "decode" such messages. This corresponds to `interpretmessageencoding` and `interpretmultipartencoding` channel options. This leads to "successful" handling of messages that are broken due to illegally being encoded---but will not be equally satisfactory for messages that are broken due to an outright false labelling with the contents not actually being encoded.

Alternatively, the new in 6.3 `ignoremessageencoding` and `ignoremultipartencoding` channel options, when placed on a source channel, will cause the MTA to ignore any claimed Content-transfer-encoding: on message parts or multipart parts, respectively, which can be more useful when broken software is emitting messages that falsely claim encoding of such parts. (Note that since what RFC 2045 specifies as the permitted and legal 7BIT, 8BIT, and BINARY content-transfer-encodings are all identity encodings---no transformation of the data is involved, with the content-transfer-encoding label merely recording what sort of material the part contains, which the MTA can determine for itself---it causes no harm to RFC 2045 conformant message or multipart parts to ignore the content-transfer-encoding. So for the moment, use of `ignore*encoding` channel options is "safe" for RFC 2045 legal messages. **However**, the experimental EAI (Email Address Internationalization) specifications are likely

to change this MIME restriction, permitting encodings on such parts; at such time, support for correct messages would require respecting and interpreting any encodings on such parts. So the `ignore*encoding` channel options, while a useful and safe-for-the-moment short-term workaround for broken, remote software, must be considered short-term: they may not continue to be safe to use in future.)

Note that the `imsimta test -mime` utility has switches for testing and describing the (MIME) structure of messages, switches which correspond to these channel keywords.

Note that in Messaging Server 7.0u3 and prior versions, the `ignoremultipartencoding` and `ignoremessageencoding` channel options would have no effect (be ignored) when placed on a `conversion` or SMS channel, or on any site-written channels.

The `interpretmessageencoding` channel option is the default in all versions. Prior to 7.0.5, `interpretmultipartencoding` was also the default. But as of 7.0.5, `ignoremultipartencoding` is the default.

46.3.4.6 Soft wrap (encode) long lines in messages (`linelength`)

The SMTP specification allows for lines of text containing up to 1000 bytes. However, some transports may impose more severe restrictions on line length, and even some SMTP systems, in violation of the relevant standards, cannot handle full length lines.

First the MTA performs any appropriate header line wrapping: see the `headerlinelength` channel option. Then the `linelength` channel option provides a mechanism for limiting the maximum permissible message body line length on a channel by channel basis. Messages queued to a given channel with body lines longer than the `linelength` limit specified for that channel will have the message body encoded automatically. (Note that `linelength` is a destination channel option modifying what the MTA *emits*; for controlling how the MTA handles illegally long lines that it *receives* via SMTP, see instead the `*smtplonglines` options.) The various encodings available always result in a reduction of line length to fewer than 80 characters. The original message may be recovered after such encoding is done by applying an appropriating decoding filter. (In most cases MIME-aware mail user agents are able to detect that such decoding is necessary and perform it automatically.)

Note that encoding can only reduce line lengths to fewer than 80 characters. For this reason specification of line length values less than 80 may not actually produce lines with lengths that comply with the stated restriction.

Note also that `linelength` causes encoding of data so as to do "soft" line wrapping for transport purposes. The encoding is normally decoded at the receiving side so that the original "long" lines are recovered. For "hard" line wrapping, see instead the "Record,Text" `CHARSET-CONVERSION`.

The default for arbitrary channels is 1023 channels; but channels marked with an `smtp*` or `lmtp*` channel option will not allow more than 998 characters and attempts to set `linelength` larger (or not setting `linelength` explicitly on such channels) will result in using 998 characters on such channels.

46.3.4.7 Automatic fragmentation of large messages (`maxblocks`, `maxlines`)

Some mail systems or network transports cannot handle messages that exceed certain size limits. The MTA provides facilities to impose such limits on a channel-by-channel basis.

Messages larger than the set limits will automatically be split (fragmented) into multiple, smaller messages. The Content-type: used for such fragments is message/partial, and a unique id parameter is added so that parts of the same message can be associated with one another and, possibly, be automatically reassembled by the receiving mailer.

Message fragmentation and defragmentation may also be used to effectively provide "checkpointing" of message transmission.

The `maxblocks` and `maxlines` channel options are used to impose size limits beyond which automatic fragmentation will be activated. Both of these channel options require a single integer argument. `maxblocks` specifies the maximum number of blocks allowed in a message. An MTA block is normally 1024 bytes; this can be changed with the `block_size` MTA option. `maxlines` specifies the maximum number of lines allowed in a message. These two limits can be imposed simultaneously if necessary.

Message headers are to a certain extent included in the size of a message. Since message headers cannot be split into multiple messages, and yet they themselves may exceed the specified size limits, a rather complex mechanism is used to account for message header sizes. This logic is controlled by the `max_header_block_use` and `max_header_line_use` MTA options.

`max_header_block_use` is used to specify a real number between 0 and 1. The default value is 0.5. A message's header is allowed to occupy this much of the total number of blocks a message can consume (specified by the `maxblocks` channel option). If the message header is larger, the MTA takes the product of `max_header_block_use` and `maxblocks` as the size of the header; *i.e.,* the header size is taken to be the smaller of the actual header size and `maxblocks * max_header_block_use`.

For example, if `maxblocks` is 10 and `max_header_block_use` is the default, 0.5, any message header that is larger than 5 blocks is treated as a 5 block header, and if the message is 5 or fewer blocks in size it will not be fragmented. A value of 0 will cause headers to be effectively ignored insofar as message size limits are concerned. A value of 1 allows headers to use up all of the size that's available. Note, however, that each fragment will always contain at least one message line, regardless of whether or not the limits are exceeded by this.

The `max_header_line_use` channel option operates in a similar fashion in conjunction with the `maxlines` channel option.

See the `defragment` channel option and the Defragmentation channel for discussion of the reverse operation: that is, how the MTA can be configured to perform automatic defragmentation of message fragments that it *receives*.

46.3.4.8 Microsoft Exchange gateway channels (`msexchange`, `nomsexchange`)

The `msexchange` channel option may be used on TCP/IP channels to tell the MTA that this is a channel that communicates with Microsoft® Exchange gateways and clients. Use of the option tells the MTA to try and accomodate nonstandard behavior on the part of Microsoft Exchange. Exactly what nonstandard behaviors are dealt with is subject to change.

Currently the `msexchange` channel option on a channel configured to allow TLS use (see the `*tls*` channel options) causes advertisement (by the MTA's SMTP server) and recognition (by the MTA's SMTP client) of the non-standard TLS capability string, in addition to the standard STARTTLS capability string, to indicate that TLS is supported.

New in 7.0.5, setting `msexchange` on a destination channel will cause the MTA, if performing any sort of MIME processing operation, to remove any Content-disposition: header line from any text/calendar message parts, as despite Content-disposition:'s long-standing existence as a standardized header line, not to mention the basic MIME rule that unrecognized Content-* header lines should be ignored, Microsoft® Outlook's handling of text/calendar parts is disturbed when such parts have a Content-disposition: specified. So specifying `msexchange` on a channel sending to Microsoft Exchange, if text/calendar parts will flow through that channel, should allow Microsoft Outlook to process calendar parts more successfully.

`nomsexchange` is the default.

46.3.4.9 MIME Content-type: and Content-disposition: header line parameter lengths (`nameparameterlengthlimit`, `parameterlengthlimit`)

A number of popular e-mail clients (mail user agents) have had a history of security problems involving buffer overruns during header line processing, such as during processing of the Content-type: or Content-disposition: header lines. So although RFC 2045 (MIME) does not impose any length constraints on such parameters, keeping in mind the historical vulnerabilities of many popular e-mail clients, the MTA normally truncates MIME parameters in an attempt to protect any downstream, vulnerable clients. By default, the MTA truncates the Content-type: NAME and Content-disposition: FILENAME parameters at 128 characters each, and other general parameters at 1024 characters. These defaults may be changed by using the `nameparameterlengthlimit` and `parameterlengthlimit` channel options, respectively. Each takes an integer argument specifying the desired maximum length to allow for such parameters; (longer parameters will be truncated).

A distinct but related issue to parameter truncation is parameter segmentation, per RFC 2231 rules, which can be controlled in part by the `parameterformatdefault` and related channel options.

46.3.4.10 `noconvert_octet_stream` Option

The legacy configuration `noconvert_octet_stream` channel option has been replaced in Unified Configuration by `noconvertoctetstream`.

46.3.4.11 Convert some non-standard "attachments" to MIME format (`thurman`, `nothurman`, `uma`, `nouma`)

The `thurman` channel option on a source channel causes the MTA to "sniff" incoming, non-MIME messages and convert them to MIME format, in the process converting certain non-standard "attachment" formats (*e.g.*, uuencoded or BinHex "blobs" embedded in messages) into MIME format attachments. While this may seem like a positive transformation to perform on messages, modifications of message content should always be a last resort, the resulting MIME-ification of messages has limitations and may be considered undesirable in some circumstances or to some users, this "sniffing" does incur processing overhead, and such an approach may appear as a deceptively "easy" fix for communicating with non-standard e-mail software (when a better, more permanent solution would be to upgrade the out-of-date, non-standard software that is emitting such "blobs"). As such, the `nothurman` channel option is the default -- and any decision to configure with `thurman` should be made with due consideration and caution.

The uma source channel option is like thurman, except that with uma, the message "sniffing" and content transformation only occurs if the MTA was already performing message body processing (and hence would have been converting the message body to MIME format already), for instance cases of incoming non-MIME messages that illegally contain unlabelled eight bit characters. nouma is the default.

Note that CHARSET-CONVERSION mapping table keywords exist to configure thurman or uma type processing on a somewhat more selective basis.

The thurman or uma processing on its own merely causes "blobs" in non-MIME messages to get converted to fairly "generic" MIME parts, with Content-type of application/octet-stream and a Content-transfer-encoding of X-UUENCODE. Optionally, one may configure to guess (typically based on filename, especially filename extension) at a better Content-type labelling, and/or to convert to a different Content-transfer-encoding, using the MTA's facility for Relabelling MIME header lines.

46.3.4.12 MIME Content-type: and Content-disposition: header line parameter RFC 2231 encoding (parameterformatdefault, parameterformatminimizeencoded, parameterformatstripencoded)

As of Messaging Server 7.2-0.01, the MTA supports RFC 2231 (MIME Parameter Value and Encoded Word Extensions), thus supporting use of alternate character sets and languages in MIME parameters, as well as supporting the segmentation of "long" parameter values.

As a separate issue from the truncation of very long parameter values as controlled by parameterlengthlimit and nameparameterlengthlimit, note that as of Messaging Server 7.2-0.01 when RFC 2231 support was added, the MTA will automatically segment long parameter values according to RFC 2231 rules. (Note that the length at which RFC 2231 segmentation is triggered is not configurable.) For Messaging Server 7.2-0.01, parameter values over 65 characters in length will automatically be segmented into 40 character segments; *e.g.*,

```
filename="veryveryveryveryveryveryveryveryveryveryveryveryveryveryveryverylong.name"
```

would become

```
filename*0="veryveryveryveryveryveryveryveryveryvery";
filename*1="veryveryveryveryverylong.name"
```

As of Messaging Server 7.4-0.01 and the implementation of CR # 6924445, the length limit for triggering parameter segmentation was increased from the prior 65 characters up to 70 characters. (In particular, as RFC 2046 limits the length of MIME boundary delimiters to at most 70 characters, this larger trigger length avoids triggering MIME parameter segmentation of compliant boundary delimiters.)

New in 7.0.5 are the channel options parameterformatdefault, parameterformatminimizeencoded, and parameterformatstripencoded, with these last two options providing new features to aide with cases of dealing with other software that does not yet support RFC 2231. parameterformatdefault is the default and means to

do normal RFC 2231 encoding, as needed. `parameterformatminimizeencoded` tells the MTA to attempt to remove any unnecessary or redundant RFC 2231 encoding from MIME parameters including removing any RFC 2231 segmentation of parameters; when it is applied, parameter segmentation will be removed and those encoded words not involving charset or language information or 8 bit characters will be replaced with regular parameter values. `parameterformatstripencoded` tells the MTA to strip any characters that would require RFC 2231 encoding from MIME parameters, thereby allowing the parameter to be represented without any RFC 2231 encoding or segmentation.

For webmail (MSHTTP) generation of RFC 2231 encoded format, see the `rfc2231compliant` MSHTTP option.

46.3.5 BSMTP-specific channel options

A few (now DEPRECATED or RESTRICTED) channel options relate to BSMTP-specific protocol details. For channel options relevant to today's BSMTP channels, see instead more general options such as the SMTP and LMTP protocol channel options and the `serviceconversion` channel option.

46.3.5.1 Batch SMTP Continuation Lines (`contchar`, `contposition`)

DEPRECATED.

The `contposition` channel option specifies the point at which batch SMTP lines are folded onto a continuation line. The default value for `contposition` is 0, which disables continuation lines.

The `contchar` channel option is used to specify a continuation character for commands in batch SMTP. Commands longer than `contposition` characters long will have the character specified by the integer argument to `contchar` inserted in the `contposition` position and the remainer of the line will be wrapped to another line. The default value for `contchar` is 0.

See also the TCP/IP-channel-specific option `CONTINUATION_CHARS` which allows for specification of additional continuation characters.

These options were used to accomodate the peculiar form of batch SMTP that was employed by BITNET. Now that BITNET is no more these options are obsolete and deprecated.

46.3.5.2 Generation of TICKet BSMTP Commands (`tick`, `notick`)

Some batch SMTP (BSMTP) implementations require the presence of a ticket number, specified with the `TICK BSMTP` command. The `tick` channel option tells the MTA to issue this command; `notick` suppresses it. `tick` is the default on channels that support tickets. Currently only PMDF's `BN_MASTER` channel program uses this channel option.

46.3.5.3 Generation of VERBose BSMTP Commands (`verb_on`, `verb_off`, `verb_none`, `verb_never`)

Some batch SMTP (BSMTP) implementations support the use of the `VERB` command to control the nature of their replies. On the client side the `verb_on` command tells the MTA to issue a `VERB ON` command in the BSMTP command sequence; `verb_off` tells the MTA to issue a

VERB OFF command. The verb_never and/or the verb_none channel option tells the MTA not to issue any VERB commands. verb_never is the default, and this default should *not* be changed.

On the server side, the verb_never channel option causes VERB commands in the BSMTP stream to be accepted but ignored. verb_none can be used to enable processing of VERB commands.

46.3.6 Character sets and eight bit data channel options

A number of channel options control handling of character sets in messages, as well as eight bit data.

See also the general topic of Character set conversion.

46.3.6.1 Automatic character set labelling (charset7, charset8, charsetesc)

The MIME specification provides a mechanism to label the charset used in plain text messages: A "charset=" parameter can be specified as part of the Content-type: header line. Various charset names are defined in MIME, including US-ASCII (the default), ISO-8859-1, ISO-8859-2, and so on, and many more have been registered with the Internet Assigned Numbers Authority (IANA).

Some existing systems and user agents, however, do not provide any mechanism for generating these charset labels. The charset7, charset8 and charsetesc channel options, when placed on a source channel, provide a mechanism to specify charset names to be inserted into message headers. Each option requires an argument giving a charset name. The names are not checked for validity. Note, however, that charset conversion can only be done on charsets specified in the MTA's charset definition file charsets.txt. The names defined in this file should be used if possible.

The charset7 charset name is used if the message contains only seven bit characters; the charset8 name will be used if eight bit data is found in the message; charsetesc will be used if a message containing only seven bit data happens to contain one or more escape characters. If the appropriate option is not specified no character set name will be inserted during MIME processing into Content-type: header lines for text parts that lack an existing charset label.

When the presence of a charset* channel option on a channel causes a MIME "charset" parameter clause to be added to an incoming message, that of course also means that the message gets the more fundamental MIME-version: and Content-type: header lines added, if not already present.

New in Messaging Server 7.4-18.01, the charset7, charset8, and charsetesc channel options will also cause labelling (with the specified charset) of incoming illegal, unlabelled parameter values on MIME Content-type: or Content-disposition: header lines, when such parameters must be encoded due to their content. That is, while such parameter values have always been subject to encoding (to make them syntactically legal, if not necessarily usable) by the MTA, the new feature is that charset labelling will be inserted also, making them more usable.

Note that the charset8 option also controls the MIME encoding of eight bit characters found in message headers (where such eight bit data is unconditionally illegal). The MTA

will normally always MIME encode any such (illegal) eight bit data encountered in message headers, labelling it as the UNKNOWN charset if no `charset8` value has been specified on the current source channel. (Actual addresses are a special case. In the actual address, that is, in the RFC 822 addr-spec, where eight bit categorically must not appear, any eight bit data will be replaced by the MTA with the asterisk character, *. Note that an RFC 822 phrase, or "personal name", however, is subject to the above described MIME encoding of any illegal eight bit, using the `charset8` charset name.)

These charset specifications never override existing labels; that is, they have no effect if a message already has a charset label or is of a type other than text.

The `charsetesc` option tends to be particularly useful on channels that receive unlabelled messages using Japanese or Korean character sets that contain the escape character (*e.g.*, iso-2022-jp or iso-2022-kr).

46.3.6.2 Eight bit SMTP capability and EAI capability (`eightbit`, `eightnegotiate`, `eightstrict`, `sevenbit`, `utf8header`, `utf8negotiate`, `utf8strict`)

Some transports restrict the use of characters with ordinal values greater than 127 (decimal). Most notably, some SMTP servers will strip the high bit and thus garble messages that use characters in this "eight bit" range. Indeed, there have even been past cases of SMTP servers which will crash when presented with eight bit data.

The MTA provides facilities to automatically encode such messages so that troublesome eight bit characters do not appear directly in the message. This encoding can be applied to all messages on a given channel by specifying the `sevenbit` channel option. A channel should be marked `eightbit` if no such restriction exists.

Some transports such as extended SMTP may actually support a form of negotiation to determine if eight bit characters can be transmitted. The `eightnegotiate` channel option can be used to instruct the channel to encode messages when negotiation fails. This is the default for all channels; channels that do not support negotiation will simply assume that the transport is capable of handling eight bit data.

The `eightstrict` source channel option tells the MTA to reject any messages that contain unnegotiated eight bit data; the exact text of this error may be controlled via the `error_text_unnegotiated_eightbit` MTA option. (Note that the timing of the rejection can be postponed via the `acceptalladdresses` channel option.)

The MS 8.0.2 release adds MTA support for EAI messages and the SMTPUTF8 extension. EAI messaging is documented in RFC 6530 (overview), RFC 6531 (SMTPUTF8 extension), RFC 6532 (header format changes), and RFC 6533 (DSN and MDN format changes). Three additional channel options have been added to enable and control EAI support:

`utf8header` As a SMTP source channel option, offer the SMTPUTF8 SMTP extension. As a destination channel option, allow enqueue and dequeue of EAI messages unconditionally; in particular, the SMTPUTF8 extension will not be required. Note that delivery of EAI messages via SMTP/LMTP to a non-EAI system is a standards violation.

`utf8negotiate` As a SMTP source channel option, offer the SMTPUTF8 SMTP extension. As a destination channel option, allow enqueue unconditionally. On

dequeue, require the SMTPUTF8 extension be offered by SMTP/LMTP servers for EAI messages with EAI recipient (RCPT TO) addresses or un-downgradable EAI originator (MAIL FROM) addresses.

`utf8strict` Same as `utf8negotiate` as far as SMTP/LMTP destination channels are concerned. But additionally, for SMTP/LMTP servers (source channels), reject messages that contain 8bit headers without having negotiated the SMTPUTF8 extension and 8bit bodies without having negotiated the 8BITMIME extension. (Note that such rejections are postponed if the `acceptalladdress` channel option is used.)

As of MS 8.0.2.2 the channel default for internal channels has changed from `eightnegotiate` to `utf8always`. Note, however, that the channel default remains `eightnegotiate` on all other channels; EAI support must therefore be explicitly enabled. A channel set to `eightnegotiate` will not offer the SMTPUTF8 extensions or allow EAI messages with EAI recipient or originator addresses to be enqueued. Also note that the Message Store does not support EAI at the present time.

46.3.6.3 Unencoded non-ASCII headers (`headerset7`, `headerset8`, `headersetesc`)

In extremely rare situations very old and standards-incompliant SMTP servers must be accomodated. One of the behaviors such servers sometimes exhibit is an inability to deal with MIME encoded words in headers. Instead such servers expect headers to simply contain unencoded material in some other charset.

The `headerset7`, `headerset8`, and `headersetesc` channel options are used to deal with such situations. Each accepts a charset name as an argument. When applied to a destination channel, they cause encoded words in the specified charsets to be decoded. Any combination of the options can be specified, meaning from 1 to 3 charsets can be decoded. Note that the names of these options were selected to match up with other charset options but there is essentially no difference between the three options.

Extreme care should be exercised when using these options, as the messages they produce will be grossly standards incompliant and may cause serious interoperability problems, to the point of crashing some very old SMTP servers.

46.3.6.4 MIME Content-type: and Content-disposition: header line parameter RFC 2231 encoding (`parameterformatdefault`, `parameterformatminimizeencoded`, `parameterformatstripencoded`)

As of Messaging Server 7.2-0.01, the MTA supports RFC 2231 (MIME Parameter Value and Encoded Word Extensions), thus supporting use of alternate character sets and languages in MIME parameters, as well as supporting the segmentation of "long" parameter values.

As a separate issue from the truncation of very long parameter values as controlled by `parameterlengthlimit` and `nameparameterlengthlimit`, note that as of Messaging Server 7.2-0.01 when RFC 2231 support was added, the MTA will automatically segment long parameter values according to RFC 2231 rules. (Note that the length at which RFC 2231 segmentation is triggered is not configurable.) For Messaging Server 7.2-0.01, parameter values over 65 characters in length will automatically be segmented into 40 character segments; *e.g.*,

```
filename="veryveryveryveryveryveryveryveryveryveryveryveryveryveryveryverylong.name"
```

would become

```
filename*0="veryveryveryveryveryveryveryveryveryvery";
filename*1="veryveryveryveryverylong.name"
```

As of Messaging Server 7.4-0.01 and the implementation of CR # 6924445, the length limit for triggering parameter segmentation was increased from the prior 65 characters up to 70 characters. (In particular, as RFC 2046 limits the length of MIME boundary delimiters to at most 70 characters, this larger trigger length avoids triggering MIME parameter segmentation of compliant boundary delimiters.)

New in 7.0.5 are the channel options `parameterformatdefault`, `parameterformatminimizeencoded`, and `parameterformatstripencoded`, with these last two options providing new features to aide with cases of dealing with other software that does not yet support RFC 2231. `parameterformatdefault` is the default and means to do normal RFC 2231 encoding, as needed. `parameterformatminimizeencoded` tells the MTA to attempt to remove any unnecessary or redundant RFC 2231 encoding from MIME parameters including removing any RFC 2231 segmentation of parameters; when it is applied, parameter segmentation will be removed and those encoded words not involving charset or language information or 8 bit characters will be replaced with regular parameter values. `parameterformatstripencoded` tells the MTA to strip any characters that would require RFC 2231 encoding from MIME parameters, thereby allowing the parameter to be represented without any RFC 2231 encoding or segmentation.

For webmail (MSHTTP) generation of RFC 2231 encoded format, see the `rfc2231compliant` MSHTTP option.

46.3.7 Conversion tag and service conversion channel options

One place at which conversion tags can be added is on a destination or source channel basis, controlled by channel options.

Triggering the check for service conversions can be controlled by channel options.

46.3.7.1 Channel-based conversion tags (`destinationconversiontag`, `sourceconversiontag`)

(New in 7.0.5.) The channel options `destinationconversiontag` and `sourceconversiontag` allow for per-channel addition of conversion tags to messages. Each option accepts a single argument consisting of a comma-separated list of conversion tags. The source conversion tags are attached to all message recipients; any destination conversion tags are attached to all recipients associated with that destination channel.

See also the domain level and user level LDAP attributes for adding per-sender and per-recipient conversion tags, `ldap_domain_attr_source_conversion_tag`, `ldap_domain_attr_conversion_tag`, `ldap_source_conversion_tag`, and `ldap_conversion_tag`, and in Unified Configuration the alias option

alias_conversion_tag or in legacy configuration the [CONVERSION_TAG] alias file named parameter.

46.3.7.2 Source channel trigger for service conversions (serviceconversion, noserviceconversion)

The serviceconversion and noserviceconversion channel options are new under these names in Messaging Server 7.3-11.01; in earlier versions, the names (obsolete for Unified Configuration) service and noservice had been used.

Instead of triggering a check for applicable service conversions via a matching entry in the CHARSET-CONVERSION mapping table, setting serviceconversion on a source channel equivalently triggers the check for applicable service conversions, for all messages coming in that channel. noserviceconversion is the default, and means that the CHARSET-CONVERSION mapping table is, as normal, the trigger for whether to check for applicable service conversions.

46.3.8 Display label channel options

A couple of channel options are intended for labelling purposes, for future use.

46.3.8.1 Channel caption and description fields (caption, description)

The description channel option takes a string argument and provides a way to associate a descriptive term or phrase with a channel. This feature is intended for future management utility use. The (new in 6.3) caption channel option is similar, though it would normally be given a shorter argument, one suitable for use as the caption for a table column, for instance.

46.3.9 DKIM channel options

As of MS 7.0.5, a number of channel options can be used to affect message handling based on the presence of DKIM signatures. See also the DKIM MTA options.

MS 8.0.2.3 introduced native DKIM signing capbilities, controled by various DKIM channel options.

46.3.9.1 DKIM channel options: (destinationdkimignore, destinationdkimpreserve, destinationdkimremove)

The destinationdkim* channel options are destination channel analogues of the dkim* channel options. They operate in the same sort of way as their source channel analogues, except that note that since destination channel determination is made later in message processing, after *some* message processing has already occurred, then for instance the switch to "passthrough" mode resulting from destinationdkimpreserve applying will occur *after* some message processing may already have occurred. Thus destinationdkimpreserve may be more specific in terms of which messages it applies to, but is potentially less comprehensive in its avoidance of message processing, than dkimpreserve.

46.3.9.2 Source channel handling of DKIM-Signature: header fields (dkimignore, dkimpreserve, dkimremove)

DKIM-Signature: header fields may require special handling, or their presence may indicate the need for special handling. The `dkimignore`, `dkimpreserve`, and `dkimremove` source channel options provide various capabilities in this area.

The `dkimignore` source channel option instructs the MTA to take no special action in regards to DKIM-Signature: header fields. This option is the default.

The behavior of the `dkimpreserve` source channel option depends on whether the `dkim_preserve_domains` and `dkim_ignore_domains` MTA options are set. If neither of these options are set, the presence of any DKIM-Signature: header field in the message puts the MTA in "`passthrough`" mode, where no header rewriting will be performed.

If either of the `dkim_ignore_domains` or `dkim_preserve_domains` MTA options is set, every DKIM-Signature: header field that is present will be parsed and the domain value specified by the "`d=`" will be extracted. Each extracted domain is first compared against the space-separated list of domains specified by the `dkim_ignore_domains` MTA option. If a match is found no action is taken and processing continues with the next DKIM-Signature: field. If no match is found the domain is next checked against the space-separated list of domains specified by the `dkim_preserve_domains` MTA option. If a match is found there the MTA is placed in "`passthrough`" mode and scanning is terminated.

The behavior of the `dkimremove` source channel option depends on whether the `dkim_remove_domains` and `dkim_ignore_domains` MTA options are set. If neither of these options are set, all DKIM-Signature: fields are unconditionally removed from the message.

If either of the `dkim_remove_domains` or `dkim_ignore_domains` MTA options is set, every DKIM-Signature: header field that is present will be parsed and the domain value specified by the "`d=`" will be extracted. Each extracted domain is first compared against the space-separated list of domains specified by the `dkim_ignore_domains` MTA option. If a match is found no action is taken and processing continues with the next DKIM-Signature: field. If no match is found the domain is next checked against the space-separated list of domains specified by the `dkim_remove_domains` MTA option. If a match is found there the corresponding DKIM-Signature: field is removed from the message.

See also the analogous destination channel options `destinationdkim*`, introduced in 8.0.

46.3.9.3 Channel-based DKIM signing (`destinationdkimidentityN`, `destinationdkimselectorN`, `sourcedkimidentityN`, `sourcedkimselectorN`)

The `destinationdkimidentityN/destinationdkimselectorN` and `sourcedkimidentityN/sourcedkimselectorN` channel options provide the ability to apply DKIM signatures to messages based on destination and source channels, respectively.

The specification of one or more DKIM identities enables signing as enqueued messages are written to disk. Each identity is used to access a corresponding private key in PEM format stored as DATAROOT/dkim_private/<identity>/<selector>.pem.

Multiple "slots" are provided so that multiple signatures can be applied simultaneously. Slot values starting at 0 appear at the end of the option name. At present four slots are available, so N can range from 0 to 3.

Identity values specifies the DKIM identity. This can take the form "user@domain", "@domain", "domain", or the special value "*" can be given which specifies that the domain of From: header address should be used.

Some DKIM errors will be sent to syslog (see `mta.sndopr_priority`). Additional diagnostics are available by turning on MTA debugging, setting `mta.mm_debug` to at least 3, and setting dkim-related `base.debugkeys` as desired.

New in MS 8.1, when a "*" is specified an additional check is made to see if a `DKIM_SIGN_DOMAINS` mapping exists. If it does it is consulted with a probe of the form:

`source-channel|destination-channel|from-address`

If $Y is specified the result of the mapping is used as the DKIM identity. If $N is specified DKIM signing is disabled.

For example, a mapping that would cause the foo.example.com subdomain to be signed with the bar.example.com identity, all other subdomains of example.com to be signed with the example.com identity, and example.com without a subdomain not to be signed would look like:

```
DKIM_SIGN_DOMAINS

  *|*|*@foo.example.com   bar.example.com$Y
  *|*|*@*.example.com     example.com$Y
  *|*|*@example.com       $N
```

The optional selector value given by the `destinationdkimselectorN` options specify a space-separated list of selectors that may be used. The newest key associated with the identity will be used if no selector is specified.

Note that `CONVERSION` mappings can also specifify DKIM identity and selector values. If multiple values for the same slot are specified the `CONVERSION` mapping value will override any destination channel value, which in turn will override any source channel value.

46.3.10 Error interpretation channel options

A couple of channel options override general MTA option settings regarding error interpretation.

46.3.10.1 Error interpretation (`usepermanenterror`, `usetemporaryerror`)

The `usepermanenterror` and `usetemporaryerror` source channel options override, on a per-source-channel basis, the `use_permanent_error` and `use_temporary_error` MTA options, respectively.

46.3.11 File creation in the MTA queue area channel options

Several channel options can affect the creation of message files in the MTA queue area.

IMPORTANT NOTE: The various MTA queue directories are reserved for use by Oracle software only. Customers MUST NOT create files in these areas.

46.3.11.1 Addresses per message copy (`multiple`, `addrsperfile`, `single`, `single_sys`)

The MTA allows multiple destination addresses to appear in each queued message copy. Some channel programs, however, may only be able to process messages with one recipient per copy, or with a limited number of recipients, or with a single destination system per message copy. For example, the SMTP client programs for TCP/IP channels only establish a connection to a single remote host in a given transaction, so only addresses to that host can be processed (this despite the fact that a single TCP/IP channel is typically used for all outbound Internet message traffic). Another example is that some SMTP servers may impose a limit on the number of recipients they can handle at one time, and they may not handle errors in this area at all gracefully.

The channel options `multiple`, `addrsperfile`, `single`, and `single_sys` can be used to control how the MTA handles multiple addresses. `single` means that a separate copy of the message should be created for each destination address on the channel. `single_sys` creates a single copy of the message for each destination system (more precisely, each destination domain name) associated with a recipient address. `multiple` creates a single copy of the message for the entire channel. Note that at least one copy of each message is created for each channel the message is queued to, regardless of the options used. `multiple` is the default for all channels marked with the `nosmtp` channel option. Channels marked with one of the `smtp*` channel options default to `single_sys` unless the `daemon` option has been set. Prior to 7.0 channels marked with one of the LMTP options defaulted to `multiple`, as of 7.0 they also default to `single_sys` unless `daemon` has been set. (Actually, calling this the "default" is something of a misnomer - without `daemon` SMTP and LMTP channels will be forced to `single_sys` regardless of the channel setting. This is done to prevent delivery of messages to the wrong system and possibly to the wrong user.)

These options also affect the Job Controller's "sorting" and organization of messages on a channel. The `single_sys` option causes the Job Controller to organize messages into separate internal lists based on destination domain. (And hence a command such as `imsimta qm messages` will show messages sorted by destination host.)

The `addrsperfile` channel option is used to put a limit on the maximum number of recipients that can be associated with a single message file in an MTA channel queue, thus limiting the number of recipients that will be processed in a single operation. This option requires a single integer argument specifying the maximum number of recipient addresses allowed in a message file; if this number is reached the MTA will automatically create additional message files to accomodate them.

Note that the default of `addrsperfile` depends on the channel type. For most channel types, `addrsperfile` defaults to effectively unlimited (2147483647), but setting an `smtp*` option on a channel causes `addrsperfile` to default to 99, while setting an `lmtp*` option on a channel causes `addrsperfile` to default to 999.

The default messages per channel copy setting varies by channel type. The `multiple` option is the default for everything except `tcp_*` channels. `tcp_*` channels default to `multiple` if `daemon` is set, and `single_sys` if it is not. The combination of an explicit `multiple` and no `daemon` isn't allowed on `tcp_*` channels and will be overridden by forcing a setting of `single_sys`.

46.3.11.2 Expansion of multiple addresses (`expandlimit`, `expandchannel`, `holdlimit`)

Most MTA channels support the specification of multiple recipient addresses in the transfer of each inbound message. The specification of many recipient addresses in a single message may result in delays in message transfer processing ("on-line" delays). In particular, multi-recipient messages that require a great deal of processing of the message body can be affected by processing delays, or that require creation of many different file copies on disk in the MTA queue area can be affected by slow disk performance. If the resulting delays are long enough, network timeouts can occur, which in turn can lead to repeated message submission attempts and other problems.

The MTA provides a special facility to force deferred ("off-line") processing of additional recipient message copies once a given number of addresses are specified for a single message. The deferral happens after processing of the "initial" recipients (those before the `expandlimit` value was reached), and after address processing for the additional recipients too, (for instance, after `*_ACCESS` mapping table checks and after alias processing), but before message processing. In particular, such deferral means that for the "additional" recipients, only *one* message file (storing all of the "additional" recipients), is written to the queue area (to a `reprocess*` or `process*` channel queue area, depending upon use of the `expandchannel` channel option). Deferral of message processing can decrease on-line delays enormously. Note, however, that the processing overhead is deferred, not avoided completely.

This special facility is activated by using a combination of, for instance, the generic reprocessing channel and the `expandlimit` channel option. The `expandlimit` option takes an integer argument that specifies at what number of recipients to begin deferring processing of the message copy (or copies) to that and additional recipient addresses. The default value is effectively infinite if the `expandlimit` channel option is not specified. A value of 1 will force deferred processing on all incoming addresses from the channel.

The `expandlimit` channel option must *not* be specified on the local channel or the reprocessing channel itself; the results of such a specification are unpredictable.

The channel actually used to perform the deferred processing may be specified on a per-source-channel basis using the `expandchannel` channel option; the reprocessing channel is used by default, if `expandchannel` is not specified, but use of some other reprocessing or processing channel may be useful for some purposes. In particular, for Messaging Server MTA versions 5.2 and earlier, typical configuration usage required that a processing channel, rather than a reprocessing channel, be used. If a channel for deferred processing is specified via `expandchannel`, that channel should be a reprocessing or processing channel; specification of other sorts of channels may lead to unpredictable results.

The reprocessing channel, or whatever channel is used to perform the deferred processing, must be added to the MTA configuration file in order for the `expandlimit` option to have any effect. If your configuration was built by the initial configuration utility, then you should already have a reprocessing channel.

(Note that typical Messaging Server sites running version 5.2 or earler could not use the `expandlimit` option unless they also marked the affected channel `expandchannel process` (or `expandchannel process_somethingorother` redirecting the expansion to an alternate `process_*` sort of channel), as enqueues to a channel marked `viaaliasrequired` would not succeed if deferred to a `reprocess*` channel.)

Extraordinarily large lists of recipient addresses are often a characteristic of so-called SPAM---junk e-mail. The `holdlimit` channel option tells the MTA that messages coming in the

channel that result in more than the specified number of recipients should be marked as `.HELD` messages and enqueued to the `reprocess` channel (or to whatever channel is specified via the `expandchannel` channel option). As `.HELD` messages, the files will sit unprocessed in that MTA queue area awaiting manual intervention by the MTA postmaster.

46.3.11.3 Using multiple subdirectories to store queued messages (`subdirs`)

The MTA by default spreads all messages queued to a channel across 20 subdirectories. However, a channel which handles a large number of messages and tends to build up a large store of message files waiting for processing, *e.g.*, a TCP/IP channel, may get better performance out of the file system if those message files are spread across even more subdirectories. The `subdirs` channel option provides this capability: it accepts an integer argument which specifies the number of subdirectories across which to spread messages for the channel. The allowed range of integer values is 1 through 999. The default value is 20.

To disable the use of subdirectories for channel queues, use the `nosubdirs` keyword.

46.3.12 Gateway or firewall or mailhub channel options

There are a number of channel options of particular interest when configuring channels intended to communicate with gateway, firewall, or mailhub systems.

46.3.12.1 Force "detour" routing of hosted users (`aliasdetourhost`, `aliasoptindetourhost`)

The (new in iMS 5.2p2, and MS 6.1) `aliasdetourhost` channel option allows source-channel-specific overriding of hosted users' `mailHost` attribute value. In particular, `aliasdetourhost` is commonly used to achieve a "detour" in the routing of messages destined for local (hosted on this system) users. It allows better configuration and use of "intermediate filtering" sorts of channels and third party filtering hosts.

The `aliasdetourhost` channel option takes a single host/domain name as an argument. When specified on a source channel, this channel option causes alias expansion of addresses stored in LDAP to stop (short-circuit) just prior to the point where `mailHost` (more precisely, the attribute named by the `ldap_mailhost` MTA option) information is checked. The host specified by the `aliasdetourhost` channel option is used as the (assumed to be non-local) `mailHost`. That is, a source route containing the specified host is added to the address (just as if a non-local `mailHost` had been found) and processing continues onward from that point. Note that in particular, this forced use of the `aliasdetourhost` specified host as a non-local `mailHost` stops further expansion of the alias for purposes of things such as application of user forwarding and Sieve filter application (which normally would occur subsequently during alias expansion when a user's real `mailHost` is this MTA).

Thus use of `aliasdetourhost` on an incoming channel lets the MTA do address validation (check that an incoming address corresponds to a valid user entry), while "delaying" complete expansion and processing (in particular, forwarding and Sieve evaluation) of the valid local recipient addresses. This combination of effects is potentially very useful.

A typical application of this channel option is for purposes of "detouring" messages through a special channel or host, most often for purposes of spam/virus filtering. It is often used in conjunction with use of an "alternate" conversion channel for such "detour" purposes, where

the "alternate" conversion channel approach is used to handle cases of non-local recipient addresses, while `aliasdetourhost` is used to handle cases of local-to-this-`mailHost` recipient addresses. (Use of an "alternate" conversion channel approach for a routing "detour" on local-to-this-`mailHost` recipient addresses incurs various problems, in particular in the areas of forwarding and Sieve filter evaluation timing. It is desirable to delay Sieve filter evaluation until after the "detour" - for instance, so that Sieve filters can look for headers added by the "detour" host. It is also desirable to delay application of user forwarding until after the "detour", to avoid potential duplication of the forwarding. Such a delay in the final parts of user alias expansion is exactly what `aliasdetourhost` can be used to achieve.)

The (new in MS 6.2p4) `aliasoptindetourhost` option has the same function as `aliasdetourhost`, except that it only applies for users in LDAP who have "opted-in" via whatever user attribute is named by the `ldap_detourhost_optin` MTA option, or whatever domain attribute is named by the `ldap_domain_attr_detourhostoptin` MTA option. The argument of the `aliasoptindetourhost` channel option specifies a list of detour hosts separated by commas. The value(s) of the optin attribute are compared with the list; the first match will be used as the "override" `mailHost` for any users who are "opted-in". However, any attribute that doesn't contain at least one period (which would be necessary to match a legitimate mail host) is treated as an effective wildcard; the first host from the list will be used in this case.

Finally, if the option value matches the special value specified by the `aliasdetourhost_null_optin` MTA option it will simply be ignored. This mechanism is provided to accomodate provisioning systems that insist on every known attribute having a value. Omitting the attribute value entirely is the preferred method for disabling detour processing, however.

One disadvantage of using `aliasoptindetourhost` is that all alias expansion is deferred, including expansions that result in mail being discarded. This can lead to messages sent to the bitbucket wasting processing resources.

One way to work around this problem is to use a `$*` rewrite rule and an associated mapping to direct such addresses to the bitbucket channel, bypassing any use of aliasdetourhost. For example:

```
$*              $E$F${bitbucket_check,$U$@$H}

BITBUCKET_CHECK

  noreply@example.com     $Y$$U%$$H@bitbucket-daemon
  unattended@example.net  $Y$$U%$$H@bitbucket-daemon
```

This will caused any mail sent to noreply@example.com and unattended@example.net to be discarded before any other lookups or redirection.

46.3.12.2 Clone messages to alternate destination (`clonehosts`)

(New in MS 8.0) A commonly requested capability is to "clone" all messages that meet some criteria and send them to an alternate destination. This can be accomplished in a variety of ways, including the Sieve "`capture`" action, the `MESSAGE-SAVE-COPY` mapping, the `FORWARD` mapping, and various sorts of address rewriting tricks, and all of these mechanisms have different characteristics as well as different advantages and disadvantages.

In the specific case when the desire is to clone all messages sent to a particular channel to another channel while preserving the initial address that expanded to that channel, none of the previously mentioned methods provide that specific result. (A `capture` action in a destination channel Sieve script can capture the message, but not the initial address. `MESSAGE-SAVE-COPY` has similar limitations and also requires playing queue management games.)

The `clonehosts` channel option provides this result. It accepts a single argument: A space-separated list of host names. When given a `clonehosts` setting of "*`host1 host2 host3`*" and a message sent to the addresses *`initial1`* and *`initial2`*, both of which expanded to one or more final recipient addresses destined to that channel, this setting will add the recipient addresses:

```
@host1:initial1
@host2:initial1
@host1:initial2
@host2:initial2
```

46.3.12.3 Forced routing to gateways (daemon)

The interpretation and usage of the `daemon` channel option depends upon the type of channel to which it is applied. Currently, the only type of channel for which the `daemon` option is relevant is SMTP over TCP/IP channels. Normally such channels connect to whatever host is listed in the envelope address of the message being processed. The `daemon` option is used to tell the channel to instead connect to a specific remote system, generally a firewall or mailhub system, regardless of the envelope address. The actual remote system name is given as an argument to `daemon`, *e.g.*:

```
msconfig> set channel:tcp_firewall.daemon firewall.domain.com
```

If the argument after the `daemon` option is not a fully qualified domain name (or alternatively a square bracket enclosed literal IP address), the argument will be ignored and the channel will connect to the channel's official host. When specifying the firewall or gateway system name as the channel's official host name, `channel:channel-name.official_host_name`, the argument given to the `daemon` option is typically specified as `router`, *e.g.*:

```
msconfig> show channel:tcp_firewall
role.channel:tcp_firewall.official_host_name = firewall.domain.com
role.channel:tcp_firewall.daemon = router
role.channel:tcp_firewall.mx (novalue)
role.channel:tcp_firewall.pool = SMTP_POOL
role.channel:tcp_firewall.smtp (novalue)
```

46.3.12.4 Specify a last resort host for delivery (lastresort)

The `lastresort` channel option is used to specify a host to which to connect when all other connection attempts fail. In effect this acts as an MX record of last resort. This is only useful on SMTP over TCP/IP channels.

Note that the `lastresort` host is attempted only for hosts that are in the DNS, having either MX records or an A record, and for whom the connection attempts to all the MX records -- or to the A record, if there were no MX records---have encountered temporary connection

failures. (In particular, the `lastresort` host will not be attempted for a host that is only in the hosts file, not in the DNS at all. Also keep in mind that a permanent 5xx error in response to a connection attempt to a host is a permanent error, and will result in bouncing a message; in particular, the `lastresort` host will not be attempted after such a permanent rejection error. Also, the `lastresort` host will not be attempted if a connection succeeds, but the MTA's wait for an SMTP banner line to be returned times out; that again is not a temporary *connection* failure.)

This channel option requires a single parameter specifying the name of the "system of last resort".

See also the `IP_ACCESS` mapping table, which can provide an alternate way of doing "fail over" for outbound IP connections for SMTP and LMTP channels.

Note that in most cases, it is preferable to fix problematic DNS records rather than to use `lastresoft`; `lastresort` is intended merely for a few, special sorts of cases where correcting DNS records may not be possible, yet some "last ditch", MX-like, re-routing may be useful.

46.3.12.5 Multiple gateways on a single channel (`multigate`, `nomultigate`)

The `multigate` channel option tells the MTA to perform an additional rewrite of the envelope To: address during message dequeue processing in order to determine the host to connect to for message delivery. This differs from the MTA's normal behavior when the `multigate` channel option is not used, in which case the MTA routes the message to whatever host is specified using the `daemon` channel keyword, and to the *not* the host specified in the message's To: address if `daemon` is not set.

`nomultigate` is the default.

The recipient address is rewriten as if it were a forward-pointing header address, so `$B$F` is typically used in rewrite rule templates intended to only apply during this specific rewrite operation.

There are a variety of caveats associated with using the `multigate` channel option; some of its former uses are now obsolete. The remaining usage is on LMTP channels.

46.3.12.6 `user` Option Under channel

The `user` channel option is used on pipe channels to indicate under what Unix user id to run.

In the 8.0 release and later, this option is deprecated and the `pipeuser` option from `restricted.cnf` is used instead.

46.3.13 Headers channel options

There are a number of channel options especially relevant regarding header line processing and handling; those channel options relating to header line processing *other* than address handling in header lines are listed here. Note that channel options that relate more to general address handling (including address handling in headers) are instead listed primarily under Addresses channel options.

46.3.13.1 Adding Return-path: header fields (addreturnpath, noaddreturnpath)

When specified on a destination channel, the addreturnpath channel option causes the MTA to add a Return-path: header field and possibly an Original-recipient: header field to all messages enqueued to the channel. noaddreturnpath disables this feature.

The Return-path: header field will contain the current envelope from (SMTP MAIL FROM) address enclosed in angle brackets. The Original-recipient: header field will contain the value of any SMTP ORCPT parameter associated with the message's recipient(s). Original-recipient: header fields are only generated when all recipients of the current copy of the message have the same ORCPT value.

Note that the addition of Return-path: and Original-recipient: header fields is usually a function of a final delivery agent (such as a final delivery channel). Most final delivery channels know to add these header fields themselves. But for the convenience of some channels such as the ims-ms channel, where adding a Return-path: header line in the channel program itself is not convenient, the MTA is also capable of adding the Return-Path: header itself if configured to do so via this channel option.

The addreturnpath channel option is the default on the ims-ms channel and any channel marked with one of the lmtp* channel options; noaddreturnpath is the default for all other channels.

46.3.13.2 Authenticated originator information processing (authrewrite)

The authrewrite option may be used on a source channel to have the MTA propagate authenticated originator information, if available, into the headers. Normally the SMTP AUTH information is used (specifically, the user's canonical e-mail address, that is, the value of the mail attribute or new in MS 8.0 the value of whatever attribute is named by the ldap_auth_attr_sender MTA option, found when looking up the user for authentication), though this may be overridden via the FROM_ACCESS mapping. authrewrite takes a required bit-encoded integer value as an argument, according to the following table:

Table 46.9 authrewrite option values

Bit	Value	Usage
0-3	1	Add a Sender: header line, or a Resent-sender: header line if a Resent-from: or Resent-sender: was already present, containing the AUTH originator
0-3	2	Add a Sender: header line containing the AUTH originator
0-3	3	Use the AUTH_REWRITE mapping table, probing with any Resent-Sender: and Resent-From: info if present, and otherwise probing with Sender: and From: info
0-3	4	Use the AUTH_REWRITE mapping table, probing with Sender: and From: info
0-3	5	Add a From: header line, or a Resent-From: header line if a Resent-From: or Resent-Sender: was already present, containing the AUTH originator. This is **NOT RECOMMENDED** and **CONTRARY TO INTERNET STANDARDS**, and likely to **HARM** the security of your users. This option should almost **NEVER** be used: **THIS MEANS YOU!**.
0-3	6	Add a From: header line containing the AUTH originator. This is **NOT RECOMMENDED** and **CONTRARY TO INTERNET STANDARDS**, and likely to **HARM** the security of your users. This option should almost **NEVER** be used: **THIS MEANS YOU!**.
4	16	(New in 6.2) If set, apply the AUTH_REWRITE mapping table, even if SMTP AUTH has not been used
5	32	(New in 6.2) If set, probes to AUTH_REWRITE include the source-channel as a prefix field, separated by a vertical bar character from the rest of the probe string; that is, when this bit is set then probes take the form:

		src-chan|*env-from*|*[resent-]sender*|*[resent-]from*|*auth-originator*
6	64	(New in 7.2-7.02.) If set, use the rewritten version of the envelope from address in constructing the AUTH_REWRITE probe.
7	128	(New in 7.2-7.02.) If set, use the canonical version of the envelope from address in constructing the AUTH_REWRITE probe. Bit 6 (value 64) is a no-op if this bit is set.
8	256	(New in 7.3-11.01.) If set, add the value of the AUTH parameter from the SMTP MAIL FROM command to the AUTH_REWRITE probe, appearing just after the authorized originator address; that is, when this bit is set then probes take the form *env-from*|*[resent-]sender*|*[resent-]from*|*auth-originator*|*auth-param*
9	512	(New in MS 7.0.5) If set, the final tag set via $T in the *_ACCESS mappings will be prefixed to the AUTH_REWRITE mapping probe; that is, when this bit is set then probes take the form: *ACCESS-tag*|*env-from*|*[resent-]sender*|*[resent-]from*|*auth-originator*

46.3.13.3 Comments in address message headers (commentinc, commentmap, commentomit, commentstrip, commenttotal, sourcecommentinc, sourcecommentmap, sourcecommentomit, sourcecommentstrip, sourcecommenttotal)

The MTA only interprets the contents of header lines when necessary. However, all registered headers containing addresses must be parsed in order to rewrite and eliminate shortform addresses and otherwise convert them to legal addresses. During this process comments (strings enclosed in parentheses) are extracted and may optionally be modified or excluded when the header line is rebuilt.

On destination channels, this behavior is controlled by the use of the commentinc, commentmap, commentomit, commentstrip, and commenttotal channel options. commentinc tells the MTA to retain comments in header lines. It is the default. commentmap tells the MTA to apply the COMMENT_STRINGS mapping table to comments in addressing header lines if such a mapping table exists, while if no such mapping table exists then commentmap is equivalent to commentstrip. commentomit tells the MTA to remove any comments from addressing headers, *e.g.*, To:, From:, Cc: headers, *etc*. commenttotal tells the MTA to remove any comments from all headers, except Received: headers; as such, this option is not normally useful or recommended. And finally, commentstrip tells the MTA to strip any nonatomic characters from all comment fields.

On source channels, this behavior is controlled by the use of the sourcecommentinc, sourcecommentmap, sourcecommentomit, sourcecommentstrip, and sourcecommenttotal channel options. sourcecommentinc tells the MTA to retain comments in header lines. It is the default. sourcecommentmap tells the MTA to apply the COMMENT_STRINGS mapping table to comments in incoming addressing header lines if such a mapping table exists, while if no such mapping table exists then sourcecommentmap is equivalent to sourcecommentstrip. sourcecommentomit tells the MTA to remove any comments from addressing headers, *e.g.*, To:, From:, Cc: headers, *etc*. sourcecommenttotal tells the MTA to remove any comments from all headers, except Received: headers; as such, this option is not normally useful or recommended. And finally, sourcecommentstrip tells the MTA to strip any nonatomic characters from all comment fields.

These options can be applied to any channel.

46.3.13.4 Two or four digit date conversion (datefour, datetwo)

The original RFC 822 specification called for two digit years in the date fields in message headers. This was later changed to four digits by RFC 1123. However, some older mail systems

cannot accommodate four digit dates. In addition, some newer mail systems can no longer tolerate two digit dates! (Please note that systems which cannot handle both formats are in violation of the standards.)

The `datefour` and `datetwo` channel options control the MTA's processing of the year field in message header dates. `datefour`, the default, instructs the MTA to expand all year fields to four digits. Two digit dates with a value less than 50 will have 2000 added while values greater than 50 will have 1900 added.

`datetwo` instructs the MTA to remove the leading two digits from four digit dates. This is intended to provide compatibility with incompliant mail systems that require two digit dates; it should never be used for any other purpose.

46.3.13.5 Day of week in date specifications (dayofweek, nodayofweek)

The RFC 822 specification allows for a leading day of the week specification in the date fields in message headers. However, some systems cannot accomodate day of the week information. This makes some systems reluctant to include this information, even though it is quite useful information to have in the headers.

The `dayofweek` and `nodayofweek` channel options control the MTA's processing of day of the week information. `dayofweek`, the default, instructs the MTA to retain any day of the week information and to add this information to date/time headers if it is missing.

`nodayofweek` instructs the MTA to remove any leading day of the week information from date/time headers. This is intended to provide compatibility with incompliant mail systems that cannot process this information properly; it should never be used for any other purpose.

46.3.13.6 Host name to use when correcting incomplete addresses (`authhost`, `noauthhost`,`defaulthost`, `nodefaulthost`, `remotehost`, `noremotehost`)

The MTA often receives addresses consisting of a bare local-part and no "@domain" from misconfigured or incompliant mailers and SMTP clients. (Note that the standards do in fact require acceptance of one special address - "postmaster" in SMTP, but do not state how such an address is to be represented in a message header.) This happens often enough that simply disallowing such addresses is rarely an acceptable strategy.

The MTA, showing at least some respect for standards, must attempt to make such addresses legal before passing the message along. The MTA does this by appending a domain name to the address (*e.g.*, appends "@acme.com" to "mrochek", producing "mrochek@acme.com").

The set of options described here control how this domain name is selected. In this process the MTA makes a distinction between envelope To (RCPT TO) addresses versus addresses appearing in all other contexts (header, MAIL FROM), as well as distinguishing SUBMIT from SMTP.

In the following table showing what domain is used when various options or protocols are used, *o.org* is the domain attached to the local channel, *a.com* is the domain associated with the current authenticated user's primary email address, *l.com* is the first argument of the `defaulthost` option setting on the current source channel, *r.com* is the second argument

of the `defaulthost` option setting on the current source channel, and *r.edu* is the domain associated with the remote SUBMIT/SMTP client.

Table 46.10 Options controlling missing domain fixups

Option	Protocol	Header/ MAIL FROM	RCPT TO
`authhost` (and authenticated)	SUBMIT/SMTP	@a.com	@a.com
`defaulthost`	SUBMIT/SMTP	@o.org	@o.org
`defaulthost` *l.com*	SUBMIT	@l.com	@l.com
`defaulthost` *l.com*	SMTP	@l.com	@o.org
`defaulthost` *l.com r.com*	SUBMIT	@l.com	@l.com
`defaulthost` *l.com r.com*	SMTP	@l.com	@r.com
`nodefaulthost` (MS 8.0.2.1 or later)	SUBMIT/SMTP	<no fixup>	<no fixup>
`remotehost`	SUBMIT	@r.edu	@r.edu
`remotethost`	SMTP	@r.edu	@o.org
<no options>	SUBMIT/SMTP	@o.org	@o.org

Note: The option in the preceding table are shown in precedence order, that is, a given option setting will override option settings further down the table.

The usual configuration is to have both arguments to `defaulthost` set to the `defaultdomain` on the defaults channel, overriding any use of the local channel host. It may be appropriate in multitenant configurations to set `authhost` on all channels that are marked with the `submit` channel option

Use of the `remotehost` channel option may be considered in rare cases where remote SMTP client exist in another administrative domain which partial addresses to refer to their own users.

Note that rewrite rules can make use of whatever default has been selected via the the `$G` and `$`*`n`*`G` substitutions.

Note that the `switchchannel`, `saslswitchchannel`, `tlsswitchchannel` and various other options can be used to associated incoming SMTP connections with a particular channel, and thus control what set of options are used.

46.3.13.7 Strip illegal blank recipient headers (`dropblank`, `nodropblank`)

In RFC 822 messages, any To:, Resent-To:, Cc:, or Resent-Cc: header is required to contain at least one address - such a header may not have a blank value. Nevertheless, some mailers may emit such illegal headers. The `dropblank` channel option, if specified on a source channel, causes the MTA to strip any such illegal blank headers from incoming messages. `nodropblank` disables this action and is the default.

46.3.13.8 Envelope tunneling via header fields (`envelopetunnel`))

The `envelopetunnel` channel option controls the transfer of envelope information to and from special header fields defined for this purpose. The use of these fields provides a means of tunneling information associated with various SMTP extensions through systems that do not support the extensions. The option's value is a bit-encoded integer, with each bit controlling a different header field and associated piece of envelope information. Setting the bit enables tunneling; clearing it disables it.

The default value of this option is 0, meaning all tunneling is disabled. Setting the option to -1 enables all available tunneling capabilities.

At present only one bit is defined: Bit 0 (value 1) controls the use of the MT-Priority: header line as a means of tunneling the message's MT-PRIORITY value. The syntax and use of the field are specified in RFC 6758 (Tunneling of SMTP Message Transfer Priorities).

46.3.13.9 Header-based message expiration(`expirysource`, `expirysource`)

(New in Messaging Server 7.0.) The `expirysource` channel option instructs the MTA to honor Expiry-date: header fields - messages will be returned as undeliverable if the time specified by this header field is exceeded. `noexpirysource` disables this check and is the default.

46.3.13.10 Syntax Error Fixup (`fixsyntaxerrors`, `passsyntaxerrors`)

The MTA normally attempts to fix common syntax errors when it processes message header fields. It is sometimes useful to disable this behavior so certain syntax errors aren't corrected. The `passsyntaxerrors` source channel keyword enables this behavior. `fixsyntaxerrors` is the default.

At present disabling syntax error fixup is limited to header fields containing addresses and message ids. This may be extended to include other types of fields in the future.

Important note: Many other agents depend on syntax error fixup by the MTA. Disabling it may fix some problem but cause unexpected side effects. It is always preferable to fix whatever is generating the syntax errors so it doesn't do that any more.

46.3.13.11 Received: from clause content (`forcedreceivedfrom`))

(New in 7.0.5.37) The `forcedreceivedfrom` source channel option is used to specify the text string that appears as the *`source`* within the "`from` *`source`*" clause value in any Received: header fields that are generated. The default, if `forcedreceivedfrom` is not specified, is for the "`from`" clause value to be generated in the usual way from the value of the remote client's HELO/EHLO command and its IP address.

Specifying an empty string as the `forcedreceivedfrom` value causes the "`from`" clause to be suppressed. Note that the "`from`" clause is required by the Received: field syntax specified in RFC 5321 but is optional in the syntax specified in RFC 822.

46.3.13.12 Location of message header (`headerbottom`, `headerinc`, `headeromit`)

VMS MAIL only provides support for four message header lines: From:, To:, Cc: and Subject:. However, RFC 822 headers can contain many additional types of header lines. On OpenVMS systems, PMDF supports these additional header lines by optionally prepending or appending them to the message body whenever a message is delivered to a local user.

This behavior is controlled by the use of the `headerinc`, `headeromit`, and `headerbottom` channel options. The default is `headerinc`, which tells PMDF to prepend the header lines to the message. On OpenVMS systems, the channel option `headerbottom`, which tells PMDF to append the header lines to the end of the message, and `headeromit`, which tells PMDF to strip all header lines, are also available.

In some rare cases an SMTP server is used to deliver message content to something other than a proper mail user agent. Under these very rare circumstances it may be appropriate to omit header information or to place it at the end of the message, so these channel options are also supported for SMTP channels.

Extreme care should be taken not to use these options on channels connecting to other message handling systems --- relocating or eliminating message headers violates RFC 821 and RFC 822 and can lead to serious problems. Note also that many seemingly "bothersome" header lines may contain valuable information required to decode messages, track down problems, or even authenticate who really sent the message and thus thwart attempts at forging mail messages.

46.3.13.13 Cutting header to fit (`headercut`)

The `headercut` channel option cuts the current message header down to no more than the specified number of bytes using a heuristic algorithm that removes or truncates header fields based on their relative importance. Unlike `headertrim`, which should be used to deal with issues of the mere presence, or the number, or the size, of specific header fields, `headercut` is intended for use to meet constraints on overall header size.

The `headercut` option requires a single nonnegative integer argument. A value of 0, the default, disables header cutting.

46.3.13.14 Controlling Sender Rewriting Scheme (SRS) rewriting in header lines (`headerdecodesrs`, `noheaderdecodesrs`)

New in 8.0.1.3. The `headerdecodesrs` channel option, if set on the current source or destination channel, causes any SRS-encoded addresses found in any address header fields to be decoded. The decoding in this case does not enforce password or timeout checks; it is sufficient that the SRS domain match for decoding to occur.

The default is `noheaderdecodesrs`.

46.3.13.15 Header alignment and folding (`headerfoldpreserve`, `headerfoldremove`, `headerlabelalignment`, `headerlineincrement`, `headerlinelength`)

The `headerlabelalignment` channel option controls the alignment point for message headers enqueued on this channel; it takes an integer-valued argument. The alignment point is the margin where the contents of headers are aligned. For example, sample headers with an alignment point of 10 would appear as follows:

```
To:      ned@innosoft.com
From:    kristin@innosoft.com
Subject: Alignment test
```

The default `headerlabelalignment` is 0, which causes headers not to be aligned.

The `headerlinelength` channel option controls the length of message header lines enqueued on this channel. The default, if this channel option is not explicitly set, is 80. Lines longer than this are folded in accordance with RFC 822 folding rules. Note that `headerlinelength` applies to all header lines; when some header lines should get different folding points than other header lines, then see instead the LINELENGTH header trimming option.

The MTA attempts to fold the lines at or before the length specified by `headerlinelength`, but if no suitable folding point can be found, then the length is adjusted by `headerlineincrement`. `headerlineincrement` takes a required non-negative integer argument. Only values between (inclusive) 1 and 100 are permitted; note that setting values that diverge dramatically from the default value of 20 may result in problematic behavior.

Note that these channel options only control the format of the headers of the message in the message queue; the actual display of headers is normally controlled by the user agent. In addition, headers are routinely reformatted as they are transported across the Internet, so these channel options may have no visible effect even when used in conjunction with simple user agents that do not reformat message headers.

Whether the MTA attempts to preserve "original" fold points in folded header lines when practicable, or whether the MTA automatically unfolds and then later re-folds header lines, is controlled by the `headerfoldremove` and `headerfoldpreserve` channel options. These options apply to source channels.

`headerfoldremove` is the default; it means that the MTA unfolds all incoming header lines when first receiving a message (and then refolds when outputting header lines, at fold points chosen in accordance with the `headerlinelength` channel option or LINELENGTH header trimming option).

The `headerfoldpreserve` channel option tells the MTA to attempt to preserve "original" fold points in header lines. Note that fold points in addressing header lines (such as To:, Cc:, Bcc:, *etc.*) are not preserved by this channel option, nor are fold points in date header lines or MIME header lines. This keyword instead affects primarily text header lines such as the Subject: header line. When this option is used, it is usually most appropriate to also set `headertrailingpreserve`; that is, when attempting to preserve original fold points, typically one also wants to preserve all original white space, including trailing white space, that might be present in the header line. However, note that enabling the `headerfoldpreserve` channel option causes any originally present horizontal tab characters to be converted to space characters, except that immediately after each fold point a horizontal tab character will be used as the initial linear white space character (regardless of whether the original white space character was a tab or a space).

Note that various aspects of this sort of header line processing can be testing using the `test -header` utility.

Note that message bodies are potentially subject to MIME encoding to ensure transport-safe line length, as controlled by the `linelength` channel option; such message body encoding is separate and distinct from (and happens after) the header line processing discussed here.

46.3.13.16 Trimming message header lines (`headertrim`, `noheadertrim`, `headerkeeporder`, `headerread`, `noheaderread`, `innertrim`, `noinnertrim`)

The MTA provides per-channel facilities for trimming or removing selected message header lines from messages. This is done through a combination of a channel option and an associated header option file or two. The `headertrim` channel option instructs the MTA to consult a header option file associated with the channel and to trim the headers on messages queued to that destination channel accordingly, *after the original message headers are processed*. The `noheadertrim` option bypasses header trimming, but does cause the MTA to re-order header lines according to its internal header line order defaults (plus any configured ordering rules). New in MS 6.3 is the `headerkeeporder` channel option, which (making use of new MTA header line handling) preserves whatever header line ordering was present in the message as enqueued. `noheadertrim` was the default in MS 6.2 and earlier; as of MS 6.3, `headerkeeporder` is the default.

The `innertrim` channel option instructs the MTA to perform header trimming on inner message parts, *i.e.*, embedded MESSAGE/RFC822 parts, as well. Note that setting `innertrim` overrides `headerkeeporder`, causing at a minimum `noheadertrim` effect (that is, potential re-ordering of header lines). The `noinnertrim` channel option, which is the default, tells the MTA not to perform any header trimming on inner message parts.

The `headerread` channel option instructs the MTA to consult a header option file associated with the channel and to trim the headers on messages enqueued by that source channel accordingly, *before the original message headers are processed*. Note that `headertrim` header trimming, on the other hand, is applied after the messages have been processed, and is destination channel, rather than source channel, related. The `noheaderread` channel option bypasses message enqueue header trimming. `noheaderread` is the default.

Unlike the `headeromit` and `headerbottom` options, the `headertrim` and `headerread` options may be applied to any channel whatsoever. Note, however, that stripping away vital header information from messages may cause improper MTA operation. Be extremely careful when selecting headers to remove or limit. This facility exists because there are occassional situations where selected header lines must be removed or otherwise limited. *Do not merely trim header lines away because you or your users find them annoying --- those header lines are there for a reason. More often than not, the header lines that users feel are superfluous are among the most important. Before trimming or removing any header line, be sure that you understand the usage of that header line and have considered the possible implications of its removal.*

Header options files for the `headertrim` and `innertrim` channel options have names of the form `channel_headers.opt` with `channel` the name of the channel with which the header option file is associated. Similarly, header options files for the `headerread` channel option have names of the form `channel_read_headers.opt`. See Header option files for information on the format of these files.

Note that as of MS 6.3, the MTA supports the Sieve`editheader` extension, which offers quite a different way to modify message header lines.

46.3.13.17 Limiting header storage (`headerlimit`)

The MTA stores outermost message headers in memory. This means that a single extremely large header could potentially consume all available memory, possibly leading to a denial of service attack. When placed on a source channel, the `headerlimit` channel option provides

a means to prevent such attacks. It accepts a single integer argument specifying the maximum number of MTA blocks that can be consumed by the message header. Messages with headers that exceed this limit will be silently truncated.

Note that the header_limit MTA option can be used to implement the same limit for all channels. The lower of the two option values is used as the actual limit.

The default value for headerlimit is essentially unlimited if the channel option isn't specified. Note, however, that since the default value for the header_limit MTA option is 2000 blocks, the effective default limit on the size of a header if no limiting options are specified is 2000 blocks.

The headerlimit channel option initially appeared in Messaging Server 6.1.

46.3.13.18 Trailing spaces on header lines (headertrailingpreserve, headertrailingremove)

The headertrailingremove and headertrailingpreserve channel options, applicable on source channels, control whether the MTA strips (removes) trailing white space from the ends of physical header lines.

By default (headertrailingremove) the MTA removes trailing white space from the ends of physical header lines; this means both from the ends of logical (unfolded) header lines, and from the ends of folded portions (physical lines) of a single (logical) header line.

The headertrailingpreserve channel option may be used to instead preserve such trailing white space. This may be of particular interest for folded header lines, when it is desired to preserve original, "interior" white space in the logical (unfolded) header line. It is also typically used in conjunction with the headerfoldpreserve channel option.

46.3.13.19 Received: from clause content (includereceivedip, suppressreceivedip))

New in 8.0.1.2. The includereceivedip and suppressreceivedip source channel options control the inclusion of IP address information in generated Received: from clauses. The default is includereceivedip.

46.3.13.20 Inner header rewriting (inner, noinner, sourceinner, nosourceinner)

The MTA only interprets the contents of header lines when necessary. However, MIME messages can contain multiple sets of message headers as a result of the ability to imbed messages within messages (message/rfc822). The MTA normally only interprets and rewrites the outermost set of message headers. The MTA can optionally be told to apply header rewriting to inner headers within the message as well.

This behavior is controlled by the use of the noinner and inner channel options on destination channels and/or the nosourceinner and (new in 8.1.0.1) sourceinner channel options on source channels. noinner and/or nosourceinner tells the MTA there is no special need to rewrite inner message header lines (though inner message header line processing may be triggered by other MTA facilities). It is the default. inner, when placed on a destination channel, or sourceinner, when placed on a source channel, tells the MTA to parse messages and rewrite inner headers.

These options can be applied to any channel.

46.3.13.21 Default language tag (`language`)

Certain MTA operations, especially those involving selection of textual content to send to users, may need to take language into account. For example, nondelivery notification text may be available in multiple languages and the `NOTIFICATION_LANGUAGE` mapping and `DISPOSITION_LANGUAGE` mapping can be used to select the appropriate language to use. The MTA also supports use (and selection amongst) language-tagged values for various `mailAutoReply*` LDAP attributes used to construct vacation messages; see the discussion of the `ldap_autoreply_subject` and `ldap_autoreply_text*` MTA options in particular.

It is axiomatic that in order to make decisions based on language langage tagging information must be available. Normally this information is derived from the message being processed, *e.g.,* from an Accept-language: header field, from a Preferred-language: header field, or even from the country code found in the From: address. However, not all messages contain such information.

The `language` channel option can be used to associaed a default language with a particular source channel. A single string argument is required specifying a language tag. Messages originating from this channel which aren't tagged in any other way will be effectively tagged with this value. The default is not to assume any language tag on a per-channel basis.

46.3.13.22 Detecting the end of the message header (`limitheadertermination`, `relaxheadertermination`)

Message headers consist of a series of fields, each folded onto one or more lines. As a result a header consists of, at the outermost syntactic level, CRLF terminated lines that begin with either one or more whitespace characters or an alphanumeric label followed by a colon. In all cases the header is supposed to be terminated by a CRLFCRLF sequence.

A header line that doesn't meet these syntactic requirement can arise in two different ways: (1) Something emitted a syntactically invalid header line or (2) The CRLFCRLF separator is missing and message content has been elided with the preceding header.

By default, the MTA handles syntactically invalid lines as part of the message content, terminating header processing. Setting the `limitheadertermination` channel option on an incoming (source) channel) will cause the MTA to treat such lines as part of the header and continue header processing.

RFC 822 was ambiguous as to whether a line containing merely white space was allowed in a message header. (RFC 5322 clarifies this by disallowing the generation of such a line in a message header and requiring that it be accepted as part of a header.) By RFC 822 rules, it is ambiguous whether such a line should be interpreted as the end of the message header (interpreted as the "blank" line separating message header from message body), or whether it is merely additional white space from the previous header line "folded" onto a new line.

By default, the MTA only interprets a strict CRLFCRLF sequence as the end of the message header. Setting the `relaxheadertermination` channel option on an incoming (source) channel) will cause the MTA to also interpret lines that contain merely white space (spaces or TABs) as terminating the message header.

`limitheadertermination` is the default, though it did not exist as a distinct channel option prior to MS 7.0.5. (In earlier versions, this default behavior was selected by *not* setting the `relaxheadertermination` channel option.)

46.3.13.23 Automatic splitting of long header lines (`maxheaderaddrs`, `maxheaderchars`)

Some message transports, notably some older sendmail implementations, cannot process long header lines properly. This often leads not just to damaged headers but to erroneous message rejection. Although this is a gross violation of standards it is nevertheless a fairly common problem.

The MTA provides per-channel facilities to split (break) long header lines into multiple, independent header lines. The `maxheaderaddrs` channel option controls how many addresses can appear on a single line. The `maxheaderchars` channel option controls how many characters can appear on a single line. Both channel options require a single integer argument that specifies the associated limit. By default, no limit is imposed on the length of a header line nor on the number of addresses which may appear.

46.3.13.24 Handling messages that lack any recipient headers (`missingrecipientpolicy`)

RFC 822, the original Internet message format standard, had a requirement that all messages contain at least one recipient header field: a To:, Cc:, or Bcc:.

As of RFC 2822, the original update to RFC 822, relaxed the RFC 822 requirement and allowed submitted messages to be lacking in any recipient header line. This change was carried forward to the current message format standard, RFC 5322.

However, there are still MTAs around that operate according to RFC 822, and in particular may try to be helpful by adding a To: field containing all of the envelope recipients when no recipient fields are present. As such, it may be unwise to emit a message lacking all recipient header lines, since the behavior of an RFC 822-compliant MTA or mail user agent may be undesirable when encountering a message that is, from its point of view, illegal---results may include rejection of such a message, potentially undesired exposure of recipient information such as recipients intended as Bcc: recipients, *etc*.

The `missingrecipientpolicy` channel option provides various capabilities that may be useful in addressing this issue. It takes an integer value specifying what approach to use to "fix" messages with no recipient field; the default value, if the channel option is not explicitly present, is to use the MTA option `missing_recipient_policy` value (which itself defaults to 0, if not set, which as of MS 6.2 is equivalent to a value of 1 meaning that messages are passed through unchanged---in MS 6.0 and MS 6.1 the default value of 0 had been equivalent to a value of 2 meaning that envelope To addresses are placed in a To: header).

Table 46.11 `missingrecipientpolicy` MTA option values

Value	Action
0	Use current best practices to resolve the situation. Prior to 6.2 this was the same as 2, in 6.2 and later it is the same as 1.
1	Pass the illegal-per-RFC 822 (though legal per RFC 5322) message through unchanged.
2	Place envelope To recipients in a To: header.
3	Place all envelope To recipients in a single Bcc: header.

4	Generate an empty group construct (*i.e.*, ;) To: header line. The phrase used in the group construct is controlled by the `missing_recipient_group_text` MTA option, so for instance "`To: Recipients not specified: ;`".
5	Generate a blank Bcc: header.
6	Reject the message (with a "`554 5.6.0 Error writing message - message is missing required recipient header fields`" error). (Note that the `acceptalladdresses` channel option, if used, modifies the timing and form of the rejection.)

Note that the `missing_recipient_policy` MTA option can be used to set an MTA system default for this behavior.

46.3.13.25 Envelope to address in Received: header (`receivedfor`, `noreceivedfor`, `receivedfrom`, `noreceivedfrom`)

The `receivedfor` channel option instructs the MTA that if a message is addressed to just one envelope recipient, to include that envelope To: address in the Received: header it constructs. In such cases, the envelope To: address will be noted within the Received: header line via a clause of the form:

`for` *`recipient`*

The `receivedfor` channel option is the default. The `noreceivedfor` channel option instructs the MTA to construct Received: headers without including any envelope addressee information.

The `receivedfrom` channel option instructs the MTA to include the original envelope From: address when constructing a Received: header for an incoming message if the MTA has changed the envelope From: address due to, for instance, certain sorts of mailing list expansions; in such cases the original envelope From: address will be noted in the Received: header line via comment of the form

`(original mail from` *`original-envelope-from`*`)`

The `receivedfrom` channel option is the default. The `noreceivedfrom` channel option instructs the MTA to construct Received: headers without including the original envelope From: address.

See also the `[RECEIVEDFOR]`, `[NORECEIVEDFOR]`, `[RECEIVEDFROM]`, and `[NORECEIVEDFROM]` alias file named parameters, or in Unified Configuration, the alias options `alias_receivedfor`, `alias_noreceivedfor`, `alias_receivedfrom`, and `alias_noreceivedfrom`, which all override the channel settings on a per-alias (or per-mailing list) basis.

46.3.13.26 XBCC SMTP Extension Support (`bccserver`, `nobccserver`)

The `bccserver` channel option, when placed on a SUBMIT server channel, enables the XBCC extension. This extension adds a single XBCC argument to the RCPT TO command. When

present, it marks the corresponding recipient as a blind carbon recipient and the MTA will generate a separate message copy to this recipient and add a Bcc: header field to the copy.

The XBCC argument value may optionally be used to specify a phrase which will preceed the recipient address in the Bcc: header field.

The `nobccserver` channel option disables this extension and is the default.

46.3.13.27 Generation of X-Envelope-to: header lines (`x_env_to`, `nox_env_to`)

The `x_env_to` and `nox_env_to` channel options control the generation or suppression of X-Envelope-to: header lines on copies of messages queued to a specific channel. On channels that are marked with the `single` channel option, the `x_env_to` channel option enables generation of these headers while the `nox_env_to` will remove such headers from enqueued messages. The default is `nox_env_to`; (note that this default behavior is a change in PMDF V5.0 from previous versions of PMDF). Note that the fact that `x_env_to` also requires the `single` channel option in order to take effect represents a change of behavior from PMDF V5.1 and earlier.

The (non-standard) X-Envelope-to: header line contains a duplicate of the recipient addresses that appear in the message envelope. The X-Envelope-to: header line for a particular copy of a message contains only the addresses that that particular copy is being sent to; it does *not* contain all the addresses on the header To: line (except in the simplest case where only a single copy of the message is needed). Also note that there can be envelope recipient addresses that are mentioned nowhere in the header due to the use of things like autoforwarders or blind carbon copies.

New in 6.3, the `x_env_to` channel option no longer requires accompanying use of the `single` channel option in order to take effect. If used without `single`, the header will simply contain a comma-separated list of all recipients this copy of the message is intended for. This can be useful in situations where the current recipient list needs to be provided as part of the header to some processing agent.

Note that the full recipient list for a message can, if retained at the time of final delivery, reveal the presence of blind carbon recipient to the other, regular recipients. As such, this facility should only be used when it is absolutely necessary.

46.3.13.28 XCLIENT SMTP Extension Support (`noxclient`, `xclient`, `xclientsasl`, `xclientrepeat`, `xclientsaslrepeat`)

(New in 8.0.) The MTA's SMTP server provides support for Postfix's XCLIENT SMTP extension. The PostFix documentation for the extension can be found here:

`http://www.postfix.org/XCLIENT_README.html`

Use of XCLIENT is controlled by three main source channel keywords, `noxclient`, `xclient`, and `xclientsasl`, and variants `xclientrepeat` and `xclientsaslrepeat`. `noxclient` is the default, and means that XCLIENT is not advertised in the response to EHLO and the XCLIENT command itself is disabled. If `xclient` is set, the XCLIENT command is enabled and the NAME, ADDR, PORT, PROTO, and HELO attributes may be used. `xclientsasl`

enables the LOGIN attribute in addition to all the others. It should be noted that LOGIN specifies an external identity that must then be bound to the session identity through the use of SASL EXTERNAL.

By default, only one set of XCLIENT commands is allowed in a single SMTP session. Specifying `xclientrepeat` allows groups of XCLIENT commands to be repeated, allowing a proxy or similar agent to share a connection between multiple clients. `xclientsaslrepeat` allows multiple groups of XCLIENT commands including LOGIN. Note that care should be taken when these keywords are used since the server cannot determine the origin of a given XCLIENT command.

The primary visible effect of XCLIENT is on the contents of the Received: field the MTA adds. For example, if this XCLIENT command was executed:

```
xclient name=foo.domain.com addr=1.2.3.4 helo=bar.domain.com port=12345
```

it would result in a header of the general form:

```
Received: from bar.domain.com (foo.domain.com [1.2.3.4])
  by server.domain.com (Oracle Communications Messaging Server 7.0.5.32
  64bit (built Aug 18 2014)) with imapsubmit
  id <01OJ9P51WPFC007KNZ@server.domain.com> for user@domain.com;
  Mon, 20 Aug 2012 08:17:31 -0700 (PDT)
```

However, the ADDR, PORT, DESTADDR, and DESTPORT attributes also change the contents of the transportinfo that appears in various mapping table probes, such as the probe to `PORT_ACCESS`. Given the preceding XCLIENT command, the *`transportinfo`* part of the mapping probes would change to something like:

```
TCP|this-mta's-ip|25|1.2.3.4|12345
```

where note that the values to use in the "source IP" and "source port" fields have been specified via ADDR and PORT, respectively.

Note: Support for DESTADDR and DESTPORT was added in MS 8.0.2.3.

46.3.13.29 Personal names in address message headers (`personalinc`, `personalmap`, `personalomit`, `personalstrip`, `sourcepersonalinc`, `sourcepersonalmap`, `sourcepersonalomit`, `sourcepersonalstrip`)

The MTA only interprets the contents of header lines when necessary. However, all registered headers containing addresses must be parsed in order to rewrite and eliminate shortform addresses and otherwise convert them to legal addresses. During this process personal names (strings preceding angle-bracket-delimited addresses) are extracted and may optionally be modified or excluded when the header line is rebuilt.

On destination channels, this behavior is controlled by the use of the `personalinc`, `personalmap`, `personalomit`, and `personalstrip` channel options. `personalinc`

tells the MTA to retain personal names in the headers. It is the default. `personalmap` tells the MTA to apply the PERSONAL_NAMES mapping table to personal names appearing in addressing header lines if such a mapping table exists, while if no such mapping table exists then `personalmap` is equivalent to `personalstrip`. `personalomit` tells the MTA to remove all personal names. And finally, `personalstrip` tells the MTA to strip any nonatomic characters from all personal name fields.

On source channels, this behavior is controlled by the use of a `sourcepersonalinc`, `sourcepersonalmap`, `sourcepersonalomit`, or `sourcepersonalstrip` channel option. `sourcepersonalinc` tells the MTA to retain personal names in the headers. It is the default. `sourcepersonalmap` tells the MTA to apply the `PERSONAL_NAMES` mapping table to personal names appearing in addressing header lines if such a mapping table exists, while if no such mapping table exists then `sourcepersonalmap` is equivalent to `sourcepersonalstrip`. `sourcepersonalomit` tells the MTA to remove all personal names. And finally, `sourcepersonalstrip` tells the MTA to strip any nonatomic characters from all personal name fields.

These options can be applied to any channel.

46.3.13.30 State clause in Received: header field (`receivedstate`)

Received: header fields can contain a "state" clause which indicates the type of processing a message is about to undergo; such state clauses were defined in RFC 6729 (Indicating Email Handling States in Trace Fields). The primary use for these clauses is to indicate when an operation is being undertaken that could cause a delivery delay, *e.g.*, the message has been quarantined.

The `receivedstate` destination channel option controls the generation of state clauses. A single arugment is required which specifies the state name to insert into the Received: fields of messages enqueued to the corresponding channel. The default, when `receivedstate` is not specified, is not to insert any state clause.

State values are restricted by RFC 6729 to be a state keyword "token" (as defined in RFC 2045), several such keywords being already registered, optionally followed by a slash character and another (unregistered) token as a detail label. Any token must consist solely of US-ASCII characters not including space, control characters, or the so-called "tspecials" characters:

```
tspecials :=  "(" / ")" / "<" / ">" / "@" /
              "," / ";" / ":" / "\" / <">
              "/" / "[" / "]" / "?" / "="
```

The initial set of registered state keywords is: `auth`, `content`, `convert`, `moderation`, `normal`, `other`, `outbound`, `quarantine`, and `timed`.

Appropriate usage with the MTA could include:

```
msconfig> show channel:*.receivedstate
role.channel:conversion = convert
role.channel:defragment = convert/defragment
role.channel:filter_discard = quarantine/sieve-discarded
role.channel:reprocess = other
role.channel:tcp_intranet = normal
```

```
role.channel:tcp_local = outbound
```

with use on the conversion channel, defragment channel, filter_discard channel, and reprocess channel being particularly relevant to note message transitions/points where messages could be delayed.

46.3.13.31 Mapping Reply-to: header when gatewaying to non RFC 822 environments (usereplyto)

The usereplyto channel option controls the mapping of the Reply-to: header in certain non RFC 822 environments. (Currently, the usereplyto channel option is relevant only for the OpenVMS local channel, and the PMDF-LAN cc:Mail, GroupWise, and Microsoft® Mail channels.) The default argument for usereplyto is 0, which means to use the channel default behavior (which varies from channel to channel).

Table 46.12 usereplyto MTA option values

Value	Action
-1	Never map Reply-to: addresses to anything.
0	Use the channel default mapping of Reply-to: addresses; (varies from channel to channel). This is the default.
1	Map Reply-to: to From: if no usable From: address exists.
2	If there is a usable Reply-to: address, then map it to From:; otherwise fall back to the From: address.

46.3.13.32 Mapping Resent- headers when gatewaying to non RFC 822 environments (useresent)

The useresent channel option controls the use of Resent- headers when gatewaying to environments that do not support RFC 822 headers. This channel option takes a single integer-valued argument. Legal values include:

Table 46.13 useresent MTA option values

Value	Action
+2	Use any Resent- headers that are present to generate address information.
+1	Only use Resent-From: headers to generate address information; all other Resent- headers are ignored.
0	Do not use Resent- headers to generate address information. This is the default.

Currently the useresent channel option applies for the l (lowercase "L") channel on OpenVMS, and for PMDF-MR, PMDF-X400, and some PMDF-LAN channels.

Note that the default of 0 constitutes a change in the behavior of the OpenVMS l channel compared with PMDF version 4.3 and earlier.

46.3.14 Host name channel options

There are three options that, for any type of channel, configure the fundamentals of a channel's own "host name" (official_host_name), the channel's knowledge of the host name of the system on which it is operating (local_host_alias), and optionally remote "hosts" with which it communicates (additional_host_names); these three basic options correspond to separate syntactic components of channel configuration in legacy configuration, but are set via options in Unified Configuration.

In addition to these three fundamental options, other channel options relating (in the case of TCP/IP channels) both to a system's own host name and to remote host names include daemon, lastresort, and the set of authhost, noauthhost, defaulthost, nodefaulthost, remotehost, and noremotehost channel options.

46.3.14.1 official_host_name Option

The official_host_name channel option specifies the "name" of the system with which this channel communicates. The official_host_name may be either a fully qualified host name, in the case of a channel dedicated to communicating with one particular system,

```
msconfig> show channel:l.official_host_name
role.channel:l.official_host_name = host.domain.com
```

or in the case of a more "generic" channel used for communicating with multiple systems (such as the Internet-communication channel tcp_local), the official_host_name tends to be a generic, place-holder name, *e.g.*,

```
msconfig> show channel:tcp_local.official_host_name
role.channel:tcp_local.official_host_name = tcp-daemon
```

In legacy configuration, the official host name is specified as the first name on the second line of a channel definition:

```
tcp_local ...keywords...
tcp-daemon
```

Each channel must have its own, unique official_host_name; no duplication with other channels is allowed. As of MS 6.1, the official host name is limited to 128 characters; in prior versions the limit was 40 characters. An official host name is required for each channel; omitting an official host name from a channel definition is an error.

Note that the official_host_name on the l channel (lowercase "L" channel) has somewhat special significance, as it is used/assumed at certain times by the MTA; and normally, it would be set to match the value of the ldap_local_host MTA option.

As of 8.0.1, the option if not set for a channel will default to *channel-name.hostname* in Unified Configurations.

46.3.14.2 local_host_alias Option

The local_host_alias channel option is used to specify an alternate name for the MTA system itself. Normally, the local host system is known by the name that appears as the

official_host_name on the l channel. But it is sometimes useful for the local host to have different names depending on the channel being used. This situation usually arises when a machine is connected to more than one network. For example, a system may need to be known as ymir.uucp on the UUCP network, ymir.claremont.edu on the Internet, and ymir.bitnet on BITNET.

If local_host_alias is specified, it is communicated as the local host's name to any remote hosts with which this channel communicates. This alias will replace the local host's name wherever it appears in the envelope and header of messages queued to the associated channel. If this alias is omitted the local host's official name (that is, the official host name associated with the l channel, channel.l.official_host_name) is used.

In legacy configuration, a local host alias is specified by placing it on the second line of a channel definition, subsequent to the official host name:

```
channel-name ...keywords...
official-host-name local-host-alias
```

The local host alias only affects the name of the local host. No other system names are affected. The effects of the local host alias are strictly limited to the channel to which the alias applies.

A local_host_alias on the SMTP server channel (typically tcp_local) overrides the TCP/IP stack's official host name for use on the SMTP server's 220 banner line. (If the TCP/IP stack doesn't have a value for some reason, we finally fall through to the official_host_name from the l channel.) A local_host_alias on an outgoing tcp_* channel overrides the TCP/IP stack's official host name for use on the EHLO/HELO/LHLO line. As of iMS 5.2, the new-in-that-version BANNER_HOST TCP/IP-channel-specific option takes precedence over the local_host_alias (in both directions, server and client).

Note: The use of local host aliases is discouraged. If at all possible, each system should be known by one and only one name on all networks. Networks should strive to make this a reality. (Back when Internet *vs.* UUCP *vs.* BITNET names were an issue, when it was impossible for a host to have the same name on both BITNET and the Internet, local host aliases were a necessary feature. Since different networks are always associated with different channels, a per-channel local host alias was an ideal way to give the local host a per-network name.) Note especially that when a single network is involved, it may appear that local host aliases can solve lots of problems, but often the end result is a worse mess than if the proper course of action is selected --- pick a single name and stick to it, living with the consequences of the conversion now instead of putting them off until it becomes even more difficult.

46.3.14.3 additional_host_names Option

In Unified Configuration, the additional_host_names channel option is used to specify the names of additional hosts, or additional destination domain names, with which the channel communicates.

In legacy configuration, each such additional host name is specified as the name on the third or subsequent lines of a channel definition:

```
tcp_local ...keywords...
tcp-daemon
special1.domain.com
special2.domain.com
```

```
...etc...
```

46.3.15 Incoming channel match and switch channel options

Many MTA configuration choices look at the incoming channel (source channel) for a message. A number of channel options affect such initial channel "matching" and channel "switching".

46.3.15.1 Selection of alternate source channels (`switchchannel`, `allowswitchchannel`, `noswitchchannel`, `userswitchchannel`)

When an MTA server process (*e.g.*, an SMTP server process) accepts an incoming connection from a remote system it must choose a so-called source channel with which to associate the connection. Normally this decision is based on the transport used; for example, an incoming TCP/IP connection to an SMTP server (a Dispatcher service running the SMTP server image) is automatically associated with the `tcp_local` channel, while an incoming TCP/IP connection to an LMTP server (a Dispatcher service running the LMTP server that delivers to the Message Store) is automatically associated with the `tcp_lmtpss` channel - unless such automatic, default associations are overridden via the Dispatcher's `parameter` option being set to a `CHANNEL=channel-name` value, *e.g.*:

```
msconfig> ! Do not need to set the dispatcher.service:SMTP_SPECIAL.image
msconfig> ! since the service name begins with "SMTP"
msconfig> set dispatcher.service:SMTP_SPECIAL.logfilename IMTA_LOG:tcp_special_server.log
msconfig# set dispatcher.service:SMTP_SPECIAL.tcp_ports special-port
msconfig# set dispatcher.service:SMTP_SPECIAL.parameter "CHANNEL=tcp_special"
```

(Note the quoting of the value of the `parameter` option, required due to the presence of the equal sign character, `=`.)

In legacy configuration, this corresponds to a definition in the `dispatcher.cnf` file along the lines of:

```
[SERVICE=SMTP_SPECIAL]
IMAGE=IMTA_BIN:tcp_smtp_server
LOGFILE=IMTA_LOG:tcp_special_server.log
PORT=special-port
PARAMETER=CHANNEL=tcp_special
```

In the case of SMTP, however, the convention of a single incoming channel breaks down when it is desired to handle connections from different sources differently. That is, in the SMTP case, it can be useful to have the association of source channel with connections be controlled not only at the Dispatcher level, but for further distinctions (so-called source channel "switching") to be performed based on additional criteria, within the SMTP server process itself.

The `switchchannel` channel option provides a way associate different incoming channels with different source IP addresses. If `switchchannel` is specified on the initial channel the SMTP server uses, the IP address of the connecting (originating) host will be rewritten (using envelope From style rewriting) and matched against the channel table and if it matches then the source channel will change accordingly. If no IP address match is found or if a match is found that matches the original default incoming channel, the MTA may optionally try

matching using the host name found by doing a DNS reverse lookup. The source channel may change to any channel marked `switchchannel` or `allowswitchchannel` (the default). `noswitchchannel` specifies that no channel switching should be done to or from the channel.

Specification of `switchchannel` on anything other than a channel that a server associates with by default will have no effect. At present `switchchannel` only affects SMTP channels, but there are actually no other channels where `switchchannel` would be reasonable. In particular, internal channels like `conversion` or `process` never need to switch. Also, LMTP servers do not support `switchchannel`.

Note that use of the (not-recommended) `CHECK_SOURCE` TCP/IP-channel-specific option setting with a value of 0 effectively disables `switchchannel` from taking effect.

The (new in MS 6.3-0.15) `userswitchchannel` channel option, if enabled on the current SMTP source channel, allows channel switching based on the envelope From address. If the envelope From address after rewriting is that of a user in the LDAP directory, then a per-user LDAP attribute (the attribute named by the `ldap_source_channel` MTA option), or if the user has no such attribute a per-domain LDAP attribute (the attribute named by the `ldap_domain_attr_source_channel` MTA option) will be consulted to find the name of a channel to which to switch as the new source channel. The source channel may change to any channel marked `switchchannel` or `allowswitchchannel` (the default).

Note that since the `userswitchchannel` plus user-or-domain LDAP attribute based switching is being done based on the envelope From (MAIL FROM) address and since such addresses are easily forged, this functionality should be used with great care. It is provided as a convenience for achieving esthetic and convenience features in the handling of messages purportedly from particular users or domains; but `userswitchchannel` does not provide the security of switching based on source IP address (`switchchannel`) or on authenticated sender information (`saslswitchchannel` and even more so the `mailSMTPSubmitChannel` LDAP attribute). When truly secure user-based channel switching is desired, instead the use of SMTP AUTH should be enforced and `mailSMTPSubmitChannel` used. (As of the 8.0 release, the LDAP attribute of relevance may be named something other than `mailSMTPSubmitChannel`, as specified via the `ldap_auth_attr_submit_channel` MTA option.)

See also the `FROM_ACCESS` mapping table's `$~` flag which provides another way to do source channel "switching" (particularly well suited for "switching" the source channel for incoming notification messages).

46.3.15.2 Channel switching based on SMTP authentication (`saslswitchchannel`, `nosaslswitchchannel`)

The `saslswitchchannel` channel option is used to cause incoming connections to be switched to a specified channel upon a client's successful SASL use. (See the `maysasl*` and `mustsasl*` channel options for configuration of permitting/requiring SMTP AUTH and SASL use.) `saslswitchchannel` takes a required value, specifying the channel to which to switch. `nosaslswitchchannel` is the default, and means that channel switching is not performed upon a client's successful SASL use.

See also the `mailSMTPSubmitChannel` user LDAP attribute, (or as of the 8.0 release, whatever LDAP attribute is named by the `ldap_auth_attr_submit_channel` MTA option) which when set on a user entry will cause channel "switching" to the specified channel;

it thus permits "finer-grained" channel switching than `saslswitchchannel` which merely switches all authenticated submissions to a particular named channel.

See also the (new in MS 6.3) `userswitchchannel` channel option which, in conjunction with site-selected user or domain LDAP attributes, also allows "fine-grained" channel switching, in this case based merely on the *purported* From: address.

The `saslswitchchannel` channel option is typically used when it is desired to distinguish between authenticated *vs.* unauthenticated submissions as a class; the `mailSMTPSubmitChannel` user LDAP attribute (or as of the 8.0 release, whatever LDAP attribute is named by the `ldap_auth_attr_submit_channel` MTA option) is typically used when it is desired to securely distinguish submissions from particular users (say to allow "special privileges" to particular users); the (new in MS 63) `userswitchchannel` channel option and associated LDAP attribute(s) are typically used when it is desired to make esthetic distinctions (rather than more critical "secure" distinctions) on users' submissions without requiring authenticated verification of the sender address.

See also Blocking SMTP relaying for an example of typical use of `saslswitchchannel`.

Note that any channel switching done by `saslswitchchannel` will be undone if/when a client issues a (nonstandard, new in 8.0) XUNAUTHENTICATE command. (SMTP server support for the nonstandard XUNAUTHENTICATE extension and associated XUNAUTHENTICATE command is new in 8.0; note that XUNAUTHENTICATE is not supported for the LMTP server. XUNAUTHENTICATE is only valid after successful authentication has been performed, and the capability only shows up in the EHLO response at this point at well. Successful execution of the XUNAUTHENTICATE command will return the SMTP session to an unauthenticated state.)

46.3.15.3 Transport Layer Security (`maytls`, `maytlsclient`, `maytlsserver`, `musttls`, `musttlsclient`, `musttlsserver`, `notls`, `notlsclient`, `notlsserver`, `tlsswitchchannel`)

The `maytls`, `maytlsclient`, `maytlsserver`, `musttls`, `musttlsclient`, `musttlsserver`, `notls`, `notlsclient`, `notlsserver`, and `tlsswitchchannel` channel options are used to configure STARTTLS use for the various protocols supported by the MTA, including but not limited to SMTP, LMTP, and MTQP.

Note that prior to 7.0.5, the LMTP server did not support TLS use; as of 7.0.5, the LMTP server does support TLS, configured via the same `maytls`, `maytlsserver`, `musttls`, `mustlsserver`, channel options used to configure SMTP server TLS support.

The ManageSieve server only supports the server subset of the TLS options since there is no ManageSieve client.

`notls` is the default, and means that STARTTLS will not be permitted or attempted. It subsumes the `notlsclient` channel option, which means that TLS use will not be attempted by the SMTP/LMTP/MTQP client on outgoing connections (the STARTTLS command will not be issued during outgoing connections) and the `notlsserver` channel option, which means that TLS use will not be permitted by the SMTP/LMTP/MTQP server on incoming connections (the STARTTLS extension will not be advertised by the SMTP/LMTP/MTQP server nor the command itself accepted).

Specifying `maytls` causes the MTA to offer TLS to incoming connections and to attempt TLS upon outgoing connections. It subsumes `maytlsclient`, which means that the SMTP/LMTP/

MTQP client will attempt TLS use when sending outgoing messages, if sending to an SMTP/LMTP/MTQP server that supports TLS, and `maytlsserver`, which means that the SMTP/LMTP/MTQP server will advertise support for the STARTTLS extension and will allow TLS use when receiving messages. Note that `maytls*` settings mean that the MTA *will* want to use TLS with remote sides that support STARTTLS, while allowing remote sides that do not have STARTTLS support to communicate without TLS; but `maytls*` settings do *not* inherently mean that the MTA will "fall back" to non-TLS use when TLS negotiation is attempted but fails: failure of TLS negotiation will result in that connection being closed as a failed connection (recorded with an "X" record). As of 8.0, with `maytlsclient` set, the MTA's client will attempt a new connection to attempt sending without TLS in cases where the remote SMTP/LMTP server advertised TLS support but where the actual TLS negotiation failed; prior to 8.0, a failure in the TLS negotiation would immediately abort the delivery attempt for the message. This support is not available in MTQP.

Specifying `musttls` will cause the MTA to insist upon TLS in both outgoing and incoming connections; e-mail will not be exchanged with remote systems that fail to successfully negotiate TLS use. It subsumes `musttlsclient`, which means that the SMTP/LMTP client will insist on TLS use when sending outgoing messages and will not send to SMTP/LMTP servers that do not successfully negotiate TLS use (the MTA will issue the STARTTLS command and that command must succeed), and `musttlsserver`, which means that the SMTP/LMTP server will advertise support for the STARTTLS extension and will insist upon TLS use when receiving incoming messages and will not accept messages from clients that do not successfully negotiate TLS use. When `musttls` or `musttlsserver` is on a channel, then unless TLS has been successfully negotiated all MAIL FROM: attempts will be rejected with the error:

```
530 5.7.0 No STARTTLS command has been given.
```

The `tlsswitchchannel` channel option is used to cause incoming connections to be switched to a specified channel upon a client's successful TLS negotiation. (This includes either successful STARTTLS use on a "regular" port, or negotiating upon connection to a "dedicated to TLS" port, usually port 465, configured via the Dispatcher's `ssl_ports` option in Unified Configuration, or its TLS_PORT option in legacy configuration.) `tlsswitchchannel` takes a required value, specifying the channel to which to switch.

Note that TLS library initialization is performed for any SMTP/LMTP channel which has any TLS usage permitted (or required). In particular, TLS library initialization will be performed by the TCP client for a channel marked merely `maytlsserver`. (This overhead is normally fairly neglible.)

Note that these options affect only TLS use negotiated at the protocol level via STARTTLS; they do not affect potential TLS use triggered by connection to a port dedicated to TLS use such as with the `ssl_ports` Dispatcher service option.

46.3.16 ISC channel options

The ISC channel options were removed in MS 8.0.2.2.

See also the ISC options.

46.3.17 Logging and debugging channel options

Basic channel logging of message transactions, and basic channel debugging, are controlled by several channel options.

For greater fine-tuning of exactly what is logged in transaction log entries, see Transaction logging MTA options. For greater detail in debug log files, see Debug MTA options.

46.3.17.1 Message transaction logging (`logging`, `nologging`, `logheader`)

The MTA provides facilities for logging each message as it is enqueued and dequeued. All log entries are made to the MTA message transaction log file `mail.log_current` in the MTA log directory, (*i.e.*, *`DATAROOT`*`/log/mail.log_current`). Message transaction logging is controlled on a per-channel basis. The `logging` channel option activates message transaction logging for a particular channel while the `nologging` channel option disables it. Logging is disabled on all channels by default although most default configurations enable logging on all channels.

The message `return_job`, which runs every night around midnight, appends any existing `mail.log_yesterday` to the cumulative log file, `mail.log`, renames the current `mail.log_current` file to `mail.log_yesterday`, and then begins a new `mail.log_current` file. Note that the MTA itself never does anything to the cumulative `mail.log` file and it is up to each site to manage (*e.g.*, delete, truncate, backup, *etc.*) that log file however they choose.

The MTA message transaction log file is written as a normal ASCII text file, whose exact format is configurable via the `log_format` MTA option.

If you wish to have all of your channels log message activity to the logging file, then simply add the `logging` channel option to a defaults channel.

When message transaction logging is enabled, the (new in MS 6.0) `logheader` option may be used on channels to additionally enable logging of message headers. It takes an encoded integer argument, where bit 0 (value 1) causes logging during both enqueue and dequeue operations, while a value of 2 causes logging during enqueue operations without enabling logging for message dequeues. As of MS 8.0.2, a value of 3 causes logging during dequeues without enabling logging for message enqueues. The specific header lines to be logged are controlled by the `log_headers.opt` file, discussed along with the MTA option `log_header`.

When enabling `logheader`, consider also enabling the `log_process` MTA option, as it is helpful for correlating header entries with corresponding regular message entries.

If the goal is to record subsets of information from one or more header lines, rather than necessarily logging full header lines via `logheader`, see as an alternative the (both new-in-MS-8.0) `log_transaction` MTA option and Sieve "`transactionlog`" action.

46.3.17.2 Debugging channel master and slave programs (`master_debug`, `nomaster_debug`, `slave_debug`, `noslave_debug`)

Some channel programs include optional code to assist in debugging by producing additional diagnostic output. Two channel options are provided to enable generation of this debugging output on a per-channel basis. The options are `master_debug`, which enables debugging output in master programs, and `slave_debug`, which enables debugging output in slave

programs. Both types of debugging output are disabled by default, corresponding to `nomaster_debug` and `noslave_debug`.

When activated, debugging output ends up in the log file associated with the channel program. The location of the log file may vary from program to program. Log files are usually kept in the MTA log directory. Master programs usually have log file names of the form `x_master.log`, where "x" is the name of the channel; slave programs usually have log file names of the form `x_slave.log`.

For the UNIX L and native channels, the "normal" debugging when the L channel is delivering is caused by `slave_debug`.

For the `reprocess` channel, since it performs some of its functions/checks as if it "were" the prior channel (the channel that enqueued to the `reprocess` channel), to get debugging of the reprocess channel's enqueuing operation, you will need to enable `master_debug` on that prior channel, rather than on the `reprocess` channel itself.

Note that the TCP/IP channel master program will produce multiple `tcp_y_master.log` files per master channel program execution when `master_debug` is enabled. The first such file produced shows the channel's determination of how many outgoing threads to start up; an additional log file will be created for each individual outgoing thread.

Similarly, the TCP/IP channel slave program -- the SMTP server or SMTP SUBMIT server -- will produce multiple files when `slave_debug` is enabled. The first such file produced is a SMTP server or SMTP SUBMIT server log file, with the base name specified via the `logfilename` Dispatcher option for the respective service (by default `tcp_smtp_server.log` and `tcp_submit_server.log`, respectively) with a unique identifying string appended, so typically `tcp_smtp_server.log-`*`uniqueid`* or `tcp_submit_server.log-`*`uniqueid`*. Some debugging regarding general server process initialization is written to such server log files: debugging regarding TLS initialization, the setting of TCP/IP-channel-specific options for the server, *etc*. However, the debugging regarding channel operation handling SMTP connections is written to channel slave log files, with names controlled by the name of the default channel for the service (see the `parameter` Dispatcher option for the service), so have names typically of the form `tcp_local_slave.log-`*`uniqueid`* or `tcp_submit_slave.log-`*`uniqueid`*.

The Message Store delivery channels, `ims-ms` and `tcp_lmtpss*` (LMTP back end TCP/IP channel, that is, the LMTP server), have two (or three) types of debug output: the MTA type of debug output (enabled as normal for MTA channels via the MTA channel options discussed here, and going to MTA channel debug log files as normal), plus some Message Store injection debugging (which is enabled by the `loglevel` option for the MTA, and which goes to the log file named, literally, `imta`, plus if message tracing is enabled (the `activate` messagetrace option is enabled) more detailed Message Store message tracing (which goes to the log file named, literally, `msgtrace`).

Not all MTA channel programs have debugging support code, and the amount of debugging output available also varies among those channel programs that include debug support.

46.3.18 Long address lists or headers channel options

Sites may desire to configure special handling of messages with many recipient addresses, or excessively long header lines. There are a number of channel options relating to such special handling.

46.3.18.1 Triggering alternate channel processing (alternatechannel, alternateblocklimit, alternatelinelimit, alternaterecipientlimit)

It is sometimes useful to force processing of messages meeting certain criteria to occur on a channel distinct from the one chosen by the MTA's alias expansion and rewriting process. The `alternatechannel` channel option provides a means to specify such a channel while the `alternateblocklimit`, `alternatelinelimit`, and `alternaterecipientlimit` channel options specify the criteria for when the alternate channel should be used.

`alternatechannel` takes the name of the alternate channel to use as an argument. `alternateblocklimit` takes an unsigned integer as an argument; the alternate channel will be used if the computed block size of the message exceeds this value. `alternaterecipientlimit` also takes an unsigned integer argument; the message will be queued to the alternate chanmel if the number of recipients queued to the current channel exceeds this value. Finally, the `alternatelinelimit` channel option takes an unsigned integer argument; the alternate channel will be used if the computed number of lines in the message exceeds this value.

Note that `alternaterecipientlimit` is a limit on envelope recipients for this message copy, on this channel; it has nothing to do with how many addresses may or may not be in the header; and envelope recipients on other channels are also irrelevant. However, the `alternaterecipientlimit` check does get performed before any message copy split-up due to storage of recipients per file controls such as `addrsperfile`, `single`, or `single_sys` channel option application.

Note that any `*SEND_ACCESS` or `*MAIL_ACCESS` mapping table probes will use the "original" destination channel name, not the alternate destination channel name, but a `CONVERSIONS` mapping table probe will use the alternate destination channel name.

Note that the alternate channel selection process is neither iterative nor recursive: Once an alternate channel has been selected it will be used regardless of what the various alternate channel options on that channel say to do.

46.3.18.2 Maximum allowed recipients or bad commands (recipientlimit, recipientcutoff, deferralrejectlimit, disconnectrecipientlimit, disconnectrejectlimit, disconnectbadcommandlimit, disconnectbadburllimit, disconnectcommandlimit)

The `recipientlimit`, `recipientcutoff` and (new in MS 6.2) `deferralrejectlimit` channel options, when placed on a source channel, impose per-channel limits on the number of recipients for a submitted message. Each of these options accepts a single integer argument; they default to no limit. (Note that setting `recipientlimit` or `recipientcutoff` to `0` has no effect; only positive limit values will be enforced.) These options are all per-channel (as opposed to per-SMTP-server) analogues of the `ALLOW_RECIPIENTS_PER_TRANSACTION`, `REJECT_RECIPIENTS_PER_TRANSACTION`, and `ALLOW_REJECTIONS_BEFORE_DEFERRAL` SMTP channel settings.

`recipientlimit` limits the total number of recipient addresses that will be accepted for the message; additional recipients will be rejected. The text in the rejection is configurable

via the error_text_recipient_over MTA option, which by default is "too many recipients specified". The error is a temporary rejection by default, but if bit 4 (value 16) of the use_permanent_error MTA option is set, then the rejection is permanent. So in the case of attempted SMTP message submissions, the default temporary error, with the default error text, would appear as:

```
451 4.5.3 too many recipients specified
```

whereas with the default error_text_recipient_over text but with bit 4 (value 16) of the use_permanent_error MTA option set, then a permanent error would appear as:

```
550 4.5.3 too many recipients specified
```

recipientcutoff compares the total number of recipients that were presented to the MTA to the specified value and a message will not be accepted for delivery to *any* recipients if the value is exceeded. In the case of attempted SMTP submissions, the message will be rejected at the DATA command with the SMTP rejection:

```
451 4.4.5 Error ending envelope - Too many recipients specified for this message
```

New in MS 6.2, and supported only for SMTP (not for LMTP), deferralrejectlimit limits the number of bad (failing) addresses that will be allowed during a single session; after this number, all subsequent recipient addresses, good or bad, will be rejected with a temporary error. In the case of attempted SMTP submissions, additional RCPT TO: commands will be rejected with the error:

```
451 4.5.3 Too many rejections; try again later
```

while attempted VRFY: commands will be rejected with the error:

```
451 4.5.3 Verification blocked; too many rejections
```

Similar limits controlled on a per-user and per-domain basis can be configured via LDAP attributes; see the MTA options ldap_recipientlimit, ldap_recipientcutoff, ldap_domain_attr_recipientlimit and ldap_domain_attr_recipientcutoff.

The disconnect* channel options are new in Messaging Server 6.2 (except: disconnectcommandlimit new in Messaging Server 7.1, disconnectbadburllimit new in Messaging Server 7.4-18.01). They are supported only for SMTP, not for LMTP. Each takes an integer argument specifying the maximum number of (recipients, rejections, bad commands, or commands, as applicable) which will be accepted for messages submitted via that source channel; any more will result in the MTA forcing a disconnect of the SMTP session, after issuing an error response to the client consisting of (for disconnectrecipientlimit):

```
421 4.7.0 Session recipient limit reached; disconnecting
```

for disconnectrejectlimit in MS 6.2:

```
450 4.7.0 Session bad recipient limit reached; disconnecting
```

or in MS 6.3 and later (MS 6.3 also being when behavior was enhanced so that rejected MAIL FROM's count against the `disconnectrejectlimit`, whereas in MS 6.2 only rejections at the RCPT TO or VRFY stages counted; MS 6.3 is also when behavior was enhanced so that `disconnectrejectlimit` is checked at the VRFY stage and with a negative value applied at the VRFY stage, whereas previously such VRFY rejections were counted but the disconnect would not be triggered until a subsequent RCPT TO attempt "noticed" that the threshold was exceeded):

```
421 4.7.0 Session rejection limit reached; disconnecting
```

or (for `disconnectcommandlimit`):

```
450 4.7.0 Maximum number of commands exceeded
```

In the case of the `disconnectrecipientlimit` or `disconnectrejectlimit` channel options, once the limit is exceeded, the error-response-and-disconnect normally will occur after the next MAIL FROM or RSET command (or in the case of `disconnectrejectlimit` in MS 6.3 and later, potentially after a failed VRFY attempt). (Note that because the disconnect usualy does not happen until after a subsequent MAIL FROM or RSET, these `disconnect*` channel options would most often be used in conjunction with other channel keywords or TCP/IP-channel-specific option settings: perhaps `recipientlimit` or `recipientcutoff` to limit the number of recipient addresses accepted, or `deferralrejectlimit` or the `ALLOW_REJECTIONS_BEFORE_DEFERRAL` TCP/IP-channel-specific option setting.)
In the case of `disconnectbadcommandlimit`, `disconnectbadburllimit`, and `disconnectcommandlimit`, once the limit is exceeded the error response is issued and the MTA forces the disconnect.

The `disconnectbadburllimit` channel option is new in Messaging Server 7.4-18.01. A single integer parameter is accepted specifying the number of invalid BURL commands that will be allowed before disconnecting. The default is 3.

Note that VRFY attempts are counted separately from RCPT TO attempts against the recipient count; that is, one may have up to the recipient limit of VRFYs *and* up to the recipient limit of RCPT TOs. The VRFYs are counted, but counted separately from RCPT TOs. In contrast, failed VRFY attempts are added to the same rejection counter used for counting failed RCPT TO attempts and MAIL FROM attempts for purposes of comparison against the rejection limit; that is, one may have up to the rejection limit of any combination of failed VRFYs, MAIL FROMs, or RCPT TOs.

When the `deferralrejectlimit` has been reached (or a TCP/IP-channel-specific option setting of `ALLOW_REJECTIONS_BEFORE_DEFERRAL` has been reached), a client VRFY attempt will receive from the MTA an error response:

```
451 4.5.2 Verification blocked; too many rejections
```

Note that prior to MS 6.3, the error was instead:

```
452 4.5.2 Verification blocked; too many bad addresses.
```

Note that the `FROM_ACCESS` mapping table's `$S` flag may also be used to set limits such as `recipientlimit` or `recipientcutoff`.

For forcing IMAP or POP disconnection after a specified number of protocol errors -- similar to the `disconnectbadcommandlimit` effect for SMTP -- see the `maxprotocolerrors`IMAP or POP option.

46.3.18.3 Expansion of multiple addresses (`expandlimit`, `expandchannel`, `holdlimit`)

Most MTA channels support the specification of multiple recipient addresses in the transfer of each inbound message. The specification of many recipient addresses in a single message may result in delays in message transfer processing ("on-line" delays). In particular, multi-recipient messages that require a great deal of processing of the message body can be affected by processing delays, or that require creation of many different file copies on disk in the MTA queue area can be affected by slow disk performance. If the resulting delays are long enough, network timeouts can occur, which in turn can lead to repeated message submission attempts and other problems.

The MTA provides a special facility to force deferred ("off-line") processing of additional recipient message copies once a given number of addresses are specified for a single message. The deferral happens after processing of the "initial" recipients (those before the `expandlimit` value was reached), and after address processing for the additional recipients too, (for instance, after `*_ACCESS` mapping table checks and after alias processing), but before message processing. In particular, such deferral means that for the "additional" recipients, only *one* message file (storing all of the "additional" recipients), is written to the queue area (to a `reprocess*` or `process*` channel queue area, depending upon use of the `expandchannel` channel option). Deferral of message processing can decrease on-line delays enormously. Note, however, that the processing overhead is deferred, not avoided completely.

This special facility is activated by using a combination of, for instance, the generic reprocessing channel and the `expandlimit` channel option. The `expandlimit` option takes an integer argument that specifies at what number of recipients to begin deferring processing of the message copy (or copies) to that and additional recipient addresses. The default value is effectively infinite if the `expandlimit` channel option is not specified. A value of 1 will force deferred processing on all incoming addresses from the channel.

The `expandlimit` channel option must *not* be specified on the local channel or the reprocessing channel itself; the results of such a specification are unpredictable.

The channel actually used to perform the deferred processing may be specified on a per-source-channel basis using the `expandchannel` channel option; the reprocessing channel is used by default, if `expandchannel` is not specified, but use of some other reprocessing or processing channel may be useful for some purposes. In particular, for Messaging Server MTA versions 5.2 and earlier, typical configuration usage required that a processing channel, rather than a reprocessing channel, be used. If a channel for deferred processing is specified via `expandchannel`, that channel should be a reprocessing or processing channel; specification of other sorts of channels may lead to unpredictable results.

The reprocessing channel, or whatever channel is used to perform the deferred processing, must be added to the MTA configuration file in order for the `expandlimit` option to have any effect. If your configuration was built by the initial configuration utility, then you should already have a reprocessing channel.

(Note that typical Messaging Server sites running version 5.2 or earler could not use the `expandlimit` option unless they also marked the affected channel `expandchannel process` (or `expandchannel process_somethingorother` redirecting the

expansion to an alternate `process_*` sort of channel), as enqueues to a channel marked `viaaliasrequired` would not succeed if deferred to a `reprocess*` channel.)

Extraordinarily large lists of recipient addresses are often a characteristic of so-called SPAM---junk e-mail. The `holdlimit` channel option tells the MTA that messages coming in the channel that result in more than the specified number of recipients should be marked as `.HELD` messages and enqueued to the `reprocess` channel (or to whatever channel is specified via the `expandchannel` channel option). As `.HELD` messages, the files will sit unprocessed in that MTA queue area awaiting manual intervention by the MTA postmaster.

46.3.18.4 Specify maximum length header line that the MTA will rewrite (`maxprocchars`)

Processing of long header lines containing lots of addresses can consume significant system resources. (Note, however, that resource consumption is much reduced in PMDF V5.0 as compared with previous versions of PMDF.) The `maxprocchars` source channel option is used to specify the maximum length header line that the MTA will process and rewrite. Messages with header lines longer than this are still accepted and delivered; the only difference is that the long header lines are not rewritten in any way. A single integer argument is required. The default is to process header lines of any length.

46.3.19 Message hash channel options

Message hash channel options are typically used in conjunction with a message archiving configuration, and hence with the Message archival and hashing MTA options.

46.3.19.1 Message hashes (`deletemessagehash`, `generatemessagehash`, `keepmessagehash`)

The `generatemessagehash`, `keepmessagehash`, and `deletemessagehash` destination channel options control whether the MTA generates, retains, or deletes a message hash, respectively. All of these channel options first apppeared in the 6.3 release. A message hash, if present, is stored in a Message-hash: header line. `deletemessagehash` is the default.

These keywords are intended to be used in conjunction with message archiving, along with message archiving MTA options, and Message Store archive options.

Note that AXS:One archiving will generate its own message hash on the messages it receives, if the MTA has not already generated and inserted such a message hash. However, in order to correlate messages in the Message Store with the messages archived by AXS:One, it is necessary that the MTA generates the hash and that that hash is retained in the messages delivered to the Message Store. Therefore, channels that deliver to the Message Store (`ims-ms` or `tcp_lmtpcs*` sorts of channels) should be marked either `generatemessagehash` or (if the message hashes are being initially generated at an earlier channel stage) `keepmessagehash`. In contrast, a channel delivering to remote Internet hosts, such as typically the `tcp_local` channel, would typically be marked `deletemessagehash` even if messages going out `tcp_local` are being archived, since there would in general be no expectation that the remote Internet sites would do anything (get any benefit) from the message hashes.

The choice of which channel(s) to mark with `generatemessagehash` will depend upon how "soon" *vs.* "late" one wishes to choose to consider a message's essential characteristics

to be established. Generating a hash "early" (as soon as a message first comes into the MTA) may be before various changes (*e.g.*, changes performed by the conversion channel) occur, or before "split up" of a message into separate copies for different classes of recipients. More "different" (in one way or another) "copies" of a message may be considered "the same" for the archival purposes when hash generation is performed "early". Whereas when hashing is performed "late" (at the final delivery channel stage), then additional sorts of differences in message "copies" can be reflected in the message hash value (more distinctions between "copies" occur). But this may be either a plus or a minus depending upon site goals.

46.3.20 Message tracking channel options

New in the 8.0 release, a general message tracking and recall facility has been implemented. There are a number of channel options relating to message tracking.

46.3.20.1 Message Tracking and Recall Channel Options (`notrackingclient`, `notrackingserver`, `trackingclient`, `trackingdelivered`, `trackingfirst`, `trackinginternal`, `trackingmultiple`, `trackingrelayed`, `trackingserver`, `trackingsingle`, `trackingtimeoutdefault`, `trackingtimeoutmax`, `trackingtimeoutmin`)

The message tracking and recall facility consists of an SMTP service extension (RFC 3885) as well as a separate MTQP server (RFC 3887). (Note that these standards only specify message tracking; message recall is an Oracle extension.) Mail clients can use this facility to track and possibly recall messages they have sent. This set of keywords controls the availability and handling of the Message Tracking SMTP extension.

The extension is enabled with the `trackingserver` source channel option. The `notrackingserver` channel option disables the availability of the extension, and is the default. The `trackingtimeoutdefault` source channel option specifies the default timeout in seconds if no timeout value is specified in the MTRK command, as allowed by the protocol. The default is 3 days.

The `trackingtimeoutmin` and `trackingtimeoutmax` source channel options specify the minimum and maximum allowed timeout value in seconds; any value greater than the maximum or less than the minimum is silently lowered or raised to the corresponding limit. The defaults are 1 and 14 days, respectively.

The SMTP client's use of the extension is controlled by the `trackingclient` and `notrackingclient` channel options. The former enables use of the extension; the latter disables it and is the default. Note that the extension must be enabled on clients and servers throughout a deployment in order for tracking and recall to work across that deployment.

The handling of messages relayed internal to a deployment, including internal channel hops, needs to be distinguished from the case where messages leave the administrative domain for tracking and recall to work properly. However, the SMTP protocol is commonly used in both cases. Additionally, the case where a successful channel dequeue results in message delivery also needs to be distinguished from dequeues where this does not occur.

Three channel options are provided to specify these semantics: `trackinginternal`, `trackingrelay`, and `trackingdelivered`. `trackinginternal`, the default, specifies

that the message is being transferred internally. `trackingrelayed` specifies that the channel transfers messages to some external system. Finally, `trackingdelivered` specifies that the channel performs final delivery of the message.

RFC 3885 specifies how the Message Tracking SMTP Extension interacts with aliases and mailing lists. In particular, it says, "MTAs MUST NOT copy MTRK certifiers when a recipient is aliased, forwarded, or otherwise redirected and the redirection results in more than one recipient. However, an MTA MAY designate one of the multiple recipients as the "primary" recipient to which tracking requests shall be forwarded; other addresses MUST NOT receive tracking certifiers. MTAs MUST NOT forward MTRK certifiers when doing mailing list expansion."

This arguably makes sense for tracking-only applications where presenting the results of a complex alias expansion process to the end user may be confusing; however, the situation with message recall is different. Users expect recall to work when feasible, including when alias expansion is involved. (Mailing lists are different; a mailing list effectively "owns" its messages once it expands, so recall past a mailing list expansion is inappropriate.)

Accordingly, three source channel options are provided to control the MTA's behavior in this regard. `trackingmultiple`, the default, tells the MTA to pass tracking id/timeout information to all recipients of an alias expansion. `trackingsingle` causes tracking id/time information to pass through only when there is a single recipient. Finally, `trackingfirst` causes tracking information to pass through to the first alias expansion recipient. (Note that in the case of aliases stored in LDAP, the first recipient is unpredictable.)

46.3.20.2 Automatic Tracking ID Generation (`trackinggenerate`)

Message tracking and recall depends on the generation, attachment, and transfer of tracking identifiers. Such identifiers are normally generated and attached to messages by the submitting client. However, essentially no clients currently support the generation of such identifiers, making it impossible to write a separate tracking/recall client to deal with messages submitted by a non-tracking-enabled client. Additionally, a user who elects to use multiple clients, some tracking-enabled and some not, will end up with only a subset of their messages able to be tracked and recalled.

Tracking identifiers can also provide, independent of their use for user tracking and recall, a stable identifier that ties MTA log entries across multiple systems together in ways that envelope ids and messag-id header fields do not and cannot. As such, automatic assignment of tracking identifiers to message on ingress as well as submission has real utility independent of user tracking and recall functions.

The `trackinggenerate` source channel addresses these needs. A single required integer parameter specifies the default tracking timeout. If set, a tracking identifier for the message is generated in one of two ways:

- If authentication has been used and the user has a general recall secret associated with their LDAP entry (see the `ldap_auth_attr_recall_secret` MTA option), then a per-message recall secret is generated by computing a SHA-1 hash of the concatenation of the content of Message-id: header field , the Date: header field (if present), and the user's general recall secret. The per-message recall is then hashed twice with SHA-1 to create the tracking identifier. The tracking timeout is controlled by the `trackinggenerate` value.

- If authentication wasn't used or no general recall secret is associated with the account, a tracking identifier is created by hashing a unique identifier with an MD4 hash. Note that

the security of this process is controlled not by the randomness of the unique identifier or the use of MD4, but rather by the infeasilbility of computing X given T, where SHA1(X) = MD4(T).

46.3.21 MLS channel options

RESTRICTED: Not yet fully implemented. There are a few channel options relating to MLS (Multi Layer Security).

46.3.21.1 MLS (Multi Layer Security) Channel options: `mlslabel` (string), `mlsrange` (string)

RESTRICTED: Not yet fully implemented.

46.3.22 Notification messages and postmaster messages channel options

Notification message handling, especially notification message generation, is an important function of the MTA with therefore a number of related channel options. See also the Notification message MTA options.

46.3.22.1 Postmaster address recognition (`aliaspostmaster`)

Specifying the `aliaspostmaster` option on a destination channel causes any messages addressed to the username "postmaster" (lowercase, uppercase, or mixed case) at the official channel name to be redirected to `postmaster@local-host`, where `local-host` is the official local host name (the `official_host_name` on the local channel). Note that Internet standards require that any domain in the DNS that accepts mail have a valid postmaster account that will receive mail. So this setting can be useful when a site wants to centralize postmaster responsibilities, rather than having separate postmaster accounts for separate domains. That is, whereas the `returnaddress` channel option controls what return postmaster address is used when a notification message is generated *from* the postmaster, `aliaspostmaster` affects what is done with messages addressed *to* the postmaster.

46.3.22.2 Returned messages (`sendpost`, `nosendpost`, `copysendpost`, `errsendpost`)

A channel program may be unable to deliver a message due to long-term service failures or invalid addresses. When this happens the MTA channel program returns the message to the sender with an accompanying explanation of why the message was not delivered. The MTA will also optionally send a copy of certain failed messages to the local postmaster. This is useful for monitoring message failures, but it can result in lots of traffic for the postmaster to deal with.

The options `sendpost`, `copysendpost`, `errsendpost`, and `nosendpost` are used to control the sending of failed messages to the postmaster. `sendpost` tells the MTA to send a copy of all failed messages to the postmaster unconditionally. `copysendpost` instructs the MTA to send a copy of the failure notice to the postmaster unless the originator address on the failing message is blank; *i.e.*, the postmaster gets copies of all failed messages except those messages that are actually themselves reporting on bounces or other notifications.

`errsendpost` instructs the MTA to only send a copy of the failure notice to the postmaster when the notice cannot be returned to the originator. No failed messages are ever sent to the postmaster if `nosendpost` is specified.

The default in releases prior to 7.3-11.01 was `copysendpost`. As of 7.3-11.01 the default has been changed to `nosendpost`.

46.3.22.3 Warning messages (`warnpost`, `nowarnpost`, `copywarnpost`, `errwarnpost`)

In addition to returning messages as undeliverable, the MTA sometimes sends warnings detailing messages that it has been unable to deliver for some period of time. This is generally due to timeouts based on the setting of the `notices` channel option, although in some cases channel programs may produce warning messages after failed delivery attempts. The warning messages contain a description of what's wrong and how long delivery attempts will continue. In most cases they also contain the headers and possibly some additional content from the message in question.

The MTA will also optionally send a copy of certain warning messages to the local postmaster. This can be somewhat useful for monitoring the state of the various MTA queues, although it does result in lots of traffic for the postmaster to deal with.

The options `warnpost`, `copywarnpost`, `errwarnpost`, and `nowarnpost` are used to control the sending of warning messages to the postmaster. `warnpost` tells the MTA to send a copy of all warning messages to the postmaster unconditionally. `copywarnpost` instructs the MTA to send a copy of the warning to the postmaster unless the originator address on the as yet undelivered message is blank; *i.e.*, the postmaster gets copies of all warnings of undelivered messages except for those as yet undelivered messages that are actually themselves reports on bounces or notifications. `errwarnpost` instructs the MTA to only send a copy of the warning to the postmaster when the notice cannot be returned to the originator. No warning messages are ever sent to the postmaster if `nowarnpost` is specified.

If no `*warnpost` channel option is in effect the default is taken from any `*sendpost` channel option setting. If no such setting exists the default in releases prior to 7.3-11.01 was `copywarnpost`. As of 7.3-11.01 the default has been changed to `nowarnpost`.

46.3.22.4 Notification and disposition channels (`dispositionchannel`, `notificationchannel`)

New in 6.2: By default, the MTA always generates notification messages (Delivery Status Notifications) such as bounce messages, warnings of delayed delivery, *etc.*, and disposition messages (Message Disposition Notifications) such as "vacation" messages, through the `process` channel. That is, the channel that needs to generate a DSN or MDN submits the DSN or MDN, respectively, to the `process` channel; and the `process` channel subsequently enqueues the DSN or MDN on to the appropriate outbound channel (back to the sender of the original message).

The `notificationchannel` channel option may be used on a channel to tell it to generate DSNs through the specified channel, rather than through the (default) `process` channel. It takes a required argument, which is the name of the channel to which to enqueue the newly generated DSNs; normally, this should be some `process_`*`something`* channel that a site defines for this purpose.

The `notificationchannel` channel option may be helpful when a channel is prone to generating an exceptionally large number of DSNs, or when it is desired to handle DSNs generated by a particular channel in some special way, in combination with source specific rewrite rules.

The `dispositionchannel` channel option may be used on a channel to tell it to generate MDNs through the specified channel, rather than through the (default) `process` channel. It takes a required argument, which is the name of the channel to which to enqueue the newly generated MDNs; normally, this should be some `process_`*`something`* channel that a site defines for this purpose.

46.3.22.5 Including altered addresses in notification messages (`includefinal`, `suppressfinal`, `useintermediate`)

When the MTA generates a notification message (bounce message, delivery receipt message, *etc.*), there may be several forms of an address available to the MTA: the preserved "original" form of a recipient address (the ORCPT form---in principle, that form originally typed by the sending user, but in practice that true original form may not have been preserved and instead some "later", transformed version may be the earliest form preserved), the "recently" active form (referred to here as the "intermediate" form) corresponding to the form of the address prior to any most recent forwarding applied by the MTA, and an altered "final" form of that recipient address (as for instance a final form after forwarding is applied). The MTA always includes the original form (assuming it is present) in the notification message, since that is the form that the recipient of the notification message (the sender of the original message which the notification message concerns) is most likely to recognize. The `includefinal`, `suppressfinal`, and `useintermediate` channel options, as set on a channel generating a notification message, control whether the MTA also includes the intermediate or final form of the address. `includefinal` means to include the final form of the recipient address; `useintermediate` is the default, and means to include the intermediate address form rather than the final address form; `suppressfinal` causes the MTA to suppress the final and intermediate address forms, if an original address form is present, from notification messages.

See Notification message format for an example of a DSN to see where these options would affect notification format.

Including the intermediate form is normally useful, especially to the postmaster of the MTA system itself, as the original address form, while presumably recognizable to the original sending user, may bear no obvious relationship to the form of address active by the time the MTA processed the message; in order to figure out what recipient on the MTA system was intended, something like the intermediate or even final address form may well be necessary. Suppressing the inclusion of any final or intermediate form of address entirely may be of interest to sites that are "hiding" their internal mailbox names from external view; such sites may prefer that only the original, "external" form of address be included in notification messages.

Note that only some channels fully support the `useintermediate` channel option; for other channels (including all channels written using the API), the effect of `useintermediate` is merely to use the final address form, that is, it is effectively equivalent to `includefinal`.

See also the special use of a colon character, `:`, as the leading character of an alias value which provides an alias-specific, rather than channel-wide, version of the `useintermediate` effect.

46.3.22.6 Default language tag (`language`)

Certain MTA operations, especially those involving selection of textual content to send to users, may need to take language into account. For example, nondelivery notification text may be available in multiple languages and the NOTIFICATION_LANGUAGE mapping and DISPOSITION_LANGUAGE mapping can be used to select the appropriate language to use. The MTA also supports use (and selection amongst) language-tagged values for various mailAutoReply* LDAP attributes used to construct vacation messages; see the discussion of the ldap_autoreply_subject and ldap_autoreply_text* MTA options in particular.

It is axiomatic that in order to make decisions based on language langage tagging information must be available. Normally this information is derived from the message being processed, *e.g.*, from an Accept-language: header field, from a Preferred-language: header field, or even from the country code found in the From: address. However, not all messages contain such information.

The language channel option can be used to associaed a default language with a particular source channel. A single string argument is required specifying a language tag. Messages originating from this channel which aren't tagged in any other way will be effectively tagged with this value. The default is not to assume any language tag on a per-channel basis.

46.3.22.7 SMTP DSN extension support (notary, refusenotary, nonotary

The notary and (the RESTRICTED) nonotary channel options control whether client TCP/IP channels attempt to use the SMTP DSN extension (defined in RFC 3461). The notary channel option is the default on SMTP over TCP/IP channels.

The nonotary channel option, if set, disables the use of the SMTP NOTARY extension. Its use on SMTP client channels is RESTRICTED, and it is normally used only on LMTP client channels. Note that setting lmtp or an lmtp_* channel option on a channel implicitly sets nonotary.

New in 8.0.1 is the refusenotary channel option. This RESTRICTED option disables the DSN extension in the SMTP/LMTP client and additionally, the SMTP server. (The DSN extension is never offered by the LMTP server.)

46.3.22.8 Undeliverable message notification times (notices, nonurgentnotices, normalnotices, urgentnotices)

The notices, nonurgentnotices, normalnotices, and urgentnotices channel options control the amount of time an undeliverable message is silently retained in a given channel queue. The MTA is capable of returning a series of warning messages to the originator and, if the message remains undeliverable, the MTA will eventually return the entire message.

Different return handling for messages of different priorities may be explicitly set using the nonurgentnotices, normalnotices, or urgentnotices channel options. Setting values for the notices option is equivalent to setting those values for nonurgentnotices, normalnotices, and urgentnotices, so those values will be used for all messages. (In particular, if you wish to have, for example, an urgentnotices setting override a more general notices setting, then the urgentnotices option must appear *after* the notices option.)

This channel option's required argument is a list of up to five monotonically increasing positive integer values. These values refer to the message ages at which warning messages are

sent. The ages have units of days if the MTA option `return_units` is 0 or not specified in the MTA option file, or hours if the MTA option `return_units` is 1. When an undeliverable message attains or exceeds the last listed age, it is returned (*i.e.*, bounced). When it attains any of the other ages, a warning notice is sent. (Note that when `return_units` is 0, so that the ages are interpreted as days, the ages to be exceeded are interpreted as full, twenty-four hour days; for instance, in order for a `notices` value of `1` to apply to a message, the message must have been tried already for a full twenty-four hours. For instance, if the `return_job`, as is usual, is configured to run at thirty minutes after midnight each day, and if the initial `notices` value is `1`, then a message originally submitted on the first of a month will not get a notification message generated until thirty minutes after midnight on the third of the month; consider that on the second of the month, the message had not yet been being tried for a *full* twenty-four hours.)

The default if no `notices` channel option is given is to use the `notices` setting for the local, l, channel. If no setting has been made for the local channel, then the defaults 3, 6, 9, 12 are used meaning that warning messages are sent when the message attains the ages 3, 6, and 9 days (or hours) and the message is returned after remaining in the channel queue for more than 12 days (or hours).

If you wish to change the notification ages for all of your channels, then the simplest thing to do is to add a `defaults` channel block at the top of your configuration (assuming you don't already have one) and set the appropriate `*notices` options there.

46.3.22.9 Postmaster address (`returnaddress`, `noreturnaddress`, `returnpersonal`, `noreturnpersonal`)

By default, the Postmaster return address used when the MTA constructs bounce or notification messages is `postmaster@local-host`, where `local-host` is the official local host name (the name on the local channel), and the Postmaster personal name is "Internet Mail Delivery" for the Messaging Server and "PMDF e-Mail Interconnect" for PMDF. Care should be taken in the selection of the Postmaster address---an illegal selection may cause rapid message looping and pile-ups of huge numbers of spurious error messages.

The `return_address` and `return_personal` MTA options can be used to set the system default for the Postmaster address and personal name. Or if per channel controls are desired, the `returnaddress` and `returnpersonal` channel options may be used. And finally, a hosted-domain specific Postmaster address can be set using the LDAP attribute (normally `mailDomainReportAddress`) named by the `ldap_domain_attr_report_address` MTA option.

These channel options `returnaddress` and `returnpersonal` each take a required argument specifying the Postmaster address and Postmaster personal name, respectively. `noreturnaddress` and `noreturnpersonal` are the defaults and mean to use the default values, either defaults established via the `return_address` and `return_personal` MTA options, or the normal default values if such options are not set.

46.3.22.10 Postmaster returned message content (`postheadonly`, `postheadbody`)

When an MTA channel program or the periodic message `return_job` returns messages to both the postmaster and the original sender, the postmaster copy can either be the entire message or just the headers. Restricting the postmaster copy to just the headers adds an additional level of privacy to user mail. Note, however, this by itself does not guarantee

message security; postmasters and system managers are typically in a position where the contents of messages can be read using system privileges if they so choose.

The channel options `postheadonly` and `postheadbody` are used to control what gets sent to the postmaster. `postheadbody` returns both the headers and the contents of the message. It is the default. `postheadonly` causes only the headers of the returned message to be sent to the postmaster.

46.3.22.11 Delivery receipt request style (`reportboth`, `reportheader`, `reportnotary`, `reportsuppress`)

The `reportboth`, `reportheader`, `reportnotary`, and `reportsuppress` channel options control which sort, if any, of delivery receipt request the MTA constructs from "foreign" delivery receipt requests, such as for messages coming in to PMDF via PMDF-LAN, PMDF-MR, PMDF-X400, or PMDF-MB400 channels, or via the addressing channel. On OpenVMS, these keywords also control the interpretation of delivery receipt requests from VMS MAIL or PMDF MAIL via L or D channels. For PMDF-LAN, PMDF-MR, PMDF-X400, and PMDF-MB400 channels, these keywords also control which sort of delivery receipt request the MTA will convert into the respective "foreign" delivery receipt request. (In the case of PMDF-X400, note that the keyword on the MIME_TO_X400 channel controls the behavior in both directions, to and from the X.400 world.) The current default is `reportheader` meaning to turn "foreign" delivery receipt requests into the old ad-hoc header style delivery receipt requests. `reportnotary` requests that only NOTARY[g] style delivery receipt requests be generated; this may become the default in a future version. `reportboth` causes the MTA to generate both a header style and a NOTARY style delivery receipt request when seeing a "foreign" delivery receipt request; setting this may result in two delivery receipts from MTAs that support both forms of delivery receipt request. `reportsuppress` causes the MTA to ignore (suppress) incoming "foreign" delivery receipt requests.

46.3.22.12 Blank envelope return addresses (`returnenvelope`)

The `returnenvelope` channel option takes a bitmask argument.

Bit 0 (value = 1) controls whether or not return notifications generated by the MTA are written with a blank envelope address or with the address of the local postmaster. Setting the bit forces the use of the local postmaster address, clearing the bit forces the use of a blank addresses. Note that the use of a blank address is mandated by RFC 1123. However, some systems do not handle blank envelope from address properly and may require the use of this option.

Bit 1 (value = 2) controls whether or not the MTA replaces all blank envelope addresses with the address of the local postmaster. Again, this is used to accomodate incompliant systems that don't conform to RFC 821, RFC 822, or RFC 1123.

Bit 2 (value = 4) controls whether or not the MTA checks that any (non-empty) envelope From address matches (rewrites to) an MTA channel.

Setting bit 3 (value = 8) is equivalent to setting the `mailfromdnsverify` channel option: it controls whether or not the MTA checks that the domain in the envelope From address resolves in the DNS. That is, setting the bit causes the MTA to require that a DNS entry can be found corresponding to the domain in the envelope From address; but the type of DNS entry does not matter.

Setting bit 4 (value = 16) causes the MTA to enforce that if the envelope From address claims a local domain name, the envelope From address must correspond to a user address (user alias).

Bit 5 (value = 32) modifies the effect of bit 3 (value 8). When bits 3 and 5 are both set (value = 40), then a DNS query resulting in an authoritative HOST_NOT_FOUND response will be treated as a temporary error (a 450 error), rather than being rejected with a permanent rejection (a 550 error) as `mailfromdnsverify` (`returnenvelope 8`) would otherwise normally cause.

New in 8.0, bit 6 (value = 64) modifies the effect of setting bit 3 (value = 8) on domain validity checks. With both these bits set, if the domain in the MAIL FROM address corresponds to a null MX domain, that address will be rejected as invalid. That is, setting bit 6 causes the bit 3 domain check to also implement support for `draft-delany-nullmx-01.txt`.

Note that the `return_envelope` MTA option can be used to set an MTA system default for this sort of behavior.

46.3.23 Processing control and job submission channel options

There are a number of important channel options reflecting the fundamental nature of the channel, and interacting with the Job Controller's scheduling of messages.

46.3.23.1 Number of message files or addresses to handle per service job or file (`addrsperjob`, `filesperjob`)

The MTA normally creates one delivery service job per channel that needs service. This applies to both immediate service and periodic service jobs: when a message is initially sent and immediate service is needed one job is created for each channel to which the message is queued, and when the MTA creates periodic jobs it normally creates one periodic job for each channel that needs service.

A single service job may not be sufficient to insure prompt delivery of all messages, however.

The `addrsperjob` and `filesperjob` channel options can be used to cause the MTA to create additional service jobs. Each one of these options takes a single positive integer parameter which specifies how many addresses or queue entries (*i.e.*, files) must be sent to the associated channel before more than one service job is created to handle them. If a value less than or equal to zero is given it is interpreted as a request to queue only one service job. Not specifying an option is equivalent to specifying a value of zero. The effect of these options is maximized; the larger number computed will be the number of service jobs that are actually created.

The `addrsperjob` channel option computes the number of services jobs to start by dividing the total number of To: addressees in all entries by the given value. The `filesperjob` channel option divides the number of actual queue entries or files by the given value. Note that the number of queue entries resulting from a given message is controlled by a large number of factors, including but not limited to the use of the `single` and `single_sys` channel options and the specification of header-modifying actions in mailing lists. Also note that the `maxjobs` channel option places an upper bound on the total number of service jobs that can be created.

For example, if a message with 4 recipient addresses is queued to a channel marked `addrsperjob 2` and `maxjobs 5` a total of 2 service jobs will be created. But if a message with 23 recipient addresses is queued to the same channel only 5 jobs will be created because of the `maxjobs` restriction.

Note that these channel options affect the creation of both periodic and immediate service jobs. In the case of periodic jobs the number of jobs created is calculated from the total number of messages in the channel queue. In the case of immediate service jobs the calculation is based only on the message being entered into the queue at the time.

Finally, note that the `addrsperjob` option is generally only useful on channels that provide per-address service granularity. Currently this is limited to PMDF-FAX channels; there is no case where it is useful for the Messaging Server.

46.3.23.2 Service job execution deferral (`after`, `urgentafter`, `normalafter`, `nonurgentafter`, `secondclassafter`, `thirdclassafter`)

Service jobs are created to deliver messages; the creation of such jobs on an as-needed basis is managed by the MTA's Job Controller. The creation of service jobs can be deferred using the `after` channel option, or deferred on a priority-sensitive basis using the other `*after` channel options. Note, however, that such deferral is seldom of interest given the modern Job Controller's internal, "smart" management of jobs.

Each `*after` option accepts an argument specifying either an absolute time at which to initiate a delivery job, or an amount of time to delay (a delta time). For the Messaging Server MTA, if the argument is an unsigned integer value, it is interpreted as an absolute time at which to initiate a delivery job, in GMT time zone; if the argument begins with the plus character, `+`, it is interpreted as the number of seconds by which to defer the execution of the job -- a delta time value. (Note that for PMDF, the argument syntax was different: all values were interpreted as delta time values.)

Historical note: For PMDF, deferred execution with a (typically small) delta time value was most often used to increase throughput (*e.g.*, as a result of cutting down on process creation overhead) for heavily used channels. By using `after` to introduce a slight latency in the creation of a service job, each such job had a window of time during which to "collect" all the messages sent to the channel in that time. Whereas otherwise a service job might handle only one (or at especially busy times perhaps two or three) messages, such use of `after` allowed a service job to handle larger numbers of messages. For channels with high connection or process activation overhead, this could result in higher overall throughput. But this is no longer the case for the Messaging Server MTA.

Separate deferral settings are allowed for messages with different effective priority values. The `urgentafter` channel option sets the delay for urgent messages, `normalafter` sets the delay for normal priority messages, and `nonurgentafter` sets the delay for non-urgent messages. `secondclassfter` and `thirdclassafter` set the delay for second-class and third-class (nonstandard priority levels below non-urgent) messages respectively. `after` sets the delay for all messages regardless of priority; setting it is equivalent to setting all of the other `*after` options to that same delay value.

46.3.23.3 Delivery retry intervals (`backoff`, `urgentbackoff`, `normalbackoff`, `nonurgentbackoff`, `ipbackoff`)

Backoff options specify the frequency of message delivery retries when messages aren't successfully delivered the first time. These options all accept a series of intervals as arguments. The first interval specifies the time to wait before the first retry, the second specifies the time to wait for the second retry, and so on. The last value given specifies the time to wait for all

subsequent retries. Up to eight intervals can be specified. Deliveries are attempted for a period of time specified by the `notices` channel option. Delivery will fail if successful delivery cannot be made within the time allowed by the last `notices` channel option setting.

Interval values use ISO 8601 periodic time syntax:

```
P[yearsY][monthsM][weeksW][daysD][T[hoursH][minutesM][secondsS]]
```

years, *months*, *weeks*, *days*, *hours*, *minutes* and *seconds* are all integer values.

Note that all of the letters in the value must be written in upper case.

Separate interval settings are allowed for messages with different priority settings. The `urgentbackoff` channel option sets the retry intervals for urgent messages, `normalbackoff` sets the retry intervals for normal priority messages, and `nonurgentbackoff` sets the interval for non urgent messages. `backoff` sets the retry intervals for all messages regardless of priority.

Additionally, as of MS 8.0.2.3, an additional `ipbackoff` option is provided to set backoff times for messages that have been placed in IP backoff mode. The ability to set ipbackoff values on a per-domin basis is also provided by the ipbackoff smartsend parameter.

The default intervals between delivery retry attempts in minutes are:

```
urgent: 30, 60, 60, 120, 120, 120, 240
normal: 60, 120, 120, 240, 240, 240, 480
nonurgent: 120, 240, 240, 480, 480, 480, 960
ip: 60, 120, 120, 240, 240, 240, 480
```

Note that setting the various options on the defaults channel can be used to override these built-in defaults, as opposed to having to set the options on every channel with an associated queue in the configuration, e.g.,

```
msconfig> set channel:defaults.backoff "PT30M PT1H PT2H PT4H"
```

Also note that the MTA has special handling of the case of problems delivering to *some* recipients of multi-recipient messages: in such cases, the failing recipients are eligible for another "immediate" delivery attempt without regard to `*backoff` setting; see the discussion of MTA message transaction log file "Z" records.

Note that `ims-ms` channels and LMTP client TCP/IP channels have special case handling that overrides normal `backoff` for the specific error condition of encountering IMAP_MAILBOX_LOCKED when attempting delivery to a Message Store user.

46.3.23.4 Initiating delivery processing (`bidirectional`, `master`, `slave`)

Three options are used to specify whether a channel is served by a master program (`master`), a slave program (`slave`), or both (`bidirectional`). The default, if none of these options is specified, is `bidirectional`. These options determine whether the MTA bothers to initiate

delivery activity when a message is queued to the channel - there is no point in doing this on a slave-only channel.

The use of these options reflects certain fundamental characteristics of the corresponding channel program or programs. The descriptions of the various channels the MTA supports indicate when and where these options should be used.

Note that the Job Controller configuration should, normally, include definitions for what actual image(s) a channel should execute for `master` or `slave` mode operations, as appropriate for that channel. For instance, a channel which is `bidirectional` (and where both directions are truly used) should normally have both `master_command` and `slave_command` Job Controller options defined, whereas a channel which operates solely in `master` mode needs only a `master_command` option, not a `slave_command`.

46.3.23.5 Deferred delivery dates (`deferredsource`, `nodeferredsource`, `deferreddestination`, `nodeferreddestination`)

The `deferredsource` and `deferreddestination` channel options implement recognition and honoring of the Deferred-delivery: header. These options are newly implemented in the 7.0 release of Messaging Server. When set on a source or destination channel respectively, messages with a deferred delivery date in the future will be held in that channel queue until the deferred delivery date is reached. See RFC 2156 for details on the format and operation of the Deferred-delivery: header line. Both channel options accept a single integer argument specifying the maximum number of seconds in the future a Deferred-delivery: date value can specify and still be honored. If both options apply to a transaction the lower of the two limits will apply. The integer arguments are optional in a traditional `imta.cnf` file - if the value is omitted a default of 60*60*24*7 (7 days) will be assumed.

Prior to the 7.0 release the `deferred` channel option provides similar functionality to `deferreddestination`. In 7.0 the MTA accepts `deferred` as a synonym for `deferreddestination` in the `imta.cnf` file; in Unified Configuration, `deferred` and `nodeferred` may no longer be used and the preferred `deferreddestination` and `nodeferreddestination` must be used instead. Note also that prior to 7.0 deferred delivery was not a reliable service. In particular, deferred handling information does not survive Job Controller restarts.

`nodeferredsource` and `nodeferreddestination` are the defaults. It is important to realize that while support for deferred message processing is mandated by RFC 2156, actual implemention of it effectively lets people use the mail system as an extension of their disk quota.

See also the [DEFERRED] alias file named parameter and, in Unified Configuration, the `alias_deferred` alias option, which provide a per-alias (per-recipient) mechanism to add a Deferred: header line. For users defined in LDAP, the attribute `mgrpAddHeader`, or whatever attribute is named by the `ldap_add_header` MTA option, also provides a way to add such a header line.

See also the `futurerelease` channel option, which enables use of the SMTP FUTURERELEASE extension, offering superior functionality over Deferred-delivery: header line based message deferral.

46.3.23.6 Expansion of multiple addresses (`expandlimit`, `expandchannel`, `holdlimit`)

Most MTA channels support the specification of multiple recipient addresses in the transfer of each inbound message. The specification of many recipient addresses in a single message may result in delays in message transfer processing ("on-line" delays). In particular, multi-recipient messages that require a great deal of processing of the message body can be affected by processing delays, or that require creation of many different file copies on disk in the MTA queue area can be affected by slow disk performance. If the resulting delays are long enough, network timeouts can occur, which in turn can lead to repeated message submission attempts and other problems.

The MTA provides a special facility to force deferred ("off-line") processing of additional recipient message copies once a given number of addresses are specified for a single message. The deferral happens after processing of the "initial" recipients (those before the `expandlimit` value was reached), and after address processing for the additional recipients too, (for instance, after `*_ACCESS` mapping table checks and after alias processing), but before message processing. In particular, such deferral means that for the "additional" recipients, only *one* message file (storing all of the "additional" recipients), is written to the queue area (to a `reprocess*` or `process*` channel queue area, depending upon use of the `expandchannel` channel option). Deferral of message processing can decrease on-line delays enormously. Note, however, that the processing overhead is deferred, not avoided completely.

This special facility is activated by using a combination of, for instance, the generic reprocessing channel and the `expandlimit` channel option. The `expandlimit` option takes an integer argument that specifies at what number of recipients to begin deferring processing of the message copy (or copies) to that and additional recipient addresses. The default value is effectively infinite if the `expandlimit` channel option is not specified. A value of 1 will force deferred processing on all incoming addresses from the channel.

The `expandlimit` channel option must *not* be specified on the local channel or the reprocessing channel itself; the results of such a specification are unpredictable.

The channel actually used to perform the deferred processing may be specified on a per-source-channel basis using the `expandchannel` channel option; the reprocessing channel is used by default, if `expandchannel` is not specified, but use of some other reprocessing or processing channel may be useful for some purposes. In particular, for Messaging Server MTA versions 5.2 and earlier, typical configuration usage required that a processing channel, rather than a reprocessing channel, be used. If a channel for deferred processing is specified via `expandchannel`, that channel should be a reprocessing or processing channel; specification of other sorts of channels may lead to unpredictable results.

The reprocessing channel, or whatever channel is used to perform the deferred processing, must be added to the MTA configuration file in order for the `expandlimit` option to have any effect. If your configuration was built by the initial configuration utility, then you should already have a reprocessing channel.

(Note that typical Messaging Server sites running version 5.2 or earler could not use the `expandlimit` option unless they also marked the affected channel `expandchannel process` (or `expandchannel process_somethingorother` redirecting the expansion to an alternate `process_*` sort of channel), as enqueues to a channel marked `viaaliasrequired` would not succeed if deferred to a `reprocess*` channel.)

Extraordinarily large lists of recipient addresses are often a characteristic of so-called SPAM---junk e-mail. The `holdlimit` channel option tells the MTA that messages coming in the channel that result in more than the specified number of recipients should be marked as

`.HELD` messages and enqueued to the `reprocess` channel (or to whatever channel is specified via the `expandchannel` channel option). As `.HELD` messages, the files will sit unprocessed in that MTA queue area awaiting manual intervention by the MTA postmaster.

46.3.23.7 SMTP Future Release Extension (`futurerelease`)

Release 7 of the Messaging Server MTA implements support for future release SMTP SUBMIT extension defined in RFC 4865. This support is enabled by placing the `futurerelease` channel option on the `submit` source channel used for initial message submission. The option takes a single integer argument: The maximum number of seconds a message can be deferred.

Care should be used when enabling future release since it allows messages to be in effect stored in the MTA's queues. Future release should only be used for channels handling initial message submission and authentication should be required.

Note that similar functionality is available in earlier Messaging Server releases: Specification of a Deferred-delivery: header field in a submitted message coupled with use of the `deferreddestination` channel option on the destination channel provided the ability to defer delivery of messages. However, future release provides superior functionality:

- The facility is controlled by a setting on the source channel, allowing it to be provided to a subset of the user population. Placing `deferreddestination` option on a destination channel opens the door to anyone submitting a message to that channel that will be deferred for some period of time.
- There's no way for a client which sets a Deferred-delivery: header field to know whether or not the header has actually caused the message to be deferred. The future delivery SMTP extension, on the other hand, lets the client know how long a message can be deferred and an error will be returned to the client if the message cannot be deferred for the time the client wants.
- There was no way to place a limit on the amount of time a message could be deferred. Instead what happened was that a message deferred longer than the channel's last `notices` value would simply be returned as undeliverable.
- Deferred-delivery settings on messages did not survive a Job Controller restart.

As part of the implementation work for future release the old Deferred-delivery: mechanism has been redesigned to address some (but not all) of these points. In particular, the `deferred` channel option has been replaced by two new channel keywords, `deferredsource` and `deferreddestination`. (The `deferred` option is now a synonym for `deferreddestination`.) Both of these options accept an integer argument (required in unified configurations, optional in `imta.cnf`) specifying in seconds the maximum amount of time in the future a Deferred-delivery: header can specify and still be honored. The default if no argument is specified is 60*60*24*7, or 7 days. `deferredsource` enables Deferred-delivery: processing on the basis of the source channel while deferreddestination operates on destination channels. Finally, Deferred-delivery settings on messages now survive job controller restarts. This addresses all of the points on the above list except the second one - use of a Deferred-delivery: header field still provides no mechanism for informing the client whether or not the setting will be honored.

However, as a purely practical matter, the mechanism chosen to provide delayed release of messages is likely to be dictated by the choice of email client and what mechanisms it supports.

46.3.23.8 Header-based message expiration(`expirysource`, `expirysource`)

(New in Messaging Server 7.0.) The `expirysource` channel option instructs the MTA to honor Expiry-date: header fields - messages will be returned as undeliverable if the time specified by this header field is exceeded. `noexpirysource` disables this check and is the default.

46.3.23.9 Maximum number of simultaneous jobs for this channel (`maxjobs`)

The `maxjobs` channel option places an upper bound on the total number of service jobs that can be created. This option must be given an integer argument; if the computed number of service jobs is greater than this value only `maxjobs` jobs will actually be created. The default for this value if `maxjobs` is not specified is 100. Normally `maxjobs` is set to a value that is less than or equal to the total number of jobs that can run simultaneously in whatever Job Controller pool the channel uses.

See also the `job_limit` Job Controller option.

Note that a `imsimta cache -change -channel=NAME -job_limit=N` command can change the effective `maxjobs` value for a channel "on the fly".

46.3.23.10 Priority of messages to be handled by periodic jobs (`minperiodicnonurgent`, `minperiodicnormal`, `minperiodicurgent`, `maxperiodicnonurgent`, `maxperiodicnormal`, `maxperiodicurgent`)

OBSOLETE: These channel options have no effect nowadays, with the Job Controller. See instead Job Controller priority-based processing.

In the past: When periodic delivery jobs were used, they normally processed all messages queued for the channel. However, on some channels it may be desirable to limit normal periodic job processing to only messages of specified priorities. Other special site-supplied periodic jobs may then process the remaining messages. For instance, a site might choose to have normal MTA periodic jobs pass over nonurgent messages, leaving those nonurgent messages to be delivered by some site-supplied job (perhaps scheduled to run at off-peak hours).

The `minperiodicnonurgent`, `minperiodicnormal`, or `minperiodicurgent` channel options specify the minimum priority of message that a periodic job should try to deliver; the job will ignore messages of lower priority. The `maxperiodicnonurgent`, `maxperiodicnormal`, or `maxperiodicurgent` options specify the maximum priority of message that a periodic job should try to deliver; the job will ignore messages of higher priority.

46.3.23.11 Per-channel MT-PRIORITY control (`mtprioritiesallowed`, `mtprioritiesrequired`)

`mtprioritiesallowed` and `mtprioritiesrequired` are new in the 8.0 release. These channel options enable the MTA's support of RFC 6710 (SMTP Extension for Message Transfer

Priorities). New in Cayenne, see the `envelopetunnel` channel option for "tunneling" MT-PRIORITY, via a header field, through systems that do not support the MT-PRIORITY SMTP extension, as described in RFC 6758 (Tunneling of SMTP Message Transfer Priorities).

The `mtprioritiesallowed` source channel option specifies the range of MT-PRIORITY values that will be accepted. MT-PRIORITY values outside this range will be adjusted up or down so they fall within the allowed range. If a single argument is given, it specifies the highest priority value that will be accepted. The default if this option is not specified is for the MT-PRIORITY extension not to be offered and for MT-PRIORITY parameters not to be accepted.

The `mtprioritiesrequired` source channel option specifies the range of MT-PRIORITY that will be accepted for enqueue. If a single argument is given, it specifies the lowest priority value that will be accepted. The message will be rejected if the message's specified MT-PRIORITY value, or if the default MT-PRIORITY value of 0 (assumed if MT-PRIORITY was not specified in the SMTP transaction), falls outside the required range with the SMTP error:

```
550 5.7.0 Message priority outside curretly allowed range
```

With either channel option, two integer arguments specify the range. Each argument must be an integer in the range -9..9. The arguments can be given in any order.

46.3.23.12 Service job pool usage (`pool`)

The Messaging Server's Job Controller creates channel jobs (jobs to deliver messages) as needed: the MTA's enqueueing processes inform the Job Controller regarding newly enqueued messages, and the Job Controller then decides which existing service job whould attempt the message's delivery, or creates a new service job, as needed.

To manage the allocation of channel delivery job processes, the Job Controller has "processing pools" (in old PMDF terminology, "queues"). Different channels may be configured to run in different processing pools via the `pool` channel option.

Note that for iMS/MS/the Oracle Messaging Server, the priority-sensitive queues of PMDF days are obsolete. Instead, the Job Controller takes care of managing different priority messages in different priority internal processing "queues" within a processing pool. That is, priority-sensitive sorting of messages is handled internally by the Job Controller, without needing explicit configuration.

46.3.23.13 Triggering new jobs (`threaddepth`)

The `threaddepth` channel option tells the Job Controller when to start a new channel "job" to handle messages: for multithreaded channels, when to start a new thread (if the process is allowed to have more threads) or failing that a new process (if more processes are allowed); for single threaded channels, when to start a new process (if more processes are allowed).

For multithreaded channels, the `threaddepth` channel option controls how many messages are handled in any one thread before the channel will consider starting to use another thread.

In particular, the MTA's SMTP client (for channels not marked with the `daemon` channel option) sorts outgoing messages to different destinations to different threads. The `threaddepth` channel option may be used to instruct the MTA's multithreaded SMTP client

to handle only the specified number of messages in any one thread, using additional threads even for messages all to the same destination (hence normally all handled in one thread). The value specified must be greater than 1 and less than 10000. The default as of MS 6.0 is `threaddepth 10`. (This is a change from previous versions, in which the default was 128.)

Use of `threaddepth` may be of particular interest for achieving multithreading with `daemon router` on a TCP/IP channel - a TCP/IP channel that connects to a single specific SMTP server - when the SMTP server to which the channel connects can handle multiple simultaneous connections.

Similarly, the `threaddepth` option affects operation of the multithreaded `ims-ms` channel.

For single threaded channels, such as the conversion, process, and reprocess channels, the `threaddepth` channel option controls how many messages are handled in a single process; more messages cause the Job Controller to create another process (up to the `maxjobs` channel option setting for the channel and the `job_limit` Job Controller option value for the `pool` in which the channel runs) to process the messages.

46.3.23.14 `user` Option Under channel

The `user` channel option is used on pipe channels to indicate under what Unix user id to run.

In the 8.0 release and later, this option is deprecated and the `pipeuser` option from `restricted.cnf` is used instead.

46.3.24 Sensitivity limits channel options

Several channel options set channel-specific message sensitivity limits.

46.3.24.1 Sensitivity checking (`sensitivitynormal`, `sensitivitypersonal`, `sensitivityprivate`, `sensitivitycompanyconfidential`)

The `sensitivitynormal`, `sensitivitypersonal`, `sensitivityprivate`, and `sensitivitycompanyconfidential` channel options set an upper limit on the sensitivity of messages that may be accepted by a destination channel. The default is `sensitivitycompanyconfidential`; *i.e.*, messages of any sensitivity are allowed through. A message with no Sensitivity: header is considered to be of normal, i.e., lowest, sensitivity. Messages with a higher sensitivity than that specified by such a channel option will be rejected when enqueued to the channel with an error:

```
message too sensitive for one or more paths used
```

Note that the MTA does this sort of sensitivity checking at a per-message, not per-recipient, level: if a destination channel for one recipient fails the sensitivity check, then the message bounces for all recipients, not just for those recipients associated with the sensitive channel. (Also note that the `acceptalladdresses` channel option, if used, postpones the timing of the message rejection.)

The `log_sensitivity` MTA option permits logging of the sensitivity of messages passing through the MTA.

46.3.25 Sieve filters and delivery flags channel options

There are a number of channel options controlling Sieve filters and message envelope and delivery flags.

46.3.25.1 Address type flags (`addrtypescan`, `addrtypescanbccdefault`, `noaddrtypescan`)

(New in 7.0.5.) If the `addrtypescan` channel option is set, then RCPT TO addresses (that is, envelope recipients) are compared with header recipient fields (To:, Cc:, Bcc:, Resent-To:, Resent-Cc:, and Resent-Bcc:). When a match is found, that fact is recorded in the delivery flags associated with that envelope recipient. Those flags are then used when generating the report part of Microsoft® Exchange 2007 envelope journaling archive messages, distinguishing between various types of envelope recipient addresses.

`addrtypescanbccdefault` operates in the same way as `addrtypescan`, except that when no matches are found for a given address, that address is assumed to be a blind carbon (Bcc:) recipient. This option should only be used when it is certain the messages have come directly from a client that implements Bcc: by simply omitting the blind carbon recipient from the header and which doesn't support any form of local mailing lists. Use in any other context is *guaranteed* to result in incorrect types being attached!

`noaddrtypescan` is the default.

Also note that since the MTA's delivery flags are used to store this informtion, the MTA's delivery flag transfer facilities may be used to transport this information between MTAs; see the `deliveryflags` channel option.

46.3.25.2 Delivery flags (`deliveryflags`, `flagtransfer`, `noflagtransfer`)

The `deliveryflags` channel option may be placed on source or destination channels. It takes a required, bit-encoded integer argument, which controls various options regarding message delivery:

Table 46.14 `deliveryflags` MTA option bit values

Bit	Value	Usage
0	1	Interpret subaddresses as folder names for delivery. This bit is also set by Sieve "`fileinto`" actions.
1	2	When placed on a source channel, enable quota bypass (that is, delivery even if the recipient user is overquota) for messages enqueued by this channel. (The `tcp_tas` channel, for example, has this set.)
2	4	Reserved for internal use only.
3	8	Reserved for internal use only.
4	16	Force single copy per recipient
5	32	Ignore `discard` or `jettison` actions (*e.g.*, from Sieve filters). This corresponds to setting the message envelope bit normally

		set automatically by the MTA when applying a `discard` or `jettison` action and enqueueing to the `filter_discard` channel, so that if a "retrieval" procedure should later be performed on such a "discarded" message (such as moving the message to the `reprocess` channel), the message will then get delivered bypassing any `discard` or `jettison` actions.
6	64	When placed on a source channel for an SMTP/LMTP server, enable transfer of delivery flags; equivalent to the `flagtransfer` channel option
7	128	Messages enqueued to the channel are considered, for purposes of `CONVERSIONS` mapping table testing, to have a conversion tag set. This bit is set automatically when it is needed and is not intended to be set using the channel option.
8	256	Reserved for internal use only.
9	512	Handle as if SMTP AUTH (SASL) had been used as far as access checks are concerned. This bit is set automatically when it is needed and is not intended to be set using the channel option.
10	1024	Handle as if TLS had been used as far as access checks are concerned.
11	2048	Handle as if address produced by alias as far as access checks are concerned.
12	4096	Bypass all list access checks.

All remaining bits in this option are reserved for internal use and should not be set. The default value for `deliveryflags` is 0.

The `flagtransfer` channel option may be placed on a SMTP server or LMTP server channel. It causes the server to advertise support of the XDFLG and XAFLG private SMTP/LMTP extension parameters to the RCPT TO command. As of MS 8.0.2.3, `flagtransfer` also causes the SMTP server (but not the LMTP server) to advertise the XCONVTAG extension.

If a Messaging Server SMTP client is sending to an SMTP server (or a Messaging Server LMTP client is sending to an LMTP server) that supports this extension, then that SMTP client (or LMTP client) will pass along (transfer) delivery flags, IMAP flags, and (in the case of SMTP) conversion tags.

For instance, this can be useful when user filters (performing `fileinto` Sieve operations) will be performed on a "front-line" system that must then relay the messages to a "back-end" system. `noflagtransfer` disables delivery flag transfer and is the default.

Some of the delivery flag bits affect server security, as such, the `flagtransfer` channel option should never be set on a channel that is exposed to untrusted traffic.

Setting `flagtransfer` is equivalent to setting bit 6 (value 64) of the `deliveryflags` channel option.

46.3.25.3 Filter file location (`filter`, `nofilter`, `destinationfilter`, `nodestinationfilter`, `sourcefilter`, `nosourcefilter`, `disablesourcefilter`, `disabledestinationfilter`)

For the Messaging Server MTA, user and group Sieve filters are normally enabled simply by storing them in the users' (and groups') `mailSieveRuleSource` attribute - or more precisely, storing them in the attribute named by the `ldap_filter` MTA option. However, user Sieve filters may be located in an alternate sort of location (in files on disk, for instance) via use of the `filter` channel option. So while not normally used, in principle the `filter` option may be used on the `ims-ms`, native, and `tcp_lmtpc*` channels to specify the location of user Sieve filters for that channel. It takes a required URL argument describing the users' Sieve filter location -- typically a (templated, making use of substitution based on user) file location. `nofilter` is the default; it means that only filters enabled implicitly via user/group LDAP entries will be used (and no additional, external Sieve lookup will be performed by the MTA).

IMPORTANT NOTE: Due to the way the MTA caches Sieves internally - the URL is used as a cache key - it's vital that each user have a distinct Sieve file or be associated with a distinct LDAP entry when the `filter` channel option is used. Failure to insure this separation will cause Sieve ownership checks to behave in unexpected ways and may allow users to bypass certain security checks.

The `sourcefilter` and `destinationfilter` channel options may be used on general MTA channels to specify a channel-level Sieve filter to apply to incoming and outgoing messages, respectively. (More precisely, a `sourcefilter` is applied when the source channel on which it is specified is enqueueing a message; a `destinationfilter` is applied when any channel is enqueuing a message to the destination channel on which it is specified.) These channel options take a required URL argument describing the channel Sieve filter location (typically a file). `nosourcefilter` and `nodestinationfilter` are the defaults and mean that no channel Sieve filter is enabled for either direction of the channel.

The obsolete `channelfilter` and `nochannelfilter` channel options are synonyms for `destinationfilter` and `nodestinationfilter`, respectively.

IMPORTANT NOTE: It's very important not to confuse the `filter` and `destinationfilter` channel options. The critical difference is that `destinationfilter` Sieves are system-level whereas `filter` Sieves are user-level. As such, a system-level Sieve invoked with `filter` may not have access to the capabiities it needs, while a user-level Sieve invoked with `destinationfilter` would give the user control over various aspects of message disposition handling they should not be able to change.

New in Messaging Server 7.0 update 3 are the `disablesourcefilter` and `disabledestinationfilter` channel options. These options can be used to suppress the evaluation and interpretation of Sieve filters based on source or destination channel, respectively. Each option takes a single nonnegative integer argument, whose value is interpreted as follows:

Table 46.15 `disablesourcefilter` and `disabledestinationfilter` MTA options values

Value	Usage
0	Disable all Sieves
1	Only spam filter Sieves are evaluated and interpreted
2	Only spam filter and source channel Sieves are evaluated and interpreted
3	Spam filter and source channel Sieves, and the `systemfilter` MTA system Sieve (which in legacy configuration was `imta.filter`), are evaluated and interpreted

4	Spam filter, source channel, the `systemfilter` MTA system Sieve (which in legacy configuration was `imta.filter`), and destination channel Sieves are evaluated and interpreted
5	Spam filter, source channel, the `systemfilter` MTA system Sieve (which in legacy configuration was `imta.filter`), destination channel, and `ORIG_SEND_ACCESS` Sieves are evaluated and interpreted
6	Spam filter, source channel, the `systemfilter` MTA system Sieve (which in legacy configuration was `imta.filter`), destination channel, `ORIG_SEND_ACCESS`, and `SEND_ACCESS` Sieves are evaluated and interpreted
7	Spam filter, source channel, the `systemfilter` MTA system Sieve (which in legacy configuration was `imta.filter`), destination channel, `ORIG_SEND_ACCESS`, `SEND_ACCESS`, and `ORIG_MAIL_ACCESS` Sieves are evaluated and interpreted
8	Spam filter, source channel, the `systemfilter` MTA system Sieve (which in legacy configuration was `imta.filter`), destination channel, `ORIG_SEND_ACCESS`, `SEND_ACCESS`, `ORIG_MAIL_ACCESS` and `MAIL_ACCESS` Sieves are evaluated and interpreted

46.3.25.4 Sieve filter fileinto action channel options (`fileinto`, `nofileinto`)

The `fileinto` channel option, currently only especially meaningful for channels delivering into the Messaging Server Message Store (that is, `ims-ms` and `tcp_lmtpc*` channels), specifies how to alter an address when a Sieve filter "`fileinto`" action is applied. `nofileinto` is the default, and means that a Sieve filter "`fileinto`" action has no address-modifying meaning for that destination channel.

For `ims-ms` channels, the usual usage is

```
fileinto $U+$S@$D
```

meaning that the folder name should be inserted as a subaddress into the original address, replacing any originally present subaddress. (The default value for the FILEINTO ims-ms-channel-specific option then results in the `ims-ms` channel interpreting that subaddress as a request for folder delivery.)

For `tcp_lmtpc*` channels, the usual usage is

```
fileinto @$4O:$U+$S@$D
```

(where note that in `$4O` the `O` is the capital or majuscule letter "o", *not* the numeral zero 0). The effect is that the explicit source route to the mailhost should be preserved if present, and the foldername should be inserted as a subaddress into the original address, replacing any originally present subaddress.

The Message Store delivery code normally considers any "trusted" subaddress present on a recipient address as a request to deliver directly into the correspondingly named folder. (This can be overridden for the `ims-ms` channel by disabling the FILEINTO ims-ms-channel-specific option.) Application of the `fileinto` channel option also sets a bit in the message

envelope that means that for Message Store delivery "trust this subaddress as a folder name for delivery purposes". So when the `fileinto` channel option is applied on an `ims-ms` channel or a `tcp_lmtpcs*` channel, subaddresses added due to a Sieve filter "`fileinto`" action will cause folder delivery. Note that unless a subaddress has been added/replaced due to such a Sieve "`fileinto`" action and the `fileinto` channel option's resulting setting of the proper message envelope bit, any other subaddress will not normally be considered as a valid request for folder delivery---not unless the IMAP post ACL (RFC 4314, IMAP4 Access Control List (ACL) Extension) has been set on that folder in the Message Store.

46.3.25.5 Sieve filter and delivery flags channel options: `scriptlimit` (integer), `sievelimit` (integer), `sizelimit` (integer)

The `scriptlimit`, `sievelimit`, and `sizelimit` source channel options set limits on how many Sieve scripts a user may have, how large each individual script may be, and the total size limit with scripts combined.

46.3.26 Size limits on messages channel options

A number of channel options relate to message size limits. See also the Message size MTA options. The SMTP server also has some message size related limits; see TCPIP-channel-specific options. And for web-based email clients, see also the `maxmessagesize` MSHTTP option.

46.3.26.1 Triggering alternate channel processing (`alternatechannel`, `alternateblocklimit`, `alternatelinelimit`, `alternaterecipientlimit`)

It is sometimes useful to force processing of messages meeting certain criteria to occur on a channel distinct from the one chosen by the MTA's alias expansion and rewriting process. The `alternatechannel` channel option provides a means to specify such a channel while the `alternateblocklimit`, `alternatelinelimit`, and `alternaterecipientlimit` channel options specify the criteria for when the alternate channel should be used.

`alternatechannel` takes the name of the alternate channel to use as an argument. `alternateblocklimit` takes an unsigned integer as an argument; the alternate channel will be used if the computed block size of the message exceeds this value. `alternaterecipientlimit` also takes an unsigned integer argument; the message will be queued to the alternate chanmel if the number of recipients queued to the current channel exceeds this value. Finally, the `alternatelinelimit` channel option takes an unsigned integer argument; the alternate channel will be used if the computed number of lines in the message exceeds this value.

Note that `alternaterecipientlimit` is a limit on envelope recipients for this message copy, on this channel; it has nothing to do with how many addresses may or may not be in the header; and envelope recipients on other channels are also irrelevant. However, the `alternaterecipientlimit` check does get performed before any message copy split-up due to storage of recipients per file controls such as `addrsperfile`, `single`, or `single_sys` channel option application.

Note that any `*SEND_ACCESS` or `*MAIL_ACCESS` mapping table probes will use the "original" destination channel name, not the alternate destination channel name, but a `CONVERSIONS` mapping table probe will use the alternate destination channel name.

Note that the alternate channel selection process is neither iterative nor recursive: Once an alternate channel has been selected it will be used regardless of what the various alternate channel options on that channel say to do.

46.3.26.2 Message size limits (`blocklimit`, `linelimit`, `sourceblocklimit`, `noblocklimit`, `nolinelimit`)

Although fragmentation may be used to break messages into smaller pieces automatically, it may also be appropriate in some cases to simply reject outright messages larger than some administratively defined limit, (*e.g.*, so as to avoid service denial attacks on the system or individual mailboxes).

The `blocklimit`, `linelimit` and `sourceblocklimit` channel options are used to impose absolute size limits. Each of these options requires a single integer argument. `blocklimit` specifies the maximum number of blocks allowed in a message. The MTA will reject attempts to queue messages containing more blocks than this to the channel. The `sourceblocklimit` specifies the maximum number of blocks allowed in an incoming message. The MTA will reject attempts to submit a message containing more blocks than this to the channel. In other words, `blocklimit` applies to destination channels;

`sourceblocklimit` applies to source channels. An MTA block is normally 1024 bytes; this can be changed with the `block_size` MTA option. `linelimit` specifies the maximum number of lines allowed in a message. The MTA will reject attempts to queue messages containing more than this number of lines to the channel. These limits can be imposed simultaneously if necessary.

Note that the `line_limit` and `block_limit` MTA options can be used to impose similar limits on all channels. These limits have the advantage that since they apply across all channels the MTA can make them known to mail clients via the SMTP SIZE extension prior to obtaining message recipient information. This simplifies the process of message rejection in some situations.

The `nolinelimit` and `noblocklimit` settings are the default and mean that no per-channel limits are imposed. But message size may still be limited via other configuration choices: global limits imposed via the `line_limit` or `block_limit` MTA options, per-domain limits imposed via the attributes named by the `ldap_domain_attr_blocklimit` or `ldap_domain_attr_sourceblocklimit` MTA options, or per-user limits imposed via the attributes named by the `ldap_blocklimit` or `ldap_sourceblocklimit` MTA options, or a per-group/mailing list limit imposed via the attribute named by the `ldap_maximum_message_size` MTA option, or per-group/mailing list limits imposed via the `alias_blocklimit` or `alias_linelimit` alias options (or in legacy configuration the equivalent [BLOCKLIMIT] or [LINELIMIT] alias file named parameters), or a limit imposed via use of the `$S` flag in the `FROM_ACCESS` mapping table.

Note that the `block_limit` MTA option, or similarly the `sourceblocklimit` channel option on an incoming TCP/IP channel, causes the MTA's SMTP server to advertise the stated size (the minimum of `block_limit` and the channel's `sourceblocklimit`) as the maximum size accepted in response to a sender's EHLO command. This means that clients/senders that understand the SIZE SMTP extension (see RFC 1870, ESMTP message size extension) may not bother to even *try* to submit larger messages after seeing the MTA's EHLO response. Or if they do start to submit a larger message, if they at least specify the SIZE via the SMTP extension on the MAIL FROM command, then the MTA's SMTP server will reject the message at the MAIL FROM. This contrasts with the effect of the `blocklimit` channel option

which cannot be applied (even if the sender used the SIZE extension on the MAIL FROM) until after the RCPT TO is specified so that the MTA can determine the `blocklimit` for the relevant destination channel.

Related to the above effects, is the fact that messages rejected due to the `block_limit` MTA option, or similarly due to the `sourceblocklimit` channel option, do not necessarily result in a "J" rejection entry in the `mail.log*` file, since potentially a client/sender-SMTP doesn't even bother to submit a message when it sees the advertised size limit. Or even if the MTA does perform a "rejection" itself, it may occur at the MAIL FROM stage (if the client uses the SIZE SMTP extension to include the expected message size on the MAIL FROM command line); this is before the MTA has its normal log information (such as receipient information), but will nevertheless be logged as a "J" record (missing some fields such as recipient fields) as of MS 6.0 and later. (In earlier versions, such rejections at the MAIL FROM stage would not be recorded in a `mail.log*` record; in particular, would not cause a "J" record to be generated.) This contrasts with messages rejected due to `blocklimit` on the destination channel which do, and have even in older versions, get logged as "J" entries with recipient field(s) filled in "normally".

(Note also that the `acceptalladdresses` channel option, if used, may modify the timing and form of rejections due to exceeding message size constraints.)

46.3.26.3 Expansion of multiple addresses (`expandlimit`, `expandchannel`, `holdlimit`)

Most MTA channels support the specification of multiple recipient addresses in the transfer of each inbound message. The specification of many recipient addresses in a single message may result in delays in message transfer processing ("on-line" delays). In particular, multi-recipient messages that require a great deal of processing of the message body can be affected by processing delays, or that require creation of many different file copies on disk in the MTA queue area can be affected by slow disk performance. If the resulting delays are long enough, network timeouts can occur, which in turn can lead to repeated message submission attempts and other problems.

The MTA provides a special facility to force deferred ("off-line") processing of additional recipient message copies once a given number of addresses are specified for a single message. The deferral happens after processing of the "initial" recipients (those before the `expandlimit` value was reached), and after address processing for the additional recipients too, (for instance, after `*_ACCESS` mapping table checks and after alias processing), but before message processing. In particular, such deferral means that for the "additional" recipients, only *one* message file (storing all of the "additional" recipients), is written to the queue area (to a `reprocess*` or `process*` channel queue area, depending upon use of the `expandchannel` channel option). Deferral of message processing can decrease on-line delays enormously. Note, however, that the processing overhead is deferred, not avoided completely.

This special facility is activated by using a combination of, for instance, the generic reprocessing channel and the `expandlimit` channel option. The `expandlimit` option takes an integer argument that specifies at what number of recipients to begin deferring processing of the message copy (or copies) to that and additional recipient addresses. The default value is effectively infinite if the `expandlimit` channel option is not specified. A value of 1 will force deferred processing on all incoming addresses from the channel.

The `expandlimit` channel option must *not* be specified on the local channel or the reprocessing channel itself; the results of such a specification are unpredictable.

The channel actually used to perform the deferred processing may be specified on a per-source-channel basis using the `expandchannel` channel option; the reprocessing channel is used by default, if `expandchannel` is not specified, but use of some other reprocessing or processing channel may be useful for some purposes. In particular, for Messaging Server MTA versions 5.2 and earlier, typical configuration usage required that a processing channel, rather than a reprocessing channel, be used. If a channel for deferred processing is specified via `expandchannel`, that channel should be a reprocessing or processing channel; specification of other sorts of channels may lead to unpredictable results.

The reprocessing channel, or whatever channel is used to perform the deferred processing, must be added to the MTA configuration file in order for the `expandlimit` option to have any effect. If your configuration was built by the initial configuration utility, then you should already have a reprocessing channel.

(Note that typical Messaging Server sites running version 5.2 or earler could not use the `expandlimit` option unless they also marked the affected channel `expandchannel process` (or `expandchannel process_somethingorother` redirecting the expansion to an alternate `process_*` sort of channel), as enqueues to a channel marked `viaaliasrequired` would not succeed if deferred to a `reprocess*` channel.)

Extraordinarily large lists of recipient addresses are often a characteristic of so-called SPAM---junk e-mail. The `holdlimit` channel option tells the MTA that messages coming in the channel that result in more than the specified number of recipients should be marked as `.HELD` messages and enqueued to the `reprocess` channel (or to whatever channel is specified via the `expandchannel` channel option). As `.HELD` messages, the files will sit unprocessed in that MTA queue area awaiting manual intervention by the MTA postmaster.

46.3.26.4 Message size affecting priority (`urgentblocklimit`, `normalblocklimit`, `nonurgentblocklimit`, `secondclassblocklimit`)

Note that as of the 8.0 release, these size-based priority override channel option effects are nullified if the MT-PRIORITY SMTP extension has been used to set an explicit priority value.

The `urgentblocklimit`, `normalblocklimit`, `nonurgentblocklimit` and `secondclassblocklimit` channel options may be used to instruct the MTA to downgrade the priority of messages based on size. These options all require a single integer argument specifying the message size, in MTA blocks, at which to perform the priority downgrading. An MTA block is normally 1024 bytes; this can be changed with the `block_size` MTA option. This effective priority, in turn, affects the Job Controller's scheduling of delivery attempts, higher priority messages normally being attempted before lower priority messages, or see the `*_delivery` Job Controller options for further control over the scheduling of even initial message delivery attempts, or the `*backoff` channel options for further control over the scheduling of additional delivery attempts, as well as the `*notices` channel options for further control over the "timing out" (bouncing) of undelivered messages.

The `urgentblocklimit` channel option instructs the MTA to downgrade messages larger than the specified size to normal priority. The `normalblocklimit` channel option instructs the MTA to downgrade messages larger than the specified size to nonurgent priority. The `nonurgentblocklimit` channel option instructs the MTA to downgrade messages larger than the specified size to second-class priority. Finally, the `secondclassblocklimit` instructs the MTA to downgrade messages larger than the specified size to third-class priority.

Note: Both second-class and third-class are nonstandard priority values.

46.3.27 Spamfilter channel options

The MTA supports use of up to eight external spam/virus filter packages. For each such spam/virus filter package, there is a set of channel options selecting which channel(s) invoke the spam/virus filter package. For conciseness, listed here are solely the options for spam/virus filter package 1; but note that there are analogous channel options `*spamfilterN*` for *N*=`2,...,8` as well.

See also the Spamfilter MTA options for configuration of the location and operation of the spam/virus filter package interfaces. Note that "opt in" to spam/virus filter package processing may also be selected on a per-user, per-domain, or per-alias basis.

As of Messaging Server 7.0.5, `imexpire` also supports invoking spam/virus filter packages; in particular, this can be used to perform post-delivery removal of spam/virus-infected messages from the Message Store. For this purpose, `imexpire` is told a source channel "as which" to execute, and then any `sourcespamfilterN` or `sourcespamfilterNoptin` for that channel will be invoked by `imexpire`.

46.3.27.1 `destinationspamfilterN`, `destinationspamfilterNoptin`, `sourcespamfilterN`, `sourcespamfilterNoptin`, `disabledestinationspamfilterN`, `disablesourcespamfilterN` Channel Options

The `destinationspamfilterN`, `destinatationspamfilterNoptin`, `sourcespamfilterN`, `sourcespamfilterNoptin`, `disabledestinationspamfilterN`, and `disablesourcespamfilterN` channel options control whether spam/virus filter package processing is invoked by the MTA during message enqueue processing.

As of Messaging Server 7.0.5, the `imexpire` utility is also capable of invoking spam/virus filter packages, "as if" it were an MTA channel. For such use, `imexpire` is told a source channel as which to operate, and then any `sourcespamfilterN` and `sourcespamfilterNoptin` channel options for that channel specify what spam/virus filter package(s) to invoke.

The MTA supports the use of up to eight distinct spam/virus filtering packages, as configured via the `spamfilterN_*` MTA options (with *N* ranging between `1` and `8`); the set of options with the same number all configure one of the distinct packages. And the number in a `*spamfilterN*` channel option correlates with which spam/virus filter package is to be invoked (or not invoked). (Note that the `*brightmail*` options, and the `*spamfilter*` options without an explicit number, are deprecated synonyms for the `*spamfilter1*` options. These deprecated forms are not allowed in a Unified Configuration.)

The `*spamfilterNoptin` channel options not only trigger spam/virus filter package processing, but do so with a particular "opt-in" value or values set, as some spam/virus filter packages (such as Brightmail) support different "choices" or "opt-in" values for what type of filtering will be performed (*e.g.*, `spam` vs. `virus`). The MTA supports use of multiple, comma-separated "opt-in" values as an argument to an `*optin` channel option. Spam/virus filter package processing may also be triggered, with a specific "opt-in" value or values, via use of a per-user attribute (see the `ldap_optinN` and `ldap_source_optinN` MTA options) or a per-domain attribute (see the `ldap_domain_attr_optinN` MTA options). When "opt-in" values from multiple sources apply for a message -- for instance, if an "opt-in" value is set via a

channel option as well as via an attribute---the MTA will pass all the applicable "opt-in" values to the spam/virus filter package.

The `sourcespamfilter*` channel options enable spam/virus filter package processing based upon source channel; when such a channel option applies, the spam/virus filter package will be activated towards the start of the SMTP dialogue (MAIL FROM stage). (For even earlier spam/virus filter package activation, see Spamfilter early verdicts.) The `destinationspamfilter*` channel options enable spam/virus filter package processing based upon destination channel, which is determined for each recipient at the RCPT TO stage of the SMTP dialogue; so if a `destinationspamfilter*` channel option applies, that spam/virus filter package activation occurs at RCPT TO stage.

The `disable*spamfilter`*N* channel options can be used to disable, on a channel-specific basic, spam/virus filtering that would otherwise be performed. In particular, note that the `disable*spamfilter`*N* channel options override any user-level opt-in to spam/filter package processing (as for instance selected via an LDAP attribute named by an `ldap_optin`*N* MTA option), and override any channel level opt-in (as for instance via a `*spamfilter`*N*`optin` channel option). For instance, one might use `disablesourcespamfilter1` on a `tcp_auth` channel to disable spam/virus filtering (by spam/virus filter package number 1) for all messages coming in the `tcp_auth` channel, overriding any spam/virus filter package use that might normally be triggered due to the destination channel or recipient address(es).

As of MS 8.0.1.3, the $+^ flag in the `FROM_ACCESS` mapping table can also be used to disable source channel spam filter optins. Also as of 8.0.1.3, the same $+^ flag in a recipient access mapping table can be used to disable any active spam filter optins at the current aliasing level. In either case the flag takes a comma separated list of spam filters to disable.

46.3.28 SMTP and LMTP protocol channel options

For additional channel options affecting the SMTP protocol, specifically those relating to the SMTP extensions AUTH or STARTTLS (SASL or TLS use), see TLS and SASL channel options.

For additional channel options affecting TCP/IP connections and DNS lookups, see TCP/IP connections and DNS lookups channel options.

46.3.28.1 Receiving an SMTP ETRN command (`allowetrn`, `blocketrn`, `disableetrn`, `domainetrn`, `silentetrn`)

The `allowetrn`, `blocketrn`, `disableetrn`, `domainetrn`, and `silentetrn` channel options affect the MTA's response when a sending SMTP client issues the SMTP ETRN command, requesting that the MTA attempt to deliver messages in the MTA's queues. See RFC 1985 for the specification of the SMTP ETRN command syntax. In particular, note that the MTA's SMTP server interprets a received `ETRN` *`hostname`* command as a request to deliver all messages for *`hostname`*, a received `ETRN #`*`channelname`* command as a request to run the *`channelname`* channel, and a received `ETRN @`*`hostname`* command as a request to run the channel which *`hostname`* rewrites to.

`allowetrn` means that the MTA will attempt to honor all ETRN commands and will echo back the name of the channel that will be run in response to the ETRN command. `silentetrn` tells the MTA to honor all ETRN commands, but without echoing back the name of the channel which the domain matched and which the MTA will hence be attempting to run. `domainetrn` tells the MTA to honor only those ETRN commands that specify a domain;

it also causes the MTA not to echo back the name of the channel which the domain matched and which the MTA will hence be attempting to run. `disableetrn` disables support for the ETRN command entirely; ETRN will not be advertised by the SMTP server as a supported command. The default behavior, if none of these channel options is explicitly specified, corresponds most closely to `silentetrn`.

When ETRN is permitted (`allowetrn`, `domainetrn`, or `silentetrn` is set, or no option is set), the `ETRN_ACCESS` mapping table can be used to exert more precise control over which SMTP clients are allowed to issue which ETRN commands (and optionally control over what channel is actually run as a result of the ETRN command).

The `blocketrn` channel option tells the MTA not to honor an ETRN command if the ETRN command attempts to run that channel. Note that this channel option is therefore relevant on a destination channel, not on the incoming TCP/IP channel (unless that incoming channel would also be the destination channel for an attempted ETRN command). Note that having `disableetrn` set on a destination channel also has this effect.

Also see the discussion of the `ALLOW_ETRNS_PER_SESSION` SMTP channel setting, which may be used to limit the number of ETRN commands which the MTA will honor during a single session.

46.3.28.1.1 ETRN_ACCESS mapping table

When the MTA's SMTP server is configured to support (at least some uses of) the ETRN command (`allowetrn`, `domainetrn`, or `silentetrn` is set, or the default behavior when no `*etrn` option is set), then the `ETRN_ACCESS` mapping table can be used to exert more precise control over which SMTP clients are allowed to issue which ETRN commands (and optionally control over what channel is actually run as a result of the ETRN command). Probes of the `ETRN_ACCESS` mapping table have the form:

`transport-info``|`*`app-info`*`|`*`channel-to-run`*`|`*`full-name`*`|`*`claimed-system`*

(Here *`claimed-system`* is the ETRN parameter, and *`full-name`* is a processed version of that parameter. See discussion of the `PORT_ACCESS` mapping table, or the `MAIL_ACCESS` mapping table, for discussion of the *`transport-info`* and *`app-info`* portions of the probe string.) If the mapping table returns a `$N`, `$n`, `$F`, or `$f`, the ETRN command is rejected with a "`459 4.5.0`" error. If the mapping table returns a `$S` or `$s`, the ETRN is attempted. If the mapping table also returns a `$D`*`channel-name`* or `$d`*`channel-name`*, then the MTA tries to lookup *`channel-name`* (in the channel/host table from the configuration file) and if that lookup is successful, runs that channel (rather than whatever channel the original ETRN command might have run).

46.3.28.2 XBCC SMTP Extension Support (`bccserver`, `nobccserver`)

The `bccserver` channel option, when placed on a SUBMIT server channel, enables the XBCC extension. This extension adds a single XBCC argument to the RCPT TO command. When present, it marks the corresponding recipient as a blind carbon recipient and the MTA will generate a separate message copy to this recipient and add a Bcc: header field to the copy.

The XBCC argument value may optionally be used to specify a phrase which will preceed the recipient address in the Bcc: header field.

The `nobccserver` channel option disables this extension and is the default.

46.3.28.3 Binary SMTP (`binaryclient`, `nobinaryclient`, `binaryserver`, `nobinaryserver`)

The BINARYMIME SMTP extension defined in RFC 3030 provides support for transferring messages containing binary parts without encoding over SMTP.

New in MS 8.0, the `binaryserver` source channel option enables this extension in the SMTP server. The `nobinaryserver` source channel option disables it, and is the default. Note that `binaryserver` enables the BDAT command for BODY=BINARYMIME messages even if `chunkingserver` is not in effect.

Binary messages submitted using this extension are immediately converted by the MTA to regular 8bit MIME so the format of messages in the MTA queues is not affected, nor is the format of messages that are passed through the spam filter interface.

The BINARYMIME extension is not presently supported by the SMTP client, so the `binaryclient` and `nobinaryclient` channel options are currently unimplemented.

46.3.28.4 SMTP EHLO command (`ehlo`, `checkehlo`, `noehlo`, `refuseehlo`)

The SMTP protocol has been extended (RFC 1869) to allow for negotiation of additional commands. This is done via the new EHLO command, which replaces RFC 821's HELO command. Extended SMTP servers respond to EHLO by providing a list of the extensions they support. Unextended servers return an unknown command error and the client then sends the old HELO command instead.

This fallback strategy normally works well with both extended and unextended servers. Problems can arise, however, with servers that do not implement SMTP according to RFC 821. In particular, some incompliant servers are known to drop the connection on receipt of an unknown command. And in some cases use of facilities negotiated by EHLO will confuse a standards-incompliant proxy intermediary.

The MTA's SMTP client implements a strategy whereby it will attempt to reconnect and use HELO when any server drops the connection on receipt of an EHLO. However, this strategy still may not work if the remote server not only drops the connection but also goes into a problematic state upon receipt of EHLO.

The channel options `ehlo`, `noehlo`, and `checkehlo` are provided to deal with such situations. `ehlo` tells the MTA to use the EHLO command on all initial connection attempts. `noehlo` disables all use of the EHLO command. `checkehlo` tests the greeting banner returned by the remote SMTP server for the string "ESMTP". If this string is found EHLO is used; if not HELO is used. The default behavior is to use EHLO on all initial connection attempts, unless the banner line contains the string "fire away", in which case HELO is used; note that there is no option corresponding to this default behavior, which lies between the behaviors resulting from the `ehlo` and `checkehlo` options.

Finally, in the event of the MTA's SMTP server not working properly with a remote SMTP client due to the use of some SMTP extension that isn't understood by a broken intermediate proxy, the `refuseehlo` channel option can be used to simultaneously disable client use of EHLO and cause the SMTP server to refuse to accept EHLO, insisting on HELO instead. Note that this option should be used sparingly if at all: A far superior approach is to either fix or eliminate the incompliant intermediary.

46.3.28.5 Recipient validity date check (checkrrvs, ignorerrvs)

The checkrrvs and ignorerrvs source channel options, for support of RFC 7293, are new in MS 8.0. ignorerrvs is the default.

ignorerrvs means that the SMTP server will not offer or support the RRVS SMTP extension. In particular, client attempts to use an RRVS parameter in a RCPT TO command will cause an error, and the MTA will ignore any Require-Recipient-Valid-Since: header line.

checkrrvs when set on an SMTP source channel means that the SMTP server offers and supports use of the SMTP RRVS extension. In particular, the MTA will check for a valid date for recipient mailbox ownership, whether specified (preferentially) in a RRVS parameter in the RCPT TO command, or in a Require-Recipient-Valid-Since: header field, and check for a valid date for the domain in the recipient address.

If the checkrrvs check fails on the recipient mailbox address, the recipient will be rejected with the SMTP error:

```
550 5.7.15 account information on file is older than actual user account
```

or alternate text as controlled by the error_text_wrong_account MTA option; if the checkrrvs check fails due to the domain creation date, the recipient will be rejected with the SMTP error:

```
550 5.7.18 domain owner has changed
```

or alternate text as controlled by the error_text_wrong_domain MTA option.

46.3.28.6 Chunking SMTP (chunkingclient, nochunkingclient, chunkingserver, nochunkingserver)

RFC 3030 defines the CHUNKING extension to SMTP. Chunking provides an alternative BDAT command that can be used instead of the normal DATA command to tranfer message content. BDAT uses octet counts rather than dot-stuffing and hence is more efficient. The chunkingclient option, the default, tells the SMTP client to use BDAT if the server says it supports it. nochunkingclient disables this usage.

The chunkingserver option tells the SMTP server to announce support for and allow use of the CHUNKING extension. nochunkingserver disables chunking support in the server. chunkingserver is the default.

46.3.28.7 Channel operation type (submit, relay, passthrough, conditionalpassthrough, conditionalrelay, destinationpassthrough, destinationrelay)

The MTA supports the concept of a general "operating mode" for message enqueue. Different modes provide different levels of message inspection, fixup, and error checking. There are four basic modes: default, submit, relay, and passthrough.

The MTA supports RFC 6409's Message Submission protocol (which is an update of RFC 4409, which is in turn an update of RFC 2476). The `submit` source channel option may be used to mark a channel as a submit-only channel. This is normally useful mostly on TCP/IP channels, such as an SMTP server run on a special port used solely for submitting messages; RFC 2476, since updated by RFC 6409, established port 587 for such message submission use.

Note that a channel marked `submit` has ETRN unconditionally disabled; that is, it gets the effect of `disableetrn`, irrespective of any `*etrn` channel option setting. A channel marked `submit` will also add a Date: header line, if one was missing from the original submitted message, *without* also adding a Date-Warning: header line; that is, since submission of messages without the (normally required for regular SMTP submission) Date: header line is legal on the Message Submission port, the MTA does not flag such messages originally lacking a Date: header line with the Date-Warning: header line it would generate in the case of such messages improperly submitted to the regular SMTP port.

Proper practice (configuration) on a `submit` channel includes requiring some form of user authentication, typically use of SMTP AUTH, and permitting (if not requiring) use of STARTTLS; see RFC 6409 (Message Submission for Mail). Thus a properly configured `submit` channel should normally be marked with `mustsaslserver` and `maytlsserver` (or `musttlsserver` if a site wishes to require STARTTLS use). Although requiring use of SMTP AUTH is what Message Submission channels *should* do, sites that wish to allow message submission without authentication (submission to the Message Submission port without requiring SMTP AUTH) *may* do so *if* enforcing some other form of sender verification, such as limiting such submissions only to certain "trusted" IP sources; see for instance the `FROM_ACCESS` mapping table which may be used to enforce IP source based restrictions.

Relay mode performs fewer checks than submit mode, however, certain structural message problems will cause message enqueue to fail with an error. For example, a missing Date: header field will result in an SMTP-level error in relay mode.

Relay mode is specified by adding the `relay` option to the appropriate source channel.

Passthrough mode disables as many checks and message modification steps as practical. For example, a message that is missing its required Date: header field will not have one added.

Passthrough mode is specified by adding the `passthrough` option to the appropriate source channel.

IMPORTANT NOTE: Passthrough can be a dangerous setting because it disables a number of checks clients are known to depend on. Additionally, various internal MTA functionality that depends on message inspection taking place, such as header field canonicalization, is disabled in passthrough mode. While it is tempting to use passthrough mode in some cases to work around problems caused by agents that insist on receiving standards-incompliant messages, field experience has shown that this "cure" is almost invariably worse than the disease.

Default mode (which of course is the default) lies somewhere between submit and relay. Most available checks and fixups are performed but few will cause an enqueue failure. Continuing the example of the missing Date: header field, in default mode a Date: field will be added by the MTA and a Date-warning: header field will also be added explaining that this was done.

There is no option associated with default mode.

New in MS 8.0, the `destinationpassthrough` channel option, if set on a destination channel, causes any enqueue of a message to that channel to be done in passthrough mode

as long as the source channel isn't itself marked with the submit channel keyword. If submit mode is engaged the destinationpassthrough channel option is a no-op.

The default is `destinationrelay`, meaning the destination channel does not activate passthrough mode.

Finally, there are two additional mode setting options: `conditionalrelay` and `conditionalpassthrough`. These settings first check to see if the message already contains any Received: header fields. If such fields exist the mode specified in the option name is enabled, if not the MTA stays in its original mode.

For the Sieve "`environment`" extension, the MTA supports a private item `vnd.oracle.operation-type`, allowing Sieve scripts to discover what the current operation mode is.

New in 8.0, see the Sieve "`setoperation`" action, which enables system-level Sieve scripts to set what mode of operation to use for a message.

A common use-case for passthrough mode is to prevent message modification after DKIM signing. This is normally done by introducing an additional channel hop so that normal message rewriting, canonicalization, and so on can take place, attaching an appropriately configured DKIM signing milter to that channel, and marking the channel with the `passthrough` channel option to prevent any additional modifications. For example, assuming that all traffic from the tcp_submit channel to the tcp_local should be signed, an appropriate DKIM signing milter is set up on spam filter slot 3, the following configuration could be used:

Conversion mapping:

```
CONVERSION

  IN-CHAN=TCP_SUBMIT;OUT-CHAN=TCP_LOCAL;CONVERT  YES,CHANNEL=PROCESS-DKIM-SIGN
```

Channel definition:

```
process-dkim-sign sourcespamfilter3 passthrough \
 noreceivedfor noreceivedfrom enqueueremoveroute
dkim-sign.example.com
```

46.3.28.8 Maximum allowed recipients or bad commands (`recipientlimit`, `recipientcutoff`, `deferralrejectlimit`, `disconnectrecipientlimit`, `disconnectrejectlimit`, `disconnectbadcommandlimit`, `disconnectbadburllimit`, `disconnectcommandlimit`)

The `recipientlimit`, `recipientcutoff` and (new in MS 6.2) `deferralrejectlimit` channel options, when placed on a source channel, impose per-channel limits on the number of recipients for a submitted message. Each of these options accepts a single integer argument; they default to no limit. (Note that setting `recipientlimit` or `recipientcutoff` to `0` has no effect; only positive limit values will be enforced.) These options are all per-channel (as opposed to per-SMTP-server) analogues of the `ALLOW_RECIPIENTS_PER_TRANSACTION`,

REJECT_RECIPIENTS_PER_TRANSACTION, and ALLOW_REJECTIONS_BEFORE_DEFERRAL SMTP channel settings.

recipientlimit limits the total number of recipient addresses that will be accepted for the message; additional recipients will be rejected. The text in the rejection is configurable via the error_text_recipient_over MTA option, which by default is "too many recipients specified". The error is a temporary rejection by default, but if bit 4 (value 16) of the use_permanent_error MTA option is set, then the rejection is permanent. So in the case of attempted SMTP message submissions, the default temporary error, with the default error text, would appear as:

```
451 4.5.3 too many recipients specified
```

whereas with the default error_text_recipient_over text but with bit 4 (value 16) of the use_permanent_error MTA option set, then a permanent error would appear as:

```
550 4.5.3 too many recipients specified
```

recipientcutoff compares the total number of recipients that were presented to the MTA to the specified value and a message will not be accepted for delivery to *any* recipients if the value is exceeded. In the case of attempted SMTP submissions, the message will be rejected at the DATA command with the SMTP rejection:

```
451 4.4.5 Error ending envelope - Too many recipients specified for this message
```

New in MS 6.2, and supported only for SMTP (not for LMTP), deferralrejectlimit limits the number of bad (failing) addresses that will be allowed during a single session; after this number, all subsequent recipient addresses, good or bad, will be rejected with a temporary error. In the case of attempted SMTP submissions, additional RCPT TO: commands will be rejected with the error:

```
451 4.5.3 Too many rejections; try again later
```

while attempted VRFY: commands will be rejected with the error:

```
451 4.5.3 Verification blocked; too many rejections
```

Similar limits controlled on a per-user and per-domain basis can be configured via LDAP attributes; see the MTA options ldap_recipientlimit, ldap_recipientcutoff, ldap_domain_attr_recipientlimit and ldap_domain_attr_recipientcutoff.

The disconnect* channel options are new in Messaging Server 6.2 (except: disconnectcommandlimit new in Messaging Server 7.1, disconnectbadburllimit new in Messaging Server 7.4-18.01). They are supported only for SMTP, not for LMTP. Each takes an integer argument specifying the maximum number of (recipients, rejections, bad commands, or commands, as applicable) which will be accepted for messages submitted via that source channel; any more will result in the MTA forcing a disconnect of the SMTP session, after issuing an error response to the client consisting of (for disconnectrecipientlimit):

```
421 4.7.0 Session recipient limit reached; disconnecting
```

for `disconnectrejectlimit` in MS 6.2:

```
450 4.7.0 Session bad recipient limit reached; disconnecting
```

or in MS 6.3 and later (MS 6.3 also being when behavior was enhanced so that rejected MAIL FROM's count against the `disconnectrejectlimit`, whereas in MS 6.2 only rejections at the RCPT TO or VRFY stages counted; MS 6.3 is also when behavior was enhanced so that `disconnectrejectlimit` is checked at the VRFY stage and with a negative value applied at the VRFY stage, whereas previously such VRFY rejections were counted but the disconnect would not be triggered until a subsequent RCPT TO attempt "noticed" that the threshold was exceeded):

```
421 4.7.0 Session rejection limit reached; disconnecting
```

or (for `disconnectcommandlimit`):

```
450 4.7.0 Maximum number of commands exceeded
```

In the case of the `disconnectrecipientlimit` or `disconnectrejectlimit` channel options, once the limit is exceeded, the error-response-and-disconnect normally will occur after the next MAIL FROM or RSET command (or in the case of `disconnectrejectlimit` in MS 6.3 and later, potentially after a failed VRFY attempt). (Note that because the disconnect usualy does not happen until after a subsequent MAIL FROM or RSET, these `disconnect*` channel options would most often be used in conjunction with other channel keywords or TCP/IP-channel-specific option settings: perhaps `recipientlimit` or `recipientcutoff` to limit the number of recipient addresses accepted, or `deferralrejectlimit` or the `ALLOW_REJECTIONS_BEFORE_DEFERRAL` TCP/IP-channel-specific option setting.)
In the case of `disconnectbadcommandlimit`, `disconnectbadburllimit`, and `disconnectcommandlimit`, once the limit is exceeded the error response is issued and the MTA forces the disconnect.

The `disconnectbadburllimit` channel option is new in Messaging Server 7.4-18.01. A single integer parameter is accepted specifying the number of invalid BURL commands that will be allowed before disconnecting. The default is 3.

Note that VRFY attempts are counted separately from RCPT TO attempts against the recipient count; that is, one may have up to the recipient limit of VRFYs *and* up to the recipient limit of RCPT TOs. The VRFYs are counted, but counted separately from RCPT TOs. In contrast, failed VRFY attempts are added to the same rejection counter used for counting failed RCPT TO attempts and MAIL FROM attempts for purposes of comparison against the rejection limit; that is, one may have up to the rejection limit of any combination of failed VRFYs, MAIL FROMs, or RCPT TOs.

When the `deferralrejectlimit` has been reached (or a TCP/IP-channel-specific option setting of `ALLOW_REJECTIONS_BEFORE_DEFERRAL` has been reached), a client VRFY attempt will receive from the MTA an error response:

```
451 4.5.2 Verification blocked; too many rejections
```

Note that prior to MS 6.3, the error was instead:

```
452 4.5.2 Verification blocked; too many bad addresses.
```

Note that the FROM_ACCESS mapping table's $S flag may also be used to set limits such as recipientlimit or recipientcutoff.

For forcing IMAP or POP disconnection after a specified number of protocol errors -- similar to the disconnectbadcommandlimit effect for SMTP -- see the maxprotocolerrorsIMAP or POP option.

46.3.28.9 Delivery flags (deliveryflags, flagtransfer, noflagtransfer)

The deliveryflags channel option may be placed on source or destination channels. It takes a required, bit-encoded integer argument, which controls various options regarding message delivery:

Table 46.16 deliveryflags MTA option bit values

Bit	Value	Usage
0	1	Interpret subaddresses as folder names for delivery. This bit is also set by Sieve "fileinto" actions.
1	2	When placed on a source channel, enable quota bypass (that is, delivery even if the recipient user is overquota) for messages enqueued by this channel. (The tcp_tas channel, for example, has this set.)
2	4	Reserved for internal use only.
3	8	Reserved for internal use only.
4	16	Force single copy per recipient
5	32	Ignore discard or jettison actions (*e.g.*, from Sieve filters). This corresponds to setting the message envelope bit normally set automatically by the MTA when applying a discard or jettison action and enqueueing to the filter_discard channel, so that if a "retrieval" procedure should later be performed on such a "discarded" message (such as moving the message to the reprocess channel), the message will then get delivered bypassing any discard or jettison actions.
6	64	When placed on a source channel for an SMTP/LMTP server, enable transfer of delivery flags; equivalent to the flagtransfer channel option
7	128	Messages enqueued to the channel are considered, for purposes of CONVERSIONS mapping table testing, to have a conversion tag set. This bit is set automatically when it is needed and is not intended to be set using the channel option.
8	256	Reserved for internal use only.
9	512	Handle as if SMTP AUTH (SASL) had been used as far as access checks are concerned. This bit is set automatically when it is needed and is not intended to be set using the channel option.

10	1024	Handle as if TLS had been used as far as access checks are concerned.
11	2048	Handle as if address produced by alias as far as access checks are concerned.
12	4096	Bypass all list access checks.

All remaining bits in this option are reserved for internal use and should not be set. The default value for `deliveryflags` is 0.

The `flagtransfer` channel option may be placed on a SMTP server or LMTP server channel. It causes the server to advertise support of the XDFLG and XAFLG private SMTP/LMTP extension parameters to the RCPT TO command. As of MS 8.0.2.3, `flagtransfer` also causes the SMTP server (but not the LMTP server) to advertise the XCONVTAG extension.

If a Messaging Server SMTP client is sending to an SMTP server (or a Messaging Server LMTP client is sending to an LMTP server) that supports this extension, then that SMTP client (or LMTP client) will pass along (transfer) delivery flags, IMAP flags, and (in the case of SMTP) conversion tags.

For instance, this can be useful when user filters (performing `fileinto` Sieve operations) will be performed on a "front-line" system that must then relay the messages to a "back-end" system. `noflagtransfer` disables delivery flag transfer and is the default.

Some of the delivery flag bits affect server security, as such, the `flagtransfer` channel option should never be set on a channel that is exposed to untrusted traffic.

Setting `flagtransfer` is equivalent to setting bit 6 (value 64) of the `deliveryflags` channel option.

46.3.28.10 Limiting time to deliver (`deliverbychannel`))

The `deliverbychannel` source channel option specifies the source channel used for the generation of nondelivery receipts associated with the DELIVERYBY SMTP extension in the absence of any other information. The default is to use the l channel if this option is not specified. Note that there should be few if any cases where this option should be set.

46.3.28.11 Limiting time to deliver (`deliverbymin`))

The `deliverbymin` channel option controls the availability and the minimum by-time allowed by the DELIVERBY SMTP extension specified in RFC 2852. A value of -1, the default, disables the extension. A value of 0 enables the extension with no minimum by-time. Any other value is treated as the minimum by-time.

46.3.28.12 Solicitation control (`destinationnosolicit`, `sourcenosolicit`)

The NO-SOLICITING SMTP extension described in RFC 3865 provides the means to label messages with solicitation types and for MTAs to block solicitations by type. The `sourcenosolicit` source channel option is used to specify a list of solicitation field values that will be blocked in mail submitted by this channel. This list of values will appear in the NO-SOLICITING EHLO response. Glob-style wildcards can be used in the values; however, values containing wildcards will not appear in the EHLO announcement.

The `destinationnosolicit` channel option specifies a list of solicitation field values that will not be accepted in mail queued to this channel.

Note that alternatively, recipient-based no-solicitation settings can be established using the Unified Configuration alias option `alias_nosolicit`, or the alias file named parameter [NOSOLICIT], or the LDAP attributes named by the `ldap_nosolicit` and `ldap_domain_attr_nosolicit` MTA options.

46.3.28.13 SMTP transaction limit (`transactionlimit`, `disconnecttransactionlimit`)

`transactionlimit`: new in Messaging Server 6.1. The `transactionlimit` channel option may be used to impose a limit on how many transactions (that is, messages) will be accepted during a single SMTP session (that is, connection). It is a channel analogue of the `ALLOW_TRANSACTIONS_PER_SESSION` TCP/IP-channel-specific option setting, which applies more generally to all incoming connections on all channels handled by the same Dispatcher SMTP service. After `transactionlimit` is exceeded, additional attempts to submit messages (additional MAIL FROM: commands) will be rejected with an error response:

```
450 4.5.3 number of transactions exceeds allowed maximum
```

The text in the above error message may be site-customized by using the (new in MS 6.3) `error_text_transaction_limit_exceeded` MTA option.

`disconnecttransactionlimit`: new in MS 6.2. The `disconnecttransactionlimit` channel option causes the MTA to actually disconnect after the specified transaction limit is exceeded. Once the limit is reached, the MTA will issue an error response

```
450 4.7.0 Session transaction limit reached; disconnecting
```

after the next MAIL FROM or RSET command, and then disconnect.

46.3.28.14 Sending an SMTP VRFY command (`domainvrfy`, `localvrfy`, `novrfy`)

These options control the MTA's use of the VRFY command in its SMTP client. Under normal circumstances there is no reason for the MTA to issue a VRFY command as part of an SMTP dialogue - the SMTP MAIL TO command should perform the same function that VRFY does and return an appropriate error. However, while fairly rare, SMTP servers exist that will accept any address in a MAIL TO (and bounce it later), whereas they perform more extensive checking as part of a VRFY command.

Therefore the MTA can be configured to issue SMTP VRFY commands for each recipient address. The channel option `domainvrfy` causes the MTA to issue a VRFY command with a full address (*e.g.*, `user@host`) as its argument. The `localvrfy` option causes the MTA to issue a VRFY command with just the local part of the address (*e.g.*, `user`). `novrfy` is the default.

Note that while RFC 1123 updated RFC 821 to require support of the VRFY command so modern SMTP servers should have VRFY support, originally RFC 821 did not require

that SMTP implementations support VRFY so obsolete SMTP implementations may not have any VRFY support at all. Also note that RFC 821 intentionally left it up to individual implementations to decide on the syntax of the VRFY argument---to decide, that is, what sorts of arguments would get successful responses. So relying on getting a successful response to any sort of VRFY command to determine whether or not to try submitting an address is not, in general, wise. Thus use of `localvrfy` or `domainvrfy` is normally only suitable on special channels sending to known special SMTP hosts with well-understood and special VRFY response behavior.

For controlling the MTA's SMTP server responses to VRFY commands, see the `vrfy*` channel options.

46.3.28.15 Eight bit SMTP capability and EAI capability (`eightbit`, `eightnegotiate`, `eightstrict`, `sevenbit`, `utf8header`, `utf8negotiate`, `utf8strict`)

Some transports restrict the use of characters with ordinal values greater than 127 (decimal). Most notably, some SMTP servers will strip the high bit and thus garble messages that use characters in this "eight bit" range. Indeed, there have even been past cases of SMTP servers which will crash when presented with eight bit data.

The MTA provides facilities to automatically encode such messages so that troublesome eight bit characters do not appear directly in the message. This encoding can be applied to all messages on a given channel by specifying the `sevenbit` channel option. A channel should be marked `eightbit` if no such restriction exists.

Some transports such as extended SMTP may actually support a form of negotiation to determine if eight bit characters can be transmitted. The `eightnegotiate` channel option can be used to instruct the channel to encode messages when negotiation fails. This is the default for all channels; channels that do not support negotiation will simply assume that the transport is capable of handling eight bit data.

The `eightstrict` source channel option tells the MTA to reject any messages that contain unnegotiated eight bit data; the exact text of this error may be controlled via the `error_text_unnegotiated_eightbit` MTA option. (Note that the timing of the rejection can be postponed via the `acceptalladdresses` channel option.)

The MS 8.0.2 release adds MTA support for EAI messages and the SMTPUTF8 extension. EAI messaging is documented in RFC 6530 (overview), RFC 6531 (SMTPUTF8 extension), RFC 6532 (header format changes), and RFC 6533 (DSN and MDN format changes). Three additional channel options have been added to enable and control EAI support:

`utf8header` As a SMTP source channel option, offer the SMTPUTF8 SMTP extension. As a destination channel option, allow enqueue and dequeue of EAI messages unconditionally; in particular, the SMTPUTF8 extension will not be required. Note that delivery of EAI messages via SMTP/LMTP to a non-EAI system is a standards violation.

`utf8negotiate` As a SMTP source channel option, offer the SMTPUTF8 SMTP extension. As a destination channel option, allow enqueue unconditionally. On dequeue, require the SMTPUTF8 extension be offered by SMTP/LMTP servers for EAI messages with EAI recipient (RCPT TO) addresses or un-downgradable EAI originator (MAIL FROM) addresses.

`utf8strict` Same as `utf8negotiate` as far as SMTP/LMTP destination channels are concerned. But additionally, for SMTP/LMTP servers (source channels), reject messages that contain 8bit headers without having negotiated the SMTPUTF8 extension and 8bit bodies without having negotiated the 8BITMIME extension. (Note that such rejections are postponed if the `acceptalladdress` channel option is used.)

As of MS 8.0.2.2 the channel default for internal channels has changed from `eightnegotiate` to `utf8always`. Note, however, that the channel default remains `eightnegotiate` on all other channels; EAI support must therefore be explicitly enabled. A channel set to `eightnegotiate` will not offer the SMTPUTF8 extensions or allow EAI messages with EAI recipient or originator addresses to be enqueued. Also note that the Message Store does not support EAI at the present time.

46.3.28.16 Responding to SMTP EXPN commands (`expnallow`, `expndefault`, `expndisable`)

New in MS 6.1-0.01: These options control, at a channel level, the SMTP server's response when a sending SMTP client issues an SMTP EXPN command. (These channel options do not apply to or affect LMTP servers.) When placed on a source channel, the `expnallow` option tells the SMTP server to issue a detailed, informative response. The `expndefault` tells the SMTP server to provide a detailed, informative response, unless the TCP/IP channel option `DISABLE_EXPAND=1` has been specified. The `expndisable` channel option tells the SMTP server to reject the command with an error:

```
550 5.7.2 EXPN command has been disabled
```

Thus these options allow per-channel control of EXPN responses, as opposed to the `DISABLE_EXPAND` TCPIP-channel-specific option setting which normally applies to all incoming TCP/IP channels handled via the same SMTP server.

Note that even when EXPN responses are allowed in general, mailing lists or address groups may be configured to disallow EXPN expansion of their membership set of addresses. Such mailing list controls are configured via either the `alias_nonexpandable` alias option (in legacy configuration, the aliases file [NONEXPANDABLE] named parameter), or the LDAP attributes named by the `ldap_expandable` MTA option (normally the `mgmanMemberVisibility` and `expandable` LDAP attributes). The channel restriction on EXPN, if any, is applied first; only if the channel permits EXPN does any mailing list specific restriction get checked.

46.3.28.17 SMTP Future Release Extension (`futurerelease`)

Release 7 of the Messaging Server MTA implements support for future release SMTP SUBMIT extension defined in RFC 4865. This support is enabled by placing the `futurerelease` channel option on the `submit` source channel used for initial message submission. The option takes a single integer argument: The maximum number of seconds a message can be deferred.

Care should be used when enabling future release since it allows messages to be in effect stored in the MTA's queues. Future release should only be used for channels handling initial message submission and authentication should be required.

Note that similar functionality is available in earlier Messaging Server releases: Specification of a Deferred-delivery: header field in a submitted message coupled with use of the

deferreddestination channel option on the destination channel provided the ability to defer delivery of messages. However, future release provides superior functionality:

- The facility is controlled by a setting on the source channel, allowing it to be provided to a subset of the user population. Placing deferreddestination option on a destination channel opens the door to anyone submitting a message to that channel that will be deferred for some period of time.
- There's no way for a client which sets a Deferred-delivery: header field to know whether or not the header has actually caused the message to be deferred. The future delivery SMTP extension, on the other hand, lets the client know how long a message can be deferred and an error will be returned to the client if the message cannot be deferred for the time the client wants.
- There was no way to place a limit on the amount of time a message could be deferred. Instead what happened was that a message deferred longer than the channel's last notices value would simply be returned as undeliverable.
- Deferred-delivery settings on messages did not survive a Job Controller restart.

As part of the implementation work for future release the old Deferred-delivery: mechanism has been redesigned to address some (but not all) of these points. In particular, the deferred channel option has been replaced by two new channel keywords, deferredsource and deferreddestination. (The deferred option is now a synonym for deferreddestination.) Both of these options accept an integer argument (required in unified configurations, optional in imta.cnf) specifying in seconds the maximum amount of time in the future a Deferred-delivery: header can specify and still be honored. The default if no argument is specified is 60*60*24*7, or 7 days. deferredsource enables Deferred-delivery: processing on the basis of the source channel while deferreddestination operates on destination channels. Finally, Deferred-delivery settings on messages now survive job controller restarts. This addresses all of the points on the above list except the second one - use of a Deferred-delivery: header field still provides no mechanism for informing the client whether or not the setting will be honored.

However, as a purely practical matter, the mechanism chosen to provide delayed release of messages is likely to be dictated by the choice of email client and what mechanisms it supports.

46.3.28.18 Channel protocol selection (smtp, smtp_cr, smtp_crlf, smtp_crorlf, smtp_lf, nosmtp, lmtp, lmtp_cr, lmtp_crlf, lmtp_crorlf, lmtp_lf)

These channel options specify whether or not a channel supports the SMTP protocol (or LMTP protocol) and what type of SMTP line terminator (or LMTP line terminator) the MTA expects to see as part of that protocol. nosmtp means that the channel doesn't support either SMTP or LMTP; all the rest of these channel options imply either SMTP or LMTP support.

The selection of whether or not to use the SMTP or LMTP protocol is implicit for most channels; the correct protocol is chosen by the use of the appropriate channel program or programs.

The channel option smtp---or one of the smtp_* variants---should be set explicitly on all SMTP channels; but if no such option is set on a tcp_* channel, the channel will default to

smtp_crorlf. The channel option lmtp---or one of the lmtp_* variants---is mandatory for all LMTP channels.

The channel options smtp_cr, smtp_crlf, smtp_crorlf, and smtp_lf may be used on SMTP channels to specify what character sequences to accept as line terminators. smtp or smtp_crlf means that lines must be terminated with a carriage return (CR) line feed (LF) sequence. smtp_crorlf means that lines may be terminated with any of a carriage return (CR), or a line feed (LF) sequence, or a full CRLF. (Note that prior to MS 6.0, smtp used to be synonymous with smtp_crorlf, rather than with smtp_crlf as currently; this change to a more strict insistence on proper SMTP line terminators was made in accordance with RFC 2821.) smtp_lf means that a LF without a preceding CR will be accepted. Finally, smtp_cr means that a CR will be accepted without a following LF. It is normal to use CRLF sequences as the SMTP line terminator, and this is what the MTA itself always generates; this option only affects the MTA's handling of incoming material.

The lmtp* channel options are similar, applying to the LMTP protocol rather than the SMTP protocol.

Note that the setting of the original, "default" incoming TCP/IP channel is what controls the behavior for all incoming TCP/IP channels to which that channel may subsequently "switch". That is, subsequent "switching" (due, for instance, to switchchannel, saslswitchchannel, tlsswitchchannel, or mailSMTPSubmitChannel sorts of effects) will not result in a change of SMTP line terminator regardless of what may be set on that "switched to" channel; the option specified on the original incoming TCP/IP channel (typically tcp_local) stays in effect.

46.3.28.19 The XLOOP SMTP extension for blocking message loops (loopcheck, noloopcheck)

The SMTP server unconditionally includes the XLOOP extension and an identifying string in its EHLO response.

Specifying the loopcheck channel option tells the SMTP client to make use of XLOOP if advertised by a "remote" server. An SMTP client can then check a hash (of the configuration file), to compare with that advertised by the SMTP server to which it is connected to see if it, too, is on the same system. If so, the SMTP client bounces the message, generating a notification message with a "SMTP client-server loop detected" reason and a "5.4.6 (SMTP client-server loop detected)" error status in the notification message. Note that this rejection is done by the SMTP client itself, immediately upon processing the SMTP server's EHLO response. Thus using loopcheck causes certain sorts of looping messages to be immediately bounced, rather than looping until they become .HELD files.

In terms of logging of such cases if the logging channel option is used, note that the SMTP server does not generate a "J" record rejecting the message, since the SMTP server did not in fact reject the message, but rather it was the SMTP client that decided to abort sending of the message. And the SMTP client's "R" record for the rejection of the message(s) does not show an SMTP error (such as the 5.4.6 error shown in the notification message itself) issued from the SMTP server; (the SMTP server did not in fact issue that error). The fact that it was a rejection due to loopcheck is instead implicit in the fact that the host connected to was the same as the SMTP client host. This may be seen via the transport information in the "R" record, if bit 1 (value 2) of the log_connection MTA option was enabled.

noloopcheck is the default.

See also the (new in 6.3) IP_ACCESS mapping table, which provides an alternate way to block connecting to specified destination IP addresses (*e.g.*, 127.0.0.1).

46.3.28.20 Verify that the domain on the MAIL FROM: line is in the DNS (mailfromdnsverify, nomailfromdnsverify)

Setting mailfromdnsverify on an incoming TCP/IP channel causes the MTA to verify that an entry in the DNS exists for the domain used on the SMTP MAIL FROM: command, and to reject the message if no such entry exists. nomailfromdnsverify is the default, and means that no such check is performed.

Note that performing DNS checks on the return address domain may result in rejecting some desired valid messages (for instance, from legitimate sites that simply have not yet registered their domain name, or at times of bad information in the DNS); it is contrary to the spirit of being generous in what you accept and getting the e-mail through, expressed in RFC 1123, Requirements for Internet Hosts. However, some sites may desire to perform such checks in cases where junk e-mail (SPAM) is being sent with forged e-mail addresses from non-existant domains.

The introduction of DNS wildcard entries in the COM and ORG top level domains which occurred in September 2003 severely limited the effectiveness of the mailfromdnsverify channel option. (The wildcards have subsequently been removed, however, such practices could resume at any time.) As of the 6.1 release of the Messaging Server MTA, mailfromdnsverify code has been modified to address this. When the DNS returns one or more A records (which would normally be considered a "success" and the message would be allowed in), their values are compared against the domain literals specified by the MTA option blocked_mail_from_ips. If a match is found, then the domain is considered to be invalid.

With mailfromdnsverify on, as of Messaging Server 6.0 and later the MTA attempts an MX lookup on the domain of the MAIL FROM: command. As of MS 6.1 and later, if that MX lookup returns no data (no MX record exists) then the MTA moves on to attempting a gethostbyname call. That is, a success at the MX record lookup stage allows the message in; errors other than simply no such MX record (*e.g.*, a nameserver "server failed" error) at this MX record lookup stage will result in a temporary rejection with error

```
450 4.1.8 invalid/host-not-in-DNS return address not allowed
```

while (with MS 6.1 or later) a no such MX record found case moves onward to checking the result of a gethostbyname call. (In iMS 5.2, only the gethostbyname was attempted; no explicit MX record lookup was performed.)

When the MTA does a gethostbyname call, if this DNS query results in an authoritative "host not found" response, then the message will be rejected with a permanent rejection

```
550 5.1.8 invalid/host-not-in-DNS return address not allowed
```

error message. A no data response, as would occur for the case of a name which has only a CNAME record in the DNS, is considered a successful response; the message will be allowed in. Any other error responses from the DNS will result in a temporary error

```
450 4.1.8 invalid/host-not-in-DNS return address not allowed
```

deferring the message: the MTA will not accept the message at the present time, but the sending side should try sending it again later (in case perhaps their DNS problem, whatever it was, gets fixed).

New in 8.0 is specialized handling for MX entries of the form:

```
nomail          IN MX 0     .
```

Such entries are intended to be an indication that host "nomail" does not operate a mail server. Support has been added so that `mailfromdnsverify` will treat such hosts as not being a valid source of mail. (Additionally, attempts to send to such a host will fail immediately after the MX lookup instead of attempting any sort of A record lookup.)

If the `logging` channel option has been enabled on an incoming channel, then rejections due to a `mailfromdnsverify` check on that channel will be logged to the `mail.log*` file as a "J" record.

46.3.28.21 Microsoft Exchange gateway channels (`msexchange`, `nomsexchange`)

The `msexchange` channel option may be used on TCP/IP channels to tell the MTA that this is a channel that communicates with Microsoft® Exchange gateways and clients. Use of the option tells the MTA to try and accomodate nonstandard behavior on the part of Microsoft Exchange. Exactly what nonstandard behaviors are dealt with is subject to change.

Currently the `msexchange` channel option on a channel configured to allow TLS use (see the `*tls*` channel options) causes advertisement (by the MTA's SMTP server) and recognition (by the MTA's SMTP client) of the non-standard TLS capability string, in addition to the standard STARTTLS capability string, to indicate that TLS is supported.

New in 7.0.5, setting `msexchange` on a destination channel will cause the MTA, if performing any sort of MIME processing operation, to remove any Content-disposition: header line from any text/calendar message parts, as despite Content-disposition:'s long-standing existence as a standardized header line, not to mention the basic MIME rule that unrecognized Content-* header lines should be ignored, Microsoft® Outlook's handling of text/calendar parts is disturbed when such parts have a Content-disposition: specified. So specifying `msexchange` on a channel sending to Microsoft Exchange, if text/calendar parts will flow through that channel, should allow Microsoft Outlook to process calendar parts more successfully.

`nomsexchange` is the default.

46.3.28.22 Per-channel MT-PRIORITY control (`mtprioritiesallowed`, `mtprioritiesrequired`)

`mtprioritiesallowed` and `mtprioritiesrequired` are new in the 8.0 release. These channel options enable the MTA's support of RFC 6710 (SMTP Extension for Message Transfer Priorities). New in Cayenne, see the `envelopetunnel` channel option for "tunneling" MT-PRIORITY, via a header field, through systems that do not support the MT-PRIORITY SMTP extension, as described in RFC 6758 (Tunneling of SMTP Message Transfer Priorities).

The `mtprioritiesallowed` source channel option specifies the range of MT-PRIORITY values that will be accepted. MT-PRIORITY values outside this range will be adjusted up or down so they fall within the allowed range. If a single argument is given, it specifies the

highest priority value that will be accepted. The default if this option is not specified is for the MT-PRIORITY extension not to be offered and for MT-PRIORITY parameters not to be accepted.

The `mtprioritiesrequired` source channel option specifies the range of MT-PRIORITY that will be accepted for enqueue. If a single argument is given, it specifies the lowest priority value that will be accepted. The message will be rejected if the message's specified MT-PRIORITY value, or if the default MT-PRIORITY value of 0 (assumed if MT-PRIORITY was not specified in the SMTP transaction), falls outside the required range with the SMTP error:

```
550 5.7.0 Message priority outside curretly allowed range
```

With either channel option, two integer arguments specify the range. Each argument must be an integer in the range -9..9. The arguments can be given in any order.

46.3.28.23 SMTP DSN extension support (`notary`, `refusenotary`, `nonotary`

The `notary` and (the RESTRICTED) `nonotary` channel options control whether client TCP/IP channels attempt to use the SMTP DSN extension (defined in RFC 3461). The `notary` channel option is the default on SMTP over TCP/IP channels.

The `nonotary` channel option, if set, disables the use of the SMTP NOTARY extension. Its use on SMTP client channels is RESTRICTED, and it is normally used only on LMTP client channels. Note that setting `lmtp` or an `lmtp_*` channel option on a channel implicitly sets `nonotary`.

New in 8.0.1 is the `refusenotary` channel option. This RESTRICTED option disables the DSN extension in the SMTP/LMTP client and additionally, the SMTP server. (The DSN extension is never offered by the LMTP server.)

46.3.28.24 Proxy protocol support

New in MS 8.1.0.1, the `proxyprotocol` enables server-side use of the proxy protocol. Note that the proxy protocol is not negotiated; enabling it on the server side will cause connections to hang if the client doesn't send the necessary PROXY command. Presently, only proxy protocol v1 (text format) is supported.

At present only the SMTP and MMP servers support the proxy protocol for incoming connections. This is supported with SMTP and Submission protocols (port 25 & 587), but works incorrectly with the submissions protocol (port 465) so it's important to make sure any slave channel used to offer submissions service is configured with noproxyprotocol.

46.3.28.25 Sending an SMTP ETRN command (`sendetrn`, `nosendetrn`)

The extended SMTP command ETRN (RFC 1985) allows an SMTP client to request that a remote SMTP server start up processing of the remote side's message queues destined for sending to the original SMTP client; that is, it allows an SMTP client and SMTP server to negotiate "switching roles", where the side originally the sender becomes the receiver, and the side originally the receiver becomes the sender. Or in other words, ETRN provides a way to implement "polling" of remote SMTP systems for messages incoming to one's own system.

This can be useful for systems that only have transient connections between each other, for instance, over dial up lines. When the connection is brought up and one side sends to the other, via the ETRN command the SMTP client can also tell the remote side that it should now try to deliver any messages that need to travel in the reverse direction.

The SMTP client specifies on the SMTP ETRN command line the name of the system to which to send messages (generally the SMTP client system's own name). If the remote SMTP server supports the ETRN command, it will trigger execution of a separate process to connect back to the named system and send any messages awaiting delivery for that named system.

The `sendetrn` and `nosendetrn` channel options control whether the SMTP client sends an ETRN command at the beginning of an SMTP connection. The default is `nosendetrn`, meaning that the MTA will not send an ETRN command. The `sendetrn` channel option tells the MTA to send an ETRN command, if the remote SMTP server says it supports ETRN. The `sendetrn` requires an argument giving the name of the system requesting that its messages receive a delivery attempt to send in the ETRN command.

46.3.28.26 SMTP TURN command channel options (`noturn`, `turn`, `turn_in`, `turn_out`)

RFC 821 defined an optional TURN command, for the client (sender) and server (receiver) to switch roles. It is not normally appropriate to enable use of TURN: it is quite dangerous, as it allows any arbitrary client to "snatch" your messages! Use of the default `noturn` is thus STRONGLY RECOMMENDED!

For a safer "relay upon demand" feature, see the ATRN SMTP extension (RFC 2645).

46.3.28.27 XCLIENT SMTP Extension Support (`noxclient`, `xclient`, `xclientsasl`, `xclientrepeat`, `xclientsaslrepeat`)

(New in 8.0.) The MTA's SMTP server provides support for Postfix's XCLIENT SMTP extension. The PostFix documentation for the extension can be found here:

`http://www.postfix.org/XCLIENT_README.html`

Use of XCLIENT is controlled by three main source channel keywords, `noxclient`, `xclient`, and `xclientsasl`, and variants `xclientrepeat` and `xclientsaslrepeat`. `noxclient` is the default, and means that XCLIENT is not advertised in the response to EHLO and the XCLIENT command itself is disabled. If `xclient` is set, the XCLIENT command is enabled and the NAME, ADDR, PORT, PROTO, and HELO attributes may be used. `xclientsasl` enables the LOGIN attribute in addition to all the others. It should be noted that LOGIN specifies an external identity that must then be bound to the session identity through the use of SASL EXTERNAL.

By default, only one set of XCLIENT commands is allowed in a single SMTP session. Specifying `xclientrepeat` allows groups of XCLIENT commands to be repeated, allowing a proxy or similar agent to share a connection between multiple clients. `xclientsaslrepeat` allows multiple groups of XCLIENT commands including LOGIN. Note that care should be taken when these keywords are used since the server cannot determine the origin of a given XCLIENT command.

The primary visible effect of XCLIENT is on the contents of the Received: field the MTA adds. For example, if this XCLIENT command was executed:

```
xclient name=foo.domain.com addr=1.2.3.4 helo=bar.domain.com port=12345
```

it would result in a header of the general form:

```
Received: from bar.domain.com (foo.domain.com [1.2.3.4])
  by server.domain.com (Oracle Communications Messaging Server 7.0.5.32
  64bit (built Aug 18 2014)) with imapsubmit
  id <01OJ9P51WPFC007KNZ@server.domain.com> for user@domain.com;
  Mon, 20 Aug 2012 08:17:31 -0700 (PDT)
```

However, the ADDR, PORT, DESTADDR, and DESTPORT attributes also change the contents of the transportinfo that appears in various mapping table probes, such as the probe to PORT_ACCESS. Given the preceding XCLIENT command, the *transportinfo* part of the mapping probes would change to something like:

```
TCP|this-mta's-ip|25|1.2.3.4|12345
```

where note that the values to use in the "source IP" and "source port" fields have been specified via ADDR and PORT, respectively.

Note: Support for DESTADDR and DESTPORT was added in MS 8.0.2.3.

46.3.28.28 SMTP long line handling (rejectsmtplonglines, truncatesmtplonglines, wrapsmtplonglines)

The SMTP protocol is a line oriented protocol, and in particular, SMTP transmissions are limited to a maximum of 1000 characters including the carriage-return CR and line-feed LF characters, or 998 characters not including the CRLF sequence; (though see RFC 3030 for a proposed extension of the SMTP protocol that relaxes this definition). Nevertheless, there are some clients (typically arising in HTML applications) that try to send illegally long lines over SMTP.

The channel options `truncatesmtplonglines`, `rejectsmtplonglines`, and `wrapsmtplonglines` control the MTA's behavior when it sees such illegal long lines in incoming SMTP messages. `truncatesmtplonglines` is the default, and causes the MTA to truncate illegally long SMTP lines to the legal length limit; the MTA also in MS 6.0 inserts a header line

```
Sun-ONE-SMTP-Warning: Lines longer than SMTP allows found and truncated.
```

or in MS 6.1 or later, a header line

```
Sun-Java-System-SMTP-Warning: Lines longer than SMTP allows found and truncated.
```

when it sees such long lines. The `rejectsmtplonglines` option normally causes the MTA to reject such illegal messages with a

```
550 5.6.0 lines longer than SMTP allows encountered; message rejected
```

SMTP error (but see the `acceptalladdresses` channel option which postpones the error generation), and may be useful when it is desired to enforce strict standards compliance upon message submissions. The `wrapsmtplonglines` keyword causes the MTA to forcibly wrap (insert hard line breaks) into illegally long incoming lines, and insert a header line of (in MS 6.0)

```
Sun-One-SMTP-Warning: Lines longer than SMTP allows found and wrapped.
```

or in MS 6.1 or later

```
Sun-Java-System-SMTP-Warning: Lines longer than SMTP allows found and wrapped.
```

The MTA will attempt to find a space or TAB character in the line as a suitable place at which to perform the line break. In the absence of such a white space character, the MTA may have to add the hard line break at a less suitable location, changing the character of the data; in particular, `wrapsmtplonglines` when applying to a header line (to an illegally long line in a message header) may damage the message header since the forced line break may (in the absence of white space characters) cause a syntactically illegal line. `wrapsmtplonglines` is hence only intended for dealing with cases of illegally long lines in the message body. Furthermore, some charsets (*e.g.*, ISO-2022-JP) have encoding requirements that are triggered at line wraps, so that forcible line wrapping can interact badly with such charsets; or even when a message body is in a charset that has no line wrap/encoding issues, the message content itself may be "damaged" by line wrapping. `wrapsmtplonglines` is thus only a partial workaround to cases of illegally long data in SMTP transmitted messages; it makes an attempt to more-or-less preserve message contents, but some damage is not unexpected.

Note that these channel options must be placed on the initial (default) incoming TCP/IP channel in order to take effect, that is, the SMTP server default channel; for instance, these options would typically be used on a `tcp_local` or `tcp_submit` channel. These channel options do not take effect on a channel "switched to" subsequently (due for instance to a `switchchannel`, `tlsswitchchannel`, or `saslswitchchannnel` channel option effect, or a `mailSMTPSubmitChannel` LDAP attribute effect).

46.3.28.29 Protocol streaming (`streaming`)

Some mail protocols support streaming operations. This means that the MTA can issue more than one operation at a time and wait for replies to each operation to arrive in batches. The `streaming` channel option controls the degree of protocol streaming used in the protocol associated with a channel. This option requires an integer argument; how the argument is interpreted is specific to the protocol in use.

Currently the MTA only supports the use of streaming on SMTP channels. Streaming is enabled automatically for the MTA's SMTP client if the SMTP server to which the MTA has connected offers the pipelining extension and the streaming setting is nonnegative. The `streaming` option can be used to enable (force) streaming by the MTA's SMTP client even when a remote SMTP server doesn't offer the pipelining extension.

The streaming values available for SMTP range from -2 to 4. Negative values (new in 7.2-7.02) disables streaming completely; not even the remote SMTP server advertising pipelining can enable it. A value of 0 specifies no streaming, a value of 1 causes groups of RCPT TO

commands to stream, a value of 2 causes MAIL FROM/RCPT TO to stream, a value of 3 causes HELO/MAIL FROM/RCPT TO or RSET/MAIL FROM/RCPT TO streaming to be used, and a value of 4 enables streaming all the way through DATA (equivalent to the remote server advertising pipelining). The default value is 0.

The SMTP server offers the pipelining extension by default. A streaming value of -2 (new in 7.2-7.02) can be used to disable pipelining announcment.

Some SMTP implementations are known to react badly to streaming. In particular, many versions of sendmail are known to be incapable of handling streaming levels greater than 1. The MTA's server implementation of SMTP should work properly at any streaming level.

New in Messaging Server 7.0, MTA message transaction log entries will record whether PIPELINING was used by means of a "Q" modifier on the relevant "E" (Enqueue) and "D" (Dequeue) entries.

46.3.28.30 Responding to SMTP VRFY commands (`vrfyallow`, `vrfydefault`, `vrfyhide`)

These channel options control the MTA's SMTP server's response when a sending SMTP client issues an SMTP VRFY command. The `vrfyallow` channel option tells the SMTP server to issue a detailed, informative response. The `vrfydefault` option tells the SMTP server to provide a detailed, informative response, unless the TCP/IP-channel-specific option `HIDE_VERIFY=1` has been specified. The `vrfyhide` option tells the MTA to issue only a vague, ambiguous response. Thus these channel options allow per-channel control of VRFY responses, as opposed to the `HIDE_VERIFY` TCP/IP-channel-specific option which normally applies to all incoming TCP/IP channels handled via the same SMTP server.

For controlling the MTA's SMTP client use of VRFY commands, see the `*vrfy` channel options.

46.3.29 TCP/IP connections and DNS lookups channel options

A number of channel options affect TCP/IP connections and DNS lookups.

46.3.29.1 Channel connection information caching (`cacheeverything`, `cachesuccesses`, `cachefailures`, `nocache`)

Channels using the SMTP and LMTP protocols maintain a per-process cache containing a history of prior connection attempts. This cache is used to avoid reconnecting multiple times to inaccessible hosts, which can waste lots of time and delay other messages. The cache only lasts for the duration of the delivery process; subsequent processes start with an empty cache.

(In this context, "connection failure" includes both connection transaction log file "Y" entries -- where the MTA's client couldn't even make a connection -- and at least some "X" entries, such as connecting but immediately seeing a 5xx or 4xx error instead of an SMTP banner.)

Such a process cache normally records both connection successes and failures. (Successful connection attempts are recorded in order to offset subsequent failures --- a host that succeeded before but fails now doesn't warrant as long of a delay before making another connection attempt as does one that has never been tried or one that has failed previously.)

However, the caching strategy used by the MTA is not necessarily appropriate for all situations. For example, a channel that is used to connect to a single flakey host does not benefit from caching. Or in the case of connection attempts to an internal LMTP "back end", it may be desirable to continue to try to connect regardless of previous connection failures. Therefore channel options are provided to adjust the MTA's SMTP and LMTP client process caches.

The `cacheeverything` channel option enables all forms of caching and is the default. `nocache` disables all caching. `cachefailures` enables caching of connection failures but not successes --- this forces a somewhat more draconian retry than `cacheeverything` does. Finally, `cachesuccesses` caches only successes. This last option is effectively equivalent to `nocache` for SMTP and LMTP channels.

In the MTA message transaction log file, "Q" entries with the notation:

`Too many failures to this host during this run; skipping this host: `*`error-text`*

are cases where a process cache had come into play.

46.3.29.2 Envelope address rewriting upon message dequeue (`connectalias`, `connectcanonical`)

The MTA normally rewrites addresses as it enqueues messages to its channel queues. No additional rewriting is done during message dequeue. This presents a potential problem when host names change while there are messages in the channel queues still addressed to the old name.

The `connectalias` option tells the MTA to simply deliver to whatever host is listed in the recipient address. This is the default. `connectcanonical` tells the MTA to compare the recipient envelope address domain with the channel host proper names, and if the domain name matches one of the channel's host proper names, then connect to the host name corresponding to that host proper name. For instance, if a channel is defined (in pmdf.cnf/ imta.cnf format) as:

```
tcp_scanner smtp connectcanonical ...rest-of-keywords...
SCANNER-DAEMON
scanner1.domain.com  host1.domain.com
scanner2.domain.com  host2.domain.com
```

then an address of `user@host1.domain.com` that rewrites to the `tcp_scanner` channel will be routed out to the host scanner1.domain.com, rather than to host1.domain.com as would occur by default.

`connectcanonical` should only be used specifically to deal with problems with queued messages---it may have unintended effects on other message traffic.

46.3.29.3 Forced routing to gateways (`daemon`)

The interpretation and usage of the `daemon` channel option depends upon the type of channel to which it is applied. Currently, the only type of channel for which the `daemon` option is relevant is SMTP over TCP/IP channels. Normally such channels connect to whatever host is listed in the envelope address of the message being processed. The `daemon` option is used to

tell the channel to instead connect to a specific remote system, generally a firewall or mailhub system, regardless of the envelope address. The actual remote system name is given as an argument to `daemon`, *e.g.*:

```
msconfig> set channel:tcp_firewall.daemon firewall.domain.com
```

If the argument after the `daemon` option is not a fully qualified domain name (or alternatively a square bracket enclosed literal IP address), the argument will be ignored and the channel will connect to the channel's official host. When specifying the firewall or gateway system name as the channel's official host name, `channel:channel-name.official_host_name`, the argument given to the `daemon` option is typically specified as `router`, *e.g.*:

```
msconfig> show channel:tcp_firewall
role.channel:tcp_firewall.official_host_name = firewall.domain.com
role.channel:tcp_firewall.daemon = router
role.channel:tcp_firewall.mx (novalue)
role.channel:tcp_firewall.pool = SMTP_POOL
role.channel:tcp_firewall.smtp (novalue)
```

46.3.29.4 TCP/IP nameserver and MX record support (`mx`, `nomx`, `nodns`, `defaultmx`, `randommx`, `nonrandommx`, `affinitylist`, `nameservers`, `defaultnameservers`)

Most TCP/IP networks support the use of MX (mail forwarding) records for SMTP relay but a few do not. The MTA's TCP/IP channel programs can be configured to not use MX records if they are not provided by the network to which the MTA system is connected. Some TCP/IP channel programs can be configured to not do DNS (nameserver) lookups at all. `randommx` specifies that MX lookups should be done and MX record values of equal precedence should be processed in random order. `nonrandommx` specifies that MX lookups should be done and MX values of equal precedence should be processed in the same order in which they were received. The `mx` option is currently equivalent to `nonrandommx`; it may change to be equivalent to `randommx` in a future release. The `nomx` option disables MX lookups. The `defaultmx` option specifies that `mx` should be used (with randomization) if the network says that that MX records are supported, and if the destination port is port 25 for SMTP; (with `defaultmx`, destination ports other than port 25 do not get MX lookups by default).

LMTP channels do not normally make use of MX lookups. Additionally, LMTP channels need to connect to the correct store taking failover events into account. As of the 8.0 release, the `affinitylist` channel option provides this functionality. `affinitylist` disables MX lookups completely and translates the logical host given into the corresponding affinity group. Connections are then attempted sequentially to all the hosts in the group.

The default is `defaultmx` on channels that support MX lookups in any form.

New in MS 8.0 is specialized handling for MX entries of the form:

```
nomail          IN MX 0     .
```

Such entries are intended to be an indication that host "nomail" does not operate a mail server. So when MX lookups are enabled, attempts to send to such a host will fail immediately

after the MX lookup instead of attempting any sort of A record lookup. (Additionally, `mailfromdnsverify` will treat such hosts as not being a valid source of mail.)

Whether the operating system's TCP/IP local host tables are used in addition to the DNS for lookups is generally controlled by `/etc/nsswitch.conf` or the equivalent. Generally, operating system distributions are configured so that local host tables will indeed be consulted.

When nameserver lookups are being performed, that is, unless the `nsswitch.conf` file selects no use of nameservers, then prior to Messaging Server 7.0 the `nameservers` channel option may be used to specify a list of nameservers to consult rather than consulting the TCP/IP stack's own choice of nameservers. This affects the SMTP server and client and LMTP client, but *not* the LMTP server (which, if it needs to do any lookups, always relies on the TCP/IP stack's own choice of nameservers). Futhermore, as of Messaging Server 7.0, the `nameservers` channel option only affects MX record lookups, with all other lookups using the TCP/IP stack's choice of nameservers regardless of any `nameservers` channel option setting. `nameservers` requires a space separated list of IP addresses for the nameservers, *e.g.*,

```
1.2.3.1 1.2.3.2
```

`defaultnameservers` is the default, and means to use the TCP/IP stack's own choice of nameservers.

Note that while a `nameservers` setting is primarily meaningful to the SMTP client -- hence TCP/IP destination channels -- it also, prior to Messaging Server 7.0, potentially had meaning to the SMTP server -- hence TCP/IP source channels -- as for instance in cases where the SMTP server channel had been configured to perform DNS reverse lookups on incoming connections, or to perform forms of DNS verification.

46.3.29.5 Name lookup failure handling(`dnsforcetemporary`, `nodnsforcetemporary`)

When attempting to make an outgoing connection, name lookups that return a "host not found" or "no addresses" sorts of errors are normally treated as permanent failures. The `dnsforcetemporary` channel option, which places on the dequeuing channel, alters this behavior and causes this errors to be treated as temporary. `nodnsforcetemporary` is the default.

Important note: This restricted option is only intended for use in special situations where the list of possible remote hosts is tightly controlled. Use in other situatiions, especially ones where users are able to specify the remote host, will lead to delays in reporting failures conditions.

46.3.29.6 Reverse DNS and IDENT lookups on incoming SMTP connections (`identtcp`, `identtcplimited`, `identtcpnumeric`, `identtcpsymbolic`, `identnone`, `identnonelimited`, `identnonenumeric`, `identnonesymbolic`, `forwardchecknone`, `forwardchecktag`, `forwardcheckdelete`)

The `identtcp` channel option tells the MTA to perform a connection and lookup using the IDENT protocol (RFC 1413). The information obtained from the IDENT protocol (usually the identity of the user making the SMTP connection) is then inserted into the Received: header for

the message, with the hostname corresponding to the incoming IP number, as reported from a DNS reverse lookup, and the IP number itself.

The `identtcpsymbolic` channel option tells the MTA to perform a connection and lookup using the IDENT protocol (RFC 1413). The information obtained from the IDENT protocol (usually the identity of the user making the SMTP connection) is then inserted into the Received: header for the message, with the hostname corresponding to the incoming IP number, as reported from a DNS reverse lookup; the IP number itself is not included in the Received: header.

The `identtcpnumeric` channel option tells the MTA to perform a connection and lookup using the IDENT protocol (RFC 1413). The information obtained from the IDENT protocol (usually the identity of the user making the SMTP connection) is then inserted into the Received: headers of the message, with the actual incoming IP number --- no DNS reverse lookup on the IP number is performed.

Note that the remote system must be running an IDENT server in order for the IDENT lookup caused by the `identtcp`, `identtcpsymbolic`, or `identtcpnumeric` options to be useful. In addition, be aware that IDENT query attempts may incur a serious performance hit. Increasingly routers simply "black hole" attempted connections to ports that they don't recognize; if this happens on an IDENT query, then the MTA does not hear back until the connection times out (a TCP/IP package controlled timeout, typically on the order of a minute or two). A lesser performance factor is that when comparing `identtcp` or `identtcpsymbolic` *vs.* `identtcpnumeric`, note that the DNS reverse lookup called for with `identtcp` or `identtcpsymbolic` incurs some additional overhead to obtain the more "user-friendly" hostname.

The `identnone` channel option disables this IDENT lookup, but does do IP to hostname translation, and both IP number and hostname will be included in the Received: header for the message. The `identnonesymbolic` channel option disables this IDENT lookup, but does do IP to hostname translation; only the hostname will be included in the Received: header for the message. The `identnonenumeric` channel option disables this IDENT lookup and inhibits the usual DNS reverse lookup translation of IP number to hostname, and may therefore result in a performance improvement at the cost of less user-friendly information in the Received: headers. `identnone` is the default.

The `identtcplimited` and `identnonelimited` channel options have the same effect as `identtcp` and `identnone`, respectively, as far as IDENT lookups, reverse DNS lookups, and information displayed in Received: header lines. Where they differ is that with `identtcplimited` or `identnonelimited` the IP literal address is always used as the sole basis for any channel switching due to use of the `switchchannel` channel option, regardless of whether the DNS reverse lookup succeeds in determining a host name. Note that since channel switching is always performed preferentially based on IP address rather than host name, the effect of `identtcplimited` or `identnonelimited` is merely to disable ever trying host name switching in case all IP address rewriting failed.

Table 46.17 Available `ident*` MTA options and interpretations

Channel option	IDENT lookup	DNS reverse lookup	IP address in Received: header line	Reverse hostname in Received: header line	Fall back to hostname channel switch
`identtcp`	Yes	Yes	Yes	Yes	Yes

identtcplimited	Yes	Yes	Yes	Yes	No
identtcpnumeric	Yes	No	Yes	No	No
identtcpsymbolic	Yes	Yes	No	Yes	Yes
identnone	No	Yes	Yes	Yes	Yes
identnonelimited	No	Yes	Yes	Yes	No
identnonenumeric	No	No	Yes	No	No
identnonesymbolic	No	Yes	No	Yes	Yes

The `forwardchecknone`, `forwardchecktag`, and `forwardcheckdelete` channel options can modify the effects of doing reverse lookups, controlling whether the MTA does a forward lookup of an IP name found via a DNS reverse lookup, and if such forward lookups are requested, further control what the MTA does in case the forward lookup of the IP name does not match the original IP number of the connection. The `forwardchecknone` channel option is the default, and means that no forward lookup is done. The `forwardchecktag` channel option tells the MTA to do a forward lookup after each reverse lookup and to tag the IP name with an asterisk, `*`, if the number found via the forward lookup does not match that of the original connection. The `forwardcheckdelete` channel option tells the MTA to do a forward lookup after each reverse lookup and to ignore (delete) the reverse lookup returned name if the forward lookup of that name does not match the original connection IP address, and stick with the original IP address instead. (Note that having the forward lookup not match the original IP address is normal at many sites, where a more "generic" IP name is used for several different IP addresses.)

These options are only useful on SMTP channels that run over TCP/IP.

46.3.29.7 TCP/IP interface address (`interfaceaddress`)

The `interfaceaddress` channel option controls the address to which a TCP/IP channel binds as the source address for outbound connections; that is, on a system with multiple interface addresses this channel option controls which address will be used as the source IP address when the MTA sends outgoing SMTP messages. Note that it complements the Dispatcher option `listenaddr` (INTERFACE_ADDRESS in legacy configuration), which controls which interface address a TCP/IP channel's SMTP server program listens on for accepting incoming connections and messages. Also note that such channel `interfaceaddress` settings are quite separate from the Job Controller's own `listenaddr` setting (INTERFACE_ADDRESS setting in legacy configuration), which merely controls what IP address the Job Controller listens on for purposes of its own, internal communications.

As of MS 8.0.2.3 two different addresses, one used for logging and the other as the actual TCP/IP source address, can be specified. Normally the same address is used for both purposes, but in cases where NAT or other forms of address translation are in use it may be useful to have the actual IP address that appears to external agents appear as the address in transport information fields in the logs. The address that's actually used does need to be logged somewhere, so it is appended to the application information field with the usual "/" separator, prefixed with a sharp sign.

When two addresses are specified they must be separated by a sharp sign with the logging address appearing first, i.e., "logging-address#bind-address".

46.3.29.8 Specify a last resort host for delivery (`lastresort`)

The `lastresort` channel option is used to specify a host to which to connect when all other connection attempts fail. In effect this acts as an MX record of last resort. This is only useful on SMTP over TCP/IP channels.

Note that the `lastresort` host is attempted only for hosts that are in the DNS, having either MX records or an A record, and for whom the connection attempts to all the MX records -- or to the A record, if there were no MX records---have encountered temporary connection failures. (In particular, the `lastresort` host will not be attempted for a host that is only in the hosts file, not in the DNS at all. Also keep in mind that a permanent 5xx error in response to a connection attempt to a host is a permanent error, and will result in bouncing a message; in particular, the `lastresort` host will not be attempted after such a permanent rejection error. Also, the `lastresort` host will not be attempted if a connection succeeds, but the MTA's wait for an SMTP banner line to be returned times out; that again is not a temporary *connection* failure.)

This channel option requires a single parameter specifying the name of the "system of last resort".

See also the `IP_ACCESS` mapping table, which can provide an alternate way of doing "fail over" for outbound IP connections for SMTP and LMTP channels.

Note that in most cases, it is preferable to fix problematic DNS records rather than to use `lastresoft`; `lastresort` is intended merely for a few, special sorts of cases where correcting DNS records may not be possible, yet some "last ditch", MX-like, re-routing may be useful.

46.3.29.9 Verify that the domain on the MAIL FROM: line is in the DNS (`mailfromdnsverify`, `nomailfromdnsverify`)

Setting `mailfromdnsverify` on an incoming TCP/IP channel causes the MTA to verify that an entry in the DNS exists for the domain used on the SMTP MAIL FROM: command, and to reject the message if no such entry exists. `nomailfromdnsverify` is the default, and means that no such check is performed.

Note that performing DNS checks on the return address domain may result in rejecting some desired valid messages (for instance, from legitimate sites that simply have not yet registered their domain name, or at times of bad information in the DNS); it is contrary to the spirit of being generous in what you accept and getting the e-mail through, expressed in RFC 1123, Requirements for Internet Hosts. However, some sites may desire to perform such checks in cases where junk e-mail (SPAM) is being sent with forged e-mail addresses from non-existant domains.

The introduction of DNS wildcard entries in the COM and ORG top level domains which occurred in September 2003 severely limited the effectiveness of the `mailfromdnsverify` channel option. (The wildcards have subsequently been removed, however, such practices could resume at any time.) As of the 6.1 release of the Messaging Server MTA, `mailfromdnsverify` code has been modified to address this. When the DNS returns one or more A records (which would normally be considered a "success" and the message would be allowed in), their values are compared against the domain literals specified by the MTA option `blocked_mail_from_ips`. If a match is found, then the domain is considered to be invalid.

With `mailfromdnsverify` on, as of Messaging Server 6.0 and later the MTA attempts an MX lookup on the domain of the MAIL FROM: command. As of MS 6.1 and later, if that

MX lookup returns no data (no MX record exists) then the MTA moves on to attempting a `gethostbyname` call. That is, a success at the MX record lookup stage allows the message in; errors other than simply no such MX record (*e.g.*, a nameserver "server failed" error) at this MX record lookup stage will result in a temporary rejection with error

```
450 4.1.8 invalid/host-not-in-DNS return address not allowed
```

while (with MS 6.1 or later) a no such MX record found case moves onward to checking the result of a `gethostbyname` call. (In iMS 5.2, only the `gethostbyname` was attempted; no explicit MX record lookup was performed.)

When the MTA does a `gethostbyname` call, if this DNS query results in an authoritative "host not found" response, then the message will be rejected with a permanent rejection

```
550 5.1.8 invalid/host-not-in-DNS return address not allowed
```

error message. A no data response, as would occur for the case of a name which has only a CNAME record in the DNS, is considered a successful response; the message will be allowed in. Any other error responses from the DNS will result in a temporary error

```
450 4.1.8 invalid/host-not-in-DNS return address not allowed
```

deferring the message: the MTA will not accept the message at the present time, but the sending side should try sending it again later (in case perhaps their DNS problem, whatever it was, gets fixed).

New in 8.0 is specialized handling for MX entries of the form:

```
nomail          IN MX 0     .
```

Such entries are intended to be an indication that host "nomail" does not operate a mail server. Support has been added so that `mailfromdnsverify` will treat such hosts as not being a valid source of mail. (Additionally, attempts to send to such a host will fail immediately after the MX lookup instead of attempting any sort of A record lookup.)

If the `logging` channel option has been enabled on an incoming channel, then rejections due to a `mailfromdnsverify` check on that channel will be logged to the `mail.log*` file as a "J" record.

46.3.29.10 Maximum rate to connect to a domain (`maxconnectionrateperdomain`)

The `maxconnectionrateperdomain` smartsend channel option provides the means to limit the rate at which connections are made from the channel. The value of this option is one or two space-separated rate limit lists. The first limit list value specifies the rate limits to use when things are operating normally; the second specifies the limits to use when operating in IP backoff mode. If the IP backoff value is omitted it defaults to the first value.

Note that the identically named `maxmessagerateperdomain` smartsend parameter provides the same functionality at the domain or IP level.

This option requires that the smartsend callouts, in particular the callout from the AUTH_ACCESS mapping, be installed. This option will be ignored if smartsend is not configured.

This option also currently requires that a memcache or Redis protocol server be configured at either the MTA or channel level.

46.3.29.11 Maximum number of connections from an IP to a domain (maxconnectionsperdomain)

The maxconnectionsperdomain smartsend channel option implements limits on the number of simultaneous connections that can be opened to a destination domain. The value of this parameter is one or two space-separated limit lists. The first value specifies the limits to use when the IP address is operating normally; the second specifies the limits to use when operating in IP backoff mode. If the IP backoff value is omitted it defaults to the first value.

Note that the identically named maxconnectionsperdomain smartsend parameter provides the same functionality at the domain or IP level.

This option requires that the smartsend callouts, in particular the callouts from the AUTH_ACCESS and AUTH_DEACCESS mappings, be installed. This option will be ignored if smartsend is not configured.

46.3.29.12 Maximum rate to send to a domain (maxmessagerateperdomain)

The maxmessagerateperdomain smartsend channel option provides the means to limit the rate at which messages are delivered from the channel queue. The value of this option is one or two space-separated rate limit lists. The first limit list value specifies the rate limits to use when things are operating normally; the second specifies the limits to use when operating in IP backoff mode. If the IP backoff value is omitted it defaults to the first value.

Note that the identically named maxmessagerateperdomain smartsend parameter provides the same functionality at the domain or IP level.

This option requires that the smartsend callouts, in particular the callout from the AUTH_ACCESS mapping, be installed. This option will be ignored if smartsend is not configured.

This option also currently requires that a memcache or Redis protocol server be configured at either the MTA or channel level.

46.3.29.13 SOCKS connections (nosocks, socksnoauth, socksuserpassword)

SOCKS connections (see RFC 1928 and RFC 1929) can be used to traverse a firewall that would not normally permit outbound SMTP message traffic. If the firewall offers a SOCKS service, then one can connect to the firewall's SOCKS server and authenticate, pass over the remote host name and remote port to which one wishes to make an SMTP connection, and then the SOCKS server on the firewall will make the remote connection and transform the SOCKS connection into the desired SMTP connection. The nosocks and socksuserpassword channel options control whether a TCP/IP channel uses a SOCKS connection, rather than

attempting a normal, direct SMTP connection. `nosocks`, the default, specifies that no SOCKS connection will be used. `socksuserpassword` tells the channel to attempt a SOCKS connection (using the username/password method of SOCKS authentication), rather than attempting a direct SMTP connection.

To achieve a SOCKS connection, one must set additional options. In legacy configuration, one must set TCP/IP-channel-specific options specifying the SOCKS host and port to which to connect, and the username and password with which to authenticate the SOCKS connection; see the SOCKS_HOST, SOCKS_PORT, SOCKS_USERNAME, and SOCKS_PASSWORD channel settings. In Unified Configuration, one must instead set channel options `sockshost`, `socksport`, `socksusername`, and `sockspassword`.

Note that the SOCKS protocol is a general protocol for TCP/IP-based applications (*e.g.*, SMTP), and makes no provision for application-specific issues such as, in the case of SMTP, MX host name DNS lookups. Thus when using a `socksuserpassword` channel, one must be sure that the host names that the channel is attempting to send messages to are all fully resolved hostnames (A record names). As such, `socksuserpassword` channels are all, in effect, `nomx` channels, and hence should only be used for special, point-to-point connections to known, specific remote systems where the proper mail host name is "known" (need not be looked up as a possible MX record in the DNS). In particular, any rewrite rules that direct domains to a `socksuserpassword` channel should output only domain names that are proper mail destination host systems (fully resolved domain names, with any MX references already taken into account).

46.3.29.14 `port` Option Under channel

SMTP over TCP/IP channels normally connect to the remote system's port 25 when sending messages. The `port` channel option may be used to instruct an SMTP over TCP/IP channel to connect to a non-standard port.

46.3.29.15 SOCKS connections channel options: `sockshost` (host), `socksport` (port), `socksusername` (string) `sockspassword` (string)

The `sockshost`, `socksport`, `socksusername`, `sockspassword` channel options (for SMTP client channels) are used to configure SOCKS connections. SOCKS connections (see RFC 1928 and RFC 1929) can be used to traverse a firewall that would not normally permit outbound SMTP message traffic. If the firewall offers a SOCKS service, then one can connect to the firewall's SOCKS server (`sockshost` and `socksport`) and authenticate (`socksusername` and `sockspassword`), pass over the remote host name and remote port to which one wishes to make an SMTP connection, and then the SOCKS server on the firewall will make the remote connection and transform the SOCKS connection into the desired SMTP connection. The `sockshost` option specifies the host name of the SOCKS server system. The `socksport` option specifies the SOCKS port on the SOCKS server system; by convention, port 1080 is usually used as the SOCKS port. The MTA's SOCKS implementation currently only supports the username/password method of SOCKS authentication; the username and password to be used are controlled by the `socksusername` and `sockspassword` channel options, respectively.

The `sockshost`, `socksusername`, and `sockspassword` options have no default; the default for the `socksport` option is 1080.

In order for these `socks*` channel options to take effect, the outbound TCP/IP channel must also be marked with the `socksuserpassword` channel option.

46.3.29.16 SPF DNS lookups (spfhelo, spfmailfrom, spfnone, spfrcptto)

New in MS 6.3-0.15. The spfhelo, spfmailfrom, and spfrcptto channel options, when placed on a source TCP/IP channel, cause the MTA to attempt an SPF lookup at the corresponding stage of the SMTP dialogue. spfnone, the default, disables such SPF lookups.

With spfhelo set (so that SPF verification of the claimed EHLO/HELO domain is attempted), possible SMTP error results (rejections) are:

```
451 4.4.3 Temporary error in SPF verification of HELO domain
500 5.5.2 Permanent error in SPF verification of HELO domain
451 4.4.3 Permanent error in SPF verification of HELO domain
500 5.5.2 Permanent error in SPF verification of HELO domain
451 4.3.0 SPF verification failed
451 4.3.0 SPF verification failed: explanation
550 5.7.1 SPF verification failed
550 5.7.1 SPF verification failed: explanation
```

The specific cases are as follows. The interpretation of the result of an SPF lookup is controlled by MTA options such as spf_smtp_status_temperror and spf_smtp_status_permerror. While temporary SPF lookup errors are normally configured to be considered as temporary errors and permanent SPF lookup errors are normally configured to be considered as permanent errors, accomplished by setting spf_smtp_status_temperror to 4 and spf_smtp_status_permerror to 5 respectively, each such option can take any of the values 2 (ignore the error condition), 4 (treat it as temporary), or 5 (treat it as permanent). Thus, with a temporary error from the SPF lookup, then the setting of the spf_smtp_status_temperror MTA option to 2, 4, or 5 controls, respectively, whether that SPF lookup problem is considered okay, or results in a temporary error such as (in this example, when spfhelo is set):

```
451 4.4.3 Temporary error in SPF verification of HELO domain
```

or a permanent error such as (in this example, when spfhelo is set):

```
500 5.5.2 Temporary error in SPF verification of HELO domain
```

Similarly, with a permanent error returned from the SPF lookup, the setting of the spf_smtp_status_permerror MTA option to 2, 4, or 5 controls, respectively, whether the permanent error returned by the SPF lookup is ignored (considered to be an okay condition) or results in a temporary error such as (in this example, when spfhelo is set):

```
451 4.4.3 Permanent error in SPF verification of HELO domain
```

or a permanent error such as (in this example, when spfhelo is set):

```
500 5.5.2 Permanent error in SPF verification of HELO domain
```

New in 8.0, an SPF HELO/EHLO check failure will result in a "J" record in the MTA message transaction log file, if message transaction logging has been enabled.

New in 8.0, the error text is configurable via various `error_text_spf_ehlo_*` MTA options. Also, the SMTP error codes and extended codes have been adjusted to accord with `draft-ietf-appsawg-email-auth-codes-07`.

With `spfmailfrom` set (so that SPF verification of the claimed MAIL FROM address is attempted), possible SMTP error results (rejections) are, in the case of temporary errors, and depending upon the setting of the `spf_smtp_status_temperror` MTA option, either:

```
451 4.4.3 Temporary error in SPF verification of MAIL FROM domain
```

or

```
550 5.5.2 Temporary error in SPF verification of MAIL FROM domain
```

In the case of permanent errors, depending upon the setting of the `spf_smtp_status_permerror` MTA option, either:

```
451 4.4.3 Permanent error in SPF verification of MAIL FROM domain
```

or

```
550 5.5.2 Permanent error in SPF verification of MAIL FROM domain
```

In the case of an SPF fail result (the lookup shows that such a MAIL FROM address is *not* authorized), depending upon the setting of the `spf_smtp_status_fail` and `spf_smtp_status_fail_all` MTA options, either

```
451 4.4.3 SPF verification failed
```

or

```
550 5.7.1 SPF verification failed
```

or when additional explanation is available, either

```
451 4.4.3 SPF verification failed: explanation
```

or

```
550 5.7.1 SPF verification failed: explanation
```

In the case of an SPF soft failure, depending upon the setting of the `spf_smtp_status_softfail` and `spf_smtp_status_softfail_all` MTA options, either:

```
451 4.4.3 SPF verification failed (soft)
```

or

```
550 5.7.1 SPF verification failed (soft)
```

With `spfrcptto` set, so that the attempt to perform an SPF verification of the MAIL FROM address is delayed until the RCPT TO stage of processing, possible errors are:

```
450 4.5.1 temporary error in SPF verification of MAIL FROM domain (domain)
550 5.5.0 temporary error in SPF verification of MAIL FROM domain (domain)
450 4.5.1 permanent error in SPF verification of MAIL FROM domain(domain)
550 5.5.0 permanent error in SPF verification of MAIL FROM domain(domain)
450 4.5.1 SPF verification of MAIL FROM domain (domain) failed
450 4.5.1 SPF verification of MAIL FROM domain (domain) failed: spf-explanation
550 5.5.0 SPF verification of MAIL FROM domain (domain) failed
550 5.5.0 SPF verification of MAIL FROM domain (domain) failed: spf-explanation
450 4.5.1 SPF verification of MAIL FROM domain (domain) failed (soft)
550 5.5.0 SPF verification of MAIL FROM domain (domain) failed (soft)
```

New in 8.0, the error text used at MAIL FROM stage (`spfmailfrom`) and RCPT TO stage (`spfrcptto`) is configurable via various `error_text_spf_*` MTA options; note that these options had existed since MS 6.3, but were not effective until 8.0. Also new in 8.0, the SMTP error codes and extended codes have been adjusted to accord with `draft-ietf-appsawg-email-auth-codes-07`.

Note that when SPF lookups are configured and a message is allowed in (due to either passing the SPF lookup check, or due to a configuration that allows in even messages with certain sorts of SPF lookup failures, or failure responses from SPF), then the MTA will add a "Received-SPF:" header line:

```
Received-SPF: spf-result (spf-explanation)
```

Note that SPF is prone to causing problems for autoforwarding; (such problems are *not* with the MTA's implementation, but rather are due to fundamental oversights in the original design of SPF). Use of SRS address encoding is one approach to work around SPF's fundamental difficulties with autoforwarding.

46.3.29.16.1 SPF_LOCAL mapping table

The `SPF_LOCAL` mapping table, if defined, provides a way to avoid performing actual DNS lookups for SPF verification of any domains matching a pattern in the mapping table: instead, the mapping table template of a matching entry will be used as if it were the DNS result of an

SPF lookup. Thus, this mapping table allows providing "short-circuited" results for specified (typically local) domains.

The syntax is:

```
SPF_LOCAL

  domain-pattern    result
```

46.3.29.17 Triggering new jobs (threaddepth)

The threaddepth channel option tells the Job Controller when to start a new channel "job" to handle messages: for multithreaded channels, when to start a new thread (if the process is allowed to have more threads) or failing that a new process (if more processes are allowed); for single threaded channels, when to start a new process (if more processes are allowed).

For multithreaded channels, the threaddepth channel option controls how many messages are handled in any one thread before the channel will consider starting to use another thread.

In particular, the MTA's SMTP client (for channels not marked with the daemon channel option) sorts outgoing messages to different destinations to different threads. The threaddepth channel option may be used to instruct the MTA's multithreaded SMTP client to handle only the specified number of messages in any one thread, using additional threads even for messages all to the same destination (hence normally all handled in one thread). The value specified must be greater than 1 and less than 10000. The default as of MS 6.0 is threaddepth 10. (This is a change from previous versions, in which the default was 128.)

Use of threaddepth may be of particular interest for achieving multithreading with daemon router on a TCP/IP channel - a TCP/IP channel that connects to a single specific SMTP server - when the SMTP server to which the channel connects can handle multiple simultaneous connections.

Similarly, the threaddepth option affects operation of the multithreaded ims-ms channel.

For single threaded channels, such as the conversion, process, and reprocess channels, the threaddepth channel option controls how many messages are handled in a single process; more messages cause the Job Controller to create another process (up to the maxjobs channel option setting for the channel and the job_limit Job Controller option value for the pool in which the channel runs) to process the messages.

46.3.30 TLS and SASL channel options

A number of channel options relate to SASL (SMTP AUTH) and/or TLS use.

For global MTA configuration, see also Password and TLS MTA options. And for general Messaging Server configuration of authentication and certificate handling, see the Auth options, various base.auth*, base.ssl*, and base.tls* options (and for LDAP connections, the ugldapusessl and ldaprequiretls base options), the Base certmap options, and the sectoken options.

46.3.30.1 authusername Option Under channel

The authusername channel option is described in the externalidentity section.

46.3.30.2 `authpassword` Option Under channel

The `authpassword` channel option is described in the `externalidentity` section.

46.3.30.3 Credentials for client SMTP AUTH use channel options: `authpassword`, `acceptvalidaddresses`, `externalidentity`

The `authusername`, `authpassword`, and `externalidentity` channel options may only be set (are only valid) in Unified Configuration; they replace the (legacy configuration only) TCP/IP-channel-specific options AUTH_PASSWORD, AUTH_USERNAME, and EXTERNAL_IDENTITY.

SASL authentication will be attempted if either the `maysaslclient` or `mustsaslclient` channel option is set, with success required for message transmission if `mustsaslclient` is set.

The PLAIN and EXTERNAL SASL mechanisms are currently supported. The `authusername` and `authpassword` channel options provide the credentials for the PLAIN mechanism and the `externalidentity` channel option provides the identity string for SASL EXTERNAL. (`externalidentity` can be set to the empty string to enable SASL EXTERNAL without an identity string.)

See the Base certmap options for general configuration of certificate mapping, as needed for EXTERNAL authentication via client certificates.

46.3.30.4 Authenticated originator information processing (`authrewrite`)

The `authrewrite` option may be used on a source channel to have the MTA propagate authenticated originator information, if available, into the headers. Normally the SMTP AUTH information is used (specifically, the user's canonical e-mail address, that is, the value of the `mail` attribute or new in MS 8.0 the value of whatever attribute is named by the `ldap_auth_attr_sender` MTA option, found when looking up the user for authentication), though this may be overridden via the `FROM_ACCESS` mapping. `authrewrite` takes a required bit-encoded integer value as an argument, according to the following table:

Table 46.18 `authrewrite` option values

Bit	Value	Usage
0-3	1	Add a Sender: header line, or a Resent-sender: header line if a Resent-from: or Resent-sender: was already present, containing the AUTH originator
0-3	2	Add a Sender: header line containing the AUTH originator
0-3	3	Use the `AUTH_REWRITE` mapping table, probing with any Resent-Sender: and Resent-From: info if present, and otherwise probing with Sender: and From: info
0-3	4	Use the `AUTH_REWRITE` mapping table, probing with Sender: and From: info
0-3	5	Add a From: header line, or a Resent-From: header line if a Resent-From: or Resent-Sender: was already present, containing the AUTH originator. This is **NOT RECOMMENDED** and **CONTRARY TO INTERNET STANDARDS**, and likely to **HARM** the security of your users. This option should almost **NEVER** be used: **THIS MEANS YOU!**.
0-3	6	Add a From: header line containing the AUTH originator. This is **NOT RECOMMENDED** and **CONTRARY TO INTERNET STANDARDS**, and likely to **HARM** the security of your users. This option should almost **NEVER** be used: **THIS MEANS YOU!**.
4	16	(New in 6.2) If set, apply the `AUTH_REWRITE` mapping table, even if SMTP AUTH has not been used
5	32	(New in 6.2) If set, probes to `AUTH_REWRITE` include the source-channel as a prefix field, separated by a vertical bar character from the rest of the probe string; that is, when this bit is set then probes take the form:

		src-chan|env-from|[resent-]sender|[resent-]from|auth-originator
6	64	(New in 7.2-7.02.) If set, use the rewritten version of the envelope from address in constructing the AUTH_REWRITE probe.
7	128	(New in 7.2-7.02.) If set, use the canonical version of the envelope from address in constructing the AUTH_REWRITE probe. Bit 6 (value 64) is a no-op if this bit is set.
8	256	(New in 7.3-11.01.) If set, add the value of the AUTH parameter from the SMTP MAIL FROM command to the AUTH_REWRITE probe, appearing just after the authorized originator address; that is, when this bit is set then probes take the form *env-from|[resent-]sender|[resent-]from|auth-originator|auth-param*
9	512	(New in MS 7.0.5) If set, the final tag set via $T in the *_ACCESS mappings will be prefixed to the AUTH_REWRITE mapping probe; that is, when this bit is set then probes take the form: *ACCESS-tag|env-from|[resent-]sender|[resent-]from|auth-originator*

46.3.30.4.1 AUTH_REWRITE mapping table

Certain values of the authrewrite channel option cause the AUTH_REWRITE mapping table to be consulted to allow for more complex decision making and alterations of addresses. And bits of authrewrite also affect the form of probe to the AUTH_REWRITE mapping table.

Probes for the AUTH_REWRITE mapping table normally have the following format:

env-from|[resent-]sender|[resent-]from|auth-originator

If (new in MS 6.2) bit 5 (value 32) is set in the the authrewrite argument, the probe is prefixed with the source channel and a vertical bar; if (new in MS 7.3-11.01) bit 8 (value 256) is set in the authrewrite argument, the probe is suffixed with a vertical bar and the AUTH parameter from the MAIL FROM command; if (new in MS 7.0.5) bit 9 (value 512) is set in the authrewrite argument, the probe is prefixed with the final tag set by the FROM_ACCESS or recipient address *_ACCESS mapping tables and a vertical bar. Thus with these three optional bits set, the probe has the format:

ACCESS-tag|src-chan|env-from|[resent-]sender|[resent-]from|auth-originator|auth-param

New in MS 8.0.2.3, the authrewrite_extra_headers MTA option may be used to specify additional header fields to include in the mapping probe. These fields always appear at the end of the probe, separated by vertical bars.

With authrewrite 3, the probes preferentially use any Resent-Sender: or Resent-From: header line values present, whereas with authrewrite 4 the probes always use Sender: and From:. (Note that normally the AUTH_REWRITE mapping table is only consulted when a submission has included SMTP AUTH info; that is, in order for the AUTH_REWRITE mapping table to be consulted not only must the relevant incoming channel be marked with an authrewrite value of 3 or 4, but also the submission included use of the SMTP AUTH command. However, if bit 4 (value 16) is set in the authrewrite channel option's argument, then AUTH_REWRITE will be consulted even for non-authenticated submissions.)

New in 7.2-7.02, bit 6 (value 64) of authrewrite will, if set, cause a rewritten version of the envelope from address to be used for the *env-from* address in the probe as opposed to the original form given in the SMTP MAIL FROM command. The specific rewritten form used is controlled by bit 7 (value 128): if set, the canonical form return address will be used, if clear the normally rewritten form will be used instead. These rewritten forms are useful when access checking is done using the AUTH_REWRITE mapping in order to prevent envelope From forgery by authenticated users.

If the mapping table output contains a $J, $j, $K, or $k, then the envelope From address is replaced with the specified string. If the mapping table output contains a $Y, $y, $T, or $t, then a Sender: header line is added (if `authrewrite 3` was specified and if a Resent-Sender: or Resent-From: was already present, then a Resent-Sender: header line is added instead of a Sender: header line) containing the specified string.

If the mapping table output contains a $Z or $z, then a From: header line is added (a Resent-From: in the case of `authrewrite 3` and a Resent-From: or Resent-Sender: header line already being present) containing the specified string. (Such replacing of the From: header address is **NOT RECOMMENDED** and **CONTRARY TO INTERNET STANDARDS** and quite likely to **HARM** the overall security of your users. It should almost **NEVER** be done: **THIS MEANS YOU!** Despite the wishes and mistaken notions of many sites and users, the From: header line, in Internet e-mail, is **NOT INTENDED** to represent the "real" originator of a message; it is intentionally defined permitting alternate usages.)

New in MS 7.0, if a $A is specified, then its argument is interpreted as a header line to add to the primary message header.

New in 7.3-11.01, if a $O is specified, then another vertical-bar-separated string will be read from the mapping result string and used to set or override the value of the SMTP AUTH parameter for the current transaction. The `saslpassauth` channel option may then be applied to the destination channel to cause this value to be propagated as an AUTH parameter on the SMTP MAIL FROM command.

New in MS 6.2, if a $N is specified, then the message will be rejected. Optional rejection text may be specified after another vertical bar character, |. And as of MS 6.3, $X may also be used to specify the extended error code (specified before the $N text, separated by a |) in the form *x.y.z*. In the absence of such optional text and optional extended error code, the default text "`invalid originator address used`" and default extended error code `5.7.0` will be used. (Note that use of the `acceptalladdresses` channel option postpones the rejection.)

When using multiple such flags, separate the string arguments with the vertical bar character, |, and specify the string arguments in the order listed in the paragraphs above; for instance,

JYZA$O*env-from*|*sender*|*from-hdr*|*hdr-line-to-add*|*auth-param*

or

XN|*error-code*|*rejection-text*

Technically, one could use all seven flags in the same entry, though it does not seem likely to be useful (as in particular the changes to the message, such as changes of address or addition of a header line) do not apply since the rejection is going to occur at the SMTP protocol level):

JYZAOX$N*env-from*|*sender*|*from-hdr*|*hdr-line-to-add*|*auth-param*|*error-code*|*rejection-text*

As of the 8.0 release, the following input flags will be set:

- $A if SASL authentication has succeeded
- $E if EHLO (EMSMTP) was used

- $L if LHLO (LMTP) was used
- $P if POP-before-SMTP was used
- $R if this is an internal channel enqueue operation, *i.e.*, from a conversion, process, reprocess, or similar sort of channel
- $T if a SSL/TLS security layer has been negotiated

AUTH_REWRITE mapping flags summarizes the available (output) flags and input flags.

Table 46.19 AUTH_REWRITE mapping flags

Flag	Description
$*	(New in MS 7.0u2) Force disconnect of the SMTP session
Flags with arguments, in argument reading order[1]	
$J*address*	Override original envelope From with specified *address*
$K*address*	Override original envelope From with specified *address*
$T	Force addition of a Sender: *address* or Resent-Sender: *address* header line
$Y	Force addition of a Sender: *address* or Resent-Sender: *address* header line
$Z*address*	Force replacement of the original From: (or Resent-From:) header line with From: *address* or Resent-From: *address*; note this is **NOT RECOMMENDED**, as it is **CONTRARY TO INTERNET STANDARDS** and quite likely to **HARM** the overall security of your users. It should almost **NEVER** be done--- *THIS MEANS YOU!*
$A*header-line*	Add the specified *header-line*
$O*AUTH-parameter*	(New in MS 7.0u3) Use the specified *AUTH-parameter* as the new value to relay as the AUTH value for this message in MAIL FROM.
$<*syslog-text*	(New in MS 8.0.2.3) Send the specified text to syslog.
$>*syslog-text*	(New in MS 8.0.2.3) Send the specified text to syslog if $N is also specified.
$>*syslog-text*	(New in MS 8.0.2.3) Send the specified text to syslog if $N is also specified.
$D*dkim-parameters*	(New in MS 8.1.0.1) Specify one or more comma-separated DKIM signing parameters to enable DKIM signing. The format is the same as that used in the CONVERSIONS mapping.
$H*received-domain*	(New in MS 8.1.0.1) Specify a value to override the current received_domain option setting.
$I*id-domain*	(New in MS 8.1.0.1) Specify a value to override the current id_domain option setting.
$+L*header1,header2,...*	(New in MS 8.1.0.1) Specifies a comma-separated list of header fields to include in transaction log records that are generated.
$X*x.y.z*	(New in MS 6.3) Set the extended error code to *x.y.z*, in place of the default of 5.7.0. $X is only active if $N is also specified.

`$N`*`error-text`*	(New in MS 6.2) Reject the message, optionally specifying *`error-text`* to use in place of the default text "`invalid original address used`".
Input flag comparisons	Description
`$:|`	(New in an MS 7.0 patch) Match only if external material (*e.g.*, an envelope address) in the probe contained a vertical bar
`$;|`	(New in an MS 7.0 patch) Match only if no vertical bars were present in any external material in the probe
`$:A`	(New in MS 8.0) Match only if SASL authentication (SMTP AUTH) has succeeded
`$;A`	(New in MS 8.0) Match only if SASL authentication (SMTP AUTH) has not been used, or if attempted has not succeeded
`$:E`	(New in MS 8.0) Match only if EHLO (ESMTP) was used
`$;E`	(New in MS 8.0) Match only if EHLO (ESMTP) was not used
`$:L`	(New in MS 8.0) Match only if LHLO (LMTP) was used
`$;L`	(New in MS 8.0) Match only if LHLO (LMTP) was not used
`$:P`	(New in MS 8.0) Match only if POP-before-SMTP was used
`$;P`	(New in MS 8.0) Match only if POP-before-SMTP was not used
`$:R`	(New in MS 8.0) Match if the current, enqueueing channel is an "internal" channel such as the reprocess channel
`$;R`	(New in MS 8.0) Match if the current, enqueueing channel is something other than an "internal" channel
`$:T`	(New in MS 8.0) Match only if a SSL/TLS security layer has been negotiated
`$;T`	(New in MS 8.0) Match only if SSL/TLS was not used

[1] To use multiple flags with arguments, separate the arguments with the vertical bar character, `|`, placing the arguments in the order listed in this table.

An example of an AUtH_REWRITE mapping that prevents authenticated users from sending messages from addresses other than the ones listed in their mail, mailAltnerateAddress, or mailEquivalentAddress mappings would be:

```
AUTH_REWRITE

! Probe format: env-from|[resent-]sender|[resent-]from|auth-originator
! Check to see if the From: matches the authenticated user's mail attribute;
! exit with success if it does
     *|*|*|$2*   $E
! Fetch the base DN we'll need to look up the user
     *|*@*|*@*   $CBASE|$}$4,_base_dn_{|$1@$2|$3@$4
! Probe now: BASE|base-DN|from|auth-originator
! Check to see if the From: matches the authenticated user's
! mailAlternateAddress or mailEquivalentAddress attributes.
     BASE|*|*|*  $CFOUND|$]ldap:///$0?uid?sub?(&(mail=$=$2$_)(|(mailAlternateAddress=$=$1$_)(mailEquivalentAddress=$=$1$_)))
! Exit with success if it does
     FOUND|*|*|* $E
! Fail any other From: address
     *           $NFrom$ address$ is$ not$ one$ of$ your$ addresses.
```

Note that the `authrewrite` source channel option needs to be set to 3 for the AUTH_REWRITE mapping to be invoked.

A more sophisticated version of this mapping that allows users to specify arbitrary subaddresses would be:

```
REMOVE_SUBADDRESS

  "$[a-z0-9.#$&'*\-/=?^_`{}\~]*+$_*"@*  $Y$0@$2
  "$_*+$_*"@*                           $Y"$0"@$2
  $_*+$_*@*                             $Y$0@$2
  *                                     $Y$0

REMOVE_SUB_LDAP_QUOTE

  "$[a-z0-9.#$&'*\-/=?^_`{}\~]*+$_*"@*  $Y$=$0@$2$_
  "$_*+$_*"@*                           $Y$="$0"@$2$_
  $_*+$_*@*                             $Y$=$0@$2$_
  *                                     $Y$=$0$_

MATCH_NOSUBADDRESS

  *|*   $C$|REMOVE_SUBADDRESS;$0||$|REMOVE_SUBADDRESS;$1|
  *|$0* $Y

AUTH_REWRITE

! Check to see if the From: matches the authenticated user's mail attribute;
! exit with success if it does
  *|*|*|* $C$|MATCH_NOSUBADDRESS;$2$|$3|$E
! Fetch the base DN we'll need to look up the user
  *|*@*|*@* $CBASE|$}$4,_base_dn_{|$1@$2|$3@$4
! Check to see if the From: matches the authenticated user's
! mailAlternateAddress or mailEquivalentAddress attributes.
  BASE|*|*|* \
  $CFOUND|$]ldap:///$0?uid?sub?(&(mail=$=$2$_)(|(mailAlternateAddress=$|REMOVE_SUB_LDAP_QUOTE;$1|)(mailEquivalentAddress=$|REMOVE_SUB_LDAP_QUOTE;$1|)))[|$1|$2
! Exit with success if it does
  FOUND|*|*|* $E
! Fail any other From: address
  * $NFrom$ address$ is$ not$ one$ of$ your$ addresses.
```

An even more sophisticated approach that provides "send on behalf of" functionality is possible. Assuming a sendOnBehalfOf attribute has been added to the user's entry listing the addresses the user is authorized to send on behalf of, the following mapping could be used:

```
REMOVE_SUBADDRESS

  "$[a-z0-9.#$&'*\-/=?^_`{}\~]*+$_*"@*  $Y$0@$2
  "$_*+$_*"@*                           $Y"$0"@$2
  $_*+$_*@*                             $Y$0@$2
  *                                     $Y$0

REMOVE_SUB_LDAP_QUOTE

  "$[a-z0-9.#$&'*\-/=?^_`{}\~]*+$_*"@*  $Y$=$0@$2$_
  "$_*+$_*"@*                           $Y$="$0"@$2$_
  $_*+$_*@*                             $Y$=$0@$2$_
  *                                     $Y$=$0$_

MATCH_NOSUBADDRESS

  *|*   $C$|REMOVE_SUBADDRESS;$0||$|REMOVE_SUBADDRESS;$1|
  *|$0* $Y

AUTH_REWRITE

! Check to see if the From: matches the authenticated user's mail attribute;
! exit with success if it does
  *|*|*|* $C$|MATCH_NOSUBADDRESS;$2$|$3|$E
! Fetch the base DN we'll need to look up the user
  *|*@*|*@* $CBASE|$}$4,_base_dn_{|$1@$2|$3@$4
! Check to see if the From: matches the authenticated user's
! mailAlternateAddress or mailEquivalentAddress attributes.
  BASE|*|*|* \
  $CFOUND|$]ldap:///$0?uid?sub?(&(mail=$=$2$_)(|(mailAlternateAddress=$|REMOVE_SUB_LDAP_QUOTE;$1|)(mailEquivalentAddress=$|REMOVE_SUB_LDAP_QUOTE;$1|)(sendOnBehalfOf=$1)))[|$1|$2
! Exit with success if it does
  FOUND|*|*|* $E
! Fail any other From: address
  * $NYou$ are$ not$ authorized$ to$ send$ from$ the$ address$ you$ specified
```

If the "send on behalf of" permissions are instead stored on the "other side" - in, say, an, mailGrantSendPermissionsTo on the granting user's entry that specifies the mail attribute of the user permissions are being granted to, the following mapping could be used:

```
REMOVE_SUBADDRESS

  "$[a-z0-9.#$&'*\-/=?^_`{}\~]*+$_*"@*  $Y$0@$2
  "$_*+$_*"@*                           $Y"$0"@$2
  $_*+$_*@*                             $Y$0@$2
  *                                     $Y$0

REMOVE_SUB_LDAP_QUOTE

  "$[a-z0-9.#$&'*\-/=?^_`{}\~]*+$_*"@*  $Y$=$0@$2$_
  "$_*+$_*"@*                           $Y$="$0"@$2$_
  $_*+$_*@*                             $Y$=$0@$2$_
  *                                     $Y$=$0$_

MATCH_NOSUBADDRESS

  *|*   $C$|REMOVE_SUBADDRESS;$0||$|REMOVE_SUBADDRESS;$1|
  *|$0* $Y

AUTH_REWRITE

! Check to see if the From: matches the authenticated user's mail attribute;
! exit with success if it does
  *|*|*|* $C$|MATCH_NOSUBADDRESS;$2$|$3|$E
! Fetch the base DN we'll need to look up the user
  *|*@*|*@* $CBASE|$}$4,_base_dn_{|$1@$2|$3@$4
! Check to see if the From: matches the authenticated user's
! mailAlternateAddress, mailEquivalentAddress, or sendOnBehalfOf attributes.
  BASE|*|*|* \
  $CFOUND|$]ldap:///$0?uid?sub?(&(mail=$=$2$_)(|(mailAlternateAddress=$|REMOVE_SUB_LDAP_QUOTE;$1|)(mailEquivalentAddress=$|REMOVE_SUB_LDAP_QUOTE;$1|)(sendOnBehalfOf=$1)))[|$1|$2
! Exit with success if it does
  FOUND|*|*|* $E
! Now switch the base DN to that of the domain specified in the From: address
  BASE|*|*@*|*@* $CSECONDARY_BASE|$}$2,_base_dn_{|$1@$2|$3@$4
! Check and see if the address owner granted send-on-behalf-of permissions
  SECONDARY_BASE|*|*|* \
  $CSECONDARY_FOUND|$]ldap:///$0?uid?sub?(&(|(mail=$=$1$_)(mailAlternateAddress=$=$1$_)(mailEquivalentAddress=$=$1$_))(mailGrantSendPermissionsTo=$=$2$_))[|$2
```

```
! Exit with success if permission was granted - also add a Sender: field
  SECONDARY_FOUND|*|* $Y$1
! Fail any other From: address
  * $NYou$ are$ not$ authorized$ to$ send$ from$ the$ address$ you$ specified
```

In the case of a "mailGrantSendPermissionsTo" granting permission, this mapping also adds a Sender: field containing the authenticated address of the actual sender. This can be disabled by changing the "Y!" in the SECONDARY_FOUND check to "$E".

Note that this example retains the ability to specify a sendOnBehalfOf attribute on the user permissions are being granted to. If this is not desirable the "(sendOnBehalfOf=$1))" search clause should be removed from the associated LDAP URL.

Also note that neither of the two preceding examples grant permissions to "send on behalf of" using subaddresses; adding this capability is straightforward.

Finally, if permission checks on both sides must succeed - a logical AND rather than an OR - the following set of mappings could be used:

```
REMOVE_SUBADDRESS

  "$[a-z0-9.#$&'*\-/=?^_`{}\~]*+$_*"@*  $Y$0@$2
  "$_*+$_*"@*                           $Y"$0"@$2
  $_*+$_*@*                             $Y$0@$2
  *                                     $Y$0

REMOVE_SUB_LDAP_QUOTE

  "$[a-z0-9.#$&'*\-/=?^_`{}\~]*+$_*"@*  $Y$=$0@$2$_
  "$_*+$_*"@*                           $Y$="$0"@$2$_
  $_*+$_*@*                             $Y$=$0@$2$_
  *                                     $Y$=$0$_

MATCH_NOSUBADDRESS

  *|*   $C$|REMOVE_SUBADDRESS;$0||$|REMOVE_SUBADDRESS;$1|
  *|$0* $Y

AUTH_REWRITE

! Check to see if the From: matches the authenticated user's mail attribute;
! exit with success if it does
  *|*|*|* $C$|MATCH_NOSUBADDRESS;$2$|$3|$E
! Fetch the base DN we'll need to look up the user
  *|*@*|*@* $CBASE|$}$4,_base_dn_{|$1@$2|$3@$4
! Check to see if the From: matches the authenticated user's
! mailAlternateAddress, mailEquivalentAddress
  BASE|*|*|* \
  $CUSER|$]ldap:///$0?uid?sub?(&(mail=$=$2$_)(|(mailAlternateAddress=$|REMOVE_SUB_LDAP_QUOTE;$1|)(mailEquivalentAddress=$|REMOVE_SUB_LDAP_QUOTE;$1|)))[|$1|$2
! Exit with success if it does
  USER|*|*|* $E
! Must now match the sendOnBehalfOf attribute.
  BASE|*|*|* $CFOUND|$]ldap:///$0?uid?sub?(&(mail=$=$2$_)(sendOnBehalfOf=$=$1$_))[|$1|$2

! Fail any other From: address
  * $NYou$ are$ not$ authorized$ to$ send$ from$ the$ address$ you$ specified
```

46.3.30.4.2 Additional fields in AUTH_REWRITE probe (`authrewrite_extra_headers`)

New in MS 8.0.2.3. The `authrewrite_extra_headers` MTA option provides the means to include the content of additional header fields in `AUTH_REWRITE` mapping probes. The value consists of a space-separated list of header field names. Each field name specified creates an additional AUTH_REWRITE string argument at the end of the AUTH_REWRITE mapping probe, separated by vertical bars. If one or more of the specified field is present in the message header the value of the first such field will be included in the probe. Note that the separators are always present regardless of whether or not the associated field is part of the message.

All of the header field names must be known to the MTA; an error will be signalled if an unknown field name is specified. A colon, if specified at the end of a field name, will be ignored.

46.3.30.5 SMTP authentication and SASL (`maysasl`, `maysaslclient`, `maysaslserver`, `mustsasl`, `mustsaslclient`, `mustsaslserver`, `nosasl`, `nosaslclient`, `nosaslserver`, `disconnectbadauthlimit`)

As of Messaging Server 7.0-3.01, `maysasl` and `mustsasl` take effect for the SMTP client direction, as well as the SMTP server direction.

The `maysasl`, `maysaslclient`, `maysaslserver`, `mustsasl`, `mustsaslclient`, `mustsaslserver`, `nosasl`, `nosaslclient`, `nosaslserver`, and `disconnectbadauthlimit` channel options are used to configure SASL use, specifically the use of the AUTH command, during the SMTP protocol by SMTP based channels such as TCP/IP channels. `nosasl` is the default, and means that SASL authentication will not be permitted nor attempted. It subsumes `nosaslserver`, which means that the SMTP server will not permit SASL authentication, and `nosaslclient`, which means that the SMTP client will not attempt SASL authentication.

Specifying `maysaslserver` will cause the SMTP server to permit clients to attempt to use SASL authentication. Specifying `mustsaslserver` will cause the SMTP server to insist that clients use SASL authentication: the SMTP server will not accept messages unless the remote client successfully authenticates. Unless authentication has been performed, the SMTP server will issue an error to any attempted EXPN: command of:

```
530 5.7.0 Authentication required prior to EXPAND
```

while any attempted MAIL FROM: command will receive an error of:

```
520 5.7.0 Authentication required prior to MAIL/SAML/SEND/SOML
```

Note that the authentication code performs various checks on the user account when attempting to authenticate, as when a client attempts to authenticate to the MTA's SMTP server. This may result in authentication errors being returned to the SMTP server, which will in turn issue an SMTP error back in response to the SMTP AUTH attempt. Some errors of note are discussed in Authentication errors and resultant SMTP errors.

New in Messaging Server 7.0 update 1 (Messaging Server 7.0-3.01) is support for limited SASL capabilities in the MTA's SMTP client. Thus it is new in Messaging Server 7.0 update 1 that the (previously existing but not meaningful) keywords `maysaslclient`, `mustsaslclient` have meaning, and the (previously existing but now with enhanced meaning) `nosaslclient`, `maysasl`, and `mustsasl` channel options truly affect SMTP client operation. SASL authentication will be attempted by the SMTP/LMTP client if the `maysaslclient`, `mustsaslclient`, `maysasl`, or `mustsasl` channel options are set---and must succeed in order for message transmission if `mustsaslclient` or `mustsasl` is set. The PLAIN and EXTERNAL SASL mechanisms are currently supported. In legacy configuration, the AUTH_PASSWORD and AUTH_USERNAME TCP/IP-channel-specific options provide the credentials for the plain mechanism and the EXTERNAL_IDENTITY TCP/IP-channel-specific option provides the identity string for SASL EXTERNAL. (EXTERNAL_IDENTITY can be set to the empty string to enable SASL EXTERNAL without an identity string.) In Unified Configuration, those TCP/IP-channel-specific options have been replaced by the `authpassword`, `authusername`, and `externalidentity` channel options.

Normal configuration includes setting `maysaslserver` on the `tcp_local` channel and `mustsaslserver` on the `tcp_submit` channel. As of Messaging Server 7.0u1, `maysaslserver` is placed also on the `tcp_intranet` channel definition. Additional discussion of normal configuration can also be found in Blocking SMTP relaying.

New in MS 6.2 is the `disconnectbadauthlimit` channel option, applicable to source channels. It takes a (required) integer argument, specifying an upper limit on the number of bad (failed) SMTP AUTH attempts that will be permitted during a single SMTP session (connection). The default is 3. (Note that this default of 3 complies with the recommendation in RFC 4954 that servers permit at least 3 authentication attempts prior to disconnecting due to failed attempts.) Once a client's unsuccessful SMTP AUTH attempts reaches the specified number, the SMTP server will close the connection after rejecting the SMTP AUTH attempt, including in the SMTP AUTH rejection error the additional text: "`(bad authentication limit reached; disconnecting)`".

See also the `saslswitchchannel` channel option, to cause source channel "switching" based upon successful client authentication. And see also the `sasltrustauth` and `saslpassauth` channel options for control of the handling of any MAIL FROM AUTH parameter value. And see also the `authrewrite` channel option for some options on propagating SMTP AUTH information into message headers.

Note that client configuration may be required in order to get clients to make use of the MTA's SMTP AUTH support (that is, to get clients to attempt to authenticate). For instance, in order for Messenger Express (Webmail) and Communications Express (UWC) to use SMTP AUTH (SASL), one must set the `smtpauthuser` and `smtpauthpassword` MSHTTP options in Unified Configuration (or the `smtpauthuser` and `smtpauthpassword configutil` http parameters in legacy configuration) to the user ID (and corresponding password) of a store administrator (a user who exists in the list in the `admins` Message Store option in Unified Configuration, or in legacy configuration the `store.admins` list---often for instance, a user id of `admin`). (This will cause the mshttpd server to use the specified credentials to "vouch" for the identity of the sending user---who in turn has already had to login to mshttpd.)

Note that the `plaintextmincipher` MTA option, if set to a value greater than `0`, will restrict the user of plaintext passwords for authentication unless a security layer (SSL or TLS) is activated; see TLS and SASL channel options and Password and TLS MTA options for further discussion of SSL/TLS configuration for the MTA.

46.3.30.6 Automatic use of AUTH EXTERNAL at MAIL FROM (`explicitsaslexternal`, `implicitsaslexternal`)

The SUBMIT/SMTP authentication model when authentication credentials are provided by an SSL/TLS client certification is for the SUBMIT/SMTP client to issue an AUTH EXTERNAL command after the connection is secured with SSL/TLS. Unfortunately, several popular clients do not issue an AUTH EXTERNAL command and instead rely on the binding being done automatically.

The `implicitsaslexternal` source channel option causes the SMTP/SUBMIT server to perform an implicit AUTH EXTERNAL SASL operation when a MAIL FROM command is received and the following conditions have been met:

- The `mustsaslserver` channel option at a minimum (or `mustsasl`) is in effect and no authentication operations have been performed.
- An SSL/TLS layer has been successfully negotiated.

- The client provided a valid certificate as part of the SSL/TLS exchange.

The `explicitsaslexternal` source channel option disables this behavior. It is the default.

46.3.30.7 Transport Layer Security (`maytls`, `maytlsclient`, `maytlsserver`, `musttls`, `musttlsclient`, `musttlsserver`, `notls`, `notlsclient`, `notlsserver`, `tlsswitchchannel`)

The `maytls`, `maytlsclient`, `maytlsserver`, `musttls`, `musttlsclient`, `musttlsserver`, `notls`, `notlsclient`, `notlsserver`, and `tlsswitchchannel` channel options are used to configure STARTTLS use for the various protocols supported by the MTA, including but not limited to SMTP, LMTP, and MTQP.

Note that prior to 7.0.5, the LMTP server did not support TLS use; as of 7.0.5, the LMTP server does support TLS, configured via the same `maytls`, `maytlsserver`, `musttls`, `mustlsserver`, channel options used to configure SMTP server TLS support.

The ManageSieve server only supports the server subset of the TLS options since there is no ManageSieve client.

`notls` is the default, and means that STARTTLS will not be permitted or attempted. It subsumes the `notlsclient` channel option, which means that TLS use will not be attempted by the SMTP/LMTP/MTQP client on outgoing connections (the STARTTLS command will not be issued during outgoing connections) and the `notlsserver` channel option, which means that TLS use will not be permitted by the SMTP/LMTP/MTQP server on incoming connections (the STARTTLS extension will not be advertised by the SMTP/LMTP/MTQP server nor the command itself accepted).

Specifying `maytls` causes the MTA to offer TLS to incoming connections and to attempt TLS upon outgoing connections. It subsumes `maytlsclient`, which means that the SMTP/LMTP/MTQP client will attempt TLS use when sending outgoing messages, if sending to an SMTP/LMTP/MTQP server that supports TLS, and `maytlsserver`, which means that the SMTP/LMTP/MTQP server will advertise support for the STARTTLS extension and will allow TLS use when receiving messages. Note that `maytls*` settings mean that the MTA *will* want to use TLS with remote sides that support STARTTLS, while allowing remote sides that do not have STARTTLS support to communicate without TLS; but `maytls*` settings do *not* inherently mean that the MTA will "fall back" to non-TLS use when TLS negotiation is attempted but fails: failure of TLS negotiation will result in that connection being closed as a failed connection (recorded with an "X" record). As of 8.0, with `maytlsclient` set, the MTA's client will attempt a new connection to attempt sending without TLS in cases where the remote SMTP/LMTP server advertised TLS support but where the actual TLS negotiation failed; prior to 8.0, a failure in the TLS negotiation would immediately abort the delivery attempt for the message. This support is not available in MTQP.

Specifying `musttls` will cause the MTA to insist upon TLS in both outgoing and incoming connections; e-mail will not be exchanged with remote systems that fail to successfully negotiate TLS use. It subsumes `musttlsclient`, which means that the SMTP/LMTP client will insist on TLS use when sending outgoing messages and will not send to SMTP/LMTP servers that do not successfully negotiate TLS use (the MTA will issue the STARTTLS command and that command must succeed), and `musttlsserver`, which means that the SMTP/LMTP server will advertise support for the STARTTLS extension and will insist upon TLS use when receiving incoming messages and will not accept messages from clients that do not successfully negotiate TLS use. When `musttls` or `musttlsserver` is on a channel, then

unless TLS has been successfully negotiated all MAIL FROM: attempts will be rejected with the error:

```
530 5.7.0 No STARTTLS command has been given.
```

The `tlsswitchchannel` channel option is used to cause incoming connections to be switched to a specified channel upon a client's successful TLS negotiation. (This includes either successful STARTTLS use on a "regular" port, or negotiating upon connection to a "dedicated to TLS" port, usually port 465, configured via the Dispatcher's `ssl_ports` option in Unified Configuration, or its TLS_PORT option in legacy configuration.) `tlsswitchchannel` takes a required value, specifying the channel to which to switch.

Note that TLS library initialization is performed for any SMTP/LMTP channel which has any TLS usage permitted (or required). In particular, TLS library initialization will be performed by the TCP client for a channel marked merely `maytlsserver`. (This overhead is normally fairly neglible.)

Note that these options affect only TLS use negotiated at the protocol level via STARTTLS; they do not affect potential TLS use triggered by connection to a port dedicated to TLS use such as with the `ssl_ports` Dispatcher service option.

46.3.30.8 Microsoft Exchange gateway channels (`msexchange`, `nomsexchange`)

The `msexchange` channel option may be used on TCP/IP channels to tell the MTA that this is a channel that communicates with Microsoft® Exchange gateways and clients. Use of the option tells the MTA to try and accomodate nonstandard behavior on the part of Microsoft Exchange. Exactly what nonstandard behaviors are dealt with is subject to change.

Currently the `msexchange` channel option on a channel configured to allow TLS use (see the `*tls*` channel options) causes advertisement (by the MTA's SMTP server) and recognition (by the MTA's SMTP client) of the non-standard TLS capability string, in addition to the standard STARTTLS capability string, to indicate that TLS is supported.

New in 7.0.5, setting `msexchange` on a destination channel will cause the MTA, if performing any sort of MIME processing operation, to remove any Content-disposition: header line from any text/calendar message parts, as despite Content-disposition:'s long-standing existence as a standardized header line, not to mention the basic MIME rule that unrecognized Content-* header lines should be ignored, Microsoft® Outlook's handling of text/calendar parts is disturbed when such parts have a Content-disposition: specified. So specifying `msexchange` on a channel sending to Microsoft Exchange, if text/calendar parts will flow through that channel, should allow Microsoft Outlook to process calendar parts more successfully.

`nomsexchange` is the default.

46.3.30.9 XCLIENT SMTP Extension Support (`noxclient`, `xclient`, `xclientsasl`, `xclientrepeat`, `xclientsaslrepeat`)

(New in 8.0.) The MTA's SMTP server provides support for Postfix's XCLIENT SMTP extension. The PostFix documentation for the extension can be found here:

`http://www.postfix.org/XCLIENT_README.html`

Use of XCLIENT is controlled by three main source channel keywords, `noxclient`, `xclient`, and `xclientsasl`, and variants `xclientrepeat` and `xclientsaslrepeat`. `noxclient` is the default, and means that XCLIENT is not advertised in the response to EHLO and the XCLIENT command itself is disabled. If `xclient` is set, the XCLIENT command is enabled and the NAME, ADDR, PORT, PROTO, and HELO attributes may be used. `xclientsasl` enables the LOGIN attribute in addition to all the others. It should be noted that LOGIN specifies an external identity that must then be bound to the session identity through the use of SASL EXTERNAL.

By default, only one set of XCLIENT commands is allowed in a single SMTP session. Specifying `xclientrepeat` allows groups of XCLIENT commands to be repeated, allowing a proxy or similar agent to share a connection between multiple clients. `xclientsaslrepeat` allows multiple groups of XCLIENT commands including LOGIN. Note that care should be taken when these keywords are used since the server cannot determine the origin of a given XCLIENT command.

The primary visible effect of XCLIENT is on the contents of the Received: field the MTA adds. For example, if this XCLIENT command was executed:

```
xclient name=foo.domain.com addr=1.2.3.4 helo=bar.domain.com port=12345
```

it would result in a header of the general form:

```
Received: from bar.domain.com (foo.domain.com [1.2.3.4])
  by server.domain.com (Oracle Communications Messaging Server 7.0.5.32
  64bit (built Aug 18 2014)) with imapsubmit
  id <01OJ9P51WPFC007KNZ@server.domain.com> for user@domain.com;
  Mon, 20 Aug 2012 08:17:31 -0700 (PDT)
```

However, the ADDR, PORT, DESTADDR, and DESTPORT attributes also change the contents of the transportinfo that appears in various mapping table probes, such as the probe to `PORT_ACCESS`. Given the preceding XCLIENT command, the *`transportinfo`* part of the mapping probes would change to something like:

```
TCP|this-mta's-ip|25|1.2.3.4|12345
```

where note that the values to use in the "source IP" and "source port" fields have been specified via ADDR and PORT, respectively.

Note: Support for DESTADDR and DESTPORT was added in MS 8.0.2.3.

46.3.30.10 AUTH parameter handling (`saslpassauth`, `nosaslpassauth`, `sasltrustauth`, `nosasltrustauth`)

The SMTP Service Extension for Authentication, specified in RFC 4954, defines an AUTH parameter for the MAIL FROM command. This parameter is normally used to pass information about the identity associated with the agent that submitted the message between SMTP servers. As required by the specification, the MTA always accepts and retains any value presented in an AUTH parameter.

If the saslpassauth channel option is set on a destination channel, any AUTH parameter value associated with the message will be passed on to the next SMTP server, assuming that server supports the authentication extension. nosaslpassauth is the default.

New in Messaging Server 7.3-11.01, if the sasltrustauth channel option is set on a source channel, any value presented in the AUTH parameter will be promoted to the authenticated originator address that's used throughout the MTA. nosasltrustauth is the default. The sasltrustauth option should be used with great care because the AUTH parameter is not, in general, trustworthy and the authenticated originator address is used for a variety of authentication checks. So setting sasltrustauth, if not done thoughtfully and carefully, may negate the value of certain authentication checks and allow more malicious spoofing of e-mail. Normally sasltrustauth would only be appropriate on a channel that is dedicated to receiving messages from a trustworthy (and itself careful and meticulous to require authentication) source; note that such a source must not only verify any authentication on the messages it accepts, but indeed *require* authentication on any of its incoming messages that it will relay to your host, or itself be part of a chain of such trusted relaying. The situation to avoid is trusting MAIL FROM AUTH values relayed by a -- possibly reliable enough on what it happened to authenticate itself---host that itself accepted for relaying a message with an unreliable MAIL FROM AUTH parameter.

An example of appropriate sasltrustauth use would be where there is a user-client-facing, dedicated-to-accepting-message-submissions host that relays to your host. Then on your host, on a channel dedicated to accepting only messages from that client-submission host, use of sasltrustauth could allow desirable passing along of known-to-be-accurate AUTH parameters, without opening the security door wide to passing along potentially inaccurate AUTH parameters.

See also the AUTH_ACCESS mapping table and AUTH_REWRITE mapping table, both of which can affect the MAIL FROM AUTH parameter.

46.3.30.11 saslruleset Option

RESTRICTED: Not yet implemented.

46.3.30.12 Channel switching based on SMTP authentication (saslswitchchannel, nosaslswitchchannel)

The saslswitchchannel channel option is used to cause incoming connections to be switched to a specified channel upon a client's successful SASL use. (See the maysasl* and mustsasl* channel options for configuration of permitting/requiring SMTP AUTH and SASL use.) saslswitchchannel takes a required value, specifying the channel to which to switch. nosaslswitchchannel is the default, and means that channel switching is not performed upon a client's successful SASL use.

See also the mailSMTPSubmitChannel user LDAP attribute, (or as of the 8.0 release, whatever LDAP attribute is named by the ldap_auth_attr_submit_channel MTA option) which when set on a user entry will cause channel "switching" to the specified channel; it thus permits "finer-grained" channel switching than saslswitchchannel which merely switches all authenticated submissions to a particular named channel.

See also the (new in MS 6.3) userswitchchannel channel option which, in conjunction with site-selected user or domain LDAP attributes, also allows "fine-grained" channel switching, in this case based merely on the *purported* From: address.

The saslswitchchannel channel option is typically used when it is desired to distinguish between authenticated *vs.* unauthenticated submissions as a class; the mailSMTPSubmitChannel user LDAP attribute (or as of the 8.0 release, whatever LDAP attribute is named by the ldap_auth_attr_submit_channel MTA option) is typically used when it is desired to securely distinguish submissions from particular users (say to allow "special privileges" to particular users); the (new in MS 63) userswitchchannel channel option and associated LDAP attribute(s) are typically used when it is desired to make esthetic distinctions (rather than more critical "secure" distinctions) on users' submissions without requiring authenticated verification of the sender address.

See also Blocking SMTP relaying for an example of typical use of saslswitchchannel.

Note that any channel switching done by saslswitchchannel will be undone if/when a client issues a (nonstandard, new in 8.0) XUNAUTHENTICATE command. (SMTP server support for the nonstandard XUNAUTHENTICATE extension and associated XUNAUTHENTICATE command is new in 8.0; note that XUNAUTHENTICATE is not supported for the LMTP server. XUNAUTHENTICATE is only valid after successful authentication has been performed, and the capability only shows up in the EHLO response at this point at well. Successful execution of the XUNAUTHENTICATE command will return the SMTP session to an unauthenticated state.)

46.3.30.13 tlsmaxversion Option

The tlsmaxversion channel option determines the maximum acceptable version of TLS (the modern version of the SSL protocol). This presently takes a value of TLS1.0, TLS1.1, TLS1.2, orTLS1.3. This option defaults to TLS1.3.

46.4 Header option files

Some special option files may be associated with a channel that describe how to trim the headers on messages either enqueued to, or enqueued by, that channel. This facility is completely general and may be applied to any channel; it is controlled by the headertrim, noheadertrim, innertrim, noinnertrim, headerread, and noheaderread channel options.

Various MTA channels have their own channel-level option files as well. Header option files have a different format than other MTA option files and thus a header option file is always a separate file.

Note that the test -header utility with its -option switch can be used to test the effects of header trimming option files.

As of MS 6.3, note that the Sieve "editheader" extension provides an alternate way to alter header lines. While header trimming may be a simpler approach for performing simple changes, the Sieve "editheader" approach is more powerful in some respects such as allowing changes to specific, unrecognized-by-the-MTA, header lines, or alterations of the values on header lines.

46.4.1 Header option file location

For destination channel based header trimming to be applied upon message enqueue after normal header processing, the MTA looks in the table directory, IMTA_TABLE:, for header options files with names of the form channel_headers.opt, where channel is the name

of the channel with which the header option file is associated. (In Unified Configuration, such header options files continue to be used.) The `headertrim` channel option and/or the `innertrim` channel option must be specified on the channel to enable the use of such a header option file.

For source channel based header trimming to be applied upon message enqueue before normal header processing, the MTA looks in the table directory, `IMTA_TABLE:`, for header options files with names of the form `channel_read_headers.opt`, where `channel` is the name of the channel with which the header option file is associated. (In Unified Configuration, such header options files continue to be used.) The `headerread` channel option must be specified on the channel to enable the use of such a header option file.

Header option files should be world readable.

46.4.2 Header option file format

Simply put, the contents of a header option file are formatted as a set of message header lines. Note, however, that the bodies of the header lines do not conform to RFC 822.

The general structure of a line from a header options file is then:

`Header-name``: OPTION=VALUE, OPTION=VALUE, OPTION=VALUE, ...`

where `Header-name` is the name of a header line that the MTA recognizes. (Any of the header lines described in this manual may be specified, plus any of the header lines standardized in RFC 822, RFC 987, RFC 1049, RFC 1421, RFC 1422, RFC 1423, RFC 1424, RFC 2156, and RFC 2045. More generally, see the file `mtasdkhdr.h` in the MTA include directory.)

Header lines not recognized by the MTA are controlled by the special header line name Other:. A set of options to be applied to all header lines not named in the header option file can also be given on a special Defaults: line. Use of Defaults: guards against the inevitable expansion of the MTA's known header line table in future releases.

Various options may then be specified to control the retention of the corresponding header lines. The available options are:

46.4.2.1 ADD (quoted string)

The ADD option creates a completely new header line of the given type. The new header line contains the specified string. The header line created by ADD will appear after any existing header lines of the same type. The ADD option cannot be used in conjunction with the Defaults: header line type; it will be ignored if it is specified as part of an Other: option list.

46.4.2.2 FILL (quoted string)

The FILL option creates a completely new header line of the given type if and only if there are no existing header lines of the same type. The new header line contains the specified string. The FILL option cannot be used in conjunction with the header line type; it will be ignored if it is specified as part of an Other: option list.

46.4.2.3 FOLDITEMS (integer)

This option takes an integer that specifies the maximum number of "items" that can appear on a line before folding. "Items" are normally defined as comma-separated sets of tokens, but if FOLDITEMS is set to a negative value, then encoded words are also considered to be "items".

This option can be useful, for instance, when dealing with Netscape 4.7* clients which have a bug whereby they will insert an extra space between successive encoded words, unless there is a CRLF between the encoded word items.

46.4.2.4 GROUP (integer 0 or 1)

This option controls grouping of header lines of the same type at a particular precedence level. A GROUP value of 0 is the default, and indicates that all header lines of a particular type should appear together. A value of 1 indicates that only one header line of the respective type should be output and the scan over all header lines at the associated level should resume, leaving any header lines of the same type unprocessed. Once the scan is complete it is then repeated in order to pick up any remaining header lines. This header option is primarily intended to accomodate Privacy Enhanced Mail (PEM) header processing.

46.4.2.5 LINELENGTH (integer)

This option controls the length at which to fold headers. See also the discussion of the `headerlinelength` channel option.

46.4.2.6 MAXCHARS (integer)

This option controls the maximum number of characters which may appear in a single header line of the specified type. Any header line exceeding that length is truncated to a length of MAXCHARS. This option pays no attention to the syntax of the header line and should never be applied to header lines containing addresses and other sorts of structured information. The length of structured header lines should be controlled with the `maxheaderchars` and `maxheaderaddrs` channel options.

46.4.2.7 MAXIMUM (integer)

This option controls the maximum number of header lines of this type that may appear. This has no effect on the number of lines, after wrapping, each individual header line might consume. A value of -1 is interpreted as a request to suppress this header line type completely.

46.4.2.8 MAXLINES (integer)

This option controls the maximum number of lines all header lines of a given type may occupy. It complements the MAXIMUM option in that it pays no attention to how many header lines are involved, only to how many lines of text they collectively occupy. As with the MAXIMUM option, headers are trimmed from the bottom to meet the specified requirement.

46.4.2.9 PRECEDENCE (integer)

This option controls the order in which header lines are output. All header lines have a default precedence of zero. The smaller the value, the higher the precedence. Thus, positive PRECEDENCE values will push header lines towards the bottom of the header while negative values will push them towards the top. Equal precedence ties are broken using the MTA's internal rules for header line output ordering.

Note that prior to MS 6.3, the MTA's header line precedence processing was always applied. As of MS 6.3, the MTA by default does not do header line re-ordering, and so header line re-ordering only takes place if header trimming is enabled. (This change was made to improve interoperability with poorly designed message signing mechanisms.)

46.4.2.10 RELABEL (header name)

This option changes a header line to another header line; that is, the name of the header is changed, but the value remains the same. For instance,

```
X-MSMail-Priority: RELABEL="Priority"
X-Priority: RELABEL="Importance"
```

46.4.3 Header Fields Known to the MTA

The MTA maintains an internal list of "known" header fields. This list is used to perform and in some cases optimize various operations the MTA performs on message headers. In particular, the MTA's header trimming facilities are built on top of this list and only the specific fields on this list can be individually manipulated using header trimming. (The header addition facility, on the other hand, does not depend on this list in the same way and can be used to add arbitrary headers.)

The header fields currently on the list are:

Chapter 47 Rewrite rules

Domain rewriting rules, or, as they are more frequently called, *rewrite rules*, play two important roles for the MTA: rewrite rules are used to convert addresses into true domain addresses, and to determine their corresponding channels. These rules are used to rewrite addresses appearing in both the transport layer and the message header. The transport layer is the message's "envelope", which contains routing information and is invisible to the user. The determination of to which channels a message should be enqueued results from rewriting its envelope To addresses.

The rewrite rules and the table of channels cooperate to determine the disposition of each address. Each address detected in a message is rewritten, starting[a] with the envelope To address(es). The result of the rewrite process is a rewritten address and a "routing system" (as determined from rewriting the envelope To address); *i.e.*, the system to which the message is to be sent. Depending upon the topology of the network, the routing system may only be the first step along the path the message takes to reach its destination or it may be the final destination system itself.

After the rewrite process has finished, a search is made for the routing system among the MTA's channels. Each channel will have one or more host names associated with it. The routing system name is compared against each of these names to determine to which channel to enqueue the message.

Note that the MTA provides (many) other means of manipulating addresses for the purposes of changing them for varied purposes, such as cosmetic changes, message forwarding, mailing list processing, *etc.* See for instance Aliases. Rewrite rules are appropriate for global, unconditional transformations of domain names to be controlled purely by the MTA (as opposed to provisioning of domain name handling in, for instance, an LDAP directory), and are required for configuring MTA routing of messages based on envelope To address.

Every rewrite rule consists of two parts: a pattern (left hand side) followed by an equivalence string or template (right hand side). The two parts must be separated by one or more spaces. Spaces are not allowed in the parts themselves. In general, the template specifies a mailbox name (*e.g.*, username), a host/domain specification, and the name of a system attached to an existing MTA channel to which messages to this address should be enqueued. The total length of a line in the configuration file is limited to 1024 characters; the pattern is limited to 256 characters, and template (prior to substitutions) is also limited to 256 characters.

In legacy configuration, note that each rewrite rule would appear on a single line in the upper half of the MTA configuration file. Comment lines (lines beginning with a comment character such as exclamation point in the first column) but *not* blank lines could be placed between rules. Rewrite rules could also, optionally, be stored in an auxiliary database called the domain database.

In Unified Configuration, rewrite rules are stored under the `rewrite` XML element. But they are most conveniently viewed and editted "as if" they were in the legacy configuration `imta.cnf` file, by using the `msconfig` command `EDIT REWRITES`.

The syntax of rewrite rules is discussed in further detail in Rewrite rule patterns and tags and Rewrite rule templates. First, however, Application of rewrite rules to addresses gives an overview of the action of rewrite rules in operation.

[a]Technically, rewriting begins with a preliminary rewrite of the envelope From address, for access control and source channel determination purposes. After that, the envelope To address is rewritten (possibly sensitive to the source channel), and then with destination channel(s) determined (due to the rewriting of the envelope To address) the envelope From address receives another, "real" rewriting now that the destination channels are known.

47.1 The rewrite group

In Unified Configuration, the `rewrite` group is not an option itself, but rather a list of all the MTA's rewrite rules. For instance:

```
msconfig> show rewrite *
role.rewrite.rule = $* $A$E$F$U%$H$V$H@&/IMTA_HOST/
role.rewrite.rule = &/IMTA_HOST/ $U%$D@&/IMTA_HOST/
role.rewrite.rule = &/IMTA_DEFAULTDOMAIN/ $U%$D@&/IMTA_HOST/
role.rewrite.rule = .ims-ms-daemon $U%$H.ims-ms-daemon@ims-ms-daemon
role.rewrite.rule = .pipe-daemon $U%$H.pipe-daemon@pipe-daemon
role.rewrite.rule = . $U%$H$,$H@TCP-DAEMON
role.rewrite.rule = [] $E$R${INTERNAL_IP,$L}$U%[$L]@tcp_intranet-daemon
role.rewrite.rule = hold-daemon $U%$H@hold-daemon
role.rewrite.rule = .hold-daemon $U%$H@hold-daemon
```

Rewrite rules are typically most conveniently manipulated by using the `msconfig` command `EDIT REWRITES`, which allows viewing them and editting them "as if" they were the upper half of a legacy `imta.cnf` file.

47.2 Application of rewrite rules to addresses

This section presents a discussion of the operation of domain rewriting rules: how an address is parsed and then transformed via rewrite rules. This section touches briefly on the syntax of

rewrite rules as such syntax relates to example addresses, but for full details on rewrite rule syntax, see Rewrite rule patterns and tags and Rewrite rule templates.

There are four steps in the application of the domain rewriting rules to a given address:

1. The first host or domain specification is extracted from the address. (Note that an address may specify more than one host or domain name as is the case with the address jdoe %host1@domain.com.)

2. After extracting the first host or domain name specification, the rewrite rules are scanned for a matching rewrite rule. That is, a search is conducted for a rewrite rule whose pattern portion matches the extracted host/domain name.

3. Once a matching rewrite rule is found, the address is rewritten according to the template portion of that rule. The template also specifies the name of a routing system to which messages to this address should be routed.[8]

4. The routing system name is then compared with the host names associated with each channel. If a match is found, then the message is enqueued to that channel; otherwise, the rewriting process is considered to have failed. If the matching channel is the local channel, then some additional rewriting of the address may occur.

These four steps are described in detail in the following subsections. There are also special template formats which allow for variations in these four steps.

Note [8]The term "routing system" can be misleading. It does not necessarily mean the name of a system through which the message will be routed but rather is a host name, possibly fictitious, associated with a specific channel.

47.2.1 Rewriting: extraction of the first host or domain specification

The process of rewriting an address starts by extracting the first host/domain specification from the address. (Readers who are not familiar with RFC 822 address conventions are advised to read that standard, at least in a cursory fashion, at this point in order to understand the following discussion.) The order in which host/domain specifications in the address are scanned is as follows:

1. Hosts in source routes (read from left to right).

2. Hosts appearing to the right of the at sign.

3. Hosts appearing to the right of the last singleton percent sign.

4. Hosts appearing to the left of the first exclamation point.

The order of the last two items are switched if the `bangoverpercent` channel option is in effect on the channel that is doing the address rewriting, that is, if the channel which is attempting to enqueue the message is itself marked with the `bangoverpercent` channel option.[9]

Some highly hypothetical examples of addresses and the host name that would be extracted first are shown below:

Table 47.1 Example Host Name Extractions During Rewriting

Address	First host/domain specification	Comments
user@a	a	a is a "short-form" domain name
user@a.b.c	a.b.c	a.b.c is a "fully-qualified" domain name (FQDN)
user@[0.1.2.3]	[0.1.2.3]	[0.1.2.3] is a "domain literal"
@a:user@b.c.d	a	This is a source-routed address with a a short-form domain name, the "route"
@a.b.c:user@d.e.f	a.b.c	Source routed address, route part is fully-qualified
@[0.1.2.3]:user@d.e.f	[0.1.2.3]	Source-routed address, route part is a domain literal
@a,@b,@c:user@d.e.f	a	Source-routed address with an a to b to c routing
@a,@[0.1.2.3]:user@b	a	Source-routed address with a domain literal in the route part
user%A@B	B	This non-standard form of routing is called a "percent hack"
user%A%B%C@D	D	A built up percent hack
user%A	A	
user%A%B	B	
user%%A%B	B	
user%A%%B	A%%B	Of questionable value
@A:user%B@C	A	
A!user	A	"Bang-style" addressing; commonly used for UUCP
A!user@B	B	
A!user%B@C	C	
A!user%B	B	`nobangoverpercent` channel option active; the default
A!user%B	A	`bangoverpercent` channel option active
@A:B!user@C	A	
@A,@B:C!user%D@E	A	Too grotesque to consider, really

Note that RFC 822 does not say anything about the interpretation of exclamation points, `!`, and percent signs, `%`, in addresses. It is customary to interpret percent signs in the same manner as at signs, `@`, if no at sign is present, so this convention is adopted by the MTA.

The special interpretation of repeated percent signs is used to allow percent signs as part of local usernames, which is used in handling PSIMail and other foreign mail system addresses. The interpretation of exclamation points conforms to RFC 976's "bang-style" address conventions and makes it possible to use UUCP addresses with the MTA.

The order of interpretation of exclamation points *vs.* percent signs is not specified by either RFC 822 or RFC 976, so the `bangoverpercent` and `nobangoverpercent` keywords can be used to control the order in which they are applied by the channel doing the rewriting. Note that the default is more "standard", although the alternate setting may be useful under some circumstances.

[9] For instance, if this is a message being submitted to the SMTP port from a "local" client, then the enqueueing channel is typically `tcp_intranet`, or `tcp_auth` if the user authenticates. If this is a message being submitted to the SMTP SUBMIT port from a "local" client, then the enqueueing channel is typically `tcp_submit`. If it is a message coming in from a remote Internet user, then usually it will be the `tcp_local` channel doing the enqueueing.

47.2.2 Rewriting: scanning for a domain match

Once the first host/domain specification has been extracted from the address, the MTA consults the rewrite rules to find out what to do with it. Initially, the exact host/domain specification is compared with the pattern part of each rule (*i.e.,* the left-hand side of each rule). This comparison is (and the rest of the comparisons discussed below are also) case insensitive. Case insensitivity is mandated by RFC 822, UUCP addresses notwithstanding. The MTA is insensitive to case but preserves it whenever possible.

As of MS 8.0.2.2, if A-labels (see RFC 5890 section 2.3.2.1) are present they are both looked up as-is and in U-label form. Similarly, if U-labels are present they are converted to A-labels, looked up, then converted back to U-labels and looked up. Finally, any U-labels specified on the left hand side of a rewrite rule are converted to A-labels and back again when the rewrite rules are loaded, so they will match even if they are specified in uncanonical and/or unnormalized formats.

If the pattern matches, then the host/domain is transformed as specified by the rewrite rule template (right hand side). If that (transformed, as appropriate) host/domain specification then matches a channel official host name, the rewriting is considered complete and the address is considered to match that channel.

New in Comms Suite 7.0 is support for attempting an initial, special rewrite of a host/domain with a trailing dot. (Such a trailing dot on a host/domain name is illegal in Internet domain names, but has been tolerated in *some* contexts by the MTA for a long time. RFC 1123 points out that trailing dots are syntactically illegal in email but notes that some convention needs to exist in user interfaces where short form names can be used. Accordingly, it may be handy in contexts like SMTP submission of messages, SMTP SUBMIT, to be able to accept addresses with trailing dots, and then remove the dot while attaching special semantics to its initial presence.) New in 7.0, the MTA will attempt to rewrite the host/domain with the trailing dot present; if that fails, then the MTA will remove the trailing dot from the host/domain and then continue rewriting attempts, as normal, from that point on with the trailing dot removed.

As of MS 7.0U3, if the host/domain doesn't match and is a domain literal of the form "[channel:name]", where "name" is the name of an existing channel, a rewrite rule of the form:

```
[channel:name]          $U%$D@official-host-name
```

where "official-host-name" is the official channel host associated with the channel "name", is synthesized and used. This channel name form for domain names is primarily intended for use in source routes.

If the host/domain specification does not match any pattern, in which case it is said to "not match any rule", then the first part of the host/domain specification --- the part before the

first period, usually the host name --- is removed and replaced with an asterisk and another attempt is made to locate the resulting host/domain specification, but only in the regular rewrite rules (those in the `imta.cnf` file or in Unified Configuration `rewrite` group -- the domain database is not consulted). If this fails the first part is removed and the process is repeated. If this also fails the next part is removed (usually a subdomain) and the rewriter tries again, first with asterisks and then without, as long as there is still at least one portion of the original host/domain specification remaining. All probes that contain asterisks are only done in the regular rewrite rules table (those rewrite rules in `imta.cnf` or in the `rewrite` group in Unified Configuration); the domain database is not checked. This process proceeds until either a match is found or the host/domain specification up to (but not including) its last portion is exhausted. The effect of this procedure is to try to match the most specific domain first, working outward to less specific and more general domains.

If the entire host/domain specification with the exception of its last (right-most) portion has been exhausted looking for a rewrite rule pattern that matches and a match has still not been found, then an additional check of the entire host/domain specification is performed; namely the channel host table is scanned for a matching host name associated with a channel; that is, the entire host/domain specification is compared against any channel official host names and host name aliases on channel definitions to look for a mtach.

If a match has still not been found, then a special all-components-replaced-by-asterisks attempt is made, (in particular, in the case of short-form host names an * lookup is attempted) in the regular rewrite rules (those in `imta.cnf` or in the `rewrite` group in Unified Configuration), see Rules to match domains containing exact numbers of components; and if that did not succeed then the special "match-all" rule described in A_rule_to_match_any_address is attempted.

A somewhat more algorithmic view of this matching procedure is given below.

1. The host/domain specification is used as the initial value for the comparison strings spec_1 and spec_2. *E.g.,* spec_1 = spec_2 = a.b.c).

2. The comparison string spec_1 is compared with the pattern part of each rewrite rule in the `imta.cnf` configuration file (legacy configuration) or the `rewrite` group (Unified Configuration), and then the domain database, until a match is found. The matching procedure is exited if a match is found.

3. If no match is found then the leftmost, non-asterisk part of spec_2 is converted to an asterisk. *E.g.,* if spec_2 is a.b.c then it is changed to *.b.c; if spec_2 is *.b.c then it is changed to *.*.c; *etc.* The resulting comparison string spec_2 is compared with *only* the configuration file (legacy configuration) or the `rewrite` group (Unified Configuration). The domain database is not consulted. The matching procedure is exited if a match is found.

4. If no match is found then the first part, including any leading period, of the comparison string spec_1 is removed. In the case where spec_1 has only one part (*e.g.,* .c or c), the string is replaced with a single period, ".". If the resulting string spec_1 is of non-zero length, then we return to Step 1. If the resulting string has zero length (*i.e.,* was previously ".") then the lookup process has failed and we exit the matching procedure.

For example, suppose the address dan@sc.cs.cmu.edu is to be rewritten. This causes the rewriter to look for the following patterns in the given order:

Table 47.2 Rewriting dan@sc.cs.cmu.edu Example

Pattern	Files Scanned

$*	configuration file/`rewrite` group rules and then domain database; this is the Initial match-all rule
sc.cs.cmu.edu	configuration file/`rewrite` group rules and then domain database
*.cs.cmu.edu	configuration file/`rewrite` group rules only
.cs.cmu.edu	configuration file/`rewrite` group rules and then domain database
..cmu.edu	configuration file/`rewrite` group rules only
.cmu.edu	configuration file/`rewrite` group rules and then domain database
..*.edu	configuration file/`rewrite` group rules only
.edu	configuration file/`rewrite` group rules and then domain database
sc.cs.cmu.edu	channel host name table (those official host names and host name aliases specified in channel definitions)
..*.*	configuration file/`rewrite` group rules only; this is an example of Rules to match domains containing exact numbers of components
.	match-all rule described in A rule to match any address

Note: Always remember that patterns involving asterisks (except the initial match-all pattern, $*) are only searched for in the configuration file's set of rewrite rules; no searching is done for these patterns in the domain database.

47.2.3 Rewriting: applying the rewrite rule template

Once a host/domain specification matches a rewrite rule, it is rewritten using the template part of the rule. The template specifies three things:

1. a new username for the address,
2. a new host/domain specification for the address, and
3. the name of a system attached to an existing MTA channel (the "routing system") to which messages to this address should actually be sent.

Template format is discussed in detail in Rewrite_rule_templates. As a quick overview, note that the most common format for templates is *A%B@C*, where *A* is the new username, *B* is the new host/domain specification, and *C* is the routing system. And the format *A@C* (which is an abbreviation for *A%C@C*) is also commonly used.

Substitution strings are allowed in the template. For instance, to mention some of the more commonly used substitution strings, any occurrences of `$U` in the template are replaced with the username from the original address, any occurrences of `$H` are replaced with the portion of the host/domain specification that was *not* matched by the rule, and any occurrences of `$D` are replaced by the portion of the host/domain specification that *was* matched by the rewrite rule. Summary of template substitutions and control sequences contains a summary of these and other substitution strings which are presented in detail in Rewrite rule template substitutions and control sequences.

As an example, suppose that the host/domain specification jdoe@domain.com has matched the rewrite rule

```
domain.com        $U@DOMAIN.COM
```

Then the template will produce the username jdoe, the host/domain specification DOMAIN.COM, and the routing system DOMAIN.COM. In a slightly more complicated example, assume that the host/domain specification has matched the rewrite rule

```
.com            $U%$H$D@TCP-DAEMON
```

In this case, `$U` = jdoe, `$H` = domain, and `$D` = .com. The template produces the username jdoe, the host/domain specification domain.com, and the routing system TCP-DAEMON.

47.2.4 Rewriting: finishing the rewriting process

One of two things can happen once the host/domain specification is rewritten. If the routing system is not associated with either the local channel or a channel explicitly marked with the `routelocal` channel option, or in any case when there are no additional host/domain specifications in the address, then the rewritten specification is substituted into the address replacing the original specification that was extracted for rewriting, and the rewriting process terminates.

If the routing system matches the local channel (or a channel marked with the `routelocal` channel option) and there are additional host/domain specifications that appear in the address, then the rewritten address is discarded, the original (initial) host/domain specification is removed from the address, a new host/domain specification is extracted from the address and the entire process is repeated. Rewriting will continue until either all the host/domain specifications are gone or a route through a non-local, non-`routelocal` channel is found. This iterative mechanism is the MTA's way of providing support for source routing. In effect, superfluous routes through the "local system" are removed from addresses by this process.

47.2.5 Rewriting: rewrite rule failure

If a host/domain specification fails to match any rewrite rule and no default rule (that is, match-all rule) is present, the MTA simply uses the specification "as-is"; *i.e.*, the original specification becomes both the new specification and the routing system. If the address has a nonsensical host/domain specification it will be detected when the routing system does not match any system name associated with any channel. This relaxed interpretation of rewrite rule failures allows isolated MTA sites that only communicate with a small number of systems to get by without any rewrite rules whatsoever.

47.2.6 Syntax checks after rewriting

No additional syntax checking is done after the rewrite rules have been applied to an address. This laxity is deliberate --- it makes it possible for rewrite rules to be used to convert addresses into formats that do not conform to RFC 822. However, this also means that configuration mistakes in the rewrite rules may result in messages leaving the MTA system with incorrect or illegal addresses.

47.2.7 Rewriting: domain literals

Domain literals are handled specially during the rewriting process. If a domain literal appearing in the domain portion of an address does not match a rewrite rule pattern as-is, the literal is interpreted as a group of strings separated by periods and surrounded by square brackets.[a] The rightmost string is removed and the search is repeated. If this does not work the next string is removed, and so on until only empty brackets are left. If the search for empty brackets fails, the entire domain literal is removed and rewriting proceeds with the next

section of the domain address, if there is one. No asterisks are used in the internal processing of domain literals; when an entire domain literal is replaced by an asterisk the number of asterisks corresponds to the number of elements in the domain literal.

Like normal domain/host specifications, domain literals are also tried in most specific to least specific order. The first rule whose pattern matches will be the one used to rewrite the host/domain specification. If there are two identical patterns in the rules list, the one which appears first will be used.

As an example, suppose the address dan@[128.6.3.40] is to be rewritten. The rewriter looks for [128.6.3.40], then [128.6.3.], then [128.6.], then [128.], then [], then [*.*.*.*], and finally the match-all rule ".".

When domain literals are combined with domain names the number of lookup attempts gets to be quite large. This is *not* normal usage and its use is *strongly discouraged*. For example, the address dan@[1.2].a.[3.4].b would generate requests for:

```
[1.2].a.[3.4].b
[1.].a.[3.4].b
[].a.[3.4].b
[*.*].a.[3.4].b
.a.[3.4].b
[*.*].*.[3.4].b
.[3.4].b
[*.*].*.[3.].b
.[3.].b
[*.*].*.[].b
.[].b
[*.*].*.[*.*].b
.b
[*.*].*.[*.*].*
.
```

New in MS 7.0, the MTA supports the RFC 2822 definition of spaces in domain literals as FWP, or in other words, semantically null; (note that the meaning of such spaces had not been specified in RFC 822). That is, as of MS 7.0, the MTA will canonicalize `user@[a . b . c . d]` as `user@[a.b.c.d]`, which would not have occurred in previous versions.

[a] Note that the support of numeric domain literals is not required by either the MTA or RFC 822. Their support is enabled by including IP literal rewrite rules in the MTA configuration.

47.3 Rewrite rule patterns and tags

Most rewrite rule patterns consist either of a specific host name that will match only and exactly that host, *e.g.*,

```
host.domain.com
```

or consist of a subdomain pattern that will match any host/domain in the entire subdomain, *e.g.*,

```
.domain.com
```

A rewrite rule pattern such as the above would match any host.domain.com or host.subnet.domain.com sort of host/domain name. Note, however, that it will *not* match the exact host name domain.com; to match the exact host name domain.com, a separate domain.com pattern would be needed.

The matching in rewrite rule patterns is case-insensitive: uppercase and lowercase are not significant, in either the pattern, or in the domain of the address being rewritten. (Note, however, that rewrite rule templates preserve case.)

Since as discussed in Rewriting: scanning for a domain match the MTA attempts to rewrite host/domain names starting from the specific host name and then incrementally generalizing the name to make it less specific, this means that a more specific rewrite rule pattern will be preferentially used over more general rewrite rule patterns. For instance, if the rewrite rule patterns

```
hosta.subnet.domain.com
.subnet.domain.com
.domain.com
```

are present in the configuration file (legacy configuration) or the `rewrite` group (Unified Configuration),[b] then an address of jdoe@hosta.subnet.domain.com will match the specific hosta.subnet.domain.com rewrite rule pattern, while an address of jdoe@hostb.subnet.domain.com will match the more general .subnet.domain.com rewrite rule pattern, and an address of jdoe@hostc.domain.com will match the .domain.com rewrite rule pattern.

In particular, the use of rewrite rules incorporating subdomain rewrite rule patterns is common for sites on the Internet. Such a site will typically have a number of rewrite rules for their own internal hosts and subnets, and then will include rewrite rules for the top-level Internet subdomains into their configuration: in older configuration, from the file `internet.rules` stored in the MTA's table (config) directory, or in newer configurations from the `tlds.txt` file.

In older configurations, the incorporation of rewrite rules from `internet.rules` such as

```
!    Ascension Island
.AC                                     $U%$H$D@TCP-DAEMON
  ...[text removed for brevity]...
!    Zimbabwe
.ZW                                     $U%$H$D@TCP-DAEMON
```

with rewrite rule patterns that match the top level Internet domains and rewrite rule templates that rewrite addresses matching such patterns to an outgoing TCP/IP channel, ensure that messages to Internet destinations (other than to the internal host destinations handled via more specific rewrite rules) will be properly rewritten and routed out an outgoing TCP/IP channel.

In newer configurations, a similar effect is obtained via the special rewrite rule:

```
. $U%$H$,$H@TCP-DAEMON
```

where the special `$,$H` sequence causes a lookup of the entire unmatched domain (the `$H`) in the `tlds.txt` file (the `$,`) listing current Top Level Domains.

IP domain literals follow a similar hierarchical matching pattern, though with right-to-left (rather than left-to-right) matching. For instance, the pattern

```
[1.2.3.4]
```

matches only and exactly the IP literal [1.2.3.4], while

```
[1.2.3.]
```

matches anything in the 1.2.3.0 subnet.

In addition to the more common sorts of host or subdomain rewrite rule patterns discussed above, rewrite rules may also make use of several special patterns, summarized in Summary of special patterns for rewrite rules, and discussed in the following subsections.

Table 47.3 Summary of special patterns for rewrite rules

Pattern	Name	Usage
$*	Match-first rule	Initial, prior-to-all-else rewrite rule, matches everything
$%	Percent hack rule	Matches any host/domain specification of the form A%B.
$!	Bang-style rule	Matches any host/domain specification of the form B!A.
[]	IP literal match-all rule	Match any IP domain literal.
*, *.*, *.*.*, *etc.*	Match-exactly-*n*-components-domain-names rules	A rule with all asterisks will match any domain name containing that exact number of components; in particular, * matches any short form host.
.	Match-all rule	Matches any host/domain specification.

In addition to these special patterns, the MTA also has the concept of "tags" which may appear in rewrite rule patterns. These tags are used in situations where an address may be rewritten several times and, based upon previous rewritings, distinctions must be made in subsequent rewritings by controlling which rewrite rules match the address; see Tagged rewrite rule sets.

47.3.1 Initial match-all rule

The special pattern `$*` is applied before any other rewriting, and matches all addresses. Its usual use is as a fundamental part of a "direct LDAP" setup, to achieve LDAP-based routing of domains. That is, its usual use is in conjunction with a template looking up domains in LDAP, so that domains are looked up in LDAP prior to any other rewriting. For example:

```
$*    $A$E$F$U%$H$V$H@official-host-name-of-l-channel
```

47.3.2 A rule to match percent hacks

If the MTA tries to rewrite an address of the form A%B and fails, it tries one extra rule before falling through and treating this address form as A%B@*localhost*. This extra rule is the percent hack rule. The pattern is $%. The pattern never changes. This rule is only activated when a

local part containing a percent sign has failed to rewrite any other way (including the match-all rule described below).

The percent hack rule is useful for assigning some special, internal meaning to percent hack addresses.

47.3.3 A rule to match bang-style addresses

If the MTA tries to rewrite an address of the form B!A and fails, it tries one extra rule before falling through and treating this address form as B!A@*localhost*. This extra rule is the bang-style rule. The pattern is $!. The pattern never changes. This rule is only activated when a local part containing an exclamation point has failed to rewrite any other way (including the match-all rule).

The bang-style rule can be used to force UUCP style addresses to be routed to a system with comprehensive knowledge of UUCP systems and routing.

47.3.4 A rule to match any domain literal

If the MTA tries to rewrite an address whose domain is of the form `[n.m.p.q]` and fails, it tries one extra rule (prior to trying `[*.*.*.*]`, and then the "`.`" match-all rule). This extra rule is the IP literal match-all rule. The pattern is `[]`. The pattern never changes. This rule is only activated when more specific probes including all or part of the IP address have not matched. (See Handling of domain literals for a discussion of the order in which portions of an IP address are checked for a match.)

In particular, a rewrite rule using the `[]` pattern and with `$E$R` in the template (thus meaning that the rewrite rule applies only to envelope From addresses) is typically used in modern MTA configurations to perform a lookup of a pseudo-address constructed from the incoming source IP of SMTP connections against the `INTERNAL_IP` mapping table and then to "switch" the incoming SMTP connection to an "internal" channel such as `tcp_intranet`, if appropriate.

47.3.5 Rules to match domains containing exact numbers of components

Special patterns of the form `*`, `*.*`, `*.*.*`, *etc.*, may be used to provide penultimate, fall-through matches for domains containing the specified number of components (the same number of components in the original host/domain specification as the number of asterisks in the pattern). A rewrite rule pattern with the same number of asterisks as components in the original host/domain specification will be checked after the comparison of the original, unmatched host/domain specification against the channel host name table, and before the "`.`" match-all rule. That is, when no more specific rewrite rule match has been found, nor has a match been found in the channel host name table, then all components of the original host/domain specification are replaced by asterisks for one last probe (prior to the "." match-all rule). If a rewrite rule pattern containing that exact same number of asterisk components is found, then that rewrite rule is considered to match the host/domain and is applied.

One of the more common uses of this form of pattern is that of a `*` pattern for matching all short form host names (host names unadorned by any higher-level domain components). For example:

```
*       $U%$H.domain.com
```

(Though in the modern Internet environment, in the interests of encouraging proper use of correct domain names, it is often better to instead discourage all use/acceptance of short form names.)

Note that, as with all asterisk-in-place-of-component(s) probes, these probes are only made to the configuration file (legacy configuration) or `rewrite` group (Unified Configuration), not to the domain database.

47.3.6 A rule to match any address

The special pattern "`.`" (a single period) will match any host/domain specification if no other rule matches and the host/domain specification cannot be found anywhere in the channel table. In other words, the "`.`" rule is used as a last resort when address rewriting would fail otherwise.

In times past, with a slower changing set of Top Level Domains, the "`.`" rewrite rule was less commonly used. Instead, in the past, use of an `internet.rules` file of rewrite rules for matching the (seldom changing) known top-level Internet Domains permitted immediate feedback on addresses with clearly invalid Top Level Domains -- immediate feedback on obvious mispellings of TLDs. With that approach, "known" Internet TLDs could be routed by the rewrite rules in `internet.rules`, but "bogus" TLDs, not matching any rewrite rule, would be detected during rewriting, and rejected. As such, in the past, the special "`.`" rule tended to be used only when the MTA did not have complete routing information available and had to defer judgment of address validity to another system or systems. In those cases, the "`.`" pattern was used to simplify the MTA configuration at the expense of allowing propagation of possibly bogus addresses.

However, nowadays "`.`" is routinely used in an important rewrite rule making a comparison against a (frequently updated) `tlds.txt` list of Top Level Domains to achieve routing of Internet addresses with apparently valid TLDs, while not propagating addresses with invalid TLDs. Nowadays, the `internet.rules` file, instead of containing distinct rewrite rules for each Top Level Domain, merely contains the one special rewrite rule:

```
.       $U%$H$,$H@TCP-DAEMON
```

Here the "`.`" pattern causes all domain names not matched by other, more specific rewrite rules to get matched. However, the `$,` compares the top-level portion of the domain substituted by `$H` (in the case of this rewrite rule with a "`.`" match, the `$H` substitutes back the entire domain in the address) against the list in `tlds.txt` and the rewrite rule will only succeed if a match is found: this rewrite rule will only succeed if the top-level portion of the domain of the address being rewritten can be found in `tlds.txt`.

Note: When the match-all rule matches and its template is expanded, `$H` expands to the full host name and `$D` expands to a single dot "`.`". Thus, `$D` is of limited use in a match-all rule template!

47.3.7 Tagged rewrite rule sets

As the rewrite process proceeds it may be appropriate to bring different sets of rules into play. This is accomplished by the use of the rewrite rule tag. The current tag is prepended to each pattern before looking it up in the configuration file (legacy configuration) or `rewrite` group (Unified Configuration), or domain database. The tag can be changed by any rewrite rule that matches by using the `$T` substitution string in the rewrite rule template (described below).

Tags are somewhat sticky; once set they will continue to apply to all hosts that are extracted from a single address. This means that care must be taken to provide alternate rules that begin with the proper tag values once any tags are used. In practice this is rarely a problem since tags are usually used in only very specialized applications. Once the rewriting of the address is finished the tag is reset to the default tag --- an empty string.

By convention all tag values end in a vertical bar |. This character is not used in normal addresses and thus is free to delineate tags from the rest of the pattern.

See Section 2.2.6.19 for an example of using tagged rewrite rules.

47.4 Rewrite rule templates

Once a host/domain specification matches a rewrite rule, it is rewritten using the template part (right hand side) of the rule. The template specifies three things:

1. a new username for the address,
2. a new host/domain specification for the address, and
3. the name of a system attached to an existing MTA channel (the "routing system") to which messages to this address should actually be sent.

There are several general formats for rewrite rule templates, which will be discussed in Rewrite rule template formats, depending upon whether an address is merely being changed or whether source routing should be explicitly specified (or even added to the address). Various substitutions and control sequences are available to further fine-tune the application of rewrite rules.

Note that the character case in templates is preserved. This is necessary when using rewrite rules to provide an interface to a mail system such as UUCP which is sensitive to character case. Substitution sequences like $U and $D that substitute material extracted from addresses also preserve the original case of characters. (Special Rewrite case control substitutions may be used when it is desirable to alter case, rather than preserve it.)

47.4.1 Rewrite rule template formats

A summary of the template formats for rewrite rules is presented in Summary of template formats for rewrite rules. The substitution strings and control sequences which may be used with templates are discussed in Rewrite rule template substitutions and control sequences.

Table 47.4 Summary of template formats for rewrite rules

Template	Usage
A%B	A becomes the new user/mailbox name, B becomes the new host/domain specification, rewrite again
A@B	Treated as A%B@B
A%B@C	A becomes the new user/mailbox name, B becomes the new host/domain specification, route to C
A@B@C	Treated as A@B@C@C.
A@B@C@D	A becomes the new user/mailbox name, B becomes the new host/domain specification, insert C as a source route, route to D

Other formats, such as A%B%C and so forth, are reserved for the implementation of future capabilities in the MTA and should not be used as their function may change in a future release.

47.4.1.1 Ordinary rewriting templates, A@B or A%B@C

The most commonly used form of rewrite rule template is A%B@C, where A is the new username, B is the new host/domain specification, and C is the routing system (official channel name). If B and C are identical, %B may be omitted; *i.e.*, you may simply use A@C when B and C are identical.

For instance, if an MTA for domain.com has the system (host) name `host.domain.com` (the official host name of the "l" channel), and if the default email domain name is `mail.domain.com`, then typical rewrite rules could include:

```
host.domain.com     $U%host.domain.com@hostname.domain.com
mail.domain.com     $U%mail.domain.com@hostname.domain.com
```

meaning that addresses with domain names of `host.domain.com` or `mail.domain.com` will be routed, (without any beforehand domain name change) to the "l" channel.

Note that in a current Unified Configuration, such rewrite rules would typically be automatically generated, and make use of the `$D` and `&/IMTA_HOST/` and `&/IMTA_DEFAULTDOMAIN/`substitutions, to appear as:

```
msconfig> show rewrite
...other rewrite rules...
role.rewrite.rule = &/IMTA_HOST/ $U%$D@&/IMTA_HOST/
role.rewrite.rule = &/IMTA_DEFAULTDOMAIN/ $U%$D@&/IMTA_HOST/
...other rewrite rules
```

47.4.1.2 Repeated rewriting template, A%B

The special rewrite rule template format A%B is used for "meta-rules" that require additional rewriting after their application. When an A%B pattern is encountered, A becomes the new username and B becomes the new host/domain specification, and then the entire rewriting process is repeated on the resulting new address. All other rewrite rule formats cause the rewriting process to terminate after the rule has been applied.

For example, the rule

```
.removeable       $U%$H
```

has the effect of removing all occurrences of the `.removeable` domain from the ends of addresses.

Extreme care must be taken when using these repeating rules; careless use can create a "rules loop" that will hang the MTA in an infinite loop. (The MTA will attempt to detect simple cases of such loops to abort out after 100 repetitions: but even so this is (a) inefficient use of the MTA computation time, and (b) not fail-safe, as more complex loops may not be detectedable by the MTA.) For this reason meta-rules should only be used when absolutely necessary. Be sure to test them with the command `imsimta test -rewrite`.

47.4.1.3 Specified route rewriting templates, A@B@C or A@B@C@D

The special rewrite rule template format A@B@C works in the same way as the usual A%B@C rule, except that the routing system C will also be inserted into the address as a source route. This inclusion of the routing system in the address may be needed by some channels that have to establish a connection to the routing system and determine the name of the routing system from the envelope To address. For instance, the rewrite rule

```
host1.domain.com      $U@host1.domain.com@hub.domain.com
```

would rewrite the address jdoe@host1.domain.com into the source routed address @hub.domain.com:jdoe@host1.domain.com. The routing system will be hub.domain.com.

The template format A@B@C@D uses A as the new username, B is the new host/domain specification, C is inserted as a source route, and D is the routing system. This is the most general template format available.

47.4.2 Rewrite rule template substitutions and control sequences

Substitutions are used to substitute into the rewritten address a character string the value of which is determined by the particular substitution sequence used. For instance in the template

```
$U@domain.com
```

the `$U` is a substitution sequence. It causes the username portion of the address being rewritten to be substituted into the output of the template. Thus, if jdoe@host1.domain.com was being rewritten by this template, the resulting output would be jdoe@domain.com, the `$U` substituting in the username portion, jdoe, of the original address.

Special control sequences may also appear in rewrite rule templates. These sequences impose additional conditions to the applicability of a given rewrite rule: not only must the pattern portion of the rewrite rule match the host/domain specification being examined, but other aspects of the address being rewritten must meet conditions set by the control sequence or sequences. For instance, the `$E` control sequence requires that the address being rewritten be an envelope address while the `$F` sequence requires that it be a forward pointing address. Thus, the rewrite rule

```
domain.com     $U@domain.com$E$F
```

will only apply to (*i.e.*, only rewrite) envelope To addresses of the form user@domain.com. If a domain/host specification matches the pattern portion of a rewrite rule but doesn't meet all of the criteria imposed by control sequences in the rule's template, then the rewrite rule fails and the rewriter continues to look for other applicable rules. This makes possible sets of rewrite rules such as

```
domain.com     $U%domain.com@conversion-daemon$Nconversion
domain.com     $U@domain.com
```

which will result in messages to user@domain.com being passed to the conversion channel. However, should the conversion channel rewrite a message with the address user@domain.com, that message will not again pass through the conversion channel. This then allows all mail to user@domain.com to pass through the conversion channel and for the conversion channel to emit mail to that address without causing a mail loop. (Note: This is not a realistic example, as actual routing through the conversion channel is normally instead handling via the `CONVERSIONS` mapping table rather than through rewrite rules; but this sort of rewrite rule approach could be used with other channels, such as a `tcp_scanner` type of channel.)

A summary of template substitutions and control sequences is presented in Summary of template substitutions and control sequences.

Table 47.5 Summary of template substitutions and control sequences

Substitution sequence	Substitutes
$D	Portion of domain specification that matched
$G	Insert current `default host`
$*n*G	Insert nth element, counting from left to right, of current `default host`
$H	Unmatched portion of host/domain specification; left of dot in pattern
$L	Unmatched portion of domain literal; right of dot in pattern literal
$U	Username from original address
$0U	Local part (username) from original address, minus any subaddress
$1U	Subaddress, if any, from local part (username) of original address
$$	Inserts a dollar sign (literal)
$%	Inserts a percent sign (literal)
$@	Inserts an at sign (literal)
$\	Force substituted material to lowercase
$^	Force substituted material to uppercase
$_	Use original case (and do not do LDAP URL character encoding)
$=	Force subsequent material to be properly quoted (encoded) according to LDAP URL syntax rules
$.*text*.	Specify text to use as the rewrite result in cases of temporary LDAP lookup failures and as of MS 8.1.0.6, temporary failures from routine callouts
$..	Turn off special handling of temporary failures; temporary failures will be interpreted as rewrite rule failure
$W	Substitutes in a random, unique string
$<...>	Substitute in a hash of the argument
$*n*<...>	Substitute in a hash of the argument, modulo *n*
$]...[	LDAP search URL lookup
$(*text*)	General "database" substitution; rule fails if lookup fails
${...}	Apply specified mapping to supplied string
$n{...}	Apply specified mapping to supplied string along with prefixes specified by n.

$[...]	Invoke customer supplied routine; substitute in result
$&*n*	*n*th part of unmatched (or wildcarded) host as counting from left to right starting from 0
$!*n*	*n*th part of unmatched (wildcarded) host as counted from right to left starting from 0
$**n*	*n*th part of matching pattern as counting from left to right starting from 0
$#*n*	*n*th part of matching pattern as counted from right to left starting from 0
$*n*D	Portion of domain specification that matched, preserving from the *n*th leftmost part starting from 0
$*n*H	Portion of host/domain specification that didn't match, preserving from the *n*th leftmost part starting from 0
$Y	Equivalent to $1Y; that is, substitute in the 1st (counting from the left, starting from 0) field of the transport information; for the case of incoming SMTP messages, this corresponds to the SMTP server IP address
$*n*Y	Substitute in the *n*th (counting from the left, starting from 0) field of the transport information; hence, for incoming SMTP messages $0Y substitutes in the literal string " `TCP`", $1Y (see also $Y) substitutes in the SMTP server IP address, $2Y substitutes in the SMTP server port, $3Y substitutes in the SMTP client IP address, and $4Y substitutes in the SMTP client port
Control sequence	Effect on rewrite rule
$1~	Force channel match "success" effect, although truncating the rewrite rule at this point if the "real" channel match failed
$,	(New in MS 7.0.5) Rewrite rule succeeds only if the top-level part of the domain name argument following this metacharacter is present in the current list of known Top Level Domains (the list as constructed from the `tlds.txt` file)
$>	(New in MS 7.0.5) Rewrite rule succeeds only if the top-level part of the domain name argument following this metacharacter is not present in the current list of known Top Level Domains (the list as constructed from the `tlds.txt` file)
$:	Apply only if the address being rewritten is the result of an alias
$;	Fail if the address being rewritten is the result of an alias
$E	Apply only to envelope addresses
$B	Apply only to header/body addresses
$F	Apply only to forward-directed (*e.g.,* To:) addresses
$R	Apply only to backwards-directed (*e.g.,* From:) addresses
$M*channel*	Apply only if channel *channel* is rewriting the address
$1M	Apply only if an "internal" channel is rewriting the address
$N*channel*	Fail if channel *channel* is rewriting the address
$1N	Fail if an "internal" channel is rewriting the address
$Q*channel*	Apply if sending to channel *channel*
$C*channel*	Fail if sending to channel *channel*
$S	Apply if host is from a source route
$A	Apply if host is to the right of the at sign

$P	Apply if host is to the right of a percent sign
$X	Apply if host is to the left of an exclamation point
$T*newtag*	Set the rewrite rule tag to *newtag*
$I*list-name*	Apply only if the *list-name* matches
$O*list-name*	Fail if the *list-name* matches
$?*errmsg*	If rewriting fails, return *errmsg* instead of the default error message
$*nxxxyyy*?*errmsg*	If rewriting fails, return SMTP error code *n.xxx.yyy* and error text *errmsg* instead of the default SMTP error code and error message
$V*domain*	Succeed if domainMap succeeds (that is, if the domain name *domain* is found in the LDAP directory)
$Z*domain*	Succeed if domainMap fails (that is, if the domain name *domain* is *not* found in the LDAP directory)
$*n*J	Set mailbox flags
$*n*K	Clear mailbox flags
$nT	Set override `alias_magic` value to be used for the domain which matched this rewrite rule when the rewrite rule is being used during alias expansion; *n* must be an appropriate `alias_magic` value
$n=B	(New in MS 8.0) Rewrite fails unless n is the message block size
$n>B	(New in MS 8.0) Rewrite fails unless n is greater than the message block size
$n>=B	(New in MS 8.0) Rewrite fails unless n is greater than or equal to the message block size
$n<B	(New in MS 8.0) Rewrite fails unless n is less than the message block size
$n<=B	(New in MS 8.0) Rewrite fails unless n is less than or equal to the message block size
$n<>B	(New in MS 8.0) Rewrite fails when n is the message block size
$n=L	(New in MS 8.0) Rewrite fails unless n is the number of lines in the message
$n>L	(New in MS 8.0) Rewrite fails unless n is greater than the number of lines in the message
$n>=L	(New in MS 8.0) Rewrite fails unless n is greater than or equal to the number of lines in the message
$n<L	(New in MS 8.0) Rewrite fails unless n is less than the number of lines in the message
$n<=L	(New in MS 8.0) Rewrite fails unless n is less than or equal to the number of lines in the message
$n<>L	(New in MS 8.0) Rewrite fails when n is the number of lines in the message
$n=P	(New in MS 8.0) Rewrite fails unless n is the message priority
$n>P	(New in MS 8.0) Rewrite fails unless n is greater than the message priority
$n>=P	(New in MS 8.0) Rewrite fails unless n is greater than or equal to the message priority
$n<P	(New in MS 8.0) Rewrite fails unless n is less than the message priority
$n<=P	(New in MS 8.0) Rewrite fails unless n is less than or equal to the message priority
$n<>P	(New in MS 8.0) Rewrite fails when n is the message priority

47.4.2.1 Rewrite username and subaddress substitutions, $U, $0U, $1U

Any occurrences of $U in the template are replaced with the username (local part) from the original address. Note that usernames of the form a."b" will be replaced by "a.b" as current Internet standardization work is deprecating the former syntax from RFC 822 and it is expected that the latter usage will become mandatory in future.

Any occurrences of $0U in the template are replaced with the username from the original address, minus any subaddress (and subaddress indication character such as +). Any occurrences of $1U in the template are replaced with the subaddress and subaddress indication character, if any, from the original address. (See the discussion of the `subaddressexact` channel option and Subaddresses in aliases for background on subaddresses.) So note that $0U and $1U are complementary pieces of the username, with $0U $1U being equivalent to a simple $U.

$0U and $1U might be used when it is desired to force the account portion of the local-part to lowercase, while retaining original case in the subaddress since the subaddress indicates a folder name. For instance, a rewrite rule:

```
org.domain.com    $\$0U$_$1U@org.domain.com
```

will cause an address such as nAmE@org.domain.com to be transformed (rewritten) to name@org.domain.com, while an address such as nAmE+sUbAdDrEsS@org.domain.com would be transformed to name+sUbAdDrEsS@org.domain.com.

47.4.2.2 Rewrite host/domain and IP literal substitutions, $D, $H, $nD, $nH, $L

Any occurrences of $H are replaced with the portion of the host/domain specification that was not matched by the rule. Any occurrences of $D are replaced by the portion of the host/domain specification that was matched by the rewrite rule. $*n*H and $*n*D are variants that preserve the normal $H or $D portion from the *n*th leftmost part starting counting from 0. Or another way of putting it is that $*n*H and $*n*D omit the leftmost *n* parts (starting counting from 1) of what would normally be a $H or $D, substitution, respectively. In particular, $0H is equivalent to $H and $0D is equivalent to $D.

For example, suppose the address jdoe@host.domain.com matches the rewrite rule

```
host.domain.com     $U%$1D@TCP-DAEMON
```

Then the result of the rewrite rule will be jdoe@domain.com with TCP-DAEMON used as the outgoing channel. Here where $D would have substituted in the entire domain that matched, host.domain.com, the $1D instead substitutes in the portions of the match starting from part 1 (part 1 being domain), so substitutes in domain.com.

$L substitutes the portion of a domain literal that was not matched by the rewrite rule.

47.4.2.3 Rewrite subdomain single field substitutions, $&n, $!n, $*n, $#n

Subdomain single field substitutions extract a single subdomain part from the host/domain specification being rewritten. The available single field substitutions are shown in Single field substitutions.

Table 47.6 Single field substitutions

Control Sequence	Usage
$&*n*	Substitute the *n*th element, *n*=0,1,2,..,9, in the host specification (the part that did not match explicit text in the pattern or matched a wildcard of some kind). Elements are separated by dots; the first element on the *left* is element zero. The rewrite fails if the requested element does not exist.
$!*n*	Substitute the *n*th element, *n*=0,1,2,..,9, in the host specification (the part that did not match explicit text in the pattern or matched a wildcard of some kind). Elements are separated by dots; the first element on the *right* is element zero. The rewrite fails if the requested element does not exist.
$**n*	Substitute the *n*th element, *n*=0,1,2,...,9, in the domain specification (the part that did match explicit text in the pattern). Elements are separated by dots; the first element on the *left* is element zero. The rewrite fails if the requested element does not exist.
$#*n*	Substitute the *n*th element, *n*=0,1,2,...,9, in the domain specification (the part that did match explicit text in the pattern). Elements are separated by dots; the first element on the *right* is element zero. The rewrite fails if the requested element does not exist.

Suppose the address jdoe@msgstore.domain.com matches the rewrite rule

```
*.DOMAIN.COM      $U%$&0.domain.com@mailhub.domain.com
```

Then the result from the template will be jdoe@msgstore.domain.com with mailhub.domain.com used as the routing system.

47.4.2.4 Rewrite default host substitutions, $G, $*n*G

Any occurrences of `$G` are replaced with the current default host, as selected by the `defaulthost` and related channel option settings on the current source channel. Any occurrences of `$`*n*`G` are replaced with the value of the *n*th element, counting from zero, of the current default host; thus if the current default host has been determined to be `a.b.c.d.com`, `$0G` will substitute "`a`", `$1G` will substitute "`b`", *etc*. If no default host is set, *e.g.* through the use of `nodefaulthost`, then `$G` or `$`*n*`G` rewrite rules will fail (will not be considered to have matched).

47.4.2.5 Rewrite literal character substitutions, $$, $%, $@

The `$`, `%`, and `@` characters are normally metacharacters in rewrite rule templates. To insert a literal such character, quote it with a dollar character, `$`. *I.e.*, `$$` expands to a single dollar sign, `$`; `$%` expands to a single percent, `%` (the percent is not interpreted as a template field separator in this case); and `$@` expands to a single at sign, `@` (also not interpreted as a field separator).

47.4.2.6 Rewrite case control substitutions, $\, $^, $_

Character case in templates is normally preserved. In addition to preservation of the case of the literal text in a template, note that substitution sequences such as $U or $D that substitute material extracted from original addresses also preserve the original case of that material.

When it is desirable to force substituted material to use a particular case, for instance, to force mailboxes to lowercase on UNIX systems, special substitution sequences can be used in templates to force substituted material to a desired case. Specifically, $\ forces subsequent substituted material into lower case, $^ forces subsequent substituted material into upper case, and $_ says to use the original case (as well as turning off LDAP URL character encoding). So you can use a rule such as

```
unix.domain.com    $\$U$_%unix.domain.com
```

to force mailboxes to lowercase for unix.domain.com addresses.

47.4.2.7 Rewrite LDAP query URL substitutions, $]...[, $=

A substitution of the form $]*ldap-url*[is handled specially. *ldap-url* is interpreted as an LDAP query URL and the result of the LDAP query is substituted. (If the LDAP query fails, it is as if the rewrite rule never matched in the first place.) Standard LDAP URLs as per RFC 2255 are used, with the host and port typically omitted; the host and port are instead typically specified via the ldap_host and ldap_port MTA options. (Indeed, prior to MS 7.0u4 the host and port could not be specified in the URL itself; as of MS 7.0u4 explicitly specifying the host and/or port in the URL is supported.) That is, the LDAP URL should be specified as

```
ldap:///dn[?attributes[?scope?filter]]
```

or if specifying the LDAP host and LDAP port explicitly

```
ldap://ldap-host:ldap-port/dn[?attributes[?scope?filter]]
```

where the square bracket characters *[* and *]* shown above indicate optional portions of the URL. The *dn* is required and is a distinguished name specifying the search base. The optional *attributes*, *scope*, and *filter* portions of the URL further refine what information to return. For a rewrite rule, the desired *attributes* to specify returning might be a mailRoutingSystem attribute (or some similar attribute). The *scope* may be any of base (the default), one, or sub. And the desired *filter* might be to request the return of the object whose mailDomain value matches the domain being rewritten.

For instance, at a site domain.com with an LDAP server running on port 389 of the system ldap.domain.com, a legacy configuration MTA option file might set

```
LDAP_HOST=ldap.domain.com
LDAP_PORT=389
```

or in Unified Configuration

```
msconfig> show mta.ldap_host
role.mta.ldap_host = ldap.domain.com
```

```
msconfig> show mta.ldap_port
msconfig> show -default mta.ldap_port
mta.ldap_port: 389
```

If the LDAP directory schema includes attributes `mailRoutingSystem` and `mailDomain`, then a possible rewrite rule to determine to which system to route a given sort of address might appear as:

```
.domain.com  \
    $U%$H$D@$]ldap:///o=domain.com?mailRoutingSystem?sub?(mailDomain=$D)[
```

where here the rewrite substitution sequence `$D` is used to substitute in the current domain name into the LDAP query constructed; for ease in reading, the backslash character, \, is used to continue the single logical rewrite rule line onto a second physical line.

Note that LDAP URLs have special character quoting (encoding) requirements. The `$=` metacharacter forces subsequent material to be properly quoted (encoded) for LDAP URL usage as shown in LDAP character encoding rules. Note that the "leave case as-is" substitution, `$_`, discussed in Rewrite case control substitutions can be used to turn off LDAP URL character encoding.

Table 47.7 LDAP character encoding rules

Original character	Quoted (encoded) version
	%20
$	%24
&	%26
(	%5C28
)	%5C29
*	%5C2A
+	%2B
,	%2C
:	%3A
;	%3B
=	%3D
?	%3F
\	%5C5C

That is, any of the characters

```
$ &+,:;=?
```

will be converted to the percent character, "%", followed by the hexadecimal representation of their location in US-ASCII; any of the characters

```
()*
```

will be converted to "`%5C`" followed by the hexadecimal representation of their location in US-ASCII (the encoded form of the backslash character followed by the hexadecimal for the particular character); while the backslash character itself

```
\
```

will be converted to "`%5C5C`".

The overall length of the LDAP URL (after any substitutions are performed) is limited to 252 characters in iMS 5.2, limited to 256 characters in MS 6.0 through MS 6.2, and limited to 1024 characters as of MS 6.3. Note also that the length of the original template in which such an LDAP URL appears is limited: to 252 characters in iMS 5.2 and earlier, or to 256 characters as of MS 6.0 and later; but substitutions in the template, and in particular substitutions used to construct the LDAP URL, may increase the LDAP URL length.

47.4.2.8 Rewrite general database substitutions, $(...)

A substitution of the form `$(`*`text`*`)` is handled specially. The *`text`* part is used as a key to access the MTA's *general database*. If *`text`* is found in the database, then the corresponding template from the database is substituted. If *`text`* does not match an entry in the database, then the rewrite process fails; it is as if the rewrite rule never matched in the first place. If the substitution is successful, then the template extracted from the database is re-scanned for additional substitutions. However, additional `$(`*`text`*`)` substitutions from the extracted template are prohibited in order to prevent endless recursive references.

Depending upon the setting of the MTA option `use_text_databases`, the general "database" is either stored and accessed as an on-disk database (formerly the default; now deprecated), or as an in-memory structure constructed (during configuration compilation or MTA initialization) from an on-disk flat text file. Or new in MS 8.0, the general "database" can instead be stored in memcache; see the `general_database_url` MTA option. The on-disk database, if that is what is being used, is `IMTA_DATAROOT:db/generaldb` (which formerly could be redirected via the now-deleted `imta_general_database` MTA Tailor option), which must be generated using the `imsimta crdb` utility from some site-supplied source text file. If an in-memory database structure is instead being used, then when the MTA configuration is compiled (or at MTA process initialization time, if a compiled configuration is not in use) the MTA reads the `IMTA_TABLE:general.txt` file (which formerly could be redirected via the now-deleted `imta_general_data` MTA Tailor file option) and compiles it into an in-memory structure. Use of an in-memory "database" is normally recommended (for reasons of performance and reliability); however, do note that use of this in-memory "database" does require recompiling the configuration to get changes to the "database" (changes to the source text file) incorporated into the compiled configuration.

As an example, suppose that the address jdoe@host1.domain.privateuse matches the rewrite rule

```
.privateuse     $($H)
```

Then, the text string host1.domain will be looked up in the general database and the result of that look up, if any, instead used for the rewrite rule's template. Suppose that the result of looking up host1.domain is $u%mailhost.domain.com@tcp_intranet-daemon. Then the output of the template will be jdoe@mailhost.domain.com (*i.e.*, username = jdoe, host/domain

specification = mailhost.domain.com), and the routing system will be `tcp_intranet-daemon` (the typical official host name of the `tcp_intranet` channel).

If a general database exists it should be world readable to insure that it operates properly.

47.4.2.9 Rewrite apply specified mapping substitutions, ${...}, $n{...}

A substitution of the form ${*mapping*,*argument*} is handled specially. The *mapping*,*argument* part is used to find and apply an MTA mapping table. The *mapping* field specifies the name of the mapping table to use while *argument* specifies the string to pass to the mapping. The mapping must exist and must set the $Y flag in its output if it is successful; if it doesn't exist or doesn't set $Y, then the rewrite will fail. If successful, the result of the mapping is merged into the template at the current location and reexpanded.

A substitution of the form $n{*mapping*,*argument*}, where n is a non-zero bit-encoded value works in same way, except that one or more |-separated prefixes are added to the mapping probe. The available prefixes are:

Table 47.8 Rewrite rule mapping probe prefixes

Bit	Value	Prefix
0	1	Transport information in the usual "TCP|*server-address*|*server-port*|*client-address*|*client-port*" format.
1	2	Application information.
2	4	Source channel (blank if no source channel is currently active).
3	8	Destination channel (blank if no destination channel is currently active).
4	16	Authenticated sender address (blank if no authenticated sender is currently active).

If multiple bits are set the corresponding prefixes are added in numerical order with the least significant bit on the left.

The ability to call out to a mapping can be used to make up for the lack of flexibility in rewrite rule matching - which sacrifices flexibility for speed. For example, a rewrite rule that matches and blocks attempts to send to DHCP client host names that take the form "dhcp-*.example.com" can be constructed using a mapping of the form:

```
DHCP_MATCH

  dhcp-*        $Y
```

And a rewrite rule of the form:

```
*.example.com  $E$F${DHCP_MATCH,$H}$?Cannot$ send$ to$ DHCP$ client
```

This mechanism also allows the MTA's rewriting process to be extended in complex ways. Substring matches on subdomains can be implemented and so can changes that cross subdomain boundaries. For example, suppose that domains of the form *-

subdomain.example.org are to be rewritten to *.subdomain.example.org in both header and envelope addresses and routed to the tcp_local channel. This can be done with a table:

```
DASH_TO_SUBDOMAIN

  *-subdomain    $Y$0.subdomain
```

And a rewrite rule of the form:

```
*.example.org    $U%${DASH_TO_SUBDOMAIN,$H}$D@TCP-DAEMON
```

The username part of an address can also be be selectively analyzed and modified, either alone or in conjunction with the domain part. For example, the following table and rewrite rule removes enclosing single quotes from all addresses, modifying both the local part and domain:

```
QUOTE_CHECK

  '*@*'          $Y$0%$1

$*               ${QUOTE_CHECK,$U$@$H}
```

47.4.2.10 Rewrite routine substitutions, $[. . .]

A substitution of the form `$[`*`image`*`,`*`routine`*`,`*`argument`*`]` is handled specially. The *`image`*`,`*`routine`*`,`*`argument`* part is used to find and call an Oracle-supplied or customer-supplied routine. At run-time on UNIX, the MTA uses `dlopen` and `dlsym` to dynamically load and call the routine *`routine`* from the shared library *`image`*. The routine *`routine`* is then called as a function with the following argument list:

`status` `:=` *`routine`* `(`**`argument`**`,` **`arglength`**`,` **`result`**`,` **`reslength`**`)`

where **argument** and **result** are 256 byte long (252 byte long in iMS 5.2 and earlier) character string buffers. On Solaris, **argument** and **result** are passed as a pointer to a character string, (*e.g.*, in C, as char*). **arglength** and **reslength** are signed, long integers passed by reference. On input, **argument** contains the *`argument`* string from the rewrite rule template, and **arglength** the length of that string. On return, the resultant string should be placed in **result** and its length in **reslength**. This resultant string will then replace the "`$[image,routine,argument]`" in the rewrite rule template. The routine *`routine`* should return 0 if the rewrite rule should fail and -1 if the rewrite rule should succeed. As of MS 8.1.0.6, the special value 1112064044 may be returned to indicate a temporary failure.

This mechanism allows the MTA's rewriting process to be extended in all sorts of complex ways. For example, a call to some type of name service could be performed and the result used to alter the address in some fashion. For instance, directory service lookups for forward pointing addresses (*e.g.*, To: addresses) to the host domain.com might be performed as follows with the following rewrite rule (the $F, described in Address direction and location-specific rewrites causes this rule to only be used for forward pointing addresses):

```
domain.com       $F$[LOOKUP_IMAGE,LOOKUP,$U]
```

A forward pointing address jdoe@domain.com will, when it matches this rewrite rule, cause LOOKUP_IMAGE (which is a shared library on UNIX) to be loaded into memory, and then cause the routine LOOKUP called with "jdoe" as the **argument** parameter. The routine LOOKUP might then return a different address, say, John.Doe%specialhost.domain.com in the **result** parameter and the value -1 to indicate that the rewrite rule succeeded. The percent sign in the result string causes, as described in Repeated rewriting template, the rewriting process to start over again using John.Doe@specialhost.domain.com as the address to be rewritten.

The site-supplied shared library image *image* should be readable but not writable by the Messaging Server user.

Note: This facility is not designed for use by casual users; it is intended to be used to extend the MTA's capabilities system-wide.

47.4.2.11 Rewrite temporary failure handling, $.*text*., $..

By default, temporary LDAP failures and as of MS 8.1.0.6, routine callout failures, cause the current rewrite rule to fail. This is problematic in cases where different actions need to be taken depending on, say, whether the LDAP lookup failed to find anything versus the directory server being unavailable or misconfigured. As of MS 6.3, the $. metacharacter sequence can be used in a rewrite rule to establish a string which will be processed as the rewrite rule result in the event of a temporary LDAP lookup failure. As of MS 8.1.0.6, this functionality has been extended to cover callout routine failures. The temporary failure string is terminated by an unescaped ".". Thus the format is $.*text*. in its complete form.

For rewrite rules, (unlike the similar $.*text*. mechanism available in mapping tables where the temporary failure string is "sticky"), a temporary failure string remains set only for the duration of the current rewrite rule. "$.." can be used to return to the default state where no temporary failure string is set and temporary failures cause rewrite rule failure.

Note that all LDAP errors other than failure to match an entry in the directory are considered to be temporary errors; in general it isn't possible to distinguish between errors caused by incorrect LDAP URLs and errors caused by directory server configuration problems. This is in constrast to callout routines, where an explicit return value (1112064044) is used to indicate a temporary failure.

47.4.2.12 Rewrite unique string substitution, $W

Each use of the $W substitution inserts a text string composed of upper case letters and numbers that is designed to be unique and unrepeatable. $W is useful in situations where nonrepeating address information must be constructed.

47.4.2.13 Rewrite hash substitutions, $<...>, $n<...>

$<*text*> substitutes a hash of *text*. $*n*<*text*> substitutes a hash of *text*, modulo *n*.

47.4.2.14 Rewrite transport substitutions, $Y, $*n*Y

$*n*Y substitutes in the *n*th field of the transport information, with a plain $Y being synonymous with $1Y. Transport information is as it would appear in PORT_ACCESS mapping table probes, or optionally various other access mapping tables as enabled via the include_connectioninfo MTA option, or be logged in MTA transaction log entries, as controlled by the log_connection MTA option (bit 1/value 2 causes generation of

connection transaction entries, which normally include tranport information, and bit 3/value 8 caused inclusion of tranport information in message transaction log entries); that is, transport information has the format:

`TCP|`*`server-address`*`|`*`server-port`*`|`*`client-address`*`|`*`client-port`*

Hence for incoming SMTP/SMTP SUBMIT messages, `$0Y` substitutes in the literal string "`TCP`"; `$1Y` (or `$Y` which is synonymous) substitutions in the SMTP/SMTP SUBMIT server IP address; `$2Y` substitutes in the SMTP/SMTP SUBMIT server port; `$3Y` substitutes in the SMTP/SMTP SUBMIT client IP address; and `$4Y` substitutes in the SMTP/SMTP SUBMIT client port.

If `$Y` and `$`*`n`*`Y` is used in a rewrite rule template but transport information is not available for the address being rewritten, the rewrite rule will fail.

47.4.2.15 Source channel-specific rewrites, $M, $N, $1M, $1N

It is possible to have rewrite rules that act only in conjunction with specific source channels. This can be useful when a hostname has a different meaning when it appears in a message arriving on one channel and another when it appears in a message arriving on a different channel -- such name "collisions" used to arise in Bitnet days. Source channel-specific rewrite rules can also be useful when it is desired to achieve different routing for messages coming in on different channels:[a] perhaps routing through a spam/virus scanner box for messages from some "untrusted" source.

Source channel-specific rewriting is associated with the channel that is operating and the channel options `rules` and `norules`. If `norules` is specified on the channel associated with an MTA component that is doing the rewriting, no channel-specific rewrite checking is done. If `rules` is specified on the channel, channel-specific rule checks are enforced. `rules` is the default.

Source channel-specific rewriting is *not* associated with the channel a given address matches. It depends only on the MTA component doing the rewriting and that component's channel table entry.

Source channel-specific rewrite checking is triggered by the presence of a `$N` or `$M` control sequence in the template part of a rewrite rule. The characters following the `$N` or `$M`, up until either an at sign, `@`, percent sign, `%`, or subsequent `$N`, `$M`, `$Q`, `$C`, `$T`, or `$?` are interpreted as a channel name.

`$M`*`channel`* causes the rule to fail if the channel *`channel`* is not currently doing the rewriting. `$N`*`channel`* causes the rule to fail if the channel *`channel`* is doing the rewriting.

Multiple `$M` and `$N` clauses may be specified. If any one of multiple `$M` clauses matches, the rule will succeed. If any of multiple `$N` clauses matches, the rule will fail.

The `$1M` control sequence causes the rule to fail if a non-"internal" channel is currently doing the rewriting; that is, the rule will succeed only if an "internal" channel is doing the rewriting. The `$1N` control sequence causes the rule to fail if an "internal" channel is currently doing the rewriting; that is, the rule will succeed only if a non-"internal" channel is doing the rewriting. ("Internal" here means internal-to-the-MTA: a reprocess, process, or conversion channel type of channel; it does *not* mean a `tcp_intranet` type of channel.)

[a] Alternatively, and often more conveniently, source-specific routing can be achieved via the `CONVERSIONS` mapping table.

47.4.2.16 Destination channel-specific rewrites, $C, $Q

It is possible to have rewrite rules whose application is dependent upon the channel to which a message is being enqueued. This is useful when there are two names for some host, one known to one group of hosts and one known to another. By using different channels to send mail to each group, addresses can be rewritten to refer to the host under the name known to each group.

Destination channel-specific rewriting is associated with the channel to which a message is being enqueued and the channel options `rules` and `norules` on that channel. If `norules` is specified on the destination channel, no channel-specific rewrite checking is done. If `rules` is specified on the destination channel, channel-specific rule checks are enforced. `rules` is the default.

Destination channel-specific rewriting is *not* associated with the channel a given address matches. It depends only on the message's envelope To address. When a message is enqueued, its envelope To address is first rewritten to determine to which channel the message will be enqueued. *During the rewriting of the envelope To address any* `$C` *and* `$Q` *control sequences are ignored.* Once the envelope To address is rewritten and the destination channel determined, then the `$C` and `$Q` control sequences are honored as other addresses associated with the message are rewritten.

Destination channel-specific rewrite checking is triggered by the presence of a `$C` or `$Q` control sequence in the template part of a rule. The characters following the `$C` or `$Q`, up until either an at sign, `@`, percent sign, `%`, or subsequent `$N`, `$M`, `$C`, `$Q`, `$T`, or `$?`, are interpreted as a channel name.

`$Q`*`channel`* causes the rule to fail if the channel *`channel`* is not the destination. `$C`*`channel`* causes the rule to fail if the channel *`channel`* is the destination.

Multiple `$Q` and `$C` clauses may be specified. If any one of multiple `$Q` clauses matches, the rule will succeed. If any of multiple `$C` clauses matches, the rule will fail.

For example, suppose the local host's TCP/IP channel used to communicate with the Internet is the `tcp_local` channel. Then, to prevent "raw" user@host.bitnet style addresses from appearing on messages queued to that channel, a rewrite rule of the form

```
.BITNET       $U$%$H$D@interbit.cren.net$Qtcp_local
```

might be used. This will, in messages destined to the `tcp_local` channel, transform addresses of the form user@host.bitnet to user%host.bitnet@interbit.cren.net.

47.4.2.17 Address direction and location-specific rewrites, $B, $E, $F, $R

It is sometimes useful to specify rewrite rules that only apply to envelope addresses or, alternately, only apply to header addresses. The control sequence `$E` forces a rewrite to fail if the address being rewritten is not an envelope address. The control sequence `$B` forces a rewrite to fail if the address being rewritten is not from the message header or body. These sequences have no other effects on the rewrite and may appear anywhere in the rewrite rule template.

Addresses may also be categorized by direction. A forward-pointing address is an envelope To address or an address that originates on a To:, Cc:, Resent-To:, or other header line that

refers to a destination. A backwards-pointing address is an envelope From address or an address from a header line such as From:, Sender:, or Resent-From:, referring to a source. The control sequence $F causes the rewrite to fail if the address is backwards-pointing. The control sequence $R causes the rewrite to fail if the address is forward-pointing.

The first of the following rewrite rules causes forward pointing envelope addresses (*i.e.*, envelope To addresses) of the form user@oldhost.domain.com to be rewritten to user@newhost.domain.com and the message routed to the tcp_intranet channel:

```
oldhost.domain.com      $U%newhost.domain.com@tcp_intranet-daemon$E$F
oldhost.domain.com      $U@domain.com
```

All other, non-envelope-To occurrences, of addresses of the form user@oldhost.domain.com are rewritten to user@domain.com by the second rewrite rule.

47.4.2.18 Host location-specific rewrites, $A, $P, $S, $X

Circumstances occasionally require rewriting that's sensitive to the location where a host name appears in an address. Host names can appear in several different contexts in an address: in a source route, to the right of the at sign, to the right of a percent sign in the local-part, or to the left of an exclamation point in the local-part. Under normal circumstances a host name should be handled in the same way regardless of where it appears. Situations can arise, however, which may necessitate specialized handling.

Four control sequences are used to control matching on the basis of the host's location in the address. $S specifies that the rule may match a host extracted from a source route, $A specifies that the rule may match a host found to the right of the at sign, $P specifies that the rule may match a host found to the right of a percent sign, and $X specifies that the rule may match a host found to the left of an exclamation point. The rule will fail if the host is from a location other than one specified.

These sequences can be combined in a single rewrite rule. For example, if $S and $A are specified the rule will match hosts specified in either a source route or to the right of the at sign. Specifying none of these sequences is equivalent to specifying all of them; the rule can match regardless of location.

47.4.2.19 Deployment map role-specific rewrites, $/, $|

As of the MS 8.0.2 release, it is possible to have rewrite rules whose application is dependent on the role of a host in the current deployment map.

Deployment map role rewrite checking is triggered by the presence of a $/ or $| control sequence in the template part of a rule. The characters following the $C or $Q, up until either an at sign, @, percent sign, %, subsequent channel, domain, or TLD check, or an error message $?, is should be of the form "*host*|*role*", where *host* is a host name and *role* is a role pattern.

A $/*channel* control sequence causes the rule to fail if the host *host* is not in the deployment map or it's role doesn't match the role pattern *role*. $|*host*|*role* causes the rule to fail if the role pattern matches the host's role in the deployment map.

Normally the *host* specification will itself be some sort of substitution, e.g. HD, $H, or $D. The exact form will depend on the desired effect as well as the form of the rewrite rule pattern.

The role pattern can contain glob-style wildcards.

Multiple $/ and $| clauses may be specified. If any one of multiple $/ clauses matches, the rule will succeed. If any of multiple $| clauses matches, the rule will fail.

47.4.2.20 Domain LDAP lookup rewrites, $V, $Z

The $V and $Z flags interpret the material following (up to the first @ or % character, or $C, $M, $N, $Q, or $T) as a domain name to look up in the LDAP directory; (in Schema 1, this would be a lookup in the DC tree within the directory; in Schema 2, domains are stored as part of the Organization tree so it is a lookup in the Organization tree). $V means succeed if the LDAP lookup of the domain succeeds (*i.e.*, the domain is found, as a local/hosted/vanity domain). $Z means succeed if the LDAP lookup of the domain fails (*i.e.*, the domain is not a local/hosted/vanity domain).

Note that the `imsimta test -domain_map` utility, and in particular its ENUMERATE command, can be used to probe/check/list domain definitions stored in LDAP.

For instance, a typical Oracle Messaging Server MTA configuration will include a rewrite rule:

```
$*      $A$E$F$U%$H$V$H@local-channel-official-hostname
```

where *local-channel-official-hostname* corresponds to the value of `channel:l.official_host_name`. Note that this fundamental rewrite rule of Direct LDAP configuration makes use of the Initial match-all rule, $*, so that it is the very first rewrite rule checked for any domain name appearing to the right of the @ sign ($A control sequence) in an envelope To address ($E and $F control sequences).

Note that in Unified Configuration, this same rewrite rule would typically be expressed using the `&/IMTA_HOST/` substitution, so appear as:

```
msconfig> show rewrite * "$*"
role.rewrite.rule = $* $A$E$F$U%$H$V$H@&/IMTA_HOST/
```

The LDAP server to query, as well as other basic LDAP query parameters relevant in domainMap lookups, are controlled by certain MTA options and/or (in legacy configuration) `configutil` parameters; see Basic configuration settings relevant to domain LDAP lookups. The MTA options, if explicitly set, take precedence over (override) their corresponding configutil parameters.

Table 47.9 Basic configuration settings relevant to domain LDAP lookups

msconfig base option	configutil parameter	MTA option	Default	Description
ugldaphost	local.ugldaphost	ldap_host	++	LDAP host to which to connect
ugldapport	local.ugldapport	ldap_port	389	LDAP port to which to connect
ldapsearchtimeout+	local.ldapsearchtimeout+	ldap_timeout	180000	Time out, in seconds, for LDAP queries
ugldapbinddn	local.ugldapbinddn	ldap_username		The username with which to bind when doing LDAP queries
ugldapbindcred	local.ugldapbindcred	ldap_password		The password with which to bind when doing LDAP queries
ldaprequiretls			0	(New in 8.0) If SSL is not already being used on a given LDAP connection (*e.g.*, due to ugldapusessl being set or use of an ldaps: URL), then enabling base.ldaprequiretls will require successful negotiation of TLS (using

				LDAP StartTLS) before proceeding with the connection.
		ldap_max_connections	1024	The maximum number of simultaneous LDAP connections to allow using
defaultdomain	service.defaultdomain	ldap_default_domain		The default domain name
dcroot	service.dcroot	ldap_domain_root	o=internet	The base DN for the domain portion of the DIT
	local.imta.schematag	ldap_schematag	ims50	The tag for the schema in use
ldap_domain_ filter_schema1		ldap_domain_ filter_schema1	(|(objectclass= inetDomain) (objectclass= inetdomainalias))	Specifies the filter for domains when schema 1 is in use
ldap_domain_ filter_schema2		ldap_domain_ filter_schema2		Specifies the filter for domains when schema 2 is in use
ldap_domain_ known_attributes		ldap_domain_ known_attributes	-1	This option controls whether the MTA requests the return of all domain attributes, or (the default) requests the return of only "known" domain attributes, specifically the per-domain attributes listed in Table of MTA LDAP attribute name options
		domain_match_url		Specify an additional LDAP query URL to attempt if a domain name cannot be found as a "real" domain; for instance, this option would be set to ldap:///$B?msgVanityDomain?sub?(msgVanityDomain=$D) if one wishes to support vanity domains
		domain_uplevel	0	This option affects how domain names are searched for and used; in particular, it controls whether the MTA iteratively looks "up" for a domain when a subdomain cannot be found
		domain_failure	reprocess-daemon $Mtcp_local$1M $1~-error$4000000? Temporary lookup failure	What rewrite template to use if a $V or $Z rewrite rule lookup encounters an LDAP error, such as an LDAP connection error
ldap_domain_timeout		ldap_domain_timeout	900	Time (in seconds) to retain cached results of domain lookups (in the domain map library code cache)
		domain_match_ cache_size	100000	Number of domain lookup results to cache (in the MTA's cache)
		domain_match_ cache_timeout	600	Time (in seconds) to retain (in the MTA's cache) cached results of domain lookups

+The ldapsearchtimeout base option (Unified Configuration) or local.ldapsearchtimeout configutil parameter (legacy configuration) is a global default for all searches done through the LDAP pool API, including those done by the MTA.

++The MTA option ldap_host defaults to the value of the ugldaphost base option, which in turn defaults, if not set, to the loopback interface.

Compare this Basic configuration settings relevant to domain LDAP lookups with Table of Basic configuration settings relevant to alias LDAP lookups.

The domain_match_url and domain_uplevel MTA options further affect domain lookups, with domain_match_url potentially specifying an additional lookup to look for vanity domains (which are not real domains), and with domain_uplevel controlling things such as whether if a subdomain is not found, the MTA then looks instead for the domain "over" the subdomain.

If a $V or $Z lookup attempt encounters an LDAP error condition (such as the LDAP directory being temporarily inaccessible), then the MTA option domain_failure specifies what the MTA will take to be the rewriting process result. The default value for domain_failure means that LDAP error conditions will result in messages being diverted to the reprocess channel for additional subsequent rewriting and lookup attempts.

The results of a domain name lookup due to a $V and $Z flag will be cached; that is, the MTA caches not only whether the domain name lookup was successful, but also (in the

case of a successful lookup) any attribute values successfully returned. In its queries, the MTA can request that successful lookups return either all attributes for the domain, or instead request an explicit list of "known to the MTA attributes" (see the per-domain attributes in Table of MTA LDAP attribute name options); note that for some directory setups, there may be an LDAP directory performance difference between requesting all attributes or requesting an explicit (even large explicit) list of attributes. Whether domain name lookup requests are for all attributes, or a list of known attributes, is controlled by the `ldap_domain_known_attributes` MTA option; the default is to request the return of all domain attributes. For control of domain name lookup result caching at the MTA-level, see the `domain_match_cache_size` and `domain_match_cache_timeout` MTA options; note that the underlying domain Map code also does its own caching, with timeout (when called by the MTA) controlled by the `ldap_domain_timeout` MTA option.

47.4.2.21 Channel match force truncation rewrite, $1~

The special-purpose $1~ rewrite rule control sequence is normally used in conjunction with the `domain_failure` MTA option.

The `$1~` control sequence modifies the effect of channel matching checks, such as the $C, $Q, $M, and $N channel match checks. Normally such checks either succeed, in which case the rewrite rule is used, or fail, in which case it is as if the rewrite rule never even matched and the rewrite rule is not used at all for the address in question. The `$1~` control sequence is used when it is desired to instead have the rewrite rule always be used, but with a different right hand side depending upon whether the initial channel match succeeded or failed. That is, the `$1~` control sequence overrides the original channel match results (forces a channel match success state), and then either truncates the rewrite rule template (if the original channel match check failed), or allows additional material to be suffixed to the rewrite rule template (if the original channel match check succeeded).

For instance, given channel definitions such as

```
tcp_local smtp mx ...rest-of-keywords...
tcp-daemon

tcp_domainrelay smtp mx ...rest-of-keywords...
tcp-daemon-domainrelay
```

then a rewrite rule such as

```
domain.com      $U%domain.com@tcp-daemon$Mtcp_local$1~-domainrelay
```

means that when the `tcp_local` channel is rewriting a domain.com address, then the effective template used will be

```
$U%domain.com@tcp-daemon-domainrelay
```

whereas when any other channel is rewriting a domain.com address, then the effective template used will be

```
$U%domain.com@tcp-daemon
```

That is, messages coming in the `tcp_local` channel addressed to domain.com will be routed out the `tcp_domainrelay` channel, whereas messages coming in from any non-`tcp_local` channel addressed to domain.com will be routed out the `tcp_local` channel.

The `$1~` control sequence is typically used in the value of the `domain_failure` MTA option; see the discussion of that option which includes another example of use of `$1~`.

47.4.2.22 TLD comparison rewrites, $, and $>

New in 7.0.5, the `$,` and `$>` control sequences allow checking domain top level portions against the current[1] TLD (Top Level Domain) list. They act like `$V` and `$W`, respectively, except that instead of checking for a domain known to the directory, they check the top-level part of the current domain against the list of known valid TLDs. `$,` succeeds if the top-level part is on the list; `$>` succeeds if the top-level part isn't on the list.

[1] To keep the `tlds.txt` file on your host up-to-date, it is recommended that you regularly fetch a new version. See, for instance, `https://data.iana.org/TLD/tlds-alpha-by-domain.txt`. After fetching a new `tlds.txt` file, issue the command `imsimta chbuild` to have the MTA rebuild its list.

As of MS 8.0.2.2, U-labels (see RFC 5890 section 2.3.2.1) are converted to A-labels before looking them up in tlds.txt. Note that the opposite is not true and specification of U-label domains in tlds.txt will not work.

47.4.2.23 alias_magic override rewrite, $*n*T

Rewrite rules can override the `alias_magic` MTA option setting and `aliasmagic` (source) channel option setting. Specifically, a construct of the form `$`*n*`T`, where *n* is an appropriate value for the `alias_magic` MTA option, overrides the setting for the domain when the rule matches during alias expansion.

47.4.2.24 Alias-sensitive rewrites, $: and $;

It is possible to have rewrite rules whose application is dependent upon whether or not the address being rewritten was the result of an alias. (Note that inherently, only envelope To addresses can possibly be the result of an alias.) This can be useful in the case, for instance, where certain rewrite rule(s) should be applied only before alias expansion has occurred, while other rewrite rule(s) should be applied only after alias expansion has occured.

Alias-sensitive rewrite checking is triggered by the presence of the `$:` or `$;` control sequence in the template part of a rule. The `$:` control sequence means that the rewrite rule will match only if the address being rewritten is the result of an alias. (So note that such a rewrite rule also is implicitly a `$E$F` rewrite rule---it can only ever match envelope To addresses.) The `$;` control sequence means that the rewrite rule will match only if the address being rewritten is not the result of an alias.

47.4.2.25 List-name-sensitive rewrites, $I, $O

Mailing lists defined in the MTA can have amn associated list name, *list-name*, established via the `mgrpListName` LDAP attribute (or whatever LDAP attribute is named by the `ldap_list_name` MTA option), or via the `alias_list_name` alias option, or via the [LIST_NAME] alias file named parameter.

List name sensitive rewrite checking is triggered, when rewriting addresses that have a list name set, by the presence of a `$I` or `$O` control sequence in the template part of the rule. The

characters following the $I or $O, up until either an at sign, percent sign, or subsequent $N, $M, $C, $Q, $T, or $?, are interpreted as a list name. If the address being rewritten has an associated list name, then the list name specified must match that in a $I rewrite rule, or must not match that in a $O rewrite rule.

Note that if the address being rewritten has no associated list name, which would normally be the case for most addresses, then any list name check clauses in a rewrite rule are ignored.

47.4.2.26 Message size or priority comparison rewrites

As of MS 8.0, rewrite rules can be made sensitive to the expected size and/or priority (SMTP MT-PRIORITY; see RFC 6710 (SMTP Extension for Message Transfer Priorities)) of an incoming message. Such checking is triggered by the presence of a

$*N*comparison*C*

control sequence in the template part of a rule, where *N* is an appropriate numeric value (which note should be in the range -9 through 9 for MT-PRIORITY checks), *comparison* is one of =, >, >=, <, <=, or <>, and where *C* (the characteristic code) is one of B, L, or P (indicating message block size, message number of lines, and message priority, respectively).

So for instance the control sequences:

```
$100<B
$2000>=L
$4=P
```

would limit a rewrite rule to applying only when a message matched the conditions, respectively, (1) block size less than 100, (2) line size greater than or equal to 2000, (3) MT-PRIORITY value of 4.

47.4.2.27 Changing the current tag value, $T

The $T control sequence is used to change the current rewrite rule tag. The rewrite rule tag is prepended to all rewrite rule patterns before they are looked up in the configuration file/rewrite group and domain database. Text following the $T, up until either an at sign, percent sign, $N, $M, $Q, $C, $T, or $?, is taken to be the new tag.

Tags are useful in handling special addressing forms where the entire nature of an address is changed when a certain component is encountered. For example, suppose that the special host name internet, when found in a source route, should be removed from the address and the resulting address forcibly matched against the channel whose official_host_nameTCP-DAEMON. This could be implemented with rules like the following (localhost is assumed to be the official name of the local host):

```
internet                $S$U@localhost$Ttcp-force|
tcp-force|.             $U%$H@TCP-DAEMON
```

The first rule will match the special host name internet if it appears in the source route. It forcibly matches internet against the local channel, which insures that it will be removed from the address. A rewrite tag is then set. Rewriting proceeds, but no regular rule will match because of the tag. Finally, the default rule is tried with the tag, and the second rule of this set

fires, forcibly matching the address against the channel with `official_host_name` of `TCP-DAEMON`, regardless of any other criteria.

47.4.2.28 Controlling error messages associated with rewriting, $?, $nxxxyyy?

The MTA provides default error messages when rewriting and channel matching fail. The ability to change these messages can be useful under certain circumstances. For example, if someone tries to send mail to an ethernet router box, it may be considered more informative to say something like "our routers cannot accept mail" rather than the usual "unknown host or domain" (see the `error_text_unknown_host` MTA option). A special control sequence can be used to change the error message that will be printed if the rule fails. The sequence $? is used to specify an error message. Text following the $?, up until either an at sign, percent sign, $N, $M, $Q, $C, $T, or $? is taken to be the text of the error message to print if the result of this rewrite fails to match any channel. The setting of an error message is "sticky" and will last through the rewriting process.

A rule that contains a $? operates just like any other rule. The special case of a rule containing only a $? and nothing else receives special attention --- the rewriting process is terminated without changing the mailbox or host portions of the address and the host is looked up as-is in the channel table. This lookup is expected to fail and the error message will be returned as a result.

For instance, if the final rewrite rule in the MTA configuration file is

```
.     $?Unrecognized address; contact postmaster@xyzzy.com
```

then any unrecognized host/domain specifications which will fail will, in the process of failing, generate the error message "Unrecognized address; contact postmaster@xyzzy.com".

Optionally, an extended SMTP error code may be included in the $? template, controlling among other things whether the error returned is a temporary error, or a permanent error; the format is:

$*nxxxyyy?error-text*

where the `n` is either `4` (meaning a temporary error) or `5` (meaning a permanent error) and the `xxx` and `yyy` specify the second and third digits, respectively, of the extended SMTP error code. *E.g.*,

```
offline.domain.com   $4002001?Mailboxes$ temporarily$ unavailable;$ try$ later
```

will result in extended SMTP error code and error text "4.2.1 Mailboxes temporarily unavailable; try later". If an extended SMTP error code is specified but no `error-text` is specified, then the text of `error_text_temporary_failure` or `error_text_permanent_failure` will be used, as appropriate.

47.5 Domain database

The MTA's domain database, seldom used nowadays, provided an alternate location for storing rewrite rules, for cases of exceptionally large numbers of rewrite rules.

In early versions of the MTA, the format of the domain database was an on-disk database, built using the `imsimta crdb` utility based upon a flat text file input. The allowed format of the flat text input file is:

`key value`

one entry per line, with the `key` beginning in column one, one or more white space (SP or TAB) characters, and then the `value` on the right hand side.

The `comment_chars` MTA option controls which characters (by default exclamation point and semicolon) in column one of a line are considered to indicate a comment line. The left angle character may be used to read another file into the domain database text input file.

For a `crdb` "on disk" database, the left hand side (the key) cannot contain spaces or tabs unless the `-quoted` switch is used; the maximum length of the key and value depend upon whether the `-long_records` switch is used.

New in the 8.0 release, the MTA supports use of memcache for certain database/storage uses, including the domain database; see the `domain_database_url` MTA option.

The `use_domain_database` MTA option controls whether or not the MTA makes use of the domain database. In MS 7.2 and earlier, the default for `use_domain_database` was 1, so the mere presence of the domain database file was enough to activate this database facility in the MTA. As of MS 7.3, the default for `use_domain_database` changed to 0 from the prior default of 1, so as of MS 7.3 it is necessary to explicitly set `use_domain_database=1` (and then if using a compiled configuration, recompile the configuration), and restart any long-running processes (*e.g.*, SMTP server processes) to enable consultation of the domain database. Note that the domain database is consulted only when no match was found among the rules in the `rewrite` group (Unified Configuration) or the configuration file (legacy configuration). That is, the domain database is only consulted if a given rule is *not* found in the `rewrite` group or configuration file, so rules can always be added to override those in the database.

Chapter 48 Aliases

As part of the MTA's central role of routing messages, the MTA must recognize and potentially transform addresses to determine whither to route them. Aliases -- addresses that translate to one or more other addresses -- are a fundamental part of the processing. The MTA supports various mechanisms for implementing aliases, and *many* variants on alias handling.

Aliases are used for "simple" forwarding (which may not be all that simple), for supporting "hosted domains", for defining "mail forwarders" (mail groups), for defining true mailing lists (which have additional semantics beyond mail groups), and for "centralized naming". The term *address reversal* is used for the process (and techniques) of esthetic transformations of addresses (as in the appearance of addresses in header lines) for purposes of centralized naming, or conforming to site addressing conventions.

Typical site provisioning nowadays is to store the bulk of user definitions (and therefore local domain definitions), as well as group and mailing list definitions, in an LDAP directory. The MTA supports such usage, often referred to as *Direct LDAP* configuration.

The MTA also supports the older style of defining user aliases via the MTA's alias file (legacy configuration), or alias options (Unified Configuration) -- techniques which are still used for special users (*e.g.*, postmaster) or special, limited purposes even in primarily LDAP-based configurations.

Note that the MTA limits aliases, and addresses in general, to a maximum of 256 characters. (Internet mailers were originally only required to support domain names up to a length of 63

characters, though support for lengths up to 255 characters was recommended, and similarly are only required to support a local-part -- that is, the part to the left of the "@" sign -- of up to 64 characters. See for instance RFC 1123, Requirements for Internet Hosts, Section 2.1, and RFC 5321, SMTP, Section 4.5.3.1. Keep such limits in mind if you wish your addresses to work reliably on the Internet.) This limit of 256 characters is on the actual address itself; the RFC 822 "phrase" more commonly referred to as a personal name is a separate string with its own 256 character limit.

48.1 Overview of Direct LDAP configuration

A normal *Direct LDAP* configuration, as typically used at most sites nowadays, consists of provisioning local domain definitions and local user entries in LDAP, plus optionally provisioning mail group and mailing list entries in LDAP, and then configuring the MTA to consult LDAP to find and use those domain and user (and group and mailing list) definitions.

Once domains and users (and optionally mail groups and mailing lists) are provisioned in LDAP, then configuring the MTA to make use of this information has five main steps:

1. *Inform the MTA where the LDAP directory resides.* In legacy configuration, the MTA consults the `local.ugldaphost` and `local.ugldapport` configutil parameters (which may be overridden specifically for the MTA's purposes by the MTA options `ldap_host` and `ldap_port`, respectively); in Unified Configuration, the MTA consults the base options `ugldaphost` and `ugldapport` (which similarly may be overridden for MTA purposes by the MTA options `ldap_host` and `ldap_port`). Various other configuration settings can further adjust aspects of the MTA's connections and consultations of LDAP, for instance, those discussed in LDAP bind and connect MTA options.

2. *Configure the MTA to consult LDAP to determine which domains are "local", that is, which domains are hosted by this site.* This is achieved by a special rewrite rule, which in legacy configuration appears as:

```
$*    $A$E$F$U%$H$V$H@official-host-name-of-l-channel
```

   or in Unified Configuration:

```
msconfig> show rewrite.rule * $*
role.rewrite.rule = $* $A$E$F$U%$H$V$H@&/IMTA_HOST/
```

   This rewrite rule uses the match-all match-first `$*` template (so that it matches all domains and will be consulted before all other rewrite rules---see Initial match-all rule), but with `$E $F` in the template so that it applies only to envelope To addresses (see Address direction and location-specific rewrites), then uses a pattern that uses `$V$H` to look up the currently-being-rewritten-envelope-to domain in LDAP (see Domain LDAP lookup rewrites) to determine whether the domain is a "local" domain.

   a. If the domain is *not* "local" (is not found in LDAP), then the rewrite fails, and the envelope To address is routed per the rest of the rewrite rules.

   b. If the domain is "local" (is found in LDAP) but the domain is provisioned for override routing, as with the `mailRoutingHosts` LDAP attribute (or more precisely whatever LDAP attribute is named by the `ldap_domain_attr_routing_hosts` MTA option), then the envelope To address is converted to a form using source-routing to the routing

host, and then routed per the rest of the rewrite rules (typically out a `tcp_intranet` channel).

c. If the domain is "local" (found in LDAP) and has no override routing provisioned, then this rewrite rule forces this envelope To address to "match" the local channel. Such forcing of the recipient address to match-the-local-channel then sets the stage for step 3...

3. *Configure the MTA to consult LDAP to find "local" recipient addresses.* Recipient (envelope To) addresses matching the local channel are looked up in LDAP via the `alias_url0` MTA option template to determine whether the recipient address corresponds to a valid "local" user (or group or mailing list).

4. *Configure the interpretation of routing and delivery settings.* When a recipient (envelope To) address (user, group, or mailing list) is found in LDAP (step 3), then the MTA checks whether or not this MTA system should apply the recipient's `mailDeliveryOption` values, (more precisely, the values of the LDAP attribute named by the `ldap_delivery_option` MTA option), with interpretation of such `mailDeliveryOption` values performed as defined via the MTA's `delivery_options` option.

   a. If the recipient address has a `mailHost` (MTA option `ldap_mailhost`) value set which does not match "this" host (as determined by comparing with the `ldap_local_host` and `ldap_host_alias_list` MTA options' values) and at least some of the recipient address's `mailDeliveryOption` clauses are "mailhost-sensitive", or if the source channel was configured with `aliasdetourhost` or `aliasoptindetourhost` , then the address is converted to a source-routed form which explicitly routes to the `mailHost` or `aliasdetourhost` system.

   b. If the recipient address has a `mailHost` value matching "this" host (as determined by comparing with the `ldap_local_host` and `#ldap_host_alias_list~mta` MTA options' value), or has no `mailHost` attribute at all (common for groups and lists), or has `mailDeliveryOption` clauses which are all "mailhost-independent", then its `mailDeliveryOption` value(s) (more precisely, the values of whatever LDAP attribute is named by the `ldap_delivery_option` MTA option) will be interpreted as specified by the `delivery_options` MTA option, and any appropriate address changes or forwarding will be applied. For instance, a recipient address that is found to correspond to a local user LDAP entry with a `mailDeliveryOption` value of `mailbox` will be converted to the proper local mailbox address as defined by `delivery_options`; and a recipient address that is found to have a `mailDeliveryOption` value of `forward` will (in accordance with `delivery_options`) be converted to any specified `mailForwardingAddress` value(s) (more precisely, be converted to values of the LDAP attribute named by the `ldap_forwarding_address` MTA option).

5. *Configure canonicalization of all non-envelope-To occurrences of "local" addresses.* All non-envelope-To addresses (all addresses which didn't meet the `$E$F` criteria of the rewrite rule in step (2)) are looked up in LDAP via the `reverse_url` MTA option template to determine whether (and if so, how) the address should be "reversed" (canonicalized) to some preferred form.

A great many refinements, adjustments, and further optional processing can be configured for the MTA---see especially the various LDAP attribute semantics supported by the MTA listed in Direct LDAP attribute name MTA options as some modify address handling, as well as further MTA options discussed in Direct LDAP attribute interpretation MTA options, Direct LDAP usergroup lookup MTA options, and Direct LDAP domain lookup MTA options---so the above steps provide merely a somewhat over-simplified description of the *major* components

of Direct LDAP configuration. Note that combinations of Direct LDAP address handling and more traditional MTA aliasing (via alias file, alias database, or Unified Configuration alias options) are also possible.

48.2 Aliases in LDAP

If at least one of the `alias_url0`, `alias_url1`, `alias_url2`, or `alias_url3` MTA options is specified, then for each address matching the local channel (or any channel marked `aliaslocal`) the MTA will automatically perform the LDAP query specified by the `alias_urlN` option(s). (If more than one such option is specified, then queries are normally performed in order beginning with `alias_url0` and ending with `alias_url3`; but see the `alias_magic` MTA option and `aliasmagic` channel option.)

The LDAP server to query, as well as other basic LDAP query parameters, are controlled by certain MTA options and/or configutil parameters (legacy configuration) or Unified Configuration base options and PAB options; see Table of Basic configuration settings relevant to alias LDAP lookups. The MTA options, if explicitly set, for MTA lookup purposes take precedence over (override) their corresponding configutil parameters (legacy configuration) or base options and PAB options (Unified Configuration).

Note that the MTA's SMTP AUTH user authentication lookups are done using general SASL library code, also used for IMAP, POP, or MSHTTP user logins (authentication). The SASL code does not use the MTA-specific options, but rather uses the configutil parameters or Unified Configuration options.

Table 48.1 Basic configuration settings relevant to alias LDAP lookups

msconfig base option	configutil parameter	MTA option	Default	Description
`ugldaphost`	`local.ugldaphost`	`ldap_host`	++	LDAP host to which to connect
`ugldapport`	`local.ugldapport`	`ldap_port`	389	LDAP port to which to connect
`ldapconnecttimeout`	`local.ldapconnecttimeout`		10	Time out, in seconds, for LDAP connections
`ldapsearchtimeout+`	`local.ldapsearchtimeout+`	`ldap_timeout`	180000	Time out, in seconds, for LDAP queries
`ugldapbinddn`	`local.ugldapbinddn`	`ldap_username`		The username with which to bind when doing LDAP queries
`ugldapbindcred`	`local.ugldapbindcred`	`ldap_password`		The password with which to bind when doing LDAP queries
`ugldapusessl`	`local.ugldapusessl`		no	Whether to use SSL (LDAP-S) to connect to the user/group LDAP directory; also controls use of SSL for LDAP PAB lookups, and "external" LDAP (extldap) lookups. If set to yes, then the MTA will expect to find a certificate located either in the `local.ssldbpath` directory, if it is specified, or in the MTA's config directory (located as `local.instancedir/config`, rather than via the usual IMTA_TABLE option value), named `local.ssldbprefix.secmod.db`. In that directory also must be the password file named `sslpassword.conf`.
`ldaprequiretls`			0	(New in 8.0) If SSL is not already being used on a given LDAP connection (*e.g.*, due to `ugldapusessl` being set or use of an `ldaps:` URL), then enabling `base.ldaprequiretls` will require successful negotiation of TLS (using LDAP StartTLS) before proceeding with the connection.
Not used as of 7.0	`local.instancedir`			Prefix for where Messaging Server is installed. In particular, `/config` is appended onto this as the location for where to find the certificate (if SSL is being used; that is, if `local.ugldapusessl` is set).
Deleted in 7.0u4 (never used)	`service.imta.ldappoolsize`		0	The initial number of LDAP connections to start up

		ldap_max_connections	1024	The maximum number of simultaneous LDAP connections to allow using
defaultdomain	service.defaultdomain	ldap_default_domain		The default domain name
dcroot	service.dcroot	ldap_domain_root	o=internet	The base DN for the domain portion of the DIT
ugldapbasedn	local.ugldapbasedn	ldap_user_root	o=isp	The LDAP user root, that is, the base DN for the user and group portion of the DIT
	local.imta.schematag	ldap_schematag	ims50	The tag for the schema in use
		ldap_group_object_classes	*Varies with the schema tag*	The object classes required for a group; the default depends upon the schema tag; in particular, for the default schema tag of ims50, the default required object classes are inetLocalMailRecipient+inetmailgroup
		ldap_user_object_classes	*Varies with the schema tag*	The object classes required for a user; the default depends upon the schema tag; in particular, for the default schema tag of ims50, the default required object classes are inetLocalMailRecipient+inetmailuser
	local.imta.mailaliases	ldap_mail_aliases	*Varies with schema tag*	The attributes in which aliases are stored; the default depends upon the schema tag; in particular, for the default schema tag of ims50, the default alias attributes are mail, mailAlternateAddress, and mailEquivalentAddress
hostname	local.hostname	ldap_local_host		The local host name (official host name for the "l" channel)
	local.imta.hostnamealiases	ldap_host_alias_list		Local host aliases
ldappoolrefreshinterval	local.ldappoolrefreshinterval		35	Time (minutes) LDAP connections are maintained
msconfig PAB option	configutil parameter	MTA option	Default	Description
ldaphost	local.service.pab.ldaphost	ldap_pab_host		(New in 7.0)
ldapbinddn	local.service.pab.ldapbinddn	ldap_pab_username		(New in Messaging Server 7.0)
ldappasswd	local.service.pab.ldappasswd	ldap_pab_password		(New in 7.0)
ldapport	local.service.pab.ldapport	ldap_pab_port	*ldap_port value*	(New in 7.0) If neither pab.ldapport nor local.service.pab.ldapport is set, then the ldap_port value is used.
		ldap_pab_max_connections	1024	(New in 7.0u1) Maximum simultaneous connections to the PAB

+The `ldapsearchtimeout` base option (Unified Configuration) or `local.ldapsearchtimeout configutil` parameter (legacy configuration) is a global default for all searches done through the LDAP pool API, including those done by the MTA.

++The MTA option `ldap_host` defaults to the value of the `ugldaphost` base option, which in turn defaults, if not set, to the loopback interface.

Compare this Table of Basic configuration settings relevant to alias LDAP lookups with Basic configuration settings relevant to domain LDAP lookups.

For the `alias_url0`, `alias_url1`, `alias_url2`, or `alias_url3` MTA options, standard LDAP URLs as per RFC 2255 must be used, with the following exception and special interpretations:

- The LDAP server and port are typically omitted, and are instead specified via MTA options or `configutil` parameters (legacy configuration) or base options (Unified Configuration), as shown above in Table of Basic LDAP settings relevant to alias lookups. Indeed, prior to Messaging Server 7.0u4, the host and port had to be omitted; as of Messaging Server 7.0u4, specifying the host and port in the URL itself is supported.

- The MTA makes a distinction between a completely omitted attributes field, which as per RFC 2255 means to request the return of *all* attributes, and an attributes field consisting of the asterisk character, *, which the MTA instead interprets as meaning to request the return of *all known-to-the-MTA attributes*, that is, all attributes specified by direct LDAP attribute name MTA options. This distinction is available since for some directory setups, there may

be a noticeable performance difference in LDAP directory response to one type of query (all attributes requested) *vs*. the other type of query (specific, though large, list of attributes requested).

- Also, certain substitution sequences are available, as shown in Table of LDAP URL substitution sequences.

Thus the LDAP URL value for an `alias_urlN` option should be specified as

`ldap:///dn[?attributes[?scope?filter]]`

where the square bracket characters `[` and `]` shown above indicate optional portions of the URL. The `dn` is required and is a distinguished name specifying the search base; it might correspond to the organization's top level in the Directory Information Tree. The optional `attributes`, `scope`, and `filter` portions of the URL further refine what information to return. For an alias, the desired `attributes` to specify returning would typically be the `mail` attribute (or some similar attribute). The `scope` may be any of `base` (the default), `one`, or `sub`. And the desired `filter` would typically be based upon the mailbox (local portion) of the incoming addresses.

Note that the usual LDAP URL encoding rules should be followed; see especially RFC 1738 (Uniform Resource Locators (URL)) and RFC 2255 (LDAP URL Format).

Substitution sequences, as shown in Table of LDAP URL substitution sequences, are available for use in constructing the LDAP URL.

The LDAP URL, before any substitutions, is limited to 256 characters in length (252 characters in iMS 5.2 and earlier); the substitutions may insert additional material and the length after such substitutions is limited to 1024 characters. Note that the substitution of "known" attributes when asterisk, `*`, is specified as the attribute to return, is not considered as part of the regular substitution; this substitution is performed at a later step and the length after this "known" attributes substitution is limited to 4096 characters.

For instance, at a Messaging Server site using direct LDAP mode, `alias_url0` is typically set as follows:

```
domain_uplevel=2
alias_url0=ldap:///$V?*?sub?$R
```

Here the `domain_uplevel=2` setting means that:

- Since bit 0 (value 1) is not set, domain matches must be exact; (*e.g.*, a domain entry in the DC tree for siroe.com will not imply that *host*.siroe.com should also be considered a "local" domain).

- Since bit 2 (value 2) is set, then user alias lookups will be performed looking not only for the exact address presented, but also for that address with the domain name replaced by the "canonical" domain name; for instance, if a domain name is an alias for another domain name (see `ldap_domain_attr_alias` in Schema 1 mode or `ldap_attr_domain2_schema2` in Schema 2 mode), then the user alias lookup will be performed both with the address as originally presented, and with the address with the domain name replaced by the aliased (to) domain name.

The `alias_url0` setting means that the result of a previous domainMap lookup will be used as the base for the search (this is the `$V` substitution), and the MTA will look for its standard set of mail alias attributes (the `$R` substitution); see the `ldap_mail_aliases` MTA option.

If a Messaging Server site is using direct LDAP mode with vanity domains enabled, then typical settings are:

```
domain_uplevel=2
alias_url0=ldap:///$V?*?sub?$R
alias_url1=ldap:///$B?*?sub?(&(msgVanityDomain=$D)$R)
alias_url2=ldap:///$1V?*?sub?(mailAlternateAddress=@$D)
domain_match_url=ldap:///$B?msgVanityDomain?sub?(msgVanityDomain=$D)
```

In addition to the usual settings (see above), notice the additional `alias_url1`, `alias_url2`, and `domain_match_url` settings. Here the `domain_match_url` setting, used to do an extra lookup when doing domainMap checking, means that the user tree base will be used as the base for the search (the `$B` substitution), searching for a `msgVanityDomain` attribute that has the value of the domain name of the address being processed; that is, this is enabling the finding of vanity domain names. The `alias_url1` setting means that the user tree base will be used as the base for a search for entries with `msgVanityDomain` attribute equal to the domain name of the address being processed, and with at least one of the entry's standard mail alias attributes (see the `ldap_mail_aliases` MTA option) equal to the address being processed. The `alias_url2` setting, used if neither the `alias_url0` nor `alias_url1` searches resulted in a match, is looking for an entry that is the "catch-all" address for the domain or vanity domain of the address being processed.

48.3 Aliases in Unified Configuration

In Unified Configuration, plain MTA aliases (but see also Aliases in LDAP) are set as a named set of options under an `alias` group. At the simplest, an alias can be set as:

```
msconfig> set alias:alias-with-quoted-periods.alias_entry address-or-alias
```

e.g.,

```
msconfig> set alias:first\.last@subdomain\.domain.\com.alias_entry "mailbox@mailhost.domain.com"
```

where the *`alias-with-quoted-periods`* (appearing between `alias:` and `.alias_entry`) is the alias, and the value on the right hand side is an address or alias to which the alias translates.

Note that each period in the alias name itself must be quoted with the backslash character. After the alias name, an unquoted period marks the end of the alias name, and the start of an alias option. The `alias_entry` option is required, being the fundamental definition of the alias; additional alias options are optional.

An alias may translate to multiple addresses or aliases, (forming a so-called *mail group*). For such an alias, use multiple `set` commands, *e.g.*,

```
msconfig> set alias:first\.last@subdomain\.domain.\com.alias_entry "mailbox@mailhost.domain.com"
```

```
msconfig> set alias:first\.last@subdomain\.domain.\com.alias_entry "remote-mailbox@remote-domain.com"
```

Optionally, other alias options in addition to `alias_entry` may be set on an alias. Such optional alias options are especially relevant when defining a mailing list (which is merely a specially decorated form of alias, from the MTA's point of view), but may also be set on individual user aliases, *e.g.*:

```
msconfig> set alias:first\.last@subdomain\.domain\.com.alias_blocklimit 200
```

As an alternative to using `msconfig set` commands, you may instead issue the command `edit aliases` within `msconfig` to enter an interactive mode of editting aliases as if they were in the legacy configuration alias file; use `:q` to quit interactive editting mode, or `:x` to save your edits and exit interactive editting mode.

48.3.1 The alias group

In Unified Configuration, the `alias` group is not an option itself, but rather a grouping of alias setting defining a particular named alias.

48.4 Alias options

Alias options are the Unified Configuration equivalent of what in legacy configuration were termed Alias file named parameters, plus the alias translation value itself (specified by the `alias_entry` alias option). The alias options under each named `alias` group, together with the name, comprise the alias.

The action of those alias options that cause addition of a header, *e.g.*, `alias_deferredalias_importance`, *etc.*, can be modified by special characters suffixed on the end of the value, as discussed in Alias header addition modifiers.

48.4.1 Alias options: `alias_entry` (alias or address)

The `alias_entry` alias option is the fundamental part of an alias: it specifies a translation address (or alias) for an alias. For an alias that translates to multiple addresses or aliases, multiple `alias_entry` settings may be made. Each value specified as an `alias_entry` may be a fully qualified address, or a short form alias name itself. Each individual `alias_entry` value corresponds to what in legacy configuration would be one address or alias on the right hand side of an alias. The entire set of `alias_entry` values for an alias corresponds to what in legacy configuration would be the list of addresses/aliases on the right hand side of an alias.

Every MTA configuration should include at least a postmaster alias. *E.g.*,

```
msconfig> show alias.*
role.alias:root@default-domain.alias_entry = postmast
role.alias:root@mta-host.alias_entry = postmast
role.alias:postmaster@mta-host.alias_entry = postmast
```

Since the initial configuration creates in LDAP a postmaster group with `postmaster@default-domain` as the primary address (`mail` attribute) and with `postmast@default-domain` as an alias (`mailAlternateAddress` attribute), these

alias entries ensure that alternate "postmaster-ish" sorts of addresses, such as for instance `postmaster@mta-host`, will be directed to the postmaster group.

The distinction between *default-domain* and *mta-host* is the distinction between the default domain for users' e-mail addresses, *vs.* the (possibly different -- indeed a different name is recommended) DNS name of the host system itself. For instance:

```
msconfig> show alias.*
role.alias:root@example\.com.alias_entry = postmast
role.alias:root@host\.example\.com.alias_entry = postmast
role.alias:postmaster@host\.example\.com.alias_entry = postmast
```

48.4.2 alias_alternate_recipient Option

(New in MS 8.0.1.) The alias_alternate_recipient alias option is used to associate additional alternate recipient addresses with a group or mailing list.

For users defined in LDAP, see the ldap_alternate_recipient MTA option.

48.4.3 Alias options: alias_and and alias_or

The alias_and and alias_or alias options control whether subsequent access control clauses (*e.g.*, alias_auth_list, alias_auth_mapping, *etc.*) are ANDed or ORed. They are analogues of the legacy configuration alias file named parameters [AND] and [OR], respectively. The default is controlled by the or_clauses MTA option---and is AND (for backwards compatibility) by default.

For groups and lists defined in LDAP, see also the AND and OR values for the mgrpBroadcasterPolicy attribute (or more precisely, the attribute named by the ldap_auth_policy MTA option). For a more detailed discussion, see Mailing list multiple access control interpretation.

48.4.4 Alias options: alias_auth_channel and alias_cant_channel

The alias_auth_channel alias option is used to specify a source channel or channels that may submit messages to the mailing list. The alias_cant_channel alias option is used to specify a source channel or channels that may not submit messages to the mailing list. These alias options are analogues of the legacy configuration alias file named parameters [AUTH_CHANNEL] and [CANT_CHANNEL], respectively. The argument for such options should be a (possibly wildcarded) channel name, or a space-separated list of (possibly wildcarded) channel names.

48.4.5 Alias options: alias_auth_list, alias_cant_list, alias_username_auth_list, and alias_username_cant_list

These options are analogues of the alias file named parameters [AUTH_LIST], [CANT_LIST], [USERNAME_AUTH_LIST], and [USERNAME_CANT_LIST], respectively.

48.4.6 Alias options: alias_auth_mapping and alias_cant_mapping

These options are analogues of the alias file named parameters [AUTH_MAPPING] and [CANT_MAPPING], respectively.

48.4.7 Alias options: alias_auth_username and alias_cant_username

The alias_auth_username and alias_cant_username alias options are analogues of the alias file named parameters [AUTH_USERNAME] and [CANT_USERNAME], respectively.

48.4.8 Alias options: alias_autosecretary

RESTRICTED: Not yet implemented.

48.4.9 Alias options: alias_blocklimit and alias_linelimit

The alias_blocklimit and alias_linelimit alias options may be used to limit the size of messages that may be posted to the address (whether user or group or list). The *value* must be an integer number of MTA blocks for alias_blocklimit, or an integer number of lines for alias_linelimit. The number of bytes in a block is specified via the block_size MTA option. By default, neither alias_blocklimit nor alias_linelimit is set; being unset (or being set to a value of 0) means that they impose no limit on the size of message that may be posted to the address (though other limits, such as channel or system wide limits, may be in effect). In particular, neither alias_blocklimit and alias_linelimit will override more general limits that may be in effect; they are minimized with any such general limits.

For user, groups, and lists defined in LDAP, see mailMsgMaxBlocks attribute (or more precisely, the attribute named by the ldap_blocklimit MTA option).

The legacy configuration analogues are the [BLOCKLIMIT] and [LINELIMIT] alias file named parameters.

48.4.10 Alias options: alias_capture and alias_journal

The alias_capture alias option may be used to set an address to which to direct an encapsulated, "captured" copy of each message posted to the list. The alias_journal alias option works similarly, but generates an envelope "journal" format message. The *value* item should be the address to which to send the "captured" message copies. These alias options are exactly analogous to use of the LDAP attribute named by the ldap_capture MTA option on a user or group or mailing list defined via an LDAP entry.

The legacy configuration analogues are the [CAPTURE] and [JOURNAL] alias file named parameters.

New in MS 8.0.1, see also the alias_capture_header alias option.

48.4.11 Alias options: alias_capture_header and alias_journal_header

(New in MS 8.0.1) The alias_capture_header alias option may be used to set an address to which to direct an encapsulated, "captured" copy of the message header of each message posted to the list. The alias_journal_header alias option works similarly, but generates an envelope "journal" format message header. (For full message content, not merely message header, in the captured copies, see the alias_capture and alias_journal alias options.) The *value* item should be the address to which to send the "captured" message copies. The alias_capture_header and alias_journal_header alias options are exactly analogous to use of the LDAP attribute named by the ldap_capture MTA option on a user or group or mailing list defined via an LDAP entry, when the LDAP attribute's value is tagged, respectively, ;format-report-header or ;format-journal-header.

The legacy configuration analogues are the [CAPTURE_HEADER] and [JOURNAL_HEADER] alias file named parameters.

48.4.12 Alias options: alias_conversion_tag

The alias_conversion_tag alias option may be used to set a tag which conversion file entries can match upon. The *value* item should be the string to use as the tag. For instance, if a list is defined

```
msconfig> show alias:testlist@domain\.com.*
role.alias:testlist@domain\.com.alias_entry = user1@domain.com
role.alias:testlist@domain\.com.alias_entry = user2@domain.com
role.alias:testlist@domain\.com.alias_entry = remoteuser@remote.com
role.alias:testlist@domain\.com.conversion_tag = listtag
role.alias:testlist@domain\.com.envelope_from = user2@domain.com
```

then conversion entries could include a tag=listtag; clause to match. For instance, if for some mailing list it was desired to convert any text/html parts in posted messages to text/plain, and if a site had an HTML to TEXT converter called htmltotextconvert stored in the IMTA_PROGRAM directory (*data-root*/site-programs/), and had set up the conversion channel and a CONVERSIONS mapping table to apply to list postings, then a conversion file entry could be

```
in-chan=*; out-chan=*; in-type=text; in-subtype=html; tag=listtag;
 out-type=text; out-subtype=plain; parameter-copy-0=*;
 command="IMTA_PROGRAM:htmltotextconvert $INPUT_FILE $OUTPUT_FILE"
```

For users, groups, and lists defined in LDAP, see the mailConversionTag attribute (or more precisely, the attribute named by the ldap_conversion_tag MTA option).

In legacy configuration, the analogue is the [CONVERSION_TAG] alias file named parameter.

48.4.13 Alias options: alias_creation_date

(New in 8.0.) The alias_creation_date alias option may be used to set a creation date for the alias (intended to be used for RRVS purposes). The creation date value must be in RFC

3339 (Date and Time on the Internet: Timestamps) format (a profile of ISO 8601 format), along the lines of:

*YYYY-MM-DD*THH:*MM*:*SS.ss*Z

or

*YYYY-MM-DD*THH:*MM*:*SS.ssplus-or-minus*HH:*MM*

where the hundredths of seconds portion is optional, and T and (if used) Z are not case sensitive. For instance:

2014-02-28T12:13:14.30-07:00

This alias option is analogous to use of the LDAP attribute named by the ldap_creation_date MTA option on a user or group or mailing list defined via an LDAP entry, or to use of the LDAP attribute named by the ldap_domain_attr_creation_date MTA option on a domain entry.

The legacy configuration analogue is the [CREATION_DATE] alias file named parameter.

48.4.14 Alias options: alias_deferred (ISO 8601 P time duration string), alias_deferred_list (filepath or MTA URL), alias_deferred_mapping (MTA mapping name)

The alias_deferred alias option may be used to add a Deferred-delivery: header line. The value should be a date and time, in ISO 8601 P format.

The alias_deferred_list alias option takes two values, a file specification for a file containing a list of originator addresses (or a URL returning a list of originator addresses) to whose postings to add a Deferred-delivery: header, and the deferral date/time in ISO 8601 format.

As of 8.0 (in prior versions, this feature "existed" but was not working), the alias_deferred_mapping alias option may be used to specify a mapping table through which to run originator addresses. The alias_deferred_mapping alias option takes one or two arguments, with a space between if the optional second argument is included. The first argument is required and must contain at a minimum the name of an MTA mapping table; the first argument may also, optionally, include a vertical bar followed by a string to use as a prefix in the mapping table probe, prior to the originator address. The second argument is optional, consisting of a deferral date/time in ISO 8601 format.

mapping-name[|*probe-prefix*] *ISO-8601-deferral-time*

Originator addresses will will be run through the specified mapping. If the mapping template does not begin with an N, n, F, or f, and if it contains a valid date/time specification in ISO 8601 format, then that date/time will be used as a deferral time. If the mapping template does not contain a date/time specification yet does not begin with N, n, F, or f, then the deferral date/time specified as the second argument to alias_deferred_mapping will be used. The default, if no mapping entry matches, or if an entry that begins with an N, n, F, or f matches, is not to add a Deferred-delivery: header.

Note that the intended purpose of a *probe-prefix* is for convenience in using a single MTA mapping table for multiple mailing list deferral settings, *e.g.*, by using a probe prefix consisting of the list name, so that entries in the mapping table may be list specific. Similarly, a deferral time specified as the second argument permits a default deferral time, that may then be overridden in the case of specific originators in the mapping table result.

Setting bit 3/value 8 of the include_connectioninfo MTA option will cause additional information to be included in the input probe of the mapping named by alias_deferred_mapping. Thus if a *probe-prefix* has also been specified, then the probe will take the form:

transport-info|*application-info*|*probe-prefix*|*originator-address*

Note that by default the MTA does not honor Deferred-delivery: headers; see the deferreddestination channel option for a discussion. As a functionally preferable alternative to the Deferred-delivery: header line approach for retaining/deferring messages, see also the SMTP SUBMIT FUTURERELEASE extension.

48.4.15 Alias options: alias_delay_notifications and alias_nodelay_notifications

The alias_delay_notifications and alias_nodelay_notifications alias options are analogues of the [DELAY_NOTIFICATIONS] and [NODELAY_NOTIFICATIONS] alias file named parameters. The alias_delay_notifications alias option requests that NOTARY delay notifications be sent for mailing list postings; the alias_nodelay_notifications alias option requests that NOTARY delay notifications not be sent for mailing list postings.

For lists defined in LDAP, the analogous settings are controlled via whatever attribute is named by the ldap_delay_notifications MTA option, by default mgrpDelayNotifications.

48.4.16 alias_description Option

The alias_description alias option takes a string argument and provides a way to associate a descriptive term or phrase with an alias. The value is unused otherwise.

48.4.17 Alias options: alias_digest_recurrence

RESTRICTED: Not yet fully implemented.

The alias_digest_recurrence alias option takes an ISO 8601 argument.

48.4.18 Alias options: alias_direct_list and alias_direct_mapping

RESTRICTED: Not yet fully implemented.

alias_direct_list takes a file specification for a file containing a list of originator addresses (or a URL returning a list of originator addresses).

alias_direct_mapping takes the name of a mapping table through which to run originator addresses.

48.4.19 Alias options: alias_envelope_from

The alias_envelope_from alias option takes a required value specifying an address to replace the message's original envelope From address. The legacy configuration analogue is the [ENVELOPE_FROM] alias file named parameter. This sets only the envelope From address, (unlike the alias file error-return-address positional parameter which also sets an Errors-to: address).

Setting the value to an address of the form user+*@domain has a special meaning. The asterisk character will be expanded into a representation of the recipient address; thus a separate copy of the list message is generated for each recipient, with each copy including the intended recipient address as a subaddress within the return address. If delivery errors subsequently occur, the subaddress will indicate which was the failing address. In some cases, when dealing with remote MTAs that generate nonstandard, uninformative delivery error messages, this can in theory be useful as a way of determining which recipient address(es) failed, even when the bounce message's inner content is relatively uninformative. And it may make processing of such bounce messages by an automated program more convenient. However, the tradeoff is that such per-user-specific return address values require that a separate message copy be generated and sent for each recipient; for a "large" list, with many recipients in the same destination domains, this can be a large increase in overhead (a large decrease in efficiency). And with more prevalent use nowadays of standard format notification messages, the "need" for this sort of approach, with its extra (potentially large) overhead, is much less (since the intended recipient information can instead be extracted from the standard field in the contents of a standard format notification message).

(New in MS 6.3.) Setting the value to the forward slash character, /, has a special meaning. It tells the MTA to revert to using the original envelope From address that had been present on the incoming message, yet in all other respects use mailing list semantics. This can be useful for setting up mailing lists that report all forms of list errors to the original sender.

For groups and lists defined in LDAP, see the mgrpErrorsTo attribute (or more precisely, the attribute named by the ldap_errors_to MTA option).

48.4.20 Alias options: alias_error_text

The alias_error_text alias option specifies a string to use as the "reason" which will be returned to the attempted sender if and when an attempted posting fails due to an access failure, overriding the usual error text that would be returned in such a case. For groups defined in LDAP, see the mgrpRejectText attribute or mgrpMsgRejectText attribute (or more precisely, whatever attribute(s) are named by the ldap_reject_text MTA option).

For aliases defined in the alias file or alias database, the analogous setting is the [ERROR_TEXT] alias file named parameter.

48.4.21 Alias options: alias_expandable and alias_nonexpandable

The alias_expandable alias option (analogue of the legacy configuration alias file named parameter [EXPANDABLE]) is used to specify that the associated list can be expanded (and

hence its contents seen) by various protocols which may attempt such an operation. It does not mean, or imply, that the membership of the list will be expanded into message headers; for that, instead see alias_header_expansion.

The alias_nonexpandable alias option (analogue of the legacy configuration alias file named parameter [NONEXPANDABLE]) specifies that the associated list may not be expanded.

alias_expandable is the default, unless the expandable_default MTA option has been set, in which case the default is alias_nonexpandable.

alias_nonexpandable is useful in blocking the expansion of mailing lists via SMTP's EXPN command. Note that mailing list access controls, *e.g.*, alias_auth_list, alias_auth_mapping, *etc.*, also affect the expansion of mailing lists via SMTP's EXPN command; the SMTP server will only permit the EXPN if the SMTP client passes the access control (*e.g.*, has issued a prior MAIL FROM: command that passes the access control).

48.4.22 Alias options: alias_expiry

The alias_expiry alias option is used to add an Expiry-date: header line. The *value* should be a date and time, in ISO 8601 P format. (The MTA will convert the specified value into the appropriate corresponding RFC 5322 date value needed for the header line.) The MTA's periodic return job will return messages whose Expiry-date: has passed.

48.4.23 Alias options: alias_filter

The alias_filter alias option is the analogue of the legacy configuration [FILTER] alias file named parameter. It takes a URL argument specifying the location of a Sieve filter to apply on attempted message postings. The argument may be any supported form of URL that makes sense; in particular, besides supporting file:file-spec URLs or simply file specifications without the leading file:, LDAP URLs, and data:sieve-commands are also supported. Note that when specifying a file, it must be the full file specification for the filter file to apply.

48.4.24 Alias options: alias_header_addition and alias_header_trim

The alias_header_trim and alias_header_addition alias options are analogues of the legacy configuration [HEADER_TRIM] and [HEADER_ADDITION] alias file named parameters. The alias_header_trim alias option may be used to add headers to or remove headers from posted messages. The argument must be a full file specification for a header trimming option file; see Header option files for information on the format of these files. alias_header_addition is more specialized than alias_header_trim, being used when there are merely headers to be added. alias_header_addition may be used to specify a file of headers to be added to posted messages. The argument must be a full file specification for the file containing headers to be added.

In particular this facility can be used to add the standard mailing list headers defined in RFC 2369. For instance, a site domain.com that has set up a list named listname, that has a list owner address of listname-owner@domain.com and a list members administrator address of listname-request@domain.com, and with certain list information and archives available at an FTP site, might use a header addition file along the lines of the following:

```
List-Help: <ftp://ftp.domain.com/pub/listname-help.txt> (FTP),
     <mailto:listname-owner@domain.com?subject=help> (List Manager)
List-Subscribe:
     <mailto:listname-request@domain.com?subject=subscribe%20listname?body=subscribe%20listname>
List-Unsubscribe:
     <mailto:listname-request@domain.com?subject=unsubscribe%20listname?body=unsubscribe%20listname>
List-Post: <mailto:listname@domain.com>
List-Owner: <mailto:listname-owner@domain.com?Subject=listname>
List-Archive: <ftp://ftp.domain.com/pub/listname/archive/>,
    <mailto:listname-request@domain.com?subject="send%20listname%20archives?body=send%20/pub/listname/archive/*>
```

48.4.25 Alias options: alias_header_alias and alias_header_expansion

The alias_header_alias and alias_header_expansion alias options are Unified Configuration analogues of the [HEADER_ALIAS] and [HEADER_EXPANSION] alias file named parameters. Because their effect is limited to cases such as messages submitted via the L channel, they have almost no relevance in modern Messaging Server configuration.

48.4.26 Alias options: alias_header_check

(New in Messaging Server 7.0.5.) The alias_header_check alias option is used in conjunction with a addrtypescan* channel option. Valid arguments are jettison or discard. This alias option is an analogue of the LDAP attribute named by the ldap_check_header MTA option.

48.4.27 Alias options: alias_hold_list, alias_nohold_list, alias_hold_mapping, alias_nohold_mapping

The alias_hold_list alias option may be used to specify a list of originator addresses whose attempts to post to the list should be sidelined as .HELD messages. The argument may be any supported form of URL that makes sense. The alias_nohold_list alias option may be used to specify the list of originator addresses whose postings should not be so sidelined, while all other postings will be sidelined. The *value* must be a full file specification for a file of addresses, or an LDAP URL returning a list of addresses. The alias_hold_mapping and alias_nohold_mapping alias options are used analogously, but via mapping tables rather than via lists. The *value* should be the name of an MTA mapping table.

These alias options are analogues of the alias file/alias database named parameters HOLD_LIST, NOHOLD_LIST, HOLD_MAPPING and NOHOLD_MAPPING.

48.4.28 Alias options: alias_importance, alias_precedence, alias_priority, and alias_keep_read

The alias_importance, alias_precedence, alias_priority, and alias_sensitivity alias options are used to generate respective header lines; the value specified is inserted on the respective header line. Alias file/alias database analogues exist; see the [IMPORTANCE], [PRECEDENCE], [PRIORITY], and [SENSITIVITY] alias file named parameters.

Note that the more general alias_header_addition alias option -- in legacy configuration, the alias file/alias database [HEADER_ADDITION] named parameter -- provides an alternate way to add these and other header lines. Or for aliases defined in LDAP, see the ldap_add_header MTA option.

48.4.29 Alias options: alias_keep_delivery and alias_keep_read

The alias_keep_delivery and alias_keep_read alias options are Unified Configuration analogues of the alias file named parameters [KEEP_DELIVERY] and [KEEP_READ].

48.4.30 Alias options: alias_list_name

New in Messaging Server 7.4-0.01. RESTRICTED: Reserved for future use.

48.4.31 Alias options: alias_moderator_address, alias_moderator_list, alias_moderator_mapping, alias_username_moderator_list

The alias_moderator_* alias options are used to establish a moderated mailing list. All postings to the list not originating from a moderator are sent to the list's moderator. The address of the moderator must be specified with the alias_moderator_address alias option. The moderator address determines where moderator mail is sent when someone other than the moderator posts. The value of that named parameter is the moderator's address. For example,

```
msconfig> show alias:test-list@domain\.com
instance.alias:test-list@domain\.com.alias_entry = <IMTA_TABLE:test.dis
instance.alias:test-list@domain\.com.alias_moderator_address = bob@domain.com
```

When there may be multiple moderator addresses (for instance, both robert@mail1.domain.com and bob@domain.com), use alias_moderator_list, alias_username_moderator_list, or alias_moderator_mapping to specify all addresses from which postings should be passed directly to the list and not sent to the list's moderator.

alias_moderator_list specifies either the name of a file containing a list of moderator addresses, or an LDAP URL returning a list of moderator addresses.

alias_username_moderator_list specifies as its argument a URL that "makes sense": either the name of a file containing a list of (possibly wildcarded) moderator usernames, or an LDAP URL returning a list of (possibly wildcarded) moderator usernames; note that usernames are generally only useful for messages submitted from the L channel or submitted with SASL authentication via SMTP (SMTP AUTH) since for messages submitted from other sources the username will simply be that of the account under which the submitting MTA process is running. Note that for messages submitted via SMTP with authentication (SMTP AUTH), the username that authenticated will be prefixed with the asterisk, *, character. For instance, to specify that only the user JDOE is the list moderator, whether submitting from the L channel or via SMTP (*e.g.*, from a POP or IMAP client that performs SASL SMTP

authentication), the alias_username_moderator_list file would need to contain the entries:

```
JDOE
$*JDOE
```

where the first entry would match for messages submitted from the L channel and the second entry would match for messages submitted via SMTP AUTH. Note that as asterisk is normally a wildcard character, matching of only the exact literal asterisk character is specified by using the dollar character to quote the asterisk.

alias_moderator_mapping specifies the name of a mapping table used to verify whether or not an address is a moderator address.

See also the alias_sasl_moderator_list and alias_sasl_moderator_mapping alias options, which operate similarly but *require* that an authenticated address be present in the attempted posting.

If an alias_moderator_list, alias_moderator_mapping, alias_sasl_moderator_list, or alias_sasl_moderator_mapping alias option is used, thereby specifying who may post directly to the list, then an alias_moderator_address alias option should also be present to specify the address to which to send postings not from any moderator.

The use of the alias_moderator_address alias option alone, without the alias_moderator_list alias option, is equivalent to using alias_moderator_address and an alias_moderator_list consisting of just the one moderator address.

Legacy configuration has analogous named parameters [MODERATOR_ADDRESS], [MODERATOR_LIST], [MODERATOR_MAPPING], and [USERNAME_MODERATOR_LIST], as well as named parameters [SASL_MODERATOR_LIST] and [SASL_MODERATOR_MAPPING].

For lists defined in LDAP, the configuration of moderation is structured somewhat differently; see the LDAP attributes named by the ldap_reject_action, ldap_moderator_url, and ldap_auth_url MTA options.

48.4.32 Alias options: alias_originator_reply, alias_nooriginator_reply

The alias_originator_reply alias option is used to control whether or not the originator's address is added to any generated Reply-to: header. The value item should be the full file path specification for a world readable file, or a resolvable URL, containing the list of addresses that should never be added. (This is usually the mailing list itself.) The MTA will match the envelope From address against the addresses in the list; if no match occurs, the originator's address will be added to any generated Reply-to: header.

alias_nooriginator_reply specifies that any generated Reply-to: header should contain only explicitly specified addresses. A value is required, but ignored.

If neither alias_originator_reply nor alias_nooriginator_reply is explicitly set, the MTA's default behavior is effectively equivalent to alias_nooriginator_reply.

In legacy configuration, the analogous alias file named parameters are NOORIGINATOR_REPLY and ORIGINATOR_REPLY.

48.4.33 Alias options: alias_receivedfor, alias_noreceivedfor, alias_receivedfrom, alias_noreceivedfrom

The alias_receivedfor, alias_noreceivedfor, alias_receivedfrom, and alias_noreceivedfrom alias options control features of what appears in the Received: header constructed when expanding the alias, and override normal channel receivedfor, noreceivedfor, receivedfrom, or noreceivedfrom channel option settings. The value specification is currently ignored and should always be NONE.

In legacy configuration, the analogues for these alias options are the alias file named parameters [RECEIVEDFOR], [NORECEIVEDFOR], [RECEIVEDFROM], and [NORECEIVEDFROM].

48.4.34 Alias options: alias_nosolicit

The alias_nosolicit alias option sets a solicitation keyword, or a comma-separated list of solicitation keywords, that will not be allowed on postings to the list. Attempted postings to an alias address that has such a keyword set will be rejected with SMTP error:

```
550 5.7.1 Solicitation check failure on SOLICIT=solicitation-keyword: recipient-address
```

In legacy configuration, the analogous alias file named parameter is [NOSOLICIT].

48.4.35 Alias options: alias_optin

The legacy configuration alias_optin alias option has been replaced in Unified Configuration by alias_optin1.

48.4.36 Spam/virus filter "opt in" alias options: alias_optinN (string)

The alias_optin*N* alias options each respectively set an opt-in value for "opting in" to spam/virus filter package *N*, for *N* in the range 1 to 8. (alias_optin is a synonym for alias_optin1.)

These alias options are analogues of the legacy configuration alias file named parameters [OPTIN*n*].

See also the ldap_optin*N* MTA options for similar functionality for aliases stored in LDAP.

48.4.37 Spam/virus filter "opt out" alias options: alias_optoutN (string)

The alias_optoutN alias options each respectively specify that the current alias is "opting out" of the corresponding spam/virus filter package N, for N in the range 1 to 8.

Note that the scope of opt-outs only extends to the immediate expansion values of the alias - if the alias expands to another alias that alias will not honor the outer level opt-out.

These alias options are analogues of the legacy configuration alias file named parameters [OPTOUTn].

See also the ldap_optinN MTA options for similar functionality for aliases stored in LDAP.

48.4.38 Password protection for postings: alias_password (string)

The alias_password alias option specifies a password, or a comma-separated list of passwords, that allow posting to the list. An attempted posting to the list must contain one of these values on an Approved: header line in order for the posting to be allowed. During mailing list expansion, the password value will be removed from the Approved: header line; indeed, if that is the only value on the Approved: header line, then the entire header line will be removed. See Password-protected mailing lists.

In legacy configuration, the analogous alias file named parameter is [PASSWORD].

For aliases/lists defined in LDAP, the analogous setting is the LDAP attribute named by the ldap_auth_password MTA option.

48.4.39 Disclaimer/text addition alias options: alias_prefix_text (string), alias_suffix_text (string)

The alias_prefix_text and alias_suffix_text alias options cause insertion of, respectively, prefix or suffix text into messages as they undergo list expansion. Prior to Messaging Server 7.3-11.01, text could only be inserted into initial, TEXT/PLAIN parts; new in Messaging Server 7.3-11.01, text can be inserted into the first text part within a nested multipart (excluding multipart/alternative). The value (the text) is specified in UTF-8; this is then converted to match the charset of the part into which the text is being inserted.

In legacy configuration, the analogous alias file named parameters are [PREFIX_TEXT] and [SUFFIX_TEXT].

For aliases/lists defined in LDAP, see the ldap_prefix_text and ldap_suffix_text MTA options.

Or see the Sieve addprefix and addsuffix extensions.

48.4.40 Alias options: alias_presence

RESTRICTED: Not yet implemented.

48.4.41 Alias options: alias_private and alias_public

The alias_private and alias_public alias options are analogues of the [PRIVATE] and [PUBLIC] alias file named parameters. The alias_public alias option specifies that the associated alias is public and hence can appear in any constructed header lines. The value specification is currently ignored and should always be NONE. alias_public is the default. The alias_private alias option specifies that the alias is private and should

appear as an empty group construct in message headers. The value specification is used as the name for the group. Neither alias_public nor alias_private have any effect if the alias_header_expansion alias option is also specified.

Note that these parameters are only valid when headers are originally being constructed, as for instance for messages submitted via the L channel. These parameters are not relevant for incoming messages (such as incoming SMTP messages) for which the headers are already present in one form or another.

48.4.42 Deferred expansion alias option: alias_reprocess (string)

The alias_reprocess alias option is used to request deferred expansion of the mailing list, where rather than expanding the mailing list "on line", the message should instead be enqueued to the reprocess channel; the reprocess channel can then perform the mailing list processing in a separate step. The *value* specification is currently ignored and should always be reprocess.

Use of this alias option defers much of the processing overhead of handling the message to the later step when the reprocess channel runs, rather than doing the processing as the message is initially accepted. This deferred processing can be especially helpful in cases such as incoming SMTP messages addressed to large mailing lists, where "on line" delays could lead to connection time outs.

Use of this parameter as in:

```
listname:       </pmdf/table/listname.dis, [REPROCESS] reprocess
```

thus provides essentially identical functionality as defining a mailing list in two stages through the reprocess channel to obtain deferred expansion (the mailing list addresses aren't even expanded until the reprocess channel runs) such as:

```
listname:        listname-expand@reprocess
listname-expand: </pmdf/table/listname.dis
```

In legacy configuration, the analogous alias file named parameter is [REPROCESS].

For aliases/lists defined in LDAP, see the ldap_reprocess MTA option.

48.4.43 SASL-based access alias options: alias_sasl_auth_list (file or URL), alias_sasl_auth_mapping (MTA mapping name), alias_sasl_cant_list (file or URL), alias_sasl_cant_mapping (MTA mapping name), alias_sasl_moderator_list (file or URL), alias_sasl_moderator_mapping (MTA mapping name)

The alias_sasl_* alias options are analogues of the non-SASL similar alias options, but with the additional requirement that an authenticated address be present in the message (whether that be a address literally authenticated via SMTP AUTH, or forced via, *e.g.*, an authrewrite or FROM_ACCESS effect).

In legacy configuration, they have analogues in the alias file named parameters [SASL_AUTH_LIST], [SASL_AUTH_MAPPING], [SASL_CANT_LIST], [SASL_CANT_MAPPING], [SASL_MODERATOR_LIST], [SASL_MODERATOR_MAPPING].

48.4.44 Alias options: alias_sequence_prefix (file-path), alias_sequence_suffix (file-path), alias_sequence_strip (string)

The alias_sequence_prefix and alias_sequence_suffix alias options request that a sequence number be prepended or appended to the Subject: lines of messages posted to the list. They are analogues of the legacy alias file named parameters [SEQUENCE_PREFIX] and [SEQUENCE_SUFFIX]. The value item gives the full file path specification of a sequence number file. This file is read, incremented, and updated each time a message is posted to the list. The number read from the file is prepended, in the case of alias_sequence_prefix, or appended, in the case of alias_sequence_suffix, to the message's Subject: header line. This mechanism provides a way of uniquely sequencing each message posted to a list so that recipients can more easily track postings and determine whether or not they have missed any.

By default, a response to a previously posted message (with a previous sequence number) retains the previous sequence number as well as adding a new sequence number to the subject line; the build up of sequence numbers shows the entire "thread" of the message in question. However, the alias_sequence_strip alias option (analogue of the alias file named parameter [SEQUENCE_STRIP]) can be used to request that only the highest numbered, *i.e.*, most recent, sequence number be retained on the subject line. The value item is currently ignored and should always be NONE.

Important note: To ensure that sequence numbers are only incremented for successful postings, an alias_sequence_prefix or alias_sequence_suffix alias option should always be set as the last alias option; that is, if other alias options are also being used, the alias_sequence_* options should be set (and appear when shown) at the end of the list of alias options on an alias entry.

Sequence number files are binary files and must have the proper file attributes and access permissions in order to function correctly.

48.4.45 Per-recipient message copy alias option: alias_single (string)

The alias_single alias option, if set, forces a separate message copy per recipient (per list member). Thus it can be considered a per-list analogue of the single channel option. It takes string argument, currently ignored, which should be set to the value "NONE".

In legacy configuration, its analogue is the alias file named parameter [SINGLE].

48.4.46 Extra value alias options: alias_spare* (string)

The alias_spare*N* alias options (*N* = 1,...,18) are analogous to the attributes named by the ldap_spare_*N* MTA options, except with these options the corresponding spare slot is filled in when the alias is expanded. In legacy configuration, the analogous alias file named parameters are [SPARE*].

The spare value slots are intended for site-customizable purposes, to be made known to the MTA (and hence be more easily accessible in MTA LDAP URLs and certain MTA mapping tables, *etc.*).

48.4.47 Tag inserted on Subject: header line alias option: alias_tag (string)

The alias_tag alias option may be used to prefix specified text to the Subject: header of posted messages. The value should be the string to be added. The string should not contain the vertical bar, |, character; prior to MS 6.3, the string should not have contained the space character. For instance,

```
msconfig> set alias:schedule-list@domain\.com.alias_tag "Schedule posting -- "
msconfig# show alias:schedule-list@domain\.com
instance.alias:schedule-list@domain\.com.alias_entry = "<ldap:///o=usergroup?mail?sub?(isMember=schedule-list)"
instance.alias:schedule-list@domain\.com.alias_auth_list = "<ldap:///o=usergroup?mail?sub?(isMember=schedule-list)"
instance.alias:schedule-list@domain\.com.alias_tag = "Schedule posting -- "
```

will cause any postings to the list schedule-list to have a Subject: header that begins "Schedule posting -- " followed by whatever the original subject of the posting might have been. See the ldap_add_tag MTA option for setting an attribute name to provide analogous functionality for lists defined in LDAP, and in legacy configuration, see instead the alias file named parameter [TAG].

48.4.48 To: header line alias option: alias_to (string)

The alias_to alias option specifies what to put on the To: header line of postings to the mailing list.

In legacy configuration, see the alias file named parameter [TO].

48.4.49 Alias options: alias_username (string)

The alias_username alias option may be used to set the "username" that the MTA will consider to "own" these mailing list messages. (The legacy configuration alias file named parameter equivalent is [USERNAME].) The imsimta qm utility will allow that username to inspect and bounce messages in the queue resulting from expansion of this mailing list. The value item should be the username of the account to "own" the mailing list postings.

48.5 Alias file

In legacy configuration, especially in older MTA configurations, aliases were stored in the MTA alias file, normally named aliases and stored in the MTA table (config) directory. In more modern MTA configurations, most aliases are stored instead in LDAP, with only a few basic aliases stored elsewhere: either in the aliases file in legacy configuration, or as a set of values in an alias group in Unified Configuration.

Even though in Unified Configuration the old `aliases` file is not actually used, the `alias` settings may be viewed "as if" they were in the `aliases` file by using the `msconfig` command `edit aliases`:

```
msconfig> edit aliases
```

48.5.1 Alias file format

The alias file format is as follows:

```
alias1: a1,a2,...,am
alias2: b1,b2,...,bm
  .             .
  .             .
  .             .
aliasn: n1,n2,...,nm
  .             .
  .             .
  .             .
```

where *aliasn* is translated into the addresses *n1*, *n2*, *n3*, ..., *nm*. The aliases *alias1*, *alias2*, ..., *aliasn* are limited to 128 characters each. (In iMS 5.2 and earlier, the limit had been 64 characters.) Each address *a1*, *a2*, *etc.*, may contain up to 256 characters (252 characters in iMS 5.2 and earlier). There is no limit to the number of addresses that can be specified for an alias (that is, appear in a single list on the right hand side of an alias definition), although excessive numbers of addresses may eat up excessive amounts of memory. A physical line of the alias file may contain at most 1024 characters. To specify a list of addresses containing more than that number of characters, the line must be continued onto multiple physical lines. Long lines may be continued by ending them with a backslash, \. A backslash must follow a comma. There can be no white space preceding the colon separating the alias name from its translation value.

An alias expansion address prefixed with a colon character, `:`, has a special interpretation. The alias expansion address will be used as normal *except* when the MTA is generating a notification message (a Delivery Status Notification such as a bounce message, or a Message Disposition Notification such as a vacation messages); when generating a notification message regarding the alias, the unexpanded alias will be used rather than the alias expansion value (which would normally be used). This mechanism can be useful in cases where an alias expansion address is an "internal" address that should not be exposed to the outside. It is essentially an alias-specific analogue of the `useintermediate` channel option. For instance, with aliases defined as

```
adam: :bob@ims-ms-daemon
carl: donald@ims-ms-daemon
```

messages sent to adam will be redirected to bob@ims-ms-daemon. But if a notification message needs to be sent back to an original message sender, the notification message will refer to address adam, rather than to bob@ims-ms-daemon. This contrasts with the case of notification messages regarding messages sent to carl; in this case, any notification messages will refer to the donald@ims-ms-daemon address.

The matching process is configurable for aliases containing a subaddress, that is, aliases of a form such as:

```
adam+hobbylist: adam-personal-mailbox@domain.com
```

See the subaddress* channel options for details.

An address (or addresses) on the right hand side of an alias file entry may optionally have various so-called named parameters associated with it (or them). Such named parameters are more commonly of interest and used with mailing list definitions, but some (in particular, [BLOCKLIMIT], [CAPTURE], [JOURNAL], [CONVERSION_TAG], and [FILTER]), can be of interest for individual aliases as well. Such parameters are specified by listing them at the *beginning* of the right hand (translation) side of the alias entry; the parameters then apply to all addresses on the right hand. Thus an alias entry using named parameters and translating to a single addresses would have the form:

alias: [*p-name-1*] *p-value-1*,...,[*p-name-k*] *p-value-k*,*address*

while an alias entry using named parameters and translating to multiple addresses (hence an e-mail group, or perhaps mailing list, depending upon which named parameters are set) would have the form:

alias: [*p-name-1*] *p-value-1*,...,[*p-name-k*] *p-value-k*,*address-1*,...,*address-j*

corresponding to Unified Configuration alias option settings along the lines of:

```
msconfig> show alias:alias
alias:alias.alias_entry = address-1
alias:alias.alias_entry = address-2
...
alias:alias.alias_entry = address-j
alias:alias.p-name-1 = p-value-1
alias:alias.p-name-2 = p-value-2
...
alias:alias.p-name-k = p-value-k
```

Alternatively, rather than having an address or (in legacy configuration) a comma separated list of addresses as the translation of an alias, in the alias file an alias may translate to a mailing list reference as discussed in Alias file mailing list aliases, or to an LDAP URL reference as discussed in Alias file LDAP URL alias values.

A typical, minimal alias file will include at least a postmaster alias definition. (See alias_entry for a discussion of minimal such postmaster alias definition in a modern, Unified Configuration setup.)

In older versions of the MTA, an alias was normally simply a valid RFC 822 "local-part"; however, in more modern MTA configurations, with the alias_domains MTA option set to a value of 6, an alias consists of an entire address, including the domain name, rather than just the local-part. In particular, aliases must follow RFC 822 syntax rules for local-parts (or addresses, when alias_domains has selected use of addresses); this means that for proper functioning, with the exception of periods which are specifically allowed in local-parts without quoting, the presence of any other RFC 822 "specials" character or a space in an alias will require that the alias be enclosed in double quotes, *e.g.*,

```
"John Doe": doe@acme.com
```

```
john.doe: doe@acme.com
```

Comment lines are allowed in the alias file. A comment line is any line that begins with an exclamation point, `!`, in column one.

Duplicate aliases (identical left hand sides) are not allowed in the alias file.

Note that prior to MS 6.1, certain sorts of errors in the format of aliases would not result in an immediate error message, but rather mail to the bad addresses would just be silently dropped. For instance, use of an apparently local (and syntacticaly unexceptional) but in fact non-existant user address as a value (on the right hand side) would not necessarily result in any error message---not if there was at least one apparently valid value on the right hand side. (This is in contrast to overt syntactic errors in the alias file format itself, which have always been report ed at MTA process startup time, or at `imsimta cnbuild` time if a compiled configuration is in use. It is also in contrast to delivery problems to addresses that, at alias expansion time, appear potentially valid; delivery problems are and always have been reported back to the appropriate notification address, if any. It is also in contrast to the case where *all* of the values appear to be invalid.) As of MS 6.1, errors apparent at alias expansion time in aliases are reported to the other members of the alias. But in any case, when defining an alias it is a good idea to use `imsimta test -rewrite -check_expansions` to check aliases, and see Alias restrictions for further general information on alias operation and the alias file.

48.5.1.1 Alias file include files

Other files can be included in the primary alias file. A line of the form

```
<file-spec
```

directs the MTA to read the file *`file-spec`*. The file specification must be a complete file path specification and the file must have the same protections as the primary alias file; *i.e.,* it must be world readable.

The contents of the included file are inserted into the alias file at its point of reference. The same effect can be achieved by replacing the reference to the included file with the file's actual contents. The format of include files is identical to that of the primary alias file itself. Indeed, include files may themselves include other files. Up to three levels of include file nesting are allowed.

If a compiled configuration is being used, then the configuration must be recompiled and reinstalled before changes to any included file (or the primary alias file itself) will take effect. Note that this is not the case for mailing list membership files described in Alias file mailing list aliases.

48.5.1.2 Alias file named parameters

This discussion describes alias file named parameters as set in legacy configuration in the aliases file. In Unified Configuration, the equivalent settings are alias options.

The `named-parameters` appearing in an alias file mailing list definition such as

```
alias: <file-spec, named-parameters, error-return-address, \
```

```
        reply-to-address, errors-to-address, \
        warnings-to-address, comments
```

or

```
alias: <ldap-url, named-parameters, error-return-address, \
        reply-to-address, errors-to-address, \
        warnings-to-address, comments
```

or in an individual alias definition (see Alias file format) such as

```
alias: named-parameters,address-1,...,address-n
```

are used to specify optional modifiers to the list expansion process. There can be zero or more named parameters, separated by commas, and they must appear before any positional parameters (*e.g.*, `error-return-address`, `reply-to-address`, *etc.*). The general syntax of a named parameter is:

```
[name] value
```

Here `name` is the name of the parameter and `value` is its corresponding value. The square brackets are a mandatory part of the syntax: they do not indicate an optional field.

See Alias header addition modifiers for a description of controls on the effect of named parameters relating to the addition of headers, such as specifying whether a header is to be added only if not originally present, or added unconditionally, and whether the header supplements or substitutes for an originally present header.

The available named parameters are:

48.5.1.2.1 AND, OR

AND and OR control whether subsequent access control clauses (*e.g.*, [AUTH_LIST], [AUTH_MAPPING], etc.) are ANDed or ORed. The default is controlled by the `or_clauses` MTA option---and is AND (for backwards compatibility) by default. For groups and lists defined in LDAP, see also the `AND` and `OR` values for the `mgrpBroadcasterPolicy` attribute (or more precisely, the attribute named by the `ldap_auth_policy` MTA option). For a more detailed discussion, see Mailing list multiple access control interpretation.

In Unified Configuration, see the `alias_and` and `alias_or` alias options.

48.5.1.2.2 AUTH_CHANNEL, CANT_CHANNEL

AUTH_CHANNEL is used to specify a source channel or channels that may submit messages to the mailing list. CANT_CHANNEL is used to specify a source channel or channels that may not submit messages to the mailing list. The argument should be a (possibly wildcarded) channel name, or a space-separated list of (possibly wildcarded) channel names.

In Unified Configuration, see the `alias_auth_channel` and `alias_cant_channel` alias options.

48.5.1.2.3 AUTH_LIST, CANT_LIST, USERNAME_AUTH_LIST, USERNAME_CANT_LIST

AUTH_LIST is used to specify a list of addresses that are allowed to post to the mailing list. The *value* item must be either the full file path specification for a world readable file containing the list of addresses allowed to post to the list, or an LDAP URL that returns the list of addresses allowed to post to the list. The MTA will match the envelope From address against the addresses in the list; if no match occurs, the attempted posting fails and an error is returned to the would be posting's originator. USERNAME_AUTH_LIST is analogous to AUTH_LIST, but for (possibly wildcarded) usernames rather than addresses; note that usernames are generally only useful for messages submitted from the L channel or submitted with SASL authentication via SMTP (SMTP AUTH) since for messages submitted from other sources the username will simply be that of the account under which the submitting MTA process is running. Note that for messages submitted via SMTP with authentication (SMTP AUTH), the username that authenticated will be prefixed with the asterisk, *, character. For instance, to specify that only the user JDOE may submit to a list, whether submitting from the L channel or via SMTP (*e.g.*, from a POP or IMAP client that performs SASL SMTP authentication), the USERNAME_AUTH_LIST file would need to contain the entries:

```
JDOE
$*JDOE
```

where the first entry would match for messages submitted from the L channel and the second entry would match for messages submitted via SMTP AUTH. Note that as asterisk is normally a wildcard character, matching of only the exact literal asterisk character is specified by using the dollar character to quote the asterisk.

CANT_LIST has the opposite effect as AUTH_LIST: it supplies the full file path specification of a world readable file containing a list of addresses, or an LDAP URL returning a list of addresses, specifying which addresses may not post to the list. USERNAME_CANT_LIST is analogous to CANT_LIST, but for (possibly wildcarded) usernames rather than addresses; note that usernames are generally only useful for messages submitted from the L channel or submitted with SASL authentication via SMTP (SMTP AUTH) since for messages submitted from other sources the username will simply be that of the account under which the submitting MTA process is running.

One common use of this facility is to restrict a list so that only list members can post. This can be done by specifying the same file as both the list file and the AUTH_LIST file. For example, assuming that the list is named test-list and the list file is `IMTA_TABLE:test-list.dis`, the alias file entry would be:

```
test-list: <IMTA_TABLE:test-list.dis, \
             [auth_list] IMTA_TABLE:test-list.dis
```

For groups and lists defined in LDAP, the closest analogues are the `mgrpAllowedBroadcaster` and `mgrpDisallowedBroadcaster` attributes (more precisely, the attributes named by the `ldap_auth_url` and `ldap_cant_url` MTA options); and if wishing to compare against authenticated submission addresses, see also the `SMTP_AUTH_REQUIRED` value for the `mgrpBroadcasterPolicy` attribute (or whatever attribute is named by the `ldap_auth_policy` MTA option).

In Unified Configuration, see the `alias_auth_list`, `alias_cant_list`, `alias_username_auth_list`, and `alias_username_cant_list` alias options.

48.5.1.2.4 AUTH_MAPPING, CANT_MAPPING

AUTH_MAPPING and CANT_MAPPING are similar to AUTH_LIST and CANT_LIST except that they use mappings rather than explicit files of addresses. The `value` item associated with these named parameters is the name of a mapping table to use; the mapping is given the envelope From address as input.

If AUTH_MAPPING is used at least one mapping entry must match or the posting is rejected. If an entry does match the resulting string is checked; if it begins with an F, f, N, or n the posting is rejected. The mailing list will expand normally if the resulting string begins with any other character.

If CANT_MAPPING is used, the posting is accepted if no entry matches. If an entry does match the resulting string is checked; if it begins with a T, t, Y, or y the posting is accepted. The posting is rejected if the resulting string begins with any other character.

The most common use of AUTH_MAPPING is to restrict postings to all users of a given (usually local) host. For example, if the local host name is ymir.claremont.edu, the following mailing list definition could be used for the gripes-list:

```
gripes: <pmdf_table:gripes-list.dis, [auth_mapping] x-gripes
```

The corresponding mapping file entries would be:

```
X-GRIPES

    *@ymir.claremont.edu    Y
```

Using a mapping table name beginning X- is recommended, so that this private mapping table name will not collide with a standard Oracle mapping table name.

In Unified Configuration, see the `alias_auth_mapping` and `alias_cant_mapping` alias options.

48.5.1.2.5 AUTH_USERNAME, CANT_USERNAME

AUTH_USERNAME is used to specify a username or wildcarded username pattern for an account or accounts allowed to post to the list. Note that this is generally only useful for senders submitting from the L channel or for senders who used the SMTP AUTH extension during their message submission; for messages submitted from other sources, the messages are considered to be submitted under the username of the MTA process that received and enqueued the message, *e.g.*, the account under which the MTA's SMTP server is running. Attempted postings from any other sender will be rejected.

CANT_USERNAME may be used to specify a username or wildcarded username pattern for an account or accounts whose postings should be rejected.

Note that for messages submitted via SMTP with authentication (SMTP AUTH), the username that authenticated will be prefixed with the asterisk, *, character. Also note that the asterisk character is normally a wildcard, and must be quoted with the dollar character in order to be interpreted as a literal asterisk character. For instance, to specify that the only sender who may post to a list is user JDOE who will be submitted solely via SMTP with SMTP AUTH, you would use:

```
[AUTH_USERNAME] $*JDOE
```

Without the dollar sign, specifying just `*JDOE` would allow postings not only from user JDOE but also from any users AJDOE, BOBJDOE, *etc*.

For specifying more than one username (or wildcarded username pattern), see the USERNAME_AUTH_LIST and USERNAME_CANT_LIST parameters described above. For groups and lists defined in LDAP, the closest analogues are the `mgrpAllowedBroadcaster` and `mgrpDisallowedBroadcaster` attributes (or more precisely, the attributes named by the `ldap_auth_url` and `ldap_cant_url` MTA options).

In Unified Configuration, see the `alias_auth_username` and `alias_cant_username` alias options.

48.5.1.2.6 BLOCKLIMIT, LINELIMIT

The BLOCKLIMIT and LINELIMIT parameters may be used to limit the size of messages that may be posted to the list. The `value` item must be an integer number of blocks for [BLOCKLIMIT], or an integer number of lines for [LINELIMIT]. The number of bytes in a block is specified via the `block_size` MTA option. The default value is 0, meaning that no limit is imposed on the size of message that may be posted to the list (apart, that is, from any channel or system wide limits). For user, groups, and lists defined in LDAP, see `mailMsgMaxBlocks` attribute (or more precisely, the attribute named by the `ldap_blocklimit` MTA option).

In Unified Configuration, see also the `alias_blocklimit` and `alias_linelimit` alias options.

48.5.1.2.7 CAPTURE, JOURNAL

(CAPTURE is new in MS 6.2; JOURNAL is new in Messaging Server 7.2-0.01.) The CAPTURE named parameter may be used to set an address to which to direct an encapsulated, "captured" copy of each message posted to the list. The JOURNAL named parameter works similarly, but generates an envelope "journal" format message. The `value` item should be the address to which to send the "captured" message copies. These parameters are exactly analogous to use of the LDAP attribute named by the `ldap_capture` MTA option on a group or mailing list defined via an LDAP entry.

In Unified Configuration, see also the `alias_capture` and `alias_journal` alias options.

New in MS 8.0.1, see also the CAPTURE_HEADER and JOURNAL_HEADER named parameters.

48.5.1.2.8 CAPTURE_HEADER, JOURNAL_HEADER

(CAPTURE_HEADER and JOURNAL_HEADER are new in MS 8.0.1.) The CAPTURE_HEADER named parameter may be used to set an address to which to direct an encapsulated, "captured" copy of the message header of each message posted to the list. The JOURNAL_HEADER named parameter works similarly, but generates an envelope "journal" format message. The *`value`* item should be the address to which to send the "captured" message copies. These parameters are exactly analogous to use of the LDAP attribute named by the `ldap_capture` MTA option on a group or mailing list defined via an LDAP entry, when the LDAP attribute's value is tagged `;format-report-header` or `;format-journal-header`.

In Unified Configuration, see also the alias_capture_header and alias_journal_header alias options.

48.5.1.2.9 CONVERSION_TAG

The CONVERSION_TAG named parameter may be used to set a tag which conversion file entries can match upon. The value item should be the string to use as the tag. For instance, if a list is defined

```
listname: </pmdf/table/listname.dis, [CONVERSION_TAG] listtag
```

then conversion file entries could include a tag=listtag; clause to match. For instance, if for some mailing list it was desired to convert any text/html parts in posted messages to text/plain, and if a site had an HTML to TEXT converter called htmltotextconvert and had set up the conversion channel and a CONVERSIONS mapping table to apply to list postings, then a conversion file entry could be

```
in-chan=*; out-chan=*; in-type=text; in-subtype=html; tag=listtag;
 out-type=text; out-subtype=plain; parameter-copy-0=*;
 command="IMTA_PROGRAM:htmltotextconvert $INPUT_FILE $OUTPUT_FILE"
```

For users, groups, and lists defined in LDAP, see the mailConversionTag attribute (or more precisely, the attribute named by the ldap_conversion_tag MTA option).

In Unified Configuration, see also the alias_conversion_tag alias option.

48.5.1.2.10 CREATION_DATE

New in the 8.0 release.

The CREATION_DATE named parameter may be used to set a creation date for the alias (intended to be used for RRVS purposes). The creation date value must be in RFC 3339 (Date and Time on the Internet: Timestamps) format (a profile of ISO 8601 format), along the lines of:

*YYYY-MM-DD*T*HH*:*MM*:*SS*.*ss*Z

or

*YYYY-MM-DD*T*HH*:*MM*:*SS*.*ss**plus-or-minus**HH*:*MM*

where the hundredths of seconds portion is optional, and T and (if used) Z are not case sensitive. For instance:

2014-02-28T12:13:14.30-07:00

In Unified Configuration, see the alias_creation_date alias option. Or for users defined in LDAP, the analogous setting is controlled by whatever attribute is named by the ldap_creation_date MTA option, or at a domain level by whatever attribute is named by the ldap_domain_attr_creation_date MTA option.

48.5.1.2.11 DEFERRED, DEFERRED_LIST, DEFERRED_MAPPING

In Unified Configuration, see the alias_deferred, alias_deferred_list, and alias_deferred_mapping alias options.

The DEFERRED named parameter may be used to add a Deferred-delivery: header line. The value should be a date and time, in ISO 8601 P format. Note that by default the MTA does not honor Deferred-delivery: headers; see the `deferreddestination` channel option for a discussion.

The DEFERRED_LIST named parameter takes two (space-separated) values, a file specification for a list of originator addresses (or alternatively, a URL returning a list of addresses) to whose postings to add a Deferred-delivery: header, and the deferral date/time in ISO 8601 format.

As of the 8.0 release (in prior versions, this feature "existed" but was not working), the DEFERRED_MAPPING named parameter may be used to run originator addresses through the specified mapping. DEFERRED_MAPPING takes one or two arguments, with a space between if the optional second argument is included. The first argument is required and must contain at a minimum the name of an MTA mapping table; the first argument may also, optionally, include a vertical bar character followed by a string to use as a prefix in the mapping table probe, prior to the originator address. The second argument is optional, consisting of a deferral date/time in ISO 8601 format.

`mapping-name``[|`*`probe-prefix`*`]` *`ISO-8601-deferral-time`*

Originator addresses will be run through the specified mapping. If the mapping template does not begin with an N, n, F, or f, and if it contains a valid date/time specification in ISO 8601 format, then that date/time will be used as a deferral time. The default, if no mapping entry matches, or if an entry that begins with an N, n, F, or f, is not to add a Deferred-delivery: header. Note that the intended purpose of a `probe-prefix` is for convenience in using a single MTA mapping table for multiple mailing list deferral settings, *e.g.*, by using a probe prefix consisting of the list name, so that entries in the mapping table may be list specific. Similarly, a deferral time specified as the second argument permits a default deferral time, that may then be overridden in the case of specific originators in the mapping table result.

Setting bit 3/value 8 of the `include_connectioninfo` MTA option will cause additional information to be included in the DEFERRED_MAPPING input probe. Thus if a `probe-prefix` has also been specified, then the probe will take the form:

`transport-info``|`*`application-info`*`|`*`probe-prefix`*`|`*`originator-address`*

Note that by default the MTA does not honor Deferred-delivery: headers; see the `deferreddestination` channel option for a discussion. As a functionally preferable alternative to the Deferred-delivery: header line approach for retaining/deferring messages, see also the SMTP SUBMIT FUTURERELEASE extension.

48.5.1.2.12 DELAY_NOTIFICATIONS, NODELAY_NOTIFICATIONS

The DELAY_NOTIFICATIONS named parameter requests that NOTARY delay notifications be sent for mailing list postings; the NODELAY_NOTIFICATIONS named parameter requests that NOTARY delay notifications not be sent for mailing list postings. The `value` specification is currently ignored and should always be `NONE`.

In Unified Configuration, see the `alias_delay_notifications` alias option. Or for users defined in LDAP, the analogous settings are controlled by whatever attribute is named by the `ldap_delay_notifications` MTA option, by default `mgrpDelayNotifications`.

48.5.1.2.13 DIGEST_RECURRENCE

RESTRICTED: Not yet fully implemented.

The DIGEST_RECURRENCE parameter takes an ISO 8601 argument.

48.5.1.2.14 DIRECT_LIST, DIRECT_MAPPING

RESTRICTED: Not yet fully implemented.

48.5.1.2.15 ENVELOPE_FROM

This ENVELOPE_FROM parameter takes a required value specifying an address to replace the message's original envelope From address. This sets only the envelope From address, unlike the `error-return-address` positional parameter which also sets an Errors-to: address.

Setting the value to an address of the form `user+*@domain` has a special meaning. The asterisk character will be expanded into a representation of the recipient address; thus a separate copy of the list message is generated for each recipient, with each copy including the intended recipient address as a subaddress within the return address. If delivery errors subsequently occur, the subaddress will indicate which was the failing address. In some cases, when dealing with remote MTAs that generate nonstandard, uninformative delivery error messages, this can in theory be useful as a way of determining which recipient address(es) failed, even when the bounce message's inner content is relatively uninformative. And it may make processing of such bounce messages by an automated program more convenient. However, the tradeoff is that such per-user-specific return address values require that a separate message copy be generated and sent for each recipient; for a "large" list, with many recipients in the same destination domains, this can be a large increase in overhead (a large decrease in efficiency). And with more prevalent use nowadays of standard format notification messages, the "need" for this sort of approach, with its extra (potentially large) overhead, is much less (since the intended recipient information can instead be extracted from the standard field in the contents of a standard format notification message).

(New in MS 6.3.) Setting the value to the forward slash character, `/`, has a special meaning. It tells the MTA to revert to using the original envelope From address that had been present on the incoming message, yet in all other respects use mailing list semantics. This can be useful for setting up mailing lists that report all forms of list errors to the original sender.

In Unified Configuration, see the `alias_envelope_from` alias option. Or for groups and lists defined in LDAP, see the `mgrpErrorsTo` attribute (or more precisely, the attribute named by the `ldap_errors_to` MTA option).

48.5.1.2.16 ERROR_TEXT (string)

Specify a string to use as the "reason" which will be returned to the attempted sender if and when an attempted posting fails. For groups defined in LDAP, see the `mgrpRejectText` attribute or `mgrpMsgRejectText` attribute (or more precisely, whatever attribute(s) are named by the `ldap_reject_text` MTA option).

In Unified Configuration, see also the `alias_error_text` alias option.

48.5.1.2.17 EXPANDABLE, NONEXPANDABLE

The EXPANDABLE named parameter is used to specify that the associated list can be expanded (and hence its contents seen) by various protocols which may attempt such an operation. It does not mean, or imply, that the contents of the list will be expanded into message headers. The `value` specification is currently ignored and should always be `NONE`. The NONEXPANDABLE named parameter specifies that the associated list may not be expanded. Again, the `value` specified is currently ignored and should always be `NONE`.

EXPANDABLE is the default, unless the `expandable_default` MTA option has been set, in which case the default is NONEXPANDABLE.

NONEXPANDABLE is useful in blocking the expansion of mailing lists via SMTP's EXPN command. Note that mailing list access controls, *e.g.*, AUTH_LIST, AUTH_MAPPING, *etc.*, also affect the expansion of mailing lists via SMTP's EXPN command; the SMTP server will only permit the EXPN if the SMTP client passes the access control (*e.g.*, has issued a prior MAIL FROM: command that passes the access control).

In Unified Configuration, see also the `alias_expandable` and `alias_nonexpandable` alias options.

48.5.1.2.18 EXPIRY

The EXPIRY named parameter is used to add an Expiry-date: header line. The value should be a date and time, in ISO 8601 P format (as described for the DEFERRED parameter above). (The MTA will convert the specified value into the appropriate corresponding RFC 2822 date value needed for the header line.) The MTA's periodic return job will return messages whose Expiry-date: has passed.

For groups or lists defined in LDAP, see the `ldap_add_header` MTA option. In Unified Configuration, see also the `alias_expiry` alias option.

48.5.1.2.19 FILTER

The FILTER parameter takes a URL argument specifying the location of a Sieve filter to apply on attempted message postings. The argument may be any supported form of URL that makes sense; in particular, besides supporting `file:file-spec` URLs or simply file specifications without the leading `file:`, LDAP URLs, and `data:sieve-commands` are also supported. Note that when specifying a file, it must be the full file specification for the filter file to apply.

In Unified Configuration, see the `alias_filter` alias option. Or for users defined in LDAP, the analogous setting is controlled by whatever attribute is named by the `ldap_filter` MTA option, by default `mailSieveRuleSource`.

48.5.1.2.20 HEADER_ADDITION, HEADER_TRIM

HEADER_TRIM may be used to add headers to or remove headers from posted messages. The argument must be a full file specification for a header trimming option file; see Header option files for information on the format of these files. HEADER_ADDITION is more specialized than HEADER_TRIM, being used when there are merely headers to be added. HEADER_ADDITION may be used to specify a file of headers to be added to posted messages. The argument must be a full file specification for the file containing headers to be added.

In particular, this facility can be used to add the standard mailing list headers defined in RFC 2369. For instance, a site domain.com that has set up a list named listname, using the MAILSERV channel to manage subscription and unsubscription requests, and with certain list information and archives available at an FTP site, might use a header addition file along the lines of the following:

```
List-Help: <ftp://ftp.domain.com/pub/listname-help.txt> (FTP),
     <mailto:mailserv@domain.com?body=send%20/pub/listname-help.txt>,
     <mailto:mailserv@domain.com?body=help> (MAILSERV Instructions),
     <mailto:listname-owner@domain.com?subject=help> (List Manager)
```

```
List-Subscribe:
     <mailto:mailserv@domain.com?body=subscribe%20listname>
List-Unsubscribe:
     <mailto:mailserv@domain.com?body=unsubscribe%20listname>
List-Post: <mailto:listname@domain.com>
List-Owner: <mailto:listname-owner@domain.com?Subject=listname>
List-Archive: <ftp://ftp.domain.com/pub/listname/archive/>,
    <mailto:mailserv@domain.com?body=send%20/pub/listname/archive/*>
```

In Unified Configuration, see the `alias_header_addition` and `alias_header_trim` MTA options. Or for mailing lists defined in LDAP, see the LDAP attributes `mgrpAddHeader` and `mgrpRemoveHeader`, or more precisely, the LDAP attributes named by the `ldap_add_header` and `ldap_remove_header` MTA options.

48.5.1.2.21 HEADER_ALIAS, HEADER_EXPANSION

The HEADER_ALIAS named parameter forces the use of the original alias in any original headers constructed using this alias. HEADER_EXPANSION forces the alias to expand into its component addresses in any constructed header lines. The `value` specification is currently ignored and should always be `NONE`. These named parameters correspond to the expand and no-expand options for entries in personal alias databases. HEADER_ALIAS is the default for entries in the system alias file and database. Note that these parameters are only valid when headers are originally being constructed, as for instance for messages submitted via the L channel. These parameters are not relevant for incoming messages (such as incoming SMTP messages) for which the headers are already present in one form or another.

In Unified Configuration, see the `alias_header_alias` and `alias_header_expansion` alias options.

48.5.1.2.22 HEADER_CHECK

(New in 7.0.5) Used in conjunction with a `addrtypescan*` channel keyword. Valid arguments are `jettison` or `discard`. In Unified Configuration, see the `alias_header_check` alias option. This named parameter is also analogous to the LDAP attribute named by the `ldap_check_header` MTA option.

48.5.1.2.23 HOLD_LIST, NOHOLD_LIST, HOLD_MAPPING, NOHOLD_MAPPING

The HOLD_LIST named parameter may be used to specify a list of originator addresses whose attempts to post to the list should be sidelined as `.HELD` messages. The NOHOLD_LIST named parameter may be used to specify the list of originator addresses whose postings should not be so sidelined, while all other postings will be sidelined. The `value` must be a full file specification for a file of addresses, or an LDAP URL returning a list of addresses. The HOLD_MAPPING and NOHOLD_MAPPING named parameters are used analogously, but via mapping tables rather than via lists. The `value` should be the name of an MTA mapping table.

In Unified Configuration, see the `alias_hold_list` and `alias_nohold_list` alias options.

48.5.1.2.24 IMPORTANCE, PRECEDENCE, PRIORITY, SENSITIVITY

The IMPORTANCE, PRECEDENCE, PRIORITY, and SENSITIVITY named parameters are used to generate respective headers; the `value` specification is inserted on the respective header line. In Unified Configuration, see the `alias_importance`, `alias_precedence`, `alias_priority`, and `alias_sensitivity` alias options.

Note that the more general HEADER_ADDITION -- in Unified Configuration, the `alias_header_addition` alias option -- provides an alternate way to add these and other header lines. Or for aliases defined in LDAP, see the `ldap_add_header` MTA option.

48.5.1.2.25 KEEP_DELIVERY, KEEP_READ

By default, the MTA strips delivery receipt and read receipt requests from messages posted to mailing lists. The KEEP_DELIVERY and KEEP_READ named parameters may be used to override this behavior, causing the MTA to retain any delivery receipt or read receipt requests, respectively, on messages posted to the list. The `value` specification is currently ignored and should always be `NONE`. Note that passing receipt requests through to mailing lists is quite dangerous; the default behavior of stripping such requests is *strongly* recommended.

In Unified Configuration, see the `alias_keep_delivery` and `alias_keep_read` alias options.

48.5.1.2.26 LIST_NAME

New in Messaging Server 7.4-0.01; RESTRICTED.

48.5.1.2.27 MODERATOR_ADDRESS, MODERATOR_LIST, MODERATOR_MAPPING, USERNAME_MODERATOR_LIST

The MODERATOR_* named parameters are used to establish a moderated mailing list. All postings to the list not originating from a moderator are sent to the list's moderator. The address of the moderator must be specified with the MODERATOR_ADDRESS named parameter. The moderator address determines where moderator mail is sent when someone other than the moderator posts. The value of that named parameter is the moderator's address. For example,

```
test-list: <IMTA_TABLE:test.dis, \
           [MODERATOR_ADDRESS] bob@domain.com
```

When there may be multiple moderator addresses (for instance, both robert@mail1.domain.com and bob@domain.com), use MODERATOR_LIST, USERNAME_MODERATOR_LIST, or MODERATOR_MAPPING to specify all addresses from which postings should be passed directly to the list and not sent to the list's moderator. MODERATOR_LIST specifies either the name of a file containing a list of moderator addresses, or an LDAP URL returning a list of moderator addresses. USERNAME_MODERATOR_LIST specifies either the name of a file containing a list of (possibly wildcarded) moderator usernames, or an LDAP URL returning a list of (possibly wildcarded) moderator usernames; note that usernames are generally only useful for messages submitted from the L channel or submitted with SASL authentication via SMTP (SMTP AUTH) since for messages submitted from other sources the username will simply be that of the account under which the submitting MTA process is running. Note that for messages submitted via SMTP with authentication (SMTP AUTH), the username that authenticated will be prefixed with the asterisk, *, character. For instance, to specify that only the user JDOE is the list moderator, whether submitting from the L channel or via SMTP (*e.g.*, from a POP or IMAP client that performs SASL SMTP authentication), the USERNAME_MODERATOR_LIST file would need to contain the entries:

```
JDOE
```

```
$*JDOE
```

where the first entry would match for messages submitted from the L channel and the second entry would match for messages submitted via SMTP AUTH. Note that as asterisk is normally a wildcard character, matching of only the exact literal asterisk character is specified by using the dollar character to quote the asterisk.

MODERATOR_MAPPING specifies the name of a mapping table used to verify whether or not an address is a moderator address.

If a MODERATOR_LIST or MODERATOR_MAPPING parameter is used, thereby specifying who may post directly to the list, then a MODERATOR_ADDRESS parameter should also be present to specify the address to which to send postings not from any moderator.

The use of the MODERATOR_ADDRESS parameter alone, without the MODERATOR_LIST parameter, is equivalent to using MODERATOR_ADDRESS and a MODERATOR_LIST consisting of just the one moderator address.

Unified Configuration has analogous alias options `alias_moderator_address`, `alias_moderator_list`, `alias_moderator_mapping`, and `alias_username_moderator_list`. Or for lists defined in LDAP, see the `mgrpMsgRejectAction` and `mgrpModerator` attributes, or more precisely whatever LDAP attributes are named by the `ldap_reject_action` and `ldap_moderator_url` MTA options.

48.5.1.2.28 NOSOLICIT (comma-separated list of strings)

New in MS 6.2. Set a solicitation keyword, or a list of solicitation keywords, that will not be allowed on postings to the list. Attempted postings that have such a keyword set will be rejected with "Solicitation check failure on SOLICIT=*keyword*" error text.

In Unified Configuration, see the `alias_nosolicit` alias option. Or for lists defined in LDAP, see the `ldap_nosolicit` MTA option.

48.5.1.2.29 OPTIN, OPTIN1, OPTIN2, OPTIN3, OPTIN4, OPTIN5, OPTIN6, OPTIN7, OPTIN8

Set optin values for spam filtering.

In Unified Configuration, see the `alias_optin*` alias options.

For aliases/lists defined in LDAP, see the `ldap_optinN` and `ldap_optoutN` MTA options.

48.5.1.2.30 ORIGINATOR_REPLY, NOORIGINATOR_REPLY

ORIGINATOR_REPLY is used to control whether or not the originator's address is added to any generated Reply-to: header. The `value` item should be the full file path specification for a world readable file, or a resolvable URL, containing the list of addresses that should never be added. (This is usually the mailing list itself.) The MTA will match the envelope From address against the addresses in the list; if no match occurs, the originator's address will be added to any generated Reply-to: header.

NOORIGINATOR_REPLY specifies that any generated Reply-to: header should contain only explicitly specified addresses. The `value` item is ignored. NOORIGINATOR_REPLY is the default.

In Unified Configuration, see the alias_originator_reply and alias_nooriginator_reply alias options.

48.5.1.2.31 PASSWORD

Specify a password, or a comma-separated list of passwords, that allow posting to the list. An attempted posting to the list must contain one of these values on an Approved: header line in order for the posting to be allowed. During mailing list expansion, the password value will be removed from the Approved: header line; indeed, if that is the only value on the Approved: header line, then the entire header line will be removed. See Password-protected mailing lists.

In Unified Configuration, see the alias_password alias option.

For aliases/lists defined in LDAP, see the ldap_auth_password MTA option.

48.5.1.2.32 PREFIX_TEXT, SUFFIX_TEXT

(New in MS 6.0.) Insert prefix or suffix text into messages as they undergo list expansion. Prior to Messaging Server 7.0 update 3, text could only be inserted into initial, TEXT/PLAIN parts; new in Messaging Server 7.0 update 3, text can be inserted into the first text part within a nested multipart (excluding multipart/alternative). The attribute values are given in UTF-8; this is then converted to match the charset of the part into which the text is being inserted.

In Unified Configuration, see the alias_prefix_text and alias_suffix_text alias options. Or for lists defined in LDAP, see the mgrpMsgPrefixText and mgrpMsgSuffixText attributes, or more precisely whatever attributes are named by the ldap_prefix_text and ldap_suffix_text MTA options. More generally, for adding prefix or suffix text to *any* message, not just postings to groups or lists, see the Sieve addprefix and addsuffix extensions.

48.5.1.2.33 PUBLIC, PRIVATE

The PUBLIC named parameter specifies that the associated alias is public and hence can appear in any constructed header lines. The value specification is currently ignored and should always be NONE. The PRIVATE named parameter specifies that the alias is private and should appear as an empty group construct in message headers. The value specification is used as the name for the group. Neither PUBLIC nor PRIVATE have any effect if the HEADER_EXPANSION named parameter is also specified. These named parameters correspond to the public and private options for entries in personal alias databases. PUBLIC is the default for entries in the system alias file and database.

Note that these parameters are only valid when headers are originally being constructed, as for instance for messages submitted via the L channel. These parameters are not relevant for incoming messages (such as incoming SMTP messages) for which the headers are already present in one form or another.

In Unified Configuration, see the alias_private and alias_public alias options.

48.5.1.2.34 RECEIVEDFOR, NORECEIVEDFOR, RECEIVEDFROM, NORECEIVEDFROM

These named parameters control features of what appears in the Received: header constructed when expanding the alias, and override normal channel receivedfor, noreceivedfor, receivedfrom, or noreceivedfrom channel option settings. The value specification is currently ignored and should always be NONE.

In Unified Configuration, see the alias_receivedfor, alias_noreceivedfor, alias_receivedfrom, and alias_noreceivedfrom alias options.

48.5.1.2.35 REPROCESS

The REPROCESS named parameter is used to request deferred expansion of the mailing list, where rather than expanding the mailing list "on line", the message should instead be enqueued to the reprocess channel; the reprocess channel can then perform the mailing list processing in a separate step. The value specification is currently ignored and should always be reprocess.

Use of this parameter defers much of the processing overhead of handling the message to the later step when the reprocess channel runs, rather than doing the processing as the message is initially accepted. This deferred processing can be especially helpful in cases such as incoming SMTP messages addressed to large mailing lists, where "on line" delays could lead to connection time outs.

Use of this parameter as in:

```
listname: </pmdf/table/listname.dis, [REPROCESS] reprocess
```

thus provides essentially identical functionality as defining a mailing list in two stages through the reprocess channel to obtain deferred expansion (the mailing list addresses aren't even expanded until the reprocess channel runs) such as:

```
listname:        listname-expand@reprocess
listname-expand: </pmdf/table/listname.dis
```

In Unified Configuration, the analogous alias option is alias_reprocess. Or for aliases defined in LDAP, see the mailDeferProcessing attribute, or more precisely whatever LDAP attribute is named by the ldap_reprocess MTA option.

48.5.1.2.36 SASL_AUTH_LIST, SASL_AUTH_MAPPING, SASL_CANT_LIST, SASL_CANT_MAPPING, SASL_MODERATOR_LIST, SASL_MODERATOR_MAPPING

These named parameters are analogues of the non-SASL named parameters, but with the additional requirement that an authenticated address be present in the message (whether that be a address literally authenticated via SMTP AUTH, or forced via, *e.g.*, an authrewrite or FROM_ACCESS effect).

In Unified Configuration, see the alias_sasl_* alias options.

48.5.1.2.37 SEQUENCE_PREFIX, SEQUENCE_SUFFIX, SEQUENCE_STRIP

The SEQUENCE_PREFIX and SEQUENCE_SUFFIX named parameters request that a sequence number be prepended or appended to the Subject: lines of messages posted to the list. The value item gives the full file path specification of a sequence number file. This file is read, incremented, and updated each time a message is posted to the list. The number read from the file is prepended, in the case of SEQUENCE_PREFIX, or appended, in the case of SEQUENCE_SUFFIX, to the message's Subject: header line. This mechanism provides a way of uniquely sequencing each message posted to a list so that recipients can more easily track postings and determine whether or not they have missed any.

By default, a response to a previously posted message (with a previous sequence number) retains the previous sequence number as well as adding a new sequence number to the subject line; the build up of sequence numbers shows the entire "thread" of the message in question. However, the SEQUENCE_STRIP named parameter can be used to request that only the highest numbered, *i.e.*, most recent, sequence number be retained on the subject line. The `value` item is currently ignored and should always be `NONE`.

Important note: To ensure that sequence numbers are only incremented for successful postings, a SEQUENCE_PREFIX or SEQUENCE_SUFFIX named parameter should always appear as the last named parameter; that is, if other named parameters are also being used, the SEQUENCE_* named parameter should appear at the end of the list of named parameters.

Sequence number files are binary files and must have the proper file attributes and access permissions in order to function correctly.

In Unified Configuration the analogous alias options are `alias_sequence_prefix`, `alias_sequence_suffix`, and `alias_sequence_strip`.

48.5.1.2.38 SINGLE

Force a separate message copy per recipient (per list member). Thus it can be considered a per-list analogue of the `single` channel option.

In Unified Configuration, its analogue is the `alias_single` alias option.

48.5.1.2.39 SPARE1,...,SPARE18

(New in Messaging Server 7.0 update 2) Analogous to the attributes named by the `ldap_spare_N` MTA options. In Unified Configuration, the analogous alias options are `alias_spare*`.

48.5.1.2.40 TAG

The TAG named parameter may be used to prefix specified text to the Subject: header of posted messages. The `value` item should be the string to be added. The string should not contain the vertical bar, `|`, character; prior to MS 6.3, the string should not have contained the space character. For instance,

```
schedule-list: <d1:[adam]schedule-list.dis, [TAG] Schedule posting -- , \
               [AUTH_LIST] d1:[adam]schedule-list.dis
```

will cause any postings to the list schedule-list to have a Subject: header that begins "`Schedule posting -- `" followed by whatever the original subject of the posting might have been. See the `ldap_add_tag` MTA option for setting an attribute name to provide analogous functionality for lists defined in LDAP, and in Unified Configuration, see also the `alias_tag` alias option.

48.5.1.2.41 TO

The TO named parameter specifies what to put on the To: header line of postings to the mailing list.

In Unified Configuration, see the `alias_to` alias option.

48.5.1.2.42 USERNAME

The USERNAME named parameter may be used to set the "username" that the MTA will consider to "own" these mailing list messages. The `imsimta qm` utility will allow that username to inspect and bounce messages in the queue resulting from expansion of this mailing list. The `value` item should be the username of the account to "own" the mailing list postings.

In Unified Configuration, see the `alias_username` alias option.

48.5.1.3 Alias file mailing list aliases

A mailing list address may be defined in the alias file or alias database by:

- Specifying a list of translation values for an alias, rather than simply a single translation value for the alias;
- Specifying an envelope From override address -- an [ENVELOPE_FROM] named parameter. (If no such envelope From override address is specified, then technically an alias with multiple translation values corresponds to a mail group -- an auto-forwarder forwarding to multiple recipients -- rather than, strictly speaking, a mail list.)

A mailing list address *`alias`* with associated mailing list file *`file-spec`* or LDAP URL *`ldap-url`* is specified in the alias file with an entry of, respectively, the general form

```
alias: <file-spec, optional-parameters
```

or

```
alias: <ldap-url, optional-parameters
```

Similar definitions may also be made in the alias database, (though of course omitting the colon, as just white space separates the alias from its definition in the alias database).

Mailing lists have many options associated with them; for a full discussion of mailing list aliases, see Mailing_lists, or for a discussion of the optional named parameter frequently used on mailing list alias definitions, see Alias file named parameter.

48.5.1.3.1 Alias file LDAP URL alias values

An alias value (that is, the right hand side of an alias definition) may be specified either as an address directly, *e.g.*, *`user@domain`*, or indirectly referencing an LDAP URL---specifically, an LDAP search URL---that returns one or more addresses. The format is

```
alias: <ldap-url
```

Note that this is just a special case of use of an LDAP URL for a mailing list definition, as mentioned in Alias file mailing list aliases: the LDAP query URL may be such as to return only one address rather than multiple addresses, and all of the optional mailing list parameters are omitted. Also note that if desiring to look up all incoming local channel addresses in an LDAP directory using some consistent addressing and URL format, it is generally simpler to configure such lookups globally using the `alias_urlN` options. However, the special case of looking up just a few individual local channel addresses in an LDAP directory via their own individual LDAP query URLs is of sufficient interest to warrant further discussion.

Standard LDAP URLs are used, typically with the host and port omitted; the host and part are instead typically specified with the `ldap_host` and `ldap_port` MTA options. (As of Messaging Server 7.0u4, the LDAP server host and port may instead be specified in the LDAP URL itself.) That is, the LDAP URL would typically be specified as

```
ldap:///dn[?attributes[?scope?filter]]
```

where the square bracket characters *[* and *]* shown above indicate optional portions of the URL. The *dn* is required and is a distinguished name specifying the search base. The optional *attributes*, *scope*, and *filter* portions of the URL further refine what information to return. For an alias, the desired *attributes* to specify returning would typically be the `mail` attribute (or some similar attribute). The *scope* may be any of `base` (the default), `one`, or `sub`. And the desired *filter* might be to request the return of any object that has the "objectclass=person" and "cn=John Smith" attribute-value pairs.

For instance, at a site domain.com with an LDAP server running on port 389 of the system ldap.domain.com, the MTA option file might have the lines

```
LDAP_HOST=ldap.domain.com
LDAP_PORT=389
```

set, and an alias file line might appear as:

```
John.Smith@domain.com: <ldap:///o=domain.com?mail?sub?(&(objectClass=person)(cn=John%20Smith))
```

The Unified Configuration equivalent would be:

```
msconfig> show ldap_host
role.mta.ldap_host = ldap.domain.com
msconfig> show ldap_port
role.mta.ldap_port = 389
msconfig> set alias:John\.Smith@domain\.com.alias_entry '<ldap:///o=domain.com?mail?sub?(&(objectClass=person)(cn=John%20Smith)'
msconfig> show alias:John\.Smith@domain\.com
role.alias:John\.Smith@domain\.com.alias_entry = <ldap:///o=domain.com?mail?sub?(&(objectClass=person)(cn=John%20Smith))
```

Note that certain characters, such as for instance space characters, should be encoded in URLs according to the URL character encoding rules of RFC 1738.

48.6 Alias database

The MTA's alias database, seldom used nowadays, provided an additional location for storing large numbers of aliases, supplementing the the alias options (Unified Configuration) or alias file (legacy configuration). Nowadays, with "Direct LDAP" configuration, the majority of aliases are normally stored in LDAP.

The `use_alias_database` MTA option controls whether or not the MTA makes use of the alias database. The default is 1, so the mere presence of the alias database activates the MTA's use of it as a source of aliases.

48.6.1 Using another alias source and the alias database

The alias database is a *supplement* to the alias options (Unified Configuration) or alias file (legacy configuration); it is *not* a *replacement* for them. If the alias database exists, the MTA uses *both* the usual alias source (the alias options in Unified Configuration, or the alias file in legacy configuration) *and* the alias database.

The alias database is consulted once each time the alias options/regular alias file is consulted. However, the alias database is checked *before* the alias options/regular alias file is consulted. In effect, the database acts as a sort of address rewriter that is invoked prior to using the regular alias source. Although duplicate entries are allowed in the database, it is undefined as to which of the duplicate entries will be returned when the database is accessed. Database entries are case insensitive.

The fact that limited recursion is allowed in the alias options/alias file makes the complete translation mechanism rather complex. For example, suppose that the alias file contains the entries,

```
A: C,J
B: D,K
D: G,H
E: I
```

and the alias database contains the entries,

```
D: E
C: B
F: D
```

Now suppose the address `A@local-host` was presented to the MTA. First A would be looked up in the alias database --- not found. Then A would be translated into C and J by the alias file. C would in turn be translated into B by the alias database while J would remain unchanged. B would then be translated into D and K by the alias file. D would then be translated into E by the alias database while K would remain unchanged. Finally, E would be translated into I by the alias file, and since I does not appear in the alias database the process would terminate. The final result is that A translates into the list I, J, K.

The easiest way to look at the translation process is to simply follow it step-by-step as illustrated below.

Initial look up	Data base	File	Data base	File	Data base	File	Data base	Result
A	A	C	B	D	E	I	I	I
				K	K	.	.	K
		J	J	.	.	.	.	J
B	B	D	E	I	I	.	.	I
		K	K	.	.	.	.	K
C	B	D	E	I	I	.	.	I
		K	K	.	.	.	.	K
D	E	I	I	.	.	.	.	I
E	E	I	I	.	.	.	.	I
F	D	G	G	.	.	.	.	G

```
H    H    .    .    .    .    H
```

Such complex use of the aliases facility is not encouraged and is presented for illustrative purposes only.

Note: In particular, for most normal goals any particular entry should appear in either an alias option/the alias file*or* the alias database, *not in both*!

48.6.2 Alias database format

In early versions of the MTA, the format of the alias database was an on-disk database, built using the `imsimta crdb` utility based upon a flat text file input. Alternatively, new in the 8.0 release, the MTA supports use of memcache for certain database/storage uses, including the alias database; see the `alias_database_url` MTA option.

Indeed, the alias database can be considered to have the same format as the optional domain database file. The allowed format of the flat text input file is normally:

`key value`

one entry per line, with the *`key`* beginning in column one, one or more white space (SP or TAB) characters, and then the *`value`* on the right hand side. The *`key`*, that is, the alias, is limited to 32 characters in length and can translate to a *`value`* string containing at most 80 characters unless either a "long" or a "huge" database is used. See the `-long_records` and `-huge_records` switches of the `imsimta crdb` utility for information on long databases, and on huge databases.

Length restrictions aside, alias database entries are handled in the same way as alias file entries and can be used in exactly the same way. Both multiple addresses and mailing list references are allowed. (Note that in long or huge alias databases, while the translation string may contain 256 or 1024 characters, respectively, any individual address appearing in the translation string is limited to at most 256 characters (252 characters in iMS 5.2 and earlier). The purpose of the longer translation string limit in such databases is to allow room for multiple comma-separated addresses, or for mailing list definitions that besides an "address", also contain additional named or positional parameters.)

The `comment_chars` MTA option controls which characters (by default exclamation point and semicolon) in column one of a line are considered to indicate a comment line. The left angle character may be used to read another file into the alias database text input file.

The alias database, like the alias file, must be world readable.

The MTA alias database is created from an input text file (*not* from the alias file---from a *different* input text file) using the `imsimta crdb` utility. The format of entries in the input file for `crdb` should be:

```
alias1   alias-value1
alias2   alias-value2
   .           .
   .           .
   .           .
```

Note that unlike the aliases file, the entries in the alias database source text file normally do not use a colon to separate the alias from its value.

Use the commands

```
# imsimta crdb input-file-spec IMTA_DATAROOT:db/aliasesdb-tmp
# imsimta renamedb IMTA_DATAROOT:db/aliasesdb-tmp IMTA_DATAROOT:db/aliasesdb
```

An intermediate, temporary database is used so as to minimize any window of time during which the database file is in an undefined state as it is being generated or regenerated. (Note that the "symbolic" name IMTA_ROOT can be used in such a command.)

Alternatively, a source file using colons, (that is, of the same format as the alias file), *e.g.*,

```
alias1:   alias-value1
alias2:   alias-value2
   .           .
   .           .
   .           .
```

may be used providing that the `-strip_colons` switch is used when building the database; *e.g.*, on UNIX:

```
# imsimta crdb -strip_colons input-file-spec IMTA_DATAROOT:db/aliasesdb-tmp
# imsimta renamedb IMTA_DATAROOT:db/aliasesdb-tmp IMTA_DATAROOT:db/aliasesdb
```

48.7 Subaddresses in aliases

As background on the purpose of subaddresses, the MTA interprets a + character in an address specially: in an address of the form `name+subaddress@domain` the MTA considers the portion of the mailbox after the plus character a *subaddress*. If the MTA tells the Message Store to "trust" that subaddress as a folder name for delivery purposes (see in particular the `fileinto` channel option, and the `deliveryflags` channel option), then Message Store too will treat the subaddress specially, delivering straight to that folder.[1]

When looking up an alias, the use of subaddresses introduces an extra factor. The MTA's "l" channel, or any channel marked with the `aliaslocal` channel option, will try looking up aliases.

Subaddresses in aliases are handled as follows. By default, (that is, with the `subaddressrelaxed` channel option explicitly or implicitly on the channel doing the alias lookup), the MTA first checks for an alias entry including the subaddress; if no such entry is found, the MTA next checks for an entry with an asterisk, *, in place of the subaddress. Finally, if there is no prior match, the MTA checks for an entry without any subaddress. For instance, alias entries

```
adam+privileged:   system
adam:              bob+*
carl+special:      system
carl+*:            david+*
carl:              eric
```

cause the MTA to translate adam+privileged to system, and adam to bob (note the special case handling whereby the MTA removes the trailing subaddress character, +, from the translation

value `bob+*` if there is in fact no subaddress), while adam+talklist, adam+general, *etc.*, will be translated to bob+talklist, bob+general, *etc.* carl+special will be translated to system and carl to eric, while carl+talklist, carl+general, *etc.*, will be translated to david+talklist, david+general, *etc.*

This handling of subaddresses during alias lookups is configurable; see the `subaddress*` channel options for configuration at the channel level, or for aliases stored in LDAP see the (new in MS 8.0) domain-level control available via the `ldap_domain_attr_subaddress` MTA option.

[1] Note that the `ims-ms` channel's support for folder delivery can be disabled via the FILEINTO `ims-ms`-channel-specific option.

48.8 Alias special formats

In general, alias "special formats" supported for aliases stored in the alias file are also supported for aliases stored via an `alias` group in Unified Configuration. But only some of the alias "special formats" supported for such aliases (those stored in the alias file) are also supported for aliases stored in LDAP.

In particular, for all forms of alias:

- an alias whose value begins with a leading colon has a special interpretation in regards to generation of notification messages;
- subaddress support is available;
- the `aliaswild` effect (perform a catchall * alias probe if no exact alias is found) is available (though use for LDAP aliases is strongly discouraged as for the case of LDAP aliases, use of the supported domain level attribute `mailDomainCatchallAddress` is recommended instead).

Furthermore, for aliases stored via an `alias` group in Unified Configuration:

- the `mail_off` MTA option feature is supported;
- the `post_off` MTA option feature is supported;

See the discussion of such special formats for aliases in the alias file for further details.

48.9 Alias header addition modifiers

The action of those alias options (Unified Configuration) or alias file named parameters (legacy configuration) that can add headers, *e.g.*, alias options such as `alias_deferred` or `alias_priority`, or similarly alias file named parameters `[DEFERRED]`, `[PRIORITY]`, *etc.*, can be modified by the special characters shown in Table of alias header addition modifiers, by appending the special character at the end of the value for the option or parameter.

Table 48.2 Alias header addition modifiers

Character	Description
	Insert if not already present; inserts as a Resent- if already present

*	Only insert if not already present
&	Insert if not already present; add to old field if already present
^	Delete any old field present; always insert the new field
\	Delete old field and don't insert a new one

48.10 Alias recursion and nested list definitions

Aliases may reference other aliases, in LDAP, in the alias database, in the alias file (legacy configuration), and in `alias` named group Unified Configuration option settings. To avoid possible infinite recursion reference loops, the MTA limits such nested or recursive references to a default maximum of ten levels (see the `max_alias_levels` MTA option).

If an alias references itself, either directly or indirectly, an alias loop results. The loop eventually terminates due to the level restriction, but the termination conditions may not produce consistent results in all cases.

The special case of an alias directly referencing itself is allowed and specially handled. For example, the alias file definition

`alias-name``: `*`alias-name, other-address-1, other-address-2, ...`

will expand `alias-name` into itself plus `other-address-1`, `other-address-2`, and so on. `alias-name` may in turn get expanded in some other way (the system alias database or personal alias database) but it will not be expanded further by the alias file.

Note that implicit domain name use (having the MTA itself insert its default domain name onto "bare" usernames) may affect the "matching" of alias names needed for the MTA's special code to trigger. In order for a "match" to be assured, either use a "bare" username on both the left and right hand sides, or use a fully-qualified address on both the left and right hand sides.

48.11 Alias restrictions

There are some important restrictions that should be observed when using aliases, especially aliases in the alias file or alias database.

48.11.1 General alias restrictions

1. The addresses in the alias file or alias database or stored in LDAP attributes such as `mail`, `mailAlternateAddress`, or `mailEquivalentAddress` should be formatted as pure RFC 822 addresses, *e.g.*, *`user@domain-name`*. Do not try to use DECnet or other routing conventions that you can get away with in the rewrite rules table. Not only may such things fail, they may not produce a visible error (see the next item). Source routes are the only exotica that are permitted.

2. Certain types of bogus addresses in a group or list alias would not, prior to MS 6.1, generate a "bad address" return message. Specifically, if, for a given address in the group or list, the system name was illegal or there was a syntax error in the address specification, then

the copy of the message to that address might be silently dropped and no one will be the wiser. In the case of mailing lists defined in the alias file or alias database, if the mailing list membership file associated with an alias does not exist, then mail to the list itself may be dropped. However, errors in the mailbox part of the address (e.g., "no such user") would be handled correctly. As of MS 6.1, there is enhanced handling for such cases. Errors in e-mail addresses in group definitions (but not errors in LDAP DNs or LDAP URLs, when group members are referenced via LDAP DN or LDAP URL), but where at least one apparently valid address is in the group, will be reported to (the rest of) the group; in the list case, the error will be reported to the list's notification address. Note that errors in LDAP DN or LDAP URL, when group members are defined/referenced via such, will cause expansion of the group to abort. However, as of 7.0.5, errors in LDAP DN or LDAP URL during group access checking (during expansion of the group allowed to post to the group) will be ignored (and processing of the group access check will continue); previously such errors halted the expansion process for the access group. System managers should take care to test each list they set up to insure that all the recipient addresses are correct. The `imta test -rewrite -check_expansions` utility provides a way to do such checking of syntactic correctness of list definitions and list membership addresses. Groups and lists should be checked periodically and also whenever extensive changes are made.

3. Aliases in the alias file can contain up to 60 characters. Aliases in the database can contain up to 32 characters in a short database, up to 80 characters in a long database, and up to 256 characters (252 characters in iMS 5.2 and earlier) in a huge database. In the alias file, the addresses to which aliases translate can contain up to 256 characters (252 characters in iMS 5.2 and earlier). In the case of a short database, the translation value can contain up to 80 characters; in the case of a long database the translation value can contain up to 256 characters; in the case of a huge database the translation value can contain up to 1024 characters. In some cases failing to observe length restrictions may lead to addresses being silently dropped from lists.

4. The LDAP URL template value to which a `alias_urlN` MTA is set is limited to 256 characters (252 characters in iMS 5.2 and earlier) before substitutions; the substitutions may insert additional material and the length after such substitutions is limited to 1024 characters. Note that the substitution of "known" attributes when asterisk, `*`, is specified as the attribute-to-return is not considered as part of the regular substitution; this substitution is performed at a later step and the length after this "known" attributes substitution is limited to 4096 characters.

48.11.2 Additional LDAP alias restrictions

1. For performance reasons, the MTA normally caches the results of LDAP queries. Also, the LDAP server itself normally does some caching of searches. So changes to an LDAP alias will not always be "immediately" apparent to already running MTA processes.

48.11.3 Additional alias file (or database) restrictions

1. The MTA reads the alias file only as each program using the MTA initializes itself. This means that if you are using a permanently resident server (such as the SMTP server) you should be sure to stop and restart the server each time the alias file or any of the files it includes is changed -- first recompiling the MTA configuration, if you are using a compiled configuration (since a compiled configuration includes the alias file). (The `imsimta restart` utility provides a simple way to restart any such MTA detached processes.) On the other hand, mailing list membership files referenced by the alias file are read and reread as needed, so servers need not be restarted when one of these files is changed.

2. The alias file is always read into memory in its entirety each time the MTA is used. All files included by the primary alias file are also loaded into memory. (Mailing list membership files are not loaded into memory.) The use of a huge alias file can eat up lots of memory. Liberal use of the mailing list membership reference operator, <, to reference long lists is recommended. Long lists of addresses coded directly into the alias file or any files it includes should be avoided. Use of an alias database for large numbers of aliases is also recommended.

48.12 Address reversal

After address rewriting via the MTA's rewrite rules, header From: addresses and other backwards-pointing addresses and forwards-pointing header addresses normally receive one additional processing step.[1] This additional processing step is referred to as *address reversal*. Another term used is *address canonicalization*, since address reversal is most commonly used to change possible alternate address forms into a single, canonical form. Address reversal can be performed via LDAP lookups, and/or via use of a reverse database and/or REVERSE mapping. Note that an LDAP lookup, if specified via the `reverse_url` MTA option, is performed prior to checking the reverse database and/or REVERSE mapping.

Special handling of subaddresses is available during address reversal. And special handling of what might be termed address "decorations", namely RFC 822 comment strings and personal names, is also available.

New in 8.0, address reversal can be made sensitive to exactly which header field (*e.g.*, From: *vs.* Sender:, *etc.*) is being processed by setting a special bit in the `use_reverse_database` MTA option which will cause inclusion of the header field name in REVERSE mapping table probes.

The primary use of address reversal is to substitute a generic, standardized address for internal or host-specific addresses. Address reversal is a particularly powerful tool when used in conjunction with aliases.

[1] Address reversal processing *can* be restricted in various ways. Address reversal can be restricted to only backwards pointing addresses if bit 2/value 4 in the MTA option `use_reverse_database` is cleared. Application of address reversal processing to envelope From address can be disabled using the `reverse_envelope` MTA option. The `noreverse` channel option can disable address reversal from being performed during enqueues to particular destination channels. However, in modern MTA configurations using LDAP-based aliases, a great many functions are critically dependent upon the MTA performing its LDAP lookup address reversal; before considering any restrictions upon normal address reversal, consider carefully the discussion of Intended side effects of LDAP address reversal.

48.12.1 LDAP lookups for address reversal

If the `reverse_url` MTA option has been set, then each address (other than envelope To addresses) passing through the MTA will be checked against the result of an LDAP query constructed as specified by the `reverse_url` option (querying the LDAP server at the port specified by the `ugldaphost` and `ugldapport` options, which may be overridden by the MTA-specific `ldap_host` and `ldap_port` MTA options). If the LDAP query succeeds and returns a value, that value will be substituted in place of the original address.

For the `reverse_url` MTA option, standard LDAP URLs as per RFC 2255 must be used, except with the host and port normally omitted, as the host and port are normally instead specified via the base or MTA-specific option settings mentioned above. That is, the LDAP URL is typically specified along the lines of:

`ldap:///dn[?attributes[?scope?filter]]`

where the square bracket characters `[` and `]` shown above indicate optional portions of the URL. The `dn` is required and is a distinguished name specifying the search base; it might correspond to the organization's top level in the Directory Information Tree, or it might correspond to a subset of the organization, based upon the domain name in the original address. The optional `attributes`, `scope`, and `filter` portions of the URL further refine what information to return. For address reversal, the desired `attributes` to specify returning would typically be the `mail` attribute (or some similar attribute). The `scope` may be any of `base` (the default), `one`, or `sub`. And the desired `filter` would typically be based upon the mailbox (local portion) of the incoming addresses.

Certain substitution sequences may be used to construct the LDAP search URL; see Table of LDAP URL substitution sequences in LDAP URL substitution sequences for details.

48.12.1.1 Intended side effects of LDAP address reversal

Doing a `reverse_url` lookup actually has effects beyond pure address reversal. (And this is why a `reverse_url` lookup normally uses the $R substitution for a filter that searches for a given address as the canonical `mail` attribute, as well as searching for the attributes that would actually require address reversal: one wants the `reverse_url` lookup to find an entry even for an address that is already in canonical form.) The recommended setting for the `reverse_url` MTA option makes use of the LDAP URL `$N` substitution to specify an extensive list of attributes to be fetched; so `reverse_url` lookups also normally make use of (or at least fetch and cache) the attributes named by the MTA options:

- `ldap_primary_address` (normally `mail`),
- `ldap_alias_addresses` (normally `mailAlternateAddress`),
- `ldap_equivalence_addresses` (normally `mailEquivalentAddress`),
- `ldap_personal_name`,
- `ldap_capture`,
- `ldap_recipientlimit`,
- `ldap_recipientlimit`,
- `ldap_sourceblocklimit`,
- `ldap_preferred_language` (normally `preferredLanguage`),
- `ldap_source_conversion_tag` (as of MS 6.2),
- `ldap_blocklimit` (as of MS 6.3) (normally `mailMsgMaxBlocks`),
- `ldap_source_channel` (as of MS 6.3),
- `ldap_source_optin`*`N`* (as of MS 6.3),
- `ldap_preferred_country` (as of MS 6.3), and
- `ldap_spare_`*`N`* (as of MS 6.3-0.15).

The recommended setting for the `reverse_url` MTA option also uses the $V substitution for locating the domain in which the sending user address is located. Because of this implied lookup of the sending user's domain, the MTA's message processing can then also make use of per-sending-domain LDAP attributes including those named by the MTA options:

- `ldap_domain_attr_report_address` (normally `mailDomainReportAddress`),
- `ldap_domain_attr_blocklimit` (normally `mailDomainMsgMaxBlocks`),
- `ldap_domain_attr_recipientlimit`,
- `ldap_domain_attr_recipientcutoff`,

- ldap_domain_attr_source_conversion_tag,
- ldap_domain_attr_sourceblocklimit, and
- ldap_domain_attr_source_channel.

Note: In actual operation, the MTA and domain map caching of domain lookup results means that the domain attributes are often available from a cache, without need for an additional actual LDAP query at this point. That is, while the reverse_url caused fetching of the sending user's personal LDAP attributes is relatively likely to involve a query all the way to the backend LDAP server, the "fetching" of the sending user domain LDAP attributes is often short-circuited, with the domain attributes cached due to a prior lookup.

So the list of potential side-effects resulting from address reversal, when it is properly configured to fetch these various per-sending-user and per-sending-domain LDAP attributes, is quite extensive, including effects on message size limits, message recipient limits, conversion tags, message capture, spam/virus filter processing opt-in, archiving opt-in, source channel "switching", and (if a notification message must be generated), notification language preference, non-return-of-content in notification messages, and per-domain postmaster address selection, *etc.*

New in the 8.0 release, bits of the use_reverse_database MTA option can be set to disable use of either the envelope From (MAIL FROM) address, or the authenticated sender address, for purposes of source-based message size or recipient limit settings, as well as capture actions.

48.12.2 Reverse database

During the address reversal stage of address processing (which note occurs after rewriting via the MTA's rewrite rules), first any reverse_url LDAP-based address reversal is performed, as discussed in LDAP lookups for address reversal. After any such LDAP-based address reversal, then header From: addresses and other backwards-pointing addresses and forwards-pointing header addresses may receive yet another address reversal processing step which makes use of the address reversal database and REVERSE mapping.[9]

The relevance of the address reversal database is quite limited nowadays, as nowadays the sorts of changes it used to be used to make are instead performed via LDAP lookups for address reversal. However, the process of its use will be described below.

When use of the address reversal database has been configured, the MTA uses each address specification, with any routing address but less any personal name fields, as an index key to the special database called the *reverse database*.[10]

Note that the format of probes to the reverse database (and to the REVERSE mapping table) can be affected by the use_reverse_database MTA option.

If the address is found in the reverse database, the corresponding right hand side from the database is substituted for the address.

If the address is not found, then an attempt is made to locate a mapping table named REVERSE. No substitution is made and rewriting terminates normally if the table does not exist or no entries from the table match. But if the address does match a REVERSE mapping entry, then the result of the mapping is tested. The resulting string will replace the address if the entry specifies a $Y; a $N will discard the result of the mapping. If the mapping entry specifies $D in addition to $Y, the resulting string will be run through the reversal database once more, and if a match occurs the template from the database will replace the mapping result (and hence the address).

Note that you do not need to have an address reversal database in order to use a REVERSE mapping. That is, you can use a REVERSE mapping without having an address reversal database. And, of course, the reverse is true: you do not need to have a REVERSE mapping to use an address reversal database. Prior to the implementation of LDAP lookups for address reversal, this back-and-forth consultation of reverse database, REVERSE mapping, optionally reverse database again, was intended to allow convenient use and combination of the strengths of each facility: the reverse database's ability to make changes exactly targeted to a single address, and the REVERSE mapping's ability to make generic, pattern-based changes to addresses. Nowadays, typically changes targeted to a single address are made via the LDAP entry for the user with that address, superceding former uses of the address reversal database, and even the REVERSE mapping table tends to get used only for special circumstances.

Entries in the address reversal database consist of two e-mail addresses: the address to match against and the address with which to replace a match. The database is usually created by preparing a text file and processing it with the `imsimta crdb` utility.

For example, suppose a site wishes to replace all reverse pointing addresses of the form *user*`@domain.com` with an address of the form *first.last*`@domain.com` where *first.last* is formed from the first (given) and last (family) names of the owner of the account `user`. This will then cause the outside world to only see addresses of the form *first.last*`@domain.com` and never see internal addresses. A text file `reverse.txt` containing lines of the form

```
user1@domain.com  first1.last1@domain.com
user2@domain.com  first2.last2@domain.com
     .                    .     .                    .     .
```

could then be set up and converted to an address reversal database with the UNIX commands,

```
# imsimta crdb reverse.txt IMTA_DATAROOT:db/reversedb-tmp
# imsimta renamedb IMTA_DATAROOT:db/reversedb-tmp IMTA_DATAROOT:db/reversedb
```

An intermediate, temporary database is used so as to minimize any window of time during which the database file is in an undefined state as it is being generated or regenerated.

As another example, suppose that the internal addresses at domain.com are actually of the form user@hostX.domain.com, but, fortunately, the username space is such that user@hosta.domain.com and user@hostb.domain.com specify the same person for all hosts at domain.com. Then, rather than have to enter all possible user and host combinations in the address reversal database, the following, very simple REVERSE mapping may be used in conjunction with the address reversal database:

```
REVERSE

  *@*.domain.com            $0@domain.com$Y$D
```

This mapping maps addresses of the form *user*`@`*host*`.domain.com` to *user*`@domain.com`. The `$D` flag causes the address reversal database to then be consulted. The address reversal database should contain entries of the form shown in the previous example.

Although there is no address reversal database or REVERSE mapping table by default, their use for address reversal is activated automatically once such an address reversal database (depending upon the `use_reverse_database` MTA option value) or REVERSE mapping exists.

[9] Address reversal processing can be restricted to only backwards pointing addresses if the third bit, bit 2, in the MTA option `use_reverse_database` is cleared. Application of this processing to envelope From address can be disabled using the `reverse_envelope` MTA option. The `noreverse` channel option can disable address reversal from being performed during enqueues to particular destination channels. However, note that at typical Messaging Server sites such options should **not** be used -- address reversal should **not** be disabled -- as a wide range of functionality, including functionality that might not at first glance seem to be address reversal related, depends critically upon normal address reversal processing.

[10] Depending upon the setting of the MTA option `use_text_databases`, the reverse "database" is either stored and accessed as an on-disk database (the default), or as an in-memory structure constructed (during configuration compilation or MTA initialization) from an on-disk flat text file. Or new in MS 8.0, the reverse "database" can be stored in memcache; see the `reverse_database_url` MTA option. The on-disk database, if that is what is being used, used to be located via the (now deleted) `imta_reverse_database` MTA Tailor option; nowadays its location is simply `IMTA_DATAROOT:db/reversedb`. This database file is built with the `imsimta crdb` utility from some site-supplied source text file, and the database itself must be world-readable for proper operation. If an in-memory database structure is instead being used, then when the MTA configuration is compiled (or at MTA process initialization time, if a compiled configuration is not in use) the MTA reads the file `IMTA_TABLE:reverse.txt` (formerly relocatable via the `imta_reverse_data` MTA Tailor option) and compiles it into an in-memory structure. This file should be world-readable for proper operation. Use of an in-memory "database" is normally recommended (for reasons of performance and reliability); however, do note that use of this in-memory "database" does require recompiling and reloading the configuration to get changes to the "database" (changes to the source text file) incorporated into the active configuration.

48.12.3 REVERSE mapping table

During the address reversal stage of address processing (which note occurs after rewriting via the MTA's rewrite rules), first any `reverse_url` LDAP-based address reversal is performed, as discussed in LDAP lookups for address reversal. After any such LDAP-based address reversal, then header From: addresses and other backwards-pointing addresses and forwards-pointing header addresses may receive yet another address reversal processing step which makes use of the address reversal database and REVERSE mapping table.[9]

Nowadays, the reverse database is very little used, having mostly been superceded for general address reversal purposes by the use of LDAP lookups for address reversal; the REVERSE mapping table is also seldom needed or used for general address reversal purposes nowadays, but does sometimes get used under special circumstances. Thus while in principle the reverse database and REVERSE mapping can apply in an alternating fashion -- see the discussion of the reverse database for details -- this discussion of the REVERSE mapping table will focus on the REVERSE mapping table alone or as an adjust to LDAP lookups for address reversal. (Note that you do not need to have an address reversal database in order to use a REVERSE mapping table. That is, you can use a REVERSE mapping without having an address reversal database. And, of course, the reverse is true: you do not need to have a REVERSE mapping to use an address reversal database.)

After the other address reversal mechanisms have applied (LDAP lookups for address reversal and the reverse database), the MTA checks for whether a REVERSE mapping table exists. If a REVERSE mapping table does exist, the MTA will probe the mapping table with, by default, simply the current (as already reversed by other mechanisms) address. Note that the exact format of probes to the REVERSE mapping table (and reverse database) can be affected by the `use_reverse_database` MTA option, which can cause inclusion of channel

names in the probe and as of MS 8.0, even the header field from which the address was taken. And as of MS 7.0.5, probes to the REVERSE mapping table can also be affected by the `include_conversiontag` MTA option.

If the address probe matches a REVERSE mapping entry, the result of the mapping is tested. The resulting string will replace the address if the entry specifies a $Y; a $N will discard the result of the mapping. (If the mapping entry specifies $D in addition to $Y, the resulting string will be run through the reversal database once more, and if a match occurs the template from the database will replace the mapping result, and hence the address.)

New in MS 7.0u1, the output (template) of the REVERSE mapping is interpreted as a series of addresses separated by commas. As always, the first address becomes the reversal result if the entry sets the $Y flag; but new in MS 7.0u1, if the $H flag is also set and the input to the REVERSE mapping was the MAIL FROM (envelope From) address, then the second address in the comma-separated list becomes the default postmaster address for this sender.

See Table of REVERSE mapping table flags for a description of additional flags available for the REVERSE mapping, and Mapping template substitutions and metacharacters for a list of general mapping table substitution sequences and metacharacters.

Table 48.3 REVERSE mapping table flags

Flags	Description
$Y	Use output as new address
$N	Address remains unchanged
$D	Run output through the reversal database
$A	Add pattern as reverse database entry
$F	Add pattern as forward database entry
$H	(New in MS 7.0u1) If the address input to the REVERSE mapping is the envelope From (MAIL FROM address for SMTP submissions) then use the second address (out of the list of comma-separated addresses in output) as the default postmaster address for this sender
$I	(New in MS 7.0) Consider address to have matched for this reversing purpose
$G	(New in MS 7.0) Consider address not to have matched for this reversing purpose
Flag comparisons	Description
$:B	Match only header (body) addresses
$;B	Match only if not a header (body) address
$:C	(New in MS 7.0u1) Match only if this probe is attempting to produce a canonical address for MTA use in comparison operations
$;C	(New in MS 7.0u1) Match only if this probe is not attempting to produce a canonical address for MTA use in comparison operations
$:D	(New in 8.0.1.3) Match only if this probe is attempting to produce a downgrade address for MTA use in EAI downgrade operations
$;D	(New in 8.0.1.3) Match only if this probe is not attempting to produce a downgrade address for MTA use in EAI downgrade operations
$:E	Match only envelope addresses

$;E	Match only if not an envelope address
$:F	Match only forward pointing addresses
$;F	Match only if not a forward pointing address
$:M	(New in MS 7.0u1) Match only if this probe is attempting to produce a reversed MAIL FROM address in address validity checks when the canonical form has not been selected
$:R	Match only backwards pointing addresses
$;R	Match only if not a backward pointing address
$:I	Match only message-ids; see Internal host names in Received: and Message-Id: header lines for an example
$;I	Match only if not a message-id

Note that if you have a compiled configuration, then you must recompile and reload your configuration in order for changes to the REVERSE mapping table (or indeed changes to any mapping table) to take effect.

[9] Address reversal processing can be restricted to only backwards pointing addresses if the third bit, bit 2, in the MTA option use_reverse_database is cleared. Application of this processing to envelope From address can be disabled using the reverse_envelope MTA option. The noreverse channel option can disable address reversal from being performed during enqueues to particular destination channels. However, note that at typical Messaging Server sites such options should **not** be used -- address reversal should **not** be disabled -- as a wide range of functionality, including functionality that might not at first glance seem to be address reversal related, depends critically upon normal address reversal processing.

48.12.4 Subaddresses and address reversal

New in 7.0.5, the MTA's address reversal logic has been extensively redesigned to improve the handling of subaddresses. Previously the presence of a subaddress would prevent address reversal from occurring. (This long-standing behavior was a remnant of the past when if a user was sophisticated enough to put on a subaddress, one could presume that the user was sophisticated enough to have already specified the exact address that they wanted to send from---so altering such an address wouldn't be necessary and indeed would be dubious. However, nowadays many other behaviors and side-effects are triggered via address reversal so matching regardless of subaddress is typically desirable, and further the old assumption that reversal is no longer desired in such cases is no longer as likely.)

As of 7.0.5, the default behavior will be to attempt to match the address with or without the subaddress. If there's a match, then the subaddress will be transferred to any rewritten address. This behavior may be explicitly specified by setting the subaddressrelaxed channel option (the default) on the source channel. subaddresswild, if set, will match against subaddresses but disables transfer of the subaddress to the rewritten address. Finally, subaddressexact disables special subaddress handling during the reversal process.

48.12.5 RFC 822 comment strings and personal name modification

While not strictly an issue of address reversal, a related topic is that of modifying the RFC 822 phrase (more commonly referred to as a "personal name") or RFC 822 comment that may appear associated with an address in a header line. Phrases appear, possibly quoted

depending on the contents, before a format address specification (where the address specification is enclosed in angle brackets); comments are text appearing within parentheses. For instance, in

```
"John Q. Doe" <John.Doe@acme.com> (V.P. of Widget Development)
```

the `"John Q. Doe"` is an RFC 822 phrase, that is, personal name, and the `(V.P. of Widget Development)` is a comment.

The MTA only interprets the contents of header lines when necessary. However, all registered headers containing addresses must be parsed in order to rewrite and eliminate shortform addresses and otherwise convert them to legal addresses. During this process personal names (strings preceding angle-bracket-delimited addresses) and comment strings (strings enclosed in parentheses) are extracted and may optionally be modified or excluded when the header line is rebuilt.

In direct LDAP mode, the LDAP attribute named by the `ldap_personal_name` MTA option if present, will be used as the personal name in an address. (Note that any eight bit characters in the value will be assumed to be UTF-8 and be encoded as such.) The MTA will quote, if appropriate, the personal name value obtained from LDAP, according to RFC 822 rules for such quoting; implemented as of MS 6.2 for normal messages, or as of MS 6.2p6 when generating messages such as vacation messages.

There are a number of channel options controlling the MTA's optional removal or modification of personal names and comment strings. This section will talk in detail about the `personalmap`, `sourcepersonalmap`, `commentmap`, and `sourcecommentmap` channel options used for triggering general, mapping table based modifications to such strings; see the `personal*` channel options and the `comment*` channel options for a complete list of additional options including channel options appropriate when you simply wish to strip off all such strings.

When the `personalmap` keyword is present on a destination channel, then the MTA will run any personal names appearing associated with addresses in addressing header lines (*e.g.*,, To:, Cc:, *etc.*, sorts of header lines) and message id header lines through a `PERSONAL_NAMES` mapping table, if such a table exists. This is performed after any address reversal. If no such table exists, then `personalmap` is equivalent to `personalstrip`; see the `personalstrip` channel option. The `sourcepersonalmap` keyword acts analogously for header lines on incoming messages; that is, it applies to source channels. The probe to the `PERSONAL_NAMES` mapping table by default takes the form

`personal-name|address`

or if (new in MS 6.1) the MTA option `use_personal_names=1` is set, then the probe takes the form

`source-channel|destination-channel|personal-name|address`

If the probe matches a mapping entry, the result of the mapping is tested. The resulting string will replace the personal name if the entry specifies a `$Y`; a `$N` will discard the result of the mapping. Note that any eight bit values in the result will be assumed to be in the UTF-8 charset, and encoded as such. As of MS 6.2p3, the MTA will quote the result of the mapping, if appropriate according to the personal name quoting rules specified in RFC 822. See Table of PERSONAL_NAMES mapping table flags for a description of additional flags available for the `PERSONAL_NAMES` mapping, and Mapping template substitutions and metacharacters for a list of general mapping table substitution sequences and metacharacters.

Table 48.4 PERSONAL_NAMES mapping table flags

Flags	Description
$Y	Use output as new personal name
$N	Personal name remains unchanged
Flag comparisons	Description
$:F	Match only forward pointing addresses
$;F	Match only if not a forward pointing address
$:R	Match only backwards pointing addresses
$;R	Match only if not a backwards pointing address
$:I	Match only message-ids
$;I	Match only if not a message-id

An example of a PERSONAL_NAMES mapping table, used in conjunction with personalmap on an appropriate channel, to cause addition of the cn LDAP attribute's value as a personal name only when no personal name was already present on an address would be:

```
PERSONAL_NAMES

! If a personal name is already present, use it as-is
!
  %*|*    $N
!
! When no personal name is already present, look up the
! domain in the address and determine whether it is one
! of "ours":
!
  |*@*   $CBDN|$0@$1|$}$1,_base_dn_{
!
! If the domain was found, we're now probing with
! BDN|address|base-DN-for-users
!
  BDN|*|*   \
$C$]ldap:///$1?cn?sub?(|(mail=$=$0$_)(mailEquivalentAddress=$=$0$_))[$Y$E
```

When the commentmap channel option is present on a destination channel, then the MTA will run any comment strings appearing associated with addresses in addressing header lines (*e.g.*,, To:, Cc:, *etc.*, sorts of header lines) and message id header lines through a COMMENT_STRINGS mapping table, if such a table exists. This is performed after any address reversal. If no such table exists, then commentmap is equivalent to commentstrip; see the comment* channel options. The sourcecommentmap channnel option acts analogously for header lines on incoming messages; that is, it applies to source channels. The probe to the COMMENT_STRINGS mapping table by default takes the form

comment-string|*address*

or if (new in MS 6.1) the MTA option use_comment_strings is set, then the probe takes the form

source-channel|*destination-channel*|*comment-string*|*address*

If the probe matches a mapping entry, the result of the mapping is tested. The resulting string (which should include enclosing parentheses) will replace the comment string if the entry specifies a $Y; a $N will discard the result of the mapping. See Table of COMMENT_STRINGS mapping flags for a description of additional flags available for the COMMENT_STRINGS mapping, and Mapping template substitutions and metacharacters for a list of general mapping table substitution sequences and metacharacters.

Table 48.5 COMMENT_STRINGS mapping table flags

Flags	Description
$Y	Use output as new comment string
$N	Comment string remains unchanged
Flag comparisons	Description
$:F	Match only forward pointing addresses
$:R	Match only backwards pointing addresses
$:I	Match only message-ids

When thinking about personal names and comment strings in address header lines, note that as of 7.5 the MTA supports private modifiers to the Sieve "address" test, ":display" and ":comment", to access the personal name and comment string, respectively.

48.13 Forwarding mail

The term *alias* often encompasses two separate types of functionality: address routing (which inherently relates specifically to envelope To addresses), and cosmetic changes to other instances of addresses (envelope From addresses, and header addresses). The cosmetic changes of address reversal do not apply per se to envelope To addresses. Rather, envelope To addresses are continuously rewritten and modified as messages proceed through the mail system. The entire goal of mail routing is to convert envelope To addresses to increasingly system and mailbox-specific formats. The canonicalization functions of address reversal are entirely inappropriate for envelope To addresses.

In addition to the transformations of domain names available via rewrite rules and domain aliases, which are generally (though not necessarily) applied to all addresses in the domain, including instances of envelope To addresses, envelope To addresses may also be modified on a per-user basis via one or more mechanisms of mail forwarding.

The MTA provides several mechanisms for forwarding mail. The method appropriate to a task at hand depends upon the scope of the forwarding:

- *Forwarding mail for selected users.* To forward mail for selected users, it is best to use aliases. You may also use aliases to accept mail for a non-existent user and forward it on to one or more real users. See Forwarding via user LDAP attributes, and alias options.
- *Forwarding mail to a list of users.* Aliases are also used to create mailing lists.
- *Forwarding mail for selected users in other than the local domain.* To forward mail for selected users in an arbitrary domain (a domain other than the local channel name), the best approach may depend on how the users are provisioned. For users provisioned via alias options, use of a rewrite rule matching the domain to the local channel and alias lookups

that include the domain name and that have a fall-through entry (see the `alias_domains` MTA option) may be appropriate. For users provisioned in LDAP, in the general case, modifying those users' LDAP entries to have appropriate LDAP attributes for forwarding is most explicit.

- *Pattern-matching the users for forwarding.* In the special case where a set of users whose mail is to be forwarded can be detected via simple string pattern matching, and where the forwarding to be performed requires only a simple string transformation, use of a domain catchall mapping on an LDAP-provisioned domain may be convenient; see the `ldap_domain_attr_catchall_mapping` MTA option.

- *Forwarding all mail for a given host to another host.* In this case there are several approaches. The most efficient method requires that you be able to blindly change `user@old-host` into `user@new-host` without any conflict in user names; *i.e.,* not have to worry that the username "`user`" on old-host conflicts with a different person on `new-host` who has the same username. When this is the case, simple MTA rewrite rules may be used. The less efficient, but just as effective, approaches involve using either a `FORWARD` mapping table, forward database, or alias lookups. Or for domains provisioned in LDAP, in some cases use of domain-level LDAP attributes may be appropriate: see the `ldap_domain_attr_smarthost` MTA option (LDAP attribute `mailRoutingSmartHost`) and `ldap_domain_attr_routing_hosts` MTA option (LDAP attribute `mailRoutingHosts`).

- *Complicated rule-based forwarding.* For performing complicated, rule-based forwarding, use of a Sieve filter to perform Sieve "`redirect`" actions allows for great flexibility; such a Sieve filter may be configured at various levels, including domain-level or user-level.

The MTA's forward database and/or `FORWARD` mapping table, and domain catchall mapping tables (see the `ldap_domain_attr_catchall_mapping` MTA option) may be used for special sorts of forwarding purposes, such as pattern based forwarding, source-specific forwarding, or "autoregistration" of addresses. Note that the forward database and `FORWARD` mapping table, as well as domain catchall mappings, are intended for use primarily for these *special* sorts of address forwarding; most sorts of address forwarding, however, are better performed using one of the MTA's other forwarding mechanisms.

48.13.1 Forwarding via user LDAP attributes

To forward the mail of a user provisioned in LDAP, the most straightforward approach is to set the value `forward` as a value of the user's `mailDeliveryOption` LDAP attribute, and then set one or more `mailForwardingAddress` LDAP attributes on the user entry with each having a value consisting of an address to which to forward the user's mail. (Note that the mentioned value "`forward`"and these mentioned LDAP attributes are configurable via MTA options: see the `delivery_options`, `ldap_delivery_option`, and `ldap_forwarding_address` MTA options, respectively.)

Note that forwarding a user's mail, and delivering the mail locally, are not mutually exclusive options: a user may have multiple values of `mailDeliveryOption`.

The questions of whether or not forwarded messages should be subject to "carryover" Sieve scripts and/or "opt in" to spam/virus filter package processing are controllable via the `sieve_user_carryoveroptin_user_carryover` MTA options.

48.13.2 FORWARD mapping table

The FORWARD mapping table provides functionality of pattern-based forwarding (analogous to the way that the REVERSE mapping table provides pattern-based changes to non-routing addresses), and the FORWARD mapping table also provides a mechanism for source specific forwarding. If a FORWARD mapping table exists, it is applied to each envelope To address. The probe of the FORWARD mapping table by default consists simply of the current envelope To address:

envelope-to

But bits of the use_forward_database MTA option and include_conversiontag MTA option control inclusion of additional fields in the probe. Bit 4 (value 16) of the use_forward_database MTA option controls including the *source-channel* and *from-address* in the probe; bit 6 (value 64) of use_forward_database controls including the current *destination-channel* in the probe; new in MS 6.3, enabling bit 2 (value 4) of the include_conversiontag MTA option causes any current conversion tags on the message to be included in a comma-separated list clause in the probe. With these additional fields enabled, the probe has the form

source-channel|*from-address*|*destination-channel*|*tag-list*|*envelope-to*

New in MS 8.0, the include_mtpriority MTA option and include_spares2 MTA option control, respectively, the inclusion of MT-PRIORITY and expected message size, and LDAP "spare" attribute values associated with the sender address, in the probe. Also new in MS 8.0 are new bits of the use_forward_database MTA option controlling inclusion of the initial form and intermediate form of the recipient address, and the authenticated sender address, in the probe. With all these options enabled as well as the previously discussed options, the probe has the form:

src-chan|*from-addr*|*dst-chan*|*auth-sender*|*tag-list*|*s1*|*s2*|*s3*|*s4*|*s5*|*s6*|*mtpriority*|*expected-size*|*initial-to*|*inter-to*|*envelope-to*

New in MS 8.0.2.2, LDAP "spare" attribute values associated with the recipient address can also be included in the probe. These appear after the sender spare attributes and are controlled by additional bits in the include_spares2 MTA option.

Note that when the *from-address* is included in the probe, then the MTA options use_orig_return, and (new in MS 6.3) use_canonical_return, and (new in MS 7.0) use_auth_return, can be used to select which form of the envelope From address is included.

If the probe matches a FORWARD mapping table entry pattern, the result of the mapping is tested. The resulting string will replace the envelope To address if the entry template specifies a $Y; a $N will discard the result of the mapping. See FORWARD mapping table flags for a list of additional flags, and see Mapping tables for general background and syntax of mapping tables. If no entries in the FORWARD mapping table match, or if no FORWARD mapping table exists, then the MTA's envelope To address processing proceeds to its next stage.

The FORWARD mapping, if present, is consulted before any forward database lookup. If a FORWARD mapping matches and has the flag $G, then the result of the FORWARD mapping will be checked against the forward database, if forward database use has been enabled via the appropriate setting of use_forward_database. (Note that if channel specific forward database use has been specified, then the source address and source channel will be prefixed to the result of the FORWARD mapping before looking up in the forward database.) If a matching

FORWARD mapping entry specifies $D, then the result of the FORWARD mapping (and optional forward database lookup) will be run through the MTA's address rewriting process again. If a matching FORWARD mapping entry specifies $H, then no further FORWARD mapping or database lookups will be performed during that subsequent address rewriting (that resulting from the use of $D).

Table 48.6 FORWARD mapping table flags

Flags	Description
$Y	Use output as new address
$N	Address remains unchanged
$D	Run output through the rewriting process again
$G	Run output through the forward database, if forward database use has been enabled
$S	Set the "trust subaddress as folder" flag, as if a folder name had been specified in a Sieve "fileinto" action
$/	(New in MS 7.0u2) In an entry with YD also set, treat the forwarding result as a mailing list with the original envelope From as the reporting address. This is similar in functionality to the specification of a / as the value of an mgrpErrorsTo value or a / as the value of a [ENVELOPE_FROM] named parameter in the alias file or alias database.
$H	Disable further forward database or FORWARD mapping lookups at this alias level.
$I	Hold the message as a .HELD file.
$J	(New in 8.0.1.3) Disable further forward database or FORWARD mapping lookups for all inner levels. (Use with caution: Careless use of this option can prevent proper alias expansion from occurring.)
$K	(New in MS 7.0.4.27.5 and MS 7.0.5.29.0) Don't reset the "intermediate" address before processing the mapping/database result; only takes effect if $Y and $D are also set. This is useful when performing a final fixup to an address produced by delivery option processing.
$P	(New in MS 7.0.4.27.5 and MS 7.0.5.29.0) Treat the FORWARD mapping result as having specified additional recipient address(es) in addition to, rather than replacing, the current recipient address; only takes effect if $Y and $D are also set.
$V	(New in MS 8.0) Do not set the internal "alias match" flag, (normally as of MS 7.0u2 set by a matching FORWARD entry, so that viaaliasrequired is satisfied); that is, $V means that viaaliasrequired is *not* satisfied by this FORWARD match
Flag comparisons	Description
$:E	(New in MS 6.3) Incoming connection used ESMTP/EHLO
$;E	(New in MS 6.3) Incoming connection did not use ESMTP/EHLO
$:L	(New in MS 6.3) Incoming connection used LMTP/LHLO
$;L	(New in MS 6.3) Incoming connection did not use LMTP/LHLO
$:F	(New in MS 6.3) NOTIFY=FAILURES active for this recipient
$;F	(New in MS 6.3) NOTIFY=FAILURES not active for this recipient

$:S	(New in MS 6.3) NOTIFY=SUCCESSES active for this recipient
$;S	(New in MS 6.3) NOTIFY=SUCCESSES not active for this recipient
$:D	(New in MS 6.3) NOTIFY=DELAYS active for this recipient
$;D	(New in MS 6.3) NOTIFY=DELAYS not active for this recipient
$:A	(New in MS 6.3) SASL (SMTP AUTH) used to authenticate connection
$;A	(New in MS 6.3) SASL (SMTP AUTH) not used
$:T	(New in 6.3) SSL/TLS used to secure connection
$;T	(New in 6.3) SSL/TLS not used
$:P	(New in MS 7.0) Match only if POP-before-SMTP was used
$;P	(New in MS 7.0) Match only if POP-before-SMTP was not used
$:R	(New in MS 8.0) Match only if the current channel is "internal" (the process channel, reprocess channel, or conversion channel).
$;R	(New in MS 8.0) Match only if the current channel is *not* "internal".
$:U	(New in MS 8.0) Match only if a UTF8 address was used.
$;U	(New in MS 8.0) Match only if the address did not use UTF8.
$:V	(New in MS 8.0) Match only if the recipient address expanded via an alias.
$;V	(New in MS 8.0) Match only if the recipient address did not expand via an alias.
$:C	(New in MS 8.0.1.3) Match only if message is the result of a capture/journal action.
$;C	(New in MS 8.0.1.3) Match only if message is not the result of a capture/journal action.

See also the `ldap_domain_attr_catchall_mapping` MTA option which may be used to specify the name of a domain-level LDAP attribute whose value names an MTA mapping table that functions, for addresses in the domain which match no specific user entry, similarly to the `FORWARD` mapping table. That is, it provides a domain-specific, more restrictive (applying only to addresses which have no explicit user entry), analogue of the `FORWARD` mapping table.

48.13.3 Forward database

For cases where address forwardings need to be autoregistered, or other cases of source specific forwarding, the MTA's forward database is available. Note that use of the forward database for simple forwarding of messages is generally not appropriate: if a database must be used, then the alias database is more efficient for straightforward forwarding; or if users are provisioned in LDAP, then forwarding can be handled via normal LDAP attributes. So by default, the forward database is not used at all; its use must be explicitly enabled via the `use_forward_database` MTA option.

Forward database lookups are performed after address rewriting and after alias expansion is performed, and after any `FORWARD` mapping is checked. If a forward database lookup succeeds, the resulting substituted address is then run through the MTA's address rewriting process all over again.

The forward database is traditionally an MTA `crdb` database, created using the `imsimta crdb` utility from a source text file. However, nowadays the `crdb` step is typically omitted

by using an MTA so-called "text database": with the relevant bit (bit 2/value 4) of the use_text_databases MTA option set, then the MTA will compile the source text file directly into its configuration. Or new in MS 8.0, the forward "database" can be stored in memcache; seethe forward_database_url MTA option. In either case, the format of the source text file by default is expected to be:

```
user1@domain1     changedmailbox1@changeddomain1
user2@domain2     changedmailbox@changeddomain2
```

But if source specific use of the forward database has been enabled by setting bit 3 of the use_forward_database MTA option, then the source text file format expected is:

```
source-channel|source-address|original-address changed-address
```

For instance, suppose a tcp_snads channel receives messages from a gateway to a SNADS system that provides (and can use) only shortform hostnames. Then an entry such as

```
tcp_snads|Bobby@BLUE|12345678@MSMTA     user.with.a.long.name@else.where.com
```

would allow the Bobby@BLUE SNADS user to send to a SNADS address of 12345678@MSMTA when they wish to send to user.with.a.long.name@else.where.com.

Chapter 49 Mailing lists

The MTA has flexible mailing list facilities, and facilities for performing automated processing of certain (typically mailing list related) messages.

In the MTA, mailing lists are implemented as a special form of MTA alias: controlling mailing list headers, access to post to mailing lists, setting up moderated mailing lists, *etc.*, are controlled via the alias that defines the mailing list. Alias features fundamental to mailing list definitions include:

- Overriding the original envelope From address of each posting with the list "owner" address,
- A variety of flexible ways to specify the addresses of list members,

And further there are optional alias features that may be of particular interest on mailing list definitions, including:

- Size limits on posted messages,
- Posting restrictions (who may post to the list address), with many variants including:
  - Permission to post restricted to list members,
  - Permission to post requires authenticated message submission,
  - Permission to post granted to certain source domains,
  - Certain users or domains "black-listed" from posting,
  - Moderated lists (posting attempts require moderator review and approval),
  - List-specific password required to post,
- Deferred expansion (*i.e.*, "offline" expansion) of list membership,
- Application of a list-specific Sieve filter to attempted list postings,
- Addition of list-specific header lines,
- List-specific removal of header lines,
- "Tagging" of the Subject: header line of postings,
- Addition of prefix text or suffix text (*e.g.*, a "disclaimer") to list postings,

- List-specific conversion tag, possibly to trigger list-specific conversion operations on list postings,
- List-specific "opt in" to spam/virus filtering,

See Aliases for background general information on aliases and their various implementation mechanisms, including Direct LDAP aliases, Unified Configuration alias options, the MTA alias file, and the (optional) MTA alias database. Details specifically on mailing list membership definitions, with their many options and variations, are described in Mailing list addresses.

See Mass mailings for a discussion of topics of particular interest in the case of sending announcements or emergency communications to very large numbers of users.

49.1 Mailing list addresses

A mailing list address is a special address created through the alias file or alias database, (or in Unified Configuration created as a set of values in an `alias` group), or stored as an alias in a group entry in LDAP ---see the discussion of aliases for general background on aliases, the alias file, and alias database, and LDAP lookups.

Associated with each mailing list address in the alias file or alias database or specified via a Unified Configuration alias option is a list of member addresses: that list of member addresses may be specified in the form of a text file which contains one or more mail addresses, or as an LDAP URL that returns one or more mail addresses. For a mailing list address stored in LDAP, the LDAP mail group with that address will have additional LDAP attributes specifying member addresses in any of a number of ways: attributes whose values specify member addresses directly, attributes whose values specify other user or group entries in LDAP (which should themselves be decorated with actual email addresses to use as member addresses), or attributes whose value is a "dynamic" LDAP URL specifying list member addresses in the LDAP directory via filter criteria. Note that regardless of whether an LDAP query URL is specified for an alias in the alias file, alias database, or an alias option, or is specified as the value of a "membership" attribute on an LDAP group entry, the LDAP query URL may return multiple addresses either because the LDAP query matches multiple entries containing a desired attribute(s), or because the LDAP query matches a multivalued attribute of a single entry.

When a message is received by the MTA for a mailing list address, the message is then passed on to each address specified in the mailing list file or LDAP URL, or specified in "membership" attributes of an LDAP mail group. Note that any such membership address may itself be an alias or another mailing list address.

For mailing lists defined via a group entry in LDAP, see the numerous LDAP attributes available for group entries as listed in MTA LDAP attribute name options with the MTA options that name them. And for defining the mailing list membership of mail group LDAP entries, see in particular the discussion of Defining membership of large lists. For mailing lists defined in the alias file or alias database, see Alias file mailing list aliases.

49.1.1 Mailing list multiple access control interpretation

Note that when specifying multiple sorts of posting access control parameters on a mailing list address (or other address), the effect is normally cumulative (a logical AND operation). For instance, specifying both `alias_cant_list` and `alias_auth_list` (in legacy

configuration, [CANT_LIST] and [AUTH_LIST]) on a list normally means that only those addresses that are in the `alias_auth_list` and not in the `alias_cant_list` may post to the list. But the interpretation of combining access control settings may be altered via the `or_clauses` MTA option; that is, with `or_clauses=1`, the interpretation defaults to a logical OR. The interpretation of combining individual access controls on mailing lists can also be controlled for individual access controls on individual lists by using the `alias_and` or `alias_or` alias options (in legacy configuration [AND] or [OR] alias file named parameters); the use of such an option causes subsequent access controls (up until another occurrence of `alias_and` or `alias_or`) to be interpreted as specified.

Note also that the `alias_auth_list`, `alias_auth_mapping`, `alias_cant_list`, and `alias_cant_mapping` alias options (the [AUTH_LIST], [AUTH_MAPPING], [CANT_LIST], and [CANT_MAPPING] parameters in legacy configuration) provide a separate sort of control from `alias_moderator_list` and `alias_moderator_mapping` alias options (the [MODERATOR_LIST] and [MODERATOR_MAPPING] parameters in legacy configuration); they do different things and may be used effectively in conjunction. The `alias_auth_*` and `alias_cant_*` options control who can post at all; only addresses that make it through those access filters then get checked for the next question, namely the `alias_moderator_*` access filter, which controls whether the sender can post directly *vs*. whether their attempted posting is referred to `alias_moderator_address` ([MODERATOR_ADDRESS] in legacy configuration).

In the direct LDAP environment, multiple list access controls are again normally essentially cumulative (a short-circuited logical AND operation) between different types of controls, although multiple values for a single type of allow control are ORed. (That is, multiple values of `mgrpAllowedBroadcaster` are effectively ORed with each other. And similarly, multiple values of `mgrpAllowedDomain` are effectively ORed with each other.) Specifically, the value(s) of the attribute named by the `ldap_cant_url` MTA option (by default, `mgrpDisallowedBroadcaster`) is/are checked first, and if that check passes (the attempting poster does not match any `mgrpDisallowedBroadcaster` value) then next the value of the attribute named by the `ldap_auth_url` MTA option (by default, `mgrpAllowedBroadcaster`) is checked (ORing the possibilities if multiple `mgrpAllowedBroadcaster` values are specified; that is, an attempted poster who matches any of the `mgrpAllowedBroadcaster` values will be allowed), and if that check passes then next the value of the attribute named by the `ldap_cant_domain` MTA option (by default, `mgrpDisallowedDomain`) is checked, and if that check passes (the attempting poster does not match any `mgrpDisallowedDomain` value) then next the value of the attribute named by the `ldap_auth_domain` MTA option (by default, `mgrpAllowedDomain`) is checked (ORing the possibilities if multiple `mgrpAllowedDomain` values are specified; that is, an attempted poster who matches any of the `mgrpAllowedDomain` values will be allowed). So this is essentially a "short-circuited" logical AND of the posting access restriction conditions. But the interpretation of combining different types of access control settings may be altered via the `or_clauses` MTA option; that is, with `or_clauses=1`, the interpretation defaults to a logical OR. Individual mailing lists or groups can override the general setting of the MTA option `or_clauses` via a value of "`OR`" or "`AND`" as one of the values of the attribute named by the `ldap_auth_policy` MTA option (by default, `mgrpBroadcasterPolicy`). Note that the configuration choice of combining different *types* of controls with OR *vs.* AND does *not* affect the interpretation of multiple values of a single type of control: for instance, multiple values of `mgrpDisallowedBroadcaster` are always ANDed together (a poster must pass all the conditions) while multiple values of `mgrpAllowedBroadcaster` are always ORed together (a poster may post if their address matches any of the conditions).

49.1.2 Password-protected mailing lists

Mailing lists may be set up to require a password in order to post. For mailing lists defined via the aliases file or alias database, the password value (or list of values) is specified via the [PASSWORD] mailing list named parameter; see Alias file named parameters. In Unified Configuration, the analogous setting is the `alias_password` alias option. For mailing lists defined in LDAP, the password value (or list of values) is specified via the `mgrpAuthPassword` attribute (or more precisely, whatever attribute is specified by the `ldap_auth_password` MTA option).

In order for a message to be posted to the list, the MTA will then require that the message include, on an Approved: header line, one of the authorizing passwords. During the mailing list expansion process, the MTA will remove that password value from the Approved: header line, and indeed remove the entire Approved: header line if that was the only value present. (In the case of multiple values, all passwords for a list will be removed. So in the case of nested lists, make sure that the list password sets for the different lists are disjoint.) So note that the Approved: header line value that allowed the message to be posted will *not* be exposed in the actual posted message. Members of the list will not see the password. The group of users who can post (who know and use the password) can be a subset, or even a completely separate group of users.

Note that since a single mailing list can have multiple allowed passwords, it is possible to assign a separate password to each allowed poster.

Since mailing lists may be nested (one mailing list may be subscribed as a member of another mailing list), and since mailing list may have its own password(s), an Approved: header line may contain multiple, comma-separated values.

Password-protected mailing lists automatically get deferred expansion of membership.

49.1.3 Moderated mailing lists

A *moderated mailing list*---a list where certain moderators are allowed to post messages, but attempted postings by others are routed to a moderator or moderators instead of being posted directly---requires three basic settings for moderation (in addition to the `mgrpErrorsTo` setting that makes it a true list, rather than a group). These are, for a list defined in LDAP:

1. The moderator(s) allowed to post directly must be among the `mgrpAllowedBroadcaster` values.

2. The `mgrpMsgRejectAction` must be set to `toModerator`, to cause messages that initially fail an access check to get routed to the moderator(s) (who may or may not resend the message to the list, at their pleasure) rather than being outright rejected.

3. The address(es) to which to re-route not-yet-approved direct posting attempts must be specified, by setting `mgrpModerator`.

(For concreteness, the above description refers to the LDAP attribute names that the MTA consults by default; but more precisely, the LDAP attributes that must be used are whatever attributes are named by the `ldap_errors_to`, `ldap_auth_url`, `ldap_reject_action`, and `ldap_moderator_url` MTA options.)

For a list defined via alias options instead of in LDAP, the required basic moderation settings, beyond the basic list setting of `alias_envelope_from`, are:

1. A moderator address, (which may be an alias/group/list address itself), must be set via the `alias_moderator_address` alias option; this is the address to which will be sent

all attempted postings *not* coming from a moderator address. This is analogous to the `mgrpModerator` LDAP setting.

2. Optionally, additional addresses may be established as allowed direct posters (additional originator addresses to be handled as if they were moderators, for purposes of allowing postings) using the `alias_moderator_list` alias option (where in this specific case the use is rather similar to that of the `ldap_auth_url` LDAP setting), or any of the `alias_moderator_mapping`, `alias_username_moderator_list`, `alias_sasl_moderator_list`, or `alias_sasl_moderator_mapping` alias options. But, unlike the LDAP case, in the absence of any settings specifying additional accepted moderator From: addresses, the basic `alias_moderator_address` address will be used not only as the moderator address to which to *send* unmoderated postings, but also be recognized as a valid moderator From: address from which to *accept* direct postings.

Once these settings are made, a list can be considered moderated. Note that while a common case is that there is only *one* moderator and *only* that one moderator can post, other cases may be just as useful. In particular, allowing specially known and privileged classes of non-moderators as additional `mgrpAllowedBroadcaster` posters can be useful; or combining (ORing) various posting access conditions via `mgrpBroadcasterPolicy` so that moderation applies only to attempted postings that fail other conditions (such as use of SMTP AUTH to authenticate, inclusion of a list password, *etc.*) can allow for moderation of messages meriting higher scrutiny, while permitting more trusted senders to post directly.

For instance, it can be useful to set up a mailing list where postings from members of the list are not moderated, but attempted postings by non-members of the list go to the moderator for human review. To set up a mailing list where members are allowed to post directly, but where attempted postings by non-members must be approved by the list moderator, include in the list entry attributes such as:

```
mgrpErrorsTo: moderator-user@domain.com
mgrpAllowedBroadcaster: mailto:list-members@domain.com
mgrpAllowedBroadcaster: mailto:moderator-user@domain.com
mgrpMsgRejectAction: TOMODERATOR
mgrpModerator: mailto:moderator-user+listname@domain.com
mailDeferProcessing: AFTER_AUTH
```

Note that in the above example, the new in MS 6.3p1 `AFTER_AUTH` value is used for `mailDeferProcessing`. In earlier versions, the less desirable `no` value would need to be used instead.

A similar example would be a mailing list where messages containing the list password are posted directly, while message lacking that password are directed to the moderator for inspection. By setting the `mgrpAllowedBroadcaster` to be the moderator, and setting `mgrpBroadcasterPolicy` to `PASSWORD_REQUIRED,OR`, the effect is that postings from the moderator will be allowed even without the normal password, while attempted postings from any other senders will only be directly posted if they contain the password.

```
mgrpErrorsTo: moderator-user@domain.com
mgrpBroadcasterPolicy: PASSWORD_REQUIRED,OR
mgrpAllowedBroadcaster: mailto:moderator-user@domain.com
mgrpAuthPassword: secret-password
mgrpModerator: mailto:moderator-user+listname@domain.com
```

```
mgrpMsgRejectAction: toModerator
```

When the moderator receives a message addressed to *moderator-user+listname*@domain.com, the moderator would either reject messages he/she does not approve, or resend the message to the list. In this example, due to the `mgrpBroadcasterPolicy` setting including `OR`, the moderator is not required to add the header line that other senders would need to include:

```
Approved: secret-password
```

That is, by setting the `mgrpAllowedBroadcaster` to be the moderator, and setting `mgrpBroadcasterPolicy` to `PASSWORD_REQUIRED,OR`, the effect is that postings from the moderator will be allowed even without the normal password, while attempted postings from any other senders will only be directly posted if they contain the password.

Many additional mailing list behaviors are best achieved by setting up one form or another of moderated list. This is true even for certain behaviors that may not immediately seem like cases of a moderated mailing list. An example: setting up a mailing list where postings directly to the list are permitted without moderation, but where replies to prior list postings -- attempts to continue a posting thread -- are disallowed can be achieved via a moderated list setup. Indeed in general, cases where it is desired to perform more elaborate checks or processing on messages before they are allowed to be posted to the list are often cases where appropriate moderation of the list may be helpful.

For instance, consider the case of a mailing list that disallows replies to prior list postings. Replies to prior list postings will be detected via a Sieve filter that looks for common "reply" prefix strings on the Subject: header line. The mailing list can be set up to include attributes:

```
mgrpErrorsTo: <hogwarts-moderator-user>@domain.com
mgrpModerator: mailto:<hogwarts-moderator-user>+hogwarts@domain.com
mailDeferProcessing: AFTER_AUTH
```

Then for the <hogwarts-moderator-user>@domain.com user, set up a Sieve filter that looks for messages addressed to the user with the subaddress hogwarts (use the Sieve subaddress extension) and then either does a '`reject`' or a '`redirect :resetmailfrom "hogwarts@domain.com";`', as appropriate. *E.g.*:

```
require ["reject","envelope","subaddress"];
if  envelope :detail "to" "hogwarts" {
  if allof ( header :contains ["To","Cc","Bcc"] "hogwarts@domain.com",
             header :matches "Subject" ["Re*:*", "RE*:*"]) {
    reject "Replies not allowed!"; }
  else { redirect :resetmailfrom "hogwarts@domain.com"; }
}
...whatever other filter stuff this user wants...
```

Another example where a technically moderated list, without involving actual human moderation, may be of interest would be the case of rejected attempted postings that include non-text parts. With a mailing list definition that includes:

```
mail: listname@domain.com
```

```
mgrpErrorsTo: listname-owner@domain.com
mgrpModerator: mailto:list-moderator+listname@domain.com
mailDeferProcessing: AFTER_AUTH
```

then the moderator user or pseudo-user (since possibly no human being corresponds to this entry, which might exist for the sole purpose of having this Sieve script), *list-moderator*@domain.com, might use a Sieve filter along the lines of:

```
require ["mime","reject","subaddress","envelope"];
if envelope :detail "to" "listname" {
  if header :mime :anychild :type "Content-type"
      ["application","audio", "image","video"]
     reject "Non-text may not be posted to this list";
  else { redirect :resetmailfrom "listname@domain.com"; }
}
...whatever other filtering this user wants...
```

An example that does involve an actual human moderator would be for a list that does not impose controls on the identity of posters, but where the attempted posts are scanned for suspicion of spam content, and then are potentially either rejected or human moderated at different levels of spam suspicion, while scanned non-spam messages get automatically posted.

```
mail: listname@domain.com
mgrpErrorsTo: listname-owner@domain.com
mgrpModerator: mailto:listname-owner+listname@domain.com
mgrpAllowedBroadcaster: mailto:listname-owner@domain.com
mgrpMsgRejectAction: toModerator
```

Then the *listname*-owner@domain.com "user":

```
mail: username@domain.com
mailEquivalentAddress: listname-owner@domain.com
```

should have a Sieve filter including:

```
require ["fileinto","reject","subaddress","spamtest","relational"];
if envelope :detail "to" "listname" {
  if spamtest :value "ge" :comparator "i;ascii-numeric" "10" {
    if spamtest :value "ge" :comparator "i;ascii-numeric" "20"
      { reject "Content appears to be spam"; }
    else
      { fileinto "listname-spam"; }
  } else { redirect "listname@domain.com"; }
}
```

Or another example of a list involving human moderator of *some* attempted postings would be where it is desired that rather than a list having an absolute limit on the size of postings (where note an absolute limit could be achieved simply by setting the desired `mgrpMsgMaxSize` on the list), that a moderator be able to selectively approve the posting of messages that would otherwise be considered "too large". Note that a size

limit such as `mgrpMsgMaxSize` can not be simply ORed with access checks such as `mgrpAllowedBroadcaster`, so this goal will require a special moderation setup.

```
mail: listname@domain.com
mgrpErrorsTo: listname-owner@domain.com
mgrpModerator: mailto:listname-owner+listname@domain.com
mgrpAllowedBroadcaster: mailto:listname-owner@domain.com
mgrpMsgRejectAction: toModerator
```

Then the *listname*-owner@domain.com "user":

```
mail: username@domain.com
mailEquivalentAddress: listname-owner@domain.com
```

could have a Sieve filter including:

```
require ["reject","subaddress","fileinto","notify"];
if envelope :detail "to" "listname" {
  if size :under 10K {
     redirect :resetmailfrom "listname@domain.com"; }
  elsif size :under 50K {
     fileinto "listname-large";
     notify :method "email" :options
       "listname-owner@domain.com"
       "Message filed to listname-large needs to be checked"
       "";
     }
  else { reject "Message too large to post"; }
}
```

which would automatically post to the list any small messages, automatically reject any extremely large messages, but notify the moderator of any new medium size message posting attempt and file that message into a `listname-large` folder for the moderator to inspect and approve or bounce, at their leisure.

Returning to yet another case of "automated moderator" processing, consider an example where it is desired to respond with an automatic message to list postings, using the Sieve "`vacation`" action. With a list entry along the lines of:

```
mail: listname@domain.com
mgrpErrorsTo: listname-owner@domain.com
mgrpModerator: mailto:moderator-pseudo-user+listname@domain.com
mgrpAllowedBroadcaster: mailto:moderator-pseudo-user@domain.com
mgrpMsgRejectAction: toModerator
mailDeferProcessing: AFTER_AUTH
```

Then the LDAP entry for *moderator-pseudo-user*@domain.com:

```
mail: moderator-pseudo-user@domain.com
```

can have a Sieve script attached along the lines of:

```
require ["subaddress","vacation"];
if envelope :detail "to" "listname" {
   vacation :addresses "listname@domain.com"
      :from "listname@domain.com"
      :subject "Welcome to listname!"
        "Thank you for your interest in listname.
You will receive a personal response soon.";
   redirect :resetmailfrom "listname@domain.com";
   }
```

49.2 Mass mailings

The term *mass mailing* may be used to refer to cases of sending a certain message to all users hosted at a site, or to all users in some domain, or to all users in some organization unit, or to all members (including "external" members) of some "large" mailing list, *etc.*---any case where the number of recipients is relatively "large". The purpose of the message might be one of great urgency (such as an emergency communication), or it might be of general interest but low urgency (such as routine announcements).

Since the MTA supports LDAP filter based (so-called "dynamic") group and list definitions, it is straightforward to define a list or group to consist of all users meeting some criteria (any criteria that may be specified in an LDAP URL filter). See in particular the MTA's support of `memberURL` and `mgrpDeliverTo` attributes (or more precisely, those attributes named by the `ldap_group_url1` and `ldap_group_url2` MTA options) in LDAP group entries. Or for MTA alias file defined groups and lists, see the LDAP URL membership syntax discussed in Alias file LDAP URL alias values. And more complex lists can be constructed, including criteria-based sets of locally-hosted members along with external members listed by address, or lists with "nested" definitions of sub-lists, or "overlapping" definitions/membership.

Groups and mailing lists are most often defined to make use of actual e-mail addresses: either directly as a list of e-mail addresses, or by defining the membership to be users who each have a canonical e-mail address. However, the MTA, via its new in MS 6.3 `ldap_url_result_mapping` MTA option (and whatever LDAP attribute `ldap_url_result_mapping` names), also supports defining groups and mailing lists for which e-mail addresses are constructed from other LDAP attributes that do not themselves contain proper e-mail addresses.

Furthermore, as of MS 6.3 and its new `process_substitutions` MTA option, it is possible to define "meta-groups" and "meta-lists": where a single meta-list definition provides what amounts to an entire collection of definitions of different lists.

As of 7.0.5 and its new `GROUP_AUTH` mapping table, it is possible to use alternate LDAP attributes and values for group/list authorization checks. In particular, this can be useful when dealing with group/list information stored in an LDAP directory using a non-Oracle schema.

Now any time that a group or list with "large" membership of e-mail recipients is defined, and any time that a message is to be sent to an especially "large" number of recipients, there are some issues worth considering; these issues will each be discussed in greater detail in sections below.

- Defining the actual list membership; see Defining_membership_of_large_lists.
- Sensible error handling; see Proper use of lists rather than groups.

- Restrictions on senders; see Restricting posting access to large lists.
- Performance in submitting the message; see Performance submitting mass mail messages.
- Impact of this message (and possibly its multiple copies requiring processing) on other message processing; see Addresses per message copy.
- The appropriate choice of processing priority for the message. This may vary from "urgent" for messages that are time-critical, to "non-urgent" for messages that while of general *interest* are not time-critical and might be more efficiently processed during "off hours". (Note that "importance" is a separate measurement than "processing priority": messages can be time-critical but not very important, as for instance a message that a party is about to start in the coffee room, or important without being time-critical, as for instance a message that system down-time is scheduled for two weeks away.)
- The timing of attempting delivery of the message: for some messages, it may be desirable to delay even *attempting* to deliver the message until some pre-determined time. See SMTP SUBMIT FUTURERELEASE support.
- Efficient storage of the messages; see Addresses per message copy.

49.2.1 Defining membership of large lists

Note: This discussion will focus on lists primarily defined in LDAP, as that is the typical mode of defining lists nowadays. However, the MTA does also support lists defined instead in an aliases file entry, or in Unified Configuration via alias options, rather than in an LDAP entry; see those topics for details.

The membership of a list *may* be defined by simply listing the e-mail addresses of the members, or (for lists defined in LDAP) by listing the DNs (location in the LDAP directory tree) of the members.

For instance, for a list defined in LDAP, the `memberURL` attribute or `mgrpDeliverTo` attribute (more precisely, the attributes named by the `ldap_group_url2` and `ldap_group_url1` MTA options, respectively) are available, *e.g.*:

```
memberURL: ldap:///o=usergroup??sub?(uid=abc123)
memberURL: ldap:///o=usergroup??sub?(cn=Adam Brown)
memberURL: mailto:Betty.Charles@domain.com
memberURL: mailto:John.Doe@external-domain.com
```

Note that an LDAP based list definition can obtain a list of actual addresses from a separate, on-disk file (accessible from the MTA performing the list expansion) by using a `file:` URL; *e.g.*:

```
memberURL: file:///IMTA_TABLE:list-members.txt
```

where the `IMTA_TABLE:list-members.txt` file itself consists of a list of e-mail addresses, one address per line, *e.g.*,

```
Betty.Charles@domain.com
```

```
John.Doe@external-domain.com
```

Or, when it is more convenient to describe a list in LDAP via the locations of the member entries rather than via their e-mail addresses, the members may be described via the `uniqueMember` attribute (more precisely, the attribute named by the `ldap_group_dn` MTA option). For each member defined via `uniqueMember`, the MTA will use the value of that member's `mail` attribute (more precisely, the value of the attribute named by the `ldap_primary_address` MTA option) as the e-mail address for that member of the list. (The `group_dn_template` MTA option controls which attributes for the user the MTA fetches, and hence which/whether additional addresses for the user can match for purposes such as comparisons with posting restrictions. See Indirect or alternate criteria for list membership for a discussion of more complex membership definitions using variants of DN semantics.)

But for "large" lists especially, it is often more convenient to instead define the list membership in terms of some criteria by which to locate the relevant users in LDAP; for instance, a list of all users in LDAP might have membership defined as:

```
memberURL: ldap:///o=usergroup??sub?(&(objectClass=inetMailUser)
                                     (objectClass=inetOrgPerson))
```

Or a list of all the users in the domain `domain.com` might have membership defined as:

```
memberURL: ldap:///dc=domain,dc=com,o=internet??sub?
            (&(objectClass=inetMailUser)(objectClass=inetOrgPerson))
```

When defining list membership via a `memberURL` or `mgrpDeliverTo` attribute (or more precisely, whatever attributes to which the MTA options `ldap_group_url1` and `ldap_group_url2` are set), unless use of some other attribute is explicitly selected, the MTA assumes that the value of the `mail` attribute (`ldap_primary_address` MTA option) should be used as the e-mail address for the list member; note how in the above example no attribute is explicitly requested (and therefore the default use of the `mail` value is assumed). If it is desired to use some other attribute that does itself contain an e-mail address, that may be selected by explicitly selecting that attribute. For instance, suppose that a no longer canonical, acquired domain name is still in use in certain users' `mailEquivalentAddress` values; a list intended for sending to those users, at their "old" addresses, could have membership defined as:

```
memberURL: ldap:///o=usergroup?mailEquivalentAddress?sub?
   (&(objectClass=inetMailUser)
     (objectClass=inetOrgPerson)
     (mailEquivalentAddress=*@acquired-domain))
```

There is one additional factor to consider when defining list membership. Definitions that reference member e-mail addresses, *e.g.*, `mgrpRFC822MailMember` (see the `ldap_group_rfc822` MTA option), allow better error reporting in cases of definition errors (such as syntax errors), than definitions that reference LDAP DNs or LDAP URLs. Syntax errors in e-mail address members will be reported to the list owner. However, syntax errors in an LDAP DN or LDAP URL used to define members, *e.g.*, syntax errors in a `uniqueMembers` or `memberURL` attribute, will cause the list membership expansion to abort at that point.

So it is especially important to check list definition, *e.g.*, via `imsimta test -rewrite -check_expansions`, when defining lists that make use of LDAP DN or LDAP URL criteria for membership.

49.2.1.1 Indirect or alternate criteria for list membership

As discussed in Defining membership of large lists, the MTA's normal interpretation of the `uniqueMember` LDAP attribute (more precisely, the attribute named by the `ldap_group_dn` MTA option) involves expanding the value of the `uniqueMember` attribute via the URL template set by the `group_dn_template` MTA option, which by default is

```
ldap:///$A??sub?(mail=*)
```

(meaning that the $A substitution inserts the `uniqueMember` value), so that by default, `uniqueMember` values are interpreted as specifying a DN location in the DIT: all e-mail addresses under that location are considered to have been specified (be members).

This sort of indirect, additional-step, expansion of an LDAP attribute value turns out to be potentially useful for alternate approaches for membership definition. In order not to interfere with the "normal" handling of `uniqueMember` DN values for list membership, in Messaging Server 7.0.5 the MTA option `ldap_group_dn2` and the mapping table `GROUP_TEMPLATES` were introduced. `ldap_group_dn2` can be used to specify the name of an LDAP attribute which will then be processed similarly to the `ldap_group_dn` (`uniqueMember`) attribute---in particular, by default values of the LDAP attribute named by `ldap_group_dn2` are expanded via the `group_dn_template` URL template just like `ldap_group_dn` values. But the real usefulness of `ldap_group_dn2` tends to be when its use is combined with use of the `GROUP_TEMPLATES` mapping table.

The `GROUP_TEMPLATES` mapping table provides a way to specify different URL expansion templates for differently named LDAP attributes (such as different templates for the attribute named by `ldap_group_dn` *vs*. the attributes named by `ldap_group_dn2`), or even for different values of such LDAP attributes. When a `GROUP_TEMPLATES` mapping table exists, it will be probed each time a group has an LDAP attribute named by either of the `ldap_group_dn` or `ldap_group_dn2` MTA options. The probe form is:

`object-classes|attribute-name|attribute-value`

where `object-classes` is a plus-separated list of the object classes associated with the current LDAP entry, (see the `ldap_group_object_classes` MTA option), `attribute-name` is the name of the group "DN" attribute being expanded (*i.e.*, the LDAP attribute name specified for either `ldap_group_dn` or `ldap_group_dn2`), and `attribute-value` is that attribute's current value.

If the mapping sets the `$Y` output flag, then the mapping output string will be used as the template for this attribute's expansion in place of using the value of `group_dn_template` as the template. If the mapping sets the `$N` output flag, then the attribute will be silently ignored.

So now that the facilities have been explained, how could they actually be used? Well, one sort of usage might be where groups/lists are defined not so much by the group/list entry pointing to (that is, listing) the members, but rather where each user entry specifies the groups/lists of which the user is a member, referring to some group/list ID. For instance, suppose group/list entries have an LDAP attribute `listID` whose value is some string unique to that group/list. Then suppose further that user entries mark which groups/lists the user belongs to by having

a `memberOf` attribute that contains a valid `listID` value. Defining group/list membership in this new way, while still allowing "traditional" `uniqueMember` membership definitions, can be achieved by configuring the MTA with an option:

```
msconfig> set mta.ldap_groupdn listID
```

and mapping table:

```
GROUP_TEMPLATES

! Normal use of ldap_group_dn attribute uniqueMember
  *|uniqueMember|*  $Yldap:///$$A?mail?sub?(mail=*)
! Find users who have a memberOf attribute set to the value of the group's
! listID attribute
  *|listID|*      $Yldap:///$$B??sub?(memberOf=$$A)
```

where here note `$B` is the substitution sequence meaning to substitute in the base of the user/group portion of the DIT (the `ldap_user_root` MTA option's value), and where the `$A` "Address" substitution means, in this context, the value of the currently used LDAP attribute (so the value of, respectively, the `uniqueMember` or `listID` attribute in the respective mapping table entries matching those attribute names). Then to make use of this type of group/list definition, provision groups and users in the directory along the lines of:

```
group1-entry
listID: group123

...

group2-entry
listID: groupXYZ

...

user1-entry
memberOf: group123
memberOf: groupXYZ
...
```

49.2.1.1.1 Constructing list member addresses

Discussions of Defining membership of large lists and Indirect or alternate criteria for list membership have touched on potentially complex list membership criteria, as dynamic definitions may make use of complex LDAP search filters. However, in those discussions, the list addresses and member addresses themselves were not especially complex; the topic of complexity in address forms is the topic of this discussion. Via the MTA's support for manipulating the results of LDAP URL lookups, it is possible to define list membership in ways that "construct" e-mail addresses from non e-mail address attribute values, or that obtain e-mail addresses from "external" LDAP sources. And it is also possible to define "meta-lists" where the list "address" itself is "dynamic".

A list of SMS users, adding a domain name to an SMS ID value

For instance, let us assume a setting of

```
msconfig> set mta.ldap_url_result_mapping mgrpURLResultMapping
```

or in legacy configuration, in the MTA option file:

```
LDAP_URL_RESULT_MAPPING=mgrpURLResultMapping
```

Also assume that the MTA has an SMS channel configured with the domain sms.domain.com associated with it for some SMSC (that is, SMS service provider), and that each user who has an account with that SMS service provider has an `smsID` attribute containing their SMS ID, and that an MTA mapping table has been configured:

```
X-SMSID-TO-ADDRESS

  *|*       "$1"@sms.domain.com$Y
```

Then a group sms-all@domain.com for the purpose of directing an SMS message to each such user could be defined via a group entry in LDAP that includes attributes:

```
mail: sms-all@domain.com
mgrpDeliverTo: ldap:///o=usergroup?smsID?sub
mgrpUrlResultMapping: X-SMSID-TO-ADDRESS
```

Adding different domain names to SMS IDs

At a site where users have various different SMS service providers, suppose with the domain for each service provider being stored in a `SMSdomain` attribute, then separate sub-lists for the different SMS service providers could be set up, with then a combined list for all the SMS users. Assuming also the following mapping table:

```
X-SMSID-DOMAIN-TO-ADDRESS

  *(SMSdomain=*)|*       "$2"@$1$Y
```

as well as for each SMS service provider a group definition such as:

```
mail: sms1@domain.com
memberURL: ldap:///o=usergroup?smsID?sub?(SMSdomain=sms1-domain)
mgrpUrlResultMapping: X-SMSID-DOMAIN-TO-ADDRESS
```

Then a list of all SMS users could be defined via:

```
mail: sms-all@domain.com
mgrpErrorsTo: sms-errors@domain.com
memberURL: mailto:sms1@domain.com
```

```
memberURL: mailto:sms2@domain.com
...
```

49.2.1.1.1.1 Meta-group list definitions

In addition to manipulating LDAP attribute values to construct list member addresses as discussed in Constructing list member addresses, the MTA also supports manipulating address forms to effectively create dynamic list names, via so called *meta-lists*.

A meta-list for per-department SMS users

As of MS 6.3 and its new `process_substitutions` MTA option, it is possible to define "meta-groups" and "meta-lists": to, for instance, pre-define via a single meta-list definition what amounts to an entire collection of different lists. For instance, with `process_substitutions=4` and `ldap_url_result_mapping=mgrpURLResultMapping` set,

```
msconfig> set mta.ldap_url_result_mapping mgrpURLResultMapping
msconfig# set mta.process_substitutions 4
```

then defining a list with attributes including

```
mail: sms@domain.com
mgrpErrorsTo: sms-errors@domain.com
memberURL: ldap:///o=usergroup?smsID?sub?(department=$S)
mgrpUrlResultMapping: X-SMSID-TO-ADDRESS
```

would make it possible to send an SMS message to every member of a given department who has an SMS account by sending to an address of the form `sms+department-value@domain.com`.

Members stored in an external LDAP directory

Another potential use of `ldap_url_result_mapping` to "construct" e-mail addresses would be where the member addresses are stored in an external LDAP directory, rather than in the usual user/group LDAP directory, with membership being defined in the external LDAP directory in an indirect fashion, via an `isMember` attribute. For instance, if the external directory stores the list definition along the lines of:

```
listName: extlist
listID: 1234abcd
listMemberRoot: dn-of-root-of-members
```

and then stores members of the list along the lines of:

```
mail: external-user1@domain.com
isMember: 1234abcd
```

then in the regular user/group LDAP directory define the list as:

```
mail: extlist@domain.com
```

```
mgrpErrorsTo: extlist-owner@domain.com
memberURL: extldap:///listname-search-base?listID?sub?(listName=extlist)
mgrpURLResultMapping: X-EXTLDAP-LISTS
```

with a mapping table

```
X-EXTLDAP-LISTS

  extldap:///*?listID?sub?*|*  $CROOT|$]extldap:///$0?listMemberRoot?sub?$1[|$2
!
! Probe is now:
!  ROOT|listMemberRoot|listID
!
  ROOT|*|*          $C$]extldap:///$0?mail?sub?(isMember=$1)[$E$Y
```

49.2.1.1.2 GROUP_TEMPLATES mapping table

The GROUP_TEMPLATES mapping table provides a way to support multiple ways of defining group membership: it extends the group_dn_template MTA option approach, allowing use of different "DN expansion templates" to combine with the values coming from the LDAP attributes named by the ldap_group_dn and ldap_group_dn2 MTA options.

The LDAP attributes named by the ldap_group_dn and ldap_group_dn2 MTA options are typically used to specify DNs, which are then expanded to find user entries using the URL template specified via the group_dn_template MTA option. By setting a different sort of value for the group_dn_template MTA option, a different sort of DN expansion approach could be used -- but it would then apply to all values of the LDAP attributes named by both ldap_group_dn and ldap_group_dn2. The GROUP_TEMPLATES mapping table, in contrast, can select alternate expansion approaches based on LDAP attribute name and value, thereby allowing support for multiple, different ways of expanding DNs to determine group membership.

When a GROUP_TEMPLATES mapping table exists, it will be probed each time a group has an LDAP attribute named by the ldap_group_dn or ldap_group_dn2 MTA option to expand. The probe form is:

object-classes|*attribute-name*|*attribute-value*

where object-classes is a plus-separated list of the object classes associated with the current LDAP entry, attribute-name is the name of the group "DN" attribute being expanded (*i.e.*, the LDAP attribute name specified for either ldap_group_dn or ldap_group_dn2), and attribute-value is that attribute's current value.

If the mapping sets the $Y output flag, then the mapping output string will be used as the template for this attribute's expansion in place of using the value of group_dn_template as the template. If the mapping sets the $N output flag, then the attribute will be silently ignored.

49.2.2 Proper use of lists rather than groups

The fundamental difference between an e-mail group *vs.* a true mailing list is in how notification messages are defined to be handled: in particular, whether the original envelope From address (the error report address) is retained (a group) or overridden with a list owner address (a true mailing list). In the case of groups and mailing lists defined in LDAP, the

distinction is whether an mgrpErrorsTo attribute has been set; in the case of groups and mailing lists defined via alias options in Unified Configuration, the distinction is whether the alias_envelope_from alias option has been set; in the case of groups and mailing lists defined via the alias file, the distinction is whether the [ENVELOPE_FROM] named parameter or alternatively the error-return-address positional parameter has been set.

For almost all cases, true mailing lists should be used. Groups, on the other hand, should be reserved for those rare cases where:

- The group membership is (very!) small: on the order of a handful of members.
- The group membership is quite cohesive in terms of roles and relationships: examples would be multiple mailboxes for the same actual person, members of a (small!) family, emergency sysadmin contacts, *etc.*
- The group membership is quite static (unchanging).

Regrettably, (mis)use of simple groups when mailing lists would be more appropriate is wide spread---and survives simply because sending messages to a group is so easy and *until something goes wrong* the difference is not apparent. Of course, once something does go wrong, it's precisely the suboptimal handling of the notifications that becomes a problem for the (misused) groups.

Many (probably most) sites do not have this distinction clear at all; they think of a group (abstractly a set of users) as essentially synonymous with the use of that group as (the membership of) a mailing list. And it's routine to plaster a mail attribute onto every "group", at which point one *can* send messages to the group, making it a pseudo-mailing list. But just plastering a mail attribute onto a group does *not* make a group a mailing list, and in fact it is perhaps unfortunate that this is so "easy" as it lets sites make these sorts of conceptual and operational mistakes so easily. (There are two possible mistakes: the more common is to use a mail-attribute-decorated group *sans* mgrpErrorsTo as an autoforwarder in cases where it is not appropriate; but simple addition of mgrpErrorsTo to a mail-attribute-decorated group thereby turning it into a true list may be another, though lesser, sort of mistake, especially when groups are nested, if one would prefer to still have the group available as a pure set of users, suitable as membership for some superset groups or lists). Except for certain special cases where it really does make sense to have a mail address for the group function as an autoforwarder, groups should not be used directly as a pseudo-list. When no nesting is needed, a group can be turned into a list definition by adding mgrpErrorsTo. Or most generally, for best overall practice, the definitions should be separate to correspond to the conceptual distinction: there is a group defining a related set of users, and then there is a separate list entry in LDAP that has that group as its membership.

So, for almost every case of an LDAP group entry to which messages will be addressed, correct definition should use an entry that includes an mgrpErrorsTo attribute (more precisely, whatever attribute is pointed to by the ldap_errors_to MTA option), pointing to some "responsible" or "list owner" address, so that the group is also in e-mail terms, a true mailing list.

To expand upon the differences and options in notification handling:

- With a plain group definition, as of MS 6.1 syntax errors or other "immediately apparent" errors (such as over quota status for local users) in the member address definitions will be reported *to the entire rest of the group membership*, whereas with a mailing list definition such syntax errors/immediately apparent errors are reported only to the "responsible list owner" address: the mgrpErrorsTo address.

Note that in neither case is informing the original sender typically appropriate: the maintenance of the correctness/usability of the addresses in a group or list definition is not the business of the original message sender, but rather best handled by either the (close and cohesive) "fellow members" of the group in the case of a (properly used) group, or by the "responsible list owner" in the case of a true mailing list. The original message sender, in contrast, could well be some remote correspondent with no ability to "fix" the "bad" address definition, and in the case of (properly used) groups, where the membership of the group is quite cohesive and overlapping in intended roles so that as long as someone in the group got the message it can be considered successfully received, a bounce message back that an address was "bad" may be misleading and unnecessarily worrisome to the original sender. Note that such cases of immediately apparent as invalid addresses (but where at least one address in the group appears initially valid) would not get reported to the original message sender even prior to MS 6.1; instead such cases were silently ignored prior to MS 6.1. Note also that a case where all address definitions in a group are bad does, of course, get reported back to the original sender: in that case the sender's message was not received at all, and the entire group address was bad. The case discussed above is where at least *some* of the group addresses appeared initially valid.

- In the case of initially apparently valid addresses that suffer delivery problems, for a plain group such delivery problems are reported back to the original sender, whereas for a true mailing list the delivery problems are reported back to the "responsible list owner" address. With only a little thought, it should become clear why with any sort of large list, or any list where membership is at all subject to change (membership "turn over"), informing merely the list owner (who may want to consider removing chronically "bad" addresses from the list membership) is desirable, and why "informing" the original sender is likely to be perceived as "pestering" the original sender with irritating, useless, and irrelevant (to them) bounce messages. Furthermore, exposing who is on the list, but suffering delivery problems, to arbitrary original senders may be considered an undesirable exposure of information in some cases. (Keep in mind that some mailing lists and groups are configured so that being allowed to post to the list or group does not imply ability to see the list membership.) So notifying only the "responsible list owner" about delivery problems to list members is a true advantage that mailing lists have over groups. Now due to the widespread (mis)use of groups for mailing list purposes, users may have gotten accustomed, when posting to what is actually a group (but being misused as a mailing list), to receiving notifications of delivery problems to the individual group members. In such cases, the proper course is, almost always, to switch to a mailing list and educate the users on what to expect with a true mailing list, rather than continue to (mis)use a group.

- For the rare cases where mailing list semantics are appropriate in general, but where it truly makes sense to notify the original message sender of delivery problems to mailing list members, new in MS 6.3 (but not working until the fix for CR # 6530591), setting `mgrpErrorsTo: /`, that is, setting to the forward slash character, has a special meaning. It tells the MTA to revert to using the original envelope From address that had been present on the incoming message, yet in all other respects use mailing list semantics. This can be useful for setting up mailing lists that report all forms of list errors to the original sender. Note that this feature should *not* be used merely to avoid having to educate users about a change from group to mailing list semantics, as this is more than a "cosmetic" feature but rather has significant semantic impliciations; use of this feature should be reserved for cases where its semantic implications are truly understood and desired.

See the discussion of the `mgrpErrorsTo` attribute (or more precisely, the attribute named by the `ldap_errors_to` MTA option) for some additional discussion and special syntaces for this attribute's value.

Another difference between groups *vs*. true mailing lists is in the area of passing through of NOTARY flags on the message "copies" to the various recipients; here too mailing list behavior tends to be distinctly more desirable, as the group behavior (as required by Internet standards!) is optimized for the case of multiple mailboxes (aliases) for a single person.

49.2.2.1 Nested groups and nested mailing lists

For many purposes, a useful thing to do is to "nest" group definitions: have groups defined that contain other subgroups as members, or which are themselves contained in bigger groups.

When wishing to use such sets of users as mailing lists, however, usually a separate list definition should be made for *each* such desired list, defining each list's membership to be an appropriate group (or groups): for instance, using the `memberURL` attribute. For instance, schematically:

```
mail: list1@domain.com
mgrpErrorsTo: list1-owner@domain.com
memberURL: url-for-group2
memberURL: url-for-group3
```

where group2 and group3 are separately defined as *groups* with their own members, not as mailing lists (in particular, no `mgrpErrorsTo` attribute). Indeed, it may be desirable to define group2 and group3 so that they do not even have a `mail` attribute of their own (are not addressable as a pseudo-list). But if it is desired to also have the sets of users in group2 and group3 be accessible for e-mail postings, then use additional, separate list definitions, that in turn reference the group2 and group3 definitions for their membership, along the lines of:

```
mail: list2@domain.com
mgrpErrorsTo: list2-owner@domain.com
memberURL: url-for-group2

mail: list3@domain.com
mgrpErrorsTo: list3-owner@domain.com
memberURL: url-for-group3
```

where note that these are indeed new list definitions, that make use of separate and distinct group definitions for the membership.

That is, when nesting of groups (or so-called nesting of mailing lists) is neither used nor desired, then converting existing group definitions to true mailing lists definitions by simply adding an `mgrpErrorsTo` attribute (and any other desired mailing list attributes) is perfectly fine. However, if nesting of groups (or mailing lists) is desired, then simply converting the group definitions to list definitions is not optimal. Instead, this is the case where the more general approach of having group definitions (possibly not even including a `mail` attribute for the group) and then separate list definitions that use the groups for membership, offers significant advantages, including:

- By having the list membership defined as combining multiple groups, or nesting groups, the LDAP search criteria on the membership uses a search filter that includes all the appropriate groups, so that duplicate elimination of members, from within all the groups and all the nested levels of groups, will happen when the MTA is initially expanding the membership of the list, rather than expanding to separate sub-lists that then do their own membership

expansion operation limited to their own membership. That is, this approach allows better elimination of duplicate addresses---a list member who is a member of multiple subgroups defining the list will get one message copy.[1]

- By not using nested lists, list-specific modifications to messages, such as additions of List-*: header lines, setting of the error return address (the list "owner" address), *etc.*, will be performed once, consistently for the entire list membership, rather than having nested levels of changes occurring at each stage of nesting, causing changes to be cumulative or override each other.

[1] A separate issue is the so-called "duplicate" message copy -- which is not truly an exact duplicate -- that a recipient will receive if the original message was addressed *directly* to them, *e.g.*, on the To: or Cc: header line, as well as being addressed to the list of which the recipient is also a member. A message copy resulting from a posting to a list is fundamentally different from the copy addressed directly to the recipient: even though the message content may be superficially "the same" (though even that is not necessarily the case, if list-specific text addition, or spam/virus cleaning, or document conversion, or character set translation, or other modifying operations have occurred), the notification address will be different for a true mailing list copy. Other differences, such as in NOTARY flags, or in Received: header lines, *etc.*, also typically exist between mailing list copies and "direct" copies. Any difference that requires different handling by MTAs handling the message means that a different copy must be created at that point, and once a message has bifurcated in such a way, further divergence is possible and even likely: separate copies *will* be delivered and they are only superficially "duplicates". So keep in mind that even if the copies do not seem "significantly" different to the recipient, some difference existed at some point in time. Furthermore, sophisticated users may themselves wish to perform different handling of different types of incoming messages; for instance, some users will subscribe to mailing lists using subaddresses, thereby allowing for more convenient Sieve filtering of their incoming list messages.

49.2.3 Restricting posting access to large lists

Especially with a relatively "large" mailing list, it is usually wise to enforce at least some restrictions on who is allowed to post (send) to the list, so that the list is not used as an easy mechanism by which to spam the members. The MTA supports a variety of forms and mechanisms for such restrictions. For "large" mailing lists, more secure forms of restriction such as password-protected list access, or posting restricted to explicitly listed senders who are required to authenticate (use SMTP AUTH) themselves when submitting, may be especially appropriate. (Note that setting such posting access controls also limits who is allowed to view the membership of the list via the SMTP EXPN command---which may be beneficial in limiting address harvesting by spambots.)

With large mailing lists, setting

```
mailDeferProcessing: AFTER_AUTH
```

(which setting is only available and valid in MS 6.3p1 and later) is especially desirable. This setting causes immediate checks of any access controls, but deferred expansion of the list membership. This then allows immediate rejection of messages that do not meet posting criteria, while deferring the (possibly time consuming) list membership expansion until later, off-line, when the reprocess channel runs.

For instance, to permit postings only when the sender authenticated (using their account password) as either `mailadmin1@domain.com` or `mailadmin2@domain.com`:

```
mgrpBroadcasterPolicy: SMTP_AUTH_REQUIRED
mgrpAllowedBroadcaster: mailadmin1@domain.com
mgrpAllowedBroadcaster: mailadmin2@domain.com
```

Or to permit postings only when the sender provided a secret password on an Approved: header line (which same header line the MTA will automatically remove from the message distributed to list members):

```
mgrpBroadcasterPolicy: PASSWORD_REQUIRED
mgrpAuthPassword: secret-password
```

For many lists, an appropriate, less stringent restriction is to limit postings to members of the lists. The check on posters may be based simply on the attempting poster's e-mail address; for instance:

```
mgrpAllowedBroadcaster: mailto:list-address
```

or may further require that a poster in fact authenticated as a list member:

```
mgrpBroadcasterPolicy: SMTP_AUTH_REQUIRED
mgrpAllowedBroadcaster: mailto:list-address
```

Note that requiring SMTP AUTH use for postings usually also implicitly requires that all members of the list be "local" members (have a local account/be able to authenticate). (Though by trusting passed-along authentication from other systems, or by combining sub-list definitions appropriately, it is possible to achieve an effect whereby "local" users must authenticate to post, while still allowing postings from external users who are not capable of authenticating against your user directory.)

Or yet another routinely useful sort of list posting restriction is to allow direct postings only by members of the list, while redirecting any attempted postings by non-members to a list moderator; for instance:

```
mail: list-y@domain.com
mgrpMsgRejectAction: toModerator
mgrpAllowedBroadcaster: mailto:list-y@domain.com
mgrpModerator: mailto:list-y-owner@domain.com
mgrpErrorsTo: list-y-owner@domain.com
```

For additional flexibility in posting access controls, see the GROUP_AUTH mapping table.

49.2.3.1 GROUP_AUTH mapping table

The MTA's group/list access control mechanisms allow for a wide variety of access and permission models. However, exploiting this flexibility often depends on being able to define what attributes and values appear in LDAP group entries. If the entries being processed cannot be modified, as for instance in the case of an externally controlled LDAP directory, it becomes necessary for the MTA to adopt a more flexible processing model in order to support different attribute syntaxes.

New in 7.0.5, the GROUP_AUTH mapping table and four new MTA options ldap_auth_mapping*N* (*N*=1-4) have been added to facilitate such processing. The MTA options are used to specify the names of up to four additional LDAP attributes to be fetched during alias expansion processing. When the GROUP_AUTH mapping is defined and at least one of the four attributes ldap_auth_mapping*N* is defined and appears on a group, then the GROUP_AUTH mapping is probed during group authorization checks (before any other authorization checks are done). The probe format is:

envelope-from|*group-address*|*auth1*|*auth2*|*auth3*|*auth4*

Here the *authN* fields are simply whatever values are associated with the ldap_auth_mapping*N* named LDAP attributes for this group. If multiple attributes or multiple attribute values appear, they will all be present in the probe field, separated by commas.

The GROUP_AUTH mapping can produce any of four possible outputs:

- $Y indicates that the authorization check has passed.
- $T indicates that the mapping result is a URL, which is then checked in the same fashion as an ldap_auth_url would be.
- $N indicates that authorization has failed.
- $F indicates that the mapping result is a URL, which is then checked in the same fashion as an ldap_cant_url would be.

49.2.4 Performance submitting mass mail messages

Deferred processing of the expansion of the list membership, with or without deferred processing of list posting access controls, and setting of relevant bits of the ldap_use_async MTA option, tends to be especially important to consider for truly large lists.

For controlling and enabling the deferred processing of expansion of membership and/or access controls, see especially the per-list mailDeferProcessing LDAP attribute (more precisely, the LDAP attribute named by the ldap_reprocess MTA option), as well as the default set via the defer_group_processing MTA option. For large lists, it is usually desirable to set either the (new in MS 6.3p1) value of -1 for defer_group_processing, or equivalently the per-list setting of AFTER_AUTH for the mailDeferProcessing attribute; this allows inline processing of access controls, while deferring membership expansion. Alternatively, when the access control itself consists of a very large list, it may be desirable to defer the access control processing as well, as selected via a value of defer_group_processing=1 or the per-list setting of Yes for the mailDeferProcessing attribute.

49.3 Special address formats for list members

There are a few special address formats that may be worth considering using for list members, or that users may wish to use if subscribing themselves to a mailing list.

For one thing, it may be worth considering subscribing using a subaddress, to aid in convenient processing, *e.g.*, by a Sieve filter, of the mailing list postings when they are received. Such Sieve filter processing might include automatically filing mailing list postings

into a special folder based on the subaddress present on the recipient address, or specialized processing if one is the list moderator; see examples in Moderated mailing lists.

On a list member address, for MTA mailing lists defined via alias options, the alias file or alias database, a comment string containing the special string (by default "NOPOST") defined by the post_off MTA option disables the ability for the list member to post: the list member can receive list messages, but may not post. Using this comment string on every list member would be one way (though not necessarily the simplest way -- see Restricting posting access to large lists) to set up a broadcast-only (no posting) mailing list.

On a list member address, for MTA mailing lists defined via alias options, the alias file or alias database, a comment string containing the special string (by default "NOMAIL") defined by the mail_off MTA option disables the ability for the list member to receive list postings: the list member might be able to make list postings (depending upon any relevant mailing list access controls), but will not receive list postings. In particular, a list moderator may wish to use this feature -- the list moderator will see the list messages initially during the moderation phase, and may not wish to receive the messages again when the actual posting goes through.

For aliases defined via user LDAP entries, note that as of MS 7.0.5 a mailDeliveryOption (or whatever LDAP attribute is named by the ldap_delivery_option MTA option) value of nomail is considered valid, but will not receive any messages (messages are discarded). This is not suitable for the normal moderator use mentioned above as such a user entry receives *no* mail, but it is suitable for unmonitored mailboxes, when it is not intended that the mailbox should ever receive *any* messages. And it may be suitable for cases where mail forwarding or application of a user Sieve filter is desired (but normal receipt of messages is not desired).

(New in MS 8.0.1.) On a list member address, a comment string containing the special string (by default "ALTERNATE-RECIPIENT") defined by the alternate_recipient MTA option will cause the address specified in that comment string to be used as an alternate delivery address, for messages which cannot be delivered to this primary list member address.

Chapter 50 Mapping tables

Many components of the MTA employ table lookup oriented information. One particular type of table is used more often in the MTA than any other. Generally speaking, this sort of table is used to transform (*i.e.*, map) an input string into an output string. Such tables, referred to as mapping tables, are usually presented as two columns, the first or left-hand column giving the possible input strings and the second or right-hand column giving the resulting output string for the input it is associated with. Indeed, most of the MTA `crdb` databases can be considered instances of just this sort of mapping table. MTA `crdb` database files, however, do not provide wildcard lookup facilities, owing to inherent inefficiencies in having to scan the entire database for wildcard matches.

For more flexible, pattern-based mappings, the MTA also supports its own mapping tables. In legacy configuration mode, such MTA mapping tables are stored in the MTA mapping file; in Unified Configuration, MTA mapping tables are `mapping` XML elements and they may be referenced from within the `msconfig` utility as

`mapping:`*`mapping-name`*

where such a mapping table named *`mapping-name`* consists of an ordered list of rules. Full wildcard facilities are provided, and multi-step and iterative mapping methods can be accommodated as well. This approach is more compute-intensive than using a database, especially when the number of entries is large. However, the attendant gain in flexibility may actually serve to eliminate the need for most of the entries in an equivalent database, and this may actually result in lower overhead overall.

A fairly complete list of the mapping table names always recognized by the MTA is available under Pre-defined mapping tables. Some of the most commonly used mapping tables are the access mapping tables used to control who can send and receive e-mail. Sites may also define arbitrary mapping tables.

You can test general mapping table processing with the `imsimta test -mapping` utility. (Note that the `imsimta test -mapping` utility tests only the general-to-all-mapping-

tables functionality. It is not specific for testing of the functional meaning of specific mapping tables, such as access controls due to address-based *_ACCESS mapping tables, or address changes due to the REVERSE mapping table. Instead, the imsimta test -rewrite utility is typically more useful for such functional or semantic testing.)

50.1 Mapping table format

Mapping tables in legacy configuration were stored in the MTA mappings file; see Mapping table format in legacy configuration for further discussion.

In Unified Configuration, mapping tables are stored as part of the Unified Configuration. They may be viewed and modified in an editor "as if" they were still in the old mappings file format, or they may be viewed and modified as Unified Configuration rules; see Mapping table format in Unified Configuration for further discussion.

50.1.1 Mapping table format in legacy configuration

The mapping file consists of a series of separate tables. Each table begins with its name. Names always have an alphabetic character in the first column. The table name is followed by the the entries in the table. Entries consist of zero or more indented lines. Each entry line consists of two columns separated by one or more spaces or tabs. Prior to 7.0.5, any spaces within an entry must be quoted with the dollar sign, $; in 7.0.5 or later unquoted spaces and tabs are allowed in the second column.

A backslash, \, at the end of a line acts as a continuation character, causing the following line to be read and appended to the current line. A literal backslash may be placed at the end of a line by preceding it with a dollar sign, $\.

For clarity, it is recommended, but not required, that a blank line appear after each mapping table name and between each mapping table. Blank lines may also appear between successive mapping table entries but not after a continuation line, as it will terminate the continuation.

Trailing spaces and tabs are stripped from all lines, so lines containing nothing but spaces or tabs are considered "blank".

Comments are introduced by an exclamation mark, !, appearing in the first column.

Pictorially, the format that results looks like this:

```
TABLE-1-NAME

   pattern1-1    template1-1
   pattern1-2    template1-2
   pattern1-3    template1-3
     .           .
     .           .
     .           .
   pattern1-n    template1-n

TABLE-2-NAME

   pattern2-1    template2-1
```

```
pattern2-2    template2-2
pattern2-3    template2-3
  .           .
  .           .
  .           .
pattern2-n    template2-n

       .
       .
       .

TABLE-m-NAME

       .
       .
       .
```

In this example an application using the mapping table *TABLE-2-NAME* would map the string *pattern2-2* into whatever is specified by *template2-2*.

A mapping table name may be up to 128 characters long. Each pattern and each template can contain up to 256 characters before substitutions; the result of applying substitutions must be no more than 1024 characters each. As of MS 6.3p1 , the template (right hand side) limit has been increased to 1024 characters, and the overall length of each line in the mapping table has been increased to 4096 characters. (Prior to MS 6.0, the mapping table name was limited to 64 characters while the pattern and template were each individually limited to at most 252 characters.) There is no limit to the number of entries that can appear in a mapping (although excessive numbers of entries may eat up huge amounts of CPU and can consume excessive amounts of memory).

When the MTA probes a mapping table, the overall probe length is also limited to 1024 characters.

The order in which mappings appear in the mappings file is not significant.

Duplicate mapping table names are not allowed in the mapping file.

50.1.1.1 Including other files in the mapping file

Other files may be included in the mapping file. This is done with a line of the form:

```
<file-spec
```

This will effectively substitute the contents of the file *file-spec* into the mapping file at the point where the include appears. The file specification should specify a full file path (device, directory, *etc.*). All files included in this fashion must be world readable. Comments are also allowed in such included mapping files. Includes can be nested up to three levels deep. Include files are loaded at the same time the mapping file is loaded --- they are not loaded on demand, so there is no performance or memory savings involved in using include files.

50.1.2 Mapping table format in Unified Configuration

In Unified Configuration, mapping tables may be editted from within `msconfig` using a command such as

```
msconfig> edit mappings mapping-name
```

which will present the mapping table in the familiar tabular form of legacy configuration.

Alternatively, the XML `mapping` elements may also be referenced from within `msconfig` as an ordered list of `rule` settings grouped in a `mapping`, *e.g.*,

```
mapping:ORIG_SEND_ACCESS.rule = tcp_local|*|tcp_local|* $N$D30|Relaying not allowed
mapping:ORIG_SEND_ACCESS.rule = tcp_*|*|native|* $N
mapping:ORIG_SEND_ACCESS.rule = tcp_*|*|hold|* $N
mapping:ORIG_SEND_ACCESS.rule = tcp_*|*|pipe|* $N
mapping:ORIG_SEND_ACCESS.rule = tcp_*|*|ims-ms|* $N
mapping:ORIG_SEND_ACCESS.rule = tcp_local|*|tcp_intranet|@*:*.* $N$D30|Explicit routing not allowed
mapping:ORIG_SEND_ACCESS.rule = tcp_local|*|tcp_intranet|*$%*@* $N$D30|Explicit routing not allowed
mapping:ORIG_SEND_ACCESS.rule = tcp_local|*|tcp_intranet|*.*!*@* $N$D30|Explicit routing not allowed
mapping:ORIG_SEND_ACCESS.rule = tcp_local|*|tcp_intranet|"*@*"@* $N$D30|Explicit routing not allowed
```

50.1.3 Mapping entry patterns

Mapping patterns can contain wildcard characters. In particular, the usual so-callled "glob style" wildcard characters are allowed: an asterisk, *, will match zero or more characters and each percent sign, %, will match a single character. Asterisks, percent signs, spaces, and tabs can be quoted by preceding them with a dollar sign, $. Quoting an asterisk or percent sign robs it of any special meaning. Spaces and tabs must be quoted to prevent them from ending prematurely a pattern or template. Literal dollar sign characters should be doubled, $$, the first dollar sign quoting the second one. Additional wildcards available in patterns are listed in the table shown below.

Table 50.1 Mapping pattern wildcards

Wildcard	Description
%	Match exactly one character
*	Match zero or more characters, with maximal or "greedy" left-to-right matching
Back match	Description
$*n**	Match the *n*th wildcard or glob
Modifiers	Description
$_ ‡	Use minimal or "lazy" left-to-right matching for the following wildcard or glob
$@ ‡	Turn off "saving" for the following wildcard or glob
$^ ‡	Turn on "saving" for the following wildcard or glob; this is the default
Glob wildcard	Description
$A or $A%	Match one alphabetic character, A-Z or a-z
$A*	Match zero or more alphabetic characters, A-Z or a-z
$B or $B%	Match one binary digit (0 or 1)

$B*	Match zero or more binary digits (0 or 1)
$C or $C%	(New in 7.0) Match one ASCII control character (other than horizontal TAB)
$C*	(New in 7.0) Match zero or more ASCII control characters (other than horizontal TAB)
$D or $D%	Match one decimal digit 0--9
$D*	Match zero or more decimal digits 0--9
$H or $H%	Match one hexadecimal digit 0-9 or A-F
$H*	Match zero or more hexadecimal digits 0-9 or A-F
$O or $O%	Match one octal digit 0-7
$O*	Match zero or more octal digits 0-7
$S or $S%	Match one symbol set character, *i.e.*, 0-9, A-Z, a-z, _, $
$S*	Match zero or more symbol set characters, *i.e.*, 0-9, A-Z, a-z, _, $
$T or $T%	Match one tab or vertical tab or space character
$T*	Match zero or more tab or vertical tab or space characters
$X or $X%	A synonym for $H%
$X*	A synonym for $H*
$[*c*] or $[*c*]%	Match character *c*
$[*c*]*	Match zero or more occurrences of character *c*
$[$c_1c_2...c_n$]	Match exactly one occurrence of character c_1, c_2, or c_n
$[$c_1c_2...c_n$]%	Match exactly one occurrence of character c_1, c_2, or c_n
$[$c_1c_2...c_n$]*	Match zero or more occurrences of any characters c_1, c_2, or c_n
$[$c_1$-$c_n$]	Match any one character in the range c_1 to c_n
$[$c_1$-$c_n$]%	Match any one character in the range c_1 to c_n
$[$c_1$-$c_n$]*	Match zero or more occurrences of characters in the range c_1 to c_n
$<*IPv4*>	Match an IPv4 address, ignoring bits
$(*IPv4*)	Match an IPv4 address, keeping prefix bits
${*IPv6*}	Match an IPv6 address

(‡) When combined with a back match or glob wildcard, only one dollar sign character is used for both; for instance, `$@0*` is a non-saved back match of the first (0th) wildcard, and similarly, `$@A` is a non-saved alphabetic character glob wildcard.

Within globs, *i.e.*, within a `$[...]` construct, the backslash character, \, is the quote character. To represent a literal hyphen, `-`, or right bracket, `]`, within a glob the hyphen or right bracket must be quoted with a backslash.

All other characters in a pattern just represent and match themselves. In particular, single and double quote characters as well as parentheses have no special meaning in either mapping patterns or templates; they are just ordinary characters. This makes it easy to write entries that correspond to illegal addresses or partial addresses.

Note that to specify multiple modifiers, or to specify modifiers and a back match, or to specify modifiers and a glob, the syntax uses just one dollar character. For instance, to back match

the initial wild card, without saving the back match itself, one would use `$@0*`, *not* `$@$0*`. Similarly, to match a decimal digit without saving the matched digit, one would use `$@D`, *not* `$@$D`.

Note that the `imsimta test -match` utility may be used to test mapping patterns and specifically to test wildcard behavior in patterns.

50.1.3.1 Back matching with $*n**

In some mapping tables, it is particularly useful to be able to compare whether two portions (fields) of the mapping table input are identical. The "back match" wildcards are provided for this purpose. Back matches of `$0*` through `$9*` are available. For instance, a `$0*` wild card looks for (matches on) the same characters already matched in the very first wildcard or glob in an entry, while a `$1*` wildcard looks for the same characters already matched in the second wildcard or glob in an entry, *etc.*

50.1.3.2 The $_ modifier: minimal *vs*. maximal matching

Asterisk, `*`, wildcards maximize what they match working from left to right across the input string. For instance, when the input string "`a/b/c`" is compared to the pattern `*/*`, the left asterisk will match "`a/b`" and the right asterisk will match "`c`".

The `$_` modifier causes wildcard matching to be minimized, where the least possible match is considered the match, working from left to right across the input string. For instance, when the input string "`a/b/c`" is compared to the pattern `$_*/$_*`, the left `$_*` will match "`a`" and the right `$_*` will match "`b/c`".

50.1.3.3 Controlling saving of wildcard or globs with $@ and $^

By default, the MTA keeps track of (saves) which character(s) are considered to have matched a wildcard or glob in a mapping table pattern for the duration of that mapping table entry (line). These retained character(s) can then be substituted back into the mapping table entry template via the `$0` through `$9` template substitutions. (That is, the character(s) matched in the left hand side (pattern) of a mapping table entry can be substituted back into the right hand side (template) of a mapping table entry, if desired.) But the MTA can only retain ten such matches. This restriction on the number of "saved" matches can always be dealt with by using multiple, iterative mapping table entries to achieve a desired effect (each entry doing only some matching/restoring, before leaving additional work to be done by a later entry). However, in many cases, where there is a desire to enforce a great deal of matching structure (more than ten wildcards or globs) but no need to reuse hence "save" the matched value(s), it is simpler to just "turn off" the saving via the `$@` modifier.

The `$^` modifier (the default behavior) turns on "saving". The `$@` modifier turns off saving. Note that such modifiers, when combined with a pattern wildcard glob or backmatch that already includes a dollar sign, `$`, in a syntax `$`*`w`*, are then indicated simply by including the modifier letter (but not the dollar sign) "within" the wildcard or back match syntax, as `$`*`mw`*, where *`m`* is the modifier character, and *`w`* is the wildcard or back match -- only one dollar sign character is used. For example, the syntax to match without saving any number of binary digits is `$@B*`, *not* `$@$B*`.

For instance, if it is desired to match fifteen of any sort of character:

```
%%%%%%%%%%$@%$@%$@%$@%$@%      $Y
```

matches and saves the first ten characters, and then matches without saving another five characters (though in fact in this example since *none* of the matched characters are actually substituted back into the template result, one could just as well have not bothered to save any of the matched characters -- that is, used the $@ modifier on all of the % character matches).

Or if it is desired to match eight alphabetic characters followed by a period followed by eight decimal digits, and retain only the first four alphabetic characters and the first four decimal digits, that could be done as:

```
$A$A$A$A$@A$@A$@A$@A.$D$D$D$D$@D$@D$@D$@D    $Y$0$1$2$3.$4$5$6$7
```

where here only the first four alphabetic characters and first four decimal digits are saved (and then substituted back into the template).

50.1.3.4 IP matching

With IPv4 "prefix bits" matching, an IP address or subnet is specified, optionally followed by a slash and the number of bits from the prefix that are significant when comparing for a match. For instance,

```
$(123.45.67.0/24)
```

will match anything in the 123.45.67.0 class C subnet.

With IPv4 "ignore bits" matching, an IP address or subnet is specified, optionally followed by a slash and the number of bits to ignore when checking for a match. For instance,

```
$<123.45.67.0/8>
```

will match anything in the 123.45.67.0 subnet. Or another example is that

```
$<123.45.67.4/2>
```

will match anything in the range 123.45.67.4--123.45.67.7.

IPv6 matching matches an IPv6 address or subnet. The syntax is:

${*xxxx*:*xxxx*:*xxxx*:*xxxx*:*xxxx*:*xxxx*:*xxxx*:*xxxx*/*n*}

where each *xxxx* can consist of one to four hexadecimal digits (digits in the range 0 to F) and where *n* is an integer in the range 0 to 128 specifying the number of prefix bits that must match. In particular, each additional 16 bits of prefix matching requires that another 4 hexadecimal digit "chunk" of the IPv6 address must match. For instance,

```
${12AF:0:0:0:0:0:0:0/16}
```

means to match any IPv6 address where the first sixteen bits correspond to the hexadecimal value 12AF, regardless of what the remaining 112 bits in the address may be.

For IPv6 ${} matching, chunks may be omitted using the :: marker. For instance, ${12AF:0:0:0:0:0:0:0/16}, ${12AF::/16}, and ${12AF::0/16} are all equivalent. In particular, a commonly used example is that to match the local host, one may use

```
${::1}
```

meaning to match `0:0:0:0:0:0:0:1`.

See the `INTERNAL_IP` mapping table for examples of IP address matching.

50.1.4 Mapping entry templates

If the comparison of the pattern in a given mapping entry fails, no action is taken; the scan proceeds to the next entry. If the comparison succeeds, the right hand side of the entry is used as a template to produce an output string. The template effectively causes the replacement of the input string with the output string that is constructed from the instructions given by the template.

Almost all characters in the template simply produce themselves in the output. The one exception is a dollar sign.

A dollar sign followed by a dollar sign, space, or tab produces a dollar sign, space, or tab in the output string. Note that all these characters must be quoted in order to be inserted into the output string.

A dollar sign followed by a digit *n* calls for a substitution; a dollar sign followed by an alphabetic character is referred to as a "metacharacter". Metacharacters themselves will not appear in the output string produced by a template. See the table below for a list of the special substitution and standard processing metacharacters. Any other metacharacters are reserved for mapping-specific applications.

Note that any of the metacharacters $C, $E, $L, or $R, when present in the template of a matching pattern, will influence the mapping process, controlling whether it terminates or continues. That is, it is possible to set up iterative mapping table entries, where the output of one entry becomes the input of another entry. If the template of a matching pattern does not contain any of the metacharacters $C, $E, $L, or $R, then $E (immediate termination of the mapping process) is assumed.

The number of iterative passes through a mapping table is limited to prevent infinite loops. A counter is incremented each time a pass is restarted with a pattern that is the same length or longer than the previous pass. If the string has a shorter length than previously, the counter is reset to zero. A request to again iterate a mapping is not honored after the counter has exceeded 10.

Table 50.2 Mapping template substitutions and metacharacters

Substitution sequence	Substitutes
$*n*	*n*th wildcarded field as counted from left to right starting from 0. n must be a single digit
$'*n*'	*n*th wildcarded field as counted from left to right starting from 0. n can contain multiple digits
$%...%	(New in MS 6.2.) Substitute in a load average value.
$#...#	Sequence number substitution.
$+n#...#	Hash substitution.
$&...&	(New in MS 6.2.) Character value substitution.

$]...[	LDAP search URL lookup; substitute in result (first value, if multiple values returned).
$]$]...[	LDAP search URL lookup requiring that only one value be returned; substitute in result.
$]$]$]...[	LDAP search URL lookup that concatenates multiple returned values separated by CRLFs.
$.*text*.	(New in MS 6.3.) Result to use in the case of temporary failures from LDAP lookups, domain attribute lookups, and routine callouts.
$}...{	LDAP domain map attribute lookup; substitute in attribute value.
${...}	General database substitution.
$|...|	Apply specified mapping table to supplied string.
$+n|...|	Apply specified mapping table to supplied string with one or more prefixes specified by the bit-encoded value *n*.
$`...'	Evaluate expression; substitute in result.
$[...]	Invoke site-supplied routine; substitute in result.
Metacharacter	Description
$C	Continue the mapping process starting with the next table entry; use the output string of this entry as the new input string for the mapping process.
$+1C	(New in MS 8.1.0.6.) End processing of the current template now (unlike $C) and continue processing with the next mapping entry.
$E	End the mapping process now; use the output string from this entry as the final result of the mapping process.
$+1E	(New in MS 6.3.) End the mapping process now and (unlike $E) do not even interpret the rest of the template; use the output string from this entry (sans interpretation of the rest of the template) as the final result of the mapping process.
$L	Continue the mapping process starting with the next table entry; use the output string of this entry as the new input string; after all entries in the table are exhausted make one additional pass starting with the first table entry. A subsequent match may override this condition with a $C, $E, or $R metacharacter.
$R	Continue the mapping process starting with the first entry of the mapping table; use the output string of this entry as the new input string for the mapping process.
$+1R	New in MS 8.0.2.2. Continue the mapping process by repeating the current entry of the mapping table; use the output string of this entry as the new input string for the mapping process.
$?*x*?	Mapping entry succeeds *x* percent of the time.
$?*a,b,c...*?	Select a random value from a list of values. New in MS 8.0.2.3
$\	Force subsequent text to lowercase.
$^	Force subsequent text to uppercase.

$_	Leave subsequent text in its original case (and without LDAP URL style quoting).
$=	Force subsequent material to be properly quoted (encoded) according to LDAP URL syntax rules.
$:*x*	Match only if the specified flag is set.
$;*x*	Match only if the specified flag is clear.

50.1.4.1 Wildcard field substitutions, $n, $'n'

A dollar sign followed by a single digit *n* or one or more digits enclosed in single quotes *n...* is replaced with the material that matched the *n*th wildcard in the pattern. The wildcards are numbered starting with 0. For example, the entry

```
PSI$%*::*    $1@$0.psi.network.org
```

would match the input string PSI%A::B and produce the resultant output string b@a.psi.network.org. The input string PSI%1234::USER would also match producing USER@1234.psi.network.org as the output string. The input string PSIABC::DEF would not match the pattern in this entry and no action would be taken; *i.e.*, no output string would result from this entry.

50.1.4.2 Controlling text case, $\, $^, $_

$\ forces subsequent text to lowercase, $^ forces subsequent text to uppercase, and $_ causes subsequent text to retain its original case (and turns off LDAP URL quoting if it had been previously turned on via the $= metacharacter. For instance, these metacharacters may be useful when using mappings to transform addresses for which case is significant.

50.1.4.3 Processing control, $C, $+1C, $L, $R, $+1R, $E, $+1E

The $C, $L, $R, and $E metacharacters influence the mapping process, controlling whether and when the mapping process terminates. $C causes the mapping process to continue with the next entry, using the output string of the current entry as the new input string for the mapping process. $L causes the mapping process to continue with the next entry, using the output string of the current entry as the new input string for the mapping process, and, if no matching entry is found, making one additional pass through the table starting with the first table entry; a subsequent matching entry with a $C, $E, or $R metacharacter overrides this condition. $R causes the mapping process to continue from the first entry of the table, using the output string of the current entry as the new input string for the mapping process. $E causes the mapping process to terminate; the output string of this entry is the final output. $E is the default.

New in MS 6.3 is the $+1E metacharacter. It acts like $E, except that unlike $E it inhibits (stops) interpretation of the rest of the template.

New in MS 8.1.0.6, the $+1C metacharacter sequence works like $C except processing of the current template is aborted and the remainder of the template is ignored. Note that this is likely to only be useful in conjunction with temporary failure handling and $..

New in MS 8.0.2.2, the $+1R metacharacter sequence provides a variant of $R: Rather than restarting the entire mapping from the first entry, it repeats the current entry with updated output from the current operation.

The $+1R is useful in constructing mappings that perform multiple replacements of all occurrences of one string with another where some of the strings overlap. A single operation of this sort can be done with $R; for example, replacing all percent signs with at-signs can be done with:

```
PERCENT_TO_AT

   *%*          $R$0@$1
   *            $0$Y
```

But when multiple replacements are involved restarting the mapping from the beginning is inefficient. And if the strings being replaced overlap restarting from the beginning won't work because the earlier, completed operations will see the later replacements and get confused. For this to work repeating the same entry until it no longer matches is required.

For example, the following mapping performs the quoting necessary for a string being inserted into an LDAP DN:

```
DN_QUOTE

   *\*          $+1R$0~$1
   *~*          $+1R$0\5c$1
   #*           $C\23$0
   *"*          $+1R$0\22$1
   *+*          $+1R$0\2b$1
   *,*          $+1R$0\2c$1
   *;*          $+1R$0\3b$1
   *<*          $+1R$0\3c$1
   *>*          $+1R$0\3e$1
   *            $0$Y
```

Note that if $R was used that the inital entry would damage the later replacement operations.

Mapping table templates are scanned left to right. So to set a $C, $L, or $R flag for entries that may "succeed" or "fail", *e.g.*, general database substitutions, or random value controlled entries, put the $C, $L, or $R metacharacter to the left of the part of the entry that may succeed or fail; otherwise, if the remainder of the entry fails, the flag will not be seen.

50.1.4.4 Check for special flags

Some mapping probes have special flags set. $:*x* causes an entry to match only if the flag *x* is set. $;*x* causes an entry to match only if the flag *x* is clear. See specific mapping table descriptions for any special flags that may apply for that table.

When the intention is that an entry should succeed and terminate if the flag check succeeds, but that the mapping process should continue if the flag check fails, then the entry should use the $C metacharacter to the left of the flag check and use the $E metacharacter to the right of the flag check.

50.1.4.5 Entry randomly succeeds or fails, $?*x*?

A $?*x*? sequence in a mapping table entry causes the entry to "succeed" *x* percent of the time; the rest of the time, the entry "fails" and the output of the mapping entry's input is taken

unchanged as the output. (Note that, depending upon the mapping, the effect of the entry "failing" is not necessarily the same as the entry not matching in the first place.) The argument between the ?'s, *x*, should consist of a real number specifying the success percentage.

For instance, suppose that a system with IP address 123.45.6.78 is sending your site just a little too much e-mail and you'd like to slow it down; if you're using the MTA's SMTP server on port 25, you can use a PORT_ACCESS mapping table in the following way. Suppose you'd like to allow through only 25 percent of its connection attempts and temporarily reject the other 75 percent of its connection attempts. The following PORT_ACCESS mapping table uses $?25? to cause the entry with the $Y (accept the connection) to succeed only 25 percent of the time; the other 75 percent of the time, when this entry fails, the initial $C on that entry causes the MTA to continue the mapping from the next entry, which causes the connection attempt to be rejected with a temporary SMTP error (in this example, 452 4.4.0) and the text message "Try again later".

```
PORT_ACCESS

  TCP|*|25|123.45.6.78|*      $C$?25?$Y
  TCP|*|25|123.45.6.78|*      $N452$ 4.4.0$ Try$ again$ later
```

Another example would be randomly issuing a temporary failure message for a certain percentage of SMTP messages from a particular envelope From address; for instance, suppose the goal is to issue a temporary failure message with extended SMTP code 4.5.9 to eighty percent of the messages that busybee@some.where attempts to send to your local channel users. Then a SEND_ACCESS mapping table could be used, *e.g.*,

```
SEND_ACCESS

  tcp_*|busybee@some.where|l|*    $C$?20?$Y
  tcp_*|busybee@some.where|l|*    $N$X4.5.9|Try$ again$ later
```

50.1.4.6 Load average substitutions, #%...%

At the present time load average substitutions are not implemented.

50.1.4.7 Select random entry from list, $?*a,b,c...*?

As of MS 8.0.2.3, a $?*a,b,c,...*? sequence consisting of two or more comma-separated string values in a mapping table entry causes one of the string values to be selected at random and retained in the output.

50.1.4.8 Sequence number substitutions, $#...#

A $#...# substitution increments the value stored in an MTA sequence file and substitutes that value into the template. This can be used to generate unique, increasing strings in cases where it is desirable to have a uniquifier in the mapping table output; for instance, when using a mapping table to generate file names.

Permitted syntax is any one of:

`$#seq-file-spec#`

or

`$#seq-file-spec|radix#`

or

`$#seq-file-spec|radix|width#`

or (new in MS 6.1)

`$#seq-file-spec|radix|width|modulus#`

where the optional *seq-file-spec* argument is a full file specification for an (already existing) MTA sequence file, and where the optional *radix*, *width*, and *modulus* arguments specify the radix (base) in which to output the sequence value, the number of digits to output, and the modulus, respectively. The *seq-file-spec* argument may be omitted, in which case the MTA will use its own temporary sequence file (that will be created and used for the duration of this image). The default radix is 10. Radices in the range -36 to 36 are also allowed; for instance, base 36 gives values expressed with digits 0,...,9,A,...,Z. By default, the sequence value is printed in its natural width, but if the specified width calls for a greater number of digits, then the output will be padded with 0's on the left to obtain the desired number of digits. Note that if a width is explicitly specified, then the radix must be explicitly specified also. If a modulus is specified, then the value inserted is the sequence number retrieved from the file mod the modulus; the default (and the only behavior available prior to MS 6.1) is not to perform any modulus operation.

As noted above, when specifying an explicit sequence file in a mapping, that file must already exist. To create a proper sequence file, on UNIX use the command:

`% touch seq-file-spec`

or

`% cat >seq-file-spec`

A sequence number file accessed via a mapping table must be world readable in order to operate properly. (In particular, the `noprivuser` user id, as specified in the `restricted.cnf` file,is used to access the file.)

50.1.4.9 Hash substitutions, $+n#...#

(New in 7.4-18.01.)

A `$+n#...#` substitution, $n > 0$, computes a hash of a specified string and inserts the hash result into the mapping result. The value *n* selects the type of hash to compute.

Permitted syntax is any one of:

$+*n*#*string*#

or

$+*n*#*string*|*radix*#

or

$+*n*#*string*|*radix*|*width*#

$+*n*#*string*|*radix*|*width*|*modulus*#

where the *string* argument is the string to be hashed, and where the optional *radix*, *width*, and *modulus* arguments specify the radix (base) in which to output the hash value, the number of digits to output, and the modulus, respectively. The default radix is 10. Radices in the range -36 to 36 are also allowed; for instance, base 36 gives values expressed with digits 0,...,9,A,...,Z. By default, the sequence value is printed in its natural width, but if the specified width calls for a greater number of digits, then the output will be padded with 0's on the left to obtain the desired number of digits. Note that if a width is explicitly specified, then the radix must be explicitly specified also. If a modulus is specified, then the value inserted is the sequence number retrieved from the file mod the modulus; the default is not to perform any modulus operation on the hash value.

As noted above, the value of *n* selects the hash operation to perform. Currently the only supported value for *n* is 1, which employs the following hash function (32 bit integers are assumed):

```
int hashvalue(char *string, int length)
{
    unsigned int hash;
    int i, j;
    unsigned int *uptr;

    uptr = (unsigned int *)string;
    hash = length;
    j = length >> 2;
    for (i = 0; i < j; i++)
    {
        hash ^= *uptr++;
        hash = (hash << 9) | (hash >> 23);
    }
    for (i = j << 2; i < length; i++)
    {
        hash ^= string[i];
        hash = (hash << 13) | (hash >> 19);
    }
    return ((hash * 0x71279461U) >> 2);
}
```

50.1.4.10 Character value substitutions, $&...&

(New in MS 6.2.) The MTA can generate UTF-8 strings from Unicode character values using the $&...& substitution sequence. Multiple Unicode character values may be specified, by separating them with the comma character. For instance, substitution sequence of the form:

```
$&A0A0,20,A1A1&
```

will produce a UTF-8 string containing the characters at position A0A0, 20, and A1A1.

50.1.4.11 LDAP query URL substitutions, $]...[, $]$]...[, $]$]$]...[, $=

A substitution of the form `$]`*`ldap-url`*`[`, `$]$]`*`ldap-url`*`[`, or `$]$]$]`*`ldap-url`*`[` is handled specially. *`ldap-url`* is interpreted as an LDAP query URL and the result of the LDAP query is substituted. The difference between the three forms is that in the case of a multi-valued result, `$]`*`ldap-url`*`[` uses the "first" returned value (note that the LDAP protocol leaves the order of values returned as unspecified and implementation-dependent -- thus you must not make any assumptions about which value might be returned "first"), whereas a multi-valued response is an error (the lookup is considered to have failed) for `$]$]`*`ldap-url`*`[`, and (new in 8.0) the `$]$]$]`*`ldap-url`*`[` form concatenates all the results together, separated by CRLFs.

Standard LDAP URLs as per RFC 2255 are used, with the host and port typically omitted. (In versions prior to 7.4-18.01, the host and port had to be omitted; as of version 7.4-18.01, specifying the LDAP host and port in the URL is permissable.) If the host and port are omitted, they are assumed from the values of the `ldap_host` and `ldap_port` MTA options (or the `ugldaphost` and `ugldapport` base options, if the MTA options are not set, corresponding to the legacy `configutil` parameters `local.ugldaphost` and `local.ugldapport`). That is, the LDAP URL should be specified as:

```
ldap:///dn[?attributes[?scope?filter]]
```

or

```
ldap://host[:port]/dn[?attributes[?scope?filter]]
```

where the square bracket characters *`[`* and *`]`* shown above indicate optional portions of the URL. The *`dn`* is required and is a distinguished name specifying the search base. The optional *`attributes`*, *`scope`*, and *`filter`* portions of the URL further refine what information to return. That is, *`attributes`* specifies the attribute or attributes to be returned from LDAP directory entries matching this LDAP query. The *`scope`* may be any of `base` (the default), `one`, or `sub`. *`filter`* describes the characteristics of matching entries.

As of Messaging Server 7.2-7.02, so-called external LDAP (extldap:) URLs are also supported. (As of the Messaging Server 7.0u4 support for explicit host and port specification directly in the LDAP URL, this functionality is somewhat redundant. But it may still be useful when a particular external directory, and perhaps one with different authentication credentials needed for access, is used.) That is, if a URL is specified as

```
extldap:///dn[?attributes[?scope?filter]]
```

then an LDAP lookup will be performed against the alternate LDAP directory configured (via the LDAP external directory lookup MTA options) as the "external LDAP" directory.

Note that LDAP URLs have special character quoting (encoding) requirements. (See RFC 1738, Section 2.2, "URL Character Encoding Issues", and RFC 2254, Section 4, "String Search Filter Definition". Note that the quoting rules in RFC 1960, Section 3, "String Search Filter Definition", have been superceded by those of RFC 2254.) The $= metacharacter forces subsequent material to be properly quoted (encoded) for LDAP URL usage; that is, any of the characters

```
$ & + , : ; = ?
```

will be converted to the percent character, "%", followed by the hexadecimal representation of their location in US-ASCII, any of the characters

```
( ) *
```

will be converted to %5C" followed by the hexadecimal representation of their location in US-ASCII (the encoded form of the backslash character followed by the hexadecimal for the particular character), while the backslash character itself

```
\
```

will be converted to %5C5C".

The $_ metacharacter disables such LDAP quoting.

So note that when using a $]...[LDAP URL callout, one should normally use the $= and $_ metacharacters around and substituted material that might contain special characters, and manually encode any fixed special characters in the material in the callout, or use just the $= and $_ metacharacters around the entire interior of the LDAP URL body, *e.g.*,

```
$]ldap:///$=...$_[
```

The overall length of the LDAP URL (after any substitutions are performed) is limited to 252 characters in iMS 5.2, limited to 256 characters in MS 6.0 through MS 6.2, and limited to 1024 characters as of MS 6.3. Note also that the length of the original template in which such an LDAP URL appears is limited: to 252 characters in iMS 5.2 and earlier, or to 256 characters as of MS 6.0 and later; but substitutions in the template, and in particular substitutions used to construct the LDAP URL, may increase the LDAP URL length.

50.1.4.12 LDAP domain map attribute substitutions, $}...{

(New in MS 6.1p1/MS 6.2.) A substitution of the form $}*domain-name*,*attribute*{ is handled specially. *domain-name* is looked up in the directory as a domain, with domain map processing of the *domain-name* to build a proper LDAP query URL being automatically performed by the MTA. (In particular, in Schema 1 mode, the *domain-name* is looked up in the DC portion of the directory; while in Schema 2 mode, the *domain-name* is looked up using the Schema 2 domain filter.) Note that this argument *domain-name* truly is a domain *name*. If the domain *domain-name* exists and has the specified *attribute*, then the attribute's initial value is substituted into the mapping result; if either the attribute or the domain does not exist, then the mapping entry fails.

The following special syntaxes are also supported:

Table 50.3 Domain map mapping template special syntaxes

Syntax	Interpretation and effect
`${`*`domain`*`,_base_dn_{`	Return the base DN for the user/group entries belonging to this domain
`${`*`domain`*`,_domain_dn_{`	Return the DN of the domain entry itself
`${`*`domain`*`,_domain_name_{`	Return the name of the domain (as opposed to an alias)
`${`*`domain`*`,_canonical_name_{`	Return the canonical name associated with the domain

(New in 8.0.) A substitution of the form `${`*`user-identifier`*`,`*`attribute`*`{` is handled specially. *`user-identifier`* is looked up in the directory as a user name.

The following attributes can be specified:

Table 50.4 User identifier mapping template attributes

Syntax	Interpretation and effect
`${`*`user-identifier`*`,#canonical_user#{`	Return the canonical form of user identifier
`${`*`user-identifier`*`,#canonical_domain#{`	Return the canonical domain the user is associated with
`${`*`user-identifier`*`,#user_dn#{`	Return the DN of the user's entry in the directory

(New in MS 8.0.2) A substitution of the form `${`*`host`*`,`*`query`*`{` is handled specially. *`host`* is treated as the name of a deployment map host.

The following queries can be specified:

Table 50.5 Deployment map mapping queries

Syntax	Interpretation and effect
`${`*`host`*`,/role/{`	return role of the specified host; fail if host does not exist in the deployment map
`${`*`host`*`,/online/{`	succeeds if the specified host exists and is online
`${`*`host`*`,/offline/{`	succeeds if the specified host is offline or does not exist
`${`*`user-identifier`*`,/<n>/{`	<n> must be an unsigned number - return the <n>th property value for the host; fail if host or specified property does not exist
`${`*`user-identifier`*`,/<p>/{`	<p> must be a string not matching any previous sort of query - succeeds if the specified host has properity <p> associated with it, fails otherwise. <p> may contain glob-style wildcards. On success the value of the first retained wildcard will be returned if it exists.

50.1.4.13 General database substitutions, ${...}

A substitution of the form ${*text*} is handled specially. The *text* part is used as a key to access the MTA's general database. If *text* is found in the database, the corresponding template from the database is substituted. If *text* does not match an entry in the database, the input string is used unchanged as the output string.

Depending upon the setting of the use_text_databases MTA option, the general "database" is either stored and accessed as an on-disk database (the default), or as an in-memory structure constructed (during configuration compilation or MTA initialization) from an on-disk flat text file. Or new in MS 8.0, the general "database" can instead be stored in memcache; see the general_database_url MTA option. The on-disk database, if that is what is being used, is IMTA_DATAROOT:db/generaldb (which formerly could be redirected via the now-deleted imta_general_database MTA Tailor option), which must be generated using the imsimta crdb utility from some site-supplied source text file. If an in-memory database structure is instead being used, then when the MTA configuration is compiled (or at MTA process initialization time, if a compiled configuration is not in use) the MTA reads the file IMTA_TABLE:general.txt (which formerly could be redirected via the now-deleted imta_general_data MTA Tailor file option), and compiles it into an in-memory structure. Use of an in-memory "database" is normally recommended (for reasons of performance and reliability); however, do note that use of this in-memory "database" does require recompiling the configuration to get changes to the "database" (changes to the source text file) incorporated into the compiled configuration.

Note that when wishing to use processing control metacharacters such as $C, $R, or $L in a mapping table entry that does a general database substitution, the processing control metacharacter should be placed to the left of the general database substitution in the mapping table template; otherwise the "failure" of a general database substitution will mean that the processing control metacharacter will not be seen.

In some cases it may be useful to test to see if a given entry exists in the general database without substituting the corresponding template value from the database entry. This can be accomplished by creating a secondary mapping of the form:

```
GENERAL_EXISTS

   *                       $E${$0}$C
   *                       $Y
```

A mapping table substitution callout, described in the following section, with the general database key as the probe, will now succeed if and only if the corresponding entry is in the database, but will not return the corresponding template from the database entry.

50.1.4.14 Mapping table substitutions, $|...|

A substitution of the form $|*mapping*;*argument*| is handled specially. The MTA looks for an auxiliary mapping table named *mapping* in the mapping file, and uses *argument* as the input (probe) to that named auxiliary mapping table. The named auxiliary mapping table must exist and must set the $Y flag in its output if it is successful; if the named auxiliary mapping table does not exist or doesn't set the $Y flag, then that auxiliary mapping table substitution fails and the original mapping entry is considered to fail: the original input string will be used as the output string.

A substitution of the form $+n|*mapping*;*argument*|, where n is a non-zero bit-encoded value works in same way, except that one or more |-separated prefixes are added to the auxiliary mapping probe. The available prefixes are:

Table 50.6 Auxiliary mapping probe prefixes

Bit	Value	Prefix
0	1	Transport information in the usual "TCP|*server-address*|*server-port*|*client-address*|*client-port*" format.
1	2	Application information.
2	4	Source channel (blank if no source channel is currently active).
3	8	Destination channel (blank if no destination channel is currently active).
4	16	Authenticated sender address (blank if no authenticated sender is currently active).

If multiple bits are enabled the corresponding prefixes are added in numerical order with the least significant bit on the left.

Note that prefixes required an enqueue context; they will be ignored in mapping calls where such a context is not available.

Note that when wishing to use processing control metacharacters such as $C, $R, or $L in a mapping table entry that does a mapping table substitution, the processing control metacharacter should be placed to the left of the mapping table substitution in the mapping table template; otherwise the "failure" of a mapping table substitution will mean that the processing control metacharacter will not be seen.

Mapping table substitutions have similarities to both subroutine calls and nesting of regular expressions using parentheses. The following recipient rate limit example illustrates the subroutine call aspect of mapping table substitutions by using a separate mapping table to remove any subaddress from an address so that subaddresses can't be used to avoid the limit.

A Metermaid throttle table with the following settings is used to implement a limit of 10 occurrence of a given recipient every 5 minutes:

```
msconfig> show metermaid.local_table:reclim
role.metermaid.local_table:reclim.data_type = string
role.metermaid.local_table:reclim.max_entries = 100000
role.metermaid.local_table:reclim.quota = 10
role.metermaid.local_table:reclim.quota_time = 300
role.metermaid.local_table:reclim.table_type = throttle
```

The following mapping removes any subaddress that's present in an address:

```
REMOVE_SUBADDRESS

  "$[a-z0-9.#$&'*\-/=?^_`{}\~]*+$_*"@*   $Y$0@$2
  "$_*+$_*"@*                            $Y"$0"@$2
  $_*+$_*@*                              $Y$0@$2
  *                                      $Y$0
```

And finally, the following callout rule added at the end of the ORIG_SEND_ACCESS mapping implements the limit:

```
tcp_*|*|*|* $C$;R$[IMTA_LIB:check_metermaid.so,throttle,reclim,$|REMOVE_SUBADDRESS;$3|]$X4.2.3|$NRate$ too$ high$E
```

Note the "$;R" (new in MS 8.0) prevents this rule from being applied to enqueues from "internal" channels (process channel, reprocess channel, conversions channel, etc.).

50.1.4.15 Expression substitutions, $`..'

In addition to basic arithmetic operations and tests listed in Operators in Order of Precedence, see Symbol table functions for a list of additional functions available for use in expressions. Note that mapping tables operate on strings; string arguments must be converted to integers (see for instance the `integer` function) before performing integer arithmetic on them, and conversely any arithmetic intermediate results must be converted back to strings (see for instance the `string` function) before being substituted back into mapping table entry templates.

Expression arithmetic can be used to manipulate IP addresses, which are a common component of many mapping probes. For example, the following mapping takes an IP address as input performs a general database lookup on successive subnets derived from the input address up to /8:

```
SUBNET_LOOKUP

  $D*.$D*.$D*.$D*    $C${$0.$1.$2.$3/32}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$2.$`$3>>1<<1'/31}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$2.$`$3>>2<<2'/30}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$2.$`$3>>3<<3'/29}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$2.$`$3>>4<<4'/28}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$2.$`$3>>5<<5'/27}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$2.$`$3>>6<<6'/26}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$2.$`$3>>7<<7'/25}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$2/24}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$`$2>>1<<1'/23}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$`$2>>2<<2'/22}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$`$2>>3<<3'/21}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$`$2>>4<<4'/20}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$`$2>>5<<5'/19}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$`$2>>6<<6'/18}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1.$`$2>>7<<7'/17}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$1/16}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$`$1>>1<<1'/15}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$`$1>>2<<2'/14}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$`$1>>3<<3'/13}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$`$1>>4<<4'/12}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$`$1>>5<<5'/11}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$`$1>>6<<6'/10}$Y$E
  $D*.$D*.$D*.$D*    $C${$0.$`$1>>7<<7'/9}$Y$E
  $D*.$D*.$D*.$D*    $C${$0/8}$Y$E
```

50.1.4.16 Mapping routine callout substitutions, $[...]

A substitution of the form `$[`*`image,routine,argument`*`]` is handled specially. The *`image,routine,argument`* part is used to find and call an Oracle-supplied or customer-supplied routine. At run-time on UNIX, the MTA uses `dlopen` and `dlsym` to dynamically

load and call the routine *routine* from the shared library *image*. The routine *routine* is then called as a function with the following argument list:

```
status = routine (argument, arglength, result, reslength);
```

The **argument** and **result** arguments are 256 byte long character string buffers in MS versions prior to 8.1.0.1. As of 8.1.0.2, the size has been increased to 1024 bytes. On UNIX systems **argument** and **result** are passed as a pointer to a character string, (*e.g.*, in C, as char*.) **arglength** and **reslength** are signed, 32 bit integers passed by reference. On input, **argument** contains the *argument* string from the mapping table template, and **arglength** the length of that string. On return, the resultant string should be placed in **result** and its length in **reslength**. This resultant string will then replace the "$[*image*,*routine*,*argument*]" in the mapping table template. The routine *routine* should return 0 if the mapping table substitution should fail and -1 if the mapping table substitution should succeed. The special value 1112064044 may be returned to indicate a temporary failure.

Note that when wishing to use processing control metacharacters such as $C, $R, or $L in a mapping table entry that does a site-supplied routine substitution, the processing control metacharacter should be placed to the left of the site-supplied routine substitution in the mapping table template; otherwise the "failure" of a mapping table substitution will mean that the processing control metacharacter will not be seen.

The site-supplied routine callout mechanism allows the MTA's mapping process to be extended in all sorts of complex ways. For example, in a PORT_ACCESS or SEND_ACCESS mapping table, a call to some type of load monitoring service could be performed and the result used to decide whether or not to accept a connection or message.

See the dns_verify callouts, the check_memcache.so callout, and check_metermaid callout for examples of Oracle-provided such callout routines.

50.1.4.17 Temporary failure handling, $.text., $..

(New in MS 6.3.) The $.*text*. sequence can be used in a mapping entry to establish a string *text* which will be processed as the mapping entry result in the event of a temporary failure from an LDAP lookup, domain attribute lookup, or callout routine. By default these temporary failures cause the current mapping entry to fail, which is is problematic in cases where different actions need to be taken depending on, say, whether the LDAP lookup failed versus the directory server being unavailable or misconfigured.

Once a failure string has been set using this construct, it will remain set until current mapping processing is completed. $.. can be used to return to the default state where no temporary failure string is set and temporary failures cause mapping entry failure. Note that all LDAP and domain attribute errors other than failure to match an entry in the directory are considered to be temporary errors; in general it isn't possible to distinguish between errors caused by incorrect LDAP URLs and errors caused by directory server configuration problems. In contrast, callout routines have a unique return value (1112064044) used to indicate that a temporary failure has occurred.

50.2 The mapping group

In Unified Configuration, the mapping group is not an option itself, but rather a grouping of mapping table entries defining a particular named mapping table. For instance:

```
msconfig> set mapping:X-TEST.rule A $Y
msconfig# set mapping:X-TEST.rule B $Y
msconfig# set mapping:X-TEST.rule * $N
msconfig# show mapping:X-TEST
role.mapping:X-TEST.rule = A $Y
role.mapping:X-TEST.rule = B $Y
role.mapping:X-TEST.rule = * $N
msconfig# quit
```

This defines (but does not write -- does not save) a mapping table named `X-TEST` that returns a `Y` flag to an input probe of `A` or `B`, and returns a `N` flag to any other input probe. The legacy configuration (`mappings` file) equivalent would be:

```
X-TEST

 A $Y
 B $Y
 * $N
```

50.3 Mapping operation

All MTA mapping tables are applied in a consistent way. What changes from one mapping to the next is the source of the input strings, and the use of the mapping output strings.

That is, a mapping operation always starts off with an input string and an MTA mapping table. The entries in the mapping table are scanned one at a time from first to last (top to bottom) in the order in which they appear in the table. The left hand side of each entry is used as pattern, and the input string is compared in a case-blind fashion with that pattern. If the comparison of the pattern in a given entry fails, no action is taken; the scan proceeds to the next entry. If the comparison succeeds, (that is, the input probe string "matched" the entry pattern), then the right hand side of the entry is used as a template to produce an output string. The template effectively causes the replacement of the input string with the output string that is constructed from the instructions given by the template.

50.4 Handling large numbers of mapping table entries

Sites that use very large numbers of entries in mapping tables should consider organizing their mapping tables to have a few generic wildcarded entries that call out to the general database for the specific lookups. It is much more efficient to have a few mapping table entries calling out to the general database for specific lookups than to have huge numbers of entries directly in the mapping table. (As a rule of thumb, certainly by the time a mapping table has reached about one hundred entries, it is worthwhile to consider whether the number of individual entries could be reduced by consolidating into more general entries that call out to the general database to check specific data.)

One case in particular is that some sites like to have per user controls on who can send and receive Internet e-mail. Such controls are conveniently implemented using a recipient access mapping table such as `ORIG_SEND_ACCESS`. For such uses, efficiency and performance can be

greatly improved by storing the bulk of the specific information (*e.g.*, specific addresses) in the general database with mapping table entries structured to call out appropriately to the general database.

For instance, consider a mapping table:

```
ORIG_SEND_ACCESS

! Users allowed to send to Internet
!
  *|adam@domain.com|*|tcp_local    $Y
  *|betty@domain.com|*|tcp_local   $Y
! ...etc...
!
! Users not allowed to send to Internet
!
  *|norman@domain.com|*|tcp_local  $NInternet$ access$ not$ permitted
  *|opal@domain.com|*|tcp_local    $NInternet$ access$ not$ permitted
! ...etc...
!
! Users allowed to receive from the Internet
!
  tcp_*|*|*|adam@domain.com        $Y
  tcp_*|*|*|betty@domain.com       $Y
! ...etc...
!
! Users not allowed to receive from the Internet
!
  tcp_*|*|*|norman@domain.com      $NInternet$ e-mail$ not$ accepted
  tcp_*|*|*|opal@domain.com        $NInternet$ e-mail$ not$ accepted
! ...etc...
```

Rather than using such a mapping table with each user individually entered into the table, a more efficient setup (much more efficient if hundreds or thousands of user entries are involved) would be as follows. Use general database entries of, say:

```
SEND|adam@domain.com    $Y
SEND|betty@domain.com   $Y
! ...etc...
SEND|norman@domain.com  $NInternet$ access$ not$ permitted
SEND|opal@domain.com    $NInternet$ access$ not$ permitted
! ...etc...
RECV|adam@domain.com    $Y
RECV|betty@domain.com   $Y
! ...etc...
RECV|norman@domain.com  $NInternet$ e-mail$ not$ accepted
RECV|opal@domain.com    $NInternet$ e-mail$ not$ accepted
```

with an `ORIG_SEND_ACCESS` mapping table of:

```
ORIG_SEND_ACCESS

! Check if may send to Internet
!
  *|*|*|tcp_local       $C${SEND|$1}$E
!
! Check if may receive from Internet
!
  tcp_*|*|*|*           $C${RECV|$3}$E
```

Here the use of the arbitrary strings `SEND|` and `RECV|` in the general database left hand sides (and hence in the general database probes generated by the mapping table) provides a way to distinguish between the two sorts of probes being made. The wrapping of the general database probes with the `$C` and `$E` metacharacters, as shown, is typical of mapping table callouts to the general database; see the General database substitutions topic, under Mapping entry templates for an additional discussion. For a discussion of the general database itself -- where it is located and how to build it---see General database.

The above example showed a case of simple mapping table probes getting checked against general database entries. Mapping tables with much more complex probes can also benefit from use of the general database.

50.4.1 General database

The MTA's general database is available for site-specific uses. When a site could benefit from a database lookup from a rewrite rule, from a mapping table, or from a Sieve filter (see the EXTLISTS extension), the general database provides a simple, MTA-accessible place to store such site-specific data. (Note that the MTA also supports LDAP, memcache, and MeterMaid, and Redis lookups, which could all be considered forms of "database" lookup. But what is meant here is more specifically an on-disk or in-memory, basic, key-value "database".)

In early versions of the MTA, the format of the general database was an on-disk database, built using the `imsimta crdb` utility based upon a flat text file input. As of MS 6.0, the option -- now preferred -- was introduced for storing the "database" directly in MTA process memory; use of such an "in memory database" is enabled via the `use_text_databases` MTA option. When enabled, such an "in memory database" is constructed from a flat text input file at the time of a `cnbuild` command being issued, or at process startup time (if no compiled configuration is used). The allowed format of the flat text input file is very similar whether an old `crdb` database is constructed, or whether a `use_text_databases` "in memory" database is constructed:

`key value`

one entry per line, with the *`key`* beginning in column one, one or more white space (SP or TAB) characters, and then the *`value`* on the right hand side.

When using a text, "in memory" general database (bit 0/value 1 of `use_text_databases` is set), each left hand side (key) may have a maximum of 128 characters, while each right hand side (value) may have a maximum of 1024 characters. If a key or value contains any space or tab character, such character must be backslash quoted, e.g.:

```
left\ hand\ side right-hand-side
```

Any TAB character found will be converted to a space for storage in the in-memory general database.

The comment_chars MTA option controls which characters (by default exclamation point and semicolon) in column one of a line are considered to indicate a comment line. The left angle character may be used to read another file into the general database text input file.

Note: The MTA options general_data_size and string_pool_size_3 limit the overall size of the general database; these MTA options do not normally need to be manually adjusted.

For a crdb "on disk" database, the left hand side (the key) cannot contain spaces or tabs unless the -quoted switch is used; the maximum length of the key and value depend upon whether the -long_records switch is used.

50.4.1.1 Database case sensitivity option (general_case)

New in MS 8.1.0.1. The general_case MTA option controls whether or not general database lookups are case sensitive. Setting the option to 1 makes the lookups case sensitive. The default is 0, in which case the lookups are case-insensitive.

50.5 When mapping table changes take effect

Changes to an MTA mapping table in general do not take effect until at a minimum the MTA configuration is reloaded; and if a compiled MTA configuration is in use, then the MTA configuration must be recompiled prior to the reload. Performing a restart of processes rather than a reload of the MTA configuration into already running processes is an alternative, though restarts of the Job Controller should be avoided (due to their disruptive effect on throughput) unless necessary.

50.6 Pre-defined mapping tables

The MTA has a number of pre-defined mapping tables. These include both mapping tables whose use (and names) are "hard-coded" in the MTA code for particular sorts of uses, as well as mapping tables which, while not "hard-coded", are included and referenced as part of a standard distribution. Such mapping tables include:

- AUTH_ACCESS mapping table
- AUTH_DEACCESS mapping table
- AUTH_REWRITE mapping table
- BURL_ACCESS mapping table
- CHARSET-CONVERSION mapping table
- COMMENT_STRINGS mapping table
- CONVERSIONS mapping table
- DEQUEUE_ACCESS mapping table
- DKIM_SIGN_DOMAINS mapping table
- DISPOSITION_LANGUAGE mapping table
- ETRN_ACCESS mapping table
- EXTERNAL_TO_INTERNAL mapping table
- FORWARD mapping table
- FROM_ACCESS mapping table
- GROUP_AUTH mapping table

- GROUP_TEMPLATES mapping table
- INTERNAL_IP mapping table
- IP_ACCESS mapping table
- LOG_ACTION mapping table
- MAC-TO-MIME-CONTENT-TYPES mapping table
- MAIL_ACCESS mapping table
- MESSAGE-SAVE-COPY mapping table
- MILTER_ACTIONS mapping table
- MILTER_MACROS mapping table
- MTA_STARTUP and MTA_SHUTDOWN mapping tables
- MX_ACCESS mapping table
- NOTIFICATION_LANGUAGE mapping table
- ORIG_MAIL_ACCESS mapping table
- ORIG_SEND_ACCESS mapping table
- PERSONAL_NAMES mapping table
- PORT_ACCESS mapping table
- REVERSE mapping table
- SEND_ACCESS mapping table
- SASL_ACCESS mapping table
- SIEVE_EXTLISTS mapping table
- SMTP_ACTIONS mapping table
- SPF_LOCAL mapping table
- TLS_ACCESS mapping table

Note that to avoid conflicts with these, or to-be-defined-in-future, Oracle-provided mapping tables, it is recommended that all site-supplied mapping tables be given names beginning with X-, *e.g.*, X-whatever.

In addition to the pre-defined mapping tables listed above, the MTA has various alias options, alias file named parameters, and LDAP attributes (or rather in many cases, MTA options for selecting the name of an LDAP attribute) used to store mapping table names, and a facility for defining Sieve tests via mapping tables with a specific form of name; mapping tables named via such an alias file parameter or LDAP attribute or special Sieve test name syntax are used in the appropriate way by the MTA. Look for discussions of such mapping table use under topics including:

- alias_auth_mapping
- alias_cant_mapping
- alias_deferred_mapping
- alias_direct_mapping
- alias_hold_mapping
- alias_nohold_mapping
- alias_moderator_mapping
- alias_sasl_auth_mapping
- alias_sasl_cant_mapping
- alias_sasl_moderator_mapping
- The alias file named parameters [AUTH_MAPPING], [CANT_MAPPING], [HOLD_MAPPING], [NOHOLD_MAPPING], [MODERATOR_MAPPING], [SASL_AUTH_MAPPING], [SASL_CANT_MAPPING], and [SASL_MODERATOR_MAPPING]
- ldap_url_result_mapping
- ldap_domain_attr_catchall_mapping
- FILTER_test mapping tables

- The USERNAME_MAPPING SpamAssassin option discussed in SpamAssassin spamfilterN_config_file.

50.7 Testing mapping tables

Mapping tables are a very general MTA facility, routinely used for a wide variety of purposes, in a wide variety of contexts, and with a wide variety of potential inputs and outputs. Besides all of the MTA's own standard, pre-defined mapping tables, sites may also incorporate their own, private mapping tables, for their own site-specific purposes. There is thus a "low-level" of basic mapping table output given a specific input which is a general aspect of mapping table behavior true for all mapping tables, and in contrast there is the "high-level" interpretation of mapping output which is performed by specific MTA components.

The MTA has two general, low-level command line test utilities, the `test -match` utility and the `test -mapping` utility, that can be used on any mapping table to test, respectively, the basic pattern matching and the low-level operation (the output-string and flags returned given some input-string) of mapping tables. But note that these utilities, and in particular the `test -mapping` utility, do not provide any interpretation of the *meaning* or *effect* of a particular mapping table output-string, nor do they do any "validity check" on the input-string(s) supplied for testing. (And it is frequently the case that when a mapping table is not having the effect that you desire, that the real "problem" is that the input the MTA is feeding into the mapping table is not the input that you had anticipated.)

So when you wish to test for the *meaning* or *effect* of a mapping table, when you want to see what a mapping tables does in real-world operation, these above-named utilities will not be useful. Instead, these utilities' intended purpose is for testing basic syntax of mapping tables, and they are best used primarily to answer syntax questions that arise when using fairly complex mapping tables. The `test -match` utility is useful when testing complex matching patterns, such as patterns that use "globs" or "IP subnet matching". The `test -mapping` utility is useful when testing mapping tables that contain complex recursive or iterative entries, or that include callouts to routines.

In contrast, the *effects* of commonly-used addressing and access mapping tables such as the `FORWARD` mapping table, the `REVERSE` mapping table, the `FROM_ACCESS` mapping table, or any of the recipient access mapping tables (`SEND_ACCESS`, `ORIG_SEND_ACCESS`, `MAIL_ACCESS`, `ORIG_MAIL_ACCESS`) can be conveniently tested using the `test -rewrite` utility. Note that when doing such testing, the utility's `-source_channel` and `-from` switches, and in the case of the `FROM_ACCESS`, `MAIL_ACCESS`, and `ORIG_MAIL_ACCESS` mapping tables also the `-applicationinfo` and `-transportinfo` switches, tend to be useful (indeed necessary) for proper testing.

(Aside: The `test -rewrite` utility can also be used to test posting access controls for mailing lists.)

50.7.1 Testing address access mapping tables

The `imsimta test -rewrite` utility can be useful in testing address access control mappings. Note that typically at least some of the utility's switches `-from`, `-source_channel`, `-destination_channel`, `-applicationinfo`, `-transportinfo`, and (new 6.2) `-sender` should be specified, in order to set relevant fields of the access mapping table probe and thus achieve meaningful testing. If an access control mapping table makes use of flag tests, then in order to properly test it, see also the `imsimta test -rewrite` utility's (new in 6.3) switches `-[no]esmtpused`, `-[no]lmtpused`,

`-[no]proxyused`, `-[no]saslused`, `-[no]tlsused`. For instance, an `ORIG_SEND_ACCESS` mapping table of

```
ORIG_SEND_ACCESS

  tcp_local|friendly@somewhere.com|l|AdamUser@acme.com      $Y
  tcp_local|unwelcome@elsewhere.com|l|AdamUser@acme.com     $NGo$ away!
```

can be probed as follows:

```
# imsimta test -rewrite -from="friendly@somewhere.com" \
  -source=tcp_local -destination=l AdamUser@acme.com
...
Submitted address list:
  ims-ms
    adam58@ims-ms-daemon (orig AdamUser@acme.com, inter AdamUser@acme.com, host
 ims-ms-daemon) *NOTIFY-FAILURES* *NOTIFY-DELAYS*

Submitted notifications list:

# imsimta test -rewrite -from="unwelcome@elsewhere.com" \
  -source=tcp_local -destination=l AdamUser@acme.com...
Submitted address list:
Address list error -- Go away!: AdamUser@acme.com

Submitted notifications list:
```

If the `-debug` switch is also specified, then in addition to showing the effect of access control mapping table application, the output will also show the actual mapping table probe(s) constructed. For instance:

```
# imsimta test -rewrite -from="friendly@somewhere.com" \
  -source=tcp_local -destination=ims-ms AdamUser@acme.com -debug...
*** Debug output from submitting an envelope address:
...
12:27:18.86:       - orig_send_access mapping check: tcp_local|friendly@somewhere.com|l|AdamUser@acme.com
12:27:18.86:         - passed.
12:27:18.86:       - send_access mapping check: tcp_local|friendly@somewhere.com|ims-ms|adam58@ims-ms-daemon
12:27:18.86:         - passed.
...
Submitted address list:

    adam58@ims-ms-daemon (orig AdamUser@acme.com, inter AdamUser@acme.com, host
 ims-ms-daemon) *NOTIFY-FAILURES* *NOTIFY-DELAYS*

Submitted notifications list:
```

50.8 Callout routines

The MTA's support for calling out to routines from mapping tables or rewrite rules is intended to allow sites to provide and use their own, site-written, routines. However, the MTA does ship with a few Oracle-provided routines as well.

See also the `mm_check_reputation` routine, discussed in Spamfilter early verdicts.

50.8.1 check_memcache.so callout

New in 8.0, the `check_memcache.so` mapping callout can be used to access memcache from mapping tables or rewrite rules. The callout is similar to the `check_metermaid.so` callout, and provides a number of routines that can be called.

The general parameter format for all routines is:

```
[flags],[host[:port][;host[:port]...]],key[,value/lockout/quota][,timeout/test/quota_time]
(0)     (1)   (2)                    (3)  (4)                   (5)     (6)  (7)
```

The first four arguments common to all routines are:

flags (bit-encoded integer)
: The *flags* parameter provides a number of flags that affect the entire option. The default is 0 if no value is specified. The bits and their meanings are shown in the `check_memcache.so` *flags* parameter bit values below.

host (string)
: Host name of memcached server to use. The value specified by the `memcache_host` MTA option will be used if no host is provided here. If a semicolon-separated list of *host*:*port* pairs is specified one will be chosen by applying a hash function to the key. This provides the means to distribute key-value pairs across multiple memcache servers. Note that the algorithm used is the same as for the memcache Sieve extension.

port (integer 0-65535)
: The memcached server port. The value specified by the `memcache_port` MTA option will be used if no port is provided here.

key (string)
: The key associated with the entry being accessed.

Table 50.7 `check_memcache.so` *flags* parameter bit values

Bit(s)	Value(s)	Meaning
0-2	0-7	Debug level. Higher levels produce more debug output.
3	8	If set, causes all permanent failures to return as successful.
4	16	If set, causes an empty string to be returned regardless of what the callout did or didn't do.
5	32	Sets the penalize flag for `throttle` operations.
6	64	If set, hashes the provided *key* prior to use. This can be useful in meeting encrypted at rest requirements. The hash function used is controlled by the `memcache_hash_algorithm` MTA option.
7	128	If set, normalizes the provided *key* to lower case
8	256	If set, don't add entry if it is missing. This flag applies to the `ADJUST`, `ADJUST_AND_TEST`, and `THROTTLE` routines.
9	512	If set, treat the entry (which must exist) as a throttle entry. This flag applies to the `ADJUST` and `ADJUST_AND_TEST` routines and must be used in order for these routines to handle throttle data.

Additional parameters are consumed by specific routines:

value (string or unsigned integer)	The value to be added, stored, replaced, etc.
timeout (unsigned integer)	Amount of time that the server should retain the entry, specified as an integer number of seconds. The default is 0, which means the entry should be retained indefinitely.
test	An unsigned integer preceeded by a single character indicating the type of test to perform. Possible test types are: (1) <*i* - Callout succeeds if the result is less than *i*, (2) >*i* - Callout succeeds if the result is greater than *i*, and (3) =*i* - Callout succeeds if the result is equal to *i*.
quota_time, *quota* (unsigned integers)	Throttle parameters. *quota_time* specifies the specifies the duration of the period over which counts are recorded, and *quota* specifies the maximum number of counts to permit during the period.

The available routines and their specific parameter formats are:

add,*flags*,[*host*:[*port*]],*key*,*value*,*timeoout*

Adds an entry with the specified *key*, *value* and *timeout*. This routine will fail if an entry with the specified *key* is already present. An empty string is always returned.

adjust,*flags*,[*host*:[*port*]],*key*,*value*[,*timeout*]

Adjust the entry with the specified *key* by the amount specified by *value*. The entry must contain an unsigned decimal string and *value* must be an optionally signed integer. The specified entry will be created (with a value of 0) prior to adjustment if it doesn't already exist. The adjusted value is retured as an unsigned decimal string. The *timeout* value is only used if the entry has to be created.

adjust_and_test,*flags*,[*host*:[*port*]],*key*,*value*,*test*[,*timeout*]

Adjust the entry with the specified *key* as adjust would, then test the result with the specified *test*. An empty string is always returned.

append,*flags*,[*host*:[*port*]],*key*,*value*

Append the specified *value* to the entry with the specified *key*. This routine will fail if an entry with the specified *key* is not already present. An empty string is already returned.

fetch,*flags*,[*host*:[*port*]],*key*

Return the value of the entry with the specified *key*. The callout fails if no entry with the specified *key* is present.

`prepend,flags,[host:[port]],key,value`

Prepend the specified *value* to the entry with the specified *key*. This routine will fail if an entry with the specified *key* is not already present. An empty string is already returned.

`remove,flags,[host:[port]],key[,lockout]`

Remove the entry with the specified *key*. The *lockout*, if present, is an unsigned integer specifying the amount of time to "lock" the key - during that time attempts to add an entry with that *key* will fail. A lockout value of 0 is the default and causes no lockout to occur. This routine will fail if an entry with the specified *key* is not already present. An empty string is already returned.

`replace,flags,[host:[port]],key,value,timeout`

Update value and timeout of the entry with the specified *key*. This routine will fail if an entry with the specified *key* is not already present. An empty string is always returned.

`store,flags,[host:[port]],key,value,timeout`

Creates a new entry or updates an existing entry with the specified *key*, *value*, and *timeout*.

`test,flags,[host:[port]],key,test`

Tests the value of the entry with the specified *key*.

`throttle,flags,[host:[port]],key,quota,quota_time`

Implements the MeterMaid throttle capability. See the MeterMaid documentation for details of throttle semantics. Note that since there is no server-side awareness of entry semantics, the *quota* and *quota_time* parameters must be specified in every throttle call in case the entry needs to be created. If the entry already exists, the parameter values will be checked against the corresponding values store in the entry. The call will fail if this check fails.

This callout has also been enhanced to work with the mapping table `$.` facility in order to be able to handle temporary errors in a sensible fashion.

An example of using memcached to implement a simple rate limit on a given authenticated sender to 10 messages every 5 minutes would be to add the following to the end of the FROM_ACCESS mapping:

```
FROM_ACCESS
  TCP|*|SMTP*|MAIL|tcp_*|*|*  $C$;R$[IMTA_LIB:check_memcache.so,throttle,0,memcache.example.com:22122,sendlim-$4,10,300]$X4.2.3|$NRate$ too$ high$E
```

This would limit users to 10 messages every 5 minutes (300 seconds). Here "memcache.example.com:22122" would be replaced with name and port of an actual memcached server.

A more flexible mechanism would allow the limit to be specified on a per-user basis along with a default. This could be accomplished by defining an LDAP attribute for the purpose, say

senderRateLimit, and making it available to the FROM_ACCESS mapping via the sixth spare LDAP slot:

```
msconfig> set ldap_spare_6 senderRateLimit
msconfig# set include_spares1 32
```

The follow additions to the FROM_ACCESS mapping would then be needed:

```
FROM_ACCESS

  TCP|*|SMTP*|MAIL|tcp_*|*|*|  $C$;R$[IMTA_LIB:check_memcache.so,throttle,0,memcache.example.com:22122,sendlim-$4,10,300]$X4.2.3|$NRate$ too$ high$E
  TCP|*|SMTP*|MAIL|tcp_*|*|*|*  $C$;R$[IMTA_LIB:check_memcache.so,throttle,0,memcache.example.com:22122,sendlim-$4,$5,300]$X4.2.3|$NRate$ too$ high$E
```

50.8.2 check_metermaid callouts

The `check_metermaid.so` mapping callout can be used to access MeterMaid from mapping tables or rewrite rules. A number of entry points are provided.

`adjust,`*`table`*`,`*`key`*`,`*`adjustment`*

(New in MS 7.0u2) Similar to `store`, but adjustment is treated as a delta value. It can be specified as integer, +integer, or -integer. If the *`key`* doesn't currently exist, it is presumed to be `0` and the value is set to whatever the adjustment is. Succeeds by default, fails if an error occurs.

`adjust_and_test,`*`table`*`,`*`key`*`,`*`adjustment`*`,`*`test-expr`*

(New in MS 7.0u2) This combines the adjustment with a test. The return value is the same as `test`.

`fetch,`*`table`*`,`*`key`*

(New in MS 7.0u2) Returns a string from that *`key`*'s value. Fails if an error occurs or the *`key`* is not currently set.

`greylisting,`*`table`*`,`*`key`*

`query,`*`table`*`,`*`key`*

`remove,`*`table`*`,`*`key`*

(New in MS 7.0u2) Removes the key/value pair specified by the *`key`* from the *`table`*. Return success by default, and fail if an error occurs.

`store,`*`table`*`,`*`key`*`,`*`value`*

(New in MS 7.0u2) Sets the value for the specified *`key`* in that *`table`*. Returns success if completed successfully, and fails if not.

`test,table,key,test-expr`

(New in MS 7.0u2) *`test-expr`* is a simple expression that gives the test to be done. It consists of an operator and a value. The operator can be one of =, >, >=, <, or <=. The value should be an integer.

This returns success if the *`test-expr`* returns true, and fails if it's false or an error occurs. (This flexibility permits control of whether the default should be to pass, or to fail.)

`throttle,table,key`

Apply throttling.

New in MS 8.0, `check_metermaid.so` supports use of multiple MeterMaid servers, and also supports SSL for communication.

An example of using Metermaid to implement a simple rate limit on a given authenticated sender to 10 messages every 5 minutes implemented using a FROM_ACCESS mapping would be:

```
msconfig> show metermaid.local_table:sendlim
role.metermaid.local_table:sendlim.data_type = string
role.metermaid.local_table:sendlim.max_entries = 100000
role.metermaid.local_table:sendlim.quota = 10
role.metermaid.local_table:sendlim.quota_time = 300
role.metermaid.local_table:sendlim.table_type = throttle
```

And finally, the following callout rule added at the end of the `FROM_ACCESS` mapping implements the limit:

```
FROM_ACCESS

  TCP|*|SMTP*|MAIL|tcp_*|*|*  $C$;R$[IMTA_LIB:check_metermaid.so,throttle,sendlim,$4]$X4.2.3|$NRate$ too$ high$E
```

Note the "$;R" (new in MS 8.0) prevents this rule from being applied to enqueues from "internal" channels (process channel, reprocess channel, conversions channel, etc.). Also note that the rule can be added to an existing

50.8.3 dns_verify callouts

The `dns_verify.so` library provides a collection of mapping callouts that can be used to validate and/or resolve domains names or IP addresses via the DNS or local host tables. (Exactly what sources are used, and in what order, is controlled at the operating system level, usually by settings in `/etc/resolv.conf`.) Three basic types of operations are provided:

- DNS A/AAAA record and host table lookups for domain names.
- DNS PTR record and host table lookups for IP addresses.
- TXT record lookups for checking IP addresses against blacklists.

For example, `dns_verify.so` can be used to verify that an entry in DNS or host tables exists for the domain used in the SMTP `MAIL FROM:` command, or to look up an IP address in

a blacklist supplied by such services as MAPS and ORBS. The message can be rejected or accepted based on the presence or absence of a corresponding DNS record.

IMPORTANT NOTE: Performing DNS existence checks may result in the rejection of some valid messages. For instance, this could include mail from legitimate sites that simply have not yet registered their domain name, or during periods of bad information in DNS.

The `dns_verify.so` library has several routines that can be called:

- `dns_verify`
- `dns_verify_ptr` (new in 7.0.5.34)
- `dns_verify_domain`
- `dns_verify_domain_port`
- `dns_verify_domain_warn`
- `dns_verify_ipv4` (new in 8.0.1.2)
- `dns_verify_ipv6` (new in 8.0.1.2)
- `dns_get_first_mx` (new in 8.0.2.2)

These routines are each described in the sections below.

Note that your mapping tables with `dns_verify.so` callouts can be tested by using the `imsimta test -mapping` utility.

50.8.3.1 The `dns_verify` routine

The `dns_verify` routine does a name lookup in the local host tables and an A/AAAA lookup in the DNS. One possible use for this is to check to make sure the domain from the SMTP `MAIL FROM:` command actually exists. Any mapping table action can be taken if the lookup succeeds, fails, or returns an error.

The `dns_verify` routine's argument is four strings separated by "|", as follows:

domainname`[|`*success*`[|`*failure*`[|`*unknown*`]]]`

domainname	The name to look up in the DNS and local host tables.
success (optional)	If specified, it is the mapping table string to return if *domainname* is found. If not specified, the default is "$Y".
`failure` (optional)	If specified, it is the mapping table string to return if *domainname* is not found. If not specified, the default is "$N".
unknown (optional)	If specified, it is the mapping table string to return if there was a temporary DNS failure during the lookup operation. If not specified, and the *success* string was specified, that string is used. If neither are specified, the default is "$Y".

Note that in the mapping table any $'s you wish to return need to be doubled. For example, to specify "$Y", you need to put in "$$Y".

An alternate separator can be used instead of "|". To specify an alternate separator, insert it as the first character of the routine's argument. For example, to specify "+" as the separator, use the following syntax:

+domainname+success+failure+unknown

The *success*, *failure*, and *unknown* strings can contain the following format characters:

Table 50.8 dns_verify callout substitutions

String	Value
%a	If successful, the %a substitutes the IP address returned by the lookup operation. An empty string is returned if the domain name exists but doesn't have an associated IP address.
%e	If the lookup is not successful, %e substitutes the error message associated with the lookup.
%n	If successful, %n substitutes the primary name for *domainname*. An empty string is returned if the domain name exists but doesn't have an associated IP address.

The following example shows a simple SEND_ACCESS mapping table entry to verify that the sender's hostname exists in the DNS or local host tables:

```
SEND_ACCESS

  *tcp_*|*@*|*|*          \
$C$[IMTA_LIB:dns_verify,dns_verify,$3|$$Y|$$NInvalid$ host:$ $$3$-$ %e]$E
```

The following example shows a PORT_ACCESS mapping table entry that performs a check against a hypothetical DNS blacklist dnsbl.example.net

```
PORT_ACCESS

  TCP|*|25|*.*.*.*|*     \
$C$[IMTA_LIB:dns_verify,dns_verify,\
$4.$3.$2.$1.dnsbl.example.net|$$N500$ IP$ blacklisted|$$Y
```

50.8.3.2 The dns_verify_ipv4 routine

The dns_verify_ipv4 routine is identical to dns_verify, except that it restricts its results to IPv4 addresses.

50.8.3.3 The dns_verify_ipv6 routine

The dns_verify_ipv4 routine is identical to dns_verify, except that it restricts its results to IPv6 addresses.

50.8.3.4 The dns_verify_ptr routine

The dns_verify_ptr routine does an IPv4/IPv6 address lookup in the DNS and/or host tables. Any mapping table action can be taken if the lookup succeeds, fails, or returns an error.

The dns_verify routine's argument is four strings separated by "|", as follows:

ip-address[|*success*[|*failure*[|*unknown*]]]

ip-address	The IPv4/IPv6 address to be looked up, without any enclosing brackets or prefixes.
success (optional)	If specified, it is the mapping table string to return if *ip-address* is found. If not specified, the default is "$Y".
failure (optional)	If specified, it is the mapping table string to return if *ip-address* is not found. If not specified, the default is "$N".
unknown (optional)	If specified, it is the mapping table string to return if there was a temporary DNS failure during the lookup operation. If not specified, and the *success* string was specified, that string is used. If neither are specified, the default is "$Y".

The dns_verify_ptr routine supports the same alternate delimiter and substitution strings as the dns_verify routine described above.

50.8.3.5 The dns_verify_domain and dns_verify_domain_port routines

The dns_verify_domain and dns_verify_domain_port routines are used to perform queries for DNS entries with well-defined blacklist semantics and return pre-defined success, failure, and unknown messages. The same operation can be performed using the dns_verify routine, but with more complicated setup.

The dns_verify_domain_port routine is designed for use in the PORT_ACCESS mapping table. The dns_verify_domain routine is used in the MAIL_ACCESS, SEND_ACCESS, and similar mapping tables.

The dns_verify_domain and dns_verify_domain_port routines perform the same type of action as the dns_verify_domain Dispatcher option. Using the routine allows you more control over which connections trigger the DNS lookups.

The dns_verify_domain and dns_verify_domain_port routines' argument is three strings separated by ",", as follows:

ip-address,*domainname*[,*text-string*]

ip-address	The IP address that you want to check against the blackhole list
domainname	The name of the blackhole list to check against, *e.g.*, blackholes.mail-abuse.org
text-string (optional)	If specified, it is the text to return if no TXT record is available. If not specified, the default is "No Error Text Available".

The dns_verify_domain and dns_verify_domain_port routines check the given list for the IP address. For example, if *ip-address* is 127.0.0.2, and *domainname* is bl.spamcop.net, either of dns_verify_domain or dns_verify_domain_port looks up the following name: 2.0.0.127.bl.spamcop.net. They first look up the TXT record for that name, and if it is not available, they look up the A record.

The following examples illustrate the use of these routines.

```
MAIL_ACCESS

  TCP|*|25|*|*|*|*|tcp_local|*|*|* \
$C$[IMTA_LIB:dns_verify,dns_verify_domain,$1,bl.spamcop.net]$E

PORT_ACCESS

  TCP|*|25|*|*     \
$C$[IMTA_LIB:dns_verify,dns_verify_domain_port,$1,bl.spamcop.net]$E
```

The approximate equivalent of the previous MAIL_ACCESS example using the dns_verify routine would be something like:

```
MAIL_ACCESS

  TCP|*|25|*.*.*.*|*|*|*|tcp_local|*|*|*    \
$C$[IMTA_LIB:dns_verify,dns_verify,+$4.$3.$2.$1.bl.spamcop.net+\
$$N$$X5.7.1|Blocked$ -$ see$ http://spamcop.net/bl.shtml?$$1.$$2.$$3.$$4+$$Y]$E
```

50.8.3.6 dns_verify_domain_warn

The dns_verify_domain_warn routine performs the same DNS lookup as the dns_verify_domain and dns_verify_domain_port routines, but instead of rejecting the message if the DNS entry exists, it adds a new header line to the message. The dns_verify_domain_warn routine can be used in any of the sender or recipient access mapping tables.

The dns_verify_domain_warn routine's argument is four strings separated by ",", as follows:

ip-address,*domainname*[,*text-string*[,*header*]]

The *ip-address*, *domainname*, and *text-string* arguments are the same as for dns_verify_domain and dns_verify_domain_port. *header* is optional. If specified, it is a string containing the header name, and other optional text, to include before the TXT record string or *text-string* value. The header name must be one that the MTA recognizes. The default is "X-Dispatcher: ".

The following example shows an ORIG_MAIL_ACCESS mapping table entry to query spamcop.net:

```
ORIG_MAIL_ACCESS

 TCP|*|25|*|*|*|*|*|*|* \
$C$[IMTA_LIB:dns_verify,dns_verify_domain_warn,$1,\
bl.spamcop.net,spamcop.net:$ entry$ found$ for$ $$1,\
X-Dispatcher:$ SPAMfilter$ (spamcop.net):$ ]$E
```

For a source IP address of 127.0.0.2, this example would return

```
$Y$AX-Dispatcher: SPAMfilter (spamcop.net): Blocked - see http://spamcop.net/bl.shtml?127.0.0.2
```

This is then added as a header to the message. One way to act on this is to create a system-wide, channel, or user Sieve filter containing a Sieve action along the lines of:

```
if header :contains "X-Dispatcher" "SPAMfilter" { discard; }
```

50.8.3.7 dns_get_first_mx

New in MS 8.0.2.2. The `dns_get_first_mx` routine performs an MX record lookup on the specified domain. Unlike the other DNS routines described in this section, the routine argument consists solely of the domain to look up. The routine succeeds if the lookup is successful and returns the "first" MX record using the same algorithm the MTA uses to determine record order. An empty string is returned if the lookup succeeds but no MX records are found.

The routine fails if the specified domain cannot be found in the DNS. A temporary failure condition is returned if the DNS operation fails with a temporary error.

One possible use of this routine is to determine if a given domain is serviced by a particular collection of servers - which can then be used to implement a limited form of MX rollup. For example, a mapping that will determine if a given domain is handled by Office 365 servers could (at preent) be coded as:

```
OUTLOOK_MX

  *                          $E$[IMTA_LIB:dns_verify,dns_get_first_mx,$0]$C
  *.protection.outlook.com   $Y
```

This mapping could in turn be called from either a rewrite rule or a `FORWARD` to route messages to a special channel configured to deliver to an appropriate set of MXes regardless of destination domain.

50.8.4 smartsend callouts

The `smartsend.so` library provides a collection of mapping callouts that can be used in to optimize the delivery of opt-in bulk email.

smartsend makes use of a site-provided database that provides information about senders, deployment hosts, recipient domains, and available source IPs. The MTA's general database facility is used for this purpose, although note that this can easily be configured to perform queries using the memcache or Redis protocols.

Many smartsend options also require a cache server. smartsend talks to this server using either the memcache or Redis protocols. A per-host instance of memcached is sufficient for this purpose, although a few functions require deployment of a caching server available across multiple hosts. If the memcache protocol is employed the host and port specified by the `memcache_host` and `memcache_port` channel options respectively, with fallback to the corresponding MTA options, will be used.

When used to support multiple independent message sources, it is expected that the first conversion tag associated with each message will be used as a "virtual MTA" identifier. Note

that the callouts consume the conversion tag if it is present; they do not provide the means to set it.

The following sections describe the database format as well as the various callouts smartsend provides. It is important to understand that most of the callouts are expected to be configured as a group since they work together to provide a single coherent service. Most of the callouts are designed not to have any effect, i.e., return a failure condition, when they have nothing to do, so they may be combined with other uses of the corresponding mapping.

While the following sections provide details as to how to configure the smartsend callouts, this may be done automatically in a unified configuration by using the provided smartsend recipe:

```
# msconfig
msconfig> run smartsend.rcp [debug-level]
```

An optional debug level may be specifed; if none is specified a level of 0 (debugging disabled) is assumed. The recipe may be re-run with a different debug level; if this is done the debug level will be updated in the various callouts.

Although it's included as part of the smartsend plugin, the MX rollup capability is an essentially separate facility. Accordingly, a separate recipe is provided to configure it:

```
# msconfig
msconfig> run rollup.rcp [debug-level [rollup-domain-suffix [rollup-channel]]]
```

An optional debug level, rollup domain suffix, and the channel used to handle rollups may be specified. These default to "0", ".rollup", and "tcp_rollup", respectively.

The script will create the rollup channel if it does not already exist, using the tcp_local channel as a model.

50.8.4.1 Database entry formats

Database entries make use of several common pieces of syntax, the first of which is a parameter list. Parameter lists are represented using a simplified variant of MIME content-type parameter syntax. The ABNF (RFC 2234) syntax for a smartsend parameter list is:

```
parameter-list = parameter-name-value [";" parameter-name-value]
parameter-name-value = *WSP parameter-name *WSP "=" *WSP parameter-value *WSP
parameter-name = (ALPHA / DIGIT / "-" / "_")1*
parameter-value = <any CHAR excluding ";">
```

Note that the allowable characters in a parameter-value is often further constrained by the context in which the parameter-list appears. In particular, vertical bars ("|"), commas (","), and whitespace are all used in some "outer" contexts as delimiters.

Examples of parameter lists include:

```
maxmx=5
maxmessagerateperdomain=30/1200;maxmessagesperconnection=20
dkimidentity-1=example.net;dkimselector-1=brisbane
```

```
debug=3
```

A parameterized list of IP addresses (IP list for short) is also used by several types of database entries. The following definition makes use of the IPv4address and IPv6address productions specified in RFC 5954:

```
parameterized-ip-list = [global-parameter-list "|"] ip-and-parameters ["," ip-and-parameters]
global-parameter-list = [parameter-list]
ip-and-parameters = ["-"] (IPv4address / IPv6address) ["#" (IPv4address / IPv6address)] [";" ip-parameter-list]
ip-parameter-list = [parameter-list]
```

Note that IP address parameters allow the two address form supported by the `interfaceaddress` channel option.

Parameterized IP lists are allowed to be up to 4096 characters in length.

Examples of parameterized IP lists would include:

```
1.1.1,1,2.2.2.2,-3.3.3.3,4.4.4.4
10.59.230.40;banner_host=mauve.example.com,10.59.230.169;banner_host=plum.example.com
66.218.59.24#10.59.230.40;banner_host=mauve.example.com
maxconnectionrateperdomain=2/300|10.59.230.40,10.59.230.169
maxmessagesperconnection=30|10.59.230.40;maxmessagsperconnection=10,10.59.230.169,10.59.230.170
```

A parameterized list of MTA names (MTA list for short) is also used by several types of database entries. The following definition makes use of the Domain productions specified in RFC 5321:

```
parameterized-mta-list = [global-parameter-list "|"] mta-and-parameters ["," mta-and-parameters]
global-parameter-list = [parameter-list]
mta-and-parameters = ["-"] Domain [";" mta-parameter-list]
mta-parameter-list = [parameter-list]
```

Parameterized MTA lists are allowed to be up to 4096 characters in length.

Examples of parameterized MTA lists would include:

```
host1.example.com,host2.example.com,host2.example.com
host1.example.org;received_domain=host1.example.org,host2.example.org;received_domain=host2.example.org,
id_domain=example.edu|host1.example.edu,host2.example.edu
```

50.8.4.2 auth_access callout

The `auth_access` callout is intended to be called from the `AUTH_ACCESS` mapping. It provides the ability to:

- set various limits and operating parameters based on the message's destination domain
- select a client IP address from a group of available IP addresses for each message in a round-robin fashion
- impose additional limits and opeational settings on a per-IP basis.

The `AUTH_ACCESS` mapping should be set up as follows:

```
AUTH_ACCESS
```

```
*      $C$[IMTA_LIB:smartsend.so,auth_access,<pflags>|$0]$E
```

Here <pflags> should be replaced with an unsigned integer flag value. The lowest three bits enable increasing levels of debug output, with "0" resulting in no output. Bit 3 (value 8), if set, enables routing-only mode, which is described below.

Note that the callout receives the entire mapping probe. It is designed to process the entire probe and automatically adjusts its behavior to match the variations in probe format caused by setting various MTA options.

Additionally, bit 0, value 1, of the `include_retries` MTA option should be set, and if conversion tags are to be used to select IP address groups, bit 11, value 2048, of the `include_conversiontag` MTA option should also be set. Note that the list of conversion tags is interpreted as follows:

```
<virtual-MTA>,<sender-OCID>,<tenant-OCID>,<compartment-OCID>
```

The callout normally operates as follows:

1. Parse the mapping probe into its components. The callout will fail if the input string cannot be parsed.
2. Construct a key of the form `domain_<domain>`, where <domain> is the lower cased destination domain for the message, ad look up the key in the general database. The value of any entry found is expected to be a parameter list.
3. If `<tenant-OCID>` conversion tag is present construct a key of the form `ociddomain_<tenant-OCIDA>_<domain>`, where <tenant-OCIDA> and <domain> are the lower cased tenant OCID and destination domain for the message, respectively, and look up the key in the general database. The value of any entry found is expected to be a parameter list.
4. If `<sender-OCID>` conversion tag is present construct a key of the form `ociddomain_<sender-OCIDA>_<domain>`, where <sender-OCIDA> and <domain> are the lower cased sender OCID and destination domain for the message, respectively, and look up the key in the general database. The value of any entry found is expected to be a parameter list.
5. Construct a key of the form `ips_<mtaid>_<virtual-MTA>`, where <mtaid> is the MTA id and <virtual-MTA> is the first conversion tag associated with the current message. Both the id and conversion tag are converted to lower case.

   If no MTA id has been specified the official host name on the local channel is used instead. The preceding "_" is omitted if the specified MTA id is blank.

   If there are no conversion tags associated with the message use a key of the form `ips_<mtaid>_<channel>`, where <channel> is the channel where the message is queued.
6. Look up the key in the general database. The value of any entry found is expected to be an IP list.
7. If an IP list entry is found select an IP from the list at a random starting point, and proceeding around the list in a strict round-robin fashion on subsequent dequeue attempts.

8. If an EXTERNAL_TO_INTERNAL mapping exists, apply it to any IP address selected from the IP list that just specifies an IP address (as opposed to an external#internal address pair). The entry will be skipped if the mapping doesn't produce a result and set $Y. The result can be either just the internal address, which will be become the internal IP address for the entry, or an external#internal pair, which will replace the IP address information in the entry.

9. Impose any limits and set any operational parameters specified by the various parameter lists attached to the destination domain, the IP list as a whole, and the chosen IP.

10. Limit checks may cause the selected IP addresses to be become ineligible for use. If this happens try the next IP address on the list. If all of the addresses are rejected the message dequeue attempt will fail with a temporary error, causing the MTA to try again later.

11. If no IP list entry is found and a conversion tag is present construct a third key of the form mta_<conversiontag> and look it up in the general database. Again, the conversion tag is converted to lower case.

12. If an MTA entry is found it is expected to consist of a comma or whitespace-separated list of MTA names that are able to process messages with the specified conversion tag. The list is checked to see if the current MTA is listed. If it isn't an MTA that is on the list is chosen at random and the message destination is set to that MTA.

13. If the current MTA is on the list or no MTA list is present the dequeue operation proceeds normally.

If bit 3 (value 8) of <pflags> is set, the plugin operates in routing-only mode:

1. Parse the mapping probe into its components. The callout will fail if the input string cannot be parsed or if no conversion tag is present

2. Construct a key of the form mta_<virtual-MTA> and look it up in the general database. The conversion tag is converted to lwoer case.

3. If an MTA entry is found it is expected to consist of a comma or whitespace-separated list of MTA names that are able to process messages with the specified conversion tag. The list is checked to see if the current MTA is listed. If it isn't an MTA that is on the list is chosen at random and the message destination is set to that MTA.

4. If the current MTA is on the list or no MTA list is present the dequeue operation proceeds normally.

Note that the addition of an IP address to a IP list entry when a message is being retried unavoidably results in the disruption of the strict round-robin schedule. However, a special mechanism is provided to remove an address from the rotation without causing any disruption: Placing a minus sign "-" in front of an IP address on the list will cause that address to be skipped. A count of the number of IP address skips is maintained in order to preserve the strict round-robin usage. Note that this does NOT work if the IP address is simply removed from the entry.

Also note that the log_smartsend MTA option may be used to include additional information about smartsend callout actions in transaction log records.

The following sections describe the parameters available for use in auth_access database entries. Note that while all parameters are available in all contexts, it may not make sense to,

say, specify the banner host on the basis of the destination domain or to control the use of TLS on a per-IP basis.

50.8.4.2.1 backoff - Retry frequency for messages

The backoff parameter implements the same functionality as the backoff channel option on smartsend domain entries. The syntax is identical to that of the backoff channel option in unified configuration.

50.8.4.2.2 banner_host - Override banner host

The banner_host parameter specifies the host name to use in the EHLO/HELO command that is issued once a connection is established. This overrides BANNER_HOST TCP/IP-channel-specific option for this connection.

50.8.4.2.3 chunking - Control use of SMTP CHUNKING

New in MS 8.1.0.1. The chunking parameter provides the ability to control the use of the SMTP CHUNKING extension by the SMTP client. Possible values are:

- "disable", which disables the use of chunking, as if nochunkingserver had been specified on the channel, and
- "optional", which allows the use of chunking if the channel is set to allows it.

50.8.4.2.4 debug - Enable smartsend/channel debugging

New in MS 8.1.0.1. The debug parameter provides the ability to enable debugging on a per-IP-list basis. A single integer argument is required. Positive values enable corresponding levels of smartsend debugging; master_debug is also enabled for the duration of processing the current message.

50.8.4.2.5 ipbackoff - Retry frequency for messages in IP backoff mode

The ipbackoff parameter implements the same functionality as the ipbackoff channel option on smartsend domain entries. The syntax is identical to that of the ipbackoff channel option in unified configuration.

50.8.4.2.6 ipbackofftimeout - Timeout for IP backoff entries

The ipbackofftimeout parameter implements the same functionality as the ipbackofftimeout channel option on smartsend domain entries. As with the channel option, the syntax is an integer value in seconds.

50.8.4.2.7 log_headers - Header fields to log in transaction record

The log_headers parameter is used to specify one or more additional header fields to log as part of the transaction log entry. The parameter value is a comma-separated list of header field names. Unlike header option file based logging, any field name may be specified, recognized or not. Note that the log_header MTA option must also be set appropriately.

50.8.4.2.8 maxconnectionrateperdomain - Maximum connection rate to a domain

The maxconnectionrateperdomain parameter provides the means to limit the rate at which connections are made to a destination domain. The value of this parameter is one or two

space-separated rate limit lists. The first limit list value specifies the rate limits to use when the IP address is operating normally; the second specifies the limits to use when operating in IP backoff mode. If the IP backoff value is omitted it defaults to the first value.

The syntax of rate limit lists is described in the section on message rate limits below.

50.8.4.2.9 `maxconnectionsperdomain` - Maximum connection to a domain

The `maxconnectionsperdomain` parameter implements limits on the number of simultaneous connections that can be opened from a single source IP to a destination domain. The value of this parameter is one or two space-separated connection limit lists. The first connection limit list value specifies the limits to use when the IP address is operating normally; the second specifies the limits to use when operating in IP backoff mode. If the IP backoff value is omitted it defaults to the first value.

As of MS 8.1, four types of per-domain connection limits are provided:

Table 50.9 Per-domain connection limits

Additional Qualification	Code	Probe	Description
Source IP	I	`maxconnectionsperdomain_`*<IP>*`_`*<domain>*	Per source IP per domain limit
Host	H	`maxconnectionsperdomain_`*<host>*`_`*<domain>*	Per server host per domain limit
Tag	T	`maxconnectionsperdomain_`*<tag>*`_`*<domain>*	Per conversion tag per domain limit
	N	`maxconnectionsperdomain_`*<domain>*	Per domain limit

Any or all of these limits may be engaged simultaneously. If multiple limits are used all limits must be satisfied for the connection attempt to proceed.

A connection limit list is specified as one or more limit codes followed by the limit itself, written as an unsigned integer. The "I" code may be omitted from a per-IP limit if it appears first - this is the only supported format in MS 8.0.2.3. Formally, the syntax is:

```
connection-limit-list = (ip-limit-value *limits) / 1*limits
limits = ip-limit / host-limit / tag-limit / limit
ip-limit = "I" ip-limit-value
ip-limit-value = 1*DIGIT
host-limit = "H" host-limit-value
host-limit-value = 1*DIGIT
tag-limit = "T" tag-limit-value
tag-limit-value = 1*DIGIT
limit = "N" limit-value
limit-value = 1*DIGIT
```

For example, a connection limit list value of "I4N10" specifies a 4 connection per-IP-per-domain limit and a 4 connection per-domain limit. A value of "10" specifies a 10 connection per-IP-per-domain limit.

Note that the identically named `maxconnectionsperdomain` channel option can be used to set connection limits on a per channel basis.

50.8.4.2.10 `maxmessagerateperdomain` - Maximum message rate to a domain

The `maxmessagerateperdomain` parameter provides the means to limit the rate at which messages are delivered to a destination domain. The value of this parameter is one or two space-separated rate limit lists. The first limit list value specifies the rate limits to use when the IP address is operating normally; the second specifies the limits to use when operating in IP backoff mode. If the IP backoff value is omitted it defaults to the first value.

As of MS 8.1, four types of per-domain rate limits are provided:

Table 50.10 Per-domain message rate limits

Additional Qualification	Code	Probe	Description
Source IP	I	`maxmessagerateperdomain_`*<IP>*`_`*<domain>*	Per source IP per domain limit
Host	H	`maxmessagerateperdomain_`*<host>*`_`*<domain>*	Per server host per domain limit
Tag	T	`maxmessagerateperdomain_`*<tag>*`_`*<domain>*	Per conversion tag per domain limit
	N	`maxmessagerateperdomain_`*<domain>*	Per domain limit

Any or all of these limits may be engaged simultaneously. If multiple limits are used all limits must be satisfied before a delivery attempt will be made.

A rate limit list is specified as one or more limit codes followed by the limit itself, written as an unsigned vulgar fraction or integer. The "I" code may be omitted from a per-IP limit if it appears first - this is the only supported format in MS 8.0.2.3. The numerator of the vulgar fraction specifies the number of messages to allow and the denominator specifies the time window in seconds. If a single integer is specified it is treated as a numerator with a default denominator of 3600 (one hour).

Formally, the syntax is:

```
rate-limit-list = (ip-limit-value *limits) / 1*limits
limits = ip-limit / host-limit / tag-limit / limit
ip-limit = "I" ip-limit-value
ip-limit-value = 1*DIGIT
host-limit = "H" host-limit-value
host-limit-value = 1*DIGIT
tag-limit = "T" tag-limit-value
tag-limit-value = 1*DIGIT
limit = "N" limit-value
limit-value = 1*DIGIT ["/" 1*DIGIT]
```

For example, a rate limit list value of "I100N100000/86400" specifies a 100 messages per hour per-IP-per-domain limit and a 100,000 per day per-domain limit. A value of "50" specifies a 50 messages per hour per-IP-per-domain limit. A value of "0" indicates that no rate limit is set.

Note that the identically named maxmessagerateperdomain channel option can be used to set rate limits on a per channel basis.

50.8.4.2.11 maxmessagesperconnection - Maximum messages per connection

The maxmessagesperconnection parameter limits the number of messages that can be transferred by a single connection. It overrides the ATTEMPT_TRANSACTIONS_PER_SESSION TCP/IP-channel-specific option for this connection.

50.8.4.2.12 max_mx_records - Maximum MX attempts

The max_mx_records parameter limits the number of MX records to consider when attempting to connect. It overrides MAX_MX_RECORDS TCP/IP-channel-specific option for this connection.

50.8.4.2.13 override_host - Override destination host

The override_host parameter specifies the host name to use as the destination for connections, overriding any host name that appears in any destination address.

50.8.4.2.14 status - Force hold, return of messages

The status parameter provides the means to return or hold messages. Possible values are "active", which causes deliveries to proceed normally, "hold", which suspends deliveries, and "return", which causes messages to be returned with no further delviery attempts.

50.8.4.2.15 tls - Control use of TLS

New in MS 8.1.0.1. The tls parameter provides the ability to control the use of the SMTP CHUNKING extension by the SMTP client. Possible values are:

- "disable"- disables the use of TLS, as if notlsserver had been specified on the channel,
- "optional", which allows the use of tLS if the channel is set to allows it, and
- "require", which requires the use of TLS, as if musttlsserver had been specified on the channel,

50.8.4.3 auth_deaccess callout

The auth_deaccess callout is intended to be called from the AUTH_DEACCESS mapping. It pairs with the auth_access callout described in the previous section to decrement counters associated with some of the limits auth_access implements. At present this is the only functionality provided by this callout.

The AUTH_DEACCESS mapping should be set up as follows:

```
AUTH_DEACCESS

   *     $C$[IMTA_LIB:smartsend.so,auth_deaccess,<pflags>|$0]$E
```

Here <pflags> should be replaced with an unsigned integer flag value. Currently only the lowest three bits of this bit-encoded value have any meaning -- they enable increasing levels of debug output, with "0" resulting in no output.

Note that the callout receives the entire mapping probe. It is designed to process the entire probe and adjusts its behavior to match the variations in probe format caused by setting various MTA options.

50.8.4.4 conversions callout

The `conversions` callout is intended to be called from the `CONVERSIONS` mapping to provide a database-driven means of configuring multiple DKIM signing keys.

The `CONVERSIONS` mapping should be set up as follows:

```
CONVERSIONS

   *     $C$[IMTA_LIB:smartsend.so,conversions,pflags=<pflags>;$0]$E
```

IMPORTANT NOTE: The format of the mapping probe is NOT the same as for the previously AUTH_ACCESS or AUTH_DEACCESS mapping probes. Here <pflags> should be replaced with an unsigned integer flag value. The lowest three bits of this bit-encoded value enable increasing levels of debug output, with "0" resulting in no output.

Note that the callout receives the entire mapping probe. It is designed to process the entire probe and adjusts its behavior to match the variations in probe format caused by setting various MTA options.

Additionally, bit 0, value 1, of the `include_domain` MTA option should be set, and if conversion tags are to be used to select DKIM keys using "dkim_" lookups. bit 1, value 2, of the `include_conversiontag` MTA option should also be set. IMPORTANT NOTE: "dkim_" lookups should be disabled if "ocid_" lookups in the AUTH_REWRITE mapping are enabled for DKIM use. In this case bit 4 (value 16) of pflags should be set to disable such lookups.

The callout operates as follows:

1. Parse the mapping probe into its components. The callout will fail if the input string cannot be parsed.
2. Construct a key of the form `domain_<domain>`, where <domain> is the lower cased destination domain (DOMAIN value in the CONVERSIONS mapping probe) for the message.
3. Look up the key in the general database. The value of any entry found is expected to be a parameter list.
4. If bit 4 (value 16) of the pflags value is clear, construct a second key of the form `dkim_<conversiontag>`, where <conversiontag> is the first conversion tag (TAG value in the CONVERSIONS mapping probe) associated with the current message and converted to lower case. If there are no conversion tags associated with the message use a key of the form `ips_<channel>`, where <channel> is the destination channel (OUT-CHAN value in the CONVERSIONS mapping probe) for the message.
5. Look up the key in the general database. The value of any entry found is expected to be another parameter list.
6. Use the combined parameter lists to select appropriate DKIM keys to use to sign the message, and generate a mapping result that will cause this to happen.

7. If bit 3 (value 8) of the pflags value is set and a conversion tag is present, construct a key of the form `mta_<conversiontag>` and look up the corresponding entry in the general database. If an entry is found it is expected to consist of a list of the MTAs capable of handling this conversion tag value. If an entry is found and the current MTA is not on the list the is forced into the tcp_intranet channel queue so it can be routed to the correct MTA.

50.8.4.4.1 `dkimidentity-N`, `dkimselector-N` - DKIM parameters

The actual DKIM parameters correspond exactly to the DKIM template keywords (dkimidentity-N and dkimselector-N) used in the CONVERSIONS mapping table and have the same semantics as the `destinationdkimidentityN` channel option. Note, however, that the parameter separator is a semicolon while the CONVERSIONS template keyword separator is a comma.

50.8.4.5 ip_backoff callout

New in MS 8.1. The `ip_backoff` callout is used to activate or deactivate IP backoff mode for a specified IP address and destination domain. Unlike other smartsend callouts, the `ip_backoff` callout is not associated with any specific mapping. Rather, it is designed to be used as part of site-specific checks that determine when IP backoff mode needs to be in effect.

A call to the `ip_backoff` callout should appear as follows:

```
$[IMTA_LIB:smartsend.so,ip_backoff,pflags=<pflags>|<channel>|<ip>|<domain>|<value>|<timeout>|]
```

The arguments are:

<pflags> Unsigned integer flag value. Currently only the lowest three bits of this bit-encoded value have any meaning -- they enable increasing levels of debug output, with "0" resulting in no output.

<channel> Channel associated with the IP address.

<ip> IP address for which IP backoff is to be enabled or disabled.

<domain> Destination domain for which backoff is to be enabled or disabled.

<valuet> The backoff entry's value. At the present time the entry value is ignored and this field should be left blank - but see the special value and their semantics below.

<timeout> Timeout, in seconds, for the bckoff entry. A value of 0 causes the timeout specified by the `ipbackofftimeout` channel option to be used. If no timeout value has been specified a default value of 3600 (one hour) is used. The timeout argument can be omitted, in which case it's value defaults to 0.

The callout succeeds even if the entry cannot be set.

The special value "?" causes a lookup to be performed on the backoff entry instead of a set. The callout fails if the entry is not present. If the entry is present the callout succeeds and returns the entry's value.

The specil value "-" causes the specified backoff entry to be deleted. The callout always succeeds.

The ip_backoff callout operates by creating and deleting entries in memcache or Redis. The entry's name is of the form "ip_backoff_<ip>" and at present the value is the string "mode=1".

50.8.4.6 auth_rewrite callout

The auth_rewrite callout is intended to be called from the AUTH_REWRITE mapping. It provides the ability to confirm that a conversion tag appearing in a header field has a corresponding IP list or MTA entry, the ability to activate DKIM signing, and can be used to override the received_domain and id_domain settings for the current message.

The confirmation functionality is useful in preventing messages from being routed to the wrong MTA during configuration updates. The ability to override domain settings can be used to obfuscate local host information.

If DKIM support and obfuscation support is not enabled the callout succeeds if the confirmation attempt fails, so that the mapping template itself determines the appropriate action to be taken. If, on the other hand, DKIM or obfuscation support is enabled, the callout succeeds when it needs to return a result and fails otherwise, in which case the plugin necessarily provides all results.

Note that this callout is only needed in specific circumstances and therefore is not configured by the smartsend.rcp recipe.

The AUTH_REWRITE mapping should be set up approximately as follows if bit 4 (value 16) of pflags is clear:

```
AUTH_REWRITE

    *       $C$[IMTA_LIB:smartsend.so,auth_rewrite,<pflags>|$0]$E$N$X4.7.0|Unknown$ tag
```

Note that the template in this example causes a temporary failure to be returned should confirmation fail.

The callout should be configured as follows if either bit 4 (value 16, DKIM) or bit 5 (value 32, domain obfuscation) are set:

```
AUTH_REWRITE

    *       $C$[IMTA_LIB:smartsend.so,auth_rewrite,<pflags>|$0]$E
```

Note that the template in this example simply returns the callout result if the callout succeeds.

Here <pflags> should be replaced with an unsigned integer flag value. The lowest three bits enable increasing levels of debug output, with "0" resulting in no output. Bit 3 (value 8), controls the type of lookup that is performed for confirmation and domain obfuscation information. A lookup for "ips_" entries is performed if the bit is clear; a lookup for "mta_" entries is performed if the bit is set. If bit 5 (value 32) is set the result may contain override values for received_domain and/or id_domain.

Bit 4 (value 16) or bit 5 (value 32), if set, cause a lookup to be performed on a key of the form ocid_<sender-OCID>, where <sender-OCID> is the sender OCID (see below) If this lookup

fails an additional query is done for `ocid_<tenant-OCID>`, where <tenantr-OCID> is the tenant OCID. The result is interpreted as a parameter list and can contain DKIM parameters (bit 4 set) and override values for `received_domain` and/or `id_domain` (bit 5 set).

Additionally, the `authrewrite` channel option should be set to 16 on all appropriate source channels (or on the defaults channel if the mapping is to be applied to all message flows). The header where the virtual MTA (first conversion tag) is located may be specified as the first value of the `authrewrite_extra_headers` MTA option. The header field containing the tenant and sender OCIDs may be specified as the second value if DKIM processing is enabled. At present the only supported syntax for this header field is a JSON string of the form:

```
{"tenantId":"<tenant-OCID>","senderId":"<sender-OCID>","compartmentId":"<compartment-OCID>"}
```

The tenantId and senderId OCIDs must be present. The compartmentId is optional; if it is not supplied its value defaults to that of the tenantId. Note that the parameters may appear in any order. Any additional parameters will be silently ignored.

Alternately, bit 13, value 8192 of the `include_conversiontag` MTA option, can be set to cause conversion tag information to be included in the probe if it is available. The conversion tag list is interpreted as follows:

```
<virtual-MTA>,<sender-OCID>,<tenant-OCID>,<compartment-OCID>
```

The compartment-OCID will be omitted if it has the same value as the tenant-OCID, which is the case when it specifies the root compartment for the tenancy.

50.8.4.7 send_access callout

The `send_access` callout is intended to be called from either the `SEND_ACCESS` or `ORIG_SEND_ACCESS` mapping. It provides the ability to confirm that a conversion tag transferred using the XCONVTAG extension has a corresponding IP list or MTA entry. This functionality is useful in preventing messages from being routed to the wrong MTA during configuration updates. The callout succeeds if the confirmation attempt fails, so that the mapping template itself determines the appropriate action to be taken.

Note that this callout is only needed in specific circumstances and therefore is not configured by the smartsend.rcp recipe.

The `SEND_ACCESS` mapping should be set up approximately as follows:

```
SEND_ACCESS

    *      $C$[IMTA_LIB:smartsend.so,send_access,<pflags>|$0]$E$N$X4.7.0|Unknown$ tag
```

Note that the template in this example causes a temporary failure to be returned when confirmation fails.

Here <pflags> should be replaced with an unsigned integer flag value. The lowest three bits enable increasing levels of debug output, with "0" resulting in no output. Bit 3 (value 8), controls the type of lookup that is performed. A lookup for "ips_" entries is performed if the bit is clear; a lookup for "mta_" entries is performed if the bit is set. (The latter is appropriate for an intermediate routing MTA.) Finally, bit 4 (value 16) should be set if this callout is placed

in the ORIG_SEND_ACCESS mapping (as opposed to its normal location in the SEND_ACCESS mapping).

Additionally, bit 4, value 16, of the include_conversiontag MTA option should also be set so that the conversion tag is included in the SEND_ACCESS mapping probe. Bit 3, value 8 should be set if the callout is done from the ORIG_SEND_ACCESS mapping.

50.8.4.8 forward callout

The forward callout is used in conjunction with the mx_access callout (described below) to implement a general purpose MX rollup facility that's superior to what was provided by the dns_get_first_mx mapping callout. With this approach rollups are specified in the general database, which in turn can be linked to either memcache or Redis.

The first step in configuring this functionality is to select a domain suffice to identify all of the rollups that will be defined. ".rollup" is used in other products for this purpose, but any domain can be used as long as it isn't a valid top-level domain (TLD) or internal domain.

Once the domain has been selected a rewrite rule needs to be added to route rollups to the proper tcp_ that will process rolled up messages. Assuming that ".rollup" is the rollup domain suffix, the tcp_local channel is to be used, and the channel has the usual official host name of "tcp_local-daemon", the rule would be:

```
.rollup                         $U%$H$D@tcp_local-daemon
```

The forward callout should be now added to the FORWARD mapping table as follows:

```
FORWARD

   *|*.rollup $E
   *          $C$[IMTA_LIB:smartsend.so,forward,<pflags>|$0]$E
```

Of course ".rollup" should be replaced with whatever domain is to be used to identify rollups.

The mx_access callout must also be set up, as described below, and the entries need to be added to the general database to create specific MX rollups.

The forward callout performs the following actions:

- Perform an MX record lookup on the routing domain part of the envelope recipient address. No action is taken if the lookup fails or no records are found.
- Construct a list of MX records with the lowest precedence (highest priority).
- For each MX host on the list, construct a probe of the form rolluphost_<mxhost> and look it up in the general database. The MX host name is forced to lower case as part of constructing the probe. The values of these entries are expected to either be of the form:

  ```
  mxhost1,mxhost2,mxhost3,...,mxhostN;rollupname
  ```

  or:

```
[mxhost-ip-1],[mxhost-ip-2],[mxhost-ip-3],[mxhost-ip-N];rollupname
```

Here "mxhost1...mxhostN" are the names of all the MX hosts included in the rollup, mxhost-ip-1...mxhost-ip-N are the IP addresses of all the MX hosts included in the rollup, and "rollupname" is the domain name associated with the rollup. In the case of a host name list, the list should be exactly the same as the list specified in the corresponding "rollupmx_" entry used by the `MX_ACCESS` mapping, and he domain name must end with the rollup domain suffix.

- If the initial lookup for a given host fails it is repeated with the first element of the host name replaced by a "*". If this fails a lookup is attempted with the first two elements replaced with a "*".
- If a match is found the corresponding entry value is checked to make sure all of the MXes it specified are also on the MX list for the destination domain. If they are a result is returned that adds the rollup name to the address as a source route. If not the process continues with the next host.

50.8.4.8.1 Setting up an MX rollup

A rollup consists of two sets of general database entries, one set to match the various MX hosts to the rollup and another to specify the MX hosts for the rollup. This sounds more complex than it actually is because the MX hosts in the first set have to match the set in the second.

For example, let's suppose that a large service provider, example.net, is known to provide service for many different domain, but all of the domains share the MX hosts mx1.example.net, mx2.example.net, and mx3.example.net. An appropriate set of database entries for this service provider would be:

```
rolluphost_mx1.example.net   mx1.example.net,mx2.example.net,mx3.example.net;example.net.rollup
rolluphost_mx2.example.net   mx1.example.net,mx2.example.net,mx3.example.net;example.net.rollup
rolluphost_mx3.example.net   mx1.example.net,mx2.example.net,mx3.example.net;example.net.rollup

rollupmx_example.net.rollup  mx1.example.net,mx2.example.net,mx3.example.net
```

If this seems highly duplicative, that's because it is: Denormalization is required to turn a bidirectional mapping into a set of entries in a name/value store.

In this case a wildcard could be used to lower the number of entries:

```
rolluphost_*.example.net     mx1.example.net,mx2.example.net,mx3.example.net;example.net.rollup

rollupmx_example.net.rollup  mx1.example.net,mx2.example.net,mx3.example.net
```

When wildcards are used it may be necessary to specify the matching list as a serious of IP addresses known to be associated with the service instead of a series of host names:

```
rolluphost_*.example.net     [ip1],[ip2],[ip3];example.net.rollup

rollupmx_example.net.rollup  mx1.example.net,mx2.example.net,mx3.example.net
```

50.8.4.9 mx_access callout

The `mx_access` callout is used in conjunction with the `forward` callout (described above) to implement a general purpose MX rollup facility.

Once the steps for setting up the `forward` callout have been done, the `mx_access` callout should be added to the `MX_ACCESS` mapping table as follows:

```
MX_ACCESS

   *|*.rollup     $C$[IMTA_LIB:smartsend.so,mx_access,<pflags>|$0.rollup]$E
```

The ".rollup" that appears on both sides of the mapping should be replaced with whatever domain is to be used to identify rollups.

The `mx_access` callout constructs a probe of the form `rollupmx_<domaint>`, where "domain" is the destination domain, and looks it up in the general database. If a match is found the value of the entry is expected to be of the form:

```
mxhost1,mxhost2,mxhost3,mxhostN
```

This value is then returned as the result, which then becomes the MX list for the domain.

50.8.4.10 mta_startup and mta_shutdown callouts

The `mta_startup` and `mta_shutdown` callouts are intended to be called from the `MTA_STARTUP` and `MTA_SHUTDOWN`mapping. These callouts should be set up as follows:

```
MTA_STARTUP

   *      $C$[IMTA_LIB:smartsend.so,mta_startup,<pflags>|$0]$E

MTA_SHUTDOWN

   *      $C$[IMTA_LIB:smartsend.so,mta_shutdown,<pflags>|$0]$E
```

Here <pflags> should be replaced with an unsigned integer flag value. The lowest three bits enable increasing levels of debug output, with "0" resulting in no output. Only one additional bit is defined for both mappings: Bit 3, value 8, should be set as part of configuring open connection aggregation with the log_action callout described below.

Currently the callout always fails, so it can be safely inserted before any other actions in the mapping.

At present no other functionality is provided by these callouts, so they are not configured as part of the smartsend,rcp recipe.

50.8.4.11 log_action callout

The `log_action` callout is intended to be called from the `LOG_ACTION` mapping. It provides the ability to store counter information about MTA activity using a combination of Redis sets and sorted sets. This provides the ability to determine things like the most active domains, the domain generating the most temporary failures, and so on. Currently the callout always fails, so it can be safely inserted before any other actions in the mapping.

Note that this callout is only needed in specific circumstances and therefore is not configured by the smartsend.rcp recipe.

As part of setting up the callout, bits 1 and 4, values 2 and 16, respectively, of the log_conversion_tag MTA option should also be set if conversion tags are used so that the tags are included in the LOG_ACTION mapping probe. The LOG_ACTION mapping should be set up as follows:

```
LOG_ACTION

*      $C$[IMTA_LIB:smartsend.so,log_action,<pflags>|$0]
```

Here <pflags> should be replaced with an unsigned integer flag value. The lowest three bits enable increasing levels of debug output, with "0" resulting in no output. The next three bits enable different sets of counters as described in the following sections.

50.8.4.11.1 Open SMTP Connection Aggregation (bit 3, value 8)

First, host + process pairs are tracked used the Redis set smtp_host_pid. (Note that this part of the counters is actually done by the mta_startup and mta_shutdown callouts decribed above.) Entries in this set have names of the form <omta-host>_<omta-pid>_<omta-type>. Here <omta-type> is the type of process, e.g. "smtp_client", "smtp_server", etc. All processes that engage in enqueue and dequeue operations will add entries for themselves when they initialize and remove them when they terminate.

Second, three per-process sorted sets are also maintained:

- smtp_domain_<omta-host>_<pid> <domain> <numeric-value>
- smtp_vmta_<omta-host>_<pid> <vmta> <numeric-value>
- smtp_ip_<omta-host>_<pid> <vmta>_<ip> <numeric-value>

The <numeric-value> is incremented each time a connection is opened and decremented each time one is closed.

Note that these sorted sets contain no useful information and have no pointer references when the associated MTA process terminate and are therefore deleted by the mta_shutdown callout.

Third, three global connection tracking sorted sets are maintained:

- smtp_domain_<genid> <domain> <numeric-value>
- smtp_vmta_<genid> <vmta> <numeric-value>
- smtp_ip_<genid> <vmta>_<ip> <numeric-value>

The <genid> is obtained from the Redis entry smtp_genid. If no such entry exists one is created with value "0".

Note that once entries in the global connection tracking sorted sets are created they will never be deleted; some external cleanup mechanism must be provided.

50.8.4.11.2 Queue Count Aggregations in Redis (bit 4, value 16)

First, hosts are tracked in the Redis set queue_host. Each entry is consists of a host name <host>. Note that no facility is provided to remove entries from this set. (Note that this addition is actually done by the mta_startup callout described above.)

Second, current queue message counts are tracked in a sorted set per host by two axes:

- `queue_domain_<host> <domain>_<channel> <numeric-value>`
- `queue_vmta_<host> <vmta>_<channel> <numeric-value>`

Here `<channel>` is the name of the MTA channel queue.

Third, two global queue counts are maintained:

- `queue_domain_<genid> <domain>_<channel> <numeric-value>`
- `queue_vmta_<genid> <vmta>_<channel> <numeric-value>`

The `<genid>` is obtained from the Redis entry `queue_genid`. If no such entry exists one is created with value "0".

Note that once entries in any of these sorted sets are created they will never be deleted; some external cleanup mechanism must be provided.

50.8.4.11.3 Success/Error Count Aggregations in Redis (bit 5, value 32)

These counters provide information about SMTP operation success/failure rates in a series of buckets, each represented by a sorted set:

- `<success|tempfail|permfail>_domain_<MM><00|30> <domain> <numeric-value>`
- `<success|tempfail|permfail>_vmta_<MM><00|30> <vmta> <numeric-value>`
- `<success|tempfail|permfail>_ip_<MM><00|30> <ip> <numeric-value>`

Here `<MM>` is the minute part of the current time. This has the effect of creating one bucker per minute.

Again, no mechanism exists for resetting the bucket contents, deleting entries from these buckets, or deleting the buckets themselves.

50.8.4.12 dequeue_access callout

The `dequeue_access` callout is intended to be called from the `DEQUEUE_ACCESS` mapping. It provides the ability to record overall message latency in the smartsend log field and to send this information in JSON format to a separate latency server for further processing.

Note that this callout is only needed in specific circumstances and therefore is not configured by the smartsend.rcp recipe.

As part of setting up the callout, bit 12, value 4096, of the `include_conversiontag` MTA option should also be set. (Latency computations depend on conversion tag information.) Bit 0 (value 1) of the `log_smartsend` MTA option should also be set in order for the latency information to be logged. The `DEQUEUE_ACCESS` mapping should then be set up as follows:

```
DEQUEUE_ACCESS

   *      $C$[IMTA_LIB:smartsend.so,dequeue_access,<pflags>|$0]
```

Here <pflags> should be replaced with an unsigned integer flag value. The lowest three bits enable increasing levels of debug output, with "0" resulting in no output.

Bit 3, value 8 of <pflags> enables writing of the calculated latency in the smartsend log field. Assuming that the time the message was received appears in the fifth conversion tag entry, expressed as an integer UTC time since the epoch in milliseconds (date +%s%3N on Linux), the elapsed time up to this delivery attempt will be computed and stored in the smartsend log field with the prefix "latency=".

Bit 4, value 16, enables writing of the calculated latency to the latency server.

50.8.4.13 MTA identity option: `id` (string)

The `id` MTA option specifies a name for a group of MTAs that share network connections. At present this name is only used by the smartsend facility in looking up IP address list information.

The official host name on the local channel is used if this option is not specified.

50.8.4.14 smartsend options: `smartsend_use_redis` (0 or 1)

The `smartsend_use_redis` smartsend option selects the backend database protocol used by the smartsend plugin. A value of 1 selects redis; a value of 0 selects memcache. The default if the option is not specified is to use redis if either the `redis.hostlist` or `redis.servicename` option is set, memcache otherwise.

50.8.4.15 Timeout for IP backoff entries (`ipbackofftimeout`)

An entry is made in memcache or Redis when IP backoff mode engages. This option sets the timeout value for the entry. The value is expressed in seconds, with a default value of 3600 (one hour).

Chapter 51 Message conversions

There are two broad categories of message conversions in the MTA, controlled by two corresponding mapping tables and the MTA `conversions`. In Unified Configuration, the mappings are stored under the `mapping` MTA option group, and the MTA conversion entries are stored under the `conversions` MTA option; in legacy configuration, the MTA mapping tables are stored in the `mappings` file, and the MTA conversion entries are stored in the `conversions` file.

The first category of message conversion is that of character set, formatting, and labelling conversions performed internally by the MTA. The application of such conversions is controlled by the `CHARSET-CONVERSION` mapping table. `CHARSET-CONVERSION` effects are discussed in Character set conversion and message reformatting.

The second category of message conversion is that of conversion of message attachments using external, third-party programs and site-supplied procedures, such as document converters. The application of such conversions is controlled by the `CONVERSIONS` mapping table, and messages requiring such conversions are thereby routed through the MTA's `conversion` channel; the conversion channel executes the site-specified external conversion procedures.

Note that the MTA `conversions` entries (stored in the `conversions` file in legacy configuration), are used to specify the details of `CONVERSIONS` mapping table triggered external conversions and to specify the details of some internal `CHARSET-CONVERSION` mapping table triggered conversions.

The `imsimta test -translation` utility can perform character set conversions for testing or scripting purposes; the `imsimta test -mime` utility can perform certain message conversions, for testing purposes.

Note that certain basic choices regarding the fundamental handling of attachments/MIME parts can be configured for arbitrary channels via setting of channel options, potentially not requiring any of the more complex conversion channel or message reformatting facilities discussed here; for these basic choices, see the Attachments and MIME processing channel options.

51.1 Conversion channel

The conversion channel performs arbitrary body-part-by-body-part conversions on messages flowing through the MTA. Any subset of MTA message traffic can be selected for conversion

and any set of programs or command procedures can be used to perform conversion processing. (The MTA's native conversion facilities are fairly limited, so the ability to call external converters is crucial.) A special "database" (stored as the conversions MTA option in Unified Configuration, or in the conversions file in legacy configuration) is consulted to choose an appropriate conversion for each body part.

For instance, third party document converters or virus scanning software may be hooked in for automatic execution via the conversion channel. Or sites may develop their own custom applications to hook in via the conversion channel.

Because the conversion channel is intended for "intermediate" processing of messages, the MTA has a special sort of routing available for it, whereby messages are routed without affecting the recipient address(es); see the CONVERSIONS mapping table. This special sort of routing used to route messages through the conversion channel without modification to the actual addresses can also be used for other purposes: to route through third party channel programs, or to route out to third party spam/virus SMTP hosts (that will then relay messages back to the MTA). See the discussion of alternate channel routing via the CONVERSIONS mapping.

51.1.1 CONVERSIONS mapping table

Although conversion processing is done using a regular MTA channel program, under normal circumstances this channel is never specified directly either in an address or in an MTA rewrite rule. Instead, the MTA controls routing to the conversion channel via the CONVERSIONS mapping table.

In legacy configuration, the CONVERSIONS mapping table (like all mapping tables), was stored in the mappings file. In Unified Configuration, the CONVERSIONS mapping table is stored as the settings under either a role.mapping:CONVERSIONS option or a instance.mapping:CONVERSIONS option. In Unified Configuration, most often creation or modification of such a CONVERSIONS mapping table is performed using the edit command of the msconfig utility, to edit any or all mapping tables in a format like the legacy mappings file; *e.g.*:

```
msconfig> edit mappings
```

Or from within msconfig the CONVERSIONS mapping table can be created line-by-line:

```
msconfig> set mapping:CONVERSIONS.rule "IN-CHAN=tcp_local;OUT-CHAN=ims-ms;CONVERT" Yes
msconfig# set mapping:CONVERSIONS.rule "IN-CHAN=ims-ms;OUT-CHAN=tcp_local;CONVERT" Yes
msconfig# set mapping:CONVERSIONS.rule * No
```

Note that CONVERSIONS mapping rules often include a special character such as the equal sign, =, in either or both of the pattern (left hand side of the rule) or template (right hand side of the rule), thus often require quoting of pattern and/or template when being set at the msconfig command line.

As the MTA processes each message it probes the CONVERSIONS mapping (if one is present) with a string of the default form

IN-CHAN=*source-channel*;OUT-CHAN=*destination-channel*;CONVERT

where *source-channel* is the source channel from which the message is coming and *destination-channel* is the destination channel to which the message is heading. New

in MS 6.3, setting bit 1 (value 2) of the include_conversiontag MTA option will cause the probe to instead have the form

IN-CHAN=*source-channel*;OUT-CHAN=*destination-channel*;TAG=*tag-list*;CONVERT

where *tag-list* is a comma-separated list of any conversion tags present on the message. Note that multiple conversion tags may be present; multiple tags will be included as a comma-separated list. The total, combined length of such tags (that is, the length of the list, including the commas) is limited to 256 characters. (As with all mapping tables, the overall probe length is limited to 1024 characters.)

New in the 8.0 release, setting bit 6 (value 64) of the include_mtpriority MTA option will cause an additional, compound field to be appended to the CONVERSIONS mapping table probe, immediately after any "TAG=" clause.

New in the 8.0.2.3 release, setting bit 0 (value 1) of the include_domain MTA option will casue an additiona field to be appended to the CONVERSIONS mapping table probe containing the destination domain for the current set of recipients, immediately after any "MTPRIORITY=" and "BLOCKS=" clauses.

If the probe matches the pattern (left hand side) of a CONVERSIONS mapping table entry, then the resulting string (right hand side of the mapping entry) should be a comma-separated list of keywords. Usually either just the keyword "Yes" or "No" is specified. If "Yes" is produced, the MTA will divert the message from its regular destination to the conversion channel. (By also specifying Channel=channel-name, the message can be diverted to some alternate channel rather than to the regular conversion channel.) If the message has a conversion tag set, note that the "T" flag will be set, and this can be tested for (when a match on the pattern, *i.e.*, left hand side, occurred) using a $:T test in the template (right hand side) output string. If either "No" is produced or no match is found, the message will be queued to the regular destination channel.

Some less commonly used, additional template keywords, similar to those available for the CHARSET-CONVERSION mapping table, are also available as shown below.

Table 51.1 Additional CONVERSIONS mapping keywords

Keyword	Action
Always	Force conversion even when the "conversion" channel is the same as the source channel; while not desirable when the actual conversion channel (or any other "intermediate channel") is being used, "Always" can be useful when an "alternate conversion channel", specified via a "Channel=*channel-name*" clause, is used to select some other sort of channel, such as a tcp_* channel
Appledouble	Convert other MacMIME formats to Appledouble format
Applesingle	Convert other MacMIME formats to Applesingle format
BASE64	Switch MIME encodings to BASE64
Binhex	Convert other MacMIME formats, or parts including Macintosh type and Mac creator information, to Binhex format
Block	Extract just the data fork from MacMIME format parts
Bottom	"Flatten" any message/rfc822 body part (forwarded message) into a message content part and a header part

Channel=*channel-name*	Route through the alternate channel *channel-name* rather than the regular conversion channel
Delete	"Flatten" any message/rfc822 body part (forwarded message) into a message content part, deleting the forwarded headers
dkimidentity-N=identity	New in MS 8.0.2.3. Activate DKIM signing in slot N using using the specified identity. See the description of the `destinationdkimidentityN` channel option for additional information on the value's semantics. N can range from 0 to 3. This template keyword also clears the corresponding selector value, which can subsequently be set with the dkimselector-N template keyword.
dkimselector-N=selector	New in MS 8.0.2.3. Specifies the selector list for DKIM slot N. See the description of the `destinationdselectorN` channel option for additional information on the value's semantics. N can range from 0 to 3. This template keyword must be specified after the corresponding dkimidentity-N template keyword.
Level	Remove redundant multipart levels from message
Macbinary	Convert other MacMIME formats, or parts including Macintosh type and Macintosh creator information, to Macbinary format
No	Disable conversion
Pathworks	Convert message to Pathworks Mail format
Preprocess	(New in MS 6.3) Perform any configured charset conversion *before* routing to the conversion channel
QUOTED-PRINTABLE	Switch MIME encodings to QUOTED-PRINTABLE
Record,Text	Line wrap text/plain parts at 80 characters
Record,Text=*n*	Line wrap text/plain parts at *n* characters
RFC1154	Convert message to RFC 1154 format
Thurman	Convert some non-standard "attachments" to MIME format
Top	"Flatten" any message/rfc822 body part (forwarded message) into a header part and a message content part
UUENCODE	Switch MIME encodings to X-UUENCODE
Yes	Enable conversion

For example, suppose messages coming in from the Internet and destined to the Message Store via either an `ims-ms` or `tcp_lmtpcs*` channel require conversion processing. The following mapping would then be appropriate:

```
CONVERSIONS

  IN-CHAN=tcp_local;OUT-CHAN=ims-ms;CONVERT          Yes
  IN-CHAN=tcp_local;OUT-CHAN=tcp_lmtpcs*;CONVERT     Yes
  IN-CHAN=*;OUT-CHAN=*;CONVERT                       No
```

In Unified Configuration, `msconfig`'s `edit` command could show the `CONVERSIONS` mapping as above. Alternatively,

```
msconfig> show mapping:CONVERSIONS.*
role.mapping:CONVERSIONS.rule = IN-CHAN=tcp_local;OUT-CHAN=ims-ms;CONVERT Yes
role.mapping:CONVERSIONS.rule = IN-CHAN=tcp_local;OUT-CHAN=tcp_lmtpcs*;CONVERT Yes
role.mapping:CONVERSIONS.rule = IN-CHAN=*;OUT-CHAN=*;CONVERT No
```

51.1.1.1 Alternate channel routing via the CONVERSIONS mapping

One of the CONVERSIONS mapping table template keyword clauses is Channel=*channel-name*, causing routing (if the CONVERSIONS mapping table pattern matched the probe) through the specified *channel-name* without any change to the message's recipient addresses; see the CONVERSIONS mapping table. This CONVERSIONS mapping table facility to cause routing via some alternate channel (without alteration of a message's recipient addresses) turns out to be extremely useful for a number of scenarios. Originally conceived as a convenience for hooking in third-party or site-developed message processing channels, *e.g.*,

```
CONVERSIONS

  IN-CHAN=tcp_local;OUT-CHAN=ims-ms;CONVERT   \
Yes,Channel=third-party-processing-channel
```

alternate conversion channel configuration also functions perfectly well to route messages out via SMTP to some third-party spam/virus filtering SMTP box (presumably itself configured to send processed messages back to the MTA to further delivery). For instance, if the MTA has been configured with a special tcp_* channel for sending to, and receiving from, a third-party spam/virus filtering SMTP host, with rewrite rule:

```
! Rewrite rule to recognize source IP of virus scanner box and "switch"
! messages coming from it to be considered to come in tcp_virusscanner channel
!
[IP-address-of-virusscanner]   $E$R$U%$H@TCP-VIRUSSCANNER-DAEMON
```

and channel definition:

```
! Channel for sending to virus scanner box.
! Set with "allowswitchchannel" so that it can also be considered the source
! channel for messages coming back in from virus scanner box.
!
tcp_virusscanner smtp daemon host-name-of-virusscanner \
 allowswitchchannel ...additional-keywords...
TCP-VIRUSSCANNER-DAEMON
```

then a corresponding CONVERSIONS mapping table on a front end MTA might be along the lines of:

```
CONVERSIONS

  IN-CHAN=tcp_local;OUT-CHAN=tcp_intranet;CONVERT  Yes,Channel=tcp_virusscanner
```

to cause all messages coming directly in from the Internet, destined for an internal host, to get a "side hop" through the virus scanner box. (Note that for users hosted-on-this-MTA, recipients on ims-ms or tcp_lmtpcs channel, the "side hop" routing should be configured via the aliasdetourhost channel option as the timing of its effect has better implications for local-to-this-host users; but "alternate conversion channel" routing is generally used in conjunction with aliasdetourhost in order to handle the cases of messages to remote users.)

Such "alternate conversion channel" routing has also found an important application in causing special routing of notification messages; see notification message routing.

51.1.1.2 Mapping table MTA options: `include_domain` (bitmask)

New in MS 8.0.2.3. This option selectively enables the inclusion of destination domain information in various mapping table probes. When enabled, the destination domain will be included in the probe in a table-specific way.

This option takes a bit-encoded integer value. The currently defined bits are shown in the following table:

Table 51.2 `include_domain` MTA option bit values

Bit	Value	Usage
0	1	CONVERSIONS : include in "DOMAIN=value" format after the block count

51.1.2 Conversion channel definition

A conversion channel must be present in the MTA's configuration in order for conversions to be performed. In Unified Configuration, a conversion channel is configured automatically, while in legacy configuration the post-installation configuration step normally caused an appropriate conversion channel definition to be included in the MTA configuration file. The channel definition should have the general form:

```
conversion
CONVERSION-DAEMON
```

or as displayed in Unified Configuration:

```
msconfig> show channel:conversion.*
role.channel.conversion.official_host_name = conversion-daemon
```

As of MS 8.0, use of the `receivedstate` channel option is recommended:

```
conversion receivedstate "content"
CONVERSION-DAEMON
```

or in Unified Configuration:

```
msconfig> set channel:conversion.receivedstate content
```

Rewrite rules can be added if desired to make it possible to queue mail explicitly to the conversion channel. Something like

```
conversion               $U%conversion.localhostname@conversion-daemon
conversion.localhostname $U%conversion.localhostname@conversion-daemon
```

where *`localhostname`* is the name of this MTA system, will provide the necessary functionality. Note that in Unified Configuration, such rewrite rules would typically

be automatically generated, and make use of the $D and &/IMTA_HOST/ and &/IMTA_DEFAULTDOMAIN/ substitutions, to appear as:

```
msconfig> show rewrite.rule * *conversion*
role.rewrite.rule = conversion $U%conversion.domain.com@conversion-daemon
role.rewrite.rule = conversion.&/IMTA_HOST/ $U%conversion.domain.com@conversion-daemon
```

Once such rewrite rules are present, then addresses of the form

user%host@conversion.*localhostname*

will be routed through the conversion channel regardless of what the CONVERSIONS mapping table says.

51.1.3 Conversion control

The actual conversions performed by the conversion channel are controlled by rules specified in the MTA conversions file (legacy configuration) or conversions MTA option (Unified Configuration). As of MS 7.0, the conversions file is (symbolically) IMTA_TABLE:conversions, *i.e.*, *CONFIGROOT*/conversions. (In prior versions, the conversions file was located via the IMTA tailor file option imta_conversion_file, normally pointing to IMTA_TABLE:conversions.)

Note: Even in Unified Configuration, it is most convenient to think of the conversions option as a file, accessed and modified via the command

```
msconfig> EDIT CONVERSIONS
```

so from here on, references will be simply to "the conversions file", even for a Unified Configuration.

The MTA conversions file is a text file containing entries in a format that is modelled after MIME Content-type: parameters (see RFC 2045). Each entry consists of one or more lines grouped together; each line contains one or more "*name=value*;" parameter clauses. Quoting rules conform to MIME conventions for Content-type: header line parameters. Every line except the last must end with a semicolon. Entries are terminated by either a line that does not end in a semicolon, one or more blank lines, or both. For example, the following entry specifies that application/x-ddif parts in messages sent out to the Internet should be converted to PostScript:

```
out-chan=l; in-type=application; in-subtype=x-ddif;
  out-type=application; out-subtype=postscript; parameter-copy-0=*;
  command="ddifps $INPUT_FILE $OUTPUT_FILE"
```

51.1.3.1 Conversion entry scanning and application

The conversion channel processes each message routed through it, part by part. The header of each part is read and its Content-type: and other header information is extracted. (Note that composite media types, that is, MULTIPART/* or MESSAGE/* "parts", are not made available per se to the conversion channel, though any component discrete body parts within such composite types are made available to the conversion channel for potential processing.)

The entries in the conversion file are then scanned in order from first to last; any IN-* parameters present and the OUT-CHAN parameter, if present, are checked. If all of these

parameters match the corresponding information for the body part being processed, then the conversion specified by the remainder of the entry is performed. Note that an entry **must include** an IN-TYPE clause in order to match. More specifically, the matching checks:

- if specified IN-CHAN and OUT-CHAN parameters match the channels[1] through which the message is passing;
- and if the specified PART-NUMBER matches the structured part number[2] of the message part;
- and if the (required!) IN-TYPE parameter, as well as all specified IN-PARAMETER-NAME, IN-PARAMETER-VALUE, and IN-SUBTYPE parameters, match the Content-type: of the message part;
- and if all specified IN-DISPOSITION, IN-DPARAMETER-NAME, and IN-DPARAMETER-VALUE parameters match the Content-disposition of the message part;
- and if the IN-DESCRIPTION matches the Content-description of the message part;
- and if specified IN-SUBJECT, IN-MESSAGE-CONTEXT, IN-A1-TYPE, and IN-A1-FORMAT values match those of the headers of the immediately enclosing message (message/rfc822 part);
- and (as of MS 7.0.5) if the IN-ENCODING matches the Content-transfer-encoding of the message part.

Only if all specified parameters match is the entry considered to match. Scanning terminates once a matching entry has been found or all entries have been exhausted. If no entry matches, no conversion is performed.

If the matching entry specifies DELETE=1, then the message part is deleted. Otherwise, the command specified by the COMMAND parameter is executed.

Once an entry with a COMMAND parameter has been selected, the body part is extracted to a file. The converter execution environment is prepared as specified by the PARAMETER-SYMBOL-n parameters and DPARAMETER-SYMBOL-n parameters. Finally, a subprocess is created to run the command specified by the COMMAND parameter. The command should perform the necessary conversion operation, reading the file specified by the environment variable (UNIX) and producing the file specified by the environment variable (UNIX).

The command may optionally set options in the OUTPUT_OPTIONS file to pass information back to the conversion channel.

Conversion operations are terminated and no conversion is performed if the forked command returns an error.

If the command succeeds, the resulting output file is read as specified by the OUT-MODE parameter and a new body part containing the converted material is constructed according to the OUT-ENCODING, OUT-PARAMETER-NAME-n, OUT-PARAMETER-VALUE-n, OUT-SUBTYPE, OUT-TYPE, OUT-DESCRIPTION, OUT-DISPOSITION, OUT-DPARAMETER-VALUE-n parameters.

This process is repeated for each part of the message until all parts have been processed.

See Conversion entry parameters for a complete list of the parameters available to conversion entries.

[1] The source channel and destination channel are normally the original source channel and original destination channel prior to the CONVERSIONS mapping table applying and forcing

a "hop" through the conversion channel: that is, the conversion channel itself is not normally the IN-CHAN or OUT-CHAN. However, see the original_channel_probe MTA option, and explicit routing of an address through the conversion channel for exceptions.

[2] The structured part number is the message part number as it would appear in PMDF MAIL. That is, a multipart message has outer "level" parts counted starting from 1, and with a part, if it is a multipart itself, the subparts count starting from 1, and so on for additional "levels". So a multipart with no additional sublevels may have part numbers 1, 2, 3, *etc.*, while a multipart whose second part is itself a multipart, might have part numbers 1, 2.1, 2.2, *etc.*, 3, *etc.*.

51.1.3.2 Conversion entry parameters

The rule parameters currently provided are shown listed by functional groups in Available conversion parameters.

Parameters not listed in this table (below) are ignored.

Table 51.3 Available conversion parameters, grouped by functionality

Parameter	Meaning
Command parameters	
CALL	Routine to call. The argument takes the form *image|routine|argument*.
COMMAND	Command to execute to perform conversion. This parameter (or a CALL or DELETE parameter) is normally required; if no command is specified, the entry is ignored during conversion channel processing.[1]
DELETE	0 or 1. If this flag is set, the message part will be deleted. (If this is the only part in a message, then a single empty text part will be substituted.)
RELABEL	0 or 1. This flag causes an entry to be ignored during conversion channel processing. However, if this flag is 1, then MIME header relabelling is performed during character set conversion.[3]
SERVICE-CALL	Routine to call to perform service conversion. The argument takes the form *image|routine|argument*. Note that this flag causes an entry to be ignored during conversion channel processing; SERVICE-CALL entries are instead performed during character set conversion processing.[2]
SERVICE-COMMAND	The command to execute to perform service conversion. This parameter (or SERVICE-CALL) is required in order to perform a service conversion; if no command (or call) is specified, the entry is ignored for that phase of processing. Note that this flag causes an entry to be ignored during conversion channel processing; SERVICE-COMMAND entries are instead performed during character set conversion processing.[2]
Matching parameters	
ATTACHMENT-NUMBER	Sequential number of the part, starting at number 0 for the first part of the message. Compare with PART-NUMBER, which is the MIME structured number for the part.
IN-A1-FORMAT	Input A1-Format: value from the enclosing message/rfc822 part.
IN-A1-TYPE	Input A1-Type: value from the enclosing message/rfc822 part.
IN-CHAN	Input channel to match for conversion (wildcards allowed). The conversion specified by this entry will only be performed if the message is coming from the specified channel.

IN-CHANNEL	Synonym for IN-CHAN.
IN-DESCRIPTION	Input MIME Content-description: value.
IN-DISPOSITION	Input MIME Content-disposition.
IN-DPARAMETER-DEFAULT-*n*	Input MIME Content-disposition parameter value default if parameter is not present. This value is used as a default for the IN-DPARAMETER-VALUE-*n* test when no such parameter is specified in the body part.
IN-DPARAMETER-NAME-*n*	Input MIME Content-disposition parameter name whose value is to be checked; *n* = 0, 1, 2, ...
IN-DPARAMETER-VALUE-*n*	Input MIME Content-disposition parameter value that must match corresponding IN-DPARAMETER-NAME (wildcards allowed). The conversion specified by this entry is only performed if this field matches the corresponding parameter in the body part's Content-disposition: parameter list.
IN-ENCODING	(New in MS 7.0.5) Input Content-transfer-encoding: value.
IN-LANGUAGE	Input Content-language: value.
IN-MESSAGE-CONTEXT	Input Message-context: value.
IN-PARAMETER-DEFAULT-n	Input MIME Content-type parameter value default if parameter is not present. This value is used as a default for the IN-PARAMETER-VALUE-*n* test when no such parameter is specified in the body part.
IN-PARAMETER-NAME-*n*	Input MIME Content-type parameter name whose value is to be checked; *n* = 0, 1, 2, ...
IN-PARAMETER-VALUE-*n*	Input MIME Content-type parameter value that must match corresponding IN-PARAMETER-NAME (wildcards allowed). The conversion specified by this entry is only performed if this field matches the corresponding parameter in the body part's Content-type: parameter list.
IN-SUBJECT	Input Subject from enclosing message/rfc822 part.
IN-SUBTYPE	Input MIME subtype to match for conversion (wildcards allowed). The conversion specified by this entry is only performed if this field matches the MIME subtype of the body part.
IN-TYPE	Input MIME type to match for conversion (wildcards allowed). The conversion specified by this entry is only performed if this field matches the MIME type of the body part.
OUT-CHAN	Output channel to match for conversion (wildcards allowed). The conversion specified by this entry will only be performed if the message is destined for the specified channel.
OUT-CHANNEL	Synonym for OUT-CHAN.
PART-NUMBER	Dotted integers, *e.g.*, *a.b.c*... The part number of the MIME body part.
TAG	Input conversion tag must match; such conversion tags might have been set in various ways, including via a mailing list [CONVERSION_TAG] named parameter, or via an alias_conversion_tag alias option, or in direct LDAP mode set via a user's own mailConversionTag attribute

	or via the user's domain's `mailDomainConversionTag` attribute, or via Sieve filter conversion tag actions.
Conversion script environment parameters	
`DPARAMETER-SYMBOL-`*n*	Content-disposition parameters to convert to environment variables if present; *n* = `0`, `1`, `2`, ... Takes as argument the name of the MIME parameter to convert, as matched by an `IN-DPARAMETER-NAME-`*m* clause. Each `DPARAMETER-SYMBOL-`*n* is extracted from the Content-disposition: parameter list and placed in an environment variable of the same name prior to executing the converter.
`MESSAGE-HEADER-FILE`	`0`, `1`, or `2`. If set to `1`, the original headers of the immediately enclosing message part are written to the file represented by the `MESSAGE_HEADERS` symbol. If set to `2`, the original headers of the message as a whole (the outermost message headers) are written to `MESSAGE_HEADERS`. As of MS 6.1, in the `MESSAGE-HEADER-FILE=2` case, besides the original headers, the envelope information will also be written, in the form of an X-Envelope-from: header line and an X-Envelope-to: header line.
`ORIGINAL-HEADER-FILE`	`0` or `1`. If set to `1`, the original headers of the enclosing part are written to the file represented by the `INPUT_HEADERS` symbol.
`PARAMETER-SYMBOL-`*n*	Content-type parameters to convert to environment variables if present; *n* = `0`, `1`, `2`, ... Takes as argument the name of the MIME parameter to convert, as matched by an `IN-PARAMETER-NAME-`*m* clause. Each `PARAMETER-SYMBOL-`*n* is extracted from the Content-type: parameter list and placed in an environment variable of the same name prior to executing the converter.
Override/output parameters	
`DPARAMETER-COPY-`*n*	A list of the Content-disposition: parameters to copy from the input body part's Content-disposition: parameter list to the output body part's Content-disposition: parameter list; *n* = `0`, `1`, `2`, ... Takes as argument the name of the MIME parameter to copy, as matched by an `IN-DPARAMETER-NAME-`*m* clause. Wildcards may be used in the argument. In particular, an argument of `*` means to copy all the original Content-disposition: parameters.
`OUT-A1-FORMAT`	Output A1-Format.
`OUT-A1-TYPE`	Output A1-Type.
`OUT-DESCRIPTION`	Output MIME Content-description if it is different than the input MIME Content-description.
`OUT-DISPOSITION`	Output MIME Content-disposition if it is different than the input MIME Content-disposition.
`OUT-DPARAMETER-NAME-`*n*	Output MIME Content-disposition parameter name; *n* = `0`, `1`, `2`, ...
`OUT-DPARAMETER-VALUE-`*n*	Output MIME Content-disposition parameter value corresponding to `OUT-DPARAMETER-NAME-`*n*.
`OUT-MODE`	Mode in which to read the converted file. This should be one of: `BLOCK`, `RECORD`, `RECORD-ATTRIBUTE`, `TEXT`.
`OUT-ENCODING`	Encoding to apply to the converted file.

OUT-LANGUAGE	Output Content-language: value.
OUT-MESSAGE-CONTEXT	(New in 6.0) Set the output Message-context: value
OUT-PARAMETER-NAME-*n*	Output MIME Content-type parameter name; *n* = 0, 1, 2, ...
OUT-PARAMETER-VALUE-*n*	Output MIME Content-type parameter value corresponding to OUT-PARAMETER-NAME-*n*.
OUT-SUBTYPE	Output MIME type if it is different than the input MIME type.
OUT-TYPE	Output MIME type if it is different than the input type
OVERRIDE-HEADER-FILE	0 or 1. If set, then MIME headers are read from the OUTPUT_HEADERS symbol, overriding the original MIME headers in the enclosing part.
OVERRIDE-OPTION-FILE	0 or 1. If set, then the conversion channel reads options from the OUTPUT_OPTIONS symbol.
PARAMETER-COPY-*n*	A list of the Content-type: parameters to copy from the input body part's Content-type: parameter list to the output body part's Content-type: parameter list; *n* = 0, 1, 2, ... Takes as argument the name of the MIME parameter to copy, as matched by an IN-PARAMETER-NAME-*m* clause. Wildcards may be used in the argument. In particular, an argument of * means to copy all the original Content-type: parameters.

[1] Except see the RELABEL, SERVICE-CALL, and SERVICE-COMMAND parameters, which cause entries to be ignored during conversion channel processing, but do affect character set conversion.

[2] See Service conversions for more information on character set conversion and using the SERVICE-COMMAND parameter.

[3] See Relabelling MIME header lines for more information on character set conversion and using the RELABEL parameter.

51.1.3.3 Conversion entry parameter value wildcard matching

The values of conversion entry parameter values may be specified as literal strings, or using wildcards as in MTA mapping table entry patterns.

For instance,

```
in-dparameter-name-0=filename; in-dparameter-value-0=*.wpc;
```

would match any Content-disposition: header filename parameter that has a .wpc extension. Or

```
in-dparameter-name-0=filename; in-dparameter-value-0=*.wp$[cd56]%;
```

would match any Content-disposition: header filename parameter that has a .wpc, .wpd, .wp5, or .wp6 extension.

51.1.3.4 Conversion predefined symbols and environment variables

Symbols in conversion file entries shows symbols available for use within conversion file entries; that is, symbol substitutions available directly in the conversion file. (In constrast, Environment variables for use by conversion channel shell procedures below shows environment variables available for use *within a conversion shell script procedure*.)

Table 51.4 Symbols in conversion file entries

Symbol	Description
A1-FORMAT	
A1-FUNCTION	
A1-TYPE	
DESCRIPTION	The content description of the input message part.
DISPOSITION	The content disposition of the input message part.
LANGUAGE	The language tag from the Content-language: header line of the input message part.
SERVICE	
SUBJECT	The Subject: of the enclosing message/rfc822 part.
TAG	The conversion tag(s) of the input message.

Symbols may be substituted into a conversion entry by enclosing the symbol name in single quotes.

To obtain a literal single quote in a conversion entry, quote it with the backslash character, `\'`. To obtain a literal backslash in a conversion entry, use two backslashes, `\\`.

Environment variables for use by conversion channel shell procedures shows the basic set of environment variables (UNIX) available for use by the conversion command.

Table 51.5 Environment variables for use by conversion channel shell procedures

Environment variable	Description
