Changes in This Release for Oracle Database SQL Language Reference ........ xxv

Changes in Oracle Database 12c Release 1 (12.1.0.2) ............................................................. xxv
Changes in Oracle Database 12c Release 1 (12.1.0.1) ............................................................. xxvii

1 Introduction to Oracle SQL

History of SQL ............................................................................................................................................. 1-1
SQL Standards ............................................................................................................................................. 1-1
How SQL Works ........................................................................................................................................ 1-2
Common Language for All Relational Databases .................................................................................... 1-2
Using Enterprise Manager ......................................................................................................................... 1-2
Lexical Conventions ................................................................................................................................. 1-3
Tools Support .............................................................................................................................................. 1-3

2 Basic Elements of Oracle SQL

Data Types .................................................................................................................................................... 2-1
Oracle Built-in Data Types .......................................................................................................................... 2-6
CHAR Data Type ........................................................................................................................................ 2-9
NCHAR Data Type .................................................................................................................................... 2-10
VARCHAR2 Data Type ................................................................................................................................. 2-10
VARCHAR Data Type ................................................................................................................................ 2-11
NVARCHAR2 Data Type ............................................................................................................................... 2-11
NUMBER Data Type .................................................................................................................................. 2-12
FLOAT Data Type ....................................................................................................................................... 2-14
Floating-Point Numbers ............................................................................................................................ 2-15
BINARY_FLOAT ........................................................................................................................................... 2-15
Data Type Precedence ....................................................................................................................... 2-42
Data Conversion ................................................................................................................................. 2-43
  Implicit and Explicit Data Conversion .............................................................................................. 2-43
  Implicit Data Conversion .................................................................................................................. 2-43
  Implicit Data Conversion Examples .................................................................................................. 2-45
  Explicit Data Conversion .................................................................................................................. 2-46
Security Considerations for Data Conversion ............................................................................... 2-47

Literals ........................................................................................................................................ 2-48
  Text Literals ................................................................................................................................. 2-48
  Numeric Literals .............................................................................................................................. 2-50
    Integer Literals .............................................................................................................................. 2-50
    NUMBER and Floating-Point Literals .......................................................................................... 2-50
  Datetime Literals ............................................................................................................................. 2-53
  Interval Literals ............................................................................................................................... 2-56
    INTERVAL YEAR TO MONTH ....................................................................................................... 2-56
    INTERVAL DAY TO SECOND ....................................................................................................... 2-57

Format Models ............................................................................................................................... 2-59
  Number Format Models .................................................................................................................. 2-60
    Number Format Elements ............................................................................................................ 2-60
  Datetime Format Models ................................................................................................................ 2-63
    Datetime Format Elements ......................................................................................................... 2-63
      Uppercase Letters in Date Format Elements ........................................................................... 2-64
      Punctuation and Character Literals in Datetime Format Models ............................................. 2-64
    Datetime Format Elements and Globalization Support ............................................................... 2-68
    ISO Standard Date Format Elements ........................................................................................ 2-68
    The RR Datetime Format Element .............................................................................................. 2-68
    RR Datetime Format Examples .................................................................................................. 2-69
    Datetime Format Element Suffixes ............................................................................................... 2-69
  Format Model Modifiers .................................................................................................................. 2-70
    Format Model Examples .............................................................................................................. 2-71
  String-to-Date Conversion Rules .................................................................................................... 2-72
  XML Format Model ....................................................................................................................... 2-73

Nulls ................................................................................................................................................. 2-74
  Nulls in SQL Functions .................................................................................................................... 2-75
  Nulls with Comparison Conditions ................................................................................................. 2-75
  Nulls in Conditions .......................................................................................................................... 2-75

Comments ....................................................................................................................................... 2-76
  Comments Within SQL Statements ............................................................................................... 2-76
  Comments on Schema and Nonschema Objects ............................................................................ 2-77
  Hints ............................................................................................................................................. 2-77
    Alphabetical Listing of Hints ....................................................................................................... 2-83
      ALL_ROWS Hint ......................................................................................................................... 2-83
      APPEND Hint ............................................................................................................................. 2-84
      APPEND_VALUES Hint .............................................................................................................. 2-84
      CACHE Hint ................................................................................................................................. 2-85
      CHANGE_DUPKEY_ERROR_INDEX Hint ................................................................................... 2-85
      CLUSTER Hint ............................................................................................................................ 2-86
Database Object Names and Qualifiers

Database Objects

Nonschema Objects

Schema Objects

USE_NL_WITH_INDEX Hint

USE_NL Hint

USE_MERGE Hint

USE_HASH Hint

USE_CUBE Hint

STATEMENT_QUEUING Hint

STAR_TRANSFORMATION Hint

REWRITE Hint

RETRY_ON_ROW_CHANGE Hint

RESULT_CACHE Hint

QB_NAME Hint

PX_JOIN_FILTER Hint

PUSH_SUBQ Hint

PQ_SKEW Hint

PQ_FILTER Hint

PARALLEL_INDEX Hint

PARALLEL_HINT

PQ_CONCURRENT_UNION Hint

PQ_DISTRIBUTE Hint

PQ_SKEW Hint

PUSH_PRED Hint

PUSH_SUBQ Hint

PX_JOIN_FILTER Hint

QB_NAME Hint

RESULT_CACHE Hint

RETRY_ON_ROW_CHANGE Hint

REWRITE Hint

STAR_TRANSFORMATION Hint

STATEMENT_QUEUING Hint

UNNEST Hint

USE_CONCAT Hint

USE_CUBE Hint

USE_HASH Hint

USE_MERGE Hint

USE_NL Hint

### 3 Pseudocolumns

**Hierarchical Query Pseudocolumns** ......................................................... 3-1
- CONNECT_BY_ISCYCLE Pseudocolumn .......................................................... 3-1
- CONNECT_BY_ISLEAF Pseudocolumn ............................................................ 3-2
- LEVEL Pseudocolumn .................................................................................. 3-2

**Sequence Pseudocolumns** ........................................................................ 3-3
- Where to Use Sequence Values .................................................................. 3-3
- How to Use Sequence Values ...................................................................... 3-4

**Version Query Pseudocolumns** ............................................................... 3-5
- COLUMN_VALUE Pseudocolumn ..................................................................... 3-6
- OBJECT_ID Pseudocolumn .......................................................................... 3-7
- OBJECT_VALUE Pseudocolumn ..................................................................... 3-8
- ORA_ROWSCN Pseudocolumn ....................................................................... 3-8
- ROWID Pseudocolumn .................................................................................. 3-9
- ROWNUM Pseudocolumn .............................................................................. 3-10
- XMLDATA Pseudocolumn ............................................................................. 3-11

### 4 Operators

**About SQL Operators** .................................................................................. 4-1
- Unary and Binary Operators ........................................................................ 4-2
- Operator Precedence ................................................................................... 4-2

**Arithmetic Operators** ............................................................................... 4-3

**Concatenation Operator** ........................................................................... 4-3

**Hierarchical Query Operators** ............................................................... 4-5
- PRIOR ......................................................................................................... 4-5
- CONNECT_BY_ROOT ..................................................................................... 4-5

**Set Operators** ......................................................................................... 4-5

**Multiset Operators** .................................................................................. 4-5
- MULTISET EXCEPT ..................................................................................... 4-6
- MULTISET INTERSECT ............................................................................... 4-7
- MULTISET UNION ........................................................................................ 4-8

**User-Defined Operators** ............................................................................ 4-8
6 Conditions

About SQL Conditions ........................................................................................................... 6-1
Condition Precedence ........................................................................................................... 6-3
Comparison Conditions ........................................................................................................ 6-4
Simple Comparison Conditions ............................................................................................ 6-5
Group Comparison Conditions .............................................................................................. 6-6
Floating-Point Conditions ..................................................................................................... 6-7
Logical Conditions ................................................................................................................ 6-8
Model Conditions .................................................................................................................. 6-9
IS ANY Condition .................................................................................................................... 6-9
IS PRESENT Condition .......................................................................................................... 6-10
Multiset Conditions .............................................................................................................. 6-11
IS A SET Condition ................................................................................................................. 6-11
IS EMPTY Condition ............................................................................................................. 6-12
MEMBER Condition .............................................................................................................. 6-12
SUBMULTISET Condition ....................................................................................................... 6-13
Pattern-matching Conditions ............................................................................................... 6-14
LIKE Condition ...................................................................................................................... 6-14
REGEXP_LIKE Condition ...................................................................................................... 6-17
Null Conditions ..................................................................................................................... 6-19
XML Conditions ..................................................................................................................... 6-19
EQUALS_PATH Condition ...................................................................................................... 6-19
UNDER_PATH Condition ....................................................................................................... 6-20
JSON Conditions ................................................................................................................... 6-21
IS JSON Condition .................................................................................................................. 6-21
JSON_EXISTS Condition ....................................................................................................... 6-24
JSON_TEXTCONTAINS Condition ........................................................................................ 6-27
Compound Conditions ........................................................................................................... 6-30
7 Functions

About SQL Functions .......................................................... 7-2
Single-Row Functions ......................................................... 7-3
    Numeric Functions ......................................................... 7-4
    Character Functions Returning Character Values ............ 7-4
    Character Functions Returning Number Values ............... 7-5
    Character Set Functions ................................................. 7-5
    Datetime Functions ....................................................... 7-5
    General Comparison Functions ....................................... 7-6
    Conversion Functions .................................................... 7-6
    Large Object Functions ................................................ 7-7
    Collection Functions ..................................................... 7-7
    Hierarchical Functions .................................................. 7-7
    Data Mining Functions .................................................. 7-8
    XML Functions ............................................................. 7-8
    JSON Functions ............................................................ 7-9
    Encoding and Decoding Functions ................................. 7-9
    NULL-Related Functions ............................................... 7-10
    Environment and Identifier Functions ............................. 7-10
Aggregate Functions .......................................................... 7-10
Analytic Functions ............................................................ 7-12
Object Reference Functions ............................................... 7-18
Model Functions ............................................................... 7-18
OLAP Functions ............................................................... 7-18
Data Cartridge Functions ................................................... 7-18
Alphabetical Listing of SQL Functions .................................. 7-18
    ABS ........................................................................... 7-19
    ACOS ........................................................................... 7-20
    ADD_MONTHS ................................................................ 7-21
    APPENDCHILDXML ...................................................... 7-22
    APPROX_COUNT_DISTINCT ........................................... 7-23
    ASCII .......................................................................... 7-24
    ASCIISTR ..................................................................... 7-25
    ASIN ............................................................................ 7-26
    ATAN ............................................................................ 7-27
    ATAN2 ........................................................................... 7-28
    AVG ............................................................................. 7-29
    BFILENAME ................................................................. 7-31
    BIN_TO_NUM ............................................................... 7-32
    BITAND ..................................................................... 7-34
    CARDINALITY ............................................................. 7-36
    CAST ............................................................................ 7-37
CEIL ......................................................................................................................... 7-40
CHARTOROWID ........................................................................................................ 7-41
CHR ......................................................................................................................... 7-42
CLUSTERDETAILS ...................................................................................................... 7-44
CLUSTERDISTANCE ................................................................................................. 7-48
CLUSTERID ................................................................................................................ 7-50
CLUSTERPROBABILITY ............................................................................................. 7-53
CLUSTERSET ............................................................................................................ 7-55
COALESCE .............................................................................................................. 7-58
COLLECT .................................................................................................................. 7-60
COMPOSE ................................................................................................................. 7-61
CONDBIDTOID ......................................................................................................... 7-62
CONGUIDTOID .......................................................................................................... 7-63
CONNAMETOID ......................................................................................................... 7-64
CONUIDTOID ............................................................................................................. 7-65
CONCAT .................................................................................................................... 7-66
CONVERT .................................................................................................................. 7-67
CORR ........................................................................................................................ 7-69
CORR_ ....................................................................................................................... 7-71
CORR_S ..................................................................................................................... 7-72
CORR_K ..................................................................................................................... 7-73
COS .......................................................................................................................... 7-74
COSH ......................................................................................................................... 7-75
COUNT ....................................................................................................................... 7-76
COVAR_POP ............................................................................................................. 7-78
COVAR_SAMP .......................................................................................................... 7-80
CUBE_TABLE ............................................................................................................ 7-81
CUME_DIST ............................................................................................................... 7-83
CURRENT_DATE ....................................................................................................... 7-85
CURRENT_TIMESTAMP ........................................................................................... 7-86
CV .............................................................................................................................. 7-87
DATAOBJTOR_PARTITION ...................................................................................... 7-89
DATAOBJTO_PARTITION ......................................................................................... 7-90
DBTIMEZONE ........................................................................................................... 7-91
DECODE .................................................................................................................... 7-92
DECOMPOSE ............................................................................................................ 7-94
DELETEXML ............................................................................................................ 7-95
DENSE_RANK ........................................................................................................... 7-97
DEPTH ....................................................................................................................... 7-99
DEREF ....................................................................................................................... 7-100
DUMP ......................................................................................................................... 7-101
EMPTY_BLOB EMPTY_CLOB ................................................................................ 7-103
EXISTS_NODE .......................................................................................................... 7-104
EXP ......................................................................................................................... 7-105
EXTRACT (datetime) .............................................................................................. 7-106
EXTRACT (XML) ..................................................................................................... 7-109
EXTRACTVALUE ..................................................................................................... 7-110

Index
This reference contains a complete description of the Structured Query Language (SQL) used to manage information in an Oracle Database. Oracle SQL is a superset of the American National Standards Institute (ANSI) and the International Organization for Standardization (ISO) SQL:2011 standard.

This Preface contains these topics:

- Audience
- Documentation Accessibility
- Related Documents
- Conventions

**Audience**

The *Oracle Database SQL Language Reference* is intended for all users of Oracle SQL.

**Documentation Accessibility**

**Access to Oracle Support**

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit [http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info](http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info) or visit [http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs](http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs) if you are hearing impaired.

**Related Documents**

For more information, see these Oracle resources:

- *Oracle Database PL/SQL Language Reference* for information on PL/SQL, the procedural language extension to Oracle SQL

Many of the examples in this book use the sample schemas, which are installed by default when you select the Basic Installation option with an Oracle Database.
installation. Refer to Oracle Database Sample Schemas for information on how these schemas were created and how you can use them yourself.

Conventions

The following text conventions are used in this document:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>boldface</td>
<td>Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.</td>
</tr>
<tr>
<td>italic</td>
<td>Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.</td>
</tr>
<tr>
<td>monospace</td>
<td>Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.</td>
</tr>
</tbody>
</table>
Changes in This Release for Oracle Database SQL Language Reference

This preface contains:

- Changes in Oracle Database 12c Release 1 (12.1.0.2)
- Changes in Oracle Database 12c Release 1 (12.1.0.1)

Changes in Oracle Database 12c Release 1 (12.1.0.2)

The following are changes in Oracle Database SQL Language Reference for Oracle Database 12c Release 1 (12.1.0.2).

New Features

The following features are new in this release:

- The In-Memory Column Store (IM column store) is an optional, static SGA pool that stores copies of tables and partitions in a special columnar format optimized for rapid scans.
  
  See the \texttt{inmemory} of \texttt{CREATE TABLE} on page 16-48, the \texttt{inmemory} of \texttt{CREATE TABLESPACE} on page 16-110, and the \texttt{inmemory} of \texttt{CREATE MATERIALIZED VIEW} on page 15-17

  See the following hints:
  
  - \texttt{INMEMORY} Hint on page 2-94
  - \texttt{NO_INMEMORY} Hint on page 2-99
  - \texttt{INMEMORY_PRUNING} Hint on page 2-94
  - \texttt{NO_INMEMORY_PRUNING} Hint on page 2-99

- Oracle Database now supports JavaScript Object Notation (JSON).
  
  See the following conditions:
  
  - \texttt{IS JSON} Condition on page 6-21
  - \texttt{JSON_EXISTS} Condition on page 6-24
  - \texttt{JSON_TEXTCONTAINS} Condition on page 6-27

  See the following functions:
  
  - \texttt{JSON_QUERY} on page 7-147
  - \texttt{JSON_TABLE} on page 7-154
- **JSON_VALUE** on page 7-162

See “JSON Object Access Expressions” on page 5-12

- **Attribute clustering** lets you cluster table data in close physical proximity based on the content of specified columns.

See the **attribute_clustering_clause** of CREATE TABLE on page 16-78 and the **attribute_clustering_clause** of ALTER TABLE on page 12-52

See the following hints:
- **CLUSTERING Hint** on page 2-86
- **NO_CLUSTERING Hint** on page 2-96

- **Zone maps** let you reduce the I/O and CPU costs of table scans by tracking the sets of contiguous data blocks, or zones, in which certain column values are stored. You can use zone maps with or without attribute clustering.

See the statements **CREATE MATERIALIZED ZONEMAP** on page 15-41, **ALTER MATERIALIZED ZONEMAP** on page 11-27, and **DROP MATERIALIZED ZONEMAP** on page 17-63, and the **zonemap_clause** of CREATE TABLE on page 16-79

See the **NO_ZONEMAP Hint** on page 2-105 and the function **SYS_OP_ZONE_ID** on page 7-344

- You can now create **range-partitioned hash clusters**.

See the **cluster_range_partitions** clause of CREATE CLUSTER on page 14-16 and the **allocate_extent_clause** of ALTER CLUSTER on page 10-30

- The new function **APPROX_COUNT_DISTINCT** returns the approximate number of distinct values for a column. This function is an alternative to the **COUNT** function. It processes large amounts of data significantly faster than **COUNT**, with negligible deviation from the exact result.

See **APPROX_COUNT_DISTINCT** on page 7-23

- A new type of index compression called **advanced index compression** lets you improve compression ratios significantly while still providing efficient access to indexes.

See the **advanced_index_compression** clause of CREATE INDEX on page 14-87

- For tables compressed with Hybrid Columnar Compression, you can now control whether **row-level locking** is used during DML operations.

See the **[NO] ROW LEVEL LOCKING** clause of CREATE TABLE on page 16-47

- The database now supports **force full database caching mode**, which allows you to designate the entire database, including NOCACHE LOBs, as eligible for caching in the buffer cache.

See the **[NO] FORCE FULL DATABASE CACHING** clause of ALTER DATABASE on page 10-68

- When you grant a database role to a user who is responsible for CBAC grants, you can now specify **WITH DELEGATE OPTION** in the **GRANT** statement to prevent giving the grantees additional privileges on the role. **WITH DELEGATE OPTION** is an alternative to **WITH ADMIN OPTION**. It enables a role to be granted to program units, but it does not permit the granting of the role to other principals or the administration of the role itself.

See the **WITH DELEGATE OPTION** clause of **GRANT** on page 18-40
The new **READ object privilege** and **READ ANY TABLE system privilege** allow users to query tables, materialized views, views, and their synonyms.

The **READ object privilege** is an alternative to the **SELECT object privilege**. In addition to querying objects, the **SELECT object privilege** allows users lock rows of a table with the **LOCK TABLE** and **SELECT ... FOR UPDATE** statements. The **READ object privilege** only allows users to query objects. See Table 18–2 for more information.

The **READ ANY TABLE system privilege** is an alternative to the **SELECT ANY TABLE** system privilege. In addition to querying objects, the **SELECT ANY TABLE** privilege allows users to lock rows of a table with the **SELECT ... FOR UPDATE** statement. The **READ ANY TABLE** privilege only allows users to query objects. See Table 18–1 for more information.

### Changes in Oracle Database 12c Release 1 (12.1.0.1)

The following are changes in *Oracle Database SQL Language Reference* for Oracle Database 12c Release 1 (12.1.0.1).

#### New Features

The following features are new in this release:

**Features That Introduce New SQL Statements**

The following features introduce new SQL statements:

- **The multitenant architecture** offers the capability that enables an Oracle database to function as a multitenant container database (CDB). A CDB is an Oracle database that includes one or more pluggable databases (PDBs). A PDB is a portable collection of schemas, schema objects, and nonschema objects that appears to an Oracle client as a non-CDB. You can unplug a PDB from a CDB and plug it into a different CDB.

  See the following new statements:
  - **CREATE PLUGGABLE DATABASE** on page 15-61
  - **ALTER PLUGGABLE DATABASE** on page 11-38
  - **DROP PLUGGABLE DATABASE** on page 17-68

- **Unified auditing** provides a full set of enhanced auditing features. It enables you to create named unified audit policies, enable or disable unified audit policies, apply users to or exclude users from policies, and set whether an audit record is created if the audited behavior fails, succeeds, or both. It also enables you to capture application context values in audit records.

  See the following new statements:
  - **CREATE AUDIT POLICY (Unified Auditing)** on page 14-2
  - **ALTER AUDIT POLICY (Unified Auditing)** on page 10-24
  - **DROP AUDIT POLICY (Unified Auditing)** on page 17-38
  - **AUDIT (Unified Auditing)** on page 13-45
  - **NOAUDIT (Unified Auditing)** on page 18-92

- A new unified key management interface for Transparent Data Encryption (TDE) eases key administration tasks, provides for better compliance and tracking, and improves separation of duty between the database administrator and security administrator.
ALTER DATABASE Enhancements
The following features provide enhancements to the \texttt{ALTER DATABASE} statement:

- **Storage Snapshot Optimization** enables you to use a third-party storage snapshot of the database taken without backup mode for all types of recovery operations, including point-in-time recovery. The \texttt{ALTER DATABASE} statement has been enhanced with the new \texttt{SNAPSHOT TIME} clause to enable you to recover the database using such a storage snapshot.

  See the new \texttt{SNAPSHOT TIME} clause of the \texttt{ALTER DATABASE} \texttt{full_database_recovery} clause on page 10-46.

- Move an online data file to a new location while the database is open and accessing the data file.

  See the new \texttt{move_datafile_clause} of \texttt{ALTER DATABASE} on page 10-53.

- Create a control file for a Data Guard far sync instance.

  See the enhanced \texttt{controlfile_clauses} of \texttt{ALTER DATABASE} on page 10-59.

- Performing switchovers and failovers to a physical standby database is simplified.

  See the new \texttt{ALTER DATABASE} clauses \texttt{switchover_clause} on page 10-62 and \texttt{failover_clause} on page 10-63.

- Real-time apply is now enabled by default during Redo Apply on a physical standby database. You can disable real-time apply by specifying \texttt{USING ARCHIVED LOGFILE}.

  See the enhanced \texttt{managed_standby_recovery} clause of \texttt{ALTER DATABASE} on page 10-48.

ALTER SYSTEM Enhancements
The following features provide enhancements to the \texttt{ALTER SYSTEM} statement:

- Relocate a client to the least loaded Oracle ASM instance.

  See the new \texttt{RELOCATE CLIENT} clause of \texttt{ALTER SYSTEM} on page 11-100.

- Apply one-off patches released for Oracle ASM in a rolling manner.

  See the new \texttt{rolling_patch_clauses} of \texttt{ALTER SYSTEM} on page 11-92.

AUDIT and NOAUDIT (Traditional Auditing) Enhancements
The following feature provides enhancements to the \texttt{AUDIT} and \texttt{NOAUDIT} statements for traditional auditing:

- Audit operations on a SQL translation profile.

  See the new clause \texttt{ON SQL TRANSLATION PROFILE} of \texttt{AUDIT} on page 13-36.

CREATE DISKGROUP and ALTER DISKGROUP Enhancements
The following features provide enhancements to the \texttt{CREATE DISKGROUP} statement, \texttt{ALTER DISKGROUP} statement, or both:

- Check logical data corruptions and repair them automatically in normal and high redundancy Oracle ASM disks groups.

  See the new \texttt{scrub_clause} of \texttt{ALTER DISKGROUP} on page 10-98.
- Replace a user in an Oracle ASM disk group.
  See the enhanced `user_clauses` of `ALTER DISKGROUP` on page 10-97.

- Change the permissions, owner, and user group of an Oracle ASM disk group file while it is open.
  See the enhanced `ALTER DISKGROUP` clauses `file_permissions_clause` on page 10-98 and the `file_owner_clause` on page 10-98.

- Replace one or more disks in an Oracle ASM disk group with a single operation.
  See the new `replace_disk_clause` of `ALTER DISKGROUP` on page 10-89.

- Rename a disk in an Oracle ASM disk group.
  See the new `rename_disk_clause` of `ALTER DISKGROUP` on page 10-89.

- The following are new Oracle ASM disk group attributes:
  - `CONTENT.CHECK` allows you to enable or disable content checking when performing data copy operations for rebalancing a disk group.
  - `FAILGROUP_REPAIR_TIME` allows you to specify a default repair time for the failure groups in the disk group.
  - `PHYS_META_REPLICATED` allows you to track the replication status of a disk group.
  - `THIN_PROVISIONED` allows you to enable or disable the functionality to discard unused storage space after a disk group rebalance is completed.
  See Table 14–2, ” Disk Group Attributes” on page 14-60.

CREATE FLASHBACK ARCHIVE and ALTER FLASHBACK ARCHIVE Enhancements

The following feature provides enhancements to the `CREATE FLASHBACK ARCHIVE` and `ALTER FLASHBACK ARCHIVE` statements:

- Instruct the database to optimize the storage of data in history tables.
  See the new clause `[NO] OPTIMIZE DATA` of `CREATE FLASHBACK ARCHIVE` on page 14-70 and the new clause `[NO] OPTIMIZE DATA` of `ALTER FLASHBACK ARCHIVE` on page 10-105.

CREATE INDEX and ALTER INDEX Enhancements

The following features provide enhancements to the `CREATE INDEX` statement, `ALTER INDEX` statement, or both:

- Create partial indexes on a subset of the partitions of a table.
  See the new `partial_index_clause` of `CREATE INDEX` on page 14-88.

- Remove orphaned index entries for records that were previously dropped or truncated by a table partition maintenance operation.
  See the new keyword `CLEANUP` of `ALTER INDEX ... COALESCE` on page 10-121 and the new keyword `CLEANUP` of `ALTER INDEX ... MODIFY PARTITION ... COALESCE` on page 10-123.

- Create multiple indexes on the same set of columns, column expressions, or both if the indexes are of different types, use different partitioning, or have different uniqueness properties.
  See the `index_expr` clause of `CREATE INDEX` on page 14-83.
CREATE INDEXTYPE and ALTER INDEXTYPE Enhancements

The following feature provides enhancements to the CREATE INDEXTYPE and ALTER INDEXTYPE statements:

- Create domain indexes on hash- and interval-partitioned tables.
  
  See CREATE INDEXTYPE on page 14-103 and ALTER INDEXTYPE on page 10-127.

CREATE MATERIALIZED VIEW and ALTER MATERIALIZED VIEW Enhancements

The following feature provides enhancements to the CREATE MATERIALIZED VIEW and ALTER MATERIALIZED VIEW statements:

- Materialized views, which are noneditioned objects, can depend on editioned objects.
  
  See:
  
  
  - The new clauses `evaluation_edition_clause` on page 11-16 and `unusableEditions_clause` on page 11-17 of ALTER MATERIALIZED VIEW

CREATE MATERIALIZED VIEW LOG and ALTER MATERIALIZED VIEW LOG Enhancements

The following feature provides enhancements to the CREATE MATERIALIZED VIEW LOG and ALTER MATERIALIZED VIEW LOG statements:

- Specify the refresh method for which a materialized view log will be used. You can specify synchronous refresh, which is introduced in Oracle Database 12c, or fast refresh, which is also available in earlier releases.
  
  See:
  
  - The new `forRefreshClause` of CREATE MATERIALIZED VIEW LOG on page 15-38
  
  - The new `forRefreshClause` of ALTER MATERIALIZED VIEW LOG on page 11-26

CREATE SEQUENCE and ALTER SEQUENCE Enhancements

The following features provide enhancements to the CREATE SEQUENCE and ALTER SEQUENCE statements:

- Control whether the sequence pseudocolumn `NEXTVAL` retains its original value during replay for Application Continuity.
  
  See:
  
  - The new clauses `KEEP` and `NOKEEP` of CREATE SEQUENCE on page 15-99
  
  - The new clauses `KEEP` and `NOKEEP` of ALTER SEQUENCE on page 11-63

- Create a session sequence, which is a special type of sequence that is specifically designed to be used with global temporary tables that have session visibility.
  
  See:
  
  - The new clauses `SESSION` and `GLOBAL` of CREATE SEQUENCE on page 15-99
  
  - The new clauses `SESSION` and `GLOBAL` of ALTER SEQUENCE on page 11-63
CREATE TABLE and ALTER TABLE Enhancements

The following features provide enhancements to the `CREATE TABLE` statement, `ALTER TABLE` statement, or both:

- The maximum size for the `VARCHAR2`, `NVARCHAR2`, and `RAW` data types is increased to 32767 bytes.
  See "Extended Data Types" on page 2-29.

- **Temporal Validity** support enables you to associate a valid time dimension with a table. You can use Oracle Flashback Query to retrieve rows from that table based on whether they are considered valid as of a specified time or during a specified time period.
  See:
  - The new `CREATE TABLE` clause `period_definition` on page 16-40
  - The new `ALTER TABLE` clauses `add_period_clause` on page 12-68 and `drop_period_clause` on page 12-68
  - The enhanced `SELECT flashback_query_clause` on page 19-22

- Virtual columns, which are noneditioned objects, can depend on editioned objects.
  See:
  - The new clauses `evaluation_edition_clause` on page 16-37 and `unusable_editions_clause` on page 16-38 of `CREATE TABLE`
  - The new clause `modify_virtcol_properties` on page 12-64 of `ALTER TABLE`

- Performance has been improved when you specify a `DEFAULT` value for a nullable column.
  See the `DEFAULT` clause of `ALTER TABLE` on page 12-56.

- Specify a default column value that includes the sequence pseudocolumns `CURRVAL` and `NEXTVAL`.
  See:
  - The `DEFAULT` clause of `CREATE TABLE` on page 16-34
  - The `DEFAULT` clause of `ALTER TABLE` on page 12-56

- The `DEFAULT` clause has the new clause `ON NULL`, which instructs the database to assign a specified default column value when an `INSERT` statement attempts to assign a value that evaluates to NULL.
  See:
  - The `ON NULL` clause of `CREATE TABLE` on page 16-34
  - The `ON NULL` clause of `ALTER TABLE` on page 12-57

- Specify an identity column, which is assigned an increasing or decreasing integer value from a sequence generator.
  See:
  - The new clauses `identity_clause` of `CREATE TABLE` on page 16-35 and `identity_options` of `CREATE TABLE` on page 16-35
  - The new clauses `identity_clause` of `ALTER TABLE` on page 12-57 and `identity_options` of `ALTER TABLE` on page 12-57

- Hide and unhide columns in tables.
See:
- The new clauses VISIBLE | INVISIBLE on page 16-33 of CREATE TABLE
- The new clauses VISIBLE | INVISIBLE on page 16-37 of CREATE TABLE for virtual columns
- The new clause modify_col_visibility of ALTER TABLE on page 12-64

Recursively cascade a truncate operation to child tables.
See the new keyword CASCADE of the clause truncate_partition_subpart of ALTER TABLE on page 12-87.

Recursively cascade an exchange operation to child tables.
See the new keyword CASCADE of the clause exchange_partition_subpart of ALTER TABLE on page 12-94.

Store XMLType data, and abstract data types that contain attributes of type XMLType, CLOB, BLOB, or NCLOB, in an ANYDATA column.
See the new clause modify_opaque_type of ALTER TABLE on page 12-99.

Enable a table for row archival for In-Database Archiving.
See the new ROW ARCHIVAL clause of CREATE TABLE on page 16-85.

Manage policies for Automatic Data Optimization.
See the new ilm_clause of CREATE TABLE on page 16-51 and the new ilm_clause of ALTER TABLE on page 12-45.

Create a reference-partitioned child table whose parent is an interval-partitioned table.
See the enhanced clause reference_partitioning of CREATE TABLE on page 16-76.

Specify multiple table partitions or table subpartitions for the following ALTER TABLE operations:
- Add one or more range, list, or system partitions to a table. See add_table_partition on page 12-81.
- Add one or more range subpartitions to a partition. See add_range_subpartition on page 12-77.
- Add one or more list subpartitions to a partition. See add_list_subpartition on page 12-77.
- Split one range or list partition into two or more partitions. See split_table_partition on page 12-87.
- Split one range or list subpartition into two or more subpartitions. See split_table_subpartition on page 12-89.
- Merge two or more range, list, or system partitions into one new partition. See merge_table_partitions on page 12-91.
- Merge two or more range or list subpartitions into one new subpartition. See merge_table_subpartitions on page 12-92.
- Truncate one or more partitions or subpartitions. See truncate_partition_subpart on page 12-86.
- Drop one or more partitions. See drop_table_partition on page 12-84.
- Drop one or more subpartitions. See drop_table_subpartition on page 12-85.
In earlier releases, the following DDL operations required a DML-blocking lock. You can use the new ONLINE keyword to allow the execution of DML statements during the following DDL operations:

- Dropping an index (using DROP INDEX ... ONLINE ...) on page 17-55
- Marking an index as UNUSABLE (using ALTER INDEX ... UNUSABLE ONLINE) on page 10-120
- Marking a column as UNUSED (using ALTER TABLE ... SET UNUSED ... ONLINE ...) on page 12-65
- Dropping a constraint (using ALTER TABLE ... DROP ... ONLINE ...) on page 12-72
- Moving a table partition (using ALTER TABLE ... MOVE PARTITION ... ONLINE) on page 12-80
- Moving a table subpartition (using ALTER TABLE ... MOVE SUBPARTITION ... ONLINE) on page 12-81

CREATE VIEW Enhancements
The following features provide enhancements to the CREATE VIEW statement:

- Hide and unhide columns in views.
  See the new clause VISIBLE | INVISIBLE of CREATE VIEW on page 17-20.
- Specify whether functions referenced in the view are executed using the view invoker's rights or the view definer's rights.
  See the new clause BEQUEATH of CREATE VIEW on page 17-21.

GRANT and REVOKE Enhancements
The following features provide enhancements to the GRANT and REVOKE statements:

- Grant object privileges on a user to users and roles.
  See:
  - The new clause ON USER of GRANT on page 18-42
  - The new clause ON USER of REVOKE on page 18-105
- Grant object privileges on a SQL translation profile to users and roles.
  See:
  - The new clause ON SQL TRANSLATION PROFILE of GRANT on page 18-43
  - The new clause ON SQL TRANSLATION PROFILE of REVOKE on page 18-106
- Grant code based access control (CBAC) roles to program units.
  See:
  - The new clause grant_roles_to_programs of GRANT on page 18-43
  - The new clause revoke_roles_from_programs of REVOKE on page 18-106

SELECT Enhancements
The following features provide enhancements to the SELECT statement:

- Pattern matching enables you to recognize patterns found across multiple rows in a table.
  See the new row_pattern_clause of SELECT on page 19-44.
Perform top-N queries by specifying an offset, and the number of rows or percentage of rows to return.

See the new `row_limiting_clause` of `SELECT` on page 19-41.

In a query that performs outer joins of more than two pairs of tables, a single table can now be the null-generated table for multiple tables.

See "Outer Joins" on page 9-12.

Perform a variation of an ANSI `CROSS JOIN` or an ANSI `LEFT OUTER JOIN` with left correlation support. You can specify a table reference or collection expression on the right side of the join clause.

See the new `cross_outer_apply_clause` of `SELECT` on page 19-32.

Specify a lateral inline view in a query expression.

See the new keyword `LATERAL` of `SELECT` on page 19-22.

Declare and define PL/SQL functions and procedures in the `WITH` clause of a query. You can then reference the PL/SQL functions in the query and its subqueries.

See the new clause `plsql_declarations` on `SELECT` on page 19-17.

**TRUNCATE TABLE Enhancements**
The following feature provides enhancements to the `TRUNCATE TABLE` statement:

- Recursively truncate child tables.

See the new clause `CASCADE` of `TRUNCATE TABLE` on page 19-92.

**New or Enhanced Functions**
The following are new or enhanced functions:

- `CLUSTER_DETAILS` on page 7-44 is a new function that predicts cluster membership for each row. It can use a pre-defined clustering model or perform dynamic clustering. The function returns an XML string that describes the predicted cluster or a specified cluster.

- `CLUSTER_DISTANCE` on page 7-48 is a new function that predicts cluster membership for each row. It can use a pre-defined clustering model or perform dynamic clustering. The function returns the raw distance between each row and the centroid of either the predicted cluster or a specified.

- `CLUSTER_ID` on page 7-50 has been enhanced so that it can either use a pre-defined clustering model or perform dynamic clustering.

- `CLUSTER_PROBABILITY` on page 7-53 has been enhanced so that it can either use a pre-defined clustering model or perform dynamic clustering. The data type of the return value has been changed from `NUMBER` to `BINARY_DOUBLE`.

- `CLUSTER_SET` on page 7-55 has been enhanced so that it can either use a pre-defined clustering model or perform dynamic clustering. The data type of the returned probability has been changed from `NUMBER` to `BINARY_DOUBLE`.

- `FEATURE_DETAILS` on page 7-111 is a new function that predicts feature matches for each row. It can use a pre-defined feature extraction model or perform dynamic feature extraction. The function returns an XML string that describes the predicted feature or a specified feature.

- `FEATURE_ID` on page 7-114 has been enhanced so that it can either use a pre-defined feature extraction model or perform dynamic feature extraction.
■ **FEATURE_SET** on page 7-116 has been enhanced so that it can either use a pre-defined feature extraction model or perform dynamic feature extraction. The data type of the returned probability has been changed from **NUMBER** to **BINARY_DOUBLE**.

■ **FEATURE_VALUE** on page 7-119 has been enhanced so that it can either use a pre-defined feature extraction model or perform dynamic feature extraction. The data type of the return value has been changed from **NUMBER** to **BINARY_DOUBLE**.

■ **ORA_INVOKING_USER** on page 7-223 is a new function that returns the name of the database user who invoked the current statement or view. This function takes into account the **BEQUEATH** property of intervening views referenced in the statement.

■ **ORA_INVOKING_USERID** on page 7-224 is a new function that returns the identifier of the database user who invoked the current statement or view. This function takes into account the **BEQUEATH** property of intervening views referenced in the statement.

■ **PREDICTION** on page 7-237 has been enhanced so that it can either use a pre-defined predictive model or perform dynamic prediction.

■ **PREDICTION_BOUNDS** on page 7-241 now returns the upper and lower bounds of the prediction as the **BINARY_DOUBLE** data type. It previously returned these values as the **NUMBER** data type.

■ **PREDICTION_COST** on page 7-243 has been enhanced so that it can either use a pre-defined predictive model or perform dynamic prediction. The data type of the returned cost has been changed from **NUMBER** to **BINARY_DOUBLE**.

■ **PREDICTION_DETAILS** on page 7-246 has been enhanced so that it can either use a pre-defined predictive model or perform dynamic prediction.

■ **PREDICTION_PROBABILITY** on page 7-250 has been enhanced so that it can either use a pre-defined predictive model or perform dynamic prediction. The data type of the returned probability has been changed from **NUMBER** to **BINARY_DOUBLE**.

■ **PREDICTION_SET** on page 7-254 has been enhanced so that it can either use a pre-defined predictive model or perform dynamic prediction. The data type of the returned probability has been changed from **NUMBER** to **BINARY_DOUBLE**.

■ **STANDARD_HASH** on page 7-304 is a new function that computes a hash value for a given expression using one of several standardized hash algorithms.

■ **SYS_CONTEXT** on page 7-334 enables you to query a new built-in namespace, **SYS_SESSION_ROLES**, which allows you to determine if a specified role is currently enabled for the session.

### New or Enhanced Privileges

The following are new or enhanced system privileges and object privileges:

■ The behavior has changed for the following system privilege, which is listed in **Table 18–1** on page 18-44:

  - **SELECT ANY DICTIONARY** now does not allow you to query the following objects in the **SYS** schema: **DEFAULT_PWD$**, **ENC$$**, **LINK$**, **USER$$**, **USER_HISTORY$$**, and **XS$VERIFIERS**.

■ The following new system privileges are listed in **Table 18–1** on page 18-44:
CREATE SQL TRANSLATION PROFILE, CREATE ANY SQL TRANSLATION PROFILE, ALTER
ANY SQL TRANSLATION PROFILE, USE ANY SQL TRANSLATION PROFILE, and DROP
ANY SQL TRANSLATION PROFILE allow you to manage SQL translation profiles.

EXEMPT REDACTION POLICY allows you to bypass any existing Oracle Data
Redaction policies.

INHERIT ANY PRIVILEGES allows you to execute invoker’s rights procedures
with the privileges of the invoker.

KEEP DATE TIME allows the SYSDATE and SYSTIMESTAMP functions to return their
original values during replay for Application Continuity.

KEEP SYSGUID allows the SYS_GUID function to return its original value during
replay for Application Continuity.

LOGMINING allows you to perform LogMiner operations in a multitenant
container database (CDB).

PURGE DBA_RECYCLEBIN allows you to remove all objects from the system-wide
recycle bin.

SYSBACKUP allows you to perform backup and recovery tasks.

SYSDBA allows you to manage Oracle Data Guard.

SYSKM allows you to perform encryption key management.

TRANSLATE ANY SQL allows you to translate SQL for any user.

The following new object privileges are listed in Table 18-2 on page 18-55:

- **ALTER** and **USE** privileges authorize operations on SQL translation profiles.
- **INHERIT PRIVILEGES** is a new type of object privilege that can be granted on a
  user to users and roles. It allows invoker’s rights procedures owned by the
  grantee to be executed with the privileges of the invoker when the invoker is
  the user on whom this privilege is granted.
- **KEEP SEQUENCE** allows the sequence pseudocolumn NEXTVAL to retain its
  original value during replay for Application Continuity.
- **TRANSLATE SQL** is a new type of object privilege that can be granted on a user
to users and roles. It allows the grantee to translate SQL through the grantee’s
SQL translation profile for the user on whom this privilege is granted.

**New Hints**

The following are new hints:

- The **GATHER_OPTIMIZER_STATISTICS** Hint on page 2-89 and **NO_GATHER_ OPTIMIZER_STATISTICS** Hint on page 2-97 allow you to enable and disable
  statistics gathering during bulk loads.
- The **PQ_CONCURRENT_UNION** Hint on page 2-109 and **NO_PQ_ CONCURRENT_UNION** Hint on page 2-101 allow you to enable and disable
  concurrent processing of UNION and UNION ALL operations.
- The **PQ_FILTER** Hint on page 2-112 allows you to instruct the optimizer on how to
  process rows when filtering correlated subqueries.
- The **PQ_SKEW** Hint on page 2-112 and **NO_PQ_SKEW** Hint on page 2-101 allow
  you to advise the optimizer of whether the distribution of the values of the join
  keys for a parallel join is skewed.
The USE_CUBE Hint on page 2-116 and NO_USE_CUBE Hint on page 2-103 allow you to specify whether to use or exclude cube joins.

**Deprecated Features**

The following features are deprecated in this release, and may be desupported in a future release:

- Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. SQL plan management creates SQL plan baselines, which offer superior SQL performance stability compared with stored outlines.

  See *Oracle Database SQL Tuning Guide* for more information about SQL plan management.

- The use of PKI encryption with Transparent Data Encryption is deprecated. To configure Transparent Data Encryption, use the ADMINISTER KEY MANAGEMENT statement on page 10-5.

  See *Oracle Database Advanced Security Guide* for more information.

**Desupported Features**

Some features previously described in this document are desupported in Oracle Database 12c Release 1 (12.1). See *Oracle Database Upgrade Guide* for a list of desupported features.
Structured Query Language (SQL) is the set of statements with which all programs and users access data in an Oracle Database. Application programs and Oracle tools often allow users access to the database without using SQL directly, but these applications in turn must use SQL when executing the user's request. This chapter provides background information on SQL as used by most database systems.

This chapter contains these topics:

- History of SQL
- SQL Standards
- Lexical Conventions
- Tools Support

History of SQL

Dr. E. F. Codd published the paper, "A Relational Model of Data for Large Shared Data Banks", in June 1970 in the Association of Computer Machinery (ACM) journal, Communications of the ACM. Codd's model is now accepted as the definitive model for relational database management systems (RDBMS). The language, Structured English Query Language (SEQUEL) was developed by IBM Corporation, Inc., to use Codd's model. SEQUEL later became SQL (still pronounced "sequel"). In 1979, Relational Software, Inc. (now Oracle) introduced the first commercially available implementation of SQL. Today, SQL is accepted as the standard RDBMS language.

SQL Standards

Oracle strives to comply with industry-accepted standards and participates actively in SQL standards committees. Industry-accepted committees are the American National Standards Institute (ANSI) and the International Organization for Standardization (ISO), which is affiliated with the International Electrotechnical Commission (IEC). Both ANSI and the ISO/IEC have accepted SQL as the standard language for relational databases. When a new SQL standard is simultaneously published by these organizations, the names of the standards conform to conventions used by the organization, but the standards are technically identical.

The SQL standard consists of ten parts; one part is new in 2012; five other parts were revised in 2011; for the other four parts, the 2008 version remains in place.

See Also: Appendix C, "Oracle and Standard SQL" for a detailed description of Oracle Database conformance to the SQL standard
How SQL Works

The strengths of SQL provide benefits for all types of users, including application programmers, database administrators, managers, and end users. Technically speaking, SQL is a data sublanguage. The purpose of SQL is to provide an interface to a relational database such as Oracle Database, and all SQL statements are instructions to the database. In this SQL differs from general-purpose programming languages like C and BASIC. Among the features of SQL are the following:

- It processes sets of data as groups rather than as individual units.
- It provides automatic navigation to the data.
- It uses statements that are complex and powerful individually, and that therefore stand alone. Flow-control statements were not part of SQL originally, but they are found in the optional part of SQL, ISO/IEC 9075-4:2011. Flow-control statements are commonly known as "persistent stored modules" (PSM), and the PL/SQL extension to Oracle SQL is similar to PSM.

SQL lets you work with data at the logical level. You need to be concerned with the implementation details only when you want to manipulate the data. For example, to retrieve a set of rows from a table, you define a condition used to filter the rows. All rows satisfying the condition are retrieved in a single step and can be passed as a unit to the user, to another SQL statement, or to an application. You need not deal with the rows one by one, nor do you have to worry about how they are physically stored or retrieved. All SQL statements use the optimizer, a part of Oracle Database that determines the most efficient means of accessing the specified data. Oracle also provides techniques that you can use to make the optimizer perform its job better.

SQL provides statements for a variety of tasks, including:

- Querying data
- Inserting, updating, and deleting rows in a table
- Creating, replacing, altering, and dropping objects
- Controlling access to the database and its objects
- Guaranteeing database consistency and integrity

SQL unifies all of the preceding tasks in one consistent language.

Common Language for All Relational Databases

All major relational database management systems support SQL, so you can transfer all skills you have gained with SQL from one database to another. In addition, all programs written in SQL are portable. They can often be moved from one database to another with very little modification.

Using Enterprise Manager

Many of the operations you can accomplish using SQL syntax can be done much more easily using Enterprise Manager. For more information, see the Oracle Enterprise Manager documentation set, Oracle Database 2 Day DBA, or any of the Oracle Database 2 Day + books.
Lexical Conventions

The following lexical conventions for issuing SQL statements apply specifically to the Oracle Database implementation of SQL, but are generally acceptable in other SQL implementations.

When you issue a SQL statement, you can include one or more tabs, carriage returns, spaces, or comments anywhere a space occurs within the definition of the statement. Thus, Oracle Database evaluates the following two statements in the same manner:

```sql
SELECT last_name, salary * 12, MONTHS_BETWEEN(SYSDATE, hire_date)
FROM employees
WHERE department_id = 30
ORDER BY last_name;
```

```sql
SELECT last_name,
    salary * 12,
    MONTHS_BETWEEN(SYSDATE, hire_date)
FROM employees
WHERE department_id = 30
ORDER BY last_name;
```

Case is insignificant in reserved words, keywords, identifiers, and parameters. However, case is significant in text literals and quoted names. Refer to "Text Literals" on page 2-48 for a syntax description of text literals.

---

**Note:** SQL statements are terminated differently in different programming environments. This documentation set uses the default SQL*Plus character, the semicolon (;).

---

Tools Support

Oracle provides a number of utilities to facilitate your SQL development process:

- Oracle SQL Developer is a graphical tool that lets you browse, create, edit, and delete (drop) database objects, edit and debug PL/SQL code, run SQL statements and scripts, manipulate and export data, and create and view reports. With SQL Developer, you can connect to any target Oracle Database schema using standard Oracle Database authentication. Once connected, you can perform operations on objects in the database. You can also connect to schemas for selected third-party (non-Oracle) databases, such as MySQL, Microsoft SQL Server, and Microsoft Access, view metadata and data in these databases, and migrate these databases to Oracle.

- SQL*Plus is an interactive and batch query tool that is installed with every Oracle Database server or client installation. It has a command-line user interface and a Web-based user interface called $SQL*Plus.

- Oracle JDeveloper is a multiple-platform integrated development environment supporting the complete lifecycle of development for Java, Web services, and SQL. It provides a graphical interface for executing and tuning SQL statements and a visual schema diagrammer (database modeler). It also supports editing, compiling, and debugging PL/SQL applications.

- Oracle Application Express is a hosted environment for developing and deploying database-related Web applications. SQL Workshop is a component of Oracle Application Express that lets you view and manage database objects from a Web
browser. SQL Workshop offers quick access to a SQL command processor and a SQL script repository.

**See Also:**  *SQL* Plus User’s Guide and Reference and Oracle Application Express Application Builder User’s Guide for more information on these products

The Oracle Call Interface and Oracle precompilers let you embed standard SQL statements within a procedure programming language.

- The Oracle Call Interface (OCI) lets you embed SQL statements in C programs.
- The Oracle precompilers, Pro*C/C++ and Pro*COBOL, interpret embedded SQL statements and translate them into statements that can be understood by C/C++ and COBOL compilers, respectively.

**See Also:** Oracle C++ Call Interface Programmer’s Guide, Pro*COBOL Programmer’s Guide, and Oracle Call Interface Programmer’s Guide for additional information on the embedded SQL statements allowed in each product

Most (but not all) Oracle tools also support all features of Oracle SQL. This reference describes the complete functionality of SQL. If the Oracle tool that you are using does not support this complete functionality, then you can find a discussion of the restrictions in the manual describing the tool, such as *SQL* Plus User’s Guide and Reference.
Basic Elements of Oracle SQL

This chapter contains reference information on the basic elements of Oracle SQL. These elements are the simplest building blocks of SQL statements. Therefore, before using the statements described in Chapter 10 through Chapter 19, you should familiarize yourself with the concepts covered in this chapter.

This chapter contains these sections:

- Data Types
- Data Type Comparison Rules
- Literals
- Format Models
- Nulls
- Comments
- Database Objects
- Database Object Names and Qualifiers
- Syntax for Schema Objects and Parts in SQL Statements

Data Types

Each value manipulated by Oracle Database has a data type. The data type of a value associates a fixed set of properties with the value. These properties cause Oracle to treat values of one data type differently from values of another. For example, you can add values of NUMBER data type, but not values of RAW data type.

When you create a table or cluster, you must specify a data type for each of its columns. When you create a procedure or stored function, you must specify a data type for each of its arguments. These data types define the domain of values that each column can contain or each argument can have. For example, DATE columns cannot accept the value February 29 (except for a leap year) or the values 2 or ‘SHOE’. Each value subsequently placed in a column assumes the data type of the column. For example, if you insert ‘01-JAN-98’ into a DATE column, then Oracle treats the ‘01-JAN-98’ character string as a DATE value after verifying that it translates to a valid date.

Oracle Database provides a number of built-in data types as well as several categories for user-defined types that can be used as data types. The syntax of Oracle data types appears in the diagrams that follow. The text of this section is divided into the following sections:

- Oracle Built-in Data Types
Data Types

- ANSI, DB2, and SQL/DS Data Types
- User-Defined Types
- Oracle-Supplied Types
- Data Type Comparison Rules
- Data Conversion

A data type is either scalar or nonscalar. A scalar type contains an atomic value, whereas a nonscalar (sometimes called a "collection") contains a set of values. A large object (LOB) is a special form of scalar data type representing a large scalar value of binary or character data. LOBs are subject to some restrictions that do not affect other scalar types because of their size. Those restrictions are documented in the context of the relevant SQL syntax.

**See Also:** "Restrictions on LOB Columns" on page 2-27

The Oracle precompilers recognize other data types in embedded SQL programs. These data types are called external data types and are associated with host variables. Do not confuse built-in data types and user-defined types with external data types. For information on external data types, including how Oracle converts between them and built-in data types or user-defined types, see Pro*C/++ Programmer’s Guide.

```
datatypes::=
```

The Oracle built-in data types appear in the figures that follow. For descriptions, refer to "Oracle Built-in Data Types" on page 2-6.

```
Oracle_builtin_datatypes::=
```

2-2  Oracle Database SQL Language Reference
character_datatypes ::= 

number_datatypes ::= 

long_and_raw_datatypes ::= 

datetime_datatypes ::=
The ANSI-supported data types appear in the figure that follows. "ANSI, DB2, and SQL/DS Data Types" on page 2-31 discusses the mapping of ANSI-supported data types to Oracle built-in data types.

For descriptions of user-defined types, refer to "User-Defined Types" on page 2-33.

The Oracle-supplied data types appear in the figures that follows. For descriptions, refer to "Oracle-Supplied Types" on page 2-34.
Oracle_supplied_types ::= 

any_types ::=

For descriptions of the media types, refer to "Media Types" on page 2-38.

Oracle Built-in Data Types

The table that follows summarizes Oracle built-in data types. Refer to the syntax in the preceding sections for the syntactic elements. The codes listed for the data types are used internally by Oracle Database. The data type code of a column or object attribute is returned by the DUMP function.

Table 2–1  Built-in Data Type Summary

<table>
<thead>
<tr>
<th>Code</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1    | VARCHAR2(size[BYTE | CHAR]) | Variable-length character string having maximum length size bytes or characters. You must specify size for VARCHAR2. Minimum size is 1 byte or 1 character. Maximum size is:  
- 32767 bytes or characters if MAX_STRING_SIZE = EXTENDED  
- 4000 bytes or characters if MAX_STRING_SIZE = STANDARD  
Refer to "Extended Data Types" on page 2-29 for more information on the MAX_STRING_SIZE initialization parameter. BYTE indicates that the column will have byte length semantics. CHAR indicates that the column will have character semantics. |
| 1    | NVARCHAR2(size) | Variable-length Unicode character string having maximum length size characters. You must specify size for NVARCHAR2. The number of bytes can be up to two times size for AL16UTF16 encoding and three times size for UTF8 encoding. Maximum size is determined by the national character set definition, with an upper limit of:  
- 32767 bytes if MAX_STRING_SIZE = EXTENDED  
- 4000 bytes if MAX_STRING_SIZE = STANDARD  
Refer to "Extended Data Types" on page 2-29 for more information on the MAX_STRING_SIZE initialization parameter. |
| 2    | NUMBER [(p [, s])] | Number having precision p and scale s. The precision p can range from 1 to 38. The scale s can range from -84 to 127. Both precision and scale are in decimal digits. A NUMBER value requires from 1 to 22 bytes. |
| 2    | FLOAT [(p)] | A subtype of the NUMBER data type having precision p. A FLOAT value is represented internally as NUMBER. The precision p can range from 1 to 126 binary digits. A FLOAT value requires from 1 to 22 bytes. |
| 8    | LONG | Character data of variable length up to 2 gigabytes, or 2³²⁻¹ bytes. Provided for backward compatibility. |
### Table 2–1  (Cont.) Built-in Data Type Summary

<table>
<thead>
<tr>
<th>Code</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>12</td>
<td>DATE</td>
<td>Valid date range from January 1, 4712 BC, to December 31, 9999 AD. The default format is determined explicitly by the NLS_DATE_FORMAT parameter or implicitly by the NLS_TERRITORY parameter. The size is fixed at 7 bytes. This data type contains the datetime fields YEAR, MONTH, DAY, HOUR, MINUTE, and SECOND. It does not have fractional seconds or a time zone.</td>
</tr>
<tr>
<td>100</td>
<td>BINARY_FLOAT</td>
<td>32-bit floating point number. This data type requires 4 bytes.</td>
</tr>
<tr>
<td>101</td>
<td>BINARY_DOUBLE</td>
<td>64-bit floating point number. This data type requires 8 bytes.</td>
</tr>
<tr>
<td>180</td>
<td>TIMESTAMP [(fractional_seconds_precision)]</td>
<td>Year, month, and day values of date, as well as hour, minute, and second values of time, where fractional_seconds_precision is the number of digits in the fractional part of the SECOND datetime field. Accepted values of fractional_seconds_precision are 0 to 9. The default is 6. The default format is determined explicitly by the NLS_TIMESTAMP_FORMAT parameter or implicitly by the NLS_TERRITORY parameter. The size is 7 or 11 bytes, depending on the precision. This data type contains the datetime fields YEAR, MONTH, DAY, HOUR, MINUTE, and SECOND. It contains fractional seconds but does not have a time zone.</td>
</tr>
<tr>
<td>181</td>
<td>TIMESTAMP [(fractional_seconds_precision)] WITH TIME ZONE</td>
<td>All values of TIMESTAMP as well as time zone displacement value, where fractional_seconds_precision is the number of digits in the fractional part of the SECOND datetime field. Accepted values of fractional_seconds_precision are 0 to 9. The default is 6. The default format is determined explicitly by the NLS_TIMESTAMP_FORMAT parameter or implicitly by the NLS_TERRITORY parameter. The size is fixed at 13 bytes. This data type contains the datetime fields YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, TIMEZONE_HOUR, and TIMEZONE_MINUTE. It has fractional seconds and an explicit time zone.</td>
</tr>
</tbody>
</table>
| 231  | TIMESTAMP [(fractional_seconds_precision)] WITH LOCAL TIME ZONE | All values of TIMESTAMP WITH TIME ZONE, with the following exceptions:  
- Data is normalized to the database time zone when it is stored in the database.  
- When the data is retrieved, users see the data in the session time zone.  

The default format is determined explicitly by the NLS_TIMESTAMP_FORMAT parameter or implicitly by the NLS_TERRITORY parameter. The size is 7 or 11 bytes, depending on the precision. |
| 182  | INTERVAL YEAR [(year_precision)] TO MONTH | Stores a period of time in years and months, where year_precision is the number of digits in the YEAR datetime field. Accepted values are 0 to 9. The default is 2. The size is fixed at 5 bytes. |
| 183  | INTERVAL DAY [(day_precision)] TO SECOND [(fractional_seconds_precision)] | Stores a period of time in days, hours, minutes, and seconds, where  
- day_precision is the maximum number of digits in the DAY datetime field. Accepted values are 0 to 9. The default is 2.  
- fractional_seconds_precision is the number of digits in the fractional part of the SECOND field. Accepted values are 0 to 9. The default is 6.  

The size is fixed at 11 bytes. |
The sections that follow describe the Oracle data types as they are stored in Oracle Database. For information on specifying these data types as literals, refer to "Literals" on page 2-48.

Character Data Types

Character data types store character (alphanumeric) data, which are words and free-form text, in the database character set or national character set. They are less restrictive than other data types and consequently have fewer properties. For example, character columns can store all alphanumeric values, but NUMBER columns can store only numeric values.

<table>
<thead>
<tr>
<th>Code</th>
<th>Data Type</th>
<th>Description</th>

</thead>
</table>
| 23   | RAW[size] | Raw binary data of length size bytes. You must specify size for a RAW value. Maximum size is:  
  - 32767 bytes if MAX_STRING_SIZE = EXTENDED  
  - 2000 bytes if MAX_STRING_SIZE = STANDARD  
  Refer to "Extended Data Types" on page 2-29 for more information on the MAX_STRING_SIZE initialization parameter. |
| 24   | LONG RAW | Raw binary data of variable length up to 2 gigabytes. |
| 69   | ROWID    | Base 64 string representing the unique address of a row in its table. This data type is primarily for values returned by the ROWID pseudocolumn. |
| 208  | UROWID[size] | Base 64 string representing the logical address of a row of an index-organized table. The optional size is the size of a column of type UROWID. The maximum size and default is 4000 bytes. |
| 96   | CHAR[size[BYTE | CHAR]] | Fixed-length character data of length size bytes or characters. Maximum size is 2000 bytes or characters. Default and minimum size is 1 byte. BYTE and CHAR have the same semantics as for VARCHAR2. |
| 96   | NCHAR[size] | Fixed-length character data of length size characters. The number of bytes can be up to two times size for AL16UTF16 encoding and three times size for UTF8 encoding. Maximum size is determined by the national character set definition, with an upper limit of 2000 bytes. Default and minimum size is 1 character. |
| 112  | CLOB     | A character large object containing single-byte or multibyte characters. Both fixed-width and variable-width character sets are supported, both using the database character set. Maximum size is (4 gigabytes - 1) * (database block size). |
| 112  | NCLOB    | A character large object containing Unicode characters. Both fixed-width and variable-width character sets are supported, both using the database national character set. Maximum size is (4 gigabytes - 1) * (database block size). Stores national character set data. |
| 113  | BLOB     | A binary large object. Maximum size is (4 gigabytes - 1) * (database block size). |
| 114  | BFILE    | Contains a locator to a large binary file stored outside the database. Enables byte stream I/O access to external LOBs residing on the database server. Maximum size is 4 gigabytes. |

Table 2-1 (Cont.) Built-in Data Type Summary
Character data is stored in strings with byte values corresponding to one of the character sets, such as 7-bit ASCII or EBCDIC, specified when the database was created. Oracle Database supports both single-byte and multibyte character sets.

These data types are used for character data:

- CHAR Data Type
- NCHAR Data Type
- VARCHAR2 Data Type
- NVARCHAR2 Data Type

For information on specifying character data types as literals, refer to "Text Literals" on page 2-48.

CHAR Data Type

The CHAR data type specifies a fixed-length character string in the database character set. You specify the database character set when you create your database.

When you create a table with a CHAR column, you specify the column length as \textit{size} optionally followed by a length qualifier. The qualifier \texttt{BYTE} denotes byte length semantics while the qualifier \texttt{CHAR} denotes character length semantics. In the byte length semantics, \textit{size} is the number of bytes to store in the column. In the character length semantics, \textit{size} is the number of code points in the database character set to store in the column. A code point may have from 1 to 4 bytes depending on the database character set and the particular character encoded by the code point. Oracle recommends that you specify one of the length qualifiers to explicitly document the desired length semantics of the column. If you do not specify a qualifier, the value of the \texttt{NLS_LENGTH_SEMANTICS} parameter of the session creating the column defines the length semantics, unless the table belongs to the schema \texttt{SYS}, in which case the default semantics is \texttt{BYTE}.

Oracle ensures that all values stored in a CHAR column have the length specified by \textit{size} in the selected length semantics. If you insert a value that is shorter than the column length, then Oracle blank-pads the value to column length. If you try to insert a value that is too long for the column, then Oracle returns an error. Note that if the column length is expressed in characters (code points), blank-padding does not guarantee that all column values have the same byte length.

You can omit \textit{size} from the column definition. The default value is 1.

The maximum value of \textit{size} is 2000, which means 2000 bytes or characters (code points), depending on the selected length semantics. However, independently, the absolute maximum length of any character value that can be stored into a CHAR column is 2000 bytes. For example, even if you define the column length to be 2000 characters, Oracle returns an error if you try to insert a 2000-character value in which one or more code points are wider than 1 byte. The value of \textit{size} in characters is a length constraint, not guaranteed capacity. If you want a CHAR column to be always able to store \textit{size} characters in any database character set, use a value of \textit{size} that is less than or equal to 500.

To ensure proper data conversion between databases and clients with different character sets, you must ensure that CHAR data consists of well-formed strings.

\textbf{See Also:} \textit{Oracle Database Globalization Support Guide} for more information on character set support and "Data Type Comparison Rules" on page 2-39 for information on comparison semantics.
NCHAR Data Type

The NCHAR data type specifies a fixed-length character string in the national character set. You specify the national character set as either AL16UTF16 or UTF8 when you create your database. AL16UTF16 and UTF8 are two encoding forms of the Unicode character set (UTF-16 and CESU-8, correspondingly) and hence NCHAR is a Unicode-only data type.

When you create a table with an NCHAR column, you specify the column length as size characters, or more precisely, code points in the national character set. One code point has always 2 bytes in AL16UTF16 and from 1 to 3 bytes in UTF8, depending on the particular character encoded by the code point.

Oracle ensures that all values stored in an NCHAR column have the length of size characters. If you insert a value that is shorter than the column length, then Oracle blank-pads the value to the column length. If you try to insert a value that is too long for the column, then Oracle returns an error. Note that if the national character set is UTF8, blank-padding does not guarantee that all column values have the same byte length.

You can omit size from the column definition. The default value is 1.

The maximum value of size is 1000 characters when the national character set is AL16UTF16, and 2000 characters when the national character set is UTF8. However, independently, the absolute maximum length of any character value that can be stored into an NCHAR column is 2000 bytes. For example, even if you define the column length to be 1000 characters, Oracle returns an error if you try to insert a 1000-character value but the national character set is UTF8 and all code points are 3 bytes wide. The value of size is a length constraint, not guaranteed capacity. If you want an NCHAR column to be always able to store size characters in both national character sets, use a value of size that is less than or equal to 666.

To ensure proper data conversion between databases and clients with different character sets, you must ensure that NCHAR data consists of well-formed strings.

If you assign a CHAR value to an NCHAR column, the value is implicitly converted from the database character set to the national character set. If you assign an NCHAR value to a CHAR column, the value is implicitly converted from the national character set to the database character set. If some of the characters from the NCHAR value cannot be represented in the database character set, then if the value of the session parameter NLS_NCHAR_CONV_EXCP is TRUE, then Oracle reports an error. If the value of the parameter is FALSE, non-representable characters are replaced with the default replacement character of the database character set, which is usually the question mark '?' or the inverted question mark '¿'.

See Also: Oracle Database Globalization Support Guide for information on Unicode data type support

VARCHAR2 Data Type

The VARCHAR2 data type specifies a variable-length character string in the database character set. You specify the database character set when you create your database.

When you create a table with a VARCHAR2 column, you must specify the column length as size optionally followed by a length qualifier. The qualifier BYTE denotes byte length semantics while the qualifier CHAR denotes character length semantics. In the byte length semantics, size is the maximum number of bytes that can be stored in the column. In the character length semantics, size is the maximum number of code points in the database character set that can be stored in the column. A code point may have from 1 to 4 bytes depending on the database character set and the particular
character encoded by the code point. Oracle recommends that you specify one of the length qualifiers to explicitly document the desired length semantics of the column. If you do not specify a qualifier, the value of the NLS_LENGTH_SEMANTICS parameter of the session creating the column defines the length semantics, unless the table belongs to the schema SYS, in which case the default semantics is BYTE.

Oracle stores a character value in a VARCHAR2 column exactly as you specify it, without any blank-padding, provided the value does not exceed the length of the column. If you try to insert a value that exceeds the specified length, then Oracle returns an error.

The minimum value of size is 1. The maximum value is:

- 32767 if MAX_STRING_SIZE = EXTENDED
- 4000 if MAX_STRING_SIZE = STANDARD

Refer to "Extended Data Types" on page 2-29 for more information on the MAX_STRING_SIZE initialization parameter and the internal storage mechanisms for extended data types.

While size may be expressed in bytes or characters (code points) the independent absolute maximum length of any character value that can be stored into a VARCHAR2 column is 32767 or 4000 bytes, depending on MAX_STRING_SIZE. For example, even if you define the column length to be 32767 characters, Oracle returns an error if you try to insert a 32767-character value in which one or more code points are wider than 1 byte. The value of size in characters is a length constraint, not guaranteed capacity. If you want a VARCHAR2 column to be always able to store size characters in any database character set, use a value of size that is less than or equal to 8191, if MAX_STRING_SIZE = EXTENDED, or 1000, if MAX_STRING_SIZE = STANDARD.

Oracle compares VARCHAR2 values using non-padded comparison semantics.

To ensure proper data conversion between databases with different character sets, you must ensure that VARCHAR2 data consists of well-formed strings. See Oracle Database Globalization Support Guide for more information on character set support.

See Also: "Data Type Comparison Rules" on page 2-39 for information on comparison semantics

VARCHAR Data Type

Do not use the VARCHAR data type. Use the VARCHAR2 data type instead. Although the VARCHAR data type is currently synonymous with VARCHAR2, the VARCHAR data type is scheduled to be redefined as a separate data type used for variable-length character strings compared with different comparison semantics.

NVARCHAR2 Data Type

The NVARCHAR2 data type specifies a variable-length character string in the national character set. You specify the national character set as either AL16UTF16 or UTF8 when you create your database. AL16UTF16 and UTF8 are two encoding forms of the Unicode character set (UTF-16 and CESU-8, correspondingly) and hence NVARCHAR2 is a Unicode-only data type.

When you create a table with an NVARCHAR2 column, you must specify the column length as size characters, or more precisely, code points in the national character set. One code point has always 2 bytes in AL16UTF16 and from 1 to 3 bytes in UTF8, depending on the particular character encoded by the code point.

Oracle stores a character value in an NVARCHAR2 column exactly as you specify it, without any blank-padding, provided the value does not exceed the length of the
column. If you try to insert a value that exceeds the specified length, then Oracle returns an error.

The minimum value of size is 1. The maximum value is:

- 16383 if MAX_STRING_SIZE = EXTENDED and the national character set is AL16UTF16
- 32767 if MAX_STRING_SIZE = EXTENDED and the national character set is UTF8
- 2000 if MAX_STRING_SIZE = STANDARD and the national character set is AL16UTF16
- 4000 if MAX_STRING_SIZE = STANDARD and the national character set is UTF8

Refer to "Extended Data Types" on page 2-29 for more information on the MAX_STRING_SIZE initialization parameter and the internal storage mechanisms for extended data types.

Independently of the maximum column length in characters, the absolute maximum length of any value that can be stored into an NVARCHAR2 column is 32767 or 4000 bytes, depending on MAX_STRING_SIZE. For example, even if you define the column length to be 16383 characters, Oracle returns an error if you try to insert a 16383-character value but the national character set is UTF8 and all code points are 3 bytes wide. The value of size is a length constraint, not guaranteed capacity. If you want an NVARCHAR2 column to be always able to store size characters in both national character sets, use a value of size that is less than or equal to 10922, if MAX_STRING_SIZE = EXTENDED, or 1333, if MAX_STRING_SIZE = STANDARD.

Oracle compares NVARCHAR2 values using non-padded comparison semantics.

To ensure proper data conversion between databases and clients with different character sets, you must ensure that NVARCHAR2 data consists of well-formed strings.

If you assign a VARCHAR2 value to an NVARCHAR2 column, the value is implicitly converted from the database character set to the national character set. If you assign an NVARCHAR2 value to a VARCHAR2 column, the value is implicitly converted from the national character set to the database character set. If some of the characters from the NVARCHAR2 value cannot be represented in the database character set, then if the value of the session parameter NLS_NCHAR_CONV_EXCP is TRUE, then Oracle reports an error. If the value of the parameter is FALSE, non-representable characters are replaced with the default replacement character of the database character set, which is usually the question mark '?' or the inverted question mark '¿'.

**See Also:** Oracle Database Globalization Support Guide for information on Unicode data type support and "Data Type Comparison Rules" on page 2-39 for information on comparison semantics

### Numeric Data Types

The Oracle Database numeric data types store positive and negative fixed and floating-point numbers, zero, infinity, and values that are the undefined result of an operation—"not a number" or NAN. For information on specifying numeric data types as literals, refer to "Numeric Literals" on page 2-50.

**NUMBER Data Type**

The NUMBER data type stores zero as well as positive and negative fixed numbers with absolute values from $1.0 \times 10^{-130}$ to but not including $1.0 \times 10^{126}$. If you specify an arithmetic expression whose value has an absolute value greater than or equal to $1.0 \times 10^{126}$, then Oracle returns an error. Each NUMBER value requires from 1 to 22 bytes.

Specify a fixed-point number using the following form:

```
NUMBER (p, s)
```
where:

- \( p \) is the precision, or the maximum number of significant decimal digits, where the most significant digit is the left-most nonzero digit, and the least significant digit is the right-most known digit. Oracle guarantees the portability of numbers with precision of up to 20 base-100 digits, which is equivalent to 39 or 40 decimal digits depending on the position of the decimal point.

- \( s \) is the scale, or the number of digits from the decimal point to the least significant digit. The scale can range from -84 to 127.
  - Positive scale is the number of significant digits to the right of the decimal point to and including the least significant digit.
  - Negative scale is the number of significant digits to the left of the decimal point, to but not including the least significant digit. For negative scale the least significant digit is on the left side of the decimal point, because the actual data is rounded to the specified number of places to the left of the decimal point. For example, a specification of (10,-2) means to round to hundreds.

Scale can be greater than precision, most commonly when e notation is used. When scale is greater than precision, the precision specifies the maximum number of significant digits to the right of the decimal point. For example, a column defined as `NUMBER (4,5)` requires a zero for the first digit after the decimal point and rounds all values past the fifth digit after the decimal point.

It is good practice to specify the scale and precision of a fixed-point number column for extra integrity checking on input. Specifying scale and precision does not force all values to a fixed length. If a value exceeds the precision, then Oracle returns an error. If a value exceeds the scale, then Oracle rounds it.

Specify an integer using the following form:

\[ \text{NUMBER}(p) \]

This represents a fixed-point number with precision \( p \) and scale 0 and is equivalent to `NUMBER(p, 0)`.

Specify a floating-point number using the following form:

\[ \text{NUMBER} \]

The absence of precision and scale designators specifies the maximum range and precision for an Oracle number.

**See Also:** "Floating-Point Numbers" on page 2-15

Table 2–2 show how Oracle stores data using different precisions and scales.

</tr>
</tbody>
</table>
FLOAT Data Type

The FLOAT data type is a subtype of NUMBER. It can be specified with or without precision, which has the same definition it has for NUMBER and can range from 1 to 126. Scale cannot be specified, but is interpreted from the data. Each FLOAT value requires from 1 to 22 bytes.

To convert from binary to decimal precision, multiply $n$ by 0.30103. To convert from decimal to binary precision, multiply the decimal precision by 3.32193. The maximum of 126 digits of binary precision is roughly equivalent to 38 digits of decimal precision.

The difference between NUMBER and FLOAT is best illustrated by example. In the following example the same values are inserted into NUMBER and FLOAT columns:

```
CREATE TABLE test (col1 NUMBER(5,2), col2 FLOAT(5));

INSERT INTO test VALUES (1.23, 1.23);
INSERT INTO test VALUES (7.89, 7.89);
INSERT INTO test VALUES (12.79, 12.79);
INSERT INTO test VALUES (123.45, 123.45);

SELECT * FROM test;
```

```
COL1  | COL2
----  | ----
1.23  | 1.2
7.89  | 7.9
12.79 | 13
123.45| 120
```

In this example, the FLOAT value returned cannot exceed 5 binary digits. The largest decimal number that can be represented by 5 binary digits is 31. The last row contains decimal values that exceed 31. Therefore, the FLOAT value must be truncated so that its significant digits do not require more than 5 binary digits. Thus 123.45 is rounded to 120, which has only two significant decimal digits, requiring only 4 binary digits.

Oracle Database uses the Oracle FLOAT data type internally when converting ANSI FLOAT data. Oracle FLOAT is available for you to use, but Oracle recommends that you use the BINARY_FLOAT and BINARY_DOUBLE data types instead, as they are more robust. Refer to "Floating-Point Numbers" on page 2-15 for more information.
Floating-Point Numbers

Floating-point numbers can have a decimal point anywhere from the first to the last digit or can have no decimal point at all. An exponent may optionally be used following the number to increase the range, for example, \(1.777 \times 10^{-20}\). A scale value is not applicable to floating-point numbers, because the number of digits that can appear after the decimal point is not restricted.

Binary floating-point numbers differ from \texttt{NUMBER} in the way the values are stored internally by Oracle Database. Values are stored using decimal precision for \texttt{NUMBER}. All literals that are within the range and precision supported by \texttt{NUMBER} are stored exactly as \texttt{NUMBER}. Literals are stored exactly because literals are expressed using decimal precision (the digits 0 through 9). Binary floating-point numbers are stored using binary precision (the digits 0 and 1). Such a storage scheme cannot represent all values using decimal precision exactly. Frequently, the error that occurs when converting a value from decimal to binary precision is undone when the value is converted back from binary to decimal precision. The literal 0.1 is such an example.

Oracle Database provides two numeric data types exclusively for floating-point numbers:

- \texttt{BINARY\_FLOAT} \texttt{BINARY\_FLOAT} is a 32-bit, single-precision floating-point number data type. Each \texttt{BINARY\_FLOAT} value requires 4 bytes.
- \texttt{BINARY\_DOUBLE} \texttt{BINARY\_DOUBLE} is a 64-bit, double-precision floating-point number data type. Each \texttt{BINARY\_DOUBLE} value requires 8 bytes.

In a \texttt{NUMBER} column, floating point numbers have decimal precision. In a \texttt{BINARY\_FLOAT} or \texttt{BINARY\_DOUBLE} column, floating-point numbers have binary precision. The binary floating-point numbers support the special values infinity and \texttt{NaN} (not a number).

You can specify floating-point numbers within the limits listed in Table 2-3 on page 2-15. The format for specifying floating-point numbers is defined in “Numeric Literals” on page 2-50.

Table 2–3  Floating Point Number Limits

IEEE754 Conformance  The Oracle implementation of floating-point data types conforms substantially with the Institute of Electrical and Electronics Engineers (IEEE) Standard for Binary Floating-Point Arithmetic, IEEE Standard 754-1985 (IEEE754). The floating-point data types conform to IEEE754 in the following areas:

- The SQL function \texttt{SQRT} implements square root. See \texttt{SQRT} on page 7-303.
- The SQL function \texttt{REMAINDER} implements remainder. See \texttt{REMAINDER} on page 7-284.
- Arithmetic operators conform. See "Arithmetic Operators" on page 4-3.
- Comparison operators conform, except for comparisons with \texttt{NaN}. Oracle orders \texttt{NaN} greatest with respect to all other values, and evaluates \texttt{NaN} equal to \texttt{NaN}. See "Floating-Point Conditions" on page 6-7.
- Conversion operators conform. See "Conversion Functions" on page 7-6.
- The default rounding mode is supported.
The default exception handling mode is supported.

The special values \( \text{INF}, -\text{INF}, \) and \( \text{NaN} \) are supported. See "Floating-Point Conditions" on page 6-7.

Rounding of \( \text{BINARY\_FLOAT} \) and \( \text{BINARY\_DOUBLE} \) values to integer-valued \( \text{BINARY\_FLOAT} \) and \( \text{BINARY\_DOUBLE} \) values is provided by the SQL functions \( \text{ROUND}, \text{TRUNC}, \text{CEIL}, \) and \( \text{FLOOR} \).

Rounding of \( \text{BINARY\_FLOAT}/\text{BINARY\_DOUBLE} \) to decimal and decimal to \( \text{BINARY\_FLOAT}/\text{BINARY\_DOUBLE} \) is provided by the SQL functions \( \text{TO\_CHAR}, \text{TO\_NUMBER}, \text{TO\_NCHAR}, \text{TO\_BINARY\_FLOAT}, \text{TO\_BINARY\_DOUBLE}, \) and \( \text{CAST} \).

The floating-point data types do not conform to IEEE754 in the following areas:

- \( -0 \) is coerced to \( +0 \).
- Comparison with \( \text{NaN} \) is not supported.
- All \( \text{NaN} \) values are coerced to either \( \text{BINARY\_FLOAT\_NAN} \) or \( \text{BINARY\_DOUBLE\_NAN} \).
- Non-default rounding modes are not supported.
- Non-default exception handling mode are not supported.

**Numeric Precedence**

**Numerical precedence** determines, for operations that support numeric data types, the data type Oracle uses if the arguments to the operation have different data types. \( \text{BINARY\_DOUBLE} \) has the highest numeric precedence, followed by \( \text{BINARY\_FLOAT} \), and finally by \( \text{NUMBER} \). Therefore, in any operation on multiple numeric values:

- If any of the operands is \( \text{BINARY\_DOUBLE} \), then Oracle attempts to convert all the operands implicitly to \( \text{BINARY\_DOUBLE} \) before performing the operation.
- If none of the operands is \( \text{BINARY\_DOUBLE} \) but any of the operands is \( \text{BINARY\_FLOAT} \), then Oracle attempts to convert all the operands implicitly to \( \text{BINARY\_FLOAT} \) before performing the operation.
- Otherwise, Oracle attempts to convert all the operands to \( \text{NUMBER} \) before performing the operation.

If any implicit conversion is needed and fails, then the operation fails. Refer to Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion.

In the context of other data types, numeric data types have lower precedence than the datetime/interval data types and higher precedence than character and all other data types.

**LONG Data Type**

Do not create tables with \( \text{LONG} \) columns. Use LOB columns (\( \text{CLOB}, \text{NCLOB}, \text{BLOB} \)) instead. \( \text{LONG} \) columns are supported only for backward compatibility.

\( \text{LONG} \) columns store variable-length character strings containing up to 2 gigabytes -1, or \( 2^{31} - 1 \) bytes. \( \text{LONG} \) columns have many of the characteristics of \( \text{VARCHAR2} \) columns. You can use \( \text{LONG} \) columns to store long text strings. The length of \( \text{LONG} \) values may be limited by the memory available on your computer. \( \text{LONG} \) literals are formed as described for "Text Literals" on page 2-48.

Oracle also recommends that you convert existing \( \text{LONG} \) columns to LOB columns. LOB columns are subject to far fewer restrictions than \( \text{LONG} \) columns. Further, LOB functionality is enhanced in every release, whereas \( \text{LONG} \) functionality has been static.
for several releases. See the `modify_col_properties` clause of `ALTER TABLE` on page 12-2 and `TO_LOB` on page 7-369 for more information on converting `LONG` columns to LOB.

You can reference `LONG` columns in SQL statements in these places:

- **SELECT lists**
- **SET clauses of UPDATE statements**
- **VALUES clauses of INSERT statements**

The use of `LONG` values is subject to these restrictions:

- A table can contain only one `LONG` column.
- You cannot create an object type with a `LONG` attribute.
- `LONG` columns cannot appear in `WHERE` clauses or in integrity constraints (except that they can appear in `NULL` and `NOT NULL` constraints).
- `LONG` columns cannot be indexed.
- `LONG` data cannot be specified in regular expressions.
- A stored function cannot return a `LONG` value.
- You can declare a variable or argument of a PL/SQL program unit using the `LONG` data type. However, you cannot then call the program unit from SQL.
- Within a single SQL statement, all `LONG` columns, updated tables, and locked tables must be located on the same database.
- `LONG` and `LONG RAW` columns cannot be used in distributed SQL statements and cannot be replicated.
- If a table has both `LONG` and LOB columns, then you cannot bind more than 4000 bytes of data to both the `LONG` and LOB columns in the same SQL statement. However, you can bind more than 4000 bytes of data to either the `LONG` or the LOB column.

In addition, `LONG` columns cannot appear in these parts of SQL statements:

- **GROUP BY clauses, ORDER BY clauses, or CONNECT BY clauses or with the DISTINCT operator in SELECT statements**
- The **UNIQUE operator of a SELECT statement**
- The column list of a **CREATE CLUSTER statement**
- The **CLUSTER clause of a CREATE MATERIALIZED VIEW statement**
- **SQL built-in functions, expressions, or conditions**
- **SELECT lists of queries containing GROUP BY clauses**
- **SELECT lists of subqueries or queries combined by the UNION, INTERSECT, or MINUS set operators**
- **SELECT lists of CREATE TABLE ... AS SELECT statements**
- **ALTER TABLE ... MOVE statements**
- **SELECT lists in subqueries in INSERT statements**

Triggers can use the `LONG` data type in the following manner:

- A SQL statement within a trigger can insert data into a `LONG` column.
If data from a `LONG` column can be converted to a constrained data type (such as `CHAR` and `VARCHAR2`), then a `LONG` column can be referenced in a SQL statement within a trigger.

Variables in triggers cannot be declared using the `LONG` data type.

`:NEW` and `:OLD` cannot be used with `LONG` columns.

You can use Oracle Call Interface functions to retrieve a portion of a `LONG` value from the database.

**See Also:** *Oracle Call Interface Programmer’s Guide*

### Datetime and Interval Data Types

The datetime data types are `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, and `TIMESTAMP WITH LOCAL TIME ZONE`. Values of datetime data types are sometimes called datetimes. The interval data types are `INTERVAL YEAR TO MONTH` and `INTERVAL DAY TO SECOND`. Values of interval data types are sometimes called intervals. For information on expressing datetime and interval values as literals, refer to “Datetime Literals” on page 2-53 and “Interval Literals” on page 2-56.

Both datetimes and intervals are made up of fields. The values of these fields determine the value of the data type. Table 2–4 lists the datetime fields and their possible values for datetimes and intervals.

To avoid unexpected results in your DML operations on datetime data, you can verify the database and session time zones by querying the built-in SQL functions `DBTIMEZONE` and `SESSIONTIMEZONE`. If the time zones have not been set manually, then Oracle Database uses the operating system time zone by default. If the operating system time zone is not a valid Oracle time zone, then Oracle uses UTC as the default value.

**Table 2–4  Datetime Fields and Values**

<table>
<thead>
<tr>
<th>Datetime Field</th>
<th>Valid Values for Datetime</th>
<th>Valid Values for INTERVAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>YEAR</td>
<td>-4712 to 9999 (excluding year 0)</td>
<td>Any positive or negative integer</td>
</tr>
<tr>
<td>MONTH</td>
<td>01 to 12</td>
<td>0 to 11</td>
</tr>
<tr>
<td>DAY</td>
<td>01 to 31 (limited by the values of MONTH and YEAR, according to the rules of the current NLS calendar parameter)</td>
<td>Any positive or negative integer</td>
</tr>
<tr>
<td>HOUR</td>
<td>00 to 23</td>
<td>0 to 23</td>
</tr>
<tr>
<td>MINUTE</td>
<td>00 to 59</td>
<td>0 to 59</td>
</tr>
<tr>
<td>SECOND</td>
<td>00 to 59.9(n), where 9(n) is the precision of time fractional seconds. The 9(n) portion is not applicable for DATE.</td>
<td>0 to 59.9(n), where 9(n) is the precision of interval fractional seconds</td>
</tr>
<tr>
<td>TIMEZONE_HOUR</td>
<td>-12 to 14 (This range accommodates daylight saving time changes.) Not applicable for DATE or TIMESTAMP.</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>
The DATE data type stores date and time information. Although date and time information can be represented in both character and number data types, the DATE data type has special associated properties. For each DATE value, Oracle stores the following information: year, month, day, hour, minute, and second. You can specify a DATE value as a literal, or you can convert a character or numeric value to a date value with the TO_DATE function. For examples of expressing DATE values in both these ways, refer to "Datetime Literals" on page 2-53.

Using Julian Days: A Julian day number is the number of days since January 1, 4712 BC. Julian days allow continuous dating from a common reference. You can use the date format model "J" with date functions TO_DATE and TO_CHAR to convert between Oracle DATE values and their Julian equivalents.

The default date values are determined as follows:
- The year is the current year, as returned by SYSDATE.
- The month is the current month, as returned by SYSDATE.
- The day is 01 (the first day of the month).
- The hour, minute, and second are all 0.

### Table 2–4 (Cont.) Datetime Fields and Values

<table>
<thead>
<tr>
<th>Datetime Field</th>
<th>Valid Values for Datetime</th>
<th>Valid Values for INTERVAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIMEZONE_MINUTE</td>
<td>00 to 59. Not applicable for DATE or TIMESTAMP.</td>
<td>Not applicable</td>
</tr>
<tr>
<td></td>
<td>(See note at end of table)</td>
<td></td>
</tr>
<tr>
<td>TIMEZONE_REGION</td>
<td>Query the TZNAME column of the V$TIMEZONE_NAMES data dictionary view. Not applicable for DATE or TIMESTAMP. For a complete listing of all time zone region names, refer to Oracle Database Globalization Support Guide.</td>
<td>Not applicable</td>
</tr>
<tr>
<td>TIMEZONE_ABBR</td>
<td>Query the TZABBREV column of the V$TIMEZONE_NAMES data dictionary view. Not applicable for DATE or TIMESTAMP.</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

**Note:** TIMEZONE_HOUR and TIMEZONE_MINUTE are specified together and interpreted as an entity in the format +1 - hh:mi, with values ranging from -12:59 to +14:00. Refer to Oracle Data Provider for .NET Developer’s Guide for Microsoft Windows for information on specifying time zone values for that API.

**DATE Data Type**

The DATE data type stores date and time information. Although date and time information can be represented in both character and number data types, the DATE data type has special associated properties. For each DATE value, Oracle stores the following information: year, month, day, hour, minute, and second.

You can specify a DATE value as a literal, or you can convert a character or numeric value to a date value with the TO_DATE function. For examples of expressing DATE values in both these ways, refer to "Datetime Literals" on page 2-53.

**Using Julian Days** A Julian day number is the number of days since January 1, 4712 BC. Julian days allow continuous dating from a common reference. You can use the date format model "J" with date functions TO_DATE and TO_CHAR to convert between Oracle DATE values and their Julian equivalents.

**Note:** Oracle Database uses the astronomical system of calculating Julian days, in which the year 4713 BC is specified as -4712. The historical system of calculating Julian days, in contrast, specifies 4713 BC as -4713. If you are comparing Oracle Julian days with values calculated using the historical system, then take care to allow for the 365-day difference in BC dates. For more information, see http://aa.usno.navy.mil/faq/docs/millennium.php.
These default values are used in a query that requests date values where the date itself is not specified, as in the following example, which is issued in the month of May:

```sql
SELECT TO_DATE('2009', 'YYYY')
FROM DUAL;

TO_DATE('01-MAY-09')
```

**Example**  This statement returns the Julian equivalent of January 1, 2009:

```sql
SELECT TO_CHAR(TO_DATE('01-01-2009', 'MM-DD-YYYY'),'J')
FROM DUAL;

TO_CHAR
---------
2454833
```

**See Also:** "Selecting from the DUAL Table" for a description of the DUAL table

### TIMESTAMP Data Type

The TIMESTAMP data type is an extension of the DATE data type. It stores the year, month, and day of the DATE data type, plus hour, minute, and second values. This data type is useful for storing precise time values and for collecting and evaluating date information across geographic regions. Specify the TIMESTAMP data type as follows:

```sql
TIMESTAMP [(fractional_seconds_precision)]
```

where `fractional_seconds_precision` optionally specifies the number of digits Oracle stores in the fractional part of the SECOND datetime field. When you create a column of this data type, the value can be a number in the range 0 to 9. The default is 6.

**See Also:** TO_TIMESTAMP on page 7-377 for information on converting character data to TIMESTAMP data

### TIMESTAMP WITH TIME ZONE Data Type

TIMESTAMP WITH TIME ZONE is a variant of TIMESTAMP that includes a time zone region name or a time zone offset in its value. The time zone offset is the difference (in hours and minutes) between local time and UTC (Coordinated Universal Time—formerly Greenwich Mean Time). This data type is useful for preserving local time zone information.

Specify the TIMESTAMP WITH TIME ZONE data type as follows:

```sql
TIMESTAMP [(fractional_seconds_precision)] WITH TIME ZONE
```

where `fractional_seconds_precision` optionally specifies the number of digits Oracle stores in the fractional part of the SECOND datetime field. When you create a column of this data type, the value can be a number in the range 0 to 9. The default is 6.

Oracle time zone data is derived from the public domain information available at http://www.iana.org/time-zones/. Oracle time zone data may not reflect the most recent data available at this site.
TIMESTAMP WITH LOCAL TIME ZONE Data Type

TIMESTAMP WITH LOCAL TIME ZONE is another variant of TIMESTAMP that is sensitive to time zone information. It differs from TIMESTAMP WITH TIME ZONE in that data stored in the database is normalized to the database time zone, and the time zone information is not stored as part of the column data. When a user retrieves the data, Oracle returns it in the user's local session time zone. This data type is useful for date information that is always to be displayed in the time zone of the client system in a two-tier application.

Specify the TIMESTAMP WITH LOCAL TIME ZONE data type as follows:

```
TIMESTAMP [(fractional_seconds_precision)] WITH LOCAL TIME ZONE
```

where `fractional_seconds_precision` optionally specifies the number of digits Oracle stores in the fractional part of the SECOND datetime field. When you create a column of this data type, the value can be a number in the range 0 to 9. The default is 6.

Oracle time zone data is derived from the public domain information available at http://www.iana.org/time-zones/. Oracle time zone data may not reflect the most recent data available at this site.

- TO_TIMESTAMP_TZ on page 7-378 for information on converting character data to TIMESTAMP WITH TIME ZONE data
- ALTER SESSION on page 11-65 for information on the ERROR_ON_ OVERLAP_TIME session parameter

INTERVAL YEAR TO MONTH Data Type

INTERVAL YEAR TO MONTH stores a period of time using the YEAR and MONTH datetime fields. This data type is useful for representing the difference between two datetime values when only the year and month values are significant.

Specify INTERVAL YEAR TO MONTH as follows:

```
INTERVAL YEAR [(year_precision)] TO MONTH
```

where `year_precision` is the number of digits in the YEAR datetime field. The default value of `year_precision` is 2.

You have a great deal of flexibility when specifying interval values as literals. Refer to "Interval Literals" on page 2-56 for detailed information on specifying interval values as literals. Also see "Datetime and Interval Examples" on page 2-25 for an example.
using intervals.

**INTERVAL DAY TO SECOND Data Type**

INTERVAL DAY TO SECOND stores a period of time in terms of days, hours, minutes, and seconds. This data type is useful for representing the precise difference between two datetime values.

Specify this data type as follows:

```
INTERVAL DAY [(day_precision)]
TO SECOND [(fractional_seconds_precision)]
```

where

- `day_precision` is the number of digits in the DAY datetime field. Accepted values are 0 to 9. The default is 2.
- `fractional_seconds_precision` is the number of digits in the fractional part of the SECOND datetime field. Accepted values are 0 to 9. The default is 6.

You have a great deal of flexibility when specifying interval values as literals. Refer to "Interval Literals" on page 2-56 for detailed information on specify interval values as literals. Also see "Datetime and Interval Examples" on page 2-25 for an example using intervals.

**Datetime/Interval Arithmetic**

You can perform a number of arithmetic operations on date (DATE), timestamp (TIMESTAMP, TIMESTAMP WITH TIME ZONE, and TIMESTAMP WITH LOCAL TIME ZONE), and interval (INTERVAL DAY TO SECOND and INTERVAL YEAR TO MONTH) data. Oracle calculates the results based on the following rules:

- You can use NUMBER constants in arithmetic operations on date and timestamp values, but not interval values. Oracle internally converts timestamp values to date values and interprets NUMBER constants in arithmetic datetime and interval expressions as numbers of days. For example, `SYSDATE + 1` is tomorrow. `SYSDATE - 7` is one week ago. `SYSDATE + (10/1440)` is ten minutes from now. Subtracting the `hire_date` column of the sample table `employees` from `SYSDATE` returns the number of days since each employee was hired. You cannot multiply or divide date or timestamp values.

- Oracle implicitly converts BINARY_FLOAT and BINARY_DOUBLE operands to NUMBER.

- Each DATE value contains a time component, and the result of many date operations include a fraction. This fraction means a portion of one day. For example, 1.5 days is 36 hours. These fractions are also returned by Oracle built-in functions for common operations on DATE data. For example, the `MONTHS_BETWEEN` function returns the number of months between two dates. The fractional portion of the result represents that portion of a 31-day month.

- If one operand is a DATE value or a numeric value, neither of which contains time zone or fractional seconds components, then:
  - Oracle implicitly converts the other operand to DATE data. The exception is multiplication of a numeric value times an interval, which returns an interval.
  - If the other operand has a time zone value, then Oracle uses the session time zone in the returned value.
  - If the other operand has a fractional seconds value, then the fractional seconds value is lost.
When you pass a timestamp, interval, or numeric value to a built-in function that was designed only for the DATE data type, Oracle implicitly converts the non-DATA value to a DATE value. Refer to "Datetime Functions" on page 7-5 for information on which functions cause implicit conversion to DATE.

When interval calculations return a datetime value, the result must be an actual datetime value or the database returns an error. For example, the next two statements return errors:

```
SELECT TO_DATE('31-AUG-2004', 'DD-MON-YYYY') + TO_YMINTERVAL('0-1')
FROM DUAL;

SELECT TO_DATE('29-FEB-2004', 'DD-MON-YYYY') + TO_YMINTERVAL('1-0')
FROM DUAL;
```

The first fails because adding one month to a 31-day month would result in September 31, which is not a valid date. The second fails because adding one year to a date that exists only every four years is not valid. However, the next statement succeeds, because adding four years to a February 29 date is valid:

```
SELECT TO_DATE('29-FEB-2004', 'DD-MON-YYYY') + TO_YMINTERVAL('4-0')
FROM DUAL;
```

Oracle performs all timestamp arithmetic in UTC time. For TIMESTAMP WITH LOCAL TIME ZONE, Oracle converts the datetime value from the database time zone to UTC and converts back to the database time zone after performing the arithmetic. For TIMESTAMP WITH TIME ZONE, the datetime value is always in UTC, so no conversion is necessary.

Table 2–5 is a matrix of datetime arithmetic operations. Dashes represent operations that are not supported.

29-FEB-08
Data Types

### Examples

You can add an interval value expression to a start time. Consider the sample table `oe.orders` with a column `order_date`. The following statement adds 30 days to the value of the `order_date` column:

```sql
SELECT order_id, order_date + INTERVAL '30' DAY AS "Due Date"
FROM orders
ORDER BY order_id, "Due Date";
```

### Support for Daylight Saving Times

Oracle Database automatically determines, for any given time zone region, whether daylight saving is in effect and returns local time values accordingly. The datetime value is sufficient for Oracle to determine whether daylight saving time is in effect for a given region in all cases except boundary cases. A boundary case occurs during the period when daylight saving goes into or comes out of effect. For example, in the US-Pacific region, when daylight saving goes into effect, the time changes from 2:00 a.m. to 3:00 a.m. The one hour interval between 2 and 3 a.m. does not exist. When daylight saving goes out of effect, the time changes from 2:00 a.m. back to 1:00 a.m., and the one-hour interval between 1 and 2 a.m. is repeated.

To resolve these boundary cases, Oracle uses the TZR and TZD format elements, as described in Table 2–17. TZR represents the time zone region name in datetime input strings. Examples are 'Australia/North', 'UTC', and 'Singapore'. TZD represents an abbreviated form of the time zone region name with daylight saving information. Examples are 'PST' for US/Pacific standard time and 'PDT' for US/Pacific daylight time. To see a listing of valid values for the TZR and TZD format elements, query the TZNAME and TZABBREV columns of the V$TIMEZONE_NAMES dynamic performance view.

### Note

Time zone region names are needed by the daylight saving feature. These names are stored in two types of time zone files: one large and one small. One of these files is the default file, depending on your environment and the release of Oracle Database you are using. For more information regarding time zone files and names, see Oracle Database Globalization Support Guide.

For a complete listing of the time zone region names in both files, refer to Oracle Database Globalization Support Guide.

Oracle time zone data is derived from the public domain information available at http://www.iana.org/time-zones/. Oracle time zone data may not reflect the most recent data available at this site.
See Also:

- "Datetime Format Models" on page 2-63 for information on the format elements and the session parameter `ERROR_ON_OVERLAP_TIME` on page 11-72.
- Oracle Database Globalization Support Guide for more information on Oracle time zone data

Datetime and Interval Examples

The following example shows how to specify some datetime and interval data types.

```sql
CREATE TABLE time_table
(
    start_time    TIMESTAMP,
    duration_1    INTERVAL DAY (6) TO SECOND (5),
    duration_2    INTERVAL YEAR TO MONTH);
```

The `start_time` column is of type `TIMESTAMP`. The implicit fractional seconds precision of `TIMESTAMP` is 6.

The `duration_1` column is of type `INTERVAL DAY TO SECOND`. The maximum number of digits in field `DAY` is 6 and the maximum number of digits in the fractional second is 5. The maximum number of digits in all other datetime fields is 2.

The `duration_2` column is of type `INTERVAL YEAR TO MONTH`. The maximum number of digits of the value in each field (`YEAR` and `MONTH`) is 2.

Interval data types do not have format models. Therefore, to adjust their presentation, you must combine character functions such as `EXTRACT` and concatenate the components. For example, the following examples query the `hr.employees` and `oe.orders` tables, respectively, and change interval output from the form "yy-mm" to "yy years mm months" and from "dd-hh" to "dddd days hh hours":

```sql
SELECT last_name, EXTRACT(YEAR FROM (SYSDATE - hire_date) YEAR TO MONTH) || ' years ' || EXTRACT(MONTH FROM (SYSDATE - hire_date) YEAR TO MONTH) || ' months' "Interval"
FROM employees;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>Interval</th>
</tr>
</thead>
<tbody>
<tr>
<td>OConnell</td>
<td>2 years 3 months</td>
</tr>
<tr>
<td>Grant</td>
<td>1 years 9 months</td>
</tr>
<tr>
<td>Whalen</td>
<td>6 years 1 months</td>
</tr>
<tr>
<td>Hartstein</td>
<td>5 years 8 months</td>
</tr>
<tr>
<td>Fay</td>
<td>4 years 2 months</td>
</tr>
<tr>
<td>Mavris</td>
<td>7 years 4 months</td>
</tr>
<tr>
<td>Baer</td>
<td>7 years 4 months</td>
</tr>
<tr>
<td>Higgins</td>
<td>7 years 4 months</td>
</tr>
<tr>
<td>Gietz</td>
<td>7 years 4 months</td>
</tr>
<tr>
<td>. . .</td>
<td></td>
</tr>
</tbody>
</table>

```sql
SELECT order_id, EXTRACT(DAY FROM (SYSDATE - order_date) DAY TO SECOND) || ' days ' || EXTRACT(HOUR FROM (SYSDATE - order_date) DAY TO SECOND) || ' hours' 'Interval"
FROM orders;
```
ORDER_ID Interval
---------- --------------------
2458  780 days 23 hours
2397  685 days 22 hours
2454  733 days 21 hours
2354  447 days 20 hours
2358  635 days 20 hours
2381  508 days 18 hours
2440  765 days 17 hours
2357 1365 days 16 hours
2394  602 days 15 hours
2435  763 days 15 hours

**RAW and LONG RAW Data Types**

The **RAW** and **LONG RAW** data types store data that is not to be explicitly converted by Oracle Database when moving data between different systems. These data types are intended for binary data or byte strings. For example, you can use **LONG RAW** to store graphics, sound, documents, or arrays of binary data, for which the interpretation is dependent on the use.

Oracle strongly recommends that you convert **LONG RAW** columns to binary LOB (**BLOB**) columns. LOB columns are subject to far fewer restrictions than **LONG columns**. See **TO_LOB** on page 7-369 for more information.

**RAW** is a variable-length data type like **VARCHAR2**, except that Oracle Net (which connects client software to a database or one database to another) and the Oracle import and export utilities do not perform character conversion when transmitting **RAW** or **LONG RAW** data. In contrast, Oracle Net and the Oracle import and export utilities automatically convert **CHAR**, **VARCHAR2**, and **LONG** data between different database character sets, if data is transported between databases, or between the database character set and the client character set, if data is transported between a database and a client. The client character set is determined by the type of the client interface, such as OCI or JDBC, and the client configuration (for example, the **NLS_LANG** environment variable).

When Oracle implicitly converts **RAW** or **LONG RAW** data to character data, the resulting character value contains a hexadecimal representation of the binary input, where each character is a hexadecimal digit (0-9, A-F) representing four consecutive bits of **RAW** data. For example, one byte of **RAW** data with bits 11001011 becomes the value CB.

When Oracle implicitly converts character data to **RAW** or **LONG RAW**, it interprets each consecutive input character as a hexadecimal representation of four consecutive bits of binary data and builds the resulting **RAW** or **LONG RAW** value by concatenating those bits. If any of the input characters is not a hexadecimal digit (0-9, A-F, a-f), then an error is reported. If the number of characters is odd, then the result is undefined.

The SQL functions **RAWTOHEX** and **HEXTORAW** perform explicit conversions that are equivalent to the above implicit conversions. Other types of conversions between **RAW** and character data are possible with functions in the Oracle-supplied PL/SQL packages **UTL_RAW** and **UTL_I18N**.

**Large Object (LOB) Data Types**

The built-in LOB data types **BLOB**, **CLOB**, and **NCLOB** (stored internally) and **BFILE** (stored externally) can store large and unstructured data such as text, image, video, and spatial data. The size of **BLOB**, **CLOB**, and **NCLOB** data can be up to \((2^{32} - 1)\) bytes * (the value of the **CHUNK** parameter of LOB storage). If the tablespaces in your database are of standard block size, and if you have used the default value of the **CHUNK** parameter...
of LOB storage when creating a LOB column, then this is equivalent to \((2^{32}-1 \text{ bytes}) \times \text{(database block size)}\). BFILE data can be up to \(2^{64}-1\) bytes, although your operating system may impose restrictions on this maximum.

When creating a table, you can optionally specify different tablespace and storage characteristics for LOB columns or LOB object attributes from those specified for the table.

CLOB, NCLOB, and BLOB values up to approximately 4000 bytes are stored inline if you enable storage in row at the time the LOB column is created. LOBs greater than 4000 bytes are always stored externally. Refer to ENABLE STORAGE IN ROW on page 16-58 for more information.

LOB columns contain LOB locators that can refer to internal (in the database) or external (outside the database) LOB values. Selecting a LOB from a table actually returns the LOB locator and not the entire LOB value. The DBMS_LOB package and Oracle Call Interface (OCI) operations on LOBs are performed through these locators.

LOBs are similar to LONG and LONG RAW types, but differ in the following ways:

- LOBs can be attributes of an object type (user-defined data type).
- The LOB locator is stored in the table column, either with or without the actual LOB value. BLOB, NCLOB, and CLOB values can be stored in separate tablespaces. BFILE data is stored in an external file on the server.
- When you access a LOB column, the locator is returned.
- A LOB can be up to \((2^{32}-1 \text{ bytes}) \times \text{(database block size)}\) in size. BFILE data can be up to \(2^{64}-1\) bytes, although your operating system may impose restrictions on this maximum.
- LOBs permit efficient, random, piece-wise access to and manipulation of data.
- You can define more than one LOB column in a table.
- With the exception of NCLOB, you can define one or more LOB attributes in an object.
- You can declare LOB bind variables.
- You can select LOB columns and LOB attributes.
- You can insert a new row or update an existing row that contains one or more LOB columns or an object with one or more LOB attributes. In update operations, you can set the internal LOB value to NULL, empty, or replace the entire LOB with data. You can set the BFILE to NULL or make it point to a different file.
- You can update a LOB row-column intersection or a LOB attribute with another LOB row-column intersection or LOB attribute.
- You can delete a row containing a LOB column or LOB attribute and thereby also delete the LOB value. For BFILEs, the actual operating system file is not deleted.

You can access and populate rows of an inline LOB column (a LOB column stored in the database) or a LOB attribute (an attribute of an object type column stored in the database) simply by issuing an INSERT or UPDATE statement.

**Restrictions on LOB Columns**  LOB columns are subject to a number of rules and restrictions. See Oracle Database SecureFiles and Large Objects Developer’s Guide for a complete listing.
BFILE Data Type

The BFILE data type enables access to binary file LOBs that are stored in file systems outside Oracle Database. A BFILE column or attribute stores a BFILE locator, which serves as a pointer to a binary file on the server file system. The locator maintains the directory name and the filename.

You can change the filename and path of a BFILE without affecting the base table by using the BFILENAME function. Refer to BFILENAME on page 7-31 for more information on this built-in SQL function.

Binary file LOBs do not participate in transactions and are not recoverable. Rather, the underlying operating system provides file integrity and durability. BFILE data can be up to \(2^{64}-1\) bytes, although your operating system may impose restrictions on this maximum.

The database administrator must ensure that the external file exists and that Oracle processes have operating system read permissions on the file.

The BFILE data type enables read-only support of large binary files. You cannot modify or replicate such a file. Oracle provides APIs to access file data. The primary interfaces that you use to access file data are the DBMS_LOB package and Oracle Call Interface (OCI).

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide and Oracle Call Interface Programmer’s Guide for more information about LOBs and CREATE DIRECTORY on page 14-54

BLOB Data Type

The BLOB data type stores unstructured binary large objects. BLOB objects can be thought of as bitstreams with no character set semantics. BLOB objects can store binary data up to \((4 \text{ gigabytes } -1)\) * (the value of the CHUNK parameter of LOB storage). If the tablespaces in your database are of standard block size, and if you have used the default value of the CHUNK parameter of LOB storage when creating a LOB column, then this is equivalent to \((4 \text{ gigabytes } -1)\) * (database block size).

BLOB objects have full transactional support. Changes made through SQL, the DBMS_LOB package, or Oracle Call Interface (OCI) participate fully in the transaction. BLOB value manipulations can be committed and rolled back. However, you cannot save a BLOB locator in a PL/SQL or OCI variable in one transaction and then use it in another transaction or session.

CLOB Data Type

The CLOB data type stores single-byte and multibyte character data. Both fixed-width and variable-width character sets are supported, and both use the database character set. CLOB objects can store up to \((4 \text{ gigabytes } -1)\) * (the value of the CHUNK parameter of LOB storage) of character data. If the tablespaces in your database are of standard block size, and if you have used the default value of the CHUNK parameter of LOB

See Also: Oracle Database PL/SQL Packages and Types Reference and Oracle Call Interface Programmer’s Guide for more information about these interfaces and LOBs

the modify_col_properties clause of ALTER_TABLE on page 12-2 and TO_LOB on page 7-369 for more information on converting LONG columns to LOB columns
storage when creating a LOB column, then this is equivalent to (4 gigabytes - 1) * 
(database block size).

**CLOB Data Type**

CLOB objects have full transactional support. Changes made through SQL, the DBMS_LOB package, or Oracle Call Interface (OCI) participate fully in the transaction. CLOB value manipulations can be committed and rolled back. However, you cannot save a CLOB locator in a PL/SQL or OCI variable in one transaction and then use it in another transaction or session.

**NCLOB Data Type**

The NCLOB data type stores Unicode data. Both fixed-width and variable-width character sets are supported, and both use the national character set. NCLOB objects can store up to (4 gigabytes -1) * (the value of the CHUNK parameter of LOB storage) of character text data. If the tablespaces in your database are of standard block size, and if you have used the default value of the CHUNK parameter of LOB storage when creating a LOB column, then this is equivalent to (4 gigabytes - 1) * (database block size).

NCLOB objects have full transactional support. Changes made through SQL, the DBMS_LOB package, or OCI participate fully in the transaction. NCLOB value manipulations can be committed and rolled back. However, you cannot save an NCLOB locator in a PL/SQL or OCI variable in one transaction and then use it in another transaction or session.

**Extended Data Types**

Beginning with Oracle Database 12c, you can specify a maximum size of 32767 bytes for the VARCHAR2, NVARCHAR2, and RAW data types. You can control whether your database supports this new maximum size by setting the initialization parameter MAX_STRING_SIZE as follows:

- If MAX_STRING_SIZE = STANDARD, then the size limits for releases prior to Oracle Database 12c apply: 4000 bytes for the VARCHAR2 and NVARCHAR2 data types, and 2000 bytes for the RAW data type. This is the default.
- If MAX_STRING_SIZE = EXTENDED, then the size limit is 32767 bytes for the VARCHAR2, NVARCHAR2, and RAW data types.

**Note:** Setting MAX_STRING_SIZE = EXTENDED may update database objects and possibly invalidate them. Refer to Oracle Database Reference for complete information on the implications of this parameter and how to set and enable this new functionality.

A VARCHAR2 or NVARCHAR2 data type with a declared size of greater than 4000 bytes, or a RAW data type with a declared size of greater than 2000 bytes, is an extended data type. Extended data type columns are stored out-of-line, leveraging Oracle's LOB technology. The LOB storage is always aligned with the table. In tablespace-managed with Automatic Segment Space Management (ASSM), extended data type columns are stored as SecureFiles LOBs. Otherwise, they are stored as BasicFiles LOBs. The use of LOBs as a storage mechanism is internal only. Therefore, you cannot manipulate these LOBs using the DBMS_LOB package.
Notes:

- Oracle strongly discourages the use of BasicFiles LOBs as a storage mechanism. BasicFiles LOBs not only impose restrictions on the capabilities of extended data type columns, but the BasicFiles data type is planned to be deprecated in a future release.

- Extended data types are subject to the same rules and restrictions as LOBs. Refer to Oracle Database SecureFiles and Large Objects Developer’s Guide for more information.

Note that, although you must set MAX_STRING_SIZE = EXTENDED in order to set the size of a RAW data type to greater than 2000 bytes, a RAW data type is stored as an out-of-line LOB only if it has a size of greater than 4000 bytes. For example, you must set MAX_STRING_SIZE = EXTENDED in order to declare a RAW(3000) data type. However, the column is stored inline.

You can use extended data types just as you would standard data types, with the following considerations:

- For special considerations when creating an index on an extended data type column, or when requiring an index to enforce a primary key or unique constraint, see “Creating an Index on an Extended Data Type Column” on page 14-83.

- If the partitioning key column for a list partition is an extended data type column, then the list of values that you want to specify for a partition may exceed the 4K byte limit for the partition bounds. See the list_partitions clause of CREATE TABLE for information on how to work around this issue.

- The value of the initialization parameter MAX_STRING_SIZE affects the following:
  - The maximum length of a text literal. See “Text Literals” on page 2-48 for more information.
  - The size limit for concatenating two character strings. See "Concatenation Operator" on page 4-3 for more information.
  - The length of the collation key returned by the NLSSORT function. See NLSSORT on page 7-208.
  - The size of some of the attributes of the XMLFormat object. See “XML Format Model” on page 2-73 for more information.
  - The size of some expressions in the following XML functions: XMLCOLATTVAL, XMLELEMENT, XMLFOREST, XMLPI, and XMLTABLE.

Rowid Data Types

Each row in the database has an address. The sections that follow describe the two forms of row address in an Oracle Database.

ROWID Data Type

The rows in heap-organized tables that are native to Oracle Database have row addresses called rowids. You can examine a rowid row address by querying the pseudocolumn ROWID. Values of this pseudocolumn are strings representing the address of each row. These strings have the data type ROWID. You can also create tables and clusters that contain actual columns having the ROWID data type. Oracle Database does not guarantee that the values of such columns are valid rowids. Refer to
Rowids contain the following information:

- The **data block** of the data file containing the row. The length of this string depends on your operating system.
- The **row** in the data block.
- The **database file** containing the row. The first data file has the number 1. The length of this string depends on your operating system.
- The **data object number**, which is an identification number assigned to every database segment. You can retrieve the data object number from the data dictionary views `USER_OBJECTS`, `DBA_OBJECTS`, and `ALL_OBJECTS`. Objects that share the same segment (clustered tables in the same cluster, for example) have the same object number.

Rowids are stored as base 64 values that can contain the characters A-Z, a-z, 0-9, and the plus sign (+) and forward slash (/). Rowids are not available directly. You can use the supplied package `DBMS_ROWID` to interpret rowid contents. The package functions extract and provide information on the four rowid elements listed above.

**See Also:** Oracle Database PL/SQL Packages and Types Reference for information on the functions available with the `DBMS_ROWID` package and how to use them

### UROWID Data Type

The rows of some tables have addresses that are not physical or permanent or were not generated by Oracle Database. For example, the row addresses of index-organized tables are stored in index leaves, which can move. Rowids of foreign tables (such as DB2 tables accessed through a gateway) are not standard Oracle rowids.

Oracle uses universal rowids (**urowids**) to store the addresses of index-organized and foreign tables. Index-organized tables have logical urowids and foreign tables have foreign urowids. Both types of urowid are stored in the `ROWID` pseudocolumn (as are the physical rowids of heap-organized tables).

Oracle creates logical rowids based on the primary key of the table. The logical rowids do not change as long as the primary key does not change. The `ROWID` pseudocolumn of an index-organized table has a data type of `UROWID`. You can access this pseudocolumn as you would the `ROWID` pseudocolumn of a heap-organized table (using a `SELECT ... ROWID` statement). If you want to store the rowids of an index-organized table, then you can define a column of type `UROWID` for the table and retrieve the value of the `ROWID` pseudocolumn into that column.

### ANSI, DB2, and SQL/DS Data Types

SQL statements that create tables and clusters can also use ANSI data types and data types from the IBM products SQL/DS and DB2. Oracle recognizes the ANSI or IBM data type name that differs from the Oracle Database data type name. It converts the data type to the equivalent Oracle data type, records the Oracle data type as the name of the column data type, and stores the column data in the Oracle data type based on the conversions shown in the tables that follow.
Data Types

Table 2–6 ANSI Data Types Converted to Oracle Data Types

<table>
<thead>
<tr>
<th>ANSI SQL Data Type</th>
<th>Oracle Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARACTER (n)</td>
<td>CHAR (n)</td>
</tr>
<tr>
<td>CHAR (n)</td>
<td></td>
</tr>
<tr>
<td>CHARACTER VARYING (n)</td>
<td>VARCHAR2 (n)</td>
</tr>
<tr>
<td>CHAR VARYING (n)</td>
<td></td>
</tr>
<tr>
<td>NATIONAL CHARACTER (n)</td>
<td>NCHAR (n)</td>
</tr>
<tr>
<td>NATIONAL CHAR (n)</td>
<td></td>
</tr>
<tr>
<td>NCHAR (n)</td>
<td></td>
</tr>
<tr>
<td>NATIONAL CHARACTER VARYING (n)</td>
<td>NCHAR VARYING (n)</td>
</tr>
<tr>
<td>NATIONAL CHAR VARYING (n)</td>
<td></td>
</tr>
<tr>
<td>NCHAR VARYING (n)</td>
<td></td>
</tr>
<tr>
<td>NUMERIC [(p, s)]</td>
<td>NUMBER (p, s)</td>
</tr>
<tr>
<td>DECIMAL [(p, s)] (Note 1)</td>
<td></td>
</tr>
<tr>
<td>INTEGER</td>
<td>NUMBER (p, 0)</td>
</tr>
<tr>
<td>INT</td>
<td></td>
</tr>
<tr>
<td>SMALLINT</td>
<td></td>
</tr>
<tr>
<td>FLOAT (Note 2)</td>
<td>FLOAT (126)</td>
</tr>
<tr>
<td>DOUBLE PRECISION (Note 3)</td>
<td>FLOAT (126)</td>
</tr>
<tr>
<td>REAL (Note 4)</td>
<td>FLOAT (63)</td>
</tr>
</tbody>
</table>

Notes:

1. The NUMERIC and DECIMAL data types can specify only fixed-point numbers. For those data types, the scale (s) defaults to 0.

2. The FLOAT data type is a floating-point number with a binary precision b. The default precision for this data type is 126 binary, or 38 decimal.

3. The DOUBLE PRECISION data type is a floating-point number with binary precision 126.

4. The REAL data type is a floating-point number with a binary precision of 63, or 18 decimal.

Do not define columns with the following SQL/DS and DB2 data types, because they have no corresponding Oracle data type:

- GRAPHIC
- LONG VARGRAPHIC
- VARGRAPHIC
- TIME

Note that data of type TIME can also be expressed as Oracle datetime data.

See Also: "Datetime and Interval Data Types" on page 2-18
Notes:
1. The DECIMAL data type can specify only fixed-point numbers. For this data type, \( s \) defaults to 0.
2. The FLOAT data type is a floating-point number with a binary precision \( b \). The default precision for this data type is 126 binary or 38 decimal.

User-Defined Types
User-defined data types use Oracle built-in data types and other user-defined data types as the building blocks of object types that model the structure and behavior of data in applications. The sections that follow describe the various categories of user-defined types.

See Also:
- Oracle Database Concepts for information about Oracle built-in data types
- CREATE TYPE on page 17-3 and the CREATE TYPE BODY on page 17-5 for information about creating user-defined types
- Oracle Database Object-Relational Developer’s Guide for information about using user-defined types

Object Types
Object types are abstractions of the real-world entities, such as purchase orders, that application programs deal with. An object type is a schema object with three kinds of components:

- A name, which identifies the object type uniquely within that schema.
- Attributes, which are built-in types or other user-defined types. Attributes model the structure of the real-world entity.
- Methods, which are functions or procedures written in PL/SQL and stored in the database, or written in a language like C or Java and stored externally. Methods implement operations the application can perform on the real-world entity.

REF Data Types
An object identifier (represented by the keyword OID) uniquely identifies an object and enables you to reference the object from other objects or from relational tables. A data type category called REF represents such references. A REF data type is a container for an object identifier. REF values are pointers to objects.
When a `REF` value points to a nonexistent object, the `REF` is said to be "dangling". A dangling `REF` is different from a null `REF`. To determine whether a `REF` is dangling or not, use the condition `IS [NOT] DANGLING`. For example, given object view `oc_orders` in the sample schema `oe`, the column `customer_ref` is of type `REF` to type `customer_typ`, which has an attribute `cust_email`:

```sql
SELECT o.customer_ref.cust_email
FROM oc_orders o
WHERE o.customer_ref IS NOT DANGLING;
```

**Varrays**

An array is an ordered set of data elements. All elements of a given array are of the same data type. Each element has an index, which is a number corresponding to the position of the element in the array.

The number of elements in an array is the size of the array. Oracle arrays are of variable size, which is why they are called varrays. You must specify a maximum size when you declare the varray.

When you declare a varray, it does not allocate space. It defines a type, which you can use as:

- The data type of a column of a relational table
- An object type attribute
- A PL/SQL variable, parameter, or function return type

Oracle normally stores an array object either in line (as part of the row data) or out of line (in a LOB), depending on its size. However, if you specify separate storage characteristics for a varray, then Oracle stores it out of line, regardless of its size. Refer to the `varray_col_properties` of CREATE TABLE on page 16-62 for more information about varray storage.

**Nested Tables**

A nested table type models an unordered set of elements. The elements may be built-in types or user-defined types. You can view a nested table as a single-column table or, if the nested table is an object type, as a multicoloum table, with a column for each attribute of the object type.

A nested table definition does not allocate space. It defines a type, which you can use to declare:

- The data type of a column of a relational table
- An object type attribute
- A PL/SQL variable, parameter, or function return type

When a nested table appears as the type of a column in a relational table or as an attribute of the underlying object type of an object table, Oracle stores all of the nested table data in a single table, which it associates with the enclosing relational or object table.

**Oracle-Supplied Types**

Oracle provides SQL-based interfaces for defining new types when the built-in or ANSI-supported types are not sufficient. The behavior for these types can be implemented in C/C++, Java, or PL/SQL. Oracle Database automatically provides the low-level infrastructure services needed for input-output, heterogeneous client-side
access for new data types, and optimizations for data transfers between the application and the database.

These interfaces can be used to build user-defined (or object) types and are also used by Oracle to create some commonly useful data types. Several such data types are supplied with the server, and they serve both broad horizontal application areas (for example, the Any types) and specific vertical ones (for example, the spatial types).

The Oracle-supplied types, along with cross-references to the documentation of their implementation and use, are described in the following sections:

- **Any Types**
- **XML Types**
- **Spatial Types**
- **Media Types**

### Any Types

The Any types provide highly flexible modeling of procedure parameters and table columns where the actual type is not known. These data types let you dynamically encapsulate and access type descriptions, data instances, and sets of data instances of any other SQL type. These types have OCI and PL/SQL interfaces for construction and access.

**ANYTYPE**

This type can contain a type description of any named SQL type or unnamed transient type.

**ANYDATA**

This type contains an instance of a given type, with data, plus a description of the type. ANYDATA can be used as a table column data type and lets you store heterogeneous values in a single column. The values can be of SQL built-in types as well as user-defined types.

**ANYDATASET**

This type contains a description of a given type plus a set of data instances of that type. ANYDATASET can be used as a procedure parameter data type where such flexibility is needed. The values of the data instances can be of SQL built-in types as well as user-defined types.

**See Also:** *Oracle Database PL/SQL Packages and Types Reference* for information on the ANYTYPE, ANYDATA, and ANYDATASET types

### XML Types

Extensible Markup Language (XML) is a standard format developed by the World Wide Web Consortium (W3C) for representing structured and unstructured data on the World Wide Web. Universal resource identifiers (URIs) identify resources such as Web pages anywhere on the Web. Oracle provides types to handle XML and URI data, as well as a class of URIs called DURIRef types to access data stored within the database itself. It also provides a set of types to store and access both external and internal URIs from within the database.
**XMLType**

This Oracle-supplied type can be used to store and query XML data in the database. XMLType has member functions you can use to access, extract, and query the XML data using XPath expressions. XPath is another standard developed by the W3C committee to traverse XML documents. Oracle XMLType functions support many W3C XPath expressions. Oracle also provides a set of SQL functions and PL/SQL packages to create XMLType values from existing relational or object-relational data.

XMLType is a system-defined type, so you can use it as an argument of a function or as the data type of a table or view column. You can also create tables and views of XMLType. When you create an XMLType column in a table, you can choose to store the XML data in a CLOB column, as binary XML (stored internally as a CLOB), or object relationally.

You can also register the schema (using the DBMS_XMLSCHEMA package) and create a table or column conforming to the registered schema. In this case Oracle stores the XML data in underlying object-relational columns by default, but you can specify storage in a CLOB or binary XML column even for schema-based data.

Queries and DML on XMLType columns operate the same regardless of the storage mechanism.

**See Also:** Oracle XML DB Developer’s Guide for information about using XMLType columns

**URI Data Types**

Oracle supplies a family of URI types—URIType, DBURIType, XDBURIType, and HTTPURIType—which are related by an inheritance hierarchy. URIType is an object type and the others are subtypes of URIType. Since URIType is the supertype, you can create columns of this type and store DBURIType or HTTPURIType type instances in this column.

**HTTPURIType** You can use HTTPURIType to store URLs to external Web pages or to files. Oracle accesses these files using HTTP (Hypertext Transfer Protocol).

**XDBURIType** You can use XDBURIType to expose documents in the XML database hierarchy as URIs that can be embedded in any URIType column in a table. The XDBURIType consists of a URL, which comprises the hierarchical name of the XML document to which it refers and an optional fragment representing the XPath syntax. The fragment is separated from the URL part by a pound sign (#). The following lines are examples of XDBURIType:

```
/home/oe/doc1.xml
/home/oe/doc1.xml#/orders/order_item
```

**DBURIType** DBURIType can be used to store DBURIRef values, which reference data inside the database. Storing DBURIRef values lets you reference data stored inside or outside the database and access the data consistently.

DBURIRef values use an XPath-like representation to reference data inside the database. If you imagine the database as an XML tree, then you would see the tables, rows, and columns as elements in the XML document. For example, the sample human resources user hr would see the following XML tree:

```xml
<HR>
  <EMPLOYEES>
    <ROW>
      <EMPLOYEE_ID>205</EMPLOYEE_ID>
    </ROW>
  </EMPLOYEES>
</HR>
```
The `DBURIRef` is an XPath expression over this virtual XML document. So to reference the `SALARY` value in the `EMPLOYEES` table for the employee with employee number 205, you can write a `DBURIRef` as,

```
/HR/EMPLOYEES/ROW[EMPLOYEE_ID=205]/SALARY
```

Using this model, you can reference data stored in `CLOB` columns or other columns and expose them as URLs to the external world.

**URIFactory Package**

Oracle also provides the `URIFactory` package, which can create and return instances of the various subtypes of the `URITypes`. The package analyzes the URL string, identifies the type of URL (HTTP, `DBURI`, and so on), and creates an instance of the subtype. To create a `DBURI` instance, the URL must begin with the prefix `/oradb`. For example, `URIFactory.getURI('/oradb/HR/EMPLOYEES')` would create a `DBURIType` instance and `URIFactory.getUri('/sys/schema')` would create an `XDBURIType` instance.

**Spatial Types**

Oracle Spatial and Graph is designed to make spatial data management easier and more natural to users of location-enabled applications, geographic information system (GIS) applications, and geoinaging applications. After the spatial data is stored in an Oracle Database, you can easily manipulate, retrieve, and relate it to all the other data stored in the database. The following data types are available only if you have installed Oracle Spatial and Graph.

**SDO_GEOMETRY**

The geometric description of a spatial object is stored in a single row, in a single column of object type `SDO_GEOMETRY` in a user-defined table. Any table that has a column of type `SDO_GEOMETRY` must have another column, or set of columns, that defines a unique primary key for that table. Tables of this sort are sometimes called geometry tables.

The `SDO_GEOMETRY` object type has the following definition:

```
CREATE TYPE SDO_GEOMETRY AS OBJECT
  (sgo_gtype NUMBER,
   sdo_srid NUMBER,
```
SDO_TOPO_GEOMETRY

This type describes a topology geometry, which is stored in a single row, in a single column of object type SDO_TOPO_GEOMETRY in a user-defined table.

The SDO_TOPO_GEOMETRY object type has the following definition:

```sql
CREATE TYPE SDO_TOPO_GEOMETRY AS OBJECT
    (tg_type        NUMBER,
     tg_id          NUMBER,
     tg_layer_id    NUMBER,
     topology_id    NUMBER);
```

SDO_GEORASTER

In the GeoRaster object-relational model, a raster grid or image object is stored in a single row, in a single column of object type SDO_GEORASTER in a user-defined table. Tables of this sort are called GeoRaster tables.

The SDO_GEORASTER object type has the following definition:

```sql
CREATE TYPE SDO_GEORASTER AS OBJECT
    (rasterType         NUMBER,
     spatialExtent      SDO_GEOMETRY,
     rasterDataTable    VARCHAR2(32),
     rasterID           NUMBER,
     metadata           XMLType);
```

See Also: Oracle Spatial and Graph Developer’s Guide, Oracle Spatial and Graph Topology Data Model and Network Data Model Graph Developer’s Guide, and Oracle Spatial and Graph GeoRaster Developer’s Guide for information on the full implementation of the spatial data types and guidelines for using them.

Media Types

Oracle Multimedia uses object types, similar to Java or C++ classes, to describe multimedia data. An instance of these object types consists of attributes, including metadata and the media data, and methods. The Multimedia data types are created in the ORDSYS schema. Public synonyms exist for all the data types, so you can access them without specifying the schema name.

Oracle Multimedia provides the following object types:

- ORDAudio
  
  Supports the storage and management of audio data.

- ORDDicom
  
  Supports the storage and management of Digital Imaging and Communications in Medicine (DICOM), the format universally recognized as the standard for medical imaging.

- ORDDoc
Supports storage and management of any type of media data, including audio, image and video data. Use this type when you want all media to be stored in a single column.

- **ORDImage**
  Supports the storage and management of image data.

- **ORDVideo**
  Supports the storage and management of video data.

The following data types provide compliance with the ISO-IEC 13249-5 Still Image standard, commonly referred to as SQL/MM StillImage:

- **SI_AverageColor**
  Represents a feature that characterizes an image by its average color.

- **SI_Color**
  Encapsulates color values.

- **SI_ColorHistogram**
  Represents a feature that characterizes an image by the relative frequencies of the colors exhibited by samples of the raw image.

- **SI_FeatureList**
  A list containing up to four of the image features represented by the preceding object types (SI_AverageColor, SI_ColorHistogram, SI_PositionalColor, and SI_Texture), where each feature is associated with a feature weight.

- **SI_PositionalColor**
  Given an image divided into n by m rectangles, the SI_PositionalColor object type represents the feature that characterizes an image by the n by m most significant colors of the rectangles.

- **SI_StillImage**
  Represents digital images with inherent image characteristics such as height, width, and format.

- **SI_Texture**
  Represents a feature that characterizes an image by the size of repeating items (coarseness), brightness variations (contrast), and predominant direction (directionality).

**See Also:**
- *Oracle Multimedia DICOM Developer’s Guide* for information on the ORDDicom object type
- *Oracle Multimedia Reference* for information on all other object types listed in this section

**Data Type Comparison Rules**

This section describes how Oracle Database compares values of each data type.
Data Type Comparison Rules

Numeric Values

A larger value is considered greater than a smaller one. All negative numbers are less than zero and all positive numbers. Thus, -1 is less than 100; -100 is less than -1.

The floating-point value NaN (not a number) is greater than any other numeric value and is equal to itself.

See Also: "Numeric Precedence" on page 2-16 and "Floating-Point Numbers" on page 2-15 for more information on comparison semantics

Date Values

A later date is considered greater than an earlier one. For example, the date equivalent of '29-MAR-2005' is less than that of '05-JAN-2006' and '05-JAN-2006 1:35pm' is greater than '05-JAN-2005 10:09am'.

Character Values

Character values are compared on the basis of two measures:

- Binary or linguistic sorting
- Blank-padded or nonpadded comparison semantics

The following subsections describe the two measures.

Binary and Linguistic Comparisons

In binary comparison, which is the default, Oracle compares character strings according to the concatenated value of the numeric codes of the characters in the database character set. One character is greater than another if it has a greater numeric value than the other in the character set. Oracle considers blanks to be less than any character, which is true in most character sets.

These are some common character sets:

- 7-bit ASCII (American Standard Code for Information Interchange)
- EBCDIC Code (Extended Binary Coded Decimal Interchange Code)
- ISO 8859/1 (International Organization for Standardization)
- JEUC Japan Extended UNIX

Linguistic comparison is useful if the binary sequence of numeric codes does not match the linguistic sequence of the characters you are comparing. Linguistic comparison is used if the NLS_SORT parameter has a setting other than BINARY and the NLS_COMP parameter is set to LINGUISTIC. In linguistic sorting, all SQL sorting and comparison are based on the linguistic rule specified by NLS_SORT.

See Also: Oracle Database Globalization Support Guide for more information about linguistic sorting

Blank-Padded and Nonpadded Comparison Semantics

With blank-padded semantics, if the two values have different lengths, then Oracle first adds blanks to the end of the shorter one so their lengths are equal. Oracle then compares the values character by character up to the first character that differs. The value with the greater character in the first differing position is considered greater. If two values have no differing characters, then they are considered equal. This rule means that two values are equal if they differ only in the number of trailing blanks.
Oracle uses blank-padded comparison semantics only when both values in the comparison are either expressions of data type `CHAR`, `NCHAR`, text literals, or values returned by the `USER` function.

With nonpadded semantics, Oracle compares two values character by character up to the first character that differs. The value with the greater character in that position is considered greater. If two values of different length are identical up to the end of the shorter one, then the longer value is considered greater. If two values of equal length have no differing characters, then the values are considered equal. Oracle uses nonpadded comparison semantics whenever one or both values in the comparison have the data type `VARCHAR2` or `NVARCHAR2`.

The results of comparing two character values using different comparison semantics may vary. The table that follows shows the results of comparing five pairs of character values using each comparison semantic. Usually, the results of blank-padded and nonpadded comparisons are the same. The last comparison in the table illustrates the differences between the blank-padded and nonpadded comparison semantics.

<table>
<thead>
<tr>
<th>Blank-Padded</th>
<th>Nonpadded</th>
</tr>
</thead>
<tbody>
<tr>
<td>'ac' &gt; 'ab'</td>
<td>'ac' &gt; 'ab'</td>
</tr>
<tr>
<td>'ab' &gt; 'a '</td>
<td>'ab' &gt; 'a '</td>
</tr>
<tr>
<td>'ab' &gt; 'a'</td>
<td>'ab' &gt; 'a'</td>
</tr>
<tr>
<td>'ab' = 'ab'</td>
<td>'ab' = 'ab'</td>
</tr>
<tr>
<td>'a ' = 'a'</td>
<td>'a ' &gt; 'a'</td>
</tr>
</tbody>
</table>

Portions of the ASCII and EBCDIC character sets appear in Table 2–8 and Table 2–9. Uppercase and lowercase letters are not equivalent. The numeric values for the characters of a character set may not match the linguistic sequence for a particular language.

### Table 2–8  ASCII Character Set

<table>
<thead>

<td>'</td>
<td>96</td>
</tr>
<tr>
<td>=</td>
<td>45</td>
<td>a-z</td>
<td>97–122</td>
</tr>
</tbody>
</table>
Object Values

Object values are compared using one of two comparison functions: MAP and ORDER. Both functions compare object type instances, but they are quite different from one another. These functions must be specified as part of any object type that will be compared with other object types.

See Also: CREATE TYPE on page 17-3 for a description of MAP and ORDER methods and the values they return

Varrrays and Nested Tables

Comparison of nested tables is described in "Comparison Conditions" on page 6-4.

Data Type Precedence

Oracle uses data type precedence to determine implicit data type conversion, which is discussed in the section that follows. Oracle data types take the following precedence:

- Datetime and interval data types

Data Type Comparison Rules

- BINARY_DOUBLE
- BINARY_FLOAT
- NUMBER
- Character data types
- All other built-in data types

Data Conversion

Generally an expression cannot contain values of different data types. For example, an expression cannot multiply 5 by 10 and then add 'JAMES'. However, Oracle supports both implicit and explicit conversion of values from one data type to another.

Implicit and Explicit Data Conversion

Oracle recommends that you specify explicit conversions, rather than rely on implicit or automatic conversions, for these reasons:

- SQL statements are easier to understand when you use explicit data type conversion functions.
- Implicit data type conversion can have a negative impact on performance, especially if the data type of a column value is converted to that of a constant rather than the other way around.
- Implicit conversion depends on the context in which it occurs and may not work the same way in every case. For example, implicit conversion from a datetime value to a VARCHAR2 value may return an unexpected year depending on the value of the NLS_DATE_FORMAT parameter.
- Algorithms for implicit conversion are subject to change across software releases and among Oracle products. Behavior of explicit conversions is more predictable.
- If implicit data type conversion occurs in an index expression, then Oracle Database might not use the index because it is defined for the pre-conversion data type. This can have a negative impact on performance.

Implicit Data Conversion

Oracle Database automatically converts a value from one data type to another when such a conversion makes sense.

Table 2–10 is a matrix of Oracle implicit conversions. The table shows all possible conversions, without regard to the direction of the conversion or the context in which it is made. The rules governing these details follow the table.

Table 2–10  Implicit Type Conversion Matrix

</tr>
</tbody>
</table>
The following rules govern implicit data type conversions:

- During `INSERT` and `UPDATE` operations, Oracle converts the value to the data type of the affected column.
- During `SELECT FROM` operations, Oracle converts the data from the column to the type of the target variable.
- When manipulating numeric values, Oracle usually adjusts precision and scale to allow for maximum capacity. In such cases, the numeric data type resulting from such operations can differ from the numeric data type found in the underlying tables.
- When comparing a character value with a numeric value, Oracle converts the character data to a numeric value.
- Conversions between character values or `NUMBER` values and floating-point number values can be inexact, because the character types and `NUMBER` use decimal precision to represent the numeric value, and the floating-point numbers use binary precision.
- When converting a `CLOB` value into a character data type such as `VARCHAR2`, or converting `BLOB` to `RAW` data, if the data to be converted is larger than the target data type, then the database returns an error.
- During conversion from a timestamp value to a `DATE` value, the fractional seconds portion of the timestamp value is truncated. This behavior differs from earlier releases of Oracle Database, when the fractional seconds portion of the timestamp value was rounded.
- Conversions from `BINARY_FLOAT` to `BINARY_DOUBLE` are exact.
Conversions from `BINARY_DOUBLE` to `BINARY_FLOAT` are inexact if the `BINARY_DOUBLE` value uses more bits of precision that supported by the `BINARY_FLOAT`.

When comparing a character value with a `DATE` value, Oracle converts the character data to `DATE`.

When you use a SQL function or operator with an argument of a data type other than the one it accepts, Oracle converts the argument to the accepted data type.

When making assignments, Oracle converts the value on the right side of the equal sign (=) to the data type of the target of the assignment on the left side.

During concatenation operations, Oracle converts from noncharacter data types to `CHAR` or `NCHAR`.

During arithmetic operations on and comparisons between character and noncharacter data types, Oracle converts from any character data type to a numeric, date, or rowid, as appropriate. In arithmetic operations between `CHAR/VARCHAR2` and `NCHAR/NVARCHAR2`, Oracle converts to a `NUMBER`.

Most SQL character functions are enabled to accept CLOBs as parameters, and Oracle performs implicit conversions between CLOB and character types. Therefore, functions that are not yet enabled for CLOBs can accept CLOBs through implicit conversion. In such cases, Oracle converts the CLOBs to `CHAR` or `VARCHAR2` before the function is invoked. If the CLOB is larger than 4000 bytes, then Oracle converts only the first 4000 bytes to `CHAR`.

When converting `RAW` or `LONG RAW` data to or from character data, the binary data is represented in hexadecimal form, with one hexadecimal character representing every four bits of `RAW` data. Refer to "RAW and LONG RAW Data Types" on page 2-26 for more information.

Comparisons between `CHAR` and `VARCHAR2` and between `NCHAR` and `NVARCHAR2` types may entail different character sets. The default direction of conversion in such cases is from the database character set to the national character set. Table 2–11 shows the direction of implicit conversions between different character types.

User-defined types such as collections cannot be implicitly converted, but must be explicitly converted using `CAST`...

Implicit Data Conversion Examples

**Text Literal Example**  The text literal ‘10’ has data type `CHAR`. Oracle implicitly converts it to the `NUMBER` data type if it appears in a numeric expression as in the following statement:

```sql
SELECT salary + '10'
FROM employees;
```
Character and Number Values Example  When a condition compares a character value and a NUMBER value, Oracle implicitly converts the character value to a NUMBER value, rather than converting the NUMBER value to a character value. In the following statement, Oracle implicitly converts '200' to 200:

```sql
SELECT last_name
FROM employees
WHERE employee_id = '200';
```

Date Example  In the following statement, Oracle implicitly converts '24-JUN-06' to a DATE value using the default date format 'DD-MON-YY':

```sql
SELECT last_name
FROM employees
WHERE hire_date = '24-JUN-06';
```

Explicit Data Conversion  You can explicitly specify data type conversions using SQL conversion functions. Table 2–12 shows SQL functions that explicitly convert a value from one data type to another.

You cannot specify LONG and LONG RAW values in cases in which Oracle can perform implicit data type conversion. For example, LONG and LONG RAW values cannot appear in expressions with functions or operators. Refer to "LONG Data Type" on page 2-16 for information on the limitations on LONG and LONG RAW data types.

</table>
When a datetime value is converted to text, either by implicit conversion or by explicit conversion that does not specify a format model, the format model is defined by one of the globalization session parameters. Depending on the source data type, the parameter name is NLS_DATE_FORMAT, NLS_TIMESTAMP_FORMAT, or NLS_TIMESTAMP_TZ_FORMAT. The values of these parameters can be specified in the client environment or in an ALTER SESSION statement.

The dependency of format models on session parameters can have a negative impact on database security when conversion without an explicit format model is applied to a datetime value that is being concatenated to text of a dynamic SQL statement. Dynamic SQL statements are those statements whose text is concatenated from fragments before being passed to a database for execution. Dynamic SQL is frequently associated with the built-in PL/SQL package DBMS_SQL or with the PL/SQL statement EXECUTE IMMEDIATE, but these are not the only places where dynamically constructed SQL text may be passed as argument. For example:

```sql
EXECUTE IMMEDIATE
'SELECT last_name FROM employees WHERE hire_date > ''' || start_date || '''';
```

where `start_date` has the data type DATE.

In the above example, the value of `start_date` is converted to text using a format model specified in the session parameter NLS_DATE_FORMAT. The result is concatenated into SQL text. A datetime format model can consist simply of literal text enclosed in double quotation marks. Therefore, any user who can explicitly set globalization parameters for a session can decide what text is produced by the above conversion. If the SQL statement is executed by a PL/SQL procedure, the procedure becomes vulnerable to SQL injection through the session parameter. If the procedure runs with definer’s rights, with higher privileges than the session itself, the user can gain unauthorized access to sensitive data.

See Also: "Conversion Functions" on page 7-6 for details on all of the explicit conversion functions
Implicit and explicit conversion for numeric values may also suffer from the analogous problem, as the conversion result may depend on the session parameter `NLS_NUMERIC_CHARACTERS`. This parameter defines the decimal and group separator characters. If the decimal separator is defined to be the quotation mark or the double quotation characters, if the

**See Also:**
- Oracle Database Globalization Support Guide for detailed descriptions of the session globalization parameters
- "Format Models" on page 2-59 for information on the format models

**Note:** This security risk also applies to middle-tier applications that construct SQL text from datetime values converted to text by the database or by OCI datetime functions. Those applications are vulnerable if session globalization parameters are obtained from a user preference.
quotation marks. If the syntax uses the term char, then you can specify either a text literal or another expression that resolves to character data — for example, the last_name column of the hr.employees table. When char appears in the syntax, the single quotation marks are not used.

The syntax of text literals or strings follows:

```
string ::=...
```

where \( N \) or \( n \) specifies the literal using the national character set (NCHAR or NVARCHAR2 data). By default, text entered using this notation is translated into the national character set by way of the database character set when used by the server. To avoid potential loss of data during the text literal conversion to the database character set, set the environment variable `ORA_NCHAR_LITERAL_REPLACE` to `TRUE`. Doing so transparently replaces the \( n' \) internally and preserves the text literal for SQL processing.

See Also: `Oracle Database Globalization Support Guide` for more information about N-quoted literals

In the top branch of the syntax:

- \( c \) is any member of the user’s character set. A single quotation mark (‘) within the literal must be preceded by an escape character. To represent one single quotation mark within a literal, enter two single quotation marks.
- ‘’ are two single quotation marks that begin and end text literals.

In the bottom branch of the syntax:

- Q or q indicates that the alternative quoting mechanism will be used. This mechanism allows a wide range of delimiters for the text string.
- The outermost ‘’ are two single quotation marks that precede and follow, respectively, the opening and closing `quote_delimiter`.
- \( c \) is any member of the user’s character set. You can include quotation marks (‘) in the text literal made up of \( c \) characters. You can also include the `quote_delimiter`, as long as it is not immediately followed by a single quotation mark.
- `quote_delimiter` is any single- or multibyte character except space, tab, and return. The `quote_delimiter` can be a single quotation mark. However, if the `quote_delimiter` appears in the text literal itself, ensure that it is not immediately followed by a single quotation mark.

If the opening `quote_delimiter` is one of [", {, <, or {, then the closing `quote_delimiter` must be the corresponding }, }, >, or }). In all other cases, the opening and closing `quote_delimiter` must be the same character.

Text literals have properties of both the CHAR and VARCHAR2 data types:

- Within expressions and conditions, Oracle treats text literals as though they have the data type CHAR by comparing them using blank-padded comparison semantics.
A text literal can have a maximum length of 4000 bytes if the initialization parameter `MAX_STRING_SIZE = STANDARD`, and 32767 bytes if `MAX_STRING_SIZE = EXTENDED`. See "Extended Data Types" on page 2-29 for more information.

Here are some valid text literals:

'Hello'
'ORACLE.dbs'
'Jackie''s raincoat'
'09-MAR-98'
N'nchar literal'

Here are some valid text literals using the alternative quoting mechanism:

q'!name LIKE `DBMS_%%!''
q'"So,\n\nshe said, 'It's finished.'"
q'\{SELECT * FROM employees WHERE last_name = 'Smith';\}'
nq'i\$1234 i'
q"name like '\['"

See Also: "Blank-Padded and Nonpadded Comparison Semantics" on page 2-40

**Numeric Literals**

Use numeric literal notation to specify fixed and floating-point numbers.

**Integer Literals**

You must use the integer notation to specify an integer whenever `integer` appears in expressions, conditions, SQL functions, and SQL statements described in other parts of this reference.

The syntax of `integer` follows:

\[
\text{integer} ::= \]

where `digit` is one of 0, 1, 2, 3, 4, 5, 6, 7, 8, 9.

An integer can store a maximum of 38 digits of precision.

Here are some valid integers:

7
+255

**NUMBER and Floating-Point Literals**

You must use the number or floating-point notation to specify values whenever `number` or `n` appears in expressions, conditions, SQL functions, and SQL statements in other parts of this reference.

The syntax of `number` follows:
**number::=**

where

- + or - indicates a positive or negative value. If you omit the sign, then a positive value is the default.
- digit is one of 0, 1, 2, 3, 4, 5, 6, 7, 8 or 9.
- e or E indicates that the number is specified in scientific notation. The digits after the E specify the exponent. The exponent can range from -130 to 125.
- f or F indicates that the number is a 32-bit binary floating point number of type BINARY_FLOAT.
- d or D indicates that the number is a 64-bit binary floating point number of type BINARY_DOUBLE.

If you omit f or F and d or D, then the number is of type NUMBER.

The suffixes f (F) and d (D) are supported only in floating-point number literals, not in character strings that are to be converted to NUMBER. For example, if Oracle is expecting a NUMBER and it encounters the string '9', then it converts the string to the number 9. However, if Oracle encounters the string '9f', then conversion fails and an error is returned.

A number of type NUMBER can store a maximum of 38 digits of precision. If the literal requires more precision than provided by NUMBER, BINARY_FLOAT, or BINARY_DOUBLE, then Oracle truncates the value. If the range of the literal exceeds the range supported by NUMBER, BINARY_FLOAT, or BINARY_DOUBLE, then Oracle raises an error.

Numeric literals are SQL syntax elements, which are not sensitive to NLS settings. The decimal separator character in numeric literals is always the period (.). However, if a text literal is specified where a numeric value is expected, then the text literal is implicitly converted to a number in an NLS-sensitive way. The decimal separator contained in the text literal must be the one established with the initialization parameter NLS_NUMERIC_CHARACTERS. Oracle recommends that you use numeric literals in SQL scripts to make them work independently of the NLS environment.

The following examples illustrate the behavior of decimal separators in numeric literals and text literals. These examples assume that you have established the comma (,) as the NLS decimal separator for the current session with the following statement:

```
ALTER SESSION SET NLS_NUMERIC_CHARACTERS=',. ';
```

The previous statement also establishes the period (.) as the NLS group separator, but that is irrelevant for these examples.
This example uses the required decimal separator (.) in the numeric literal 1.23 and the established NLS decimal separator (,) in the text literal '2,34'. The text literal is converted to the numeric value 2.34, and the output is displayed using commas for the decimal separators.

```
SELECT 2 * 1.23, 3 * '2,34' FROM DUAL;
```

```
 2*1.23  3*'2,34'
---------- ----------
    2,46       7,02
```

The next example shows that a comma is not treated as part of a numeric literal. Rather, the comma is treated as the delimiter in a list of two numeric expressions: 2*1 and 23.

```
SELECT 2 * 1,23 FROM DUAL;
```

```
 2*1         23
---------- ----------
    2         23
```

The next example shows that the decimal separator in a text literal must match the NLS decimal separator in order for implicit text-to-number conversion to succeed. The following statement fails because the decimal separator (.) does not match the established NLS decimal separator (,):

```
SELECT 3 * '2.34' FROM DUAL;
```

```
* ERROR at line 1: ORA-01722: invalid number
```

See Also: ALTER SESSION on page 11-65 and Oracle Database Reference

Here are some valid NUMBER literals:

- 25
- +6.34
- 0.5
- 25e-03
- -1

Here are some valid floating-point number literals:

- 25f
- +6.34f
- 0.5d
- -1D

You can also use the following supplied floating-point literals in situations where a value cannot be expressed as a numeric literal:

<table>
<thead>
<tr>
<th>Literal</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>binary_float_nan</td>
<td>A value of type BINARY_FLOAT for which the condition IS NAN is true</td>
<td>SELECT COUNT(*) FROM employees WHERE TO_BINARY_FLOAT(commission_pct) != BINARY_FLOAT_NAN;</td>
</tr>
</tbody>
</table>
Basic Elements of Oracle SQL

2-53

Literals

Basic Elements of Oracle SQL

2-53

Datetime Literals

Oracle Database supports four datetime data types: DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, and TIMESTAMP WITH LOCAL TIME ZONE.

Date Literals

You can specify a DATE value as a string literal, or you can convert a character or numeric value to a date value with the TO_DATE function. DATE literals are the only case in which Oracle Database accepts a TO_DATE expression in place of a string literal.

To specify a DATE value as a literal, you must use the Gregorian calendar. You can specify an ANSI literal, as shown in this example:

```
DATE '1998-12-25'
```

The ANSI date literal contains no time portion, and must be specified in the format 'YYYY-MM-DD'. Alternatively you can specify an Oracle date value, as in the following example:

```
TO_DATE('98-DEC-25 17:30','YY-MON-DD HH24:MI')
```

The default date format for an Oracle DATE value is specified by the initialization parameter NLS_DATE_FORMAT. This example date format includes a two-digit number for the day of the month, an abbreviation of the month name, the last two digits of the year, and a 24-hour time designation.

Oracle automatically converts character values that are in the default date format into date values when they are used in date expressions.

If you specify a date value without a time component, then the default time is midnight (00:00:00 or 12:00:00 for 24-hour and 12-hour clock time, respectively). If you specify a date value without a date, then the default date is the first day of the current month.

Oracle DATE columns always contain both the date and time fields. Therefore, if you query a DATE column, then you must either specify the time field in your query or ensure that the time fields in the DATE column are set to midnight. Otherwise, Oracle may not return the query results you expect. You can use the TRUNC date function to set the time field to midnight, or you can include a greater-than or less-than condition in the query instead of an equality or inequality condition.

Here are some examples that assume a table my_table with a number column row_num and a DATE column datecol:

```
INSERT INTO my_table VALUES (1, SYSDATE);
INSERT INTO my_table VALUES (2, TRUNC(SYSDATE));
```

<table>
<thead>
<tr>
<th>Literal</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>binary_float_</td>
<td>Single-precision positive infinity</td>
<td>SELECT COUNT(*) FROM employees WHERE salary &lt; BINARY_FLOAT_INFINITY;</td>
</tr>
<tr>
<td>infinity</td>
<td></td>
<td></td>
</tr>
<tr>
<td>binary_double</td>
<td>A value of type BINARY_DOUBLE for which the condition IS NAN is true</td>
<td>SELECT COUNT(*) FROM employees WHERE TO_BINARY_FLOAT(commission_pct) != BINARY_FLOAT_NAN;</td>
</tr>
<tr>
<td>double_nan</td>
<td></td>
<td></td>
</tr>
<tr>
<td>binary_double</td>
<td>Double-precision positive infinity</td>
<td>SELECT COUNT(*) FROM employees WHERE salary &lt; BINARY_DOUBLE_INFINITY;</td>
</tr>
<tr>
<td>infinity</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Datetime Literals

Oracle Database supports four datetime data types: DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, and TIMESTAMP WITH LOCAL TIME ZONE.

Date Literals

You can specify a DATE value as a string literal, or you can convert a character or numeric value to a date value with the TO_DATE function. DATE literals are the only case in which Oracle Database accepts a TO_DATE expression in place of a string literal.

To specify a DATE value as a literal, you must use the Gregorian calendar. You can specify an ANSI literal, as shown in this example:

```
DATE '1998-12-25'
```

The ANSI date literal contains no time portion, and must be specified in the format 'YYYY-MM-DD'. Alternatively you can specify an Oracle date value, as in the following example:

```
TO_DATE('98-DEC-25 17:30','YY-MON-DD HH24:MI')
```

The default date format for an Oracle DATE value is specified by the initialization parameter NLS_DATE_FORMAT. This example date format includes a two-digit number for the day of the month, an abbreviation of the month name, the last two digits of the year, and a 24-hour time designation.

Oracle automatically converts character values that are in the default date format into date values when they are used in date expressions.

If you specify a date value without a time component, then the default time is midnight (00:00:00 or 12:00:00 for 24-hour and 12-hour clock time, respectively). If you specify a date value without a date, then the default date is the first day of the current month.

Oracle DATE columns always contain both the date and time fields. Therefore, if you query a DATE column, then you must either specify the time field in your query or ensure that the time fields in the DATE column are set to midnight. Otherwise, Oracle may not return the query results you expect. You can use the TRUNC date function to set the time field to midnight, or you can include a greater-than or less-than condition in the query instead of an equality or inequality condition.

Here are some examples that assume a table my_table with a number column row_num and a DATE column datecol:

```
INSERT INTO my_table VALUES (1, SYSDATE);
INSERT INTO my_table VALUES (2, TRUNC(SYSDATE));
```
SELECT *
FROM my_table;

ROW_NUM DATECOL
---------- ---------
1 03-OCT-02
2 03-OCT-02

SELECT *
FROM my_table
WHERE datecol > TO_DATE('02-OCT-02', 'DD-MON-YY');

ROW_NUM DATECOL
---------- ---------
1 03-OCT-02
2 03-OCT-02

SELECT *
FROM my_table
WHERE datecol = TO_DATE('03-OCT-02','DD-MON-YY');

ROW_NUM DATECOL
---------- ---------
2 03-OCT-02

If you know that the time fields of your DATE column are set to midnight, then you can query your DATE column as shown in the immediately preceding example, or by using the DATE literal:

SELECT *
FROM my_table
WHERE datecol = DATE '2002-10-03';

ROW_NUM DATECOL
---------- ---------
2 03-OCT-02

However, if the DATE column contains values other than midnight, then you must filter out the time fields in the query to get the correct result. For example:

SELECT *
FROM my_table
WHERE TRUNC(datecol) = DATE '2002-10-03';

ROW_NUM DATECOL
---------- ---------
1 03-OCT-02
2 03-OCT-02

Oracle applies the TRUNC function to each row in the query, so performance is better if you ensure the midnight value of the time fields in your data. To ensure that the time fields are set to midnight, use one of the following methods during inserts and updates:

- Use the TO_DATE function to mask out the time fields:
  
  INSERT INTO my_table
  VALUES (3, TO_DATE('3-OCT-2002', 'DD-MON-YYYY'));
- Use the `DATE` literal:

```sql
INSERT INTO my_table
VALUES (4, '03-OCT-02');
```

- Use the `TRUNC` function:

```sql
INSERT INTO my_table
VALUES (5, TRUNC(SYSDATE));
```

The date function `SYSDATE` returns the current system date and time. The function `CURRENT_DATE` returns the current session date. For information on `SYSDATE`, the `TO_*` datetime functions, and the default date format, see "Datetime Functions" on page 7-5.

**TIMESTAMP Literals** The `TIMESTAMP` data type stores year, month, day, hour, minute, and second, and fractional second values. When you specify `TIMESTAMP` as a literal, the `fractional_seconds_precision` value can be any number of digits up to 9, as follows:

```sql
TIMESTAMP '1997-01-31 09:26:50.124'
```

**TIMESTAMP WITH TIME ZONE Literals** The `TIMESTAMP WITH TIME ZONE` data type is a variant of `TIMESTAMP` that includes a time zone region name or time zone offset. When you specify `TIMESTAMP WITH TIME ZONE` as a literal, the `fractional_seconds_precision` value can be any number of digits up to 9. For example:

```sql
TIMESTAMP '1997-01-31 09:26:56.66 +02:00'
```

Two `TIMESTAMP WITH TIME ZONE` values are considered identical if they represent the same instant in UTC, regardless of the time zone offsets stored in the data. For example,

```sql
TIMESTAMP '1999-04-15 8:00:00 -8:00'
```

is the same as

```sql
TIMESTAMP '1999-04-15 11:00:00 -5:00'
```

8:00 a.m. Pacific Standard Time is the same as 11:00 a.m. Eastern Standard Time.

You can replace the UTC offset with the `TZR` (time zone region name) format element. For example, the following example has the same value as the preceding example:

```sql
TIMESTAMP '1999-04-15 8:00:00 US/Pacific'
```

To eliminate the ambiguity of boundary cases when the daylight saving time switches, use both the `TZR` and a corresponding `TZD` format element. The following example ensures that the preceding example will return a daylight saving time value:

```sql
TIMESTAMP '1999-10-29 01:30:00 US/Pacific PDT'
```

You can also express the time zone offset using a datetime expression:

```sql
SELECT TIMESTAMP '2009-10-29 01:30:00' AT TIME ZONE 'US/Pacific'
FROM DUAL;
```

**See Also:** "Datetime Expressions" on page 5-9 for more information

If you do not add the `TZD` format element, and the datetime value is ambiguous, then Oracle returns an error if you have the `ERROR_ON_OVERLAP_TIME` session parameter set to `TRUE`. If that parameter is set to `FALSE`, then Oracle interprets the ambiguous datetime as standard time in the specified region.
TIMESTAMP WITH LOCAL TIME ZONE Literals  The TIMESTAMP WITH LOCAL TIME ZONE data type differs from TIMESTAMP WITH TIME ZONE in that data stored in the database is normalized to the database time zone. The time zone offset is not stored as part of the column data. There is no literal for TIMESTAMP WITH LOCAL TIME ZONE. Rather, you represent values of this data type using any of the other valid datetime literals. The table that follows shows some of the formats you can use to insert a value into a TIMESTAMP WITH LOCAL TIME ZONE column, along with the corresponding value returned by a query.

<table>
<thead>
<tr>
<th>Value Specified in INSERT Statement</th>
<th>Value Returned by Query</th>
</tr>
</thead>
<tbody>
<tr>
<td>'19-FEB-2004'</td>
<td>19-FEB-2004.00.00.000000 AM</td>
</tr>
<tr>
<td>SYSTIMESTAMP</td>
<td>19-FEB-04 02.54.36.497659 PM</td>
</tr>
<tr>
<td>TO_TIMESTAMP('19-FEB-2004', 'DD-MON-YYYY')</td>
<td>19-FEB-04 12.00.00.000000 AM</td>
</tr>
<tr>
<td>SYSDATE</td>
<td>19-FEB-04 02.55.29.000000 PM</td>
</tr>
<tr>
<td>TO_DATE('19-FEB-2004', 'DD-MON-YYYY')</td>
<td>19-FEB-04 12.00.00.000000 AM</td>
</tr>
<tr>
<td>TIMESTAMP'2004-02-19 8:00:00 US/Pacific'</td>
<td>19-FEB-04 08.00.00.000000 AM</td>
</tr>
</tbody>
</table>

Notice that if the value specified does not include a time component (either explicitly or implicitly), then the value returned defaults to midnight.

Interval Literals

An interval literal specifies a period of time. You can specify these differences in terms of years and months, or in terms of days, hours, minutes, and seconds. Oracle Database supports two types of interval literals, YEAR TO MONTH and DAY TO SECOND. Each type contains a leading field and may contain a trailing field. The leading field defines the basic unit of date or time being measured. The trailing field defines the smallest increment of the basic unit being considered. For example, a YEAR TO MONTH interval considers an interval of years to the nearest month. A DAY TO MINUTE interval considers an interval of days to the nearest minute.

If you have date data in numeric form, then you can use the NUMTODSINTERVAL or NUMTOYMINTERVAL conversion function to convert the numeric data into interval values.

Interval literals are used primarily with analytic functions.

See Also:  "Analytic Functions" on page 7-12, NUMTODSINTERVAL on page 7-215, and NUMTOYMINTERVAL on page 7-216

INTERVAL YEAR TO MONTH

Specify YEAR TO MONTH interval literals using the following syntax:

```
interval_year_to_month ::= 
```

![Diagram of interval_year_to_month syntax](image)
where

- `'integer [-integer]` specifies integer values for the leading and optional trailing field of the literal. If the leading field is `YEAR` and the trailing field is `MONTH`, then the range of integer values for the month field is 0 to 11.

- `precision` is the maximum number of digits in the leading field. The valid range of the leading field precision is 0 to 9 and its default value is 2.

**Restriction on the Leading Field** If you specify a trailing field, then it must be less significant than the leading field. For example, `INTERVAL '0-1' MONTH TO YEAR` is not valid.

The following `INTERVAL YEAR TO MONTH` literal indicates an interval of 123 years, 2 months:

`INTERVAL '123-2' YEAR(3) TO MONTH`

Examples of the other forms of the literal follow, including some abbreviated versions:

<table>
<thead>
<tr>
<th>Form of Interval Literal</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>INTERVAL '123-2' YEAR(3) TO MONTH</code></td>
<td>An interval of 123 years, 2 months. You must specify the leading field precision if it is greater than the default of 2 digits.</td>
</tr>
<tr>
<td><code>INTERVAL '123' YEAR(3)</code></td>
<td>An interval of 123 years 0 months.</td>
</tr>
<tr>
<td><code>INTERVAL '300' MONTH(3)</code></td>
<td>An interval of 300 months.</td>
</tr>
<tr>
<td><code>INTERVAL '4' YEAR</code></td>
<td>Maps to <code>INTERVAL '4-0' YEAR TO MONTH</code> and indicates 4 years.</td>
</tr>
<tr>
<td><code>INTERVAL '50' MONTH</code></td>
<td>Maps to <code>INTERVAL '4-2' YEAR TO MONTH</code> and indicates 50 months or 4 years 2 months.</td>
</tr>
<tr>
<td><code>INTERVAL '123' YEAR</code></td>
<td>Returns an error, because the default precision is 2, and '123' has 3 digits.</td>
</tr>
</tbody>
</table>

You can add or subtract one `INTERVAL YEAR TO MONTH` literal to or from another to yield another `INTERVAL YEAR TO MONTH` literal. For example:

`INTERVAL '5-3' YEAR TO MONTH + INTERVAL '20' MONTH = INTERVAL '6-11' YEAR TO MONTH`

**INTERVAL DAY TO SECOND**

Specify `DAY TO SECOND` interval literals using the following syntax:
interval_day_to_second::=

where

- `integer` specifies the number of days. If this value contains more digits than the number specified by the leading precision, then Oracle returns an error.
- `time_expr` specifies a time in the format `HH[:MI[:SS[.]]]` or `MI[:SS[.]]` or `SS[.][.]`, where `n` specifies the fractional part of a second. If `n` contains more digits than the number specified by `fractional_seconds_precision`, then `n` is rounded to the number of digits specified by the `fractional_seconds_precision` value. You can specify `time_expr` following an integer and a space only if the leading field is `DAY`.
- `leading_precision` is the number of digits in the leading field. Accepted values are 0 to 9. The default is 2.
- `fractional_seconds_precision` is the number of digits in the fractional part of the `SECOND` datetime field. Accepted values are 1 to 9. The default is 6.

Restriction on the Leading Field: If you specify a trailing field, then it must be less significant than the leading field. For example, `INTERVAL MINUTE TO DAY` is not valid. As a result of this restriction, if `SECOND` is the leading field, the interval literal cannot have any trailing field.

The valid range of values for the trailing field are as follows:

- `HOUR`: 0 to 23
- `MINUTE`: 0 to 59
- `SECOND`: 0 to 59.999999999

Examples of the various forms of `INTERVAL DAY TO SECOND` literals follow, including some abbreviated versions:
Underline your three favorite books from the list below.

- The Great Gatsby
- To Kill a Mockingbird
- Pride and Prejudice
- 1984
- The Catcher in the Rye
- The Odyssey
- The Lord of the Rings
- Animal Farm
- Slaughterhouse-Five
- The House of the Rising Sun

Write the title of your favorite book in the space provided:

My favorite book is **The Catcher in the Rye**.
See Also:

- **ALTER SESSION** on page 11-65 for information on changing the values of these parameters and **Format Model Examples** on page 2-71 for examples of using format models
- **TO_CHAR** (datetime) on page 7-359, **TO_CHAR** (number) on page 7-362, and **TO_DATE** on page 7-365
- *Oracle Database Reference* and *Oracle Database Globalization Support Guide* for information on these parameters

This remainder of this section describes how to use the following format models:

- **Number Format Models**
- **Datetime Format Models**
- **Format Model Modifiers**

**Number Format Models**

You can use number format models in the following functions:

- In the **TO_CHAR** function to translate a value of **NUMBER**, **BINARY_FLOAT**, or **BINARY_DOUBLE** data type to **VARCHAR2** data type
- In the **TO_NUMBER** function to translate a value of **CHAR** or **VARCHAR2** data type to **NUMBER** data type
- In the **TO_BINARY_FLOAT** and **TO_BINARY_DOUBLE** functions to translate **CHAR** and **VARCHAR2** expressions to **BINARY_FLOAT** or **BINARY_DOUBLE** values

All number format models cause the number to be rounded to the specified number of significant digits. If a value has more significant digits to the left of the decimal place than are specified in the format, then pound signs (#) replace the value. This event typically occurs when you are using **TO_CHAR** with a restrictive number format string, causing a rounding operation.

- If a positive **NUMBER** value is extremely large and cannot be represented in the specified format, then the infinity sign (~) replaces the value. Likewise, if a negative **NUMBER** value is extremely small and cannot be represented by the specified format, then the negative infinity sign replaces the value (~~).
- If a **BINARY_FLOAT** or **BINARY_DOUBLE** value is converted to **CHAR** or **NCHAR**, and the input is either infinity or **NaN** (not a number), then Oracle always returns the pound signs to replace the value. However, if you omit the format model, then Oracle returns either **Inf** or **Nan** as a string.

**Number Format Elements**

A number format model is composed of one or more number format elements. The tables that follow list the elements of a number format model and provide some examples.

Negative return values automatically contain a leading negative sign and positive values automatically contain a leading space unless the format model contains the **MI**, **S**, or **PR** format element.
### Table 2–13  Number Format Elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
</table>
| , (comma) | 9,999 | Returns a comma in the specified position. You can specify multiple commas in a number format model.  
**Restrictions:**  
- A comma element cannot begin a number format model.  
- A comma cannot appear to the right of a decimal character or period in a number format model. |
| . (period) | 99.99 | Returns a decimal point, which is a period (.) in the specified position.  
**Restriction:** You can specify only one period in a number format model. |
| $ | $9999 | Returns value with a leading dollar sign. |
| 0 | 0999 | Returns leading zeros.  
9990 | Returns trailing zeros. |
| 9 | 9999 | Returns value with the specified number of digits with a leading space if positive or with a leading minus if negative. Leading zeros are blank, except for a zero value, which returns a zero for the integer part of the fixed-point number. |
| B | B9999 | Returns blanks for the integer part of a fixed-point number when the integer part is zero (regardless of zeros in the format model). |
| C | C999 | Returns in the specified position the ISO currency symbol (the current value of the NLS_ISO_CURRENCY parameter). |
| D | 99D99 | Returns in the specified position the decimal character, which is the current value of the NLS_NUMERIC_CHARACTER parameter. The default is a period (.).  
**Restriction:** You can specify only one decimal character in a number format model. |
| EEEE | 9.9EEEE | Returns a value using in scientific notation. |
| G | 9G999 | Returns in the specified position the group separator (the current value of the NLS_NUMERIC_CHARACTER parameter). You can specify multiple group separators in a number format model.  
**Restriction:** A group separator cannot appear to the right of a decimal character or period in a number format model. |
| L | L999 | Returns in the specified position the local currency symbol (the current value of the NLS_CURRENCY parameter). |
| MI | 9999MI | Returns negative value with a trailing minus sign (-).  
Returns positive value with a trailing blank.  
**Restriction:** The MI format element can appear only in the last position of a number format model. |
| PR | 9999PR | Returns negative value in <angle brackets>.  
Returns positive value with a leading and trailing blank.  
**Restriction:** The PR format element can appear only in the last position of a number format model. |
| RN | RN | Returns a value as Roman numerals in uppercase. |
| rn | rn | Returns a value as Roman numerals in lowercase.  
Value can be an integer between 1 and 3999. |

</table>
Datetime Format Models

You can use datetime format models in the following functions:

- In the `TO_*` datetime functions to translate a character value that is in a format other than the default format into a datetime value. (The `TO_*` datetime functions are `TO_DATE`, `TO_TIMESTAMP`, and `TO_TIMESTAMP_TZ`.)
- In the `TO_CHAR` function to translate a datetime value into a character value that is in a format other than the default format (for example, to print the date from an application).

The total length of a datetime format model cannot exceed 22 characters.

The default datetime formats are specified either explicitly with the NLS session parameters `NLS_DATE_FORMAT`, `NLS_TIMESTAMP_FORMAT`, and `NLS_TIMESTAMP_TZ_FORMAT`, or implicitly with the NLS session parameter `NLS_TERRITORY`. You can change the default datetime formats for your session with the `ALTER SESSION` statement.

See Also: `ALTER SESSION` on page 11-65 and *Oracle Database Globalization Support Guide* for information on the NLS parameters

### Datetime Format Elements

A datetime format model is composed of one or more datetime format elements as listed in Table 2–15, "Datetime Format Elements" on page 2-64.

- For input format models, format items cannot appear twice, and format items that represent similar information cannot be combined. For example, you cannot use 'SYYYY' and 'BC' in the same format string.
- The second column indicates whether the format element can be used in the `TO_*` datetime functions. All format elements can be used in the `TO_CHAR` function.
The following datetime format elements can be used in timestamp and interval format models, but not in the original DATE format model: FF, TZD, TZH, TZM, and TZR.

Many datetime format elements are padded with blanks or leading zeroes to a specific length. Refer to the format model modifier FM on page 2-70 for more information.

**Note:** Oracle recommends that you use the 4-digit year element (YYYY) instead of the shorter year elements for these reasons:

- The 4-digit year element eliminates ambiguity.
- The shorter year elements may affect query optimization because the year is not known at query compile time and can only be determined at run time.

**Uppercase Letters in Date Format Elements** Capitalization in a spelled-out word, abbreviation, or Roman numeral follows capitalization in the corresponding format element. For example, the date format model 'DAY' produces capitalized words like 'MONDAY'; 'Day' produces 'Monday'; and 'day' produces 'monday'.

**Punctuation and Character Literals in Datetime Format Models** You can include these characters in a date format model:

- Punctuation such as hyphens, slashes, commas, periods, and colons
- Character literals, enclosed in double quotation marks

These characters appear in the return value in the same location as they appear in the format model.

<td>Example: PST (for US/Pacific standard time); PDT (for US/Pacific daylight time).</td>
</tr>
<tr>
<td>TZH</td>
<td>Yes</td>
<td>Time zone hour. (See T2M format element.) Valid in timestamp and interval formats, but not in DATE formats.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Example: ‘HH:MI:SS.FPTZH:T2M’.</td>
</tr>
<tr>
<td>T2M</td>
<td>Yes</td>
<td>Time zone minute. (See T2H format element.) Valid in timestamp and interval formats, but not in DATE formats.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Example: ‘HH:MI:SS.FPTZH:T2M’.</td>
</tr>
</tbody>
</table>
Oracle Database converts strings to dates with some flexibility. For example, when the 
`TO_DATE` function is used, a format model containing punctuation characters matches 
an input string lacking some or all of these characters, provided each numerical 
element in the input string contains the maximum allowed number of digits—for 
example, two digits '05' for 'MM' or four digits '2007' for 'YYYY'. The following 
statement does not return an error:

```sql
SELECT TO_CHAR(TO_DATE('0207','MM/YY'), 'MM/YY') FROM DUAL;
```

```
TO_CH
-----
02/07
```

However, the following format string does return an error, because the FX (format 
exact) format modifier requires an exact match of the expression and the format string:

```sql
SELECT TO_CHAR(TO_DATE('0207', 'fxmm/yy'), 'mm/yy') FROM DUAL;
```

```
ERROR at line 1:
ORA-01861: literal does not match format string
```

Any non-alphanumeric character is allowed to match the punctuation characters in the 
format model. For example, the following statement does not return an error:

```sql
SELECT TO_CHAR (TO_DATE('02#07','MM/YY'), 'MM/YY') FROM DUAL;
```

```
TO_CH
-----
02/07
```
Datetime Format Elements and Globalization Support

The functionality of some datetime format elements depends on the country and language in which you are using Oracle Database. For example, these datetime format elements return spelled values:

- MONTH
- MON
- DAY
- DY
- BC or AD or B.C. or A.D.
- AM or PM or A.M or P.M.

The language in which these values are returned is specified either explicitly with the initialization parameter `NLS_DATE_LANGUAGE` or implicitly with the initialization parameter `NLS_LANGUAGE`. The values returned by the `YEAR` and `SYEAR` datetime format elements are always in English.

The datetime format element `D` returns the number of the day of the week (1-7). The day of the week that is numbered 1 is specified implicitly by the initialization parameter `NLS_TERRITORY`.

ISO Standard Date Format Elements

Oracle calculates the values returned by the datetime format elements `IYYY`, `IYY`, `IY`, `I`, and `IW` according to the ISO standard. For information on the differences between these values and those returned by the datetime format elements `YYYY`, `YY`, `Y`, and `WW`, see the discussion of globalization support in Oracle Database Globalization Support Guide.

The RR Datetime Format Element

The `RR` datetime format element is similar to the `YY` datetime format element, but it provides additional flexibility for storing date values in other centuries. The `RR` datetime format element lets you store 20th century dates in the 21st century by specifying only the last two digits of the year.

If you use the `TO_DATE` function with the `YY` datetime format element, then the year returned always has the same first 2 digits as the current year. If you use the `RR` datetime format element instead, then the century of the return value varies according to the specified two-digit year and the last two digits of the current year.

That is:

- If the specified two-digit year is 00 to 49, then
  - If the last two digits of the current year are 00 to 49, then the returned year has the same first two digits as the current year.
  - If the last two digits of the current year are 50 to 99, then the first 2 digits of the returned year are 1 greater than the first 2 digits of the current year.
If the specified two-digit year is 50 to 99, then
- If the last two digits of the current year are 00 to 49, then the first 2 digits of the returned year are 1 less than the first 2 digits of the current year.
- If the last two digits of the current year are 50 to 99, then the returned year has the same first two digits as the current year.

The following examples demonstrate the behavior of the RR datetime format element.

**RR Datetime Format Examples**

Assume these queries are issued between 1950 and 1999:

```
SELECT TO_CHAR(TO_DATE('27-OCT-98', 'DD-MON-RR'), 'YYYY') "Year" FROM DUAL;

<table>
<thead>
<tr>
<th>Year</th>
<th>----</th>
</tr>
</thead>
<tbody>
<tr>
<td>1998</td>
<td></td>
</tr>
</tbody>
</table>
```

```
SELECT TO_CHAR(TO_DATE('27-OCT-17', 'DD-MON-RR'), 'YYYY') "Year" FROM DUAL;

<table>
<thead>
<tr>
<th>Year</th>
<th>----</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017</td>
<td></td>
</tr>
</tbody>
</table>
```

Now assume these queries are issued between 2000 and 2049:

```
SELECT TO_CHAR(TO_DATE('27-OCT-98', 'DD-MON-RR'), 'YYYY') "Year" FROM DUAL;

<table>
<thead>
<tr>
<th>Year</th>
<th>----</th>
</tr>
</thead>
<tbody>
<tr>
<td>1998</td>
<td></td>
</tr>
</tbody>
</table>
```

```
SELECT TO_CHAR(TO_DATE('27-OCT-17', 'DD-MON-RR'), 'YYYY') "Year" FROM DUAL;

<table>
<thead>
<tr>
<th>Year</th>
<th>----</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017</td>
<td></td>
</tr>
</tbody>
</table>
```

Note that the queries return the same values regardless of whether they are issued before or after the year 2000. The RR datetime format element lets you write SQL statements that will return the same values from years whose first two digits are different.

**Datetime Format Element Suffixes**

Table 2–16 lists suffixes that can be added to datetime format elements:

<table>
<thead>
<tr>
<th>Suffix</th>
<th>Meaning</th>
<th>Example Element</th>
<th>Example Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>TH</td>
<td>Ordinal Number</td>
<td>DDTH</td>
<td>4TH</td>
</tr>
<tr>
<td>SP</td>
<td>Spelled Number</td>
<td>DDSP</td>
<td>FOUR</td>
</tr>
<tr>
<td>SPTH or THSP</td>
<td>Spelled, ordinal number</td>
<td>DDSPTH</td>
<td>FOURTH</td>
</tr>
</tbody>
</table>

Notes on date format element suffixes:
- When you add one of these suffixes to a datetime format element, the return value is always in English.
Datetime suffixes are valid only to format output. You cannot use them to insert a date into the database.

Format Model Modifiers

The FM and FX modifiers, used in format models in the TO_CHAR function, control blank padding and exact format checking.

A modifier can appear in a format model more than once. In such a case, each subsequent occurrence toggles the effects of the modifier. Its effects are enabled for the portion of the model following its first occurrence, and then disabled for the portion following its second, and then reenabled for the portion following its third, and so on.

**FM** Fill mode. Oracle uses trailing blank characters and leading zeroes to fill format elements to a constant width. The width is equal to the display width of the largest element for the relevant format model:

- Numeric elements are padded with leading zeros to the width of the maximum value allowed for the element. For example, the YYYY element is padded to four digits (the length of '9999'), HH24 to two digits (the length of '23'), and DDD to three digits (the length of '366').

- The character elements MONTH, MON, DAY, and DY are padded with trailing blanks to the width of the longest full month name, the longest abbreviated month name, the longest full date name, or the longest abbreviated day name, respectively, among valid names determined by the values of NLS_DATE_LANGUAGE and NLS_CALENDAR parameters. For example, when NLS_DATE_LANGUAGE is AMERICAN and NLS_CALENDAR is GREGORIAN (the default), the largest element for MONTH is SEPTEMBER, so all values of the MONTH format element are padded to nine display characters. The values of the NLS_DATE_LANGUAGE and NLS_CALENDAR parameters are specified in the third argument to TO_CHAR and TO_* datetime functions or they are retrieved from the NLS environment of the current session.

- The character element RM is padded with trailing blanks to the length of 4, which is the length of 'viii'.

- Other character elements and spelled-out numbers (SP, SPTH, and THSP suffixes) are not padded.

The FM modifier suppresses the above padding in the return value of the TO_CHAR function.

**FX** Format exact. This modifier specifies exact matching for the character argument and datetime format model of a TO_DATE function:

- Punctuation and quoted text in the character argument must exactly match (except for case) the corresponding parts of the format model.

- The character argument cannot have extra blanks. Without FX, Oracle ignores extra blanks.

- Numeric data in the character argument must have the same number of digits as the corresponding element in the format model. Without FX, numbers in the character argument can omit leading zeros.

  When FX is enabled, you can disable this check for leading zeros by using the FM modifier as well.

If any portion of the character argument violates any of these conditions, then Oracle returns an error message.
Format Model Examples

The following statement uses a date format model to return a character expression:

```sql
SELECT TO_CHAR(SYSDATE, 'fmDDTH') || ' of ' ||
       TO_CHAR(SYSDATE, 'fmMonth') || ', ' ||
       TO_CHAR(SYSDATE, 'YYYY') "Ides"
FROM DUAL;
```

Ides
------------------
3RD of April, 2008

The preceding statement also uses the `FM` modifier. If `FM` is omitted, then the month is blank-padded to nine characters:

```sql
SELECT TO_CHAR(SYSDATE, 'DDTH') || ' of ' ||
       TO_CHAR(SYSDATE, 'Month') || ', ' ||
       TO_CHAR(SYSDATE, 'YYYY') "Ides"
FROM DUAL;
```

Ides
-----------------------
03RD of April , 2008

The following statement places a single quotation mark in the return value by using a date format model that includes two consecutive single quotation marks:

```sql
SELECT TO_CHAR(SYSDATE, 'fmDay') || '''s Special' "Menu"
FROM DUAL;
```

Menu
-----------------
Tuesday's Special

Two consecutive single quotation marks can be used for the same purpose within a character literal in a format model.

Table 2–17 shows whether the following statement meets the matching conditions for different values of `char` and `fmt` using `FX` (the table named `table` has a column `date_column` of data type `DATE`):

```sql
UPDATE table
  SET date_column = TO_DATE(char, 'fmt');
```

<table>
<thead>
<tr>
<th>char</th>
<th><code>fmt</code></th>
<th>Match or Error?</th>
</tr>
</thead>
<tbody>
<tr>
<td>'15/ JAN /1998'</td>
<td>'DD-MON-YYYY'</td>
<td>Match</td>
</tr>
<tr>
<td>' 15! JAN % /1998'</td>
<td>'DD-MON-YYYY'</td>
<td>Error</td>
</tr>
<tr>
<td>'15/JAN/1998'</td>
<td>'FXDD-MON-YYYY'</td>
<td>Error</td>
</tr>
<tr>
<td>'15-JAN-1998'</td>
<td>'FXDD-MON-YYYY'</td>
<td>Match</td>
</tr>
<tr>
<td>'1-JAN-1998'</td>
<td>'FXDD-MON-YYYY'</td>
<td>Error</td>
</tr>
<tr>
<td>'01-JAN-1998'</td>
<td>'FXDD-MON-YYYY'</td>
<td>Match</td>
</tr>
<tr>
<td>'1-JAN-1998'</td>
<td>'FXFMD-MON-YYYY'</td>
<td>Match</td>
</tr>
</tbody>
</table>
**Format of Return Values: Examples**  You can use a format model to specify the format for Oracle to use to return values from the database to you.

The following statement selects the salaries of the employees in Department 80 and uses the `TO_CHAR` function to convert these salaries into character values with the format specified by the number format model '$99,990.99':

```sql
SELECT last_name employee, TO_CHAR(salary, '$99,990.99')
FROM employees
WHERE department_id = 80;
```

Because of this format model, Oracle returns salaries with leading dollar signs, commas every three digits, and two decimal places.

The following statement selects the date on which each employee from Department 20 was hired and uses the `TO_CHAR` function to convert these dates to character strings with the format specified by the date format model 'fmMonth DD, YYYY':

```sql
SELECT last_name employee, TO_CHAR(hire_date, 'fmMonth DD, YYYY') hiredate
FROM employees
WHERE department_id = 20;
```

With this format model, Oracle returns the hire dates without blank padding (as specified by fm), two digits for the day, and the century included in the year.

**See Also:** "Format Model Modifiers" on page 2-70 for a description of the fm format element

**Supplying the Correct Format Model: Examples**  When you insert or update a column value, the data type of the value that you specify must correspond to the column data type of the column. You can use format models to specify the format of a value that you are converting from one data type to another data type required for a column.

For example, a value that you insert into a `DATE` column must be a value of the `DATE` data type or a character string in the default date format (Oracle implicitly converts character strings in the default date format to the `DATE` data type). If the value is in another format, then you must use the `TO_DATE` function to convert the value to the `DATE` data type. You must also use a format model to specify the format of the character string.

The following statement updates Hunold’s hire date using the `TO_DATE` function with the format mask 'YYYY MM DD' to convert the character string '2008 05 20' to a `DATE` value:

```sql
UPDATE employees
SET hire_date = TO_DATE('2008 05 20','YYYY MM DD')
WHERE last_name = 'Hunold';
```

**String-to-Date Conversion Rules**

The following additional formatting rules apply when converting string values to date values (unless you have used the FX or FXFM modifiers in the format model to control exact format checking):

- You can omit punctuation included in the format string from the date string if all the digits of the numerical format elements, including leading zeros, are specified. For example, specify 02 and not 2 for two-digit format elements such as MM, DD, and YY.
- You can omit time fields found at the end of a format string from the date string.
You can use any non-alphanumerical character in the date string to match the punctuation symbol in the format string.

If a match fails between a datetime format element and the corresponding characters in the date string, then Oracle attempts alternative format elements, as shown in Table 2–18.

**Table 2–18 Oracle Format Matching**

<table>
<thead>
<tr>
<th>Original Format Element</th>
<th>Additional Format Elements to Try in Place of the Original</th>
</tr>
</thead>
<tbody>
<tr>
<td>'MM'</td>
<td>'MON' and 'MONTH'</td>
</tr>
<tr>
<td>'MON'</td>
<td>'MONTH'</td>
</tr>
<tr>
<td>'MONTH'</td>
<td>'MON'</td>
</tr>
<tr>
<td>'YY'</td>
<td>'YYYY'</td>
</tr>
<tr>
<td>'RR'</td>
<td>'RRRR'</td>
</tr>
</tbody>
</table>

**XML Format Model**

The `SYS_XMLAgg` and `SYS_XMLGen` (deprecated) functions return an instance of type `XMLType` containing an XML document. Oracle provides the `XMLFormat` object, which lets you format the output of these functions. Table 2–19 lists and describes the attributes of the `XMLFormat` object. The function that implements this type follows the table.

See Also:
- `SYS_XMLAGG` on page 7-347 for information on the `SYS_XMLAgg` function
- `SYS_XMLGEN` on page 7-348 for information on the `SYS_XMLGen` function
- *Oracle XML Developer’s Kit Programmer’s Guide* for more information on the implementation of the `XMLFormat` object and its use

**Table 2–19 Attributes of the XMLFormat Object**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Data Type</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>enclTag</td>
<td>VARCHAR2(4000) or VARCHAR2(32767)</td>
<td>The name of the enclosing tag for the result of the <code>SYS_XMLAgg</code> or <code>SYS_XMGen</code> (deprecated) function.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>SYS_XMLAgg</code>: The default is <code>ROWSET</code>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>SYS_XMLGen</code>: If the input to the function is a column name, then the default is the column name. Otherwise the default is <code>ROW</code>. When <code>schemaType</code> is set to <code>USE_GIVEN_SCHEMA</code>, this attribute also gives the name of the XMLSchema element.</td>
</tr>
<tr>
<td>schemaType</td>
<td>VARCHAR2(100)</td>
<td>The type of schema generation for the output document. Valid values are 'NO_SCHEMA' and 'USE_GIVEN_SCHEMA'. The default is 'NO_SCHEMA'.</td>
</tr>
<tr>
<td>schemaName</td>
<td>VARCHAR2(4000) or VARCHAR2(32767)</td>
<td>The name of the target schema Oracle uses if the value of the <code>schemaType</code> is 'USE_GIVEN_SCHEMA'. If you specify <code>schemaName</code>, then Oracle uses the enclosing tag as the element name.</td>
</tr>
</tbody>
</table>
### Table 2–19  (Cont.) Attributes of the XMLFormat Object

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Data Type</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>targetNameSpace</td>
<td>VARCHAR2(4000) or</td>
<td>The target namespace if the schema is specified (that is, schemaType is GEN_SCHEMA_* or USE_GIVEN_SCHEMA)</td>
</tr>
<tr>
<td></td>
<td>VARCHAR2(32767)</td>
<td></td>
</tr>
<tr>
<td>dbUrlPrefix</td>
<td>VARCHAR2(4000) or</td>
<td>The URL to the database to use if WITH_SCHEMA is specified. If this attribute is not specified, then Oracle declares the URL to the types as a relative URL reference.</td>
</tr>
<tr>
<td></td>
<td>VARCHAR2(32767)</td>
<td></td>
</tr>
<tr>
<td>processingIns</td>
<td>VARCHAR2(4000) or</td>
<td>User-provided processing instructions, which are appended to the top of the function output before the element.</td>
</tr>
<tr>
<td></td>
<td>VARCHAR2(32767)</td>
<td></td>
</tr>
</tbody>
</table>

1 The data type for this attribute is VARCHAR2(4000) if the initialization parameter MAX_STRING_SIZE = STANDARD, and VARCHAR2(32767) if MAX_STRING_SIZE = EXTENDED. See “Extended Data Types” on page 2-29 for more information.

The function that implements the XMLFormat object follows:

```sql
STATIC FUNCTION createFormat(
    enclTag IN varchar2 := 'ROWSET',
    schemaType IN varchar2 := 'NO_SCHEMA',
    schemaName IN varchar2 := null,
    targetNameSpace IN varchar2 := null,
    dbUrlPrefix IN varchar2 := null,
    processingIns IN varchar2 := null) RETURN XMLGenFormatType

MEMBER PROCEDURE genSchema (spec IN varchar2),
MEMBER PROCEDURE setSchemaName(schemaName IN varchar2),
MEMBER PROCEDURE setTargetNameSpace(targetNameSpace IN varchar2),
MEMBER PROCEDURE setEnclosingElementName(enclTag IN varchar2),
MEMBER PROCEDURE setDbUrlPrefix(prefix IN varchar2),
MEMBER PROCEDURE setProcessingIns(pi IN varchar2),
CONSTRUCTOR FUNCTION XMLGenFormatType {
    enclTag IN varchar2 := 'ROWSET',
    schemaType IN varchar2 := 'NO_SCHEMA',
    schemaName IN varchar2 := null,
    targetNameSpace IN varchar2 := null,
    dbUrlPrefix IN varchar2 := null,
    processingIns IN varchar2 := null) RETURN SELF AS RESULT

STATIC function createFormat2{
    enclTag in varchar2 := 'ROWSET',
    flags in raw) return sys.xmlgenformatype
    deterministic parallel_enable
};
```

### Nulls

If a column in a row has no value, then the column is said to be **null**, or to contain null. Nulls can appear in columns of any data type that are not restricted by **NOT NULL** or **PRIMARY KEY** integrity constraints. Use a null when the actual value is not known or when a value would not be meaningful.

Oracle Database treats a character value with a length of zero as null. However, do not use null to represent a numeric value of zero, because they are not equivalent.
Any arithmetic expression containing a null always evaluates to null. For example, null added to 10 is null. In fact, all operators (except concatenation) return null when given a null operand.

**Nulls in SQL Functions**

For information on null handling in SQL functions, see “Nulls in SQL Functions” on page 7-2.

**Nulls with Comparison Conditions**

To test for nulls, use only the comparison conditions IS NULL and IS NOT NULL. If you use any other condition with nulls and the result depends on the value of the null, then the result is UNKNOWN. Because null represents a lack of data, a null cannot be equal or unequal to any value or to another null. However, Oracle considers two nulls to be equal when evaluating a DECODE function. Refer to DECODE on page 7-92 for syntax and additional information.

Oracle also considers two nulls to be equal if they appear in compound keys. That is, Oracle considers identical two compound keys containing nulls if all the non-null components of the keys are equal.

**Nulls in Conditions**

A condition that evaluates to UNKNOWN acts almost like FALSE. For example, a SELECT statement with a condition in the WHERE clause that evaluates to UNKNOWN returns no rows. However, a condition evaluating to UNKNOWN differs from FALSE in that further operations on an UNKNOWN condition evaluation will evaluate to UNKNOWN. Thus, NOT FALSE evaluates to TRUE, but NOT UNKNOWN evaluates to UNKNOWN.

Table 2–20 shows examples of various evaluations involving nulls in conditions. If the conditions evaluating to UNKNOWN were used in a WHERE clause of a SELECT statement, then no rows would be returned for that query.

**Note:** Oracle Database currently treats a character value with a length of zero as null. However, this may not continue to be true in future releases, and Oracle recommends that you do not treat empty strings the same as nulls.
Comments

Comments

You can create two types of comments:

- Comments within SQL statements are stored as part of the application code that executes the SQL statements.
- Comments associated with individual schema or nonschema objects are stored in the data dictionary along with metadata on the objects themselves.

Comments Within SQL Statements

Comments can make your application easier for you to read and maintain. For example, you can include a comment in a statement that describes the purpose of the statement within your application. With the exception of hints, comments within SQL statements do not affect the statement execution. Refer to “Hints” on page 2-77 on using this particular form of comment.

A comment can appear between any keywords, parameters, or punctuation marks in a statement. You can include a comment in a statement in two ways:

- Begin the comment with a slash and an asterisk (/*). Proceed with the text of the comment. This text can span multiple lines. End the comment with an asterisk and a slash (*/). The opening and terminating characters need not be separated from the text by a space or a line break.
- Begin the comment with -- (two hyphens). Proceed with the text of the comment. This text cannot extend to a new line. End the comment with a line break.

Some of the tools used to enter SQL have additional restrictions. For example, if you are using SQL*Plus, by default you cannot have a blank line inside a multiline comment. For more information, refer to the documentation for the tool you use as an interface to the database.

A SQL statement can contain multiple comments of both styles. The text of a comment can contain any printable characters in your database character set.

---

### Table 2–20 Conditions Containing Nulls

<table>
<thead>
<tr>
<th>Condition</th>
<th>Value of A</th>
<th>Evaluation</th>
</tr>
</thead>
<tbody>
<tr>
<td>a IS NULL</td>
<td>10</td>
<td>FALSE</td>
</tr>
<tr>
<td>a IS NOT NULL</td>
<td>10</td>
<td>TRUE</td>
</tr>
<tr>
<td>a IS NULL</td>
<td>NULL</td>
<td>TRUE</td>
</tr>
<tr>
<td>a IS NOT NULL</td>
<td>NULL</td>
<td>FALSE</td>
</tr>
<tr>
<td>a = NULL</td>
<td>10</td>
<td>UNKNOWN</td>
</tr>
<tr>
<td>a != NULL</td>
<td>10</td>
<td>UNKNOWN</td>
</tr>
<tr>
<td>a = NULL</td>
<td>NULL</td>
<td>UNKNOWN</td>
</tr>
<tr>
<td>a != NULL</td>
<td>NULL</td>
<td>UNKNOWN</td>
</tr>
<tr>
<td>a = 10</td>
<td>NULL</td>
<td>UNKNOWN</td>
</tr>
<tr>
<td>a != 10</td>
<td>NULL</td>
<td>UNKNOWN</td>
</tr>
</tbody>
</table>

For the truth tables showing the results of logical conditions containing nulls, see Table 6–5 on page 6-8, Table 6–6 on page 6-8, and Table 6–7 on page 6-9.
Example  These statements contain many comments:

```
SELECT last_name, employee_id, salary + NVL(commission_pct, 0),
    job_id, department_id
/* Select all employees whose compensation is
greater than that of Pataballa.*/
FROM employees e, departments d
/*The DEPARTMENTS table is used to get the department name.*/
WHERE e.department_id = d.department_id
AND salary + NVL(commission_pct,0) > /* Subquery: */
    (SELECT salary + NVL(commission_pct,0)
     /* total compensation is salary + commission_pct */
     FROM employees
     WHERE last_name = 'Pataballa')
ORDER BY last_name, employee_id;
```

```
SELECT last_name, employee_id, salary + NVL(commission_pct, 0),
    job_id, department_id
/* Select all employees whose compensation is
greater than that of Pataballa.*/
FROM employees e, departments d
WHERE e.department_id = d.department_id
AND salary + NVL(commission_pct,0) > /* Subquery: */
    (SELECT salary + NVL(commission_pct,0)
     /* total compensation is salary + commission_pct */
     FROM employees
     WHERE last_name = 'Pataballa')
ORDER BY last_name, employee_id;
```

Comments on Schema and Nonschema Objects

You can use the `COMMENT` command to associate a comment with a schema object (table, view, materialized view, operator, indextype, mining model) or a nonschema object (edition) using the `COMMENT` command. You can also create a comment on a column, which is part of a table schema object. Comments associated with schema and nonschema objects are stored in the data dictionary. Refer to `COMMENT` on page 13-54 for a description of this form of comment.

Hints

Hints are comments in a SQL statement that pass instructions to the Oracle Database optimizer. The optimizer uses these hints to choose an execution plan for the statement, unless some condition exists that prevents the optimizer from doing so.

Hints were introduced in Oracle7, when users had little recourse if the optimizer generated suboptimal plans. Now Oracle provides a number of tools, including the SQL Tuning Advisor, SQL plan management, and SQL Performance Analyzer, to help you address performance problems that are not solved by the optimizer. Oracle strongly recommends that you use those tools rather than hints. The tools are far superior to hints, because when used on an ongoing basis, they provide fresh solutions as your data and database environment change.

Hints should be used sparingly, and only after you have collected statistics on the relevant tables and evaluated the optimizer plan without hints using the `EXPLAIN PLAN` statement. Changing database conditions as well as query performance enhancements
in subsequent releases can have significant impact on how hints in your code affect performance.

The remainder of this section provides information on some commonly used hints. If you decide to use hints rather than the more advanced tuning tools, be aware that any short-term benefit resulting from the use of hints may not continue to result in improved performance over the long term.

**Using Hints**
A statement block can have only one comment containing hints, and that comment must follow the `SELECT`, `UPDATE`, `INSERT`, `MERGE`, or `DELETE` keyword.

The following syntax diagram shows hints contained in both styles of comments that Oracle supports within a statement block. The hint syntax must follow immediately after an `INSERT`, `UPDATE`, `DELETE`, `SELECT`, or `MERGE` keyword that begins the statement block.

**hint ::=**

where:

- The plus sign (+) causes Oracle to interpret the comment as a list of hints. The plus sign must follow immediately after the comment delimiter. No space is permitted.
- `hint` is one of the hints discussed in this section. The space between the plus sign and the hint is optional. If the comment contains multiple hints, then separate the hints by at least one space.
- `string` is other commenting text that can be interspersed with the hints.

The `---` syntax requires that the entire comment be on a single line.

Oracle Database ignores hints and does not return an error under the following circumstances:

- The hint contains misspellings or syntax errors. However, the database does consider other correctly specified hints in the same comment.
- The comment containing the hint does not follow a `DELETE`, `INSERT`, `MERGE`, `SELECT`, or `UPDATE` keyword.
- A combination of hints conflict with each other. However, the database does consider other hints in the same comment.
- The database environment uses PL/SQL version 1, such as Forms version 3 triggers, Oracle Forms 4.5, and Oracle Reports 2.5.
- A global hint refers to multiple query blocks. Refer to "Specifying Multiple Query Blocks in a Global Hint" on page 2-79 for more information.

**Specifying a Query Block in a Hint**
You can specify an optional query block name in many hints to specify the query block to which the hint applies. This syntax lets you specify in the outer query a hint that applies to an inline view.
The syntax of the query block argument is of the form @queryblock, where queryblock is an identifier that specifies a query block in the query. The queryblock identifier can either be system-generated or user-specified. When you specify a hint in the query block itself to which the hint applies, you omit the @queryblock syntax.

- The system-generated identifier can be obtained by using EXPLAIN PLAN for the query. Pretransformation query block names can be determined by running EXPLAIN PLAN for the query using the NO_QUERY_TRANSFORMATION hint. See "NO_QUERY_TRANSFORMATION Hint" on page 2-102.
- The user-specified name can be set with the QB_NAME hint. See "QB_NAME Hint" on page 2-113.

Specifying Global Hints
Many hints can apply both to specific tables or indexes and more globally to tables within a view or to columns that are part of indexes. The syntactic elements tablespec and indexspec define these global hints.

tablespec::=

You must specify the table to be accessed exactly as it appears in the statement. If the statement uses an alias for the table, then use the alias rather than the table name in the hint. However, do not include the schema name with the table name within the hint, even if the schema name appears in the statement.

Note: Specifying a global hint using the tablespec clause does not work for queries that use ANSI joins, because the optimizer generates additional views during parsing. Instead, specify @queryblock to indicate the query block to which the hint applies.

indexspec::=

When tablespec is followed by indexspec in the specification of a hint, a comma separating the table name and index name is permitted but not required. Commas are also permitted, but not required, to separate multiple occurrences of indexspec.

Specifying Multiple Query Blocks in a Global Hint Oracle Database ignores global hints that refer to multiple query blocks. To avoid this issue, Oracle recommends that you specify the object alias in the hint instead of using tablespec and indexspec.

For example, consider the following view v and table t:

```sql
CREATE VIEW v AS
    SELECT e.last_name, e.department_id, d.location_id
    FROM employees e, departments d
    WHERE e.department_id = d.department_id;
```
CREATE TABLE t AS
  SELECT * FROM employees
  WHERE employee_id < 200;

---

**Note:** The following examples use the `EXPLAIN PLAN` statement, which enables you to display the execution plan and determine if a hint is honored or ignored. Refer to `EXPLAIN PLAN` on page 18-20 for more information.

---

The `LEADING` hint is ignored in the following query because it refers to multiple query blocks, that is, the main query block containing table `t` and the view query block `v`:

```
EXPLAIN PLAN
SET STATEMENT_ID = 'Test 1'
INTO plan_table FOR
  (SELECT /*+ LEADING(v.e v.d t) */ *
   FROM t, v
   WHERE t.department_id = v.department_id);
```

The following `SELECT` statement returns the execution plan, which shows that the `LEADING` hint was ignored:

```
SELECT id, LPAD(' ',2*(LEVEL-1))||operation operation, options, object_name, object_alias
FROM plan_table
START WITH id = 0 AND statement_id = 'Test 1'
CONNECT BY PRIOR id = parent_id AND statement_id = 'Test 1'
ORDER BY id;
```

```
ID OPERATION OPTIONS OBJECT_NAME OBJECT_ALIAS
--- -------------------- ---------- ------------- ---------------------
0 SELECT STATEMENT
1 HASH JOIN
2 HASH JOIN
3 TABLE ACCESS FULL DEPARTMENTS D@SEL$2
4 TABLE ACCESS FULL EMPLOYEES E@SEL$2
5 TABLE ACCESS FULL T T@SEL$1
```

The `LEADING` hint is honored in the following query because it refers to object aliases, which can be found in the execution plan that was returned by the previous query:

```
EXPLAIN PLAN
SET STATEMENT_ID = 'Test 2'
INTO plan_table FOR
  (SELECT /*+ LEADING(D@SEL$2 E@SEL$2 T@SEL$1) */ *
   FROM t, v
   WHERE t.department_id = v.department_id);
```

The following `SELECT` statement returns the execution plan, which shows that the `LEADING` hint was honored:

```
SELECT id, LPAD(' ',2*(LEVEL-1))||operation operation, options, object_name, object_alias
FROM plan_table
START WITH id = 0 AND statement_id = 'Test 2'
CONNECT BY PRIOR id = parent_id AND statement_id = 'Test 2'
ORDER BY id;
```

```
ID OPERATION OPTIONS OBJECT_NAME OBJECT_ALIAS
--- -------------------- ---------- ------------- ---------------------
0 SELECT STATEMENT
1 HASH JOIN
2 HASH JOIN
3 TABLE ACCESS FULL DEPARTMENTS D@SEL$2
4 TABLE ACCESS FULL EMPLOYEES E@SEL$2
5 TABLE ACCESS FULL T T@SEL$1
```
Comments

Basic Elements of Oracle SQL

--- -------------------- ---------- ------------- -------------------
0 SELECT STATEMENT
1 HASH JOIN

Alphabetical Listing of Hints

This section provides syntax and semantics for all hints in alphabetical order.

**ALL_ROWS Hint**

The ALL_ROWS hint instructs the optimizer to optimize a statement block with a goal of best throughput, which is minimum total resource consumption. For example, the optimizer uses the query optimization approach to optimize this statement for best throughput:

```sql
SELECT /*+ ALL_ROWS */ employee_id, last_name, salary, job_id
FROM employees
WHERE employee_id = 107;
```
If you specify either the `ALL_ROWS` or the `FIRST_ROWS` hint in a SQL statement, and if the data dictionary does not have statistics about tables accessed by the statement, then the optimizer uses default statistical values, such as allocated storage for such tables, to estimate the missing statistics and to subsequently choose an execution plan. These estimates might not be as accurate as those gathered by the `DBMS_STATS` package, so you should use the `DBMS_STATS` package to gather statistics.

If you specify hints for access paths or join operations along with either the `ALL_ROWS` or `FIRST_ROWS` hint, then the optimizer gives precedence to the access paths and join operations specified by the hints.

**APPEND Hint**

![APPEND Hint](image)

The `APPEND` hint instructs the optimizer to use direct-path `INSERT` with the subquery syntax of the `INSERT` statement.

- Conventional `INSERT` is the default in serial mode. In serial mode, direct path can be used only if you include the `APPEND` hint.
- Direct-path `INSERT` is the default in parallel mode. In parallel mode, conventional insert can be used only if you specify the `NOAPPEND` hint.

The decision whether the `INSERT` will go parallel or not is independent of the `APPEND` hint.

In direct-path `INSERT`, data is appended to the end of the table, rather than using existing space currently allocated to the table. As a result, direct-path `INSERT` can be considerably faster than conventional `INSERT`.

The `APPEND` hint is only supported with the subquery syntax of the `INSERT` statement, not the `VALUES` clause. If you specify the `APPEND` hint with the `VALUES` clause, it is ignored and conventional insert will be used. To use direct-path `INSERT` with the `VALUES` clause, refer to "APPEND_VALUES Hint" on page 2-84.

**See Also:** "NOAPPEND Hint" on page 2-96 for information on that hint and *Oracle Database Administrator’s Guide* for information on direct-path inserts

**APPEND_VALUES Hint**

![APPEND_VALUES Hint](image)

The `APPEND_VALUES` hint instructs the optimizer to use direct-path `INSERT` with the `VALUES` clause. If you do not specify this hint, then conventional `INSERT` is used.

In direct-path `INSERT`, data is appended to the end of the table, rather than using existing space currently allocated to the table. As a result, direct-path `INSERT` can be considerably faster than conventional `INSERT`.

The `APPEND_VALUES` hint can be used to greatly enhance performance. Some examples of its uses are:

- In an Oracle Call Interface (OCI) program, when using large array binds or array binds with row callbacks
- In PL/SQL, when loading a large number of rows with a `FORALL` loop that has an `INSERT` statement with a `VALUES` clause
The APPEND_VALUES hint is only supported with the VALUES clause of the INSERT statement. If you specify the APPEND_VALUES hint with the subquery syntax of the INSERT statement, it is ignored and conventional insert will be used. To use direct-path INSERT with a subquery, refer to "APPEND Hint" on page 2-84.

See Also: Oracle Database Administrator’s Guide for information on direct-path inserts

CACHE Hint

(See "Specifying a Query Block in a Hint" on page 2-78, tablespec::= on page 2-79)

The CACHE hint instructs the optimizer to place the blocks retrieved for the table at the most recently used end of the LRU list in the buffer cache when a full table scan is performed. This hint is useful for small lookup tables.

In the following example, the CACHE hint overrides the default caching specification of the table:

SELECT /*+ FULL (hr_emp) CACHE(hr_emp) */ last_name
FROM employees hr_emp;

The CACHE and NOCACHE hints affect system statistics table scans (long tables) and table scans (short tables), as shown in the V$SYSSTAT data dictionary view.

CHANGE_DUPKEY_ERROR_INDEX Hint

Note: The CHANGE_DUPKEY_ERROR_INDEX, IGNORE_ROW_ON_DUPKEY_INDEX, and RETRY_ON_ROW_CHANGE hints are unlike other hints in that they have a semantic effect. The general philosophy explained in "Hints" on page 2-77 does not apply for these three hints.

The CHANGE_DUPKEY_ERROR_INDEX hint provides a mechanism to unambiguously identify a unique key violation for a specified set of columns or for a specified index. When a unique key violation occurs for the specified index, an ORA-38911 error is reported instead of an ORA-001.

This hint applies to INSERT, UPDATE operations. If you specify an index, then the index must exist and be unique. If you specify a column list instead of an index, then a unique index whose columns match the specified columns in number and order must exist.

This use of this hint results in error messages if specific rules are violated. Refer to IGNORE_ROW_ON_DUPKEY_INDEX Hint on page 2-89 for details.

Note: This hint disables both APPEND mode and parallel DML.
CLUSTER Hint

```
/*+ CLUSTER (queryblock tablespec) */
```

(See “Specifying a Query Block in a Hint” on page 2-78, `tablespec::=` on page 2-79)

The `CLUSTER` hint instructs the optimizer to use a cluster scan to access the specified table. This hint applies only to tables in an indexed cluster.

CLUSTERING Hint

```
/*+ CLUSTERING */
```

This hint is valid only for `INSERT` and `MERGE` operations on tables that are enabled for attribute clustering. The `CLUSTERING` hint enables attribute clustering for direct-path inserts (serial or parallel). This results in partially-clustered data, that is, data that is clustered per each insert or merge operation. This hint overrides a `NO ON LOAD` setting in the DDL that created or altered the table. This hint has no effect on tables that are not enabled for attribute clustering.

See Also:
- `CLUSTERING` clause of `CREATE TABLE` on page 16-79 for more information on the `NO ON LOAD` setting
- "NO_CLUSTERING Hint" on page 2-96

CURSOR_SHARING_EXACT Hint

```
/*+ CURSOR_SHARING_EXACT */
```

Oracle can replace literals in SQL statements with bind variables, when it is safe to do so. This replacement is controlled with the `CURSOR_SHARING` initialization parameter. The `CURSOR_SHARING_EXACT` hint instructs the optimizer to switch this behavior off. When you specify this hint, Oracle executes the SQL statement without any attempt to replace literals with bind variables.

DISABLE_PARALLEL_DML Hint

```
/*+ DISABLE_PARALLEL_DML */
```

The `DISABLE_PARALLEL_DML` hint disables parallel DML for `DELETE`, `INSERT`, `MERGE`, and `UPDATE` statements. You can use this hint to disable parallel DML for an individual statement when parallel DML is enabled for the session with the `ALTER SESSION ENABLE PARALLEL DML` statement.
**DRIVING_SITE** Hint

```
/*+ DRIVING_SITE(queryblock tablespec) */
```

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The **DRIVING_SITE** hint instructs the optimizer to execute the query at a different site than that selected by the database. This hint is useful if you are using distributed query optimization.

For example:

```
SELECT /*+ DRIVING_SITE(departments) */ *
    FROM employees, departments@rsite
    WHERE employees.department_id = departments.department_id;
```

If this query is executed without the hint, then rows from `departments` are sent to the local site, and the join is executed there. With the hint, the rows from `employees` are sent to the remote site, and the query is executed there and the result set is returned to the local site.

**DYNAMIC_SAMPLING** Hint

```
/*+ DYNAMIC_SAMPLING(queryblock tablespec integer) */
```

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The **DYNAMIC_SAMPLING** hint instructs the optimizer how to control dynamic sampling to improve server performance by determining more accurate predicate selectivity and statistics for tables and indexes.

You can set the value of **DYNAMIC_SAMPLING** to a value from 0 to 10. The higher the level, the more effort the compiler puts into dynamic sampling and the more broadly it is applied. Sampling defaults to cursor level unless you specify `tablespec`.

The `integer` value is 0 to 10, indicating the degree of sampling.

If a cardinality statistic already exists for the table, then the optimizer uses it. Otherwise, the optimizer enables dynamic sampling to estimate the cardinality statistic.

If you specify `tablespec` and the cardinality statistic already exists, then:

- If there is no single-table predicate (a `WHERE` clause that evaluates only one table), then the optimizer trusts the existing statistics and ignores this hint. For example, the following query will not result in any dynamic sampling if `employees` is analyzed:

  ```
  SELECT /*+ DYNAMIC_SAMPLING(e 1) */ count(*)
    FROM employees e;
  ```

- If there is a single-table predicate, then the optimizer uses the existing cardinality statistic and estimates the selectivity of the predicate using the existing statistics.

To apply dynamic sampling to a specific table, use the following form of the hint:

```
SELECT /*+ DYNAMIC_SAMPLING(employees 1) */ *
    FROM employees
    WHERE ... 
```
ENABLE_PARALLEL_DML Hint

The `ENABLE_PARALLEL_DML` hint enables parallel DML for `DELETE`, `INSERT`, `MERGE`, and `UPDATE` statements. You can use this hint to enable parallel DML for an individual statement, rather than enabling parallel DML for the session with the `ALTER SESSION ENABLE PARALLEL DML` statement.

See Also: *Oracle Database VLDB and Partitioning Guide* for information about enabling parallel DML and restrictions on parallel DML.

FACT Hint

The `FACT` hint is used in the context of the star transformation. It instructs the optimizer that the table specified in `tablespec` should be considered as a fact table.

FIRST_ROWS Hint

The `FIRST_ROWS` hint instructs Oracle to optimize an individual SQL statement for fast response, choosing the plan that returns the first `n` rows most efficiently. For `integer`, specify the number of rows to return.

For example, the optimizer uses the query optimization approach to optimize the following statement for best response time:

```sql
SELECT /*+ FIRST_ROWS(10) */ employee_id, last_name, salary, job_id
FROM employees
WHERE department_id = 20;
```

In this example each department contains many employees. The user wants the first 10 employees of department 20 to be displayed as quickly as possible.

The optimizer ignores this hint in `DELETE` and `UPDATE` statement blocks and in `SELECT` statement blocks that include any blocking operations, such as sorts or groupings. Such statements cannot be optimized for best response time, because Oracle Database must retrieve all rows accessed by the statement before returning the first row. If you specify this hint in any such statement, then the database optimizes for best throughput.

See Also: *"ALL_ROWS Hint"* on page 2-83 for additional information on the `FIRST_ROWS` hint and statistics.
FULL Hint

(See "Specifying a Query Block in a Hint" on page 2-78, \( \text{tablespec}::= \) on page 2-79)

The **FULL** hint instructs the optimizer to perform a full table scan for the specified table.

For example:

```sql
SELECT /*+ FULL(e) */ employee_id, last_name
FROM hr.employees e
WHERE last_name LIKE :b1;
```

Oracle Database performs a full table scan on the `employees` table to execute this statement, even if there is an index on the `last_name` column that is made available by the condition in the \texttt{WHERE} clause.

The `employees` table has alias \texttt{e} in the \texttt{FROM} clause, so the hint must refer to the table by its alias rather than by its name. Do not specify schema names in the hint even if they are specified in the \texttt{FROM} clause.

**GATHER_OPTIMIZER_STATISTICS** Hint

(See "Specifying a Query Block in a Hint" on page 2-78, \( \text{tablespec}::= \) on page 2-79)

The **GATHER_OPTIMIZER_STATISTICS** hint instructs the optimizer to enable statistics gathering during the following types of bulk loads:

- CREATE TABLE ... AS SELECT
- INSERT INTO ... SELECT into an empty table using a direct-path insert

**See Also:** *Oracle Database SQL Tuning Guide* for more information on statistics gathering for bulk loads

HASH Hint

(See "Specifying a Query Block in a Hint" on page 2-78, \( \text{tablespec}::= \) on page 2-79)

The **HASH** hint instructs the optimizer to use a hash scan to access the specified table.

This hint applies only to tables in a hash cluster.

**IGNORE_ROW_ON_DUPKEY_INDEX** Hint

The `IGNORE_ROW_ON_DUPKEY_INDEX` hint applies only to single-table `INSERT` operations. It is not supported for `UPDATE`, `DELETE`, `MERGE`, or multitable insert operations. `IGNORE_ROW_ON_DUPKEY_INDEX` causes the statement to ignore a unique key violation for a specified set of columns or for a specified index. When a unique key violation is encountered, a row-level rollback occurs and execution resumes with the next input row. If you specify this hint when inserting data with DML error logging enabled, then the unique key violation is not logged and does not cause statement termination.

The semantic effect of this hint results in error messages if specific rules are violated:

- If you specify `index`, then the index must exist and be unique. Otherwise, the statement causes ORA-38913.
- You must specify exactly one index. If you specify no index, then the statement causes ORA-38912. If you specify more than one index, then the statement causes ORA-38915.
- You can specify either a `CHANGE_DUPKEY_ERROR_INDEX` or `IGNORE_ROW_ON_DUPKEY_INDEX` hint in an `INSERT` statement, but not both. If you specify both, then the statement causes ORA-38915.

As with all hints, a syntax error in the hint causes it to be silently ignored. The result will be that ORA-00001 will be caused, just as if no hint were used.

---

**Note:** The `CHANGE_DUPKEY_ERROR_INDEX`, `IGNORE_ROW_ON_DUPKEY_INDEX`, and `RETRY_ON_ROW_CHANGE` hints are unlike other hints in that they have a semantic effect. The general philosophy explained in "Hints" on page 2-77 does not apply for these three hints.

---

The `INDEX` hint instructs the optimizer to use an index scan for the specified table. You can use the `INDEX` hint for function-based, domain, B-tree, bitmap, and bitmap join indexes.

The behavior of the hint depends on the `indexspec` specification:

- If the `INDEX` hint specifies a single available index, then the database performs a scan on this index. The optimizer does not consider a full table scan or a scan of another index on the table.
- For a hint on a combination of multiple indexes, Oracle recommends using `INDEX_COMBINE` rather than `INDEX`, because it is a more versatile hint. If the `INDEX` hint specifies a list of available indexes, then the optimizer considers the cost of a scan on each index in the list and then performs the index scan with the lowest cost. The database can also choose to scan multiple indexes from this list and merge the
results, if such an access path has the lowest cost. The database does not consider a full table scan or a scan on an index not listed in the hint.

- If the `INDEX` hint specifies no indexes, then the optimizer considers the cost of a scan on each available index on the table and then performs the index scan with the lowest cost. The database can also choose to scan multiple indexes and merge the results, if such an access path has the lowest cost. The optimizer does not consider a full table scan.

For example:

```sql
SELECT /*+ INDEX (employees emp_department_ix)*/ employee_id, department_id
FROM employees
WHERE department_id > 50;
```

### INDEX_ASC Hint

![INDEX_ASC Diagram](image)

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec`::= on page 2-79, `indexspec`::= on page 2-79)

The `INDEX_ASC` hint instructs the optimizer to use an index scan for the specified table. If the statement uses an index range scan, then Oracle Database scans the index entries in ascending order of their indexed values. Each parameter serves the same purpose as in "INDEX Hint" on page 2-90.

The default behavior for a range scan is to scan index entries in ascending order of their indexed values, or in descending order for a descending index. This hint does not change the default order of the index, and therefore does not specify anything more than the `INDEX` hint. However, you can use the `INDEX_ASC` hint to specify ascending range scans explicitly should the default behavior change.

### INDEX_COMBINE Hint

![INDEX_COMBINE Diagram](image)

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec`::= on page 2-79, `indexspec`::= on page 2-79)

The `INDEX_COMBINE` hint instructs the optimizer to use a bitmap access path for the table. If `indexspec` is omitted from the `INDEX_COMBINE` hint, then the optimizer uses whatever Boolean combination of indexes has the best cost estimate for the table. If you specify `indexspec`, then the optimizer tries to use some Boolean combination of the specified indexes. Each parameter serves the same purpose as in "INDEX Hint" on page 2-90. For example:

```sql
SELECT /*+ INDEX_COMBINE(e emp_manager_ix emp_department_ix) */ *
FROM employees e
WHERE manager_id = 108
   OR department_id = 110;
```
INDEX_DESC Hint

The INDEX_DESC hint instructs the optimizer to use a descending index scan for the specified table. If the statement uses an index range scan and the index is ascending, then Oracle scans the index entries in descending order of their indexed values. In a partitioned index, the results are in descending order within each partition. For a descending index, this hint effectively cancels out the descending order, resulting in a scan of the index entries in ascending order. Each parameter serves the same purpose as in "INDEX Hint" on page 2-90. For example:

```sql
SELECT /*+ INDEX_DESC(e emp_name_ix) */ * 
FROM employees e;
```

See Also: Oracle Database SQL Tuning Guide for information on full scans

INDEX_FFS Hint

The INDEX_FFS hint instructs the optimizer to perform a fast full index scan rather than a full table scan.

Each parameter serves the same purpose as in "INDEX Hint" on page 2-90. For example:

```sql
SELECT /*+ INDEX_FFS(e emp_name_ix) */ first_name 
FROM employees e;
```

INDEX_JOIN Hint

The INDEX_JOIN hint instructs the optimizer to use an index join as an access path. For the hint to have a positive effect, a sufficiently small number of indexes must exist that contain all the columns required to resolve the query.

Each parameter serves the same purpose as in "INDEX Hint" on page 2-90. For example, the following query uses an index join to access the manager_id and department_id columns, both of which are indexed in the employees table.

```sql
SELECT /*+ INDEX_JOIN(e emp_manager_ix emp_department_ix) */ department_id 
FROM employees e 
WHERE manager_id < 110
```
AND department_id < 50;

**INDEX_SS Hint**

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79, `indexspec::=` on page 2-79)

The `INDEX_SS` hint instructs the optimizer to perform an index skip scan for the specified table. If the statement uses an index range scan, then Oracle scans the index entries in ascending order of their indexed values. In a partitioned index, the results are in ascending order within each partition.

Each parameter serves the same purpose as in "INDEX Hint" on page 2-90. For example:

```sql
SELECT /*+ INDEX_SS(e emp_name_ix) */ last_name
FROM employees e
WHERE first_name = 'Steven';
```

**INDEX_SS_ASC Hint**

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79, `indexspec::=` on page 2-79)

The `INDEX_SS_ASC` hint instructs the optimizer to perform an index skip scan for the specified table. If the statement uses an index range scan, then Oracle Database scans the index entries in ascending order of their indexed values. In a partitioned index, the results are in ascending order within each partition. Each parameter serves the same purpose as in "INDEX Hint" on page 2-90.

The default behavior for a range scan is to scan index entries in ascending order of their indexed values, or in descending order for a descending index. This hint does not change the default order of the index, and therefore does not specify anything more than the `INDEX_SS` hint. However, you can use the `INDEX_SS_ASC` hint to specify ascending range scans explicitly should the default behavior change.

**INDEX_SS_DESC Hint**

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79, `indexspec::=` on page 2-79)
The `INDEX_SS_DESC` hint instructs the optimizer to perform an index skip scan for the specified table. If the statement uses an index range scan and the index is ascending, then Oracle scans the index entries in descending order of their indexed values. In a partitioned index, the results are in descending order within each partition. For a descending index, this hint effectively cancels out the descending order, resulting in a scan of the index entries in ascending order.

Each parameter serves the same purpose as in the "INDEX Hint" on page 2-90. For example:

```sql
SELECT /*+ INDEX_SS_DESC(e emp_name_ix) */ last_name
FROM employees e
WHERE first_name = 'Steven';
```

**See Also:** Oracle Database SQL Tuning Guide for information on index skip scans

### INMEMORY Hint

**Note:** The INMEMORY hint is available starting with Oracle Database 12c Release 1 (12.1.0.2).

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The INMEMORY hint enables in-memory queries.

This hint does not instruct the optimizer to perform a full table scan. If a full table scan is desired, then also specify the "FULL Hint" on page 2-89.

### INMEMORY_PRUNING Hint

**Note:** The INMEMORY_PRUNING hint is available starting with Oracle Database 12c Release 1 (12.1.0.2).

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The INMEMORY_PRUNING hint enables pruning of in-memory queries.

### LEADING Hint

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The LEADING hint instructs the optimizer to use the specified set of tables as the prefix in the execution plan. This hint is more versatile than the ORDERED hint. For example:
SELECT /*+ LEADING(e j) */ * 
FROM employees e, departments d, job_history j 
WHERE e.department_id = d.department_id 
AND e.hire_date = j.start_date;

The LEADING hint is ignored if the tables specified cannot be joined first in the order specified because of dependencies in the join graph. If you specify two or more conflicting LEADING hints, then all of them are ignored. If you specify the ORDERED hint, it overrides all LEADING hints.

**MERGE Hint**

(See "Specifying a Query Block in a Hint" on page 2-78, tablespec::= on page 2-79)

The MERGE hint lets you merge views in a query. If a view’s query block contains a GROUP BY clause or DISTINCT operator in the SELECT list, then the optimizer can merge the view into the accessing statement only if complex view merging is enabled. Complex merging can also be used to merge an IN subquery into the accessing statement if the subquery is uncorrelated.

For example:

```sql
SELECT /*+ MERGE(v) */ e1.last_name, e1.salary, v.avg_salary 
FROM employees e1, 
(SELECT department_id, avg(salary) avg_salary 
FROM employees e2 
GROUP BY department_id) v 
WHERE e1.department_id = v.department_id 
AND e1.salary > v.avg_salary 
ORDER BY e1.last_name;
```

When the MERGE hint is used without an argument, it should be placed in the view query block. When MERGE is used with the view name as an argument, it should be placed in the surrounding query.

**MODEL_MIN_ANALYSIS Hint**

The MODEL_MIN_ANALYSIS hint instructs the optimizer to omit some compile-time optimizations of spreadsheet rules—primarily detailed dependency graph analysis. Other spreadsheet optimizations, such as creating filters to selectively populate spreadsheet access structures and limited rule pruning, are still used by the optimizer.

This hint reduces compilation time because spreadsheet analysis can be lengthy if the number of spreadsheet rules is more than several hundreds.

**MONITOR Hint**
The `MONITOR` hint forces real-time SQL monitoring for the query, even if the statement is not long running. This hint is valid only when the parameter `CONTROL_MANAGEMENT_PACK_ACCESS` is set to `DIAGNOSTIC+TUNING`.

**See Also:** Oracle Database SQL Tuning Guide for more information about real-time SQL monitoring

### NATIVE_FULL_OUTER_JOIN Hint

```
/*+ NATIVE_FULL_OUTER_JOIN */
```

The `NATIVE_FULL_OUTER_JOIN` hint instructs the optimizer to use native full outer join, which is a native execution method based on a hash join.

**See Also:**
- `NO_NATIVE_FULL_OUTER_JOIN Hint` on page 2-100
- Oracle Database SQL Tuning Guide for more information about native full outer joins

### NOAPPEND Hint

```
/*+ NOAPPEND */
```

The `NOAPPEND` hint instructs the optimizer to use conventional `INSERT` by disabling parallel mode for the duration of the `INSERT` statement. Conventional `INSERT` is the default in serial mode, and direct-path `INSERT` is the default in parallel mode.

### NOCACHE Hint

```
/*+ NOCACHE */
```

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The `NOCACHE` hint instructs the optimizer to place the blocks retrieved for the table at the least recently used end of the LRU list in the buffer cache when a full table scan is performed. This is the normal behavior of blocks in the buffer cache. For example:

```
SELECT /*+ FULL(hr_emp) NOCACHE(hr_emp) */ last_name
FROM employees hr_emp;
```

The `CACHE` and `NOCACHE` hints affect system statistics `table scans(long tables)` and `table scans(short tables)`, as shown in the `V$SYSSTAT` view.

### NO_CLUSTERING Hint

```
/*+ NO_CLUSTERING */
```

**Note:** The `NO_CLUSTERING` hint is available starting with Oracle Database 12c Release 1 (12.1.0.2).
This hint is valid only for INSERT and MERGE operations on tables that are enabled for attribute clustering. The NO_CLUSTERING hint disables attribute clustering for direct-path inserts (serial or parallel). This hint overrides a YES ON LOAD setting in the DDL that created or altered the table. This hint has no effect on tables that are not enabled for attribute clustering.

**See Also:**
- `clustering_when` clause of CREATE TABLE on page 16-79 for more information on the YES ON LOAD setting
- "CLUSTERING Hint" on page 2-86

**NO_EXPAND Hint**

```
/*+ NO_EXPAND */
```

(See "Specifying a Query Block in a Hint" on page 2-78)

The NO_EXPAND hint instructs the optimizer not to consider OR-expansion for queries having OR conditions or IN-lists in the WHERE clause. Usually, the optimizer considers using OR expansion and uses this method if it decides that the cost is lower than not using it. For example:

```
SELECT /*+ NO_EXPAND */ *
FROM employees e, departments d
WHERE e.manager_id = 108
  OR d.department_id = 110;
```

**See Also:** The "USE_CONCAT Hint" on page 2-116, which is the opposite of this hint

**NO_FACT Hint**

```
/*+ NO_FACT */
```

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The NO_FACT hint is used in the context of the star transformation. It instructs the optimizer that the queried table should not be considered as a fact table.

**NO_GATHER_OPTIMIZER_STATISTICS Hint**

```
/*+ NO_GATHER_OPTIMIZER_STATISTICS */
```

The NO_GATHER_OPTIMIZER_STATISTICS hint instructs the optimizer to disable statistics gathering during the following types of bulk loads:
- CREATE TABLE AS SELECT
- INSERT INTO ... SELECT into an empty table using a direct path insert

**See Also:** *Oracle Database SQL Tuning Guide* for more information on statistics gathering for bulk loads
**NO_INDEX Hint**

(See "Specifying a Query Block in a Hint" on page 2-78, tablespec::= on page 2-79, indexspec::= on page 2-79)

The **NO_INDEX** hint instructs the optimizer not to use one or more indexes for the specified table. For example:

```sql
SELECT /*+ NO_INDEX(employees emp_empid) */ employee_id
FROM employees
WHERE employee_id > 200;
```

Each parameter serves the same purpose as in "INDEX Hint" on page 2-90 with the following modifications:

- If this hint specifies a single available index, then the optimizer does not consider a scan on this index. Other indexes not specified are still considered.
- If this hint specifies a list of available indexes, then the optimizer does not consider a scan on any of the specified indexes. Other indexes not specified in the list are still considered.
- If this hint specifies no indexes, then the optimizer does not consider a scan on any index on the table. This behavior is the same as a **NO_INDEX** hint that specifies a list of all available indexes for the table.

The **NO_INDEX** hint applies to function-based, B-tree, bitmap, cluster, or domain indexes. If a **NO_INDEX** hint and an index hint (INDEX, INDEX_ASC, INDEX_DESC, INDEX_COMBINE, or INDEX_FFS) both specify the same indexes, then the database ignores both the **NO_INDEX** hint and the index hint for the specified indexes and considers those indexes for use during execution of the statement.

**NO_INDEX_FFS Hint**

(See "Specifying a Query Block in a Hint" on page 2-78, tablespec::= on page 2-79, indexspec::= on page 2-79)

The **NO_INDEX_FFS** hint instructs the optimizer to exclude a fast full index scan of the specified indexes on the specified table. Each parameter serves the same purpose as in the "NO_INDEX Hint" on page 2-98. For example:

```sql
SELECT /*+ NO_INDEX_FFS(items item_order_ix) */ order_id
FROM order_items items;
```

**NO_INDEX_SS Hint**

(See "Specifying a Query Block in a Hint" on page 2-78, tablespec::= on page 2-79, indexspec::= on page 2-79)
The **NO_INDEX_SS** hint instructs the optimizer to exclude a skip scan of the specified indexes on the specified table. Each parameter serves the same purpose as in the "**NO_INDEX Hint**" on page 2-98.

**See Also:**  *Oracle Database SQL Tuning Guide* for information on index skip scans

**NO_INMEMORY Hint**

**Note:** The **NO_INMEMORY** hint is available starting with Oracle Database 12c Release 1 (12.1.0.2).

(See "**Specifying a Query Block in a Hint**" on page 2-78, *tablespec::* on page 2-79) The **NO_INMEMORY** hint disables in-memory queries.

**NO_INMEMORY_PRUNING Hint**

**Note:** The **NO_INMEMORY_PRUNING** hint is available starting with Oracle Database 12c Release 1 (12.1.0.2).

(See "**Specifying a Query Block in a Hint**" on page 2-78, *tablespec::* on page 2-79) The **NO_INMEMORY_PRUNING** hint disables pruning of in-memory queries.

**NO_MERGE Hint**

(See "**Specifying a Query Block in a Hint**" on page 2-78, *tablespec::* on page 2-79) The **NO_MERGE** hint instructs the optimizer not to combine the outer query and any inline view queries into a single query.

This hint lets you have more influence over the way in which the view is accessed. For example, the following statement causes view *seattle_dept* not to be merged:

```sql
SELECT /*+ NO_MERGE(seattle_dept) */ e1.last_name, seattle_dept.department_name
FROM employees e1,
     (SELECT location_id, department_id, department_name
      FROM departments
      WHERE location_id = 1700) seattle_dept
WHERE e1.department_id = seattle_dept.department_id;
```
When you use the `NO_MERGE` hint in the view query block, specify it without an argument. When you specify `NO_MERGE` in the surrounding query, specify it with the view name as an argument.

**NO_MONITOR Hint**

```
/*+ NO_MONITOR */
```

The `NO_MONITOR` hint disables real-time SQL monitoring for the query, even if the query is long running.

**NO_NATIVE_FULL_OUTER_JOIN Hint**

```
/*+ NO_NATIVE_FULL_OUTER_JOIN */
```

The `NO_NATIVE_FULL_OUTER_JOIN` hint instructs the optimizer to exclude the native execution method when joining each specified table. Instead, the full outer join is executed as a union of left outer join and anti-join.

See Also:  [NATIVE_FULL_OUTER_JOIN Hint on page 2-96](#)

**NO_PARALLEL Hint**

```
/*+ NO_PARALLEL(queryblock.tablespec) */
```

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The `NO_PARALLEL` hint instructs the optimizer to run the statement serially. This hint overrides the value of the `PARALLEL_DEGREE_POLICY` initialization parameter. It also overrides a `PARALLEL` parameter in the DDL that created or altered the table. For example, the following `SELECT` statement will run serially:

```sql
ALTER TABLE employees PARALLEL 8;
SELECT /*+ NO_PARALLEL(hr_emp) */ last_name
   FROM employees hr_emp;
```

See Also:
- "Note on Parallel Hints" on page 2-106 for more information on the parallel hints
- *Oracle Database Reference* for more information on the `PARALLEL_DEGREE_POLICY` initialization parameter

**NOPARALLEL Hint**

The `NOPARALLEL` hint has been deprecated. Use the `NO_PARALLEL` hint instead.

**NO_PARALLEL_INDEX Hint**

```
/*+ NO_PARALLEL_INDEX(queryblock.tablespec.indexspec) */
```

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79, `indexspec::=` on page 2-79)
The **NO_PARALLEL_INDEX** hint overrides a `PARALLEL` parameter in the DDL that created or altered the index, thus avoiding a parallel index scan operation.

**See Also:** "Note on Parallel Hints" on page 2-106 for more information on the parallel hints

**NOPARALLEL_INDEX Hint**
The **NOPARALLEL_INDEX** hint has been deprecated. Use the **NO_PARALLEL_INDEX** hint instead.

**NO_PQ_CONCURRENT_UNION Hint**

(See "Specifying a Query Block in a Hint" on page 2-78)
The **NO_PQ_CONCURRENT_UNION** hint instructs the optimizer to disable concurrent processing of `UNION` and `UNION ALL` operations.

**See Also:**
- "PQ_CONCURRENT_UNION Hint" on page 2-109
- Oracle Database VLDB and Partitioning Guide for information about using this hint

**NO_PQ_SKEW Hint**

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)
The **NO_PQ_SKEW** hint advises the optimizer that the distribution of the values of the join keys for a parallel join is not skewed—that is, a high percentage of rows do not have the same join key values. The table specified in `tablespec` is the probe table of the hash join.

**NO_PUSH_PRED Hint**

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)
The **NO_PUSH_PRED** hint instructs the optimizer not to push a join predicate into the view. For example:

```sql
SELECT /*+ NO_MERGE(v) NO_PUSH_PRED(v) */ *
FROM employees e,
     (SELECT manager_id
      FROM employees) v
WHERE e.manager_id = v.manager_id(+)
AND e.employee_id = 100;
```
NO_PUSH_SUBQ Hint

```
/*+ NO_PUSH_SUBQ */
```

(See "Specifying a Query Block in a Hint" on page 2-78)

The NO_PUSH_SUBQ hint instructs the optimizer to evaluate nonmerged subqueries as the last step in the execution plan. Doing so can improve performance if the subquery is relatively expensive or does not reduce the number of rows significantly.

NO_PX_JOIN_FILTER Hint

```
/*+ NO_PX_JOIN_FILTER */
```

This hint prevents the optimizer from using parallel join bitmap filtering.

NO_QUERY_TRANSFORMATION Hint

```
/*+ NO_QUERY_TRANSFORMATION */
```

The NO_QUERY_TRANSFORMATION hint instructs the optimizer to skip all query transformations, including but not limited to OR-expansion, view merging, subquery unnesting, star transformation, and materialized view rewrite. For example:

```
SELECT /*+ NO_QUERY_TRANSFORMATION */ employee_id, last_name
FROM (SELECT * FROM employees e) v
WHERE v.last_name = 'Smith';
```

NO_RESULT_CACHE Hint

```
/*+ NO_RESULT_CACHE */
```

The optimizer caches query results in the result cache if the RESULT_CACHE_MODE initialization parameter is set to FORCE. In this case, the NO_RESULT_CACHE hint disables such caching for the current query.

If the query is executed from OCI client and OCI client result cache is enabled, then the NO_RESULT_CACHE hint disables caching for the current query.

NO_REWRITE Hint

```
/*+ NO_REWRITE */
```

(See "Specifying a Query Block in a Hint" on page 2-78)

The NO_REWRITE hint instructs the optimizer to disable query rewrite for the query block, overriding the setting of the parameter QUERY_REWRITE_ENABLED. For example:

```
SELECT /*+ NO_REWRITE */ sum(s.amount_sold) AS dollars
FROM sales s, times t
WHERE s.time_id = t.time_id
GROUP BY t.calendar_month_desc;
```
NOREWRITE Hint
The NOREWRITE hint has been deprecated. Use the NO_REWRITE hint instead.

NO_STAR_TRANSFORMATION Hint

(See "Specifying a Query Block in a Hint" on page 2-78)
The NO_STAR_TRANSFORMATION hint instructs the optimizer not to perform star query transformation.

NO_STATEMENT_QUEUING Hint

The NO_STATEMENT_QUEUING hint influences whether or not a statement is queued with parallel statement queuing.

When PARALLEL_DEGREE_POLICY is set to AUTO, this hint enables a statement to bypass the parallel statement queue. However, a statement that bypasses the statement queue can potentially cause the system to exceed the maximum number of parallel execution servers defined by the value of the PARALLEL_SERVERS_TARGET initialization parameter, which determines the limit at which parallel statement queuing is initiated.

There is no guarantee that the statement that bypasses the parallel statement queue receives the number of parallel execution servers requested because only the number of parallel execution servers available on the system, up to the value of the PARALLEL_MAX_SERVERS initialization parameter, can be allocated.

For example:

```
SELECT /*+ NO_STATEMENT_QUEUING */ emp.last_name, dpt.department_name
FROM employees emp, departments dpt
WHERE emp.department_id = dpt.department_id;
```

See Also: "STATEMENT_QUEUING Hint" on page 2-115

NO_UNNEST Hint

(See "Specifying a Query Block in a Hint" on page 2-78)
Use of the NO_UNNEST hint turns off unnesting.

NO_USE_CUBE Hint

(See "Specifying a Query Block in a Hint" on page 2-78, tablespec::= on page 2-79)
The NO_USE_CUBE hint instructs the optimizer to exclude cube joins when joining each specified table to another row source using the specified table as the inner table.
NO_USE_HASH Hint

The NO_USE_HASH hint instructs the optimizer to exclude hash joins when joining each specified table to another row source using the specified table as the inner table. For example:

```sql
SELECT /*+ NO_USE_HASH(e d) */ *  
FROM employees e, departments d  
WHERE e.department_id = d.department_id;
```

NO_USE_MERGE Hint

The NO_USE_MERGE hint instructs the optimizer to exclude sort-merge joins when joining each specified table to another row source using the specified table as the inner table. For example:

```sql
SELECT /*+ NO_USE_MERGE(e d) */ *  
FROM employees e, departments d  
WHERE e.department_id = d.department_id  
ORDER BY d.department_id;
```

NO_USE_NL Hint

The NO_USE_NL hint instructs the optimizer to exclude nested loops joins when joining each specified table to another row source using the specified table as the inner table. For example:

```sql
SELECT /*+ NO_USE_NL(l h) */ *  
FROM orders h, order_items l  
WHERE l.order_id = h.order_id  
AND l.order_id > 2400;
```

When this hint is specified, only hash join and sort-merge joins are considered for the specified tables. However, in some cases tables can be joined only by using nested loops. In such cases, the optimizer ignores the hint for those tables.

NO_XML_QUERY_REWRITE Hint

The NO_XML_QUERY_REWRITE hint instructs the optimizer to prohibit the rewriting of XPath expressions in SQL statements. By prohibiting the rewriting of XPath
expressions, this hint also prohibits the use of any XMLIndexes for the current query. For example:

```sql
SELECT /*+NO_XML_QUERY_REWRITE*/ XMLQUERY('<A/>' RETURNING CONTENT)
    FROM DUAL;
```

**See Also:** "NO_XMLINDEX_REWRITE Hint" on page 2-105

### NO_XMLINDEX_REWRITE Hint

```sql
/*+ NO_XMLINDEX_REWRITE */
```

The **NO_XMLINDEX_REWRITE** hint instructs the optimizer not to use any XMLIndex indexes for the current query. For example:

```sql
SELECT /*+NO_XMLINDEX_REWRITE*/ count(*)
    FROM warehouses
    WHERE existsNode(warehouse_spec, '/Warehouse/Building') = 1;
```

**See Also:** "NO_XML_QUERY_REWRITE Hint" on page 2-104 for another way to disable the use of XMLIndexes

### NO_ZONEMAP Hint

**Note:** The **NO_ZONEMAP** hint is available starting with Oracle Database 12c Release 1 (12.1.0.2).

```sql
/*+ NO_ZONEMAP */
```

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The **NO_ZONEMAP** hint disables the use of a zone map for different types of pruning. This hint overrides an **ENABLE PRUNING** setting in the DDL that created or altered the zone map.

Specify one of the following options:

- **SCAN** - Disables the use of a zone map for scan pruning.
- **JOIN** - Disables the use of a zone map for join pruning.
- **PARTITION** - Disables the use of a zone map for partition pruning.

**See Also:**

- **ENABLE | DISABLE PRUNING** clause of `CREATE MATERIALIZED ZONEMAP` on page 15-46
- *Oracle Database Data Warehousing Guide* for more information on pruning with zone maps
OPT_PARAM Hint

The OPT_PARAM hint lets you set an initialization parameter for the duration of the current query only. This hint is valid only for the following parameters: OPTIMIZER_DYNAMIC_SAMPLING, OPTIMIZER_INDEX_CACHING, OPTIMIZER_INDEX_COST_ADJ, OPTIMIZER_SECURE_VIEW_MERGING, and STAR_TRANSFORMATION_ENABLED. For example, the following hint sets the parameter STAR_TRANSFORMATION_ENABLED to TRUE for the statement to which it is added:

```
SELECT /*+ OPT_PARAM('star_transformation_enabled' 'true') */ *
FROM ... ;
```

Parameter values that are strings are enclosed in single quotation marks. Numeric parameter values are specified without quotation marks.

ORDERED Hint

The ORDERED hint instructs Oracle to join tables in the order in which they appear in the FROM clause. Oracle recommends that you use the LEADING hint, which is more versatile than the ORDERED hint.

When you omit the ORDERED hint from a SQL statement requiring a join, the optimizer chooses the order in which to join the tables. You might want to use the ORDERED hint to specify a join order if you know something that the optimizer does not know about the number of rows selected from each table. Such information lets you choose an inner and outer table better than the optimizer could.

The following query is an example of the use of the ORDERED hint:

```
SELECT /*+ ORDERED */ o.order_id, c.customer_id, l.unit_price * l.quantity
FROM customers c, order_items l, orders o
WHERE c.cust_last_name = 'Taylor'
AND o.customer_id = c.customer_id
AND o.order_id = l.order_id;
```

PARALLEL Hint

**Note on Parallel Hints**  Beginning with Oracle Database 11g Release 2, the PARALLEL and NO_PARALLEL hints are statement-level hints and supersede the earlier object-level hints: PARALLEL_INDEX, NO_PARALLEL_INDEX, and previously specified PARALLEL and NO_PARALLEL hints. For PARALLEL, if you specify integer, then that degree of parallelism will be used for the statement. If you omit integer, then the database computes the degree of parallelism. All the access paths that can use parallelism will use the specified or computed degree of parallelism.

In the syntax diagrams below, parallel_hint_statement shows the syntax for statement-level hints, and parallel_hint_object shows the syntax for object-level hints. Object-level hints are supported for backward compatibility, and are superseded by statement-level hints.
**parallel_hint_statement**:=

```
paralell | queryblock | tablespec | integer | DEFAULT | AUTO | MANUAL
```

**parallel_hint_object**:=

```
paralell | queryblock | tablespec | integer | DEFAULT | AUTO | MANUAL
```

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The PARALLEL hint instructs the optimizer to use the specified number of concurrent servers for a parallel operation. This hint overrides the value of the PARALLEL_DEGREE_POLICY initialization parameter. It applies to the SELECT, INSERT, MERGE, UPDATE, and DELETE portions of a statement, as well as to the table scan portion. If any parallel restrictions are violated, then the hint is ignored.

**Note:** The number of servers that can be used is twice the value in the PARALLEL hint, if sorting or grouping operations also take place.

For a statement-level PARALLEL hint:

- **PARALLEL**: The statement always is run parallel, and the database computes the degree of parallelism, which can be 2 or greater.

- **PARALLEL (DEFAULT)**: The optimizer calculates a degree of parallelism equal to the number of CPUs available on all participating instances times the value of the PARALLEL_THREADS_PER_CPU initialization parameter.

- **PARALLEL (AUTO)**: The database computes the degree of parallelism, which can be 1 or greater. If the computed degree of parallelism is 1, then the statement runs serially.

- **PARALLEL (MANUAL)**: The optimizer is forced to use the parallel settings of the objects in the statement.

- **PARALLEL (integer)**: The optimizer uses the degree of parallelism specified by integer.

In the following example, the optimizer calculates the degree of parallelism. The statement always runs in parallel.

```sql
SELECT /*+ PARALLEL */ last_name
   FROM employees;
```

In the following example, the optimizer calculates the degree of parallelism, but that degree may be 1, in which case the statement will run serially.

```sql
SELECT /*+ PARALLEL (AUTO) */ last_name
   FROM employees;
```
In the following example, the PARALLEL hint advises the optimizer to use the degree of parallelism currently in effect for the table itself, which is 5:

CREATE TABLE parallel_table (col1 number, col2 VARCHAR2(10)) PARALLEL 5;

SELECT /*+ PARALLEL (MANUAL) */ col2
  FROM parallel_table;

For an object-level PARALLEL hint:

- PARALLEL: The query coordinator should examine the settings of the initialization parameters to determine the default degree of parallelism.
- PARALLEL(integer): The optimizer uses the degree of parallelism specified by integer.
- PARALLEL(DEFAULT): The optimizer calculates a degree of parallelism equal to the number of CPUs available on all participating instances times the value of the PARALLEL_THREADS_PER_CPU initialization parameter.

In the following example, the PARALLEL hint overrides the degree of parallelism specified in the employees table definition:

SELECT /*+ FULL(hr_emp) PARALLEL(hr_emp, 5) */ last_name
  FROM employees hr_emp;

In the next example, the PARALLEL hint overrides the degree of parallelism specified in the employees table definition and instructs the optimizer to calculate a degree of parallelism equal to the number of CPUs available on all participating instances times the value of the PARALLEL_THREADS_PER_CPU initialization parameter.

SELECT /*+ FULL(hr_emp) PARALLEL(hr_emp, DEFAULT) */ last_name
  FROM employees hr_emp;

Refer to CREATE TABLE on page 16-6 and Oracle Database Concepts for more information on parallel execution.

See Also:

- CREATE TABLE on page 16-6 and Oracle Database Concepts for more information on parallel execution.
- Oracle Database PL/SQL Packages and Types Reference for information on the DBMS_PARALLEL_EXECUTE package, which provides methods to apply table changes in chunks of rows. Changes to each chunk are independently committed when there are no errors.
- Oracle Database Reference for more information on the PARALLEL DEGREE_POLICY initialization parameter
- NO_PARALLEL Hint on page 2-100
PARALLEL_INDEX Hint

The PARALLEL_INDEX hint instructs the optimizer to use the specified number of concurrent servers to parallelize index range scans, full scans, and fast full scans for partitioned indexes.

The integer value indicates the degree of parallelism for the specified index. Specifying DEFAULT or no value signifies that the query coordinator should examine the settings of the initialization parameters to determine the default degree of parallelism. For example, the following hint indicates three parallel execution processes are to be used:

```
SELECT /*+ PARALLEL_INDEX(table1, index1, 3) */
```

See Also: "Note on Parallel Hints" on page 2-106 for more information on the parallel hints

PQ_CONCURRENT_UNION Hint

The PQ_CONCURRENT_UNION hint instructs the optimizer to enable concurrent processing of UNION and UNION ALL operations.

See Also:

- "NO_PQ_CONCURRENT_UNION Hint" on page 2-101
- Oracle Database VLDB and Partitioning Guide for information about using this hint

PQ_DISTRIBUTE Hint

The PQ_DISTRIBUTE hint instructs the optimizer how to distribute rows among producer and consumer query servers. You can control the distribution of rows for either joins or for load.
Control of Distribution for Load  You can control the distribution of rows for parallel
INSERT ... SELECT and parallel CREATE TABLE ... AS SELECT statements to direct how rows
should be distributed between the producer (query) and the consumer (load) servers.
Use the upper branch of the syntax by specifying a single distribution method. The
values of the distribution methods and their semantics are described in Table 2–22 on
page 2-110.

Table 2–22 Distribution Values for Load

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Description</th>
</tr>
</thead>
</table>
| NONE         | No distribution. That is the query and load operation are combined into each query server. All servers will load all partitions. This lack of distribution is useful to avoid the overhead of distributing rows where there is no skew. Skew can occur due to empty segments or to a predicate in the statement that filters out all rows evaluated by the query. If skew occurs due to using this method, then use either RANDOM or RANDOM_LOCAL distribution instead.   
  Note: Use this distribution with care. Each partition loaded requires a minimum of 512 KB per process of PGA memory. If you also use compression, then approximately 1.5 MB of PGA memory is consumed per server. |
| PARTITION    | This method uses the partitioning information of tablespec to distribute the rows from the query servers to the load servers. Use this distribution method when it is not possible or desirable to combine the query and load operations, when the number of partitions being loaded is greater than or equal to the number of load servers, and the input data will be evenly distributed across the partitions being loaded—that is, there is no skew. |
| RANDOM       | This method distributes the rows from the producers in a round-robin fashion to the consumers. Use this distribution method when the input data is highly skewed. |
| RANDOM_LOCAL | This method distributes the rows from the producers to a set of servers that are responsible for maintaining a given set of partitions. Two or more servers can be loading the same partition, but no servers are loading all partitions. Use this distribution method when the input data is skewed and combining query and load operations is not possible due to memory constraints. |

For example, in the following direct-path insert operation, the query and load portions of the operation are combined into each query server:

```sql
INSERT /*+ APPEND PARALLEL(target_table, 16) PQ_DISTRIBUTE(target_table, NONE) */
INTO target_table
SELECT * FROM source_table;
```

In the following table creation example, the optimizer uses the partitioning of target_table to distribute the rows:

```sql
CREATE /*+ PQ_DISTRIBUTE(target_table, PARTITION) */ TABLE target_table
NOLOGGING PARALLEL 16
PARTITION BY HASH (l_orderkey) PARTITIONS 512
AS SELECT * FROM source_table;
```

Control of Distribution for Joins  You control the distribution method for joins by specifying two distribution methods, as shown in the lower branch of the syntax diagram, one distribution for the outer table and one distribution for the inner table.

- outer_distribution is the distribution for the outer table.
• *inner_distribution* is the distribution for the inner table.

The values of the distributions are **HASH, BROADCAST, PARTITION, and NONE**. Only six combinations table distributions are valid, as described in Table 2–23:

### Table 2–23 Distribution Values for Joins

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HASH, HASH</td>
<td>The rows of each table are mapped to consumer query servers, using a hash function on the join keys. When mapping is complete, each query server performs the join between a pair of resulting partitions. This distribution is recommended when the tables are comparable in size and the join operation is implemented by hash-join or sort merge join.</td>
</tr>
<tr>
<td>BROADCAST, NONE</td>
<td>All rows of the outer table are broadcast to each query server. The inner table rows are randomly partitioned. This distribution is recommended when the outer table is very small compared with the inner table. As a general rule, use this distribution when the inner table size multiplied by the number of query servers is greater than the outer table size.</td>
</tr>
<tr>
<td>NONE, BROADCAST</td>
<td>All rows of the inner table are broadcast to each consumer query server. The outer table rows are randomly partitioned. This distribution is recommended when the inner table is very small compared with the outer table. As a general rule, use this distribution when the inner table size multiplied by the number of query servers is less than the outer table size.</td>
</tr>
</tbody>
</table>
| PARTITION, NONE   | The rows of the outer table are mapped using the partitioning of the inner table. The inner table must be partitioned on the join keys. This distribution is recommended when the number of partitions of the outer table is equal to or nearly equal to a multiple of the number of query servers; for example, 14 partitions and 15 query servers.  
**Note:** The optimizer ignores this hint if the inner table is not partitioned or not equijoined on the partitioning key. |
| NONE, PARTITION   | The rows of the inner table are mapped using the partitioning of the outer table. The outer table must be partitioned on the join keys. This distribution is recommended when the number of partitions of the outer table is equal to or nearly equal to a multiple of the number of query servers; for example, 14 partitions and 15 query servers.  
**Note:** The optimizer ignores this hint if the outer table is not partitioned or not equijoined on the partitioning key. |
| NONE, NONE        | Each query server performs the join operation between a pair of matching partitions, one from each table. Both tables must be equipartitioned on the join keys. |

For example, given two tables \( r \) and \( s \) that are joined using a hash join, the following query contains a hint to use hash distribution:

```sql
SELECT /*+ORDERED PQ_DISTRIBUTE(r HASH, HASH) USE_HASH (r)*/ column_list
FROM r,s
WHERE r.c=s.c;
```

To broadcast the outer table \( r \), the query is:

```sql
SELECT /*+ORDERED PQ_DISTRIBUTE(s BROADCAST, NONE) USE_HASH (s) */ column_list
FROM r,s
WHERE r.c=s.c;
```
PQ_FILTER Hint

The PQ_FILTER hint instructs the optimizer on how to process rows when filtering correlated subqueries.

- **SERIAL**: Process rows serially on the left and right sides of the filter. Use this option when the overhead of parallelization is too high for the query, for example, when the left side has very few rows.

- **NONE**: Process rows in parallel on the left and right sides of the filter. Use this option when there is no skew in the distribution of the data on the left side of the filter and you would like to avoid distribution of the left side, for example, due to the large size of the left side.

- **HASH**: Process rows in parallel on the left side of the filter using a hash distribution. Process rows serially on the right side of the filter. Use this option when there is no skew in the distribution of data on the left side of the filter.

- **RANDOM**: Process rows in parallel on the left side of the filter using a random distribution. Process rows serially on the right side of the filter. Use this option when there is skew in the distribution of data on the left side of the filter.

PQ_SKEW Hint

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The PQ_SKEW hint advises the optimizer that the distribution of the values of the join keys for a parallel join is highly skewed—that is, a high percentage of rows have the same join key values. The table specified in `tablespec` is the probe table of the hash join.

PUSH_PRED Hint

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The PUSH_PRED hint instructs the optimizer to push a join predicate into the view. For example:

```sql
SELECT /*+ NO_MERGE(v) PUSH_PRED(v) */ * 
FROM employees e,
     (SELECT manager_id 
      FROM employees) v 
WHERE e.manager_id = v.manager_id(+)
```
AND e.employee_id = 100;

**PUSH_SUBQ Hint**

(See "Specifying a Query Block in a Hint" on page 2-78)

The `PUSH_SUBQ` hint instructs the optimizer to evaluate nonmerged subqueries at the earliest possible step in the execution plan. Generally, subqueries that are not merged are executed as the last step in the execution plan. If the subquery is relatively inexpensive and reduces the number of rows significantly, then evaluating the subquery earlier can improve performance.

This hint has no effect if the subquery is applied to a remote table or one that is joined using a merge join.

**PX_JOIN_FILTER Hint**

This hint forces the optimizer to use parallel join bitmap filtering.

**QB_NAME Hint**

(See "Specifying a Query Block in a Hint" on page 2-78)

Use the `QB_NAME` hint to define a name for a query block. This name can then be used in a hint in the outer query or even in a hint in an inline view to affect query execution on the tables appearing in the named query block.

If two or more query blocks have the same name, or if the same query block is hinted twice with different names, then the optimizer ignores all the names and the hints referencing that query block. Query blocks that are not named using this hint have unique system-generated names. These names can be displayed in the plan table and can also be used in hints within the query block, or in query block hints. For example:

```sql
SELECT /*+ QB_NAME(qb) FULL(@qb e) */ employee_id, last_name
FROM employees e
WHERE last_name = 'Smith';
```

**RESULT_CACHE Hint**

The `RESULT_CACHE` hint instructs the database to cache the results of the current query or query fragment in memory and then to use the cached results in future executions of the query or query fragment. The hint is recognized in the top-level query, the `subquery_factoring_clause`, or `FROM` clause inline view. The cached results reside in the result cache memory portion of the shared pool.

A cached result is automatically invalidated whenever a database object used in its creation is successfully modified. This hint takes precedence over settings of the `RESULT_CACHE_MODE` initialization parameter.
The query is eligible for result caching only if all functions entailed in the query—for example, built-in or user-defined functions or virtual columns—are deterministic.

If the query is executed from OCI client and OCI client result cache is enabled, then RESULT_CACHE hint enables client caching for the current query.

**See Also:** Oracle Database Performance Tuning Guide for information about using this hint, Oracle Database Reference for information about the RESULT_CACHE_MODE initialization parameter, and Oracle Call Interface Programmer’s Guide for more information about the OCI result cache and usage guidelines

**RETRY_ON_ROW_CHANGE Hint**

![RETRY_ON_ROW_CHANGE](image)

*Note:* The CHANGE_DUPKEY_ERROR_INDEX, IGNORE_ROW_ON_DUPKEY_INDEX, and RETRY_ON_ROW_CHANGE hints are unlike other hints in that they have a semantic effect. The general philosophy explained in "Hints" on page 2-77 does not apply for these three hints.

This hint is valid only for UPDATE and DELETE operations. It is not supported for INSERT or MERGE operations. When you specify this hint, the operation is retried when the ORA_ROWSCN for one or more rows in the set has changed from the time the set of rows to be modified is determined to the time the block is actually modified.

**See Also:** IGNORE_ROW_ON_DUPKEY_INDEX Hint on page 2-89 and CHANGE_DUPKEY_ERROR_INDEX Hint on page 2-85

**REWRITE Hint**

![REWRITE](image)

(See "Specifying a Query Block in a Hint" on page 2-78)

The REWRITE hint instructs the optimizer to rewrite a query in terms of materialized views, when possible, without cost consideration. Use the REWRITE hint with or without a view list. If you use REWRITE with a view list and the list contains an eligible materialized view, then Oracle uses that view regardless of its cost.

Oracle does not consider views outside of the list. If you do not specify a view list, then Oracle searches for an eligible materialized view and always uses it regardless of the cost of the final plan.

**See Also:**
- Oracle Database Concepts and Oracle Database Advanced Replication for more information on materialized views
- Oracle Database Data Warehousing Guide for more information on using REWRITE with materialized views
STAR_TRANSFORMATION Hint

The STAR_TRANSFORMATION hint instructs the optimizer to use the best plan in which the transformation has been used. Without the hint, the optimizer could make a query optimization decision to use the best plan generated without the transformation, instead of the best plan for the transformed query. For example:

```sql
SELECT /*+ STAR_TRANSFORMATION */ s.time_id, s.prod_id, s.channel_id
FROM sales s, times t, products p, channels c
WHERE s.time_id = t.time_id
    AND s.prod_id = p.prod_id
    AND s.channel_id = c.channel_id
    AND c.channel_desc = 'Tele Sales';
```

Even if the hint is specified, there is no guarantee that the transformation will take place. The optimizer generates the subqueries only if it seems reasonable to do so. If no subqueries are generated, then there is no transformed query, and the best plan for the untransformed query is used, regardless of the hint.

See Also:

- Oracle Database Data Warehousing Guide for a full discussion of star transformation.
- Oracle Database Reference for more information on the STAR_TRANSFORMATION_ENABLED initialization parameter.

STATEMENT_QUEUING Hint

The NO_STATEMENT_QUEUING hint influences whether or not a statement is queued with parallel statement queuing.

When PARALLEL_DEGREE_POLICY is not set to AUTO, this hint enables a statement to be considered for parallel statement queuing, but to run only when enough parallel processes are available to run at the requested DOP. The number of available parallel execution servers, before queuing is enabled, is equal to the difference between the number of parallel execution servers in use and the maximum number allowed in the system, which is defined by the PARALLEL_SERVERS_TARGET initialization parameter.

For example:

```sql
SELECT /*+ STATEMENT_QUEUING */ emp.last_name, dpt.department_name
FROM employees emp, departments dpt
WHERE emp.department_id = dpt.department_id;
```

See Also: "NO_STATEMENT_QUEUING Hint" on page 2-103

UNNEST Hint
The UNNEST hint instructs the optimizer to unnest and merge the body of the subquery into the body of the query block that contains it, allowing the optimizer to consider them together when evaluating access paths and joins.

Before a subquery is unnested, the optimizer first verifies whether the statement is valid. The statement must then pass heuristic and query optimization tests. The UNNEST hint instructs the optimizer to check the subquery block for validity only. If the subquery block is valid, then subquery unnesting is enabled without checking the heuristics or costs.

See Also:
- "Collection Unnesting: Examples" on page 19-74 for more information on unnesting nested subqueries and the conditions that make a subquery block valid
- Oracle Database SQL Tuning Guide for additional information on subquery unnesting

USE_CONCAT Hint

The USE_CONCAT hint instructs the optimizer to transform combined OR-conditions in the WHERE clause of a query into a compound query using the UNION ALL set operator. Without this hint, this transformation occurs only if the cost of the query using the concatenations is cheaper than the cost without them. The USE_CONCAT hint overrides the cost consideration. For example:

```sql
SELECT /*+ USE_CONCAT */ * 
FROM employees e 
WHERE manager_id = 108 
  OR department_id = 110;
```

See Also: The "NO_EXPAND Hint" on page 2-97, which is the opposite of this hint

USE_CUBE Hint

When the right-hand side of the join is a cube, the USE_CUBE hint instructs the optimizer to join each specified table with another row source using a cube join. If the optimizer decides not to use the cube join based on statistical analysis, then you can use USE_CUBE to override that decision.

USE_HASH Hint
The USE_HASH hint instructs the optimizer to join each specified table with another row source using a hash join. For example:

```sql
SELECT /*+ USE_HASH(l h) */ *
FROM orders h, order_items l
WHERE l.order_id = h.order_id
AND l.order_id > 2400;
```

**USE_MERGE Hint**

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The USE_MERGE hint instructs the optimizer to join each specified table with another row source using a sort-merge join. For example:

```sql
SELECT /*+ USE_MERGE(employees departments) */ *
FROM employees, departments
WHERE employees.department_id = departments.department_id;
```

Use of the USE_NL and USE_MERGE hints is recommended with the LEADING and ORDERED hints. The optimizer uses those hints when the referenced table is forced to be the inner table of a join. The hints are ignored if the referenced table is the outer table.

**USE_NL Hint**

The USE_NL hint instructs the optimizer to join each specified table to another row source with a nested loops join, using the specified table as the inner table.

(See "Specifying a Query Block in a Hint" on page 2-78, `tablespec::=` on page 2-79)

The USE_NL hint instructs the optimizer to join each specified table to another row source with a nested loops join, using the specified table as the inner table.

Use of the USE_NL and USE_MERGE hints is recommended with the LEADING and ORDERED hints. The optimizer uses those hints when the referenced table is forced to be the inner table of a join. The hints are ignored if the referenced table is the outer table.

In the following example, where a nested loop is forced through a hint, orders is accessed through a full table scan and the filter condition `l.order_id = h.order_id` is applied to every row. For every row that meets the filter condition, order_items is accessed through the index `order_id`.

```sql
SELECT /*+ USE_NL(l h) */ h.customer_id, l.unit_price * l.quantity
FROM orders h, order_items l
WHERE l.order_id = h.order_id;
```

Adding an INDEX hint to the query could avoid the full table scan on orders, resulting in an execution plan similar to one used on larger systems, even though it might not be particularly efficient here.
USE_NL_WITH_INDEX Hint

The **USE_NL_WITH_INDEX** hint instructs the optimizer to join the specified table to another row source with a nested loops join using the specified table as the inner table. For example:

```sql
SELECT /*+ USE_NL_WITH_INDEX(l item_product_ix) */ *
FROM orders h, order_items l
WHERE l.order_id = h.order_id
AND l.order_id > 2400;
```

The following conditions apply:

- If no index is specified, then the optimizer must be able to use some index with at least one join predicate as the index key.
- If an index is specified, then the optimizer must be able to use that index with at least one join predicate as the index key.

Database Objects

Oracle Database recognizes objects that are associated with a particular schema and objects that are not associated with any particular schema, as described in the sections that follow.

Schema Objects

A **schema** is a collection of logical structures of data, or schema objects. A schema is owned by a database user and has the same name as that user. Each user owns a single schema. Schema objects can be created and manipulated with SQL and include the following types of objects:

- Clusters
- Constraints
- Database links
- Database triggers
- Dimensions
- External procedure libraries
- Index-organized tables
- Indexes
- Indextypes
- Java classes, Java resources, Java sources
- Materialized views
- Materialized view logs
- Mining models
- Object tables
- Object types
- Object views
- Operators
- Packages
- Sequences
Database Object Names and Qualifiers

Nonschema Objects

Other types of objects are also stored in the database and can be created and manipulated with SQL but are not contained in a schema:

- Contexts
- Directories
- Editions
- Restore points
- Roles
- Rollback segments
- Tablespaces
- Users

In this reference, each type of object is described in Chapter 10 through Chapter 19, in the section devoted to the statement that creates the database object. These statements begin with the keyword `CREATE`. For example, for the definition of a cluster, see `CREATE CLUSTER` on page 14-11.

**See Also:** *Oracle Database Concepts* for an overview of database objects

You must provide names for most types of database objects when you create them. These names must follow the rules listed in the sections that follow.

Database Object Names and Qualifiers

Some database objects are made up of parts that you can or must name, such as the columns in a table or view, index and table partitions and subpartitions, integrity constraints on a table, and objects that are stored within a package, including procedures and stored functions. This section provides:

- Rules for naming database objects and database object location qualifiers
- Guidelines for naming database objects and qualifiers

**Note:** Oracle uses system-generated names beginning with "SYS_" for implicitly generated database objects and subobjects, and names beginning with "ORA_" for some Oracle-supplied objects. Oracle discourages you from using these prefixes in the names you explicitly provide to your database objects and subobjects to avoid possible conflict in name resolution.

Database Object Naming Rules

Every database object has a name. In a SQL statement, you represent the name of an object with a **quoted identifier** or a **nonquoted identifier**.

- A quoted identifier begins and ends with double quotation marks (" ). If you name a schema object using a quoted identifier, then you must use the double quotation marks whenever you refer to that object.
A nonquoted identifier is not surrounded by any punctuation.

You can use either quoted or nonquoted identifiers to name any database object. However, database names, global database names, and database link names are always case insensitive and are stored as uppercase. If you specify such names as quoted identifiers, then the quotation marks are silently ignored. Refer to CREATE USER on page 17-7 for additional rules for naming users and passwords.

**Note:** Oracle does not recommend using quoted identifiers for database object names. These quoted identifiers are accepted by SQL*Plus, but they may not be valid when using other tools that manage database objects.

The following list of rules applies to both quoted and nonquoted identifiers unless otherwise indicated:

1. Names must be from 1 to 30 bytes long with these exceptions:
   - Names of databases are limited to 8 bytes.
   - Names of database links can be as long as 128 bytes.

   If an identifier includes multiple parts separated by periods, then each attribute can be up to 30 bytes long. Each period separator, as well as any surrounding double quotation marks, counts as one byte. For example, suppose you identify a column like this:

   "schema"."table"."column"

   The schema name can be 30 bytes, the table name can be 30 bytes, and the column name can be 30 bytes. Each of the quotation marks and periods is a single-byte character, so the total length of the identifier in this example can be up to 98 bytes.

2. Nonquoted identifiers cannot be Oracle SQL reserved words. Quoted identifiers can be reserved words, although this is not recommended.

   Depending on the Oracle product you plan to use to access a database object, names might be further restricted by other product-specific reserved words.

   **Note:** The reserved word ROWID is an exception to this rule. You cannot use the uppercase word ROWID, either quoted or nonquoted, as a column name. However, you can use the uppercase word as a quoted identifier that is not a column name, and you can use the word with one or more lowercase letters (for example, "Rowid" or "rowid") as any quoted identifier, including a column name.

   **See Also:**

   - "Oracle SQL Reserved Words" on page E-1 for a listing of all Oracle SQL reserved words
   - The manual for a specific product, such as Oracle Database PL/SQL Language Reference, for a list of the reserved words of that product

   3. The Oracle SQL language contains other words that have special meanings. These words include data types, schema names, function names, the dummy system table DUAL, and keywords (the uppercase words in SQL statements, such as
DIMENSION, SEGMENT, ALLOCATE, DISABLE, and so forth). These words are not reserved. However, Oracle uses them internally in specific ways. Therefore, if you use these words as names for objects and object parts, then your SQL statements may be more difficult to read and may lead to unpredictable results.

In particular, do not use words beginning with SYS_ or ORA_ as schema object names, and do not use the names of SQL built-in functions for the names of schema objects or user-defined functions.

See Also:

- "Oracle SQL Keywords" on page E-3 for information how to obtain a list of keywords
- "Data Types" on page 2-1, About SQL Functions on page 7-2, and Selecting from the DUAL Table" on page 9-16

4. You should use characters from the ASCII repertoire in database names, global database names, and database link names, because these characters provide optimal compatibility across different platforms and operating systems. You must use only characters from the ASCII repertoire in names of common users and common roles in a multitenant container database (CDB).

5. You can include multibyte characters in passwords.

6. Nonquoted identifiers must begin with an alphabetic character from your database character set. Quoted identifiers can begin with any character.

7. Nonquoted identifiers can contain only alphanumeric characters from your database character set and the underscore (_), dollar sign ($), and pound sign (#). Database links can also contain periods (.) and “at” signs (@).

Quoted identifiers can contain any characters and punctuations marks as well as spaces. However, neither quoted nor nonquoted identifiers can contain double quotation marks or the null character (\0).

8. Within a namespace, no two objects can have the same name.

The following schema objects share one namespace:

- Packages
- Private synonyms
- Sequences
- Stand-alone procedures
- Stand-alone stored functions
- Tables
- User-defined operators
- User-defined types
- Views

Each of the following schema objects has its own namespace:

- Clusters
- Constraints
- Database triggers
- Dimensions
Indexes

Materialized views (When you create a materialized view, the database creates an internal table of the same name. This table has the same namespace as the other tables in the schema. Therefore, a schema cannot contain a table and a materialized view of the same name.)

Private database links

Because tables and sequences are in the same namespace, a table and a sequence in the same schema cannot have the same name. However, tables and indexes are in different namespaces. Therefore, a table and an index in the same schema can have the same name.

Each schema in the database has its own namespaces for the objects it contains. This means, for example, that two tables in different schemas are in different namespaces and can have the same name.

Each of the following nonschema objects also has its own namespace:

- Editions
- Parameter files (PFILEs) and server parameter files (SPFILEs)
- Profiles
- Public database links
- Public synonyms
- Tablespaces
- User roles

Because the objects in these namespaces are not contained in schemas, these namespaces span the entire database.

9. Nonquoted identifiers are not case sensitive. Oracle interprets them as uppercase. Quoted identifiers are case sensitive.

By enclosing names in double quotation marks, you can give the following names to different objects in the same namespace:

"employees"
"Employees"
"EMPLOYEES"

Note that Oracle interprets the following names the same, so they cannot be used for different objects in the same namespace:

employees
EMPLOYEES
"EMPLOYEES"

10. When Oracle stores or compares identifiers in uppercase, the uppercase form of each character in the identifiers is determined by applying the upercasing rules of the database character set. Language-specific rules determined by the session setting NLS_SORT are not considered. This behavior corresponds to applying the SQL function UPPER to the identifier rather than the function NLS_UPPER.

The database character set upercasing rules can yield results that are incorrect when viewed as being in a certain natural language. For example, small letter sharp s ("ß"), used in German, does not have an uppercase form according to the database character set upercasing rules. It is not modified when an identifier is converted into uppercase, while the expected uppercase form in German is the
sequence of two characters capital letter S ("SS"). Similarly, the uppercase form of small letter i, according to the database character set uppercasing rules, is capital letter I. However, the expected uppercase form in Turkish and Azerbaijani is capital letter I with dot above.

The database character set uppercasing rules ensure that identifiers are interpreted the same in any linguistic configuration of a session. If you want an identifier to look correctly in a certain natural language, then you can quote it to preserve the lowercase form or you can use the linguistically correct uppercase form whenever you use that identifier.

11. Columns in the same table or view cannot have the same name. However, columns in different tables or views can have the same name.

12. Procedures or functions contained in the same package can have the same name, if their arguments are not of the same number and data types. Creating multiple procedures or functions with the same name in the same package with different arguments is called **overloading** the procedure or function.

**Schema Object Naming Examples**

The following examples are valid schema object names:

- `last_name`
- `horse`
- `hr.hire_date`
- `'EVEN THIS & THAT!'`
- `a_very_long_and_valid_name`

All of these examples adhere to the rules listed in "Database Object Naming Rules" on page 2-119. The following example is not valid, because it exceeds 30 characters:

- `a_very_very_long_and_not_valid_name`

Although column aliases, table aliases, usernames, and passwords are not objects or parts of objects, they must also follow these naming rules unless otherwise specified in the rules themselves.

**Schema Object Naming Guidelines**

Here are several helpful guidelines for naming objects and their parts:

- Use full, descriptive, pronounceable names (or well-known abbreviations).
- Use consistent naming rules.
- Use the same name to describe the same entity or attribute across tables.

When naming objects, balance the objective of keeping names short and easy to use with the objective of making names as descriptive as possible. When in doubt, choose the more descriptive name, because the objects in the database may be used by many people over a period of time. Your counterpart ten years from now may have difficulty understanding a table column with a name like `pmdd` instead of `payment_due_date`.

Using consistent naming rules helps users understand the part that each table plays in your application. One such rule might be to begin the names of all tables belonging to the FINANCE application with `fin_`.

Use the same names to describe the same things across tables. For example, the department number columns of the sample `employees` and `departments` tables are both named `department_id`. 
Syntax for Schema Objects and Parts in SQL Statements

This section tells you how to refer to schema objects and their parts in the context of a SQL statement. This section shows you:

- The general syntax for referring to an object
- How Oracle resolves a reference to an object
- How to refer to objects in schemas other than your own
- How to refer to objects in remote databases
- How to refer to table and index partitions and subpartitions

The following diagram shows the general syntax for referring to an object or a part:

```
database_object_or_part ::= (schema::= on page 2-126)
```

where:

- `object` is the name of the object.
- `schema` is the schema containing the object. The schema qualifier lets you refer to an object in a schema other than your own. You must be granted privileges to refer to objects in other schemas. If you omit `schema`, then Oracle assumes that you are referring to an object in your own schema.

Only schema objects can be qualified with `schema`. Schema objects are shown with list item 8 on page 2-121. Nonschema objects, also shown with list item 8, cannot be qualified with `schema` because they are not schema objects. An exception is public synonyms, which can optionally be qualified with "PUBLIC". The quotation marks are required.

- `part` is a part of the object. This identifier lets you refer to a part of a schema object, such as a column or a partition of a table. Not all types of objects have parts.

- `dblink` applies only when you are using the Oracle Database distributed functionality. This is the name of the database containing the object. The `dblink` qualifier lets you refer to an object in a database other than your local database. If you omit `dblink`, then Oracle assumes that you are referring to an object in your local database. Not all SQL statements allow you to access objects on remote databases.

You can include spaces around the periods separating the components of the reference to the object, but it is conventional to omit them.

How Oracle Database Resolves Schema Object References

When you refer to an object in a SQL statement, Oracle considers the context of the SQL statement and locates the object in the appropriate namespace. After locating the object, Oracle performs the operation specified by the statement on the object. If the named object cannot be found in the appropriate namespace, then Oracle returns an error.
The following example illustrates how Oracle resolves references to objects within SQL statements. Consider this statement that adds a row of data to a table identified by the name `departments`:

```sql
INSERT INTO departments
VALUES (280, 'ENTERTAINMENT_CLERK', 206, 1700);
```

Based on the context of the statement, Oracle determines that `departments` can be:

- A table in your own schema
- A view in your own schema
- A private synonym for a table or view
- A public synonym

Oracle always attempts to resolve an object reference within the namespaces in your own schema before considering namespaces outside your schema. In this example, Oracle attempts to resolve the name `departments` as follows:

1. First, Oracle attempts to locate the object in the namespace in your own schema containing tables, views, and private synonyms. If the object is a private synonym, then Oracle locates the object for which the synonym stands. This object could be in your own schema, another schema, or on another database. The object could also be another synonym, in which case Oracle locates the object for which this synonym stands.

2. If the object is in the namespace, then Oracle attempts to perform the statement on the object. In this example, Oracle attempts to add the row of data to `departments`. If the object is not of the correct type for the statement, then Oracle returns an error. In this example, `departments` must be a table, view, or a private synonym resolving to a table or view. If `departments` is a sequence, then Oracle returns an error.

3. If the object is not in any namespace searched in thus far, then Oracle searches the namespace containing public synonyms. If the object is in that namespace, then Oracle attempts to perform the statement on it. If the object is not of the correct type for the statement, then Oracle returns an error. In this example, if `departments` is a public synonym for a sequence, then Oracle returns an error.

If a public synonym has any dependent tables or user-defined types, then you cannot create an object with the same name as the synonym in the same schema as the dependent objects.

If a synonym does not have any dependent tables or user-defined types, then you can create an object with the same name in the same schema as the dependent objects. Oracle invalidates any dependent objects and attempts to revalidate them when they are next accessed.

**See Also:** Oracle Database PL/SQL Language Reference for information about how PL/SQL resolves identifier names

### References to Objects in Other Schemas

To refer to objects in schemas other than your own, prefix the object name with the schema name:

`schema.object`

For example, this statement drops the `employees` table in the sample schema `hr`:

```sql
DROP TABLE hr.employees;
```
References to Objects in Remote Databases

To refer to objects in databases other than your local database, follow the object name with the name of the database link to that database. A database link is a schema object that causes Oracle to connect to a remote database to access an object there. This section tells you:

- How to create database links
- How to use database links in your SQL statements

Creating Database Links

You create a database link with the statement `CREATE DATABASE LINK` on page 14-44. The statement lets you specify this information about the database link:

- The name of the database link
- The database connect string to access the remote database
- The username and password to connect to the remote database

Oracle stores this information in the data dictionary.

Database Link Names

When you create a database link, you must specify its name. Database link names are different from names of other types of objects. They can be as long as 128 bytes and can contain periods (.) and the “at” sign (@).

The name that you give to a database link must correspond to the name of the database to which the database link refers and the location of that database in the hierarchy of database names. The following syntax diagram shows the form of the name of a database link:

```
dblink::= database domain @ connection_qualifier
```

where:

- `database` should specify the `name` portion of the global name of the remote database to which the database link connects. This global name is stored in the data dictionary of the remote database. You can see this name in the `GLOBAL_NAME` data dictionary view.

- `domain` should specify the `domain` portion of the global name of the remote database to which the database link connects. If you omit `domain` from the name of a database link, then Oracle qualifies the database link name with the domain of your local database as it currently exists in the data dictionary.

- `connection_qualifier` lets you further qualify a database link. Using connection qualifiers, you can create multiple database links to the same database. For example, you can use connection qualifiers to create multiple database links to different instances of the Oracle Real Application Clusters that access the same database.

See Also: Oracle Database Administrator’s Guide and Oracle Database Advanced Replication for more information on connection qualifiers

The combination `database.domain` is sometimes called the service name.
Username and Password  Oracle uses the username and password to connect to the remote database. The username and password for a database link are optional.

Database Connect String  The database connect string is the specification used by Oracle Net to access the remote database. For information on writing database connect strings, see the Oracle Net documentation for your specific network protocol. The database connect string for a database link is optional.

References to Database Links  Database links are available only if you are using Oracle distributed functionality. When you issue a SQL statement that contains a database link, you can specify the database link name in one of these forms:

- The complete database link name as stored in the data dictionary, including the database, domain, and optional connection_qualifier components.
- The partial database link name is the database and optional connection_qualifier components, but not the domain component.

Oracle performs these tasks before connecting to the remote database:

1. If the database link name specified in the statement is partial, then Oracle expands the name to contain the domain of the local database as found in the global database name stored in the data dictionary. (You can see the current global database name in the GLOBAL_NAME data dictionary view.)

2. Oracle first searches for a private database link in your own schema with the same name as the database link in the statement. Then, if necessary, it searches for a public database link with the same name.
   - Oracle always determines the username and password from the first matching database link (either private or public). If the first matching database link has an associated username and password, then Oracle uses it. If it does not have an associated username and password, then Oracle uses your current username and password.
   - If the first matching database link has an associated database string, then Oracle uses it. Otherwise Oracle searches for the next matching (public) database link. If no matching database link is found, or if no matching link has an associated database string, then Oracle returns an error.

3. Oracle uses the database string to access the remote database. After accessing the remote database, if the value of the GLOBAL_NAMES parameter is true, then Oracle verifies that the database.domain portion of the database link name matches the complete global name of the remote database. If this condition is true, then Oracle proceeds with the connection, using the username and password chosen in Step 2. If not, Oracle returns an error.

4. If the connection using the database string, username, and password is successful, then Oracle attempts to access the specified object on the remote database using the rules for resolving object references and referring to objects in other schemas discussed earlier in this section.

You can disable the requirement that the database.domain portion of the database link name must match the complete global name of the remote database by setting to FALSE the initialization parameter GLOBAL_NAMES or the GLOBAL_NAMES parameter of the ALTER SYSTEM or ALTER SESSION statement.
References to Partitioned Tables and Indexes

Tables and indexes can be partitioned. When partitioned, these schema objects consist of a number of parts called partitions, all of which have the same logical attributes. For example, all partitions in a table share the same column and constraint definitions, and all partitions in an index share the same index columns.

Partition-extended and subpartition-extended names let you perform some partition-level and subpartition-level operations, such as deleting all rows from a partition or subpartition, on only one partition or subpartition. Without extended names, such operations would require that you specify a predicate (WHERE clause). For range- and list-partitioned tables, trying to phrase a partition-level operation with a predicate can be cumbersome, especially when the range partitioning key uses more than one column. For hash partitions and subpartitions, using a predicate is more difficult still, because these partitions and subpartitions are based on a system-defined hash function.

Partition-extended names let you use partitions as if they were tables. An advantage of this method, which is most useful for range-partitioned tables, is that you can build partition-level access control mechanisms by granting (or revoking) privileges on these views to (or from) other users or roles. To use a partition as a table, create a view by selecting data from a single partition, and then use the view as a table.

Syntax

You can specify partition-extended or subpartition-extended table names in any SQL statement in which the partition_extended_name or subpartition_extended_name element appears in the syntax.

\[
\text{partition\_extended\_name} ::= \\
\text{PARTITION} \text{partition} \text{partition\_key\_value} \\
\text{PARTITION} \text{FOR} \text{partition\_key\_value} \\
\text{subpartition\_extended\_name} ::= \\
\text{SUBPARTITION} \text{subpartition} \text{subpartition\_key\_value} \\
\text{SUBPARTITION} \text{FOR} \text{subpartition\_key\_value}
\]

The DML statements INSERT, UPDATE, and DELETE and the ANALYZE statement require parentheses around the partition or subpartition name. This small distinction is reflected in the partition_extension_clause.
**Syntax for Schema Objects and Parts in SQL Statements**

**Basic Elements of Oracle SQL**

---

The `partition_extension_clause` can be expressed as follows:

\[
\text{partition_extension_clause ::=}
\]

- **PARTITION**
  - For
    - partition
    - partition_key_value
  - In `partition_extension_clause`
- **SUBPARTITION**
  - For
    - subpartition
    - subpartition_key_value
  - In `partition_extension_clause`

In `partition_extended_name`, `subpartition_extended_name`, and `partition_extension_clause`, the `PARTITION FOR` and `SUBPARTITION FOR` clauses let you refer to a partition without using its name. They are valid with any type of partitioning and are especially useful for interval partitions. Interval partitions are created automatically as needed when data is inserted into a table.

For the respective `partition_key_value` or `subpartition_key_value`, specify one value for each partitioning key column. For multicolumn partitioning keys, specify one value for each partitioning key. For composite partitions, specify one value for each partitioning key, followed by one value for each subpartitioning key. All partitioning key values are comma separated. For interval partitions, you can specify only one `partition_key_value`, and it must be a valid `NUMBER` or `datetime` value. Your SQL statement will operate on the partition or subpartitions that contain the values you specify.

**See Also:** The `CREATE TABLE "INTERVAL Clause"` on page 16-68 for more information on interval partitions.

**Restrictions on Extended Names** Currently, the use of partition-extended and subpartition-extended table names has the following restrictions:

- **No remote tables:** A partition-extended or subpartition-extended table name cannot contain a database link (dblink) or a synonym that translates to a table with a dblink. To use remote partitions and subpartitions, create a view at the remote site that uses the extended table name syntax and then refer to the remote view.

- **No synonyms:** A partition or subpartition extension must be specified with a base table. You cannot use synonyms, views, or any other objects.

- **The PARTITION FOR and SUBPARTITION FOR clauses are not valid for DDL operations on views.**

- **In the PARTITION FOR and SUBPARTITION FOR clauses, you cannot specify the keywords DEFAULT or MAXVALUE or a bind variable for the partition_key_value or subpartition_key_value.**

- **In the PARTITION and SUBPARTITION clauses, you cannot specify a bind variable for the partition or subpartition name.**

**Example** In the following statement, `sales` is a partitioned table with partition `sales_q1_2000`. You can create a view of the single partition `sales_q1_2000`, and then use it as if it were a table. This example deletes rows from the partition.

```sql
CREATE VIEW Q1_2000_sales AS
    SELECT *
    FROM sales PARTITION (SALES_Q1_2000);
```
DELETE FROM Q1_2000_sales
WHERE amount_sold < 0;

References to Object Type Attributes and Methods

To refer to object type attributes or methods in a SQL statement, you must fully qualify the reference with a table alias. Consider the following example from the sample schema oe, which contains a type cust_address_typ and a table customers with a cust_address column based on the cust_address_typ:

```
CREATE TYPE cust_address_typ
OID '82A4AP6A4CD1656DE034080020E0EE3D'
AS OBJECT
  (street_address    VARCHAR2(40),
  postal_code       VARCHAR2(10),
  city              VARCHAR2(30),
  state_province    VARCHAR2(10),
  country_id        CHAR(2));
/
CREATE TABLE customers
  (customer_id        NUMBER(6),
  cust_first_name    VARCHAR2(20) CONSTRAINT cust_fname_nn NOT NULL,
  cust_last_name     VARCHAR2(20) CONSTRAINT cust_lname_nn NOT NULL,
  cust_address       cust_address_typ,
  . . .

In a SQL statement, reference to the postal_code attribute must be fully qualified using a table alias, as illustrated in the following example:

```
SELECT c.cust_address.postal_code
FROM customers c;
```

```
UPDATE customers c
SET c.cust_address.postal_code = '14621-2604'
WHERE c.cust_address.city = 'Rochester'
  AND c.cust_address.state_province = 'NY';
```

To reference a member method that does not accept arguments, you must provide empty parentheses. For example, the sample schema oe contains an object table categories_tab, based on catalog_typ, which contains the member function getCatalogName. In order to call this method in a SQL statement, you must provide empty parentheses as shown in this example:

```
SELECT TREAT(VALUE(c) AS catalog_typ).getCatalogName() "Catalog Type"
FROM categories_tab c
WHERE category_id = 90;
```

Catalog Type

------------------------------------
online catalog
A pseudocolumn behaves like a table column, but is not actually stored in the table. You can select from pseudocolumns, but you cannot insert, update, or delete their values. A pseudocolumn is also similar to a function without arguments (refer to Chapter 7, "Functions"). However, functions without arguments typically return the same value for every row in the result set, whereas pseudocolumns typically return a different value for each row.

This chapter contains the following sections:

- Hierarchical Query Pseudocolumns
- Sequence Pseudocolumns
- Version Query Pseudocolumns
- COLUMN_VALUE Pseudocolumn
- OBJECT_ID Pseudocolumn
- OBJECT_VALUE Pseudocolumn
- ORA_ROWSCN Pseudocolumn
- ROWID Pseudocolumn
- ROWNUM Pseudocolumn
- XMLDATA Pseudocolumn

Hierarchical Query Pseudocolumns

The hierarchical query pseudocolumns are valid only in hierarchical queries. The hierarchical query pseudocolumns are:

- CONNECT_BY_ISCYCLE Pseudocolumn
- CONNECT_BY_ISLEAF Pseudocolumn
- LEVEL Pseudocolumn

To define a hierarchical relationship in a query, you must use the CONNECT BY clause.

CONNECT_BY_ISCYCLE Pseudocolumn

The CONNECT_BY_ISCYCLE pseudocolumn returns 1 if the current row has a child which is also its ancestor. Otherwise it returns 0.
You can specify `CONNECT_BY_ISCYCLE` only if you have specified the `NOCYCLE` parameter of the `CONNECT BY` clause. `NOCYCLE` enables Oracle to return the results of a query that would otherwise fail because of a `CONNECT BY` loop in the data.

**See Also:** "Hierarchical Queries" on page 9-3 for more information about the `NOCYCLE` parameter and "Hierarchical Query Examples" on page 9-5 for an example that uses the `CONNECT_BY_ISCYCLE` pseudocolumn

### CONNECT_BY_ISLEAF Pseudocolumn

The `CONNECT_BY_ISLEAF` pseudocolumn returns 1 if the current row is a leaf of the tree defined by the `CONNECT BY` condition. Otherwise it returns 0. This information indicates whether a given row can be further expanded to show more of the hierarchy.

**CONNECT_BY_ISLEAF Example**  The following example shows the first three levels of the `hr.employees` table, indicating for each row whether it is a leaf row (indicated by 1 in the `IsLeaf` column) or whether it has child rows (indicated by 0 in the `IsLeaf` column):

```sql
SELECT last_name 'Employee', CONNECT_BY_ISLEAF 'IsLeaf', LEVEL, SYS_CONNECT_BY_PATH(last_name, '/') 'Path'
FROM employees
WHERE LEVEL <= 3 AND department_id = 80
START WITH employee_id = 100
CONNECT BY PRIOR employee_id = manager_id AND LEVEL <= 4
ORDER BY 'Employee', 'IsLeaf';
```

<table>
<thead>
<tr>
<th>Employee</th>
<th>IsLeaf</th>
<th>LEVEL</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abel</td>
<td>1</td>
<td>3</td>
<td>/King/Zlotkey/Abel</td>
</tr>
<tr>
<td>Ande</td>
<td>1</td>
<td>3</td>
<td>/King/Errazuriz/Ande</td>
</tr>
<tr>
<td>Banda</td>
<td>1</td>
<td>3</td>
<td>/King/Errazuriz/Banda</td>
</tr>
<tr>
<td>Bates</td>
<td>1</td>
<td>3</td>
<td>/King/Cambrault/Bates</td>
</tr>
<tr>
<td>Bernstein</td>
<td>1</td>
<td>3</td>
<td>/King/Russell/Bernstein</td>
</tr>
<tr>
<td>Bloom</td>
<td>1</td>
<td>3</td>
<td>/King/Cambrault/Bloom</td>
</tr>
<tr>
<td>Cambrault</td>
<td>0</td>
<td>2</td>
<td>/King/Cambrault</td>
</tr>
<tr>
<td>Cambrault</td>
<td>1</td>
<td>3</td>
<td>/King/Russell/Cambrault</td>
</tr>
<tr>
<td>Doran</td>
<td>1</td>
<td>3</td>
<td>/King/Partners/Doran</td>
</tr>
<tr>
<td>Errazuriz</td>
<td>0</td>
<td>2</td>
<td>/King/Errazuriz</td>
</tr>
<tr>
<td>Fox</td>
<td>1</td>
<td>3</td>
<td>/King/Cambrault/Fox</td>
</tr>
<tr>
<td>. . .</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**See Also:** "Hierarchical Queries" on page 9-3 and SYS_CONNECT_BY_PATH on page 7-333

### LEVEL Pseudocolumn

For each row returned by a hierarchical query, the `LEVEL` pseudocolumn returns 1 for a root row, 2 for a child of a root, and so on. A **root row** is the highest row within an inverted tree. A **child row** is any nonroot row. A **parent row** is any row that has children. A **leaf row** is any row without children. Figure 3–1 shows the nodes of an inverted tree with their `LEVEL` values.
A sequence is a schema object that can generate unique sequential values. These values are often used for primary and unique keys. You can refer to sequence values in SQL statements with these pseudocolumns:

- CURRVAL: Returns the current value of a sequence
- NEXTVAL: Increments the sequence and returns the next value

You must qualify CURRVAL and NEXTVAL with the name of the sequence:

```sql
sequence.CURRVAL
sequence.NEXTVAL
```

To refer to the current or next value of a sequence in the schema of another user, you must have been granted either SELECT object privilege on the sequence or SELECT ANY SEQUENCE system privilege, and you must qualify the sequence with the schema containing it:

```sql
schema.sequence.CURRVAL
schema.sequence.NEXTVAL
```

To refer to the value of a sequence on a remote database, you must qualify the sequence with a complete or partial name of a database link:

```sql
schema.sequence.CURRVAL@dblink
schema.sequence.NEXTVAL@dblink
```

A sequence can be accessed by many users concurrently with no waiting or locking.

**Where to Use Sequence Values**

You can use CURRVAL and NEXTVAL in the following locations:

- The select list of a SELECT statement that is not contained in a subquery, materialized view, or view
- The select list of a subquery in an `INSERT` statement
- The `VALUES` clause of an `INSERT` statement
- The `SET` clause of an `UPDATE` statement

**Restrictions on Sequence Values** You cannot use `CURRVAL` and `NEXTVAL` in the following constructs:

- A subquery in a `DELETE`, `SELECT`, or `UPDATE` statement
- A query of a view or of a materialized view
- A `SELECT` statement with the `DISTINCT` operator
- A `SELECT` statement with a `GROUP BY` clause or `ORDER BY` clause
- A `SELECT` statement that is combined with another `SELECT` statement with the `UNION`, `INTERSECT`, or `MINUS` set operator
- The `WHERE` clause of a `SELECT` statement
- The condition of a `CHECK` constraint

Within a single SQL statement that uses `CURRVAL` or `NEXTVAL`, all referenced `LONG` columns, updated tables, and locked tables must be located on the same database.

**How to Use Sequence Values**

When you create a sequence, you can define its initial value and the increment between its values. The first reference to `NEXTVAL` returns the initial value of the sequence. Subsequent references to `NEXTVAL` increment the sequence value by the defined increment and return the new value. Any reference to `CURRVAL` always returns the current value of the sequence, which is the value returned by the last reference to `NEXTVAL`.

Before you use `CURRVAL` for a sequence in your session, you must first initialize the sequence with `NEXTVAL`. Refer to `CREATE SEQUENCE` on page 15-96 for information on sequences.

Within a single SQL statement containing a reference to `NEXTVAL`, Oracle increments the sequence once:

- For each row returned by the outer query block of a `SELECT` statement. Such a query block can appear in the following places:
  - A top-level `SELECT` statement
  - An `INSERT ... SELECT` statement (either single-table or multitable). For a multitable insert, the reference to `NEXTVAL` must appear in the `VALUES` clause, and the sequence is updated once for each row returned by the subquery, even though `NEXTVAL` may be referenced in multiple branches of the multitable insert.
  - A `CREATE TABLE ... AS SELECT` statement
  - A `CREATE MATERIALIZED VIEW ... AS SELECT` statement
- For each row updated in an `UPDATE` statement
- For each `INSERT` statement containing a `VALUES` clause
- For each `INSERT` ... `[ALL | FIRST]` statement (multitable insert). A multitable insert is considered a single SQL statement. Therefore, a reference to the `NEXTVAL` of a sequence will increase the sequence only once for each input record coming from
the SELECT portion of the statement. If NEXTVAL is specified more than once in any part of the INSERT ... [ALL | FIRST] statement, then the value will be the same for all insert branches, regardless of how often a given record might be inserted.

- For each row merged by a MERGE statement. The reference to NEXTVAL can appear in the merge_insert_clause or the merge_update_clause or both. The NEXTVALUE value is incremented for each row updated and for each row inserted, even if the sequence number is not actually used in the update or insert operation. If NEXTVAL is specified more than once in any of these locations, then the sequence is incremented once for each row and returns the same value for all occurrences of NEXTVAL for that row.

- For each input row in a multitable INSERT ALL statement. NEXTVAL is incremented once for each row returned by the subquery, regardless of how many occurrences of the insert_into_clause map to each row.

If any of these locations contains more than one reference to NEXTVAL, then Oracle increments the sequence once and returns the same value for all occurrences of NEXTVAL.

If any of these locations contains references to both CURRVAL and NEXTVAL, then Oracle increments the sequence and returns the same value for both CURRVAL and NEXTVAL.

**Finding the next value of a sequence: Example**

This example selects the next value of the employee sequence in the sample schema hr:

```
SELECT employees_seq.nextval
FROM DUAL;
```

**Inserting sequence values into a table: Example**

This example increments the employee sequence and uses its value for a new employee inserted into the sample table hr.employees:

```
INSERT INTO employees
VALUES (employees_seq.nextval, 'John', 'Doe', 'jdoe', '555-1212',
TO_DATE(SYSDATE), 'PU_CLERK', 2500, null, null, 30);
```

**Reusing the current value of a sequence: Example**

This example adds a new order with the next order number to the master order table. It then adds suborders with this number to the detail order table:

```
INSERT INTO orders (order_id, order_date, customer_id)
VALUES (orders_seq.nextval, TO_DATE(SYSDATE), 106);
```

```
INSERT INTO order_items (order_id, line_item_id, product_id)
VALUES (orders_seq.nextval, 1, 2359);
```

```
INSERT INTO order_items (order_id, line_item_id, product_id)
VALUES (orders_seq.nextval, 2, 3290);
```

```
INSERT INTO order_items (order_id, line_item_id, product_id)
VALUES (orders_seq.nextval, 3, 2381);
```

**Version Query Pseudocolumns**

The version query pseudocolumns are valid only in Oracle Flashback Version Query, which is a form of Oracle Flashback Query. The version query pseudocolumns are:

- VERSIONS_STARTSCN and VERSIONS_STARTTIME: Starting System Change Number (SCN) or TIMESTAMP when the row version was created. This pseudocolumn
identifies the time when the data first had the values reflected in the row version. Use this pseudocolumn to identify the past target time for Oracle Flashback Table or Oracle Flashback Query. If this pseudocolumn is **NULL**, then the row version was created before start.

- **VERSIONS_ENDSCN** and **VERSIONS_ENDTIME**: SCN or TIMESTAMP when the row version expired. If the pseudocolumn is **NULL**, then either the row version was current at the time of the query or the row corresponds to a **DELETE** operation.

- **VERSIONS_XID**: Identifier (a **RAW** number) of the transaction that created the row version.

- **VERSIONS_OPERATION**: Operation performed by the transaction: **I** for insertion, **D** for deletion, or **U** for update. The version is that of the row that was inserted, deleted, or updated; that is, the row after an **INSERT** operation, the row before a **DELETE** operation, or the row affected by an **UPDATE** operation.

For user updates of an index key, Oracle Flashback Version Query might treat an **UPDATE** operation as two operations, **DELETE** plus **INSERT**, represented as two version rows with a **D** followed by an **I** **VERSIONS_OPERATION**.

**See Also:**
- **flashback_query_clause** on page 19-22 for more information on version queries
- *Oracle Database Development Guide* for more information on using Oracle Flashback Version Query

### COLUMN_VALUE Pseudocolumn

When you refer to an **XMLTable** construct without the **COLUMNS** clause, or when you use the **TABLE** collection expression to refer to a scalar nested table type, the database returns a virtual table with a single column. This name of this pseudocolumn is **COLUMN_VALUE**.

In the context of **XMLTable**, the value returned is of data type **XMLType**. For example, the following two statements are equivalent, and the output for both shows **COLUMN_VALUE** as the name of the column being returned:

```sql
SELECT * FROM XMLTable('<a>123</a>');
```

```
COLUMN_VALUE
------------------
<a>123</a>
```

```sql
SELECT COLUMN_VALUE FROM (XMLTable('<a>123</a>'));
```

```
COLUMN_VALUE
------------------
<a>123</a>
```

In the context of a **TABLE** collection expression, the value returned is the data type of the collection element. The following statements create the two levels of nested tables illustrated in "Creating a Table: Multilevel Collection Example" on page 16-92 to show the uses of **COLUMN_VALUE** in this context:

```sql
CREATE TYPE phone AS TABLE OF NUMBER;
/
```
CREATE TYPE phone_list AS TABLE OF phone;
/

The next statement uses COLUMN_VALUE to select from the phone type:

SELECT t.COLUMN_VALUE
  FROM TABLE(phone(1,2,3)) t;

COLUMN_VALUE
-------------
  1
  2
  3

In a nested type, you can use the COLUMN_VALUE pseudocolumn in both the select list and the TABLE collection expression:

SELECT t.COLUMN_VALUE
  FROM TABLE(phone_list(phone(1,2,3))) p, TABLE(p.COLUMN_VALUE) t;

COLUMN_VALUE
-------------
  1
  2
  3

The keyword COLUMN_VALUE is also the name that Oracle Database generates for the scalar value of an inner nested table without a column or attribute name, as shown in the example that follows. In this context, COLUMN_VALUE is not a pseudocolumn, but an actual column name.

CREATE TABLE my_customers (  cust_id       NUMBER,
    name          VARCHAR2(25),
    phone_numbers phone_list,
    credit_limit  NUMBER)
NESTED TABLE phone_numbers STORE AS outer_ntab
  (NESTED TABLE COLUMN_VALUE STORE AS inner_ntab);

See Also:

- XMLTABLE on page 7-432 for information on that function
- table_collection_expression::= on page 18-65 for information on the TABLE collection expression
- ALTER TABLE examples in "Nested Tables: Examples" on page 12-111

OBJECT_ID Pseudocolumn

The OBJECT_ID pseudocolumn returns the object identifier of a column of an object table or view. Oracle uses this pseudocolumn as the primary key of an object table. OBJECT_ID is useful in INSTEAD OF triggers on views and for identifying the ID of a substitutable row in an object table.

Note: In earlier releases, this pseudocolumn was called SYS_NC_OID$. That name is still supported for backward compatibility. However, Oracle recommends that you use the more intuitive name OBJECT_ID.
OBJECT_VALUE Pseudocolumn

The OBJECT_VALUE pseudocolumn returns system-generated names for the columns of an object table, XMLType table, object view, or XMLType view. This pseudocolumn is useful for identifying the value of a substitutable row in an object table and for creating object views with the WITH OBJECT IDENTIFIER clause.

Note: In earlier releases, this pseudocolumn was called SYS_NC_ROWINFO$. That name is still supported for backward compatibility. However, Oracle recommends that you use the more intuitive name OBJECT_VALUE.

See Also: object_table on page 16-87 and object_view_clause on page 17-20 for more information on the use of this pseudocolumn

ORA_ROWSCN Pseudocolumn

ORA_ROWSCN reflects the system change-number (SCN) of the most recent change to a row. This change can be at the level of a block (coarse) or at the level of a row (fine-grained). The latter is provided by row-level dependency tracking. Refer to CREATE TABLE ... NOROWDEPENDENCIES | ROWDEPENDENCIES on page 16-82 for more information on row-level dependency tracking. In the absence of row-level dependencies, ORA_ROWSCN reflects block-level dependencies.

Whether at the block level or at the row level, the ORA_ROWSCN should not be considered to be an exact SCN. For example, if a transaction changed row R in a block and committed at SCN 10, it is not always true that the ORA_ROWSCN for the row would return 10. While a value less than 10 would never be returned, any value greater than or equal to 10 could be returned. That is, the ORA_ROWSCN of a row is not always guaranteed to be the exact commit SCN of the transaction that last modified that row. However, with fine-grained ORA_ROWSCN, if two transactions T1 and T2 modified the same row R, one after another, and committed, a query on the ORA_ROWSCN of row R after the commit of T1 will return a value lower than the value returned after the commit of T2. If a block is queried twice, then it is possible for the value of ORA_ROWSCN to change between the queries even though rows have not been updated in the time between the queries. The only guarantee is that the value of ORA_ROWSCN in both queries is greater than the commit SCN of the transaction that last modified that row.

You cannot use the ORA_ROWSCN pseudocolumn in a query to a view. However, you can use it to refer to the underlying table when creating a view. You can also use this pseudocolumn in the WHERE clause of an UPDATE or DELETE statement.

ORA_ROWSCN is not supported for Flashback Query. Instead, use the version query pseudocolumns, which are provided explicitly for Flashback Query. Refer to the SELECT ... flashback_query_clause on page 19-22 for information on Flashback Query and “Version Query Pseudocolumns” on page 3-5 for additional information on those pseudocolumns.

See Also: Oracle Database Object-Relational Developer’s Guide for examples of the use of this pseudocolumn
**Restriction on ORA_ROWSCN:** This pseudocolumn is not supported for external tables.

**Example**  The first statement below uses the ORA_ROWSCN pseudocolumn to get the system change number of the last operation on the employees table. The second statement uses the pseudocolumn with the SCN_TO_TIMESTAMP function to determine the timestamp of the operation:

```
SELECT ORA_ROWSCN, last_name
FROM employees
WHERE employee_id = 188;

SELECT SCN_TO_TIMESTAMP(ORA_ROWSCN), last_name
FROM employees
WHERE employee_id = 188;
```

**See Also:**  SCN_TO_TIMESTAMP on page 7-295

**ROWID Pseudocolumn**

For each row in the database, the ROWID pseudocolumn returns the address of the row. Oracle Database rowid values contain information necessary to locate a row:

- The data object number of the object
- The data block in the data file in which the row resides
- The position of the row in the data block (first row is 0)
- The data file in which the row resides (first file is 1). The file number is relative to the tablespace.

Usually, a rowid value uniquely identifies a row in the database. However, rows in different tables that are stored together in the same cluster can have the same rowid.

Values of the ROWID pseudocolumn have the data type ROWID or UROWID. Refer to "Rowid Data Types" on page 2-30 and "UROWID Data Type" on page 2-31 for more information.

Rowid values have several important uses:

- They are the fastest way to access a single row.
- They can show you how the rows in a table are stored.
- They are unique identifiers for rows in a table.

You should not use ROWID as the primary key of a table. If you delete and reinsert a row with the Import and Export utilities, for example, then its rowid may change. If you delete a row, then Oracle may reassign its rowid to a new row inserted later.

Although you can use the ROWID pseudocolumn in the SELECT and WHERE clause of a query, these pseudocolumn values are not actually stored in the database. You cannot insert, update, or delete a value of the ROWID pseudocolumn.

**Example**  This statement selects the address of all rows that contain data for employees in department 20:

```
SELECT ROWID, last_name
FROM employees
WHERE department_id = 20;
```
For each row returned by a query, the ROWNUM pseudocolumn returns a number indicating the order in which Oracle selects the row from a table or set of joined rows. The first row selected has a ROWNUM of 1, the second has 2, and so on.

You can use ROWNUM to limit the number of rows returned by a query, as in this example:

```sql
SELECT *
FROM employees
WHERE ROWNUM < 11;
```

If an ORDER BY clause follows ROWNUM in the same query, then the rows will be reordered by the ORDER BY clause. The results can vary depending on the way the rows are accessed. For example, if the ORDER BY clause causes Oracle to use an index to access the data, then Oracle may retrieve the rows in a different order than without the index. Therefore, the following statement does not necessarily return the same rows as the preceding example:

```sql
SELECT *
FROM employees
WHERE ROWNUM < 11
ORDER BY last_name;
```

If you embed the ORDER BY clause in a subquery and place the ROWNUM condition in the top-level query, then you can force the ROWNUM condition to be applied after the ordering of the rows. For example, the following query returns the employees with the 10 smallest employee numbers. This is sometimes referred to as top-N reporting:

```sql
SELECT *
FROM (SELECT * FROM employees ORDER BY employee_id)
WHERE ROWNUM < 11;
```

In the preceding example, the ROWNUM values are those of the top-level SELECT statement, so they are generated after the rows have already been ordered by employee_id in the subquery.

Conditions testing for ROWNUM values greater than a positive integer are always false. For example, this query returns no rows:

```sql
SELECT *
FROM employees
WHERE ROWNUM > 1;
```

The first row fetched is assigned a ROWNUM of 1 and makes the condition false. The second row to be fetched is now the first row and is also assigned a ROWNUM of 1 and
makes the condition false. All rows subsequently fail to satisfy the condition, so no rows are returned.

You can also use ROWNUM to assign unique values to each row of a table, as in this example:

```sql
UPDATE my_table
SET column1 = ROWNUM;
```

Refer to the function ROW_NUMBER on page 7-289 for an alternative method of assigning unique numbers to rows.

---

**Note:** Using ROWNUM in a query can affect view optimization.

---

**XMLDATA Pseudocolumn**

Oracle stores XMLType data either in LOB or object-relational columns, based on XMLSchema information and how you specify the storage clause. The XMLDATA pseudocolumn lets you access the underlying LOB or object relational column to specify additional storage clause parameters, constraints, indexes, and so forth.

**Example** The following statements illustrate the use of this pseudocolumn. Suppose you create a simple table of XMLType with one CLOB column:

```sql
CREATE TABLE xml_lob_tab of XMLTYPE
  XMLTYPE STORE AS CLOB;
```

To change the storage characteristics of the underlying LOB column, you can use the following statement:

```sql
ALTER TABLE xml_lob_tab
  MODIFY LOB (XMLDATA) (STORAGE (MAXSIZE 2G) CACHE);
```

Now suppose you have created an XMLSchema-based table like the xwarehouses table created in "Using XML in SQL Statements" on page F-8. You could then use the XMLDATA column to set the properties of the underlying columns, as shown in the following statement:

```sql
ALTER TABLE xwarehouses
  ADD (UNIQUE(XMLDATA."WarehouseId"));
```
An operator manipulates data items and returns a result. Syntactically, an operator appears before or after an operand or between two operands.

This chapter contains these sections:

- About SQL Operators
- Arithmetic Operators
- Concatenation Operator
- Hierarchical Query Operators
- Set Operators
- Multiset Operators
- User-Defined Operators

This chapter discusses nonlogical (non-Boolean) operators. These operators cannot by themselves serve as the condition of a WHERE or HAVING clause in queries or subqueries. For information on logical operators, which serve as conditions, refer to Chapter 6, "Conditions."

About SQL Operators

Operators manipulate individual data items called operands or arguments. Operators are represented by special characters or by keywords. For example, the multiplication operator is represented by an asterisk (*).

If you have installed Oracle Text, then you can use the SCORE operator, which is part of that product, in Oracle Text queries. You can also create conditions with the built-in Text operators, including CONTAINS, CATSEARCH, and MATCHES. For more information on these Oracle Text elements, refer to Oracle Text Reference.

**Note:** The combined values of the NLS_COMP and NLS_SORT settings determine the rules by which characters are sorted and compared. If NLS_COMP is set to LINGUISTIC for your database, then all entities in this chapter will be interpreted according to the rules specified by the NLS_SORT parameter. If NLS_COMP is not set to LINGUISTIC, then the functions are interpreted without regard to the NLS_SORT setting. NLS_SORT can be explicitly set. If it is not set explicitly, it is derived from NLS_LANGUAGE. Refer to Oracle Database Globalization Support Guide for more information on these settings.
Unary and Binary Operators

The two general classes of operators are:

- **unary**: A unary operator operates on only one operand. A unary operator typically appears with its operand in this format:
  \[ \text{operator operand} \]

- **binary**: A binary operator operates on two operands. A binary operator appears with its operands in this format:
  \[ \text{operand1 operator operand2} \]

Other operators with special formats accept more than two operands. If an operator is given a null operand, then the result is always null. The only operator that does not follow this rule is concatenation (||).

Operator Precedence

**Precedence** is the order in which Oracle Database evaluates different operators in the same expression. When evaluating an expression containing multiple operators, Oracle evaluates operators with higher precedence before evaluating those with lower precedence. Oracle evaluates operators with equal precedence from left to right within an expression.

Table 4–1 lists the levels of precedence among SQL operators from high to low. Operators listed on the same line have the same precedence.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>+, - (as unary operators), PRIOR, CONNECT_BY_ROOT</td>
<td>Identity, negation, location in hierarchy</td>
</tr>
<tr>
<td>*, /</td>
<td>Multiplication, division</td>
</tr>
<tr>
<td>+, - (as binary operators),</td>
<td></td>
</tr>
<tr>
<td>SQL conditions are evaluated after SQL operators</td>
<td>See &quot;Condition Precedence&quot; on page 6-3</td>
</tr>
</tbody>
</table>

**Precedence Example** In the following expression, multiplication has a higher precedence than addition, so Oracle first multiplies 2 by 3 and then adds the result to 1.

\[ 1 + 2 \times 3 \]

You can use parentheses in an expression to override operator precedence. Oracle evaluates expressions inside parentheses before evaluating those outside.

SQL also supports set operators (UNION, UNION ALL, INTERSECT, and MINUS), which combine sets of rows returned by queries, rather than individual data items. All set operators have equal precedence.

**See Also**: "Hierarchical Query Operators" on page 4-5 and "Hierarchical Queries" on page 9-3 for information on the PRIOR operator, which is used only in hierarchical queries.
Arithmetic Operators

You can use an arithmetic operator with one or two arguments to negate, add, subtract, multiply, and divide numeric values. Some of these operators are also used in datetime and interval arithmetic. The arguments to the operator must resolve to numeric data types or to any data type that can be implicitly converted to a numeric data type.

Unary arithmetic operators return the same data type as the numeric data type of the argument. For binary arithmetic operators, Oracle determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type. Table 4-2 lists arithmetic operators.

See Also: Table 2-10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion, "Numeric Precedence" on page 2-16 for information on numeric precedence, and "Datetime/Interval Arithmetic" on page 2-22

<table>
<thead>
<tr>
<th>Table 4-2 Arithmetic Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operator</td>
</tr>
</tbody>
</table>
| + - | When these denote a positive or negative expression, they are unary operators. | SELECT *
FROM order_items
WHERE quantity = -1
ORDER BY order_id,
line_item_id, product_id;
SELECT *
FROM employees
WHERE -salary < 0
ORDER BY employee_id; |
| + - | When they add or subtract, they are binary operators. | SELECT hire_date
FROM employees
WHERE SYSDATE - hire_date > 365
ORDER BY hire_date; |
| * / | Multiply, divide. These are binary operators. | UPDATE employees
SET salary = salary * 1.1; |

Do not use two consecutive minus signs (--) in arithmetic expressions to indicate double negation or the subtraction of a negative value. The characters -- are used to begin comments within SQL statements. You should separate consecutive minus signs with a space or parentheses. Refer to "Comments" on page 2-76 for more information on comments within SQL statements.

Concatenation Operator

The concatenation operator manipulates character strings and CLOB data. Table 4-3 describes the concatenation operator.
The result of concatenating two character strings is another character string. If both character strings are of data type CHAR, then the result has data type CHAR and is limited to 2000 characters. If either string is of data type VARCHAR2, then the result has data type VARCHAR2 and is limited to 32767 characters if the initialization parameter MAX_STRING_SIZE = EXTENDED and 4000 characters if MAX_STRING_SIZE = STANDARD. Refer to "Extended Data Types" on page 2-29 for more information. If either argument is a CLOB, the result is a temporary CLOB. Trailing blanks in character strings are preserved by concatenation, regardless of the data types of the string or CLOB.

On most platforms, the concatenation operator is two solid vertical bars, as shown in Table 4-3. However, some IBM platforms use broken vertical bars for this operator. When moving SQL script files between systems having different character sets, such as between ASCII and EBCDIC, vertical bars might not be translated into the vertical bar required by the target Oracle Database environment. Oracle provides the CONCAT character function as an alternative to the vertical bar operator for cases when it is difficult or impossible to control translation performed by operating system or network utilities. Use this function in applications that will be moved between environments with differing character sets.

Although Oracle treats zero-length character strings as nulls, concatenating a zero-length character string with another operand always results in the other operand, so null can result only from the concatenation of two null strings. However, this may not continue to be true in future versions of Oracle Database. To concatenate an expression that might be null, use the NVL function to explicitly convert the expression to a zero-length string.

**See Also:**
- "Character Data Types" on page 2-8 for more information on the differences between the CHAR and VARCHAR2 data types
- The functions CONCAT on page 7-66 and NVL on page 7-217
- Oracle Database SecureFiles and Large Objects Developer’s Guide for more information about CLOBs

**Concatenation Example**  This example creates a table with both CHAR and VARCHAR2 columns, inserts values both with and without trailing blanks, and then selects these values and concatenates them. Note that for both CHAR and VARCHAR2 columns, the trailing blanks are preserved.

```sql
CREATE TABLE tab1 (col1 VARCHAR2(6), col2 CHAR(6),
col3 VARCHAR2(6), col4 CHAR(6));

INSERT INTO tab1 (col1, col2, col3, col4)
VALUES ('abc', 'def   ', 'ghi   ', 'jkl');

SELECT col1 || col2 || col3 || col4 'Concatenation'
FROM tab1;
```

<table>
<thead>
<tr>
<th>Operator</th>
<th>Purpose</th>
<th>Example</th>
</tr>
</thead>
</table>
| ||       | Concatenates character strings and CLOB data. | SELECT 'Name is ' || last_name
FROM employees
ORDER BY last_name; |

Table 4–3  Concatenation Operator

The result of concatenating two character strings is another character string. If both character strings are of data type CHAR, then the result has data type CHAR and is limited to 2000 characters. If either string is of data type VARCHAR2, then the result has data type VARCHAR2 and is limited to 32767 characters if the initialization parameter MAX_STRING_SIZE = EXTENDED and 4000 characters if MAX_STRING_SIZE = STANDARD. Refer to "Extended Data Types" on page 2-29 for more information. If either argument is a CLOB, the result is a temporary CLOB. Trailing blanks in character strings are preserved by concatenation, regardless of the data types of the string or CLOB.

On most platforms, the concatenation operator is two solid vertical bars, as shown in Table 4–3. However, some IBM platforms use broken vertical bars for this operator. When moving SQL script files between systems having different character sets, such as between ASCII and EBCDIC, vertical bars might not be translated into the vertical bar required by the target Oracle Database environment. Oracle provides the CONCAT character function as an alternative to the vertical bar operator for cases when it is difficult or impossible to control translation performed by operating system or network utilities. Use this function in applications that will be moved between environments with differing character sets.

Although Oracle treats zero-length character strings as nulls, concatenating a zero-length character string with another operand always results in the other operand, so null can result only from the concatenation of two null strings. However, this may not continue to be true in future versions of Oracle Database. To concatenate an expression that might be null, use the NVL function to explicitly convert the expression to a zero-length string.

**See Also:**
- "Character Data Types" on page 2-8 for more information on the differences between the CHAR and VARCHAR2 data types
- The functions CONCAT on page 7-66 and NVL on page 7-217
- Oracle Database SecureFiles and Large Objects Developer’s Guide for more information about CLOBs

**Concatenation Example**  This example creates a table with both CHAR and VARCHAR2 columns, inserts values both with and without trailing blanks, and then selects these values and concatenates them. Note that for both CHAR and VARCHAR2 columns, the trailing blanks are preserved.

```sql
CREATE TABLE tab1 (col1 VARCHAR2(6), col2 CHAR(6),
col3 VARCHAR2(6), col4 CHAR(6));

INSERT INTO tab1 (col1, col2, col3, col4)
VALUES ('abc', 'def   ', 'ghi   ', 'jkl');

SELECT col1 || col2 || col3 || col4 'Concatenation'
FROM tab1;
```

Concatenation
Hierarchical Query Operators

Two operators, PRIOR and CONNECT_BY_ROOT, are valid only in hierarchical queries.

PRIOR

In a hierarchical query, one expression in the CONNECT BY condition must be qualified by the PRIOR operator. If the CONNECT BY condition is compound, then only one condition requires the PRIOR operator, although you can have multiple PRIOR conditions. PRIOR evaluates the immediately following expression for the parent row of the current row in a hierarchical query.

PRIOR is most commonly used when comparing column values with the equality operator. (The PRIOR keyword can be on either side of the operator.) PRIOR causes Oracle to use the value of the parent row in the column. Operators other than the equal sign (=) are theoretically possible in CONNECT BY clauses. However, the conditions created by these other operators can result in an infinite loop through the possible combinations. In this case Oracle detects the loop at run time and returns an error. Refer to "Hierarchical Queries" on page 9-3 for more information on this operator, including examples.

CONNECT_BY_ROOT

CONNECT_BY_ROOT is a unary operator that is valid only in hierarchical queries. When you qualify a column with this operator, Oracle returns the column value using data from the root row. This operator extends the functionality of the CONNECT BY [PRIOR] condition of hierarchical queries.

Restriction on CONNECT_BY_ROOT

You cannot specify this operator in the START WITH condition or the CONNECT BY condition.

See Also: "CONNECT_BY_ROOT Examples" on page 9-7

Set Operators

Set operators combine the results of two component queries into a single result. Queries containing set operators are called compound queries. Table 4–4 lists SQL set operators. They are fully described, including examples and restrictions on these operators, in “The UNION [ALL], INTERSECT, MINUS Operators” on page 9-8.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNION</td>
<td>All distinct rows selected by either query</td>
</tr>
<tr>
<td>UNION ALL</td>
<td>All rows selected by either query, including all duplicates</td>
</tr>
<tr>
<td>INTERSECT</td>
<td>All distinct rows selected by both queries</td>
</tr>
<tr>
<td>MINUS</td>
<td>All distinct rows selected by the first query but not the second</td>
</tr>
</tbody>
</table>

Multiset Operators

Multiset operators combine the results of two nested tables into a single nested table.
The examples related to multiset operators require that two nested tables be created and loaded with data as follows:

First, make a copy of the oe.customers table called customers_demo:

```sql
CREATE TABLE customers_demo AS
    SELECT * FROM customers;
```

Next, create a table type called cust_address_tab_typ. This type will be used when creating the nested table columns.

```sql
CREATE TYPE cust_address_tab_typ AS
    TABLE OF cust_address_typ;
```

Now, create two nested table columns in the customers_demo table:

```sql
ALTER TABLE customers_demo
ADDITIONAL column
    ADD ( cust_address_ntab cust_address_tab_typ,
             cust_address2_ntab cust_address_tab_typ,
             cust_address3_ntab cust_address_tab_typ,
             cust_address4_ntab cust_address_tab_typ,
             cust_address5_ntab cust_address_tab_typ,
             cust_address6_ntab cust_address_tab_typ,
             cust_address7_ntab cust_address_tab_typ,
             cust_address8_ntab cust_address_tab_typ,
             cust_address9_ntab cust_address_tab_typ,
             cust_address10_ntab cust_address_tab_typ
NESTED TABLE cust_address_ntab STORE AS cust_address_ntab_store
NESTED TABLE cust_address2_ntab STORE AS cust_address2_ntab_store
NESTED TABLE cust_address3_ntab STORE AS cust_address3_ntab_store
NESTED TABLE cust_address4_ntab STORE AS cust_address4_ntab_store
NESTED TABLE cust_address5_ntab STORE AS cust_address5_ntab_store
NESTED TABLE cust_address6_ntab STORE AS cust_address6_ntab_store
NESTED TABLE cust_address7_ntab STORE AS cust_address7_ntab_store
NESTED TABLE cust_address8_ntab STORE AS cust_address8_ntab_store
NESTED TABLE cust_address9_ntab STORE AS cust_address9_ntab_store
NESTED TABLE cust_address10_ntab STORE AS cust_address10_ntab_store;
```

Finally, load data into the two new nested table columns using data from the cust_address column of the oe.customers table:

```sql
UPDATE customers_demo cd
SET cust_address_ntab =
    CAST(MULTISET(SELECT cust_address
                   FROM customers c
                   WHERE c.customer_id =
                   cd.customer_id) as cust_address_tab_typ);
```

```sql
UPDATE customers_demo cd
SET cust_address2_ntab =
    CAST(MULTISET(SELECT cust_address
                   FROM customers c
                   WHERE c.customer_id =
                   cd.customer_id) as cust_address_tab_typ);
```

**MULTISET EXCEPT**

MULTISET EXCEPT takes as arguments two nested tables and returns a nested table whose elements are in the first nested table but not in the second nested table. The two input nested tables must be of the same type, and the returned nested table is of the same type as well.

![Diagram of MULTISET EXCEPT](image)

- The **ALL** keyword instructs Oracle to return all elements in nested_table1 that are not in nested_table2. For example, if a particular element occurs \( m \) times in nested_table1 and \( n \) times in nested_table2, then the result will have \( (m-n) \) occurrences of the element if \( m > n \) and 0 occurrences if \( m \leq n \). **ALL** is the default.
- The **DISTINCT** keyword instructs Oracle to eliminate any element in nested_table1 which is also in nested_table2, regardless of the number of occurrences.
The element types of the nested tables must be comparable. Refer to "Comparison Conditions" on page 6-4 for information on the comparability of nonscalar types.

Example

The following example compares two nested tables and returns a nested table of those elements found in the first nested table but not in the second nested table:

```sql
SELECT customer_id, cust_address_ntab
  MULTISET EXCEPT DISTINCT cust_address2_ntab multiset_except
FROM customers_demo
ORDER BY customer_id;
```

<table>
<thead>
<tr>
<th>CUSTOMER_ID</th>
<th>MULTISET_EXCEPT(STREET_ADDRESS, POSTAL_CODE, CITY, STATE_PROVINCE, COUNTRY_ID)</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>CUST_ADDRESS_TAB_TYP()</td>
</tr>
<tr>
<td>102</td>
<td>CUST_ADDRESS_TAB_TYP()</td>
</tr>
<tr>
<td>103</td>
<td>CUST_ADDRESS_TAB_TYP()</td>
</tr>
<tr>
<td>104</td>
<td>CUST_ADDRESS_TAB_TYP()</td>
</tr>
<tr>
<td>105</td>
<td>CUST_ADDRESS_TAB_TYP()</td>
</tr>
<tr>
<td>. . .</td>
<td></td>
</tr>
</tbody>
</table>

The preceding example requires the table `customers_demo` and two nested table columns containing data. Refer to "Multiset Operators" on page 4-5 to create this table and nested table columns.

MULTISET INTERSECT

MULTISET INTERSECT takes as arguments two nested tables and returns a nested table whose values are common in the two input nested tables. The two input nested tables must be of the same type, and the returned nested table is of the same type as well.

- The ALL keyword instructs Oracle to return all common occurrences of elements that are in the two input nested tables, including duplicate common values and duplicate common NULL occurrences. For example, if a particular value occurs \(m\) times in `nested_table1` and \(n\) times in `nested_table2`, then the result would contain the element \(\min(m,n)\) times. ALL is the default.

- The DISTINCT keyword instructs Oracle to eliminate duplicates from the returned nested table, including duplicates of NULL, if they exist.

- The element types of the nested tables must be comparable. Refer to "Comparison Conditions" on page 6-4 for information on the comparability of nonscalar types.

Example

The following example compares two nested tables and returns a nested table of those elements found in both input nested tables:

```sql
SELECT customer_id, cust_address_ntab
  MULTISET INTERSECT DISTINCT cust_address2_ntab multiset_intersect
FROM customers_demo
ORDER BY customer_id;
```

<table>
<thead>
<tr>
<th>CUSTOMER_ID</th>
<th>MULTISET_INTERSECT(STREET_ADDRESS, POSTAL_CODE, CITY, STATE_PROVINCE, COUNTRY_ID)</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP('514 W Superior St', '46901', 'Kokomo', 'IN', 'US'))</td>
</tr>
<tr>
<td>102</td>
<td>CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP('2515 Bloyd Ave', '46218', 'Indianapolis', 'IN', 'US'))</td>
</tr>
<tr>
<td>103</td>
<td>CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP('8768 N State Rd 37', '47404', 'Bloomington', 'IN', 'US'))</td>
</tr>
<tr>
<td>. . .</td>
<td></td>
</tr>
</tbody>
</table>
The preceding example requires the table `customers_demo` and two nested table columns containing data. Refer to "Multiset Operators" on page 4-5 to create this table and nested table columns.

**MULTISET UNION**

MULTISET UNION takes as arguments two nested tables and returns a nested table whose values are those of the two input nested tables. The two input nested tables must be of the same type, and the returned nested table is of the same type as well.

- The **ALL** keyword instructs Oracle to return all elements that are in the two input nested tables, including duplicate values and duplicate NULL occurrences. This is the default.
- The **DISTINCT** keyword instructs Oracle to eliminate duplicates from the returned nested table, including duplicates of NULL, if they exist.
- The element types of the nested tables must be comparable. Refer to "Comparison Conditions" on page 6-4 for information on the comparability of nonscalar types.

**Example**

The following example compares two nested tables and returns a nested table of elements from both input nested tables:

```sql
SELECT customer_id, cust_address_ntab
       MULTISET UNION cust_address2_ntab multiset_union
FROM customers_demo
ORDER BY customer_id;
```

The preceding example requires the table `customers_demo` and two nested table columns containing data. Refer to "Multiset Operators" on page 4-5 to create this table and nested table columns.

**User-Defined Operators**

Like built-in operators, user-defined operators take a set of operands as input and return a result. However, you create them with the `CREATE OPERATOR` statement, and they are identified by user-defined names. They reside in the same namespace as tables, views, types, and standalone functions.
After you have defined a new operator, you can use it in SQL statements like any other built-in operator. For example, you can use user-defined operators in the select list of a `SELECT` statement, the condition of a `WHERE` clause, or in `ORDER BY` clauses and `GROUP BY` clauses. However, you must have `EXECUTE` privilege on the operator to do so, because it is a user-defined object.

**See Also:** CREATE OPERATOR on page 15-49 for an example of creating an operator and *Oracle Database Data Cartridge Developer’s Guide* for more information on user-defined operators.
This chapter describes how to combine values, operators, and functions into expressions. This chapter includes these sections:

- About SQL Expressions
- Simple Expressions
- Compound Expressions
- CASE Expressions
- Column Expressions
- CURSOR Expressions
- Datetime Expressions
- Function Expressions
- Interval Expressions
- JSON Object Access Expressions
- Model Expressions
- Object Access Expressions
- Placeholder Expressions
- Scalar Subquery Expressions
- Type Constructor Expressions
- Expression Lists

**About SQL Expressions**

An expression is a combination of one or more values, operators, and SQL functions that evaluates to a value. An expression generally assumes the data type of its components.
This simple expression evaluates to 4 and has data type NUMBER (the same data type as its components):

\[ 2 \times 2 \]

The following expression is an example of a more complex expression that uses both functions and operators. The expression adds seven days to the current date, removes the time component from the sum, and converts the result to CHAR data type:

\[ \text{TO_CHAR(} \text{TRUNC(SYSDATE+7)} \text{)} \]

You can use expressions in:

- The select list of the SELECT statement
- A condition of the WHERE clause and HAVING clause
- The CONNECT BY, START WITH, and ORDER BY clauses
- The VALUES clause of the INSERT statement
- The SET clause of the UPDATE statement

For example, you could use an expression in place of the quoted string 'Smith' in this UPDATE statement SET clause:

```sql
SET last_name = 'Smith';
```

This SET clause has the expression INITCAP(last_name) instead of the quoted string 'Smith':

```sql
SET last_name = INITCAP(last_name);
```

Expressions have several forms, as shown in the following syntax:
Oracle Database does not accept all forms of expressions in all parts of all SQL statements. Refer to the individual SQL statements in Chapter 10 through Chapter 19 for information on restrictions on the expressions in that statement.

You must use appropriate expression notation whenever `expr` appears in conditions, SQL functions, or SQL statements in other parts of this reference. The sections that follow describe and provide examples of the various forms of expressions.

**Simple Expressions**

A simple expression specifies a column, pseudocolumn, constant, sequence number, or null.
In addition to the schema of a user, schema can also be "PUBLIC" (double quotation marks required), in which case it must qualify a public synonym for a table, view, or materialized view. Qualifying a public synonym with "PUBLIC" is supported only in data manipulation language (DML) statements, not data definition language (DDL) statements.

You can specify ROWID only with a table, not with a view or materialized view. NCHAR and NVARCHAR2 are not valid pseudocolumn data types.

See Also: Chapter 3, "Pseudocolumns" for more information on pseudocolumns and subquery_factoring_clause on page 19-18 for information on query_name

Some valid simple expressions are:

- employees.last_name
- 'this is a text string'
- 10
- N'this is an NCHAR string'

**Compound Expressions**

A compound expression specifies a combination of other expressions.
You can use any built-in function as an expression ("Function Expressions" on page 5-10). However, in a compound expression, some combinations of functions are inappropriate and are rejected. For example, the LENGTH function is inappropriate within an aggregate function.

The PRIOR operator is used in CONNECT BY clauses of hierarchical queries.

See Also: "Operator Precedence" on page 4-2 and "Hierarchical Queries" on page 9-3

Some valid compound expressions are:

{‘CLARK’ || ‘SMITH’}
LENGTH(‘MOOSE’) * 57
SQRT(144) + 72
my_fun(TO_CHAR(sysdate,’DD-MON-YY’))

CASE Expressions

CASE expressions let you use IF ... THEN ... ELSE logic in SQL statements without having to invoke procedures. The syntax is:

\[
\text{CASE} \quad \text{simple_case_expression} \quad \text{searched_case_expression} \quad \text{else_clause} \quad \text{END}
\]

simple_case_expression::=

\[
\text{expr} \quad \text{WHEN} \quad \text{comparison_expr} \quad \text{THEN} \quad \text{return_expr}
\]

searched_case_expression::=

\[
\text{WHEN} \quad \text{condition} \quad \text{THEN} \quad \text{return_expr}
\]

else_clause::=

\[
\text{ELSE} \quad \text{else_expr}
\]
In a simple CASE expression, Oracle Database searches for the first WHEN ... THEN pair for which expr is equal to comparison_expr and returns return_expr. If none of the WHEN ... THEN pairs meet this condition, and an ELSE clause exists, then Oracle returns else_expr. Otherwise, Oracle returns null.

In a searched CASE expression, Oracle searches from left to right until it finds an occurrence of condition that is true, and then returns return_expr. If no condition is found to be true, and an ELSE clause exists, then Oracle returns else_expr. Otherwise, Oracle returns null.

Oracle Database uses short-circuit evaluation. For a simple CASE expression, the database evaluates each comparison_expr value only before comparing it to expr, rather than evaluating all comparison_expr values before comparing any of them with expr. Consequently, Oracle never evaluates a comparison_expr if a previous comparison_expr is equal to expr. For a searched CASE expression, the database evaluates each condition to determine whether it is true, and never evaluates a condition if the previous condition was true.

For a simple CASE expression, the expr and all comparison_expr values must either have the same data type (CHAR, VARCHAR2, NCHAR, or NVARCHAR2, NUMBER, BINARY_FLOAT, or BINARY_DOUBLE) or must all have a numeric data type. If all expressions have a numeric data type, then Oracle determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

For both simple and searched CASE expressions, all of the return_exprs must either have the same data type (CHAR, VARCHAR2, NCHAR, or NVARCHAR2, NUMBER, BINARY_FLOAT, or BINARY_DOUBLE) or must all have a numeric data type. If all return expressions have a numeric data type, then Oracle determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

The maximum number of arguments in a CASE expression is 65535. All expressions count toward this limit, including the initial expression of a simple CASE expression and the optional ELSE expression. Each WHEN ... THEN pair counts as two arguments. To avoid exceeding this limit, you can nest CASE expressions so that the return_expr itself is a CASE expression.

See Also:
- Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion
- "Numeric Precedence" on page 2-16 for information on numeric precedence
- COALESCE on page 7-58 and NULLIF on page 7-214 for alternative forms of CASE logic
- Oracle Database Data Warehousing Guide for examples using various forms of the CASE expression

Simple CASE Example For each customer in the sample oe.customers table, the following statement lists the credit limit as "Low" if it equals $100, "High" if it equals $5000, and "Medium" if it equals anything else.

```sql
SELECT cust_last_name,
    CASE credit_limit WHEN 100 THEN 'Low'
             WHEN 5000 THEN 'High'
             ELSE 'Medium' END AS credit
FROM customers
```
ORDER BY cust_last_name, credit;

<table>
<thead>
<tr>
<th>CUST_LAST_NAME</th>
<th>CREDIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adjani</td>
<td>Medium</td>
</tr>
<tr>
<td>Adjani</td>
<td>Medium</td>
</tr>
<tr>
<td>Alexander</td>
<td>Medium</td>
</tr>
<tr>
<td>Alexander</td>
<td>Medium</td>
</tr>
<tr>
<td>Altman</td>
<td>High</td>
</tr>
<tr>
<td>Altman</td>
<td>Medium</td>
</tr>
</tbody>
</table>

**Searched CASE Example** The following statement finds the average salary of the employees in the sample table oe.employees, using $2000 as the lowest salary possible:

```
SELECT AVG(CASE WHEN e.salary > 2000 THEN e.salary 
    ELSE 2000 END) 'Average Salary' FROM employees e;
```

<table>
<thead>
<tr>
<th>Average Salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>6461.68224</td>
</tr>
</tbody>
</table>

**Column Expressions**

A column expression, which is designated as column_expression in subsequent syntax diagrams, is a limited form of expr. A column expression can be a simple expression, compound expression, function expression, or expression list, but it can contain only the following forms of expression:

- Columns of the subject table — the table being created, altered, or indexed
- Constants (strings or numbers)
- Deterministic functions — either SQL built-in functions or user-defined functions

No other expression forms described in this chapter are valid. In addition, compound expressions using the PRIOR keyword are not supported, nor are aggregate functions.

You can use a column expression for these purposes:

- To create a function-based index.
- To explicitly or implicitly define a virtual column. When you define a virtual column, the defining column_expression must refer only to columns of the subject table that have already been defined, in the current statement or in a prior statement.

The combined components of a column expression must be deterministic. That is, the same set of input values must return the same set of output values.

**See Also:** "Simple Expressions" on page 5-3, "Compound Expressions" on page 5-4, "Function Expressions" on page 5-10, and "Expression Lists" on page 5-18 for information on these forms of expr

**CURSOR Expressions**

A CURSOR expression returns a nested cursor. This form of expression is equivalent to the PL/SQL REF CURSOR and can be passed as a REF CURSOR argument to a function.
A nested cursor is implicitly opened when the cursor expression is evaluated. For example, if the cursor expression appears in a select list, a nested cursor will be opened for each row fetched by the query. The nested cursor is closed only when:

- The nested cursor is explicitly closed by the user
- The parent cursor is reexecuted
- The parent cursor is closed
- The parent cursor is cancelled
- An error arises during fetch on one of its parent cursors (it is closed as part of the clean-up)

**Restrictions on CURSOR Expressions**  The following restrictions apply to CURSOR expressions:

- If the enclosing statement is not a SELECT statement, then nested cursors can appear only as REF CURSOR arguments of a procedure.
- If the enclosing statement is a SELECT statement, then nested cursors can also appear in the outermost select list of the query specification or in the outermost select list of another nested cursor.
- Nested cursors cannot appear in views.
- You cannot perform BIND and EXECUTE operations on nested cursors.

**Examples**  The following example shows the use of a CURSOR expression in the select list of a query:

```sql
SELECT department_name, CURSOR(SELECT salary, commission_pct
FROM employees e
WHERE e.department_id = d.department_id)
FROM departments d
ORDER BY department_name;
```

The next example shows the use of a CURSOR expression as a function argument. The example begins by creating a function in the sample OE schema that can accept the REF CURSOR argument. (The PL/SQL function body is shown in italics.)

```sql
CREATE FUNCTION f(cur SYS_REFCURSOR, mgr_hiredate DATE)
RETURN NUMBER IS
    emp_hiredate DATE;
    before number :=0;
    after number:=0;
begin
    loop
        fetch cur into emp_hiredate;
        exit when cur%NOTFOUND;
        if emp_hiredate > mgr_hiredate then
            after:=after+1;
        else
            before:=before+1;
        end if;
    end loop;
    close cur;
    if before > after then
        return 1;
    else
        return 0;
    end if;
```
The function accepts a cursor and a date. The function expects the cursor to be a query returning a set of dates. The following query uses the function to find those managers in the sample employees table, most of whose employees were hired before the manager.

```sql
SELECT e1.last_name FROM employees e1
WHERE f(
    CURSOR(SELECT e2.hire_date FROM employees e2
    WHERE e1.employee_id = e2.manager_id),
    e1.hire_date) = 1
ORDER BY last_name;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cambrault</td>
</tr>
<tr>
<td>Higgins</td>
</tr>
<tr>
<td>Hunold</td>
</tr>
<tr>
<td>Kochhar</td>
</tr>
<tr>
<td>Mourgos</td>
</tr>
<tr>
<td>Zlotkey</td>
</tr>
</tbody>
</table>

**Datetime Expressions**

A datetime expression yields a value of one of the datetime data types.

```plaintext
datetime_expression::=
```

The initial `expr` is any expression, except a scalar subquery expression, that evaluates to a value of data type `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, or `TIMESTAMP WITH LOCAL TIME ZONE`. The `DATE` data type is not supported. If this `expr` is itself a `datetime_expression`, then it must be enclosed in parentheses.

Datetimes and intervals can be combined according to the rules defined in Table 2-5 on page 2-23. The three combinations that yield datetime values are valid in a datetime expression.

If you specify `AT LOCAL`, then Oracle uses the current session time zone.

The settings for `AT TIME ZONE` are interpreted as follows:

- The string `'+[-]hh:mm'` specifies a time zone as an offset from UTC. For `hh`, specify the number of hours. For `mi`, specify the number of minutes.
Function Expressions

- **DBTIMEZONE**: Oracle uses the database time zone established (explicitly or by default) during database creation.

- **SESSIONTIMEZONE**: Oracle uses the session time zone established by default or in the most recent `ALTER SESSION` statement.

- **time_zone_name**: Oracle returns the `datetime_value_expr` in the time zone indicated by `time_zone_name`. For a listing of valid time zone region names, query the `V$TIMEZONE_NAMES` dynamic performance view.

**Note**: Time zone region names are needed by the daylight saving feature. These names are stored in two types of time zone files: one large and one small. One of these files is the default file, depending on your environment and the release of Oracle Database you are using. For more information regarding time zone files and names, see Oracle Database Globalization Support Guide.

**See Also**:  
- *Oracle Database Globalization Support Guide* for a complete listing of the time zone region names in both files  
- *Oracle Database Reference* for information on the dynamic performance views

- **expr**: If `expr` returns a character string with a valid time zone format, then Oracle returns the input in that time zone. Otherwise, Oracle returns an error.

**Example**  
The following example converts the `datetime` value of one time zone to another time zone:

```sql
SELECT FROM_TZ(CAST(TO_DATE('1999-12-01 11:00:00', 'YYYY-MM-DD HH:MI:SS') AS TIMESTAMP), 'America/New_York') 
AT TIME ZONE 'America/Los_Angeles' 'West Coast Time' 
FROM DUAL;
```

West Coast Time  
------------------------------------------------
01-DEC-99 08.00.00.000000 AM AMERICA/LOS_ANGELES

Function Expressions

You can use any built-in SQL function or user-defined function as an expression. Some valid built-in function expressions are:

- `LENGTH('BLAKE')`
- `ROUND(1234.567*43)`
- `SYSDATE`

**See Also**: "About SQL Functions" on page 7-2 and "Aggregate Functions" on page 7-10 for information on built-in functions

A user-defined function expression specifies a call to:

- A function in an Oracle-supplied package (see Oracle Database PL/SQL Packages and Types Reference)
A function in a user-defined package or type or in a standalone user-defined function (see "About User-Defined Functions" on page 7-438)

A user-defined function or operator (see CREATE OPERATOR on page 15-49, CREATE FUNCTION on page 14-71, and Oracle Database Data Cartridge Developer’s Guide)

Some valid user-defined function expressions are:

circle_area(radius)
payroll.tax_rate(empno)
hr.employees.comm_pct@remote(dependents, empno)
DBMS_LOB.getlength(column_name)
my_function(a_column)

In a user-defined function being used as an expression, positional, named, and mixed notation are supported. For example, all of the following notations are correct:

CALL my_function(arg1 => 3, arg2 => 4) ...  
CALL my_function(3, 4) ...
CALL my_function(3, arg2 => 4) ...

Restriction on User-Defined Function Expressions You cannot pass arguments of object type or XMLType to remote functions and procedures.

Interval Expressions

An interval expression yields a value of INTERVAL YEAR TO MONTH or INTERVAL DAY TO SECOND.

interval_expression ::= 

\[(\text{expr1} - \text{expr2}) \text{ DAY} (\text{leading_field_precision}) \text{ TO } \text{SECOND} (\text{fractional_second_precision})\]

\[(\text{expr1} - \text{expr2}) \text{ YEAR} (\text{leading_field_precision}) \text{ TO } \text{MONTH}\]

The expressions expr1 and expr2 can be any expressions that evaluate to values of data type DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, or TIMESTAMP WITH LOCAL TIME ZONE.

Datetimes and intervals can be combined according to the rules defined in Table 2-5 on page 2-23. The six combinations that yield interval values are valid in an interval expression.

Both leading_field_precision and fractional_second_precision can be any integer from 0 to 9. If you omit the leading_field_precision for either DAY or YEAR, then Oracle Database uses the default value of 2. If you omit the fractional_second_precision for second, then the database uses the default value of 6. If the value returned by a query contains more digits that the default precision, then Oracle Database returns an error. Therefore, it is good practice to specify a precision that you know will be at least as large as any value returned by the query.
For example, the following statement subtracts the value of the `order_date` column in the sample table `orders` (a datetime value) from the system timestamp (another datetime value) to yield an interval value expression. It is not known how many days ago the oldest order was placed, so the maximum value of 9 for the `DAY` leading field precision is specified:

```sql
SELECT (SYSTIMESTAMP - order_date) DAY(9) TO SECOND FROM orders
WHERE order_id = 2458;
```

### JSON Object Access Expressions

You can use a JSON object access expression only when querying a column of JavaScript Object Notation (JSON) data. The expression yields a character string that contains one or more JSON values found in that data. The syntax for this type of expression is sometimes called dot-notation syntax.

**Syntax:**

```
JSON_object_access_expr ::= \\
  (table_alias) . (JSON_column) \\
  (JSON_object_key)
```

- For `table_alias`, specify the alias for the table that contains the column of JSON data. This table alias is required and must be assigned to the table elsewhere in the SQL statement.
- For `JSON_column`, specify the name of the column of JSON data. The column must be of data type `VARCHAR2`, `CLOB`, or `BLOB` and an `IS JSON` check constraint must be defined on the column.
- You can optionally specify one or more JSON object keys. The object keys allow you to target specific JSON values in the JSON data. The first `JSON_object_key` must be a case-sensitive match to the key (property) name of an object member in the top level of the JSON data. If the value of that object member is another JSON object, then you can specify a second `JSON_object_key` that matches the key name of a member of that object, and so on. If a JSON array is encountered during any of these iterations, then the array is implicitly unwrapped and the elements of the array are evaluated using the `JSON_object_key`.

The expression yields a character string of data type `VARCHAR2(4000)`, which contains the targeted JSON value(s) as follows:

- For a single targeted value, the character string contains that value, whether it is a JSON scalar value, object, or array.
- For multiple targeted values, the character string contains a JSON array whose elements are those values.

If you omit `JSON_object_key`, then the expression yields a character string that contains the JSON data in its entirety. In this case, the character string is of the same data type as the column of JSON data being queried.

A JSON object access expression cannot return a value larger than 4K bytes. If the value surpasses this limit, then the expression returns null. To obtain the actual value, instead use the `JSON_QUERY` function or the `JSON_VALUE` function and specify an appropriate return type with the `RETURNING` clause.

**Examples**

The following examples use the `j_purchaseorder` table, which is created in "Creating a Table That Contains a JSON Document: Example" on page 7-158.

1. For a single targeted value:
   ```sql
   SELECT table_alias.JSON_column.JSON_object_key
   FROM j_purchaseorder
   WHERE JSON_object_key = 'some_key';
   ```

2. For multiple targeted values:
   ```sql
   SELECT table_alias.JSON_column.JSON_object_key
   FROM j_purchaseorder
   WHERE JSON_object_key = 'other_key';
   ```
Model Expressions

A model expression is used only in the `model_clause` of a SELECT statement and then only on the right-hand side of a model rule. It yields a value for a cell in a measure column previously defined in the `model_clause`. For additional information, refer to `model_clause` on page 19-35.

See Also: Oracle XML DB Developer’s Guide for more information on querying JSON data using dot-notation syntax
When you specify a measure column in a model expression, any conditions and expressions you specify must resolve to single values.

When you specify an aggregate function in a model expression, the argument to the function is a measure column that has been previously defined in the `model_clause`. An aggregate function can be used only on the right-hand side of a model rule.

Specifying an analytic function on the right-hand side of the model rule lets you express complex calculations directly in the `model_clause`. The following restrictions apply when using an analytic function in a model expression:

- Analytic functions can be used only in an `UPDATE` rule.
- You cannot specify an analytic function on the right-hand side of the model rule if the left-hand side of the rule contains a `FOR` loop or an `ORDER BY` clause.
- The arguments in the `OVER` clause of the analytic function cannot contain an aggregate.
- The arguments before the `OVER` clause of the analytic function cannot contain a cell reference.

**See Also:** "The MODEL clause: Examples" on page 19-63 for an example of using an analytic function on the right-hand side of a model rule.

When `expr` is itself a model expression, it is referred to as a **nested cell reference**. The following restrictions apply to nested cell references:

- Only one level of nesting is allowed.
- A nested cell reference must be a single-cell reference.
- **When AUTOMATIC ORDER is specified in the `model_rules_clause`, a nested cell reference can be used on the left-hand side of a model rule only if the measures used in the nested cell reference remain static.**

The model expressions shown below are based on the `model_clause` of the following `SELECT` statement:

```
SELECT country, prod, year, s
FROM sales_view_ref
MODEL
```
PARTITION BY (country)
DIMENSION BY (prod, year)
MEASURES (sale s)
IGNORE NAV
UNIQUE DIMENSION
RULES UPSERT? SEQUENTIAL ORDER
{
    s[prod='Mouse Pad', year=2000] =
    s['Mouse Pad', 1998] + s['Mouse Pad', 1999],
}
ORDER BY country, prod, year;

The following model expression represents a single cell reference using symbolic notation. It represents the sales of the Mouse Pad for the year 2000.

\[ s[\text{prod='Mouse Pad', year=2000}] \]

The following model expression represents a multiple cell reference using positional notation, using the CV function. It represents the sales of the current value of the dimension column prod for the year 2001.

\[ s[\text{CV(prod), 2001}] \]

The following model expression represents an aggregate function. It represents the sum of sales of the Mouse Pad for the years between the current value of the dimension column year less two and the current value of the dimension column year less one.

\[ \text{SUM}(s)[\text{'Mouse Pad', year BETWEEN CV()-2 AND CV()-1}] \]

See Also: CV on page 7-87 and model_clause on page 19-35

Object Access Expressions

An object access expression specifies attribute reference and method invocation.

**object_access_expression::=**

The column parameter can be an object or REF column. If you specify `expr`, then it must resolve to an object type.

When a type’s member function is invoked in the context of a SQL statement, if the SELF argument is null, Oracle returns null and the function is not invoked.

Examples The following example creates a table based on the sample oe.order_item_typ object type, and then shows how you would update and select from the object column attributes.

CREATE TABLE short_orders {

```sql
```
sales_rep VARCHAR2(25), item order_item_typ);

UPDATE short_orders s SET sales_rep = 'Unassigned';

SELECT o.item.line_item_id, o.item.quantity FROM short_orders o;

**Placeholder Expressions**

A placeholder expression provides a location in a SQL statement for which a third-generation language bind variable will provide a value. You can specify the placeholder expression with an optional indicator variable. This form of expression can appear only in embedded SQL statements or SQL statements processed in an Oracle Call Interface (OCI) program.

\[
\text{placeholder_expression} ::= \]

Some valid placeholder expressions are:

:employee_name INDICATOR :employee_name_indicator_var
:department_location

**Scalar Subquery Expressions**

A scalar subquery expression is a subquery that returns exactly one column value from one row. The value of the scalar subquery expression is the value of the select list item of the subquery. If the subquery returns 0 rows, then the value of the scalar subquery expression is NULL. If the subquery returns more than one row, then Oracle returns an error.

You can use a scalar subquery expression in most syntax that calls for an expression (\( \text{expr} \)). In all cases, a scalar subquery must be enclosed in its own parentheses, even if its syntactic location already positions it within parentheses (for example, when the scalar subquery is used as the argument to a built-in function).

Scalar subqueries are not valid expressions in the following places:

- As default values for columns
- As hash expressions for clusters
- In the RETURNING clause of DML statements
- As the basis of a function-based index
- In CHECK constraints
- In GROUP BY clauses
- In statements that are unrelated to queries, such as CREATE PROFILE

**Type Constructor Expressions**

A type constructor expression specifies a call to a constructor method. The argument to the type constructor is any expression. Type constructors can be invoked anywhere functions are invoked.
**type_constructor_expression**:=

The `NEW` keyword applies to constructors for object types but not for collection types. It instructs Oracle to construct a new object by invoking an appropriate constructor. The use of the `NEW` keyword is optional, but it is good practice to specify it.

If `type_name` is an object type, then the expressions must be an ordered list, where the first argument is a value whose type matches the first attribute of the object type, the second argument is a value whose type matches the second attribute of the object type, and so on. The total number of arguments to the constructor must match the total number of attributes of the object type.

If `type_name` is a varray or nested table type, then the expression list can contain zero or more arguments. Zero arguments implies construction of an empty collection. Otherwise, each argument corresponds to an element value whose type is the element type of the collection type.

**Restriction on Type Constructor Invocation**  In an invocation of a type constructor method, the number of parameters (`expr`) specified cannot exceed 999, even if the object type has more than 999 attributes. This limitation applies only when the constructor is called from SQL. For calls from PL/SQL, the PL/SQL limitations apply.

**See Also:** Oracle Database Object-Relational Developer’s Guide for additional information on constructor methods and Oracle Database PL/SQL Language Reference for information on PL/SQL limitations on calls to type constructors.

**Expression Example**  This example uses the `cust_address_typ` type in the sample oe schema to show the use of an expression in the call to a constructor method (the PL/SQL is shown in italics):

```sql
CREATE TYPE address_book_t AS TABLE OF cust_address_typ;
DECLARE
   myaddr cust_address_typ := cust_address_typ('500 Oracle Parkway', 94065, 'Redwood Shores', 'CA','USA');
   alladdr address_book_t := address_book_t();
BEGIN
   INSERT INTO customers VALUES (666999, 'Joe', 'Smith', myaddr, NULL, NULL, NULL, NULL,
                                  NULL, NULL, NULL, NULL, NULL, NULL, NULL);
END;
/
```

**Subquery Example**  This example uses the `warehouse_typ` type in the sample schema oe to illustrate the use of a subquery in the call to the constructor method.

```sql
CREATE TABLE warehouse_tab OF warehouse_typ;

INSERT INTO warehouse_tab
   VALUES (warehouse_typ(101, 'new_wh', 201));

CREATE TYPE facility_typ AS OBJECT {
   facility_id NUMBER,
   warehouse_ref REF warehouse_typ);
```
CREATE TABLE buildings (b_id NUMBER, building facility_typ);

INSERT INTO buildings VALUES (10, facility_typ(102,
  (SELECT REF(w) FROM warehouse_tab w
    WHERE warehouse_name = 'new_wh')));

SELECT b.b_id, b.building.facility_id "FAC_ID",
  DEREF(b.building.warehouse_ref) 'WH' FROM buildings b;

<table>
<thead>
<tr>
<th>B_ID</th>
<th>FAC_ID</th>
<th>WH(WAREHOUSE_ID, WAREHOUSE_NAME, LOCATION_ID)</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>102</td>
<td>WAREHOUSE_TYP(101, 'new_wh', 201)</td>
</tr>
</tbody>
</table>

Expression Lists

An expression list is a combination of other expressions.

expression_list ::= 

Expression lists can appear in comparison and membership conditions and in GROUP BY clauses of queries and subqueries. An expression list in a comparison or membership condition is sometimes referred to as a row value constructor or row constructor.

Comparison and membership conditions appear in the conditions of WHERE clauses. They can contain either one or more comma-delimited expressions or one or more sets of expressions where each set contains one or more comma-delimited expressions. In the latter case (multiple sets of expressions):

- Each set is bounded by parentheses
- Each set must contain the same number of expressions
- The number of expressions in each set must match the number of expressions before the operator in the comparison condition or before the IN keyword in the membership condition.

A comma-delimited list of expressions can contain no more than 1000 expressions. A comma-delimited list of sets of expressions can contain any number of sets, but each set can contain no more than 1000 expressions.

The following are some valid expression lists in conditions:

```
(10, 20, 40)
('SCOTT', 'BLAKE', 'TAYLOR')
(("Guy", 'Himuro', 'GHIMURO'), ('Karen', 'Colmenares', 'KCOLMENA'))
```

In the third example, the number of expressions in each set must equal the number of expressions in the first part of the condition. For example:

```
SELECT * FROM employees
WHERE (first_name, last_name, email) IN
  (("Guy", 'Himuro', 'GHIMURO'), ('Karen', 'Colmenares', 'KCOLMENA'))
```
In a simple GROUP BY clause, you can use either the upper or lower form of expression list:

```sql
SELECT department_id, MIN(salary) min, MAX(salary) max FROM employees
GROUP BY department_id, salary
ORDER BY department_id, min, max;
```

```sql
SELECT department_id, MIN(salary) min, MAX(salary) max FROM employees
GROUP BY (department_id, salary)
ORDER BY department_id, min, max;
```

In ROLLUP, CUBE, and GROUPING SETS clauses of GROUP BY clauses, you can combine individual expressions with sets of expressions in the same expression list. The following example shows several valid grouping sets expression lists in one SQL statement:

```sql
SELECT prod_category, prod_subcategory, country_id, cust_city, count(*)
FROM products, sales, customers
WHERE sales.prod_id = products.prod_id
AND sales.cust_id=customers.cust_id
AND sales.time_id = '01-oct-00'
GROUP BY GROUPING SETS
{
  (prod_category, prod_subcategory, country_id, cust_city),
  (prod_category, prod_subcategory, country_id),
  (prod_category, prod_subcategory),
  country_id
}
ORDER BY prod_category, prod_subcategory, country_id, cust_city;
```

**See Also:** SELECT on page 19-4
A **condition** specifies a combination of one or more expressions and logical (Boolean) operators and returns a value of **TRUE**, **FALSE**, or **UNKNOWN**.

This chapter contains the following sections:

- About SQL Conditions
- Comparison Conditions
- Floating-Point Conditions
- Logical Conditions
- Model Conditions
- Multiset Conditions
- Pattern-matching Conditions
- Null Conditions
- XML Conditions
- JSON Conditions
- Compound Conditions
- BETWEEN Condition
- EXISTS Condition
- IN Condition
- IS OF type Condition

**About SQL Conditions**

Conditions can have several forms, as shown in the following syntax.
If you have installed Oracle Text, then you can create conditions with the built-in operators that are part of that product, including CONTAINS, CATSEARCH, and MATCHES. For more information on these Oracle Text elements, refer to Oracle Text Reference.

The sections that follow describe the various forms of conditions. You must use appropriate condition syntax whenever condition appears in SQL statements.

You can use a condition in the WHERE clause of these statements:

- DELETE
- SELECT
- UPDATE

You can use a condition in any of these clauses of the SELECT statement:

- WHERE
- START WITH
- CONNECT BY
- HAVING

**Note:** The combined values of the NLS_COMP and NLS_SORT settings determine the rules by which characters are sorted and compared. If NLS_COMP is set to LINGUISTIC for your database, then all entities in this chapter will be interpreted according to the rules specified by the NLS_SORT parameter. If NLS_COMP is not set to LINGUISTIC, then the functions are interpreted without regard to the NLS_SORT setting. NLS_SORT can be explicitly set. If it is not set explicitly, it is derived from NLS_LANGUAGE. Refer to Oracle Database Globalization Support Guide for more information on these settings.
A condition could be said to be of a logical data type, although Oracle Database does not formally support such a data type.

The following simple condition always evaluates to TRUE:

\[ 1 = 1 \]

The following more complex condition adds the salary value to the commission_pct value (substituting the value 0 for null) and determines whether the sum is greater than the number constant 25000:

\[ \text{NVL(salary, 0) + NVL(salary + (salary*commission_pct, 0) > 25000) \]}

Logical conditions can combine multiple conditions into a single condition. For example, you can use the AND condition to combine two conditions:

\[ (1 = 1) \text{ AND } (5 < 7) \]

Here are some valid conditions:

- `name = 'SMITH'`
- `employees.department_id = departments.department_id`
- `hire_date > '01-JAN-08'`
- `job_id IN ('SA_MAN', 'SA_REP')`
- `salary BETWEEN 5000 AND 10000`
- `commission_pct IS NULL AND salary = 2100`

**See Also:** The description of each statement in Chapter 10 through Chapter 19 for the restrictions on the conditions in that statement

### Condition Precedence

**Precedence** is the order in which Oracle Database evaluates different conditions in the same expression. When evaluating an expression containing multiple conditions, Oracle evaluates conditions with higher precedence before evaluating those with lower precedence. Oracle evaluates conditions with equal precedence from left to right within an expression, with the following exceptions:

- Left to right evaluation is not guaranteed for multiple conditions connected using AND
- Left to right evaluation is not guaranteed for multiple conditions connected using OR

Table 6–1 lists the levels of precedence among SQL condition from high to low. Conditions listed on the same line have the same precedence. As the table indicates, Oracle evaluates operators before conditions.

<table>
<thead>
<tr>
<th>Type of Condition</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL operators are evaluated before SQL conditions</td>
<td>See “Operator Precedence” on page 4-2</td>

<tr>
<td>=, !=, &lt;, &gt;, &lt;=, &gt;=</td>
<td>comparison</td>
</tr>
<tr>
<td>IS [NOT] NULL, LIKE, [NOT] BETWEEN, [NOT] IN, EXISTS, IS OF type</td>
<td>comparison</td>
</tr>
<tr>
<td>NOT</td>
<td>exponentiation, logical negation</td>
</tr>
<tr>
<td>AND</td>
<td>conjunction</td>
</tr>
<tr>
<td>OR</td>
<td>disjunction</td>
</tr>
</tbody>
</table>
Comparison Conditions

Comparison conditions compare one expression with another. The result of such a comparison can be TRUE, FALSE, or UNKNOWN.

Large objects (LOBs) are not supported in comparison conditions. However, you can use PL/SQL programs for comparisons on CLOB data.

When comparing numeric expressions, Oracle uses numeric precedence to determine whether the condition compares NUMBER, BINARY_FLOAT, or BINARY_DOUBLE values. Refer to "Numeric Precedence" on page 2-16 for information on numeric precedence.

When comparing character expressions, Oracle uses the rules described in "Data Type Comparison Rules" on page 2-39. The rules define how the character sets of the expressions are aligned before the comparison, the use of binary or linguistic comparison (collation), and the use of blank-padded comparison semantics.

When character values are compared linguistically using the comparison conditions, they are first transformed to collation keys and then compared like RAW values. The collation keys are the same values that are returned by the function NLSSORT and are subject to the same restrictions that are described in "NLSSORT" on page 7-208. As a result of these restrictions, two expressions may compare as linguistically equal if they do not differ in the prefix that was used to produce the collation key, even if they differ in the rest of the value.

Two objects of nonscalar type are comparable if they are of the same named type and there is a one-to-one correspondence between their elements. In addition, nested tables of user-defined object types, even if their elements are comparable, must have MAP methods defined on them to be used in equality or IN conditions.

See Also: Oracle Database Object-Relational Developer’s Guide for information on using MAP methods to compare objects

Table 6–2 lists comparison conditions.

<table>
<thead>
<tr>
<th>Type of Condition</th>
<th>Purpose</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Equality test.</td>
<td>SELECT * FROM employees WHERE salary = 2500 ORDER BY employee_id;</td>
</tr>
<tr>
<td>!=</td>
<td>Inequality test. Some forms of the inequality condition may be unavailable on some platforms.</td>
<td>SELECT * FROM employees WHERE salary != 2500 ORDER BY employee_id;</td>
</tr>
<tr>
<td>^=</td>
<td></td>
<td>SELECT * FROM employees WHERE salary = 2500 ORDER BY employee_id;</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>Greater-than and less-than tests.</td>
<td>SELECT * FROM employees WHERE salary &gt; 2500 ORDER BY employee_id;</td>
</tr>
<tr>
<td>&lt;=</td>
<td></td>
<td>SELECT * FROM employees WHERE salary &lt; 2500 ORDER BY employee_id;</td>
</tr>
</tbody>
</table>
### Simple Comparison Conditions

A simple comparison condition specifies a comparison with expressions or subquery results.

**simple_comparison_condition::=**

### Table 6–2 (Cont.) Comparison Conditions

<table>
<thead>
<tr>
<th>Type of Condition</th>
<th>Purpose</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&gt;=</code></td>
<td>Greater-than-or-equal-to and less-than-or-equal-to tests.</td>
<td>SELECT * FROM employees WHERE salary &gt;= 2500 ORDER BY employee_id;</td>
</tr>
<tr>
<td><code>&lt;=</code></td>
<td></td>
<td>SELECT * FROM employees WHERE salary &lt;= 2500 ORDER BY employee_id;</td>
</tr>
<tr>
<td><strong>ANY</strong></td>
<td>Compares a value to each value in a list or returned by a query. Must be preceded by <code>=, !=, &gt;, &lt;, &lt;=, &gt;=</code>. Can be followed by any expression or subquery that returns one or more values.</td>
<td>SELECT * FROM employees WHERE salary = ANY (SELECT salary FROM employees WHERE department_id = 30) ORDER BY employee_id;</td>
</tr>
<tr>
<td><strong>SOME</strong></td>
<td>Evaluates to <strong>FALSE</strong> if the query returns no rows.</td>
<td></td>
</tr>
<tr>
<td><strong>ALL</strong></td>
<td>Compares a value to every value in a list or returned by a query. Must be preceded by <code>=, !=, &gt;, &lt;, &lt;=, &gt;=</code>. Can be followed by any expression or subquery that returns one or more values.</td>
<td>SELECT * FROM employees WHERE salary &gt;= ALL (1400, 3000) ORDER BY employee_id;</td>
</tr>
<tr>
<td></td>
<td>Evaluates to <strong>TRUE</strong> if the query returns no rows.</td>
<td></td>
</tr>
</tbody>
</table>
**expression_list**:=

If you use the lower form of this condition with a single expression to the left of the operator, then you can use the upper or lower form of `expression_list`. If you use the lower form of this condition with multiple expressions to the left of the operator, then you must use the lower form of `expression_list`. In either case, the expressions in `expression_list` must match in number and data type the expressions to the left of the operator. If you specify `subquery`, then the values returned by the subquery must match in number and data type the expressions to the left of the operator.

**See Also:** "Expression Lists" on page 5-18 for more information about combining expressions and `SELECT` on page 19-4 for information about subqueries

**Group Comparison Conditions**

A group comparison condition specifies a comparison with any or all members in a list or subquery.

**group_comparison_condition**:=

If you use the lower form of this condition with a single expression to the left of the operator, then you can use the upper or lower form of `expression_list`. If you use the lower form of this condition with multiple expressions to the left of the operator, then you must use the lower form of `expression_list`. In either case, the expressions in `expression_list` must match in number and data type the expressions to the left of the operator. If you specify `subquery`, then the values returned by the subquery must match in number and data type the expressions to the left of the operator.
expression_list::=

If you use the upper form of this condition (with a single expression to the left of the operator), then you must use the upper form of expression_list. If you use the lower form of this condition (with multiple expressions to the left of the operator), then you must use the lower form of expression_list, and the expressions in each expression_list must match in number and data type the expressions to the left of the operator. If you specify subquery, then the values returned by the subquery must match in number and data type the expressions to the left of the operator.

See Also:
- "Expression Lists" on page 5-18
- SELECT on page 19-4

Floating-Point Conditions

The floating-point conditions let you determine whether an expression is infinite or is the undefined result of an operation (is not a number or NaN).

floating_point_condition::=

In both forms of floating-point condition, expr must resolve to a numeric data type or to any data type that can be implicitly converted to a numeric data type. Table 6–3 describes the floating-point conditions.

<table>
<thead>
<tr>
<th>Type of Condition</th>
<th>Operation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IS [NOT] NaN</td>
<td>Returns TRUE if expr is the special value NaN when NOT is not specified. Returns TRUE if expr is not the special value NaN when NOT is specified.</td>
<td>SELECT COUNT(*) FROM employees WHERE commission_pct IS NOT NAN;</td>
</tr>
<tr>
<td>IS [NOT] INFINITE</td>
<td>Returns TRUE if expr is the special value +INF or -INF when NOT is not specified. Returns TRUE if expr is neither +INF nor -INF when NOT is specified.</td>
<td>SELECT last_name FROM employees WHERE salary IS NOT INFINITE;</td>
</tr>
</tbody>
</table>
A logical condition combines the results of two component conditions to produce a single result based on them or to invert the result of a single condition. Table 6–4 lists logical conditions.

**Table 6–4  Logical Conditions**

<table>
<thead>
<tr>
<th>Type of Condition</th>
<th>Operation</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT</td>
<td>Returns TRUE if the following condition is FALSE. Returns FALSE if it is TRUE. If it is UNKNOWN, then it remains UNKNOWN.</td>
<td>SELECT * FROM employees WHERE NOT (job_id IS NULL) ORDER BY employee_id;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SELECT * FROM employees WHERE NOT (salary BETWEEN 1000 AND 2000) ORDER BY employee_id;</td>
</tr>
<tr>
<td>AND</td>
<td>Returns TRUE if both component conditions are TRUE. Returns FALSE if either is FALSE. Otherwise returns UNKNOWN.</td>
<td>SELECT * FROM employees WHERE job_id = 'PU_CLERK' AND department_id = 30 ORDER BY employee_id;</td>
</tr>
<tr>
<td>OR</td>
<td>Returns TRUE if either component condition is TRUE. Returns FALSE if both are FALSE. Otherwise returns UNKNOWN.</td>
<td>SELECT * FROM employees WHERE job_id = 'PU_CLERK' OR department_id = 10 ORDER BY employee_id;</td>
</tr>
</tbody>
</table>

Table 6–5 shows the result of applying the NOT condition to an expression.

**Table 6–5  NOT Truth Table**

<table>
<thead>
<tr>
<th>--</th>
<th>TRUE</th>
<th>FALSE</th>
<th>UNKNOWN</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT</td>
<td>FALSE</td>
<td>TRUE</td>
<td>UNKNOWN</td>
</tr>
</tbody>
</table>

Table 6–6 shows the results of combining the AND condition to two expressions.

**Table 6–6  AND Truth Table**

<table>
<thead>
<tr>
<th>AND</th>
<th>TRUE</th>
<th>FALSE</th>
<th>UNKNOWN</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRUE</td>
<td>TRUE</td>
<td>FALSE</td>
<td>UNKNOWN</td>
</tr>
<tr>
<td>FALSE</td>
<td>FALSE</td>
<td>FALSE</td>
<td>FALSE</td>
</tr>
<tr>
<td>UNKNOWN</td>
<td>UNKNOWN</td>
<td>FALSE</td>
<td>UNKNOWN</td>
</tr>
</tbody>
</table>
For example, in the WHERE clause of the following SELECT statement, the AND logical condition is used to ensure that only those hired before 2004 and earning more than $2500 a month are returned:

```
SELECT * FROM employees
WHERE hire_date < TO_DATE('01-JAN-2004', 'DD-MON-YYYY')
   AND salary > 2500
ORDER BY employee_id;
```

**Table 6–7** shows the results of applying OR to two expressions.

<table>
<thead>
<tr>
<th>OR</th>
<th>TRUE</th>
<th>FALSE</th>
<th>UNKNOWN</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRUE</td>
<td>TRUE</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
<tr>
<td>FALSE</td>
<td>TRUE</td>
<td>FALSE</td>
<td>UNKNOWN</td>
</tr>
<tr>
<td>UNKNOWN</td>
<td>TRUE</td>
<td>UNKNOWN</td>
<td>UNKNOWN</td>
</tr>
</tbody>
</table>

For example, the following query returns employees who have a 40% commission rate or a salary greater than $20,000:

```
SELECT employee_id FROM employees
WHERE commission_pct = .4 OR salary > 20000
ORDER BY employee_id;
```

### Model Conditions

Model conditions can be used only in the **MODEL** clause of a SELECT statement.

#### IS ANY Condition

The **IS ANY** condition can be used only in the **model_clause** of a SELECT statement. Use this condition to qualify all values of a dimension column, including **NULL**.

**is_any_condition**:=

```
dimension_column IS ANY
```

The condition always returns a Boolean value of **TRUE** in order to qualify all values of the column.

**See Also:** [model_clause](#) on page 19-35 and "Model Expressions" on page 5-13 for information

### Example

The following example sets sales for each product for year 2000 to 0:

```
SELECT country, prod, year, s
FROM sales_view_ref
MODEL
   PARTITION BY (country)
   DIMENSION BY (prod, year)
   MEASURES (sale s)
   IGNORE NAV
   UNIQUE NAV
```
RULES UPSERT SEQUENTIAL ORDER
{
    s[ANY, 2000] = 0
}
ORDER BY country, prod, year;

<table>
<thead>
<tr>
<th>COUNTRY</th>
<th>PROD</th>
<th>YEAR</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td>France</td>
<td>Mouse Pad</td>
<td>1998</td>
<td>2509.42</td>
</tr>
<tr>
<td>France</td>
<td>Mouse Pad</td>
<td>1999</td>
<td>3678.69</td>
</tr>
<tr>
<td>France</td>
<td>Mouse Pad</td>
<td>2000</td>
<td>0</td>
</tr>
<tr>
<td>France</td>
<td>Mouse Pad</td>
<td>2001</td>
<td>3269.09</td>
</tr>
<tr>
<td>France</td>
<td>Standard Mouse</td>
<td>1998</td>
<td>2390.83</td>
</tr>
<tr>
<td>France</td>
<td>Standard Mouse</td>
<td>1999</td>
<td>2280.45</td>
</tr>
<tr>
<td>France</td>
<td>Standard Mouse</td>
<td>2000</td>
<td>0</td>
</tr>
<tr>
<td>France</td>
<td>Standard Mouse</td>
<td>2001</td>
<td>2164.54</td>
</tr>
<tr>
<td>Germany</td>
<td>Mouse Pad</td>
<td>1998</td>
<td>5827.87</td>
</tr>
<tr>
<td>Germany</td>
<td>Mouse Pad</td>
<td>1999</td>
<td>8346.44</td>
</tr>
<tr>
<td>Germany</td>
<td>Mouse Pad</td>
<td>2000</td>
<td>0</td>
</tr>
<tr>
<td>Germany</td>
<td>Mouse Pad</td>
<td>2001</td>
<td>9535.08</td>
</tr>
<tr>
<td>Germany</td>
<td>Standard Mouse</td>
<td>1998</td>
<td>7116.11</td>
</tr>
<tr>
<td>Germany</td>
<td>Standard Mouse</td>
<td>1999</td>
<td>6263.14</td>
</tr>
<tr>
<td>Germany</td>
<td>Standard Mouse</td>
<td>2000</td>
<td>0</td>
</tr>
<tr>
<td>Germany</td>
<td>Standard Mouse</td>
<td>2001</td>
<td>6456.13</td>
</tr>
</tbody>
</table>

16 rows selected.

The preceding example requires the view sales_view_ref. Refer to "The MODEL clause: Examples" on page 19-63 to create this view.

IS PRESENT Condition

`is_present_condition :=`

The IS PRESENT condition can be used only in the model_clause of a SELECT statement. Use this condition to test whether the cell referenced is present prior to the execution of the model_clause.

The condition returns **TRUE** if the cell exists prior to the execution of the model_clause and **FALSE** if it does not.

**See Also:**  `model_clause` on page 19-35 and "Model Expressions" on page 5-13 for information

**Example**

In the following example, if sales of the Mouse Pad for year 1999 exist, then sales of the Mouse Pad for year 2000 is set to sales of the Mouse Pad for year 1999. Otherwise, sales of the Mouse Pad for year 2000 is set to 0.

```
SELECT country, prod, year, s
FROM sales_view_ref
MODEL
    PARTITION BY {country}
    DIMENSION BY {prod, year}
    MEASURES {sale s}
    IGNORE NAV
```
Multiset Conditions

Multiset conditions test various aspects of nested tables.

IS A SET Condition

Use IS A SET conditions to test whether a specified nested table is composed of unique elements. The condition returns UNKNOWN if the nested table is NULL. Otherwise, it returns TRUE if the nested table is a set, even if it is a nested table of length zero, and FALSE otherwise.

\[
\text{is\_a\_set\_condition} ::= \\
\text{nested\_table} \quad \text{IS} \quad \text{NOT} \quad \text{A} \quad \text{SET}
\]

Example

The following example selects from the table customers_demo those rows in which the cust_address_ntab nested table column contains unique elements:

```sql
SELECT customer_id, cust_address_ntab
FROM customers_demo
WHERE cust_address_ntab IS A SET
ORDER BY customer_id;
```
CUSTOMER_ID CUST_ADDRESS_NTAB(STREET_ADDRESS, POSTAL_CODE, CITY, STATE_PROVINCE, COUNTRY_ID)
----------------------------------------------------------------------------------------------
101 CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP('514 W Superior St', '46901', 'Kokomo', 'IN', 'US'))
102 CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP('2515 Boyd Ave', '46218', 'Indianapolis', 'IN', 'US'))
103 CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP('8768 N State Rd 37', '47404', 'Bloomington', 'IN', 'US'))
104 CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP('6445 Bay Harbor Ln', '46254', 'Indianapolis', 'IN', 'US'))
105 CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP('4819 W 3Rd St', '47404', 'Bloomington', 'IN', 'US'))

The preceding example requires the table customers_demo and a nested table column containing data. Refer to “Multiset Operators” on page 4-5 to create this table and nested table column.

**IS EMPTY Condition**

Use the `IS [NOT] EMPTY` conditions to test whether a specified nested table is empty. A nested table that consists of a single value, a `NULL`, is not considered an empty nested table.

**is_empty_condition::=**

```
  nested_table | IS | NOT | EMPTY
```

The condition returns a Boolean value: `TRUE` for an `IS EMPTY` condition if the collection is empty, and `TRUE` for an `IS NOT EMPTY` condition if the collection is not empty. If you specify `NULL` for the nested table or varray, then the result is `NULL`.

**Example**

The following example selects from the sample table `pm.print_media` those rows in which the `ad_textdocs_ntab` nested table column is not empty:

```
SELECT product_id, TO_CHAR(ad_finaltext) AS text
FROM print_media
WHERE ad_textdocs_ntab IS NOT EMPTY
ORDER BY product_id, text;
```

**MEMBER Condition**

```
member_condition ::=  
```

A `member_condition` is a membership condition that tests whether an element is a member of a nested table. The return value is `TRUE` if `expr` is equal to a member of the specified nested table or varray. The return value is `NULL` if `expr` is null or if the nested table is empty.

- `expr` must be of the same type as the element type of the nested table.
- The `OF` keyword is optional and does not change the behavior of the condition.
- The `NOT` keyword reverses the Boolean output: Oracle returns `FALSE` if `expr` is a member of the specified nested table.
- The element types of the nested table must be comparable. Refer to “Comparison Conditions” on page 6-4 for information on the comparability of nonscalar types.
Example

The following example selects from the table customers_demo those rows in which the cust_address_ntab nested table column contains the values specified in the WHERE clause:

```
SELECT customer_id, cust_address_ntab
FROM customers_demo
WHERE cust_address_typ('8768 N State Rd 37', 47404, 'Bloomington', 'IN', 'US')
MEMBER OF cust_address_ntab
ORDER BY customer_id;
```

<table>
<thead>
<tr>
<th>CUSTOMER_ID</th>
<th>CUST_ADDRESS_NTAB(STREET_ADDRESS, POSTAL_CODE, CITY, STATE_PROVINCE, COUNTRY_ID)</th>
</tr>
</thead>
<tbody>
<tr>
<td>103</td>
<td>CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP('8768 N State Rd 37', '47404', 'Bloomington', 'IN', 'US'))</td>
</tr>
</tbody>
</table>

The preceding example requires the table customers_demo and a nested table column containing data. Refer to "Multiset Operators" on page 4-5 to create this table and nested table column.

SUBMULTISET Condition

The SUBMULTISET condition tests whether a specified nested table is a submultiset of another specified nested table.

The operator returns a Boolean value. TRUE is returned when nested_table1 is a submultiset of nested_table2. nested_table1 is a submultiset of nested_table2 when one of the following conditions occur:

- nested_table1 is not null and contains no rows. TRUE is returned even if nested_table2 is null since an empty multiset is a submultiset of any non-null replacement for nested_table2.
- nested_table1 and nested_table2 are not null, nested_table1 does not contain a null element, and there is a one-to-one mapping of each element in nested_table1 to an equal element in nested_table2.

NULL is returned when one of the following conditions occurs:

- nested_table1 is null.
- nested_table2 is null, and nested_table1 is not null and not empty.
- nested_table1 is a submultiset of nested_table2 after modifying each null element of nested_table1 and nested_table2 to some non-null value, enabling a one-to-one mapping of each element in nested_table1 to an equal element in nested_table2.

If none of the above conditions occur, then FALSE is returned.

```
submultiset_condition ::= 
```

- The OF keyword is optional and does not change the behavior of the operator.
- The NOT keyword reverses the Boolean output: Oracle returns FALSE if nested_table1 is a subset of nested_table2.
- The element types of the nested table must be comparable. Refer to "Comparison Conditions" on page 6-4 for information on the comparability of nonscalar types.
Example
The following example selects from the `customers_demo` table those rows in which the `cust_address_ntab` nested table is a submultiset of the `cust_address2_ntab` nested table:

```sql
SELECT customer_id, cust_address_ntab
FROM customers_demo
WHERE cust_address_ntab SUBMULTISET OF cust_address2_ntab
ORDER BY customer_id;
```

The preceding example requires the table `customers_demo` and two nested table columns containing data. Refer to "Multiset Operators" on page 4-5 to create this table and nested table columns.

Pattern-matching Conditions
The pattern-matching conditions compare character data.

LIKE Condition
The `LIKE` conditions specify a test involving pattern matching. Whereas the equality operator (=) exactly matches one character value to another, the `LIKE` conditions match a portion of one character value to another by searching the first value for the pattern specified by the second. `LIKE` calculates strings using characters as defined by the input character set. `LIKEC` uses Unicode complete characters. `LIKE2` uses UCS2 code points. `LIKE4` uses UCS4 code points.

\[
\text{like\_condition} :=
\]

In this syntax:
- `char1` is a character expression, such as a character column, called the **search value**.
- `char2` is a character expression, usually a literal, called the **pattern**.
- `esc_char` is a character expression, usually a literal, called the **escape character**.

The `LIKE` condition is the best choice in almost all situations. Use the following guidelines to determine whether any of the variations would be helpful in your environment:
- Use `LIKE2` to process strings using UCS-2 semantics. `LIKE2` treats a Unicode supplementary character as two characters.
- Use `LIKE4` to process strings using UCS-4 semantics. `LIKE4` treats a Unicode supplementary character as one character.
- Use `LIKEC` to process strings using Unicode complete character semantics. `LIKEC` treats a composite character as one character.
If esc_char is not specified, then there is no default escape character. If any of char1, char2, or esc_char is null, then the result is unknown. Otherwise, the escape character, if specified, must be a character string of length 1.

All of the character expressions (char1, char2, and esc_char) can be of any of the data types CHAR, VARCHAR2, NCHAR, or NVARCHAR2. If they differ, then Oracle converts all of them to the data type of char1.

The pattern can contain special pattern-matching characters:

- An underscore (_) in the pattern matches exactly one character (as opposed to one byte in a multibyte character set) in the value.
- A percent sign (%) in the pattern can match zero or more characters (as opposed to bytes in a multibyte character set) in the value. The pattern ‘%’ cannot match a null.

You can include the actual characters % or _ in the pattern by using the ESCAPE clause, which identifies the escape character. If the escape character precedes the character % or _ in the pattern, then Oracle interprets this character literally in the pattern rather than as a special pattern-matching character. You can also search for the escape character itself by repeating it. For example, if @ is the escape character, then you can use @@ to search for @.

Table 6–8 describes the LIKE conditions.

<table>
<thead>
<tr>
<th>Type of Condition</th>
<th>Operation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>x [NOT] LIKE y [ESCAPE ‘x’]</td>
<td>TRUE if x does [not] match the pattern y.</td>
<td>SELECT last_name FROM employees WHERE last_name LIKE '%A_B%' ESCAPE '';</td>
</tr>
</tbody>
</table>

To process the LIKE conditions, Oracle divides the pattern into subpatterns consisting of one or two characters each. The two-character subpatterns begin with the escape character and the other character is %, or _, or the escape character.

Let P1, P2, ..., Pn be these subpatterns. The like condition is true if there is a way to partition the search value into substrings S1, S2, ..., Sn so that for all i between 1 and n:

- If Pi is _, then Si is a single character.
- If Pi is %, then Si is any string.
- If Pi is two characters beginning with an escape character, then Si is the second character of Pi.
- Otherwise, Pi = Si.
With the **LIKE** conditions, you can compare a value to a pattern rather than to a constant. The pattern must appear after the **LIKE** keyword. For example, you can issue the following query to find the salaries of all employees with names beginning with `R`:

```sql
SELECT salary
FROM employees
WHERE last_name LIKE 'R%'
ORDER BY salary;
```

The following query uses the **=`** operator, rather than the **LIKE** condition, to find the salaries of all employees with the name `R%`:

```sql
SELECT salary
FROM employees
WHERE last_name = 'R'
ORDER BY salary;
```

The following query finds the salaries of all employees with the name `SM%`. Oracle interprets `SM%` as a text literal, rather than as a pattern, because it precedes the **LIKE** keyword:

```sql
SELECT salary
FROM employees
WHERE 'SM%' LIKE last_name
ORDER BY salary;
```

**Case Sensitivity**

Case is significant in all conditions comparing character expressions that use the **LIKE** condition and the equality (**) operators. You can perform case or accent insensitive **LIKE** searches by setting the **NLS_SORT** and the **NLS_COMP** session parameters.

See Also:  *Oracle Database Globalization Support Guide* for more information on this case- and accent-insensitive linguistic sorts

**Pattern Matching on Indexed Columns**

When you use **LIKE** to search an indexed column for a pattern, Oracle can use the index to improve performance of a query if the leading character in the pattern is not `%` or `_`. In this case, Oracle can scan the index by this leading character. If the first character in the pattern is `%` or `_`, then the index cannot improve performance because Oracle cannot scan the index.

**LIKE Condition: General Examples**

This condition is true for all `last_name` values beginning with `Ma`:

```sql
last_name LIKE 'Ma%'
```

All of these `last_name` values make the condition true:

Mallin, Markle, Marlow, Marvins, Mavris, Matos

Case is significant, so `last_name` values beginning with `MA`, `ma`, and `mA` make the condition false.

Consider this condition:

```sql
last_name LIKE 'SMITH_'
```

This condition is true for these `last_name` values:

Smithe, Smithy, Smiths

---

6-16  *Oracle Database SQL Language Reference*
Pattern-matching Conditions

This condition is false for SMITH because the special underscore character (\_) must match exactly one character of the last_name value.

**ESCAPE Clause Example**  The following example searches for employees with the pattern A_B in their name:

```sql
SELECT last_name
FROM employees
WHERE last_name LIKE '%A\_B%' ESCAPE '\'
ORDER BY last_name;
```

The ESCAPE clause identifies the backslash (\) as the escape character. In the pattern, the escape character precedes the underscore (\_). This causes Oracle to interpret the underscore literally, rather than as a special pattern matching character.

**Patterns Without % Example**  If a pattern does not contain the % character, then the condition can be true only if both operands have the same length. Consider the definition of this table and the values inserted into it:

```sql
CREATE TABLE ducks (f CHAR(6), v VARCHAR2(6));
INSERT INTO ducks VALUES ('DUCK', 'DUCK');
SELECT '*'||f||'*' "char",
     '*'||v||'*' "varchar"
FROM ducks;
```

```
char     varchar
-------- --------
*DUCK  * *DUCK*
```

Because Oracle blank-pads CHAR values, the value of f is blank-padded to 6 bytes. v is not blank-padded and has length 4.

**REGEXP_LIKE Condition**

REGEXP_LIKE is similar to the LIKE condition, except REGEXP_LIKE performs regular expression matching instead of the simple pattern matching performed by LIKE. This condition evaluates strings using characters as defined by the input character set.

This condition complies with the POSIX regular expression standard and the Unicode Regular Expression Guidelines. For more information, refer to Appendix D, "Oracle Regular Expression Support".

**regexp_like_condition::=**

```sql
REGEXP_LIKE (source_char, pattern, match_param)
```

- **source_char** is a character expression that serves as the search value. It is commonly a character column and can be of any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB.
- **pattern** is the regular expression. It is usually a text literal and can be of any of the data types CHAR, VARCHAR2, NCHAR, or NVARCHAR2. It can contain up to 512 bytes. If the data type of pattern is different from the data type of source_char, Oracle converts pattern to the data type of source_char. For a listing of the operators you can specify in pattern, refer to Appendix D, "Oracle Regular Expression Support".
■ `match_parameter` is a text literal that lets you change the default matching behavior of the function. You can specify one or more of the following values for `match_parameter`:

- `i` specifies case-insensitive matching.
- `c` specifies case-sensitive matching.
- `n` allows the period (.), which is the match-any-character wildcard character, to match the newline character. If you omit this parameter, then the period does not match the newline character.
- `m` treats the source string as multiple lines. Oracle interprets `^` and `$` as the start and end, respectively, of any line anywhere in the source string, rather than only at the start or end of the entire source string. If you omit this parameter, then Oracle treats the source string as a single line.
- `x` ignores whitespace characters. By default, whitespace characters match themselves.

If you specify multiple contradictory values, then Oracle uses the last value. For example, if you specify `ic`, then Oracle uses case-sensitive matching. If you specify a character other than those shown above, then Oracle returns an error.

If you omit `match_parameter`, then:

- The default case sensitivity is determined by the value of the `NLS_SORT` parameter.
- A period (.) does not match the newline character.
- The source string is treated as a single line.

See Also:

- "LIKE Condition" on page 6-14
- `REGEXP_INSTR` on page 7-271, `REGEXP_REPLACE` on page 7-274, and `REGEXP_SUBSTR` on page 7-277 for functions that provide regular expression support

Examples

The following query returns the first and last names for those employees with a first name of Steven or Stephen (where `first_name` begins with Ste and ends with en and in between is either v or ph):

```sql
SELECT first_name, last_name
FROM employees
WHERE REGEXP_LIKE (first_name, '^Ste(v|ph)en$')
ORDER BY first_name, last_name;
```

<table>
<thead>
<tr>
<th>FIRST_NAME</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Steven</td>
<td>King</td>
</tr>
<tr>
<td>Steven</td>
<td>Markle</td>
</tr>
<tr>
<td>Stephen</td>
<td>Stiles</td>
</tr>
</tbody>
</table>

The following query returns the last name for those employees with a double vowel in their last name (where `last_name` contains two adjacent occurrences of either a, e, i, o, or u, regardless of case):

```sql
SELECT last_name
FROM employees
```

Examples
WHERE REGEXP_LIKE (last_name, '[aeiou]\1', 'i')
ORDER BY last_name;

<table>
<thead>
<tr>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>De Haan</td>
</tr>
<tr>
<td>Greenberg</td>
</tr>
<tr>
<td>Khoo</td>
</tr>
<tr>
<td>Gee</td>
</tr>
<tr>
<td>Greene</td>
</tr>
<tr>
<td>Lee</td>
</tr>
<tr>
<td>Bloom</td>
</tr>
<tr>
<td>Feeney</td>
</tr>
</tbody>
</table>

**Null Conditions**

A NULL condition tests for nulls. This is the only condition that you should use to test for nulls.

```sql
null_condition ::= 

expr IS [NOT] NULL
```

Table 6–9 lists the null conditions.

**Table 6–9 Null Condition**

<table>
<thead>
<tr>
<th>Type of Condition</th>
<th>Operation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IS (NOT) NULL</td>
<td>Tests for nulls.</td>
<td>SELECT last_name, FROM employees, WHERE commission_pct IS NULL ORDER BY last_name;</td>
</tr>
<tr>
<td></td>
<td>See Also: 'Nulls' on page 2-74</td>
<td></td>
</tr>
</tbody>
</table>

**XML Conditions**

XML conditions determine whether a specified XML resource can be found in a specified path.

**EQUALS_PATH Condition**

The EQUALS_PATH condition determines whether a resource in the Oracle XML database can be found in the database at a specified path.

Use this condition in queries to RESOURCE_VIEW and PATH_VIEW. These public views provide a mechanism for SQL access to data stored in the XML database repository. RESOURCE_VIEW contains one row for each resource in the repository, and PATH_VIEW contains one row for each unique path in the repository.

```sql
equals_path_condition ::= 

EQUALS_PATH (.column .path_string .correlation_integer)
```
This condition applies only to the path as specified. It is similar to but more restrictive than UNDER_PATH.

For path_string, specify the (absolute) path name to resolve. This can contain components that are hard or weak resource links.

The optional correlation_integer argument correlates the EQUALS_PATH condition with its ancillary functions DEPTH and PATH.

See Also: UNDER_PATH Condition on page 6-20, DEPTH on page 7-99, and PATH on page 7-225

Example

The view RESOURCE_VIEW computes the paths (in the any_path column) that lead to all XML resources (in the res column) in the database repository. The following example queries the RESOURCE_VIEW view to find the paths to the resources in the sample schema oe. The EQUALS_PATH condition causes the query to return only the specified path:

```
SELECT ANY_PATH FROM RESOURCE_VIEW
  WHERE EQUALS_PATH(res, '/sys/schemas/OE/www.example.com')=1;
```

Compare this example with that for UNDER_PATH Condition on page 6-20.

UNDER_PATH Condition

The UNDER_PATH condition determines whether resources specified in a column can be found under a particular path specified by path_string in the Oracle XML database repository. The path information is computed by the RESOURCE_VIEW view, which you query to use this condition.

Use this condition in queries to RESOURCE_VIEW and PATH_VIEW. These public views provide a mechanism for SQL access to data stored in the XML database repository. RESOURCE_VIEW contains one row for each resource in the repository, and PATH_VIEW contains one row for each unique path in the repository.

```
under_path_condition::= UNDER_PATH column levels path_string correlation_integer
```

The optional levels argument indicates the number of levels down from path_string Oracle should search. For levels, specify any nonnegative integer.

The optional correlation_integer argument correlates the UNDER_PATH condition with its ancillary functions PATH and DEPTH.

See Also: The related condition EQUALS_PATH Condition on page 6-19 and the ancillary functions DEPTH on page 7-99 and PATH on page 7-225

Example

The view RESOURCE_VIEW computes the paths (in the any_path column) that lead to all XML resources (in the res column) in the database repository. The following example
queries the RESOURCE_VIEW view to find the paths to the resources in the sample schema oe. The query returns the path of the XML schema that was created in "XMLType Table Examples" on page 16-94:

```sql
SELECT ANY_PATH FROM RESOURCE_VIEW
    WHERE UNDER_PATH(res, '/sys/schemas/OE/www.example.com')=1;
```

ANY_PATH
----------------------------------------------
/sys/schemas/OE/www.example.com/xwarehouses.xsd

### JSON Conditions

JavaScript Object Notation (JSON) conditions allow you to test JSON data as follows:

- **IS JSON Condition** lets you test whether an expression is syntactically correct JSON data
- **JSON_EXISTS Condition** lets you test whether a specified JSON value exists in JSON data
- **JSON_TEXTCONTAINS Condition** lets you test whether a specified character string exists in JSON property values.

#### JSON_condition ::= 

```plaintext
is_JSON_condition

JSON_exists_condition

JSON_textcontains_condition
```

---

**Note:** The JSON conditions are available starting with Oracle Database 12c Release 1 (12.1.0.2).

### IS JSON Condition

Use this condition to test whether an expression is syntactically correct, or well-formed, JSON data.

- If you specify **IS JSON**, then this condition returns **TRUE** if the expression is well-formed JSON data and **FALSE** if the expression is not well-formed JSON data.
- If you specify **IS NOT JSON**, then this condition returns **TRUE** if the expression is not well-formed JSON data and **FALSE** if the expression is well-formed JSON data.

#### is_JSON_condition ::= 

```plaintext
expr IS NOT JSON FORMAT STRICT LAX WITH WITHOUT UNIQUE KEYS
```
Use \textit{expr} to specify the JSON data to be evaluated. Specify an expression that evaluates to a text literal. If \textit{expr} is a column, then the column must be of data type \texttt{VARCHAR2}, \texttt{CLOB}, or \texttt{BLOB}. If \textit{expr} evaluates to null or a text literal of length zero, then this condition returns \texttt{UNKNOWN}.

You must specify \texttt{FORMAT JSON} if \textit{expr} is a column of data type \texttt{BLOB}.

If you specify \texttt{STRICT}, then this condition considers only strict JSON syntax to be well-formed JSON data. If you specify \texttt{LAX}, then this condition also considers lax JSON syntax to be well-formed JSON data. The default is \texttt{LAX}. Refer to \textit{Oracle XML DB Developer's Guide} for more information on strict and lax JSON syntax.

If you specify \texttt{WITH UNIQUE KEYS}, then this condition considers JSON data to be well-formed only if key names are unique within each object. If you specify \texttt{WITHOUT UNIQUE KEYS}, then this condition considers JSON data to be well-formed even if duplicate key names occur within an object. A \texttt{WITHOUT UNIQUE KEYS} test performs faster than a \texttt{WITH UNIQUE KEYS} test. The default is \texttt{WITHOUT UNIQUE KEYS}.

## Examples

### Testing for STRICT or LAX JSON Syntax: Example

The following statement creates table \texttt{t} with column \texttt{col1}:

```
CREATE TABLE t (col1 VARCHAR2(100));
```

The following statements insert values into column \texttt{col1} of table \texttt{t}:

```
INSERT INTO t VALUES ( '\{ "LIT192", "CS141", "HIS160" \}' );
INSERT INTO t VALUES ( '\{ "Name": "John" \}' );
INSERT INTO t VALUES ( '\{ "Grade Values": \{ A : 4.0, B : 3.0, C : 2.0 \} \}' );
INSERT INTO t VALUES ( '\{ "isEnrolled": true \}' );
INSERT INTO t VALUES ( '\{ "isMatriculated": False \}' );
INSERT INTO t VALUES (NULL);
INSERT INTO t VALUES ('This is not well-formed JSON data');
```

The following statement queries table \texttt{t} and returns \texttt{col1} values that are well-formed JSON data. Because neither the \texttt{STRICT} nor \texttt{LAX} keyword is specified, this example uses the default \texttt{LAX} setting. Therefore, this query returns values that use strict or lax JSON syntax.

```
SELECT col1
FROM t
WHERE col1 IS JSON;
```

```
<table>
<thead>
<tr>
<th>COL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ &quot;LIT192&quot;, &quot;CS141&quot;, &quot;HIS160&quot; ]</td>
</tr>
<tr>
<td>{ &quot;Name&quot;: &quot;John&quot; }</td>
</tr>
<tr>
<td>{ &quot;Grade Values&quot;: { A : 4.0, B : 3.0, C : 2.0 } }</td>
</tr>
<tr>
<td>{ &quot;isEnrolled&quot;: true }</td>
</tr>
<tr>
<td>{ &quot;isMatriculated&quot;: False }</td>
</tr>
</tbody>
</table>
```

The following statement queries table \texttt{t} and returns \texttt{col1} values that are well-formed JSON data. This example specifies the \texttt{STRICT} setting. Therefore, this query returns only values that use strict JSON syntax.

```
SELECT col1
FROM t
WHERE col1 IS JSON STRICT;
```

```
<table>
<thead>
<tr>
<th>COL1</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ &quot;LIT192&quot;, &quot;CS141&quot;, &quot;HIS160&quot; ]</td>
</tr>
<tr>
<td>{ &quot;Name&quot;: &quot;John&quot; }</td>
</tr>
<tr>
<td>{ &quot;Grade Values&quot;: { A : 4.0, B : 3.0, C : 2.0 } }</td>
</tr>
<tr>
<td>{ &quot;isEnrolled&quot;: true }</td>
</tr>
<tr>
<td>{ &quot;isMatriculated&quot;: False }</td>
</tr>
</tbody>
</table>
```
The following statement queries table `t` and returns `col1` values that use lax JSON syntax, but omits `col1` values that use strict JSON syntax. Therefore, this query returns only values that contain the exceptions allowed in lax JSON syntax.

```sql
SELECT col1
FROM t
WHERE col1 IS NOT JSON STRICT AND col1 IS JSON LAX;
```

```
COL1
{ 'Grade Values' : { A : 4.0, B : 3.0, C : 2.0 } }
{ 'isMatriculated' : False }
```

**Testing for Unique Keys: Example**

The following statement creates table `t` with column `col1`:

```sql
CREATE TABLE t (col1 VARCHAR2(100));
```

The following statements insert values into column `col1` of table `t`:

```sql
INSERT INTO t VALUES ('{a:100, b:200, c:300}');
INSERT INTO t VALUES ('{a:100, a:200, b:300}');
INSERT INTO t VALUES ('{a:100, b : {a:100, c:300}}');
```

The following statement queries table `t` and returns `col1` values that are well-formed JSON data with unique key names within each object:

```sql
SELECT col1 FROM t
WHERE col1 IS JSON WITH UNIQUE KEYS;
```

```
COL1
{a:100, b:200, c:300}
{a:100, b : {a:100, c:300}}
```

The second row is returned because, while the key name `a` appears twice, it is in two different objects.

The following statement queries table `t` and returns `col1` values that are well-formed JSON data, regardless of whether there are unique key names within each object:

```sql
SELECT col1 FROM t
WHERE col1 IS JSON WITHOUT UNIQUE KEYS;
```

```
COL1
{a:100, b:200, c:300}
{a:100, a:200, b:300}
{a:100, b : {a:100, c:300}}
```

**Using IS JSON as a Check Constraint: Example**

The following statement creates table `j_purchaseorder`, which will store JSON data in column `po_document`. The statement uses the IS JSON condition as a check constraint to ensure that only well-formed JSON is stored in column `po_document`.

```sql
CREATE TABLE j_purchaseorder
(id RAW (16) NOT NULL,
```

[ ]{}

XML Conditions
JSON_EXISTS Condition

Use the JSON_EXISTS condition to test whether a specified JSON value exists in JSON data. This condition returns TRUE if the JSON value exists and FALSE if the JSON value does not exist.

JSON_exists_condition ::= 

JSON_EXISTS (expr FORMAT JSON, JSON_path_expression) JSON_exists_on_error_clause

JSON_path_expression ::= 

object_step array_step

object_step ::= 

simple_name complex_name'

array_step ::= 

integer integer TO integer

JSON_exists_on_error_clause ::= 

ERROR TRUE ON ERROR FALSE

expr

Use this clause to specify the JSON data to be evaluated. For expr, specify an expression that evaluates to a text literal. If expr is a column, then the column must be of data type VARCHAR2, CLOB, or BLOB. If expr evaluates to null or a text literal of length zero, then the condition returns UNKNOWN.
If \( expr \) is not a text literal of well-formed JSON data using strict or lax syntax, then the condition returns \text{FALSE} by default. You can use the \textit{JSON_exists_on_error_clause} to override this default behavior. Refer to the \textit{JSON_exists_on_error_clause} on page 6-26.

\textbf{FORMAT JSON}

You must specify \textit{FORMAT JSON} if \( expr \) is a column of data type \textit{BLOB}.

\textbf{JSON\_path\_expression}

Use this clause to specify a JSON path expression. The condition uses the path expression to evaluate \( expr \) and determine if a JSON value that matches, or satisfies, the path expression exists. The path expression must be a text literal.

The path expression must begin with a dollar sign (\$), which represents the context item, that is, the expression specified by \( expr \). The dollar sign is followed by zero or more steps, each of which can be an object step or an array step. The condition attempts to match the first step in the path expression to the context item. If the first step results in a match, then the condition attempts to match the second step to the JSON value(s) that matched the first step. If the second step results in a match, then the condition attempts to match the third step to the JSON value(s) that matched the second step, and so on. If the final step results in a match, then the condition returns \text{TRUE}. If any step in the path expression does not result in a match, then the condition returns \text{FALSE}. A path expression that consists of a dollar sign followed by zero steps (\$) matches the entire context item.

\textbf{object\_step}  
Use this clause to specify an object step.

- Use \textit{simple\_name} or \textit{complex\_name} to specify a property name. If a member with that property name exists in the JSON object being evaluated, then the object step results in a match to the property value of that member. Otherwise, the object step does not result in a match. Both types of names are case-sensitive. Therefore, a match will result only if the alphabetic character cases match in the object step and the JSON data.

  A \textit{simple\_name} can contain only alphanumeric characters and must begin with an alphabetic character. A \textit{complex\_name} can contain only alphanumeric characters and spaces, and must begin with an alphanumeric character. A \textit{complex\_name} must be enclosed in double quotation marks.

- Use the asterisk wildcard symbol (*) to specify all property names. If the JSON object being evaluated contains at least one member, then the object step results in a match to the values of all members. Otherwise, the object step does not result in a match.

If you apply an object step to a JSON array, then the array is implicitly unwrapped and the elements of the array are evaluated using the object step. This is called JSON path expression relaxation. Refer to \textit{Oracle XML DB Developer’s Guide} for more information.

If the JSON value being evaluated is not a JSON object, then the object step does not result in a match.

\textbf{array\_step}  
Use this clause to specify an array step.

- Use \textit{integer} to specify the element at index \( integer \) in a JSON array. Use \textit{integer TO integer} to specify the range of elements between the two index \( integer \) values, inclusive. If the specified elements exist in the JSON array being evaluated, then the array step results in a match to those elements. Otherwise, the array step does not result in a match. The first element in a JSON array has index 0.
Use the asterisk wildcard symbol (*) to specify all elements in a JSON array. If the JSON array being evaluated contains at least one element, then the array step results in a match to all elements in the JSON array. Otherwise, the array step does not result in a match.

If the JSON data being evaluated is not a JSON array, then the data is implicitly wrapped in an array and then evaluated using the array step. This is called JSON path expression relaxation. Refer to Oracle XML DB Developer’s Guide for more information.

**JSON_exists_on_error_clause**

Use this clause to specify the value returned by this condition when \textit{expr} is not well-formed JSON data.

You can specify the following clauses:

- **ERROR ON ERROR** - Returns the appropriate Oracle error when \textit{expr} is not well-formed JSON data.
- **TRUE ON ERROR** - Returns TRUE when \textit{expr} is not well-formed JSON data.
- **FALSE ON ERROR** - Returns FALSE when \textit{expr} is not well-formed JSON data. This is the default.

**Examples**

The following statement creates table \textit{t} with column \textit{name}:

```sql
CREATE TABLE t (name VARCHAR2(100));
```

The following statements insert values into column \textit{name} of table \textit{t}:

```sql
INSERT INTO t VALUES ('{"first":"John"}, {"middle":"Mark"}, {"last":"Smith"}');
INSERT INTO t VALUES ('{"first":"Mary"}, {"last":"Jones"}');
INSERT INTO t VALUES ('{"first":"Jeff"}, {"last":"Williams"}');
INSERT INTO t VALUES ('{"first":"Jean"}, {"middle":"Anne"}, {"last":"Brown"}');
INSERT INTO t VALUES (NULL);
INSERT INTO t VALUES ('This is not well-formed JSON data');
```

The following statement queries column \textit{name} in table \textit{t} and returns JSON data that consists of an array whose first element is an object with property name \textit{first}. The \textsc{ON ERROR} clause is not specified. Therefore, the JSON\_EXISTS condition returns FALSE for values that are not well-formed JSON data.

```sql
SELECT name FROM t
WHERE JSON_EXISTS(name, '$[0].first');
```

```
NAME
--------------------------------------------------
["first":"John"], (middle:"Mark"), (last:"Smith")
["first":"Mary"], (last:"Jones")
["first":"Jeff"], (last:"Williams")
["first":"Jean"], (middle:"Anne"), (last:"Brown")
```

The following statement queries column \textit{name} in table \textit{t} and returns JSON data that consists of an array whose second element is an object with property name \textit{middle}. The \textsc{ON ERROR} clause is not specified. Therefore, the JSON\_EXISTS condition returns FALSE for values that are not well-formed JSON data.

```sql
SELECT name FROM t
WHERE JSON_EXISTS(name, '$[1].middle');
```

```
NAME
```
The following statement is similar to the previous statement, except that the `TRUE ON ERROR` clause is specified. Therefore, the `JSON_EXISTS` condition returns `TRUE` for values that are not well-formed JSON data.

```sql
SELECT name FROM t
WHERE JSON_EXISTS(name, '$[1].middle' TRUE ON ERROR);
```

The following statement queries column `name` in table `t` and returns JSON data that consists of an array that contains an element that is an object with property name `last`. The wildcard symbol (*) is specified for the array index. Therefore, the query returns arrays that contain such an object, regardless of its index number in the array.

```sql
SELECT name FROM t
WHERE JSON_EXISTS(name, '$[*].last');
```

---

**JSON_TEXTCONTAINS Condition**

Use the `JSON_TEXTCONTAINS` condition to test whether a specified character string exists in JSON property values. You can use this condition to filter JSON data on a specific word or number.

This condition takes the following arguments:

- A table or view column that contains JSON data. A JSON search index, which is an Oracle Text index designed specifically for use with JSON data, must be defined on the column. Each row of JSON data in the column is referred to as a JSON document.
- A JSON path expression. The path expression is applied to each JSON document in an attempt to match a specific JSON object within the document. The path expression can contain only JSON object steps; it cannot contain JSON array steps.
- A character string. The condition searches for the character string in all of the string and numeric property values in the matched JSON object, including array values. The string must exist as a separate word in the property value. For example, if you search for 'beth', then a match will be found for string property value "beth smith", but not for "elizabeth smith". If you search for '10', then a match will be found for numeric property value 10 or string property value "10 main street", but a match will not be found for numeric property value 110 or string property value "102 main street".

This condition returns `TRUE` if a match is found, and `FALSE` if a match is not found.
**JSON_textcontains_condition**:=

```
JSON_TextContains \( column \) \( JSON\_path\_expression \) \( string \)
```

**JSON_path_expression**:=

```
\$
```

*(JSON_TextContains does not support array_step)*

**object_step**:=

```
\( simple\_name \) \( complex\_name \)
```

column

Specify the name of the table or view column containing the JSON data to be tested. The column must be of data type VARCHAR2, CLOB, or BLOB. A JSON search index, which is an Oracle Text index designed specifically for use with JSON data, must be defined on the column. If a column value is a null or a text literal of length zero, then the condition returns **UNKNOWN**.

If a column value is not a text literal of well-formed JSON data using strict or lax syntax, then the condition returns **FALSE**.

**JSON_path_expression**

Use this clause to specify a JSON path expression. The condition uses the path expression to evaluate **column** and determine if a JSON value that matches, or satisfies, the path expression exists. The path expression must be a text literal.

The path expression must begin with a dollar sign (\$), which represents the context item, that is, **column**. The dollar sign is followed by zero or more object steps.

The condition attempts to match the first step in the path expression to the context item. If the first step results in a match, then the condition attempts to match the second step to the JSON value(s) that matched the first step. If the second step results in a match, then the condition attempts to match the third step to the JSON value(s) that matched the second step, and so on. If any step in the path expression does not result in a match, then the condition returns **FALSE**. If the final step results in a match and the matched value contains **string**, then the condition returns **TRUE**. Otherwise, the condition returns **FALSE**.

A path expression that consists of a dollar sign followed by zero object steps (\'\$\') matches the entire context item.

**object_step** Use this clause to specify an object step.

- Use **simple_name** or **complex_name** to specify a property name. If a member with that property name exists in the JSON object being evaluated, then the object step results in a match to the property value of that member. Otherwise, the object step does not result in a match. Both types of names are case-sensitive. Therefore, a
match will result only if the alphabetic character cases match in the object step and the JSON data.

A simple_name can contain only alphanumeric characters and must begin with an alphabetic character. A complex_name can contain only alphanumeric characters and spaces, and must begin with an alphanumeric character. A complex_name must be enclosed in double quotation marks.

- Use the asterisk wildcard symbol (*) to specify all property names. If the JSON object being evaluated contains at least one member, then the object step results in a match to the values of all members. Otherwise, the object step does not result in a match.

If you apply an object step to a JSON array, then the array is implicitly unwrapped and the elements of the array are evaluated using the object step. This is called JSON path expression relaxation. Refer to Oracle XML DB Developer’s Guide for more information.

If the JSON value being evaluated is not a JSON object, then the object step does not result in a match.

string
The condition searches for the character string specified by string. The string must be enclosed in single quotation marks.

Examples
The following statement creates table families with column family_doc:

```
CREATE TABLE families (family_doc VARCHAR2(200));
```

The following statement creates a JSON search index on column family_doc:

```
CREATE INDEX ix
ON families(family_doc)
INDEXTYPE IS CTXSYS.CONTEXT
PARAMETERS ('SECTION GROUP CTXSYS.JSON_SECTION_GROUP SYNC (ON COMMIT)');
```

The following statements insert JSON documents that describe families into column family_doc:

```
INSERT INTO families
VALUES ('{family : (id:10, ages:[40,38,12], address : {street : "10 Main Street"}))}
```

```
INSERT INTO families
VALUES ('{family : (id:11, ages:[42,40,10,5], address : {street : "200 East Street", apt : 20)}}');
```

```
INSERT INTO families
VALUES ('{family : (id:12, ages:[25,23], address : {street : "300 Oak Street", apt : 10})}');
```

The following statement commits the transaction:

```
COMMIT;
```

The following query returns the JSON documents that contain 10 in any property value in the document:

```
SELECT family_doc FROM families
WHERE JSON_TEXTCONTAINS(family_doc, '$', '10');
```

```
FAMILY_DOC
--------------------------------------------------------------------------------
{family : {id:10, ages:[40,38,12], address : {street : "10 Main Street"})}
```
The following query returns the JSON documents that contain 10 in the id property value:

```
SELECT family_doc FROM families
  WHERE json_textcontains(family_doc, '$.family.id', '10');
```

```
{family : {id:10, ages:[40,38,12], address : {street : "10 Main Street"}}}
```

The following query returns the JSON documents that have a 10 in the array of values for the ages property:

```
SELECT family_doc FROM families
  WHERE JSON_TEXTCONTAINS(family_doc, '$.family.ages', '10');
```

```
{family : {id:11, ages:[42,40,10,5], address : {street : "200 East Street", apt : 20}}}
```

The following query returns the JSON documents that have a 10 in the address property value:

```
SELECT family_doc FROM families
  WHERE JSON_TEXTCONTAINS(family_doc, '$.family.address', '10');
```

```
{family : {id:10, ages:[40,38,12], address : {street : "10 Main Street"}}}
{family : {id:12, ages:[25,23], address : {street : "300 Oak Street", apt : 10}}}
```

The following query returns the JSON documents that have a 10 in the apt property value:

```
SELECT family_doc FROM families
  WHERE JSON_TEXTCONTAINS(family_doc, '$.family.address.apt', '10');
```

```
{family : {id:12, ages:[25,23], address : {street : "300 Oak Street", apt : 10}}}
```

### Compound Conditions

A compound condition specifies a combination of other conditions.

```
compound_condition::=
```

![Diagram of compound condition]

**See Also:** "Logical Conditions" on page 6-8 for more information about NOT, AND, and OR conditions
BETWEEN Condition

A BETWEEN condition determines whether the value of one expression is in an interval defined by two other expressions.

\[
\text{between\_condition}: =
\]

\[
\begin{array}{c}
\text{expr1} \ \text{NOT} \ \text{BETWEEN} \ \text{expr2} \ \text{AND} \ \text{expr3}
\end{array}
\]

All three expressions must be numeric, character, or datetime expressions. In SQL, it is possible that \( expr1 \) will be evaluated more than once. If the BETWEEN expression appears in PL/SQL, \( expr1 \) is guaranteed to be evaluated only once. If the expressions are not all the same data type, then Oracle Database implicitly converts the expressions to a common data type. If it cannot do so, then it returns an error.

See Also: "Implicit Data Conversion" on page 2-43 for more information on SQL data type conversion

The value of
\[
\text{expr1} \ \text{NOT} \ \text{BETWEEN} \ \text{expr2} \ \text{AND} \ \text{expr3}
\]
is the value of the expression
\[
\text{NOT} \ (\text{expr1} \ \text{BETWEEN} \ \text{expr2} \ \text{AND} \ \text{expr3})
\]

And the value of
\[
\text{expr1} \ \text{BETWEEN} \ \text{expr2} \ \text{AND} \ \text{expr3}
\]
is the value of the boolean expression:
\[
\text{expr2} \leq \ \text{expr1} \ \text{AND} \ \text{expr1} \ \leq \ \text{expr3}
\]

If \( \text{expr3} < \ \text{expr2} \), then the interval is empty. If \( \text{expr1} \) is NULL, then the result is NULL. If \( \text{expr1} \) is not NULL, then the value is FALSE in the ordinary case and TRUE when the keyword NOT is used.

The boolean operator AND may produce unexpected results. Specifically, in the expression \( x \ \text{AND} \ y \), the condition \( x \ \text{IS} \ \text{NULL} \) is not sufficient to determine the value of the expression. The second operand still must be evaluated. The result is FALSE if the second operand has the value FALSE and NULL otherwise. See "Logical Conditions" on page 6-8 for more information on AND.

<table>
<thead>
<tr>
<th>Type of Condition</th>
<th>Operation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>[NOT] BETWEEN ( x ) AND ( y )</td>
<td>[NOT] (( expr2 ) less than or equal to ( expr1 ) AND ( expr1 ) less than or equal to ( expr3 ))</td>
<td>SELECT * FROM employees WHERE salary BETWEEN 2000 AND 3000 ORDER BY employee_id;</td>
</tr>
</tbody>
</table>

EXISTS Condition

An EXISTS condition tests for existence of rows in a subquery.
Table 6–11 shows the EXISTS condition.

### Table 6–11 EXISTS Condition

<table>
<thead>
<tr>
<th>Type of Condition</th>
<th>Operation</th>
<th>Example</th>
</tr>
</thead>
</table>
| EXISTS            | TRUE if a subquery returns at least one row. | SELECT department_id 
FROM departments d 
WHERE EXISTS 
(SELECT * FROM employees e 
WHERE d.department_id 
= e.department_id) 
ORDER BY department_id; |

**IN Condition**

An *in_condition* is a membership condition. It tests a value for membership in a list of values or subquery

\[
\text{in\_condition}::= \\
\text{expr} \quad \text{NOT} \quad \text{IN} \quad ( \text{expression\_list} \quad \text{subquery} ) \\
\quad \text{NOT} \quad \text{IN} \quad ( \text{expression\_list} \quad \text{subquery} ) \\
\text{expr} \quad \text{IN} \quad ( \text{expression\_list} \quad \text{subquery} ) \\
\text{expr} \\
\]

**expression\_list::=**

If you use the upper form of the *in_condition* condition (with a single expression to the left of the operator), then you must use the upper form of *expression\_list*. If you use the lower form of this condition (with multiple expressions to the left of the operator), then you must use the lower form of *expression\_list*, and the expressions in each *expression\_list* must match in number and data type the expressions to the left of the operator. You can specify up to 1000 expressions in *expression\_list*.

Oracle Database does not always evaluate the expressions in an *expression\_list* in the order in which they appear in the *IN* list. However, expressions in the select list of a subquery are evaluated in their specified order.

**See Also:** "Expression Lists" on page 5-18

Table 6–12 lists the form of *IN* condition.
If any item in the list following a NOT IN operation evaluates to null, then all rows evaluate to FALSE or UNKNOWN, and no rows are returned. For example, the following statement returns the string 'True' for each row:

```sql
SELECT 'True' FROM employees
WHERE department_id NOT IN (10, 20);
```

However, the following statement returns no rows:

```sql
SELECT 'True' FROM employees
WHERE department_id NOT IN (10, 20, NULL);
```

The preceding example returns no rows because the WHERE clause condition evaluates to:

```
department_id != 10 AND department_id != 20 AND department_id != null
```

Because the third condition compares department_id with a null, it results in an UNKNOWN, so the entire expression results in FALSE (for rows with department_id equal to 10 or 20). This behavior can easily be overlooked, especially when the NOT IN operator references a subquery.

Moreover, if a NOT IN condition references a subquery that returns no rows at all, then all rows will be returned, as shown in the following example:

```sql
SELECT 'True' FROM employees
WHERE department_id NOT IN (SELECT 0 FROM DUAL WHERE 1=2);
```

**Restriction on LEVEL in WHERE Clauses**  In a [NOT] IN condition in a WHERE clause, if the right-hand side of the condition is a subquery, you cannot use LEVEL on the left-hand side of the condition. However, you can specify LEVEL in a subquery of the FROM clause to achieve the same result. For example, the following statement is not valid:

```sql
SELECT employee_id, last_name FROM employees
WHERE (employee_id, LEVEL)
```

<table>
<thead>
<tr>
<th>Type of Condition</th>
<th>Operation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IN</td>
<td>Equal-to-any-member-of test. Equivalent to =ANY.</td>
<td>SELECT * FROM employees WHERE job_id IN ('PU_CLERK', 'SH_CLERK') ORDER BY employee_id;</td>
</tr>
<tr>
<td>NOT IN</td>
<td>Equivalent to !=ALL. Evaluates to FALSE if any member of the set is NULL.</td>
<td>SELECT * FROM employees WHERE salary NOT IN (SELECT salary FROM employees WHERE department_id =30) ORDER BY employee_id;</td>
</tr>
</tbody>
</table>

**Table 6–12  IN Condition**

<table>
<thead>
<tr>
<th>Type of Condition</th>
<th>Operation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IN</td>
<td>Equal-to-any-member-of test. Equivalent to =ANY.</td>
<td>SELECT * FROM employees WHERE job_id IN ('PU_CLERK', 'SH_CLERK') ORDER BY employee_id;</td>
</tr>
<tr>
<td>NOT IN</td>
<td>Equivalent to !=ALL. Evaluates to FALSE if any member of the set is NULL.</td>
<td>SELECT * FROM employees WHERE salary NOT IN (SELECT salary FROM employees WHERE department_id =30) ORDER BY employee_id;</td>
</tr>
</tbody>
</table>
IN (SELECT employee_id, 2 FROM employees)
START WITH employee_id = 2
CONNECT BY PRIOR employee_id = manager_id;

But the following statement is valid because it encapsulates the query containing the
LEVEL information in the FROM clause:

```
SELECT v.employee_id, v.last_name, v.lev FROM
 (SELECT employee_id, last_name, LEVEL lev
  FROM employees v
  START WITH employee_id = 100
  CONNECT BY PRIOR employee_id = manager_id) v
WHERE (v.employee_id, v.lev) IN
  (SELECT employee_id, 2 FROM employees);
```

**IS OF type Condition**

Use the IS OF type condition to test object instances based on their specific type
information.

```
is_of_type_condition ::= 
```

You must have EXECUTE privilege on all types referenced by type, and all types must
belong to the same type family.

This condition evaluates to null if expr is null. If expr is not null, then the condition
evaluates to true (or false if you specify the NOT keyword) under either of these
circumstances:

- The most specific type of expr is the subtype of one of the types specified in the
type list and you have not specified ONLY for the type, or

- The most specific type of expr is explicitly specified in the type list.

The expr frequently takes the form of the VALUE function with a correlation variable.

The following example uses the sample table oe.persons, which is built on a type
hierarchy in "Substitutable Table and Column Examples" on page 16-91. The example
uses the IS OF type condition to restrict the query to specific subtypes:

```
SELECT * FROM persons p
WHERE VALUE(p) IS OF TYPE (employee_t);
```

```
NAME      SSN
----------
Joe       32456
Tim       5678
```

```
SELECT * FROM persons p
WHERE VALUE(p) IS OF (ONLY part_time_emp_t);
```

```
NAME      SSN
----------
Tim       5678
```
Functions are similar to operators in that they manipulate data items and return a result. Functions differ from operators in the format of their arguments. This format enables them to operate on zero, one, two, or more arguments:

\[ \text{function} (\text{argument}, \text{argument}, \ldots) \]

A function without any arguments is similar to a pseudocolumn (refer to Chapter 3, "Pseudocolumns"). However, a pseudocolumn typically returns a different value for each row in the result set, whereas a function without any arguments typically returns the same value for each row.

This chapter contains these sections:

- About SQL Functions
- Single-Row Functions
  - Numeric Functions
  - Character Functions Returning Character Values
  - Character Functions Returning Number Values
  - Character Set Functions
  - Datetime Functions
  - General Comparison Functions
  - Conversion Functions
  - Large Object Functions
  - Collection Functions
  - Hierarchical Functions
  - Data Mining Functions
  - XML Functions
  - JSON Functions
  - Encoding and Decoding Functions
  - NULL-Related Functions
  - Environment and Identifier Functions
- Aggregate Functions
- Analytic Functions
About SQL Functions

SQL functions are built into Oracle Database and are available for use in various appropriate SQL statements. Do not confuse SQL functions with user-defined functions written in PL/SQL.

If you call a SQL function with an argument of a data type other than the data type expected by the SQL function, then Oracle attempts to convert the argument to the expected data type before performing the SQL function.

See Also: "About User-Defined Functions" on page 7-438 for information on user functions and "Data Conversion" on page 2-43 for implicit conversion of data types

Nulls in SQL Functions Most scalar functions return null when given a null argument. You can use the NVL function to return a value when a null occurs. For example, the expression NVL(commission_pct, 0) returns 0 if commission_pct is null or the value of commission_pct if it is not null.

For information on how aggregate functions handle nulls, see "Aggregate Functions" on page 7-10.

Syntax for SQL Functions In the syntax diagrams for SQL functions, arguments are indicated by their data types. When the parameter function appears in SQL syntax, replace it with one of the functions described in this section. Functions are grouped by the data types of their arguments and their return values.

Note: When you apply SQL functions to LOB columns, Oracle Database creates temporary LOBs during SQL and PL/SQL processing. You should ensure that temporary tablespace quota is sufficient for storing these temporary LOBs for your application.

Note: The combined values of the NLS_COMP and NLS_SORT settings determine the rules by which characters are sorted and compared. If NLS_COMP is set to LINGUISTIC for your database, then all entities in this chapter will be interpreted according to the rules specified by the NLS_SORT parameter. If NLS_COMP is not set to LINGUISTIC, then the functions are interpreted without regard to the NLS_SORT setting. NLS_SORT can be explicitly set. If it is not set explicitly, it is derived from NLS_LANGUAGE. Refer to Oracle Database Globalization Support Guide for more information on these settings.

The syntax showing the categories of functions follows:
The sections that follow list the built-in SQL functions in each of the groups illustrated in the preceding diagrams except user-defined functions. All of the built-in SQL functions are then described in alphabetical order.

**See Also:** "About User-Defined Functions" on page 7-438 and CREATE FUNCTION on page 14-71

### Single-Row Functions

Single-row functions return a single result row for every row of a queried table or view. These functions can appear in select lists, WHERE clauses, START WITH and CONNECT BY clauses, and HAVING clauses.
Numeric Functions

Numeric functions accept numeric input and return numeric values. Most numeric functions return `NUMBER` values that are accurate to 38 decimal digits. The transcendental functions `COS`, `COSH`, `EXP`, `LN`, `LOG`, `SIN`, `SINH`, `SQRT`, `TAN`, and `TANH` are accurate to 36 decimal digits. The transcendental functions `ACOS`, `ASIN`, `ATAN`, and `ATAN2` are accurate to 30 decimal digits. The numeric functions are:

- `ABS`
- `ACOS`
- `ASIN`
- `ATAN`
- `ATAN2`
- `BITAND`
- `CEIL`
- `COS`
- `COSH`
- `EXP`
- `FLOOR`
- `LN`
- `LOG`
- `MOD`
- `NANVL`
- `POWER`
- `REMAINDER`
- `ROUND` (number)
- `SIGN`
- `SIN`
- `SINH`
- `SQRT`
- `TAN`
- `TANH`
- `TRUNC` (number)
- `WIDTH_BUCKET`

Character Functions Returning Character Values

Character functions that return character values return values of the following data types unless otherwise documented:

- If the input argument is `CHAR` or `VARCHAR2`, then the value returned is `VARCHAR2`.
- If the input argument is `NCHAR` or `NVARCHAR2`, then the value returned is `NVARCHAR2`.

The length of the value returned by the function is limited by the maximum length of the data type returned.

- For functions that return `CHAR` or `VARCHAR2`, if the length of the return value exceeds the limit, then Oracle Database truncates it and returns the result without an error message.
- For functions that return `CLOB` values, if the length of the return values exceeds the limit, then Oracle raises an error and returns no data.

The character functions that return character values are:

- `CHR`
- `CONCAT`
- `INITCAP`
- `LOWER`
Single-Row Functions

LPAD
LTRIM
NCHR
NLS_INITCAP
NLS_LOWER
NLS_UPPER
NLSSORT
REGEXP_REPLACE
REGEXP_SUBSTR
REPLACE
RPAD
RTRIM
SOUNDEX
SUBSTR
TRANSLATE
TRIM
UPPER

Character Functions Returning Number Values

Character functions that return number values can take as their argument any character data type. The character functions that return number values are:

ASCII
INSTR
LENGTH
REGEXP_COUNT
REGEXP_INSTR

Character Set Functions

The character set functions return information about the character set. The character set functions are:

NLS_CHARSET_DECL_LEN
NLS_CHARSET_ID
NLS_CHARSET_NAME

Datetime Functions

Datetime functions operate on date (DATE), timestamp (TIMESTAMP, TIMESTAMP WITH TIME ZONE, and TIMESTAMP WITH LOCAL TIME ZONE), and interval (INTERVAL DAY TO SECOND, INTERVAL YEAR TO MONTH) values.

Some of the datetime functions were designed for the Oracle DATE data type (ADD_MONTHS, CURRENT_DATE, LAST_DAY, NEW_TIME, and NEXT_DAY). If you provide a timestamp value as their argument, then Oracle Database internally converts the input type to a DATE value and returns a DATE value. The exceptions are the MONTHS_BETWEEN function, which returns a number, and the ROUND and TRUNC functions, which do not accept timestamp or interval values at all.

The remaining datetime functions were designed to accept any of the three types of data (date, timestamp, and interval) and to return a value of one of these types.

All of the datetime functions that return current system datetime information, such as SYSDATE, SYSTIMESTAMP, CURRENT_TIMESTAMP, and so forth, are evaluated once for each SQL statement, regardless how many times they are referenced in that statement.
The datetime functions are:

- ADD_MONTHS
- CURRENT_DATE
- CURRENT_TIMESTAMP
- DBTIMEZONE
- EXTRACT (datetime)
- FROM_TZ
- LAST_DAY
- LOCALTIMESTAMP
- MONTHS_BETWEEN
- NEW_TIME
- NEXT_DAY
- NUMTODSINTERVAL
- NUMTOYMINTERVAL
- ORA_DST_AFFECTED
- ORA_DST_CONVERT
- ORA_DST_ERROR
- ROUND (date)
- SESSIONTIMEZONE
- SYS_EXTRACT_UTC
- SYSDATE
- SYSTIMESTAMP
- TO_CHAR (datetime)
- TO_DSINTERVAL
- TO_TIMESTAMP
- TO_TIMESTAMP_TZ
- TO_YMINTERVAL
- TRUNC (date)
- TZ_OFFSET

**General Comparison Functions**

The general comparison functions determine the greatest and or least value from a set of values. The general comparison functions are:

- GREATEST
- LEAST

**Conversion Functions**

Conversion functions convert a value from one data type to another. Generally, the form of the function names follows the convention `datatype TO datatype`. The first data type is the input data type. The second data type is the output data type. The SQL conversion functions are:

- ASCIISTR
- BIN_TO_NUM
- CAST
- CHARTOROWID
- COMPOSE
- CONVERT
- DECOMPOSE
- HEXTORAW
- NUMTODSINTERVAL
- NUMTOYMINTERVAL
- RAWTOHEX
Single-Row Functions

- RAWTONHEX
- ROWIDTOCHAR
- ROWIDTONCHAR
- SCN_TO_TIMESTAMP
- TIMESTAMP_TO_SCN
- TO_BINARY_DOUBLE
- TO_BINARY_FLOAT
- TO_BLOB
- TO_CHAR (character)
- TO_CHAR (datetime)
- TO_CHAR (number)
- TO_CLOB
- TO_DATE
- TO_DSINTERVAL
- TO_LOB
- TO_MULTI_BYTE
- TO_NCHAR (character)
- TO_NCHAR (datetime)
- TO_NCHAR (number)
- TO_NCLOB
- TO_NUMBER
- TO_SINGLE_BYTE
- TO_TIMESTAMP
- TO_TIMESTAMP_TZ
- TO_YMINTERVAL
- TREAT
- UNISTR

Large Object Functions

The large object functions operate on LOBs. The large object functions are:

- BFILENAME
- EMPTY_BLOB, EMPTY_CLOB

Collection Functions

The collection functions operate on nested tables and varrays. The SQL collection functions are:

- CARDINALITY
- COLLECT
- POWERMULTISET
- POWERMULTISET_BY_CARDINALITY
- SET

Hierarchical Functions

Hierarchical functions applies hierarchical path information to a result set. The hierarchical function is:

- SYS_CONNECT_BY_PATH
Data Mining Functions

The data mining functions use Oracle Data Mining to score data. The functions can apply a mining model schema object to the data, or they can dynamically mine the data by executing an analytic clause.

The data mining functions are:

- CLUSTER_DETAILS
- CLUSTER_DISTANCE
- CLUSTER_ID
- CLUSTER_PROBABILITY
- CLUSTER_SET
- FEATURE_DETAILS
- FEATURE_ID
- FEATURE_SET
- FEATURE_VALUE
- PREDICTION
- PREDICTION_BOUNDS
- PREDICTION_COST
- PREDICTION_DETAILS
- PREDICTION_PROBABILITY
- PREDICTION_SET

See Also:
- Oracle Data Mining User’s Guide for information about scoring
- Oracle Data Mining Concepts to learn about Oracle Data Mining

XML Functions

The XML functions operate on or return XML documents or fragments. These functions use arguments that are not defined as part of the ANSI/ISO/IEC SQL Standard but are defined as part of the World Wide Web Consortium (W3C) standards. The processing and operations that the functions perform are defined by the relevant W3C standards. The table below provides a link to the appropriate section of the W3C standard for the rules and guidelines that apply to each of these XML-related arguments. A SQL statement that uses one of these XML functions, where any of the arguments does not conform to the relevant W3C syntax, will result in an error. Of special note is the fact that not every character that is allowed in the value of a database column is considered legal in XML.

<table>
<thead>
<tr>
<th>Syntax Element</th>

XMLTABLE
XMLTRANSFORM

JSON Functions

The JavaScript Object Notation (JSON) functions return values from JSON data. The JSON functions are:

JSON_QUERY
JSON_TABLE
JSON_VALUE

Encoding and Decoding Functions

The encoding and decoding functions let you inspect and decode data in the database. The encoding and decoding functions are:

DECODE
DUMP
ORA_HASH
STANDARD_HASH
VSIZE
NULL-Related Functions

The NULL-related functions facilitate null handling. The NULL-related functions are:

- COALESCE
- LNNVL
- NANVL
- NULLIF
- NVL
- NVL2

Environment and Identifier Functions

The environment and identifier functions provide information about the instance and session. The environment and identifier functions are:

- CON_DBID_TO_ID
- CON_GUID_TO_ID
- CON_NAME_TO_ID
- CON_UID_TO_ID
- ORA_INVOKING_USER
- ORA_INVOKING_USERID
- SYS_CONTEXT
- SYS_GUID
- SYS_TYPEID
- UID
- USER
- USERENV

Aggregate Functions

Aggregate functions return a single result row based on groups of rows, rather than on single rows. Aggregate functions can appear in select lists and in ORDER BY and HAVING clauses. They are commonly used with the GROUP BY clause in a SELECT statement, where Oracle Database divides the rows of a queried table or view into groups. In a query containing a GROUP BY clause, the elements of the select list can be aggregate functions, GROUP BY expressions, constants, or expressions involving one of these. Oracle applies the aggregate functions to each group of rows and returns a single result row for each group.

If you omit the GROUP BY clause, then Oracle applies aggregate functions in the select list to all the rows in the queried table or view. You use aggregate functions in the HAVING clause to eliminate groups from the output based on the results of the aggregate functions, rather than on the values of the individual rows of the queried table or view.

**See Also:** "Using the GROUP BY Clause: Examples" on page 19-60 and the "HAVING Clause" on page 19-35 for more information on the GROUP BY clause and HAVING clauses in queries and subqueries

Many (but not all) aggregate functions that take a single argument accept these clauses:

- DISTINCT and UNIQUE, which are synonymous, cause an aggregate function to consider only distinct values of the argument expression. The syntax diagrams for aggregate functions in this chapter use the keyword DISTINCT for simplicity.
- ALL causes an aggregate function to consider all values, including all duplicates.
For example, the DISTINCT average of 1, 1, 1, and 3 is 2. The ALL average is 1.5. If you specify neither, then the default is ALL.

Some aggregate functions allow the windowing clause, which is part of the syntax of analytic functions. Refer to windowing clause on page 7-15 for information about this clause. In the listing of aggregate functions at the end of this section, the functions that allow the windowing clause are followed by an asterisk (*).

All aggregate functions except COUNT(*), GROUPING, and GROUPING_ID ignore nulls. You can use the NVL function in the argument to an aggregate function to substitute a value for a null. COUNT and REGR_COUNT never return null, but return either a number or zero. For all the remaining aggregate functions, if the data set contains no rows, or contains only rows with nulls as arguments to the aggregate function, then the function returns null.

The aggregate functions MIN, MAX, SUM, AVG, COUNT, VARIANCE, and STDDEV, when followed by the KEEP keyword, can be used in conjunction with the FIRST or LAST function to operate on a set of values from a set of rows that rank as the FIRST or LAST with respect to a given sorting specification. Refer to FIRST on page 7-121 for more information.

You can nest aggregate functions. For example, the following example calculates the average of the maximum salaries of all the departments in the sample schema hr:

```sql
SELECT AVG(MAX(salary))
FROM employees
GROUP BY department_id;
```

```
AVG(MAX(SALARY))
----------------
10926.3333
```

This calculation evaluates the inner aggregate (MAX(salary)) for each group defined by the GROUP BY clause (department_id), and aggregates the results again.

In the list of aggregate functions that follows, functions followed by an asterisk (*) allow the windowing_clause.

```
APPROX_COUNT_DISTINCT
AVG
COLLECT
CORR
CORR_*
COUNT
COVAR_POP
COVAR_SAMP
CUME_DIST
DENSE_RANK
FIRST
GROUP_ID
GROUPING
GROUPING_ID
LAST
LISTAGG
MAX
MEDIAN
MIN
PERCENT_RANK
PERCENTILE_CONT
```
Analytic Functions

Analytic functions compute an aggregate value based on a group of rows. They differ from aggregate functions in that they return multiple rows for each group. The group of rows is called a window and is defined by the analytic_clause. For each row, a sliding window of rows is defined. The window determines the range of rows used to perform the calculations for the current row. Window sizes can be based on either a physical number of rows or a logical interval such as time.

Analytic functions are the last set of operations performed in a query except for the final ORDER BY clause. All joins and all WHERE, GROUP BY, and HAVING clauses are completed before the analytic functions are processed. Therefore, analytic functions can appear only in the select list or ORDER BY clause.

Analytic functions are commonly used to compute cumulative, moving, centered, and reporting aggregates.

```sql
analytic_function::=
  analytic_function arguments OVER analytic_clause

analytic_clause::=
  query_partition_clause order_by_clause windowing_clause
```
query_partition_clause ::= 

order_by_clause ::= 

windowing_clause ::= 

The semantics of this syntax are discussed in the sections that follow.

analytic_function
Specify the name of an analytic function (see the listing of analytic functions following this discussion of semantics).

arguments
Analytic functions take 0 to 3 arguments. The arguments can be any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. Oracle determines the argument with the highest numeric precedence and implicitly converts the remaining arguments to that data type. The return type is also that data type, unless otherwise noted for an individual function.

See Also: "Numeric Precedence" on page 2-16 for information on numeric precedence and Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

analytic_clause
Use OVER analytic_clause to indicate that the function operates on a query result set. This clause is computed after the FROM, WHERE, GROUP BY, and HAVING clauses. You can specify analytic functions with this clause in the select list or ORDER BY clause. To filter
the results of a query based on an analytic function, nest these functions within the parent query, and then filter the results of the nested subquery.

Notes on the analytic_clause: The following notes apply to the analytic_clause:

- You cannot nest analytic functions by specifying any analytic function in any part of the analytic_clause. However, you can specify an analytic function in a subquery and compute another analytic function over it.
- You can specify OVER analytic_clause with user-defined analytic functions as well as built-in analytic functions. See CREATE FUNCTION on page 14-71.

query_partition_clause
Use the PARTITION BY clause to partition the query result set into groups based on one or more value_expr. If you omit this clause, then the function treats all rows of the query result set as a single group.

To use the query_partition_clause in an analytic function, use the upper branch of the syntax (without parentheses). To use this clause in a model query (in the model_column_clauses) or a partitioned outer join (in the outer_join_clause), use the lower branch of the syntax (with parentheses).

You can specify multiple analytic functions in the same query, each with the same or different PARTITION BY keys.

If the objects being queried have the parallel attribute, and if you specify an analytic function with the query_partition_clause, then the function computations are parallelized as well.

Valid values of value_expr are constants, columns, nonanalytic functions, function expressions, or expressions involving any of these.

order_by_clause
Use the order_by_clause to specify how data is ordered within a partition. For all analytic functions you can order the values in a partition on multiple keys, each defined by a value_expr and each qualified by an ordering sequence.

Within each function, you can specify multiple ordering expressions. Doing so is especially useful when using functions that rank values, because the second expression can resolve ties between identical values for the first expression.

Whenever the order_by_clause results in identical values for multiple rows, the function behaves as follows:

- CUME_DIST, DENSE_RANK, NTILE, PERCENT_RANK, and RANK return the same result for each of the rows.
- ROW_NUMBER assigns each row a distinct value even if there is a tie based on the order_by_clause. The value is based on the order in which the row is processed, which may be nondeterministic if the ORDER BY does not guarantee a total ordering.
- For all other analytic functions, the result depends on the window specification. If you specify a logical window with the RANGE keyword, then the function returns the same result for each of the rows. If you specify a physical window with the ROWS keyword, then the result is nondeterministic.

Restrictions on the ORDER BY Clause The following restrictions apply to the ORDER BY clause:

- When used in an analytic function, the order_by_clause must take an expression (expr). The SIBLINGS keyword is not valid (it is relevant only in hierarchical
queries). Position (\textit{position}) and column aliases (\textit{c_alias}) are also invalid. Otherwise this \textit{order_by_clause} is the same as that used to order the overall query or subquery.

- An analytic function that uses the \texttt{RANGE} keyword can use multiple sort keys in its \texttt{ORDER BY} clause if it specifies any of the following windows:
  - \texttt{RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW}. The short form of this is \texttt{RANGE UNBOUNDED PRECEDING}.
  - \texttt{RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING}
  - \texttt{RANGE BETWEEN CURRENT ROW AND CURRENT ROW}
  - \texttt{RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING}

Window boundaries other than these four can have only one sort key in the \texttt{ORDER BY} clause of the analytic function. This restriction does not apply to window boundaries specified by the \texttt{ROW} keyword.

\textbf{ASC} | \textbf{DESC}  Specify the ordering sequence (ascending or descending). \texttt{ASC} is the default.

\textbf{NULLS FIRST} | \textbf{NULLS LAST}  Specify whether returned rows containing nulls should appear first or last in the ordering sequence. \texttt{NULLS LAST} is the default for ascending order, and \texttt{NULLS FIRST} is the default for descending order.

Analytic functions always operate on rows in the order specified in the \textit{order_by_clause} of the function. However, the \textit{order_by_clause} of the function does not guarantee the order of the result. Use the \textit{order_by_clause} of the query to guarantee the final result ordering.

\textbf{See Also:}  \textit{order_by_clause} of \texttt{SELECT} on page 19-40 for more information on this clause

\textbf{windowing_clause}

Some analytic functions allow the \textit{windowing_clause}. In the listing of analytic functions at the end of this section, the functions that allow the \textit{windowing_clause} are followed by an asterisk (*).

\textbf{ROWS} | \textbf{RANGE}  These keywords define for each row a window (a physical or logical set of rows) used for calculating the function result. The function is then applied to all the rows in the window. The window moves through the query result set or partition from top to bottom.

- \texttt{ROWS} specifies the window in physical units (rows).
- \texttt{RANGE} specifies the window as a logical offset.

You cannot specify this clause unless you have specified the \textit{order_by_clause}. Some window boundaries defined by the \texttt{RANGE} clause let you specify only one expression in the \textit{order_by_clause}. Refer to “Restrictions on the ORDER BY Clause” on page 7-14.

The value returned by an analytic function with a logical offset is always deterministic. However, the value returned by an analytic function with a physical offset may produce nondeterministic results unless the ordering expression results in a unique ordering. You may have to specify multiple columns in the \textit{order_by_clause} to achieve this unique ordering.
**BETWEEN ... AND**  Use the BETWEEN ... AND clause to specify a start point and end point for the window. The first expression (before AND) defines the start point and the second expression (after AND) defines the end point.

If you omit BETWEEN and specify only one end point, then Oracle considers it the start point, and the end point defaults to the current row.

**UNBOUNDED PRECEDING**  Specify UNBOUNDED PRECEDING to indicate that the window starts at the first row of the partition. This is the start point specification and cannot be used as an end point specification.

**UNBOUNDED FOLLOWING**  Specify UNBOUNDED FOLLOWING to indicate that the window ends at the last row of the partition. This is the end point specification and cannot be used as a start point specification.

**CURRENT ROW**  As a start point, CURRENT ROW specifies that the window begins at the current row or value (depending on whether you have specified ROW or RANGE, respectively). In this case the end point cannot be value_expr PRECEDING.

As an end point, CURRENT ROW specifies that the window ends at the current row or value (depending on whether you have specified ROW or RANGE, respectively). In this case the start point cannot be value_expr FOLLOWING.

**value_expr PRECEDING or value_expr FOLLOWING**  For RANGE or ROW:

- If value_expr FOLLOWING is the start point, then the end point must be value_expr FOLLOWING.
- If value_expr PRECEDING is the end point, then the start point must be value_expr PRECEDING.

If you are defining a logical window defined by an interval of time in numeric format, then you may need to use conversion functions.

**See Also:**  NUMTOYMINTERVAL on page 7-216 and NUMTODSINTERVAL on page 7-215 for information on converting numeric times into intervals

If you specified ROWS:

- value_expr is a physical offset. It must be a constant or expression and must evaluate to a positive numeric value.
- If value_expr is part of the start point, then it must evaluate to a row before the end point.

If you specified RANGE:

- value_expr is a logical offset. It must be a constant or expression that evaluates to a positive numeric value or an interval literal. Refer to "Literals" on page 2-48 for information on interval literals.
- You can specify only one expression in the order_by_clause.
- If value_expr evaluates to a numeric value, then the ORDER BY expr must be a numeric or DATE data type.
- If value_expr evaluates to an interval value, then the ORDER BY expr must be a DATE data type.

If you omit the windowing_clause entirely, then the default is RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW.
Analytic functions are commonly used in data warehousing environments. In the list of analytic functions that follows, functions followed by an asterisk (*) allow the full syntax, including the windowing clause.

**See Also:** *Oracle Database Data Warehousing Guide* for more information on these functions and for scenarios illustrating their use.
Object Reference Functions

Object reference functions manipulate REF values, which are references to objects of specified object types. The object reference functions are:

- DEREF
- MAKE_REF
- REF
- REFTOHEX
- VALUE

See Also: Oracle Database Object-Relational Developer’s Guide for more information about REF data types

Model Functions

Model functions can be used only in the model_clause of the SELECT statement. The model functions are:

- CV
- ITERATION_NUMBER
- PRESENTNNV
- PRESENTV
- PREVIOUS

OLAP Functions

OLAP functions returns data from a dimensional object in two-dimension relational format. The OLAP function is:

- CUBE_TABLE

Data Cartridge Functions

Data Cartridge functions are useful for Data Cartridge developers. The Data Cartridge functions are:

- DATAOBJ_TO_MAT_PARTITION
- DATAOBJ_TO_PARTITION

Alphabetical Listing of SQL Functions

The SQL functions are described in alphabetical order.
ABS

Syntax

\[ \text{ABS}(n) \]

Purpose

\( \text{ABS} \) returns the absolute value of \( n \).

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

Examples

The following example returns the absolute value of -15:

```
SELECT ABS(-15) 'Absolute'
FROM DUAL;

Absolute
---------
15
```
ACOS

Syntax

\[ \text{ACOS}\left(n\right) \]

Purpose

ACOS returns the arc cosine of \( n \). The argument \( n \) must be in the range of -1 to 1, and the function returns a value in the range of 0 to \( \pi \), expressed in radians.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If the argument is BINARY_FLOAT, then the function returns BINARY_DOUBLE. Otherwise the function returns the same numeric data type as the argument.

See Also:  Table 2–10, ” Implicit Type Conversion Matrix” on page 2-43 for more information on implicit conversion

Examples

The following example returns the arc cosine of .3:

```
SELECT ACOS(.3) 'Arc_Cosine'
  FROM DUAL;
```

Arc_Cosine
----------
1.26610367
ADD_MONTHS

Syntax

ADD_MONTHS(date, integer)

Purpose

ADD_MONTHS returns the date `date` plus `integer` months. A month is defined by the session parameter `NLS_CALENDAR`. The date argument can be a datetime value or any value that can be implicitly converted to `DATE`. The `integer` argument can be an integer or any value that can be implicitly converted to an integer. The return type is always `DATE`, regardless of the data type of `date`. If `date` is the last day of the month or if the resulting month has fewer days than the day component of `date`, then the result is the last day of the resulting month. Otherwise, the result has the same day component as `date`.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

Examples

The following example returns the month after the `hire_date` in the sample table `employees`:

```sql
SELECT TO_CHAR(ADD_MONTHS(hire_date, 1), 'DD-MON-YYYY') "Next month"
FROM employees
WHERE last_name = 'Baer';
```

```
Next Month
-----------
07-JUL-2002
```

APPENDCHILDXML

---

**Note:** The APPENDCHILDXML function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use XQuery Update instead. See Oracle XML DB Developer’s Guide for more information.

---

Syntax

```
APPENDCHILDXML(    XMLType_instance,    XPath_string,    value_expr,    namespace_string)
```

Purpose

APPENDCHILDXML appends a user-supplied value onto the target XML as the child of the node indicated by an XPath expression.

- `XMLType_instance` is an instance of XMLType.
- `XPath_string` is an XPath expression indicating one or more nodes onto which one or more child nodes are to be appended. You can specify an absolute `XPath_string` with an initial slash or a relative `XPath_string` by omitting the initial slash. If you omit the initial slash, then the context of the relative path defaults to the root node.
- `value_expr` specifies one or more nodes of XMLType. It must resolve to a string.
- The optional `namespace_string` provides namespace information for the `XPath_string`. This parameter must be of type VARCHAR2.

**See Also:** Oracle XML DB Developer’s Guide for more information about this function

Examples

The following example adds an `/Owner` node to the `/Warehouse/Building` node of `warehouse_spec` in the `oe.warehouses` table if the value of the `/Building` node is "Rented":

```sql
UPDATE warehouses
SET warehouse_spec = APPENDCHILDXML(warehouse_spec, 'Warehouse/Building',
XMLType('<Owner>Grandco</Owner>'))
WHERE EXTRACTVALUE(warehouse_spec, '/Warehouse/Building') = 'Rented';
```

```sql
SELECT warehouse_id,
    warehouse_name,
    EXTRACTVALUE(warehouse_spec, '/Warehouse/Building/Owner') "Prop.Owner"
FROM warehouses
WHERE EXISTSNODE(warehouse_spec, '/Warehouse/Building/Owner') = 1;
```

<table>
<thead>
<tr>
<th>WAREHOUSE_ID</th>
<th>WAREHOUSE_NAME</th>
<th>Prop.Owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>San Francisco</td>
<td>Grandco</td>
</tr>
<tr>
<td>3</td>
<td>New Jersey</td>
<td>Grandco</td>
</tr>
</tbody>
</table>
APPROX_COUNT_DISTINCT

**Syntax**

```
APPROX_COUNT_DISTINCT(expr)
```

**Purpose**

`APPROX_COUNT_DISTINCT` returns the approximate number of rows that contain distinct values of `expr`.

This function provides an alternative to the `COUNT(DISTINCT expr)` function, which returns the exact number of rows that contain distinct values of `expr`. `APPROX_COUNT_DISTINCT` processes large amounts of data significantly faster than `COUNT`, with negligible deviation from the exact result.

For `expr`, you can specify a column of any scalar data type other than `BFILE`, `BLOB`, `CLOB`, `LONG`, `LONG RAW`, or `NCLOB`.

`APPROX_COUNT_DISTINCT` ignores rows that contain a null value for `expr`. This function returns a `NUMBER`.

**Examples**

The following statement returns the approximate number of rows with distinct values for `manager_id`:

```sql
SELECT APPROX_COUNT_DISTINCT(manager_id) AS "Active Managers"
FROM employees;
```

```
Active Managers
---------------
18
```

The following statement returns the approximate number of distinct customers for each product:

```sql
SELECT prod_id, APPROX_COUNT_DISTINCT(cust_id) AS "Number of Customers"
FROM sales
GROUP BY prod_id
ORDER BY prod_id;
```

```
PROD_ID Number of Customers
---------------------------
 13 2516
 14 2030
 15 2105
 16 2367
 17 2093
 18 2975
 19 2630
 20 3791
...```

**Note:** The `APPROX_COUNT_DISTINCT` function is available starting with Oracle Database 12c Release 1 (12.1.0.2).
ASCII

Syntax

\[
\text{ASCII}(\text{char})
\]

Purpose

ASCII returns the decimal representation in the database character set of the first character of char.

char can be of data type CHAR, VARCHAR2, NCHAR, or NVARCHAR2. The value returned is of data type NUMBER. If your database character set is 7-bit ASCII, then this function returns an ASCII value. If your database character set is EBCDIC Code, then this function returns an EBCDIC value. There is no corresponding EBCDIC character function.

This function does not support CLOB data directly. However, CLOBs can be passed in as arguments through implicit data conversion.

See Also: "Data Type Comparison Rules" on page 2-39 for more information

Examples

The following example returns employees whose last names begin with the letter L, whose ASCII equivalent is 76:

```
SELECT last_name
FROM employees
WHERE ASCII(SUBSTR(last_name, 1, 1)) = 76
ORDER BY last_name;
```

```
LAST_NAME
------------
Ladwig
Landry
Lee
Livingston
Lorentz
```
ASCIISTR

Syntax

\[ \text{ASCIISTR}(\text{char}) \]

Purpose

ASCIISTR takes as its argument a string, or an expression that resolves to a string, in any character set and returns an ASCII version of the string in the database character set. Non-ASCII characters are converted to the form \( \backslash \text{xxxx} \), where xxxx represents a UTF-16 code unit.

See Also: Oracle Database Globalization Support Guide for information on Unicode character sets and character semantics

Examples

The following example returns the ASCII string equivalent of the text string "ABÄCDE":

```sql
SELECT ASCIISTR('ABÄCDE')
FROM DUAL;
```

```
ASCIISTR('/
----------
AB\00C4CDE
```

```sql
ASCIISTR('ABÄCDE')
```

```
AB\00C4CDE
```
ASIN

Syntax

\[ \text{ASIN} \rightarrow \text{Function}\left(n\right) \]

Purpose

ASIN returns the arc sine of \( n \). The argument \( n \) must be in the range of -1 to 1, and the function returns a value in the range of \(-\pi/2\) to \(\pi/2\), expressed in radians.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If the argument is BINARY_FLOAT, then the function returns BINARY_DOUBLE. Otherwise the function returns the same numeric data type as the argument.

See Also:  Table 2–10, “Implicit Type Conversion Matrix” on page 2-43 for more information on implicit conversion

Examples

The following example returns the arc sine of .3:

```sql
SELECT ASIN(.3) 'Arc_Sine'
FROM DUAL;
```

```
Arc_Sine
----------
.304692654
```
ATAN

Syntax

\[ \text{ATAN}(n) \]

Purpose

\text{ATAN} \text{ returns the arc tangent of } n. \text{ The argument } n \text{ can be in an unbounded range and returns a value in the range of } -\pi/2 \text{ to } \pi/2, \text{ expressed in radians.}

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If the argument is \text{BINARY_FLOAT}, then the function returns \text{BINARY_DOUBLE}. Otherwise the function returns the same numeric data type as the argument.

\textbf{See Also:} \text{ATAN2} on page 7-28 for information about the \text{ATAN2} function and \text{Table 2-10, "Implicit Type Conversion Matrix"} on page 2-43 for more information on implicit conversion

Examples

The following example returns the arc tangent of .3:

\begin{verbatim}
SELECT ATAN(.3) "Arc_Tangent"
FROM DUAL;

Arc_Tangent
----------
.291456794
\end{verbatim}
ATAN2

Syntax

\[ \text{ATAN2}(n1, n2) \]

Purpose

ATAN2 returns the arc tangent of \( n1 \) and \( n2 \). The argument \( n1 \) can be in an unbounded range and returns a value in the range of \(-\pi\) to \(\pi\), depending on the signs of \( n1 \) and \( n2 \), expressed in radians.

This function takes as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If any argument is BINARY_FLOAT or BINARY_DOUBLE, then the function returns BINARY_DOUBLE. Otherwise the function returns NUMBER.

See Also:  ATAN on page 7-27 for information on the ATAN function and Table 2–10, ” Implicit Type Conversion Matrix” on page 2-43 for more information on implicit conversion

Examples

The following example returns the arc tangent of .3 and .2:

```
SELECT ATAN2(.3, .2) "Arc_Tangent2"
FROM DUAL;

Arc_Tangent2
------------
.982793723
```

AVG

Syntax

AVG

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

AVG returns average value of expr.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

See Also: Table 2-10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

If you specify DISTINCT, then you can specify only the query_partition_clause of the analytic_clause. The order_by_clause and windowing_clause are not allowed.

See Also: "About SQL Expressions" on page 5-1 for information on valid forms of expr and "Aggregate Functions" on page 7-10

Aggregate Example

The following example calculates the average salary of all employees in the hr.employees table:

SELECT AVG(salary) "Average"
FROM employees;

Average
-------------
6461.83178

Analytic Example

The following example calculates, for each employee in the employees table, the average salary of the employees reporting to the same manager who were hired in the range just before through just after the employee:

SELECT manager_id, last_name, hire_date, salary,
       AVG(salary) OVER (PARTITION BY manager_id ORDER BY hire_date
       ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING) AS c_mavg
FROM employees
ORDER BY manager_id, hire_date, salary;

MANAGER_ID LAST_NAME   HIRE_DATE   SALARY     C_MAVG
---------- --------------- --------- ---------- ----------
100 De Haan     13-JAN-01  17000      14000
100 Raphaely    07-DEC-02  11000 11966.6667
100 Kaufling    01-MAY-03   7900 10633.3333
100 Hartstein   17-FEB-04  13000 9633.3333
<table>

</tr>
</tbody>
</table>
BFILENAME

Syntax

BFILENAME(directory, filename)

Purpose

BFILENAME returns a BFILE locator that is associated with a physical LOB binary file on the server file system.

- 'directory' is a database object that serves as an alias for a full path name on the server file system where the files are actually located.
- 'filename' is the name of the file in the server file system.

You must create the directory object and associate a BFILE value with a physical file before you can use them as arguments to BFILENAME in a SQL or PL/SQL statement, DBMS_LOB package, or OCI operation.

You can use this function in two ways:

- In a DML statement to initialize a BFILE column
- In a programmatic interface to access BFILE data by assigning a value to the BFILE locator

The directory argument is case sensitive. You must ensure that you specify the directory object name exactly as it exists in the data dictionary. For example, if an "Admin" directory object was created using mixed case and a quoted identifier in the CREATE DIRECTORY statement, then when using the BFILENAME function you must refer to the directory object as 'Admin'. You must specify the filename argument according to the case and punctuation conventions for your operating system.

See Also:

- Oracle Database SecureFiles and Large Objects Developer’s Guide and Oracle Call Interface Programmer’s Guide for more information on LOBs and for examples of retrieving BFILE data
- CREATE DIRECTORY on page 14-54

Examples

The following example inserts a row into the sample table pm.print_media. The example uses the BFILENAME function to identify a binary file on the server file system in the directory /demo/schema/product_media. The example shows how the directory database object media_dir was created in the pm schema.

CREATE DIRECTORY media_dir AS '/demo/schema/product_media';

INSERT INTO print_media (product_id, ad_id, ad_graphic)
VALUES (3000, 31001, BFILENAME('MEDIA_DIR', 'modem_comp_ad.gif'));
BIN_TO_NUM

Syntax

$$\text{BIN_TO_NUM}(\text{expr})$$

Purpose

BIN_TO_NUM converts a bit vector to its equivalent number. Each argument to this function represents a bit in the bit vector. This function takes as arguments any numeric data type, or any nonnumeric data type that can be implicitly converted to NUMBER. Each expr must evaluate to 0 or 1. This function returns Oracle NUMBER.

BIN_TO_NUM is useful in data warehousing applications for selecting groups of interest from a materialized view using grouping sets.

See Also:
- group_by_clause on page 19-34 for information on GROUPING SETS syntax
- Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion
- Oracle Database Data Warehousing Guide for information on data aggregation in general

Examples

The following example converts a binary value to a number:

```sql
SELECT BIN_TO_NUM(1, 0, 1, 0)
FROM DUAL;

BIN_TO_NUM(1, 0, 1, 0)
-------------------
10
```

The next example converts three values into a single binary value and uses BIN_TO_NUM to convert that binary into a number. The example uses a PL/SQL declaration to specify the original values. These would normally be derived from actual data sources.

```sql
SELECT order_status
FROM orders
WHERE order_id = 2441;

ORDER_STATUS
-------------
5

DECLARE
  warehouse NUMBER := 1;
  ground NUMBER := 1;
  insured NUMBER := 1;
  result NUMBER;
BEGIN
  SELECT BIN_TO_NUM(warehouse, ground, insured) INTO result FROM DUAL;
  UPDATE orders SET order_status = result WHERE order_id = 2441;
END;
```
PL/SQL procedure successfully completed.

SELECT order_status
FROM orders
WHERE order_id = 2441;

ORDER_STATUS
------------
  7

Refer to the examples for \texttt{BITAND} on page 7-34 for information on reversing this process by extracting multiple values from a single column value.
The `BITAND` function treats its inputs and its output as vectors of bits; the output is the bitwise AND of the inputs.

The types of `expr1` and `expr2` are `NUMBER`, and the result is of type `NUMBER`. If either argument to `BITAND` is NULL, the result is NULL.

The arguments must be in the range `-2^{n-1} .. (2^{(n-1)})-1`. If an argument is out of this range, the result is undefined.

The result is computed in several steps. First, each argument A is replaced with the value `SIGN(A) * FLOOR(ABS(A))`. This conversion has the effect of truncating each argument towards zero. Next, each argument A (which must now be an integer value) is converted to an n-bit two's complement binary integer value. The two bit values are combined using a bitwise AND operation. Finally, the resulting n-bit two's complement value is converted back to `NUMBER`.

**Notes on the BITAND Function**

- The current implementation of `BITAND` defines `n = 128`.
- PL/SQL supports an overload of `BITAND` for which the types of the inputs and of the result are all `BINARY_INTEGER` and for which `n = 32`.

**Examples**

The following example performs an AND operation on the numbers 6 (binary 1,1,0) and 3 (binary 0,1,1):

```sql
SELECT BITAND(6,3)
FROM DUAL;

BITAND(6,3)
---------
  2
```

This is the same as the following example, which shows the binary values of 6 and 3. The `BITAND` function operates only on the significant digits of the binary values:

```sql
SELECT BITAND(
    BIN_TO_NUM(1,1,0),
    BIN_TO_NUM(0,1,1)) "Binary"
FROM DUAL;

Binary
-------
  2
```

Refer to the example for `BIN_TO_NUM` on page 7-32 for information on encoding multiple values in a single column value.

The following example supposes that the `order_status` column of the sample table `oe.orders` encodes several choices as individual bits within a single numeric value.
For example, an order still in the warehouse is represented by a binary value 001 (decimal 1). An order being sent by ground transportation is represented by a binary value 010 (decimal 2). An insured package is represented by a binary value 100 (decimal 4). The example uses the `DECODE` function to provide two values for each of the three bits in the `order_status` value, one value if the bit is turned on and one if it is turned off.

```sql
SELECT order_id, customer_id, order_status,
    DECODE(BITAND(order_status, 1), 1, 'Warehouse', 'PostOffice') "Location",
    DECODE(BITAND(order_status, 2), 2, 'Ground', 'Air') "Method",
    DECODE(BITAND(order_status, 4), 4, 'Insured', 'Certified') "Receipt"
FROM orders
WHERE sales_rep_id = 160
ORDER BY order_id;
```

<table>
<thead>
<tr>
<th>ORDER_ID</th>

</tbody>
</table>

For the `Location` column, `BITAND` first compares `order_status` with 1 (binary 001). Only significant bit values are compared, so any binary value with a 1 in its rightmost bit (any odd number) will evaluate positively and return 1. Even numbers will return 0. The `DECODE` function compares the value returned by `BITAND` with 1. If they are both 1, then the location is "Warehouse". If they are different, then the location is "PostOffice".

The `Method` and `Receipt` columns are calculated similarly. For `Method`, `BITAND` performs the AND operation on `order_status` and 2 (binary 010). For `Receipt`, `BITAND` performs the AND operation on `order_status` and 4 (binary 100).
CARDINALITY

Syntax

```
CARDINALITY (nested_table)
```

Purpose

CARDINALITY returns the number of elements in a nested table. The return type is NUMBER. If the nested table is empty, or is a null collection, then CARDINALITY returns NULL.

Examples

The following example shows the number of elements in the nested table column ad_textdocs_ntab of the sample table pm.print_media:

```
SELECT product_id, CARDINALITY(ad_textdocs_ntab) cardinality
FROM print_media
ORDER BY product_id;
```

<table>

</tbody>
</table>
CAST

Syntax

\[
\text{CAST} \quad \rightarrow \quad \text{MULTISET} \quad \rightarrow \quad \text{AS} \quad \rightarrow \quad \text{type_name} \quad \rightarrow
\]

Purpose

CAST converts one built-in data type or collection-typed value into another built-in data type or collection-typed value.

CAST lets you convert built-in data types or collection-typed values of one type into another built-in data type or collection type. You can cast an unnamed operand (such as a date or the result set of a subquery) or a named collection (such as a varray or a nested table) into a type-compatible data type or named collection. The type_name must be the name of a built-in data type or collection type and the operand must be a built-in data type or must evaluate to a collection value.

For the operand, expr can be either a built-in data type, a collection type, or an instance of an ANYDATA type. If expr is an instance of an ANYDATA type, then CAST tries to extract the value of the ANYDATA instance and return it if it matches the cast target type, otherwise, null will be returned. MULTISET informs Oracle Database to take the result set of the subquery and return a collection value. Table 7–1 shows which built-in data types can be cast into which other built-in data types. (CAST does not support LONG, LONG RAW, or the Oracle-supplied types.)

CAST does not directly support any of the LOB data types. When you use CAST to convert a CLOB value into a character data type or a BLOB value into the RAW data type, the database implicitly converts the LOB value to character or raw data and then explicitly casts the resulting value into the target data type. If the resulting value is larger than the target type, then the database returns an error.

When you use CAST ... MULTISET to get a collection value, each select list item in the query passed to the CAST function is converted to the corresponding attribute type of the target collection element type.

<td>--</td>
<td>--</td>
<td>--</td>
</tr>
</tbody>
</table>
**Note 1:** Datetime/interval includes `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIMEZONE`, `INTERVAL DAY TO SECOND`, and `INTERVAL YEAR TO MONTH`.

**Note 2:** You cannot cast a `UROWID` to a `ROWID` if the `UROWID` contains the value of a `ROWID` of an index-organized table.

If you want to cast a named collection type into another named collection type, then the elements of both collections must be of the same type.

**See Also:** "Implicit Data Conversion" on page 2-43 for information on how Oracle Database implicitly converts collection type data into character data and "Security Considerations for Data Conversion" on page 2-47

If the result set of subquery can evaluate to multiple rows, then you must specify the `MULTISET` keyword. The rows resulting from the subquery form the elements of the collection value into which they are cast. Without the `MULTISET` keyword, the subquery is treated as a scalar subquery.

### Built-In Data Type Examples

The following examples use the `CAST` function with scalar data types. The first example converts text to a timestamp value by applying the format model provided in the session parameter `NLS_TIMESTAMP_FORMAT`. If you want to avoid dependency on this NLS parameter, then you can use the `TO_DATE` as shown in the second example.

```sql
SELECT CAST('22-OCT-1997' AS TIMESTAMP WITH LOCAL TIME ZONE) FROM DUAL;
SELECT CAST(TO_DATE('22-Oct-1997', 'DD-Mon-YYYY') AS TIMESTAMP WITH LOCAL TIME ZONE) FROM DUAL;
```

In the preceding example, `TO_DATE` converts from text to `DATE`, and `CAST` converts from `DATE` to `TIMESTAMP WITH LOCAL TIME ZONE`, interpreting the date in the session time zone (`SESSIONTIMEZONE`).

```sql
SELECT product_id, CAST(ad_sourcetext AS VARCHAR2(30)) text FROM print_media ORDER BY product_id;
```

### Collection Examples

The `CAST` examples that follow build on the `cust_address_typ` found in the sample order entry schema, `oe`.

```sql
CREATE TYPE address_book_t AS TABLE OF cust_address_typ;
/
CREATE TYPE address_array_t AS VARRAY(3) OF cust_address_typ;
/
CREATE TABLE cust_address ( custno NUMBER, street_address VARCHAR2(40), postal_code VARCHAR2(10), city VARCHAR2(30), state_province VARCHAR2(10), country_id CHAR(2));
```

```sql
CREATE TABLE cust_short (custno NUMBER, name VARCHAR2(31));
```
CREATE TABLE states (state_id NUMBER, addresses address_array_t);

This example casts a subquery:

```
SELECT s.custno, s.name,
    CAST(MULTISET(SELECT ca.street_address,
                   ca.postal_code,
                   ca.city,
                   ca.state_province,
                   ca.country_id
      FROM cust_address ca
      WHERE s.custno = ca.custno)
    AS address_book_t)
FROM cust_short s
ORDER BY s.custno;
```

CAST converts a varray type column into a nested table:

```
SELECT CAST(s.addresses AS address_book_t)
FROM states s
WHERE s.state_id = 111;
```

The following objects create the basis of the example that follows:

```
CREATE TABLE projects
    (employee_id NUMBER, project_name VARCHAR2(10));

CREATE TABLE emps_short
    (employee_id NUMBER, last_name VARCHAR2(10));

CREATE TYPE project_table_typ AS TABLE OF VARCHAR2(10);
/
```

The following example of a MULTISET expression uses these objects:

```
SELECT e.last_name,
    CAST(MULTISET(SELECT p.project_name
                   FROM projects p
                   WHERE p.employee_id = e.employee_id
                   ORDER BY p.project_name)
    AS project_table_typ)
FROM emps_short e
ORDER BY e.last_name;
```
CEIL

Syntax

```
CEIL(n)
```

Purpose

CEIL returns the smallest integer that is greater than or equal to \( n \). The number \( n \) can always be written as the difference of an integer \( k \) and a positive fraction \( f \) such that \( 0 \leq f < 1 \) and \( n = k - f \). The value of CEIL is the integer \( k \). Thus, the value of CEIL is \( n \) itself if and only if \( n \) is precisely an integer.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

See Also: Table 2–10, ” Implicit Type Conversion Matrix” on page 2-43 for more information on implicit conversion and FLOOR on page 7-126

Examples

The following example returns the smallest integer greater than or equal to the order total of a specified order:

```sql
SELECT order_total, CEIL(order_total)
FROM orders
WHERE order_id = 2434;
```

<table>
<thead>
<tr>
<th>ORDER_TOTAL</th>
<th>CEIL(ORDER_TOTAL)</th>
</tr>
</thead>
<tbody>
<tr>
<td>268651.8</td>
<td>268652</td>
</tr>
</tbody>
</table>
CHARTOROWID

Syntax

```
CHARTOROWID(char) -> ROWID
```

Purpose

CHARTOROWID converts a value from CHAR, VARCHAR2, NCHAR, or NVARCHAR2 data type to ROWID data type.

This function does not support CLOB data directly. However, CLOBs can be passed in as arguments through implicit data conversion.

See Also: "Data Type Comparison Rules" on page 2-39 for more information.

Examples

The following example converts a character rowid representation to a rowid. (The actual rowid is different for each database instance.)

```sql
SELECT last_name
FROM employees
WHERE ROWID = CHARTOROWID('AAAFd1AAFAAAABSAA/');
```

LAST_NAME
-------------
Greene
CHR

Syntax

```
CHR(n) [USING NCHAR_CS]
```

Purpose

CHR returns the character having the binary equivalent to \( n \) as a VARCHAR2 value in either the database character set or, if you specify USING NCHAR_CS, the national character set.

For single-byte character sets, if \( n > 256 \), then Oracle Database returns the binary equivalent of \( n \mod 256 \). For multibyte character sets, \( n \) must resolve to one entire code point. Invalid code points are not validated, and the result of specifying invalid code points is indeterminate.

This function takes as an argument a NUMBER value, or any value that can be implicitly converted to NUMBER, and returns a character.

---

Note: Use of the CHR function (either with or without the optional USING NCHAR_CS clause) results in code that is not portable between ASCII- and EBCDIC-based machine architectures.

---

See Also: NCHR on page 7-199 and Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion.

Examples

The following example is run on an ASCII-based machine with the database character set defined as WE8ISO8859P1:

```
SELECT CHR(67) || CHR(65) || CHR(84) "Dog"
FROM DUAL;
```

```
Dog
---
CAT
```

To produce the same results on an EBCDIC-based machine with the WE8EBCDIC1047 character set, the preceding example would have to be modified as follows:

```
SELECT CHR(195) || CHR(193) || CHR(227) "Dog"
FROM DUAL;
```

```
Dog
---
CAT
```

For multibyte character sets, this sort of concatenation gives different results. For example, given a multibyte character whose hexadecimal value is a1a2 (\( a1 \) representing the first byte and \( a2 \) the second byte), you must specify for \( n \) the decimal equivalent of 'a1a2', or 41378:

```
SELECT CHR(41378)
```

---

Oracle Database SQL Language Reference
FROM DUAL;

You cannot specify the decimal equivalent of a1 concatenated with the decimal equivalent of a2, as in the following example:

```
SELECT CHR(161) || CHR(162)
FROM DUAL;
```

However, you can concatenate whole multibyte code points, as in the following example, which concatenates the multibyte characters whose hexadecimal values are a1a2 and a1a3:

```
SELECT CHR(41378) || CHR(41379)
FROM DUAL;
```

The following example assumes that the national character set is UTF16:

```
SELECT CHR (196 USING NCHAR_CS)
FROM DUAL;
```

CH
---
Ä
CLUSTER_DETAILS

Syntax

\[ \text{cluster_details} ::= \]

\[ \text{cluster_details_analytic} ::= \]

\[ \text{mining_attribute_clause} ::= \]

\[ \text{mining_analytic_clause} ::= \]

See Also: "Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of \text{mining_analytic_clause}
Purpose

CLUSTER_DETAILS returns cluster details for each row in the selection. The return value is an XML string that describes the attributes of the highest probability cluster or the specified cluster_id.

**topN**

If you specify a value for topN, the function returns the N attributes that most influence the cluster assignment (the score). If you do not specify topN, the function returns the 5 most influential attributes.

**DESC, ASC, or ABS**

The returned attributes are ordered by weight. The weight of an attribute expresses its positive or negative impact on cluster assignment. A positive weight indicates an increased likelihood of assignment. A negative weight indicates a decreased likelihood of assignment.

By default, CLUSTER_DETAILS returns the attributes with the highest positive weights (DESC). If you specify ASC, the attributes with the highest negative weights are returned. If you specify ABS, the attributes with the greatest weights, whether negative or positive, are returned. The results are ordered by absolute value from highest to lowest. Attributes with a zero weight are not included in the output.

**Syntax Choice**

CLUSTER_DETAILS can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically mine the data by executing an analytic clause that builds and applies one or more transient mining models. Choose Syntax or Analytic Syntax:

- **Syntax** — Use the first syntax to score the data with a pre-defined model. Supply the name of a clustering model.

- **Analytic Syntax** — Use the analytic syntax to score the data without a pre-defined model. Include INTO n, where n is the number of clusters to compute, and mining_analytic_clause, which specifies if the data should be partitioned for multiple model builds. The mining_analytic_clause supports a query_partition_clause and an order_by_clause. (See "analytic_clause::=" on page 7-12.)

**mining_attribute_clause**

mining_attribute_clause identifies the column attributes to use as predictors for scoring. When the function is invoked with the analytic syntax, these predictors are also used for building the transient models. The mining_attribute_clause behaves as described for the PREDICTION function. (See "mining_attribute_clause::=" on page 7-237.)

**See Also:**

- Oracle Data Mining User's Guide for information about scoring.
- Oracle Data Mining Concepts for information about clustering.

**About the Examples:** The following examples are excerpted from the Data Mining sample programs. For more information about the sample programs, see Appendix A in Oracle Data Mining User's Guide.
Example

This example lists the attributes that have the greatest impact (more than 20% probability) on cluster assignment for customer ID 100955. The query invokes the `CLUSTER_DETAILS` and `CLUSTER_SET` functions, which apply the clustering model `em_sh_clus_sample`.

```sql
SELECT S.cluster_id, probability prob,
       CLUSTER_DETAILS(em_sh_clus_sample, S.cluster_id, 5 USING T.*) det
FROM
   (SELECT v.*, CLUSTER_SET(em_sh_clus_sample, NULL, 0.2 USING *) pset
    FROM mining_data_apply_v v
    WHERE cust_id = 100955) T,
   TABLE(T.pset) S
ORDER BY 2 DESC;
```

<table>
<thead>
<tr>
<th>CLUSTER_ID</th>
<th>PROB</th>
<th>DET</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
<td>.6761</td>
<td>&lt;Details algorithm=&quot;Expectation Maximization&quot; cluster=&quot;14&quot;&gt; &lt;Attribute name=&quot;AGE&quot; actualValue=&quot;51&quot; weight=&quot;.676&quot; rank=&quot;1&quot;/&gt; &lt;Attribute name=&quot;HOME_THEATER_PACKAGE&quot; actualValue=&quot;1&quot; weight=&quot;.557&quot; rank=&quot;2&quot;/&gt; &lt;Attribute name=&quot;FLAT_PANEL_MONITOR&quot; actualValue=&quot;0&quot; weight=&quot;.412&quot; rank=&quot;3&quot;/&gt; &lt;Attribute name=&quot;Y_BOX_GAMES&quot; actualValue=&quot;0&quot; weight=&quot;.171&quot; rank=&quot;4&quot;/&gt; &lt;Attribute name=&quot;BOOKKEEPING_APPLICATION&quot; actualValue=&quot;1&quot; weight=&quot;-.003&quot; rank=&quot;5&quot;/&gt; &lt;/Details&gt;</td>
</tr>
<tr>

**CLUSTER_DISTANCE**

Syntax

\[
\text{cluster_distance::=} \\
\text{CLUSTER_DISTANCE} (\text{schema}, \text{model}, \text{cluster_id}, \text{mining_attribute_clause})
\]

Analytic Syntax

\[
\text{cluster_distance_analytic::=} \\
\text{OVER} (\text{mining_analytic_clause})
\]

\[
\text{mining_attribute_clause::=} \\
\text{USING} (\text{schema}, \text{table}, \text{expr AS alias})
\]

See Also: "Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of \text{mining_analytic_clause}

**Purpose**

\text{CLUSTER_DISTANCE} returns a cluster distance for each row in the selection. The cluster distance is the distance between the row and the centroid of the highest probability cluster or the specified \text{cluster_id}. The distance is returned as \text{BINARY_DOUBLE}.

**Syntax Choice**

\text{CLUSTER_DISTANCE} can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically mine the data by executing an analytic clause that builds and applies one or more transient mining models. Choose Syntax or Analytic Syntax:

- **Syntax** — Use the first syntax to score the data with a pre-defined model. Supply the name of a clustering model.

- **Analytic Syntax** — Use the analytic syntax to score the data without a pre-defined model. Include INTO \text{n}, where \text{n} is the number of clusters to compute, and \text{mining_}
analytic_clause, which specifies if the data should be partitioned for multiple model builds. The mining_analytic_clause supports a query_partition_clause and an order_by_clause. (See "analytic_clause::=" on page 7-12.)

mining_attribute_clause
mining_attribute_clause identifies the column attributes to use as predictors for scoring. When the function is invoked with the analytic syntax, this data is also used for building the transient models. The mining_attribute_clause behaves as described for the PREDICTION function. (See "mining_attribute_clause::=" on page 7-237.)

About the Example: The following example is excerpted from the Data Mining sample programs. For more information about the sample programs, see Appendix A in Oracle Data Mining User’s Guide.

Example
This example finds the 10 rows that are most anomalous as measured by their distance from their nearest cluster centroid.

```
SELECT cust_id
FROM (SELECT cust_id,
            rank() over
               (order by CLUSTER_DISTANCE(km_sh_clus_sample USING *) desc) rnk
            FROM mining_data_apply_v)
WHERE rnk <= 11
ORDER BY rnk;
```

```

**mining_analyticClause::=**

```
query_partition_clause order_by_clause
```

**See Also:** "Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of **mining_analyticClause**

**Purpose**

The **CLUSTER_ID** returns the identifier of the highest probability cluster for each row in the selection. The cluster identifier is returned as an Oracle NUMBER.

**Syntax Choice**

**CLUSTER_ID** can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically mine the data by executing an analytic clause that builds and applies one or more transient mining models. Choose **Syntax** or **Analytic Syntax**:

- **Syntax** — Use the first syntax to score the data with a pre-defined model. Supply the name of a clustering model.

- **Analytic Syntax** — Use the analytic syntax to score the data without a pre-defined model. Include INTO n, where n is the number of clusters to compute, and **mining_analyticClause**, which specifies if the data should be partitioned for multiple model builds. The **mining_analyticClause** supports a **query_partition_clause** and an **order_by_clause**. (See "**analyticClause::="" on page 7-12.)
**mining_attribute_clause**

`mining_attribute_clause` identifies the column attributes to use as predictors for scoring. When the function is invoked with the analytic syntax, these predictors are also used for building the transient models. The `mining_attribute_clause` behaves as described for the `PREDICTION` function. (See "`mining_attribute_clause::="" on page 7-237.)

- *Oracle Data Mining Concepts* for information about clustering.

**About the Examples:** The following examples are excerpted from the Data Mining sample programs. For more information about the sample programs, see Appendix A in *Oracle Data Mining User’s Guide*.

### Example

The following example lists the clusters into which the customers in `mining_data_apply_v` have been grouped.

```sql
SELECT CLUSTER_ID(km_sh_clus_sample USING *) AS clus, COUNT(*) AS cnt
FROM mining_data_apply_v
GROUP BY CLUSTER_ID(km_sh_clus_sample USING *)
ORDER BY cnt DESC;

<table>
<thead>
<tr>
<th>CLUS</th>

<td>34</td>
</tr>
</tbody>
</table>
```

### Analytic Example

This example divides the customer database into four segments based on common characteristics. The clustering functions compute the clusters and return the score without a predefined clustering model.

```sql
SELECT * FROM (SELECT cust_id,
                 CLUSTER_ID(INTO 4 USING *) OVER () cls,
                 CLUSTER_DETAILS(INTO 4 USING *) OVER () cls_details
                 FROM mining_data_apply_v)
WHERE cust_id <= 100003
ORDER BY 1;

<table>
<thead>

</Details>
**CLUSTER_PROBABILITY**

**Syntax**

\[
\text{cluster\_probability} ::= \\
\text{cluster\_probability}:=(schema \cdot \text{model} \cdot \text{cluster\_id} \cdot \text{mining\_attribute\_clause})
\]

**Analytic Syntax**

\[
\text{cluster\_prob\_analytic} ::= \\
\text{cluster\_prob\_analytic}:=(\text{into} \cdot n \cdot \text{cluster\_id} \cdot \text{mining\_attribute\_clause})
\]

**mining\_attribute\_clause ::=**

\[
\text{mining\_attribute\_clause}:=(\text{using} \cdot \text{schema} \cdot \text{table} \cdot \text{expr} \cdot \text{AS} \cdot \text{alias} \cdot \text{query\_partition\_clause} \cdot \text{order\_by\_clause})
\]

**See Also:** "Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of mining\_analytic\_clause

**Purpose**

CLUSTER_PROBABILITY returns a probability for each row in the selection. The probability refers to the highest probability cluster or to the specified cluster\_id. The cluster probability is returned as BINARY\_DOUBLE.

**Syntax Choice**

CLUSTER_PROBABILITY can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically mine the data by executing an analytic clause that builds and applies one or more transient mining models. Choose Syntax or Analytic Syntax:

- **Syntax** — Use the first syntax to score the data with a pre-defined model. Supply the name of a clustering model.
- **Analytic Syntax** — Use the analytic syntax to score the data without a pre-defined model. Include INTO n, where n is the number of clusters to compute, and mining_
analytic_clause, which specifies if the data should be partitioned for multiple model builds. The `mining_analytic_clause` supports a `query_partition_clause` and an `order_by_clause`. (See "analytic_clause::=" on page 7-12.)

`mining_attribute_clause`

`mining_attribute_clause` identifies the column attributes to use as predictors for scoring. When the function is invoked with the analytic syntax, these predictors are also used for building the transient models. The `mining_attribute_clause` behaves as described for the `PREDICTION` function. (See "mining_attribute_clause::=" on page 7-237.)

**See Also:**
- *Oracle Data Mining User’s Guide* for information about scoring.
- *Oracle Data Mining Concepts* for information about clustering.

---

**Example**

The following example lists the ten most representative customers, based on likelihood, of cluster 2.

```sql
SELECT cust_id
FROM (SELECT cust_id, rank() OVER (ORDER BY prob DESC, cust_id) rnk_clus2
     FROM (SELECT cust_id, CLUSTER_PROBABILITY(km_sh_clus_sample, 2 USING *) prob
            FROM mining_data_apply_v))
WHERE rnk_clus2 <= 10
ORDER BY rnk_clus2;
```

<table>
<thead>
<tr>
<th>CUST_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>100256</td>
</tr>
<tr>

</tr>
<tr>
<td>100889</td>
</tr>
<tr>
<td>101086</td>
</tr>
<tr>
<td>101215</td>
</tr>
<tr>
<td>100390</td>
</tr>
<tr>
<td>100985</td>
</tr>
<tr>
<td>101026</td>
</tr>
<tr>
<td>100601</td>
</tr>
<tr>
<td>100672</td>
</tr>
</tbody>
</table>
**CLUSTER_SET**

**Syntax**

\[
\text{cluster
d_set}::= \\
\text{cluster
d_set\_analytic}::= \\
\text{mining\_attribute\_clause}::=
\]

**Analytic Syntax**

\[
\text{cluster\_set\_analytic}::= \\
\text{mining\_attribute\_clause}::=
\]

**Purpose**
\[\]CLUSTER_SET returns a set of cluster ID and probability pairs for each row in the selection. The return value is a varray of objects with field names **CLUSTER_ID** and **PROBABILITY**. The cluster identifier is an Oracle **NUMBER**; the probability is **BINARY_DOUBLE**.

**topN and cutoff**
You can specify **topN** and **cutoff** to limit the number of clusters returned by the function. By default, both **topN** and **cutoff** are null and all clusters are returned.

- **topN** is the \( N \) most probable clusters. If multiple clusters share the \( N \)th probability, then the function chooses one of them.

**See Also:** "Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of **mining_analytic_clause**
cutoff is a probability threshold. Only clusters with probability greater than or equal to cutoff are returned. To filter by cutoff only, specify NULL for topN.

To return up to the N most probable clusters that are greater than or equal to cutoff, specify both topN and cutoff.

**Syntax Choice**
CLUSTER_SET can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically mine the data by executing an analytic clause that builds and applies one or more transient mining models. Choose Syntax or Analytic Syntax:

- **Syntax** — Use the first syntax to score the data with a pre-defined model. Supply the name of a clustering model.
- **Analytic Syntax** — Use the analytic syntax to score the data without a pre-defined model. Include INTO n, where n is the number of clusters to compute, and mining_analytic_clause, which specifies if the data should be partitioned for multiple model builds. The mining_analytic_clause supports a query_partition_clause and an order_by_clause. (See "analytic_clause::=" on page 7-12.)

**mining_attribute_clause**
mining_attribute_clause identifies the column attributes to use as predictors for scoring. When the function is invoked with the analytic syntax, these predictors are also used for building the transient models. The mining_attribute_clause behaves as described for the PREDICTION function. (See "mining_attribute_clause::=" on page 7-237.)

**Example**
This example lists the attributes that have the greatest impact (more that 20% probability) on cluster assignment for customer ID 100955. The query invokes the CLUSTER_DETAILS and CLUSTER_SET functions, which apply the clustering model em_sh_clus_sample.

```sql
SELECT S.cluster_id, probability prob,
   CLUSTER_DETAILS(em_sh_clus_sample, S.cluster_id, 5 USING T.*) det
FROM
   (SELECT v.*, CLUSTER_SET(em_sh_clus_sample, NULL, 0.2 USING *) pset
    FROM mining_data_apply_v v
    WHERE cust_id = 100955) T,
   TABLE(T.pset) S
ORDER BY 2 DESC;
```

</Details>
COALESCE

Syntax

COALESCE(expr) -> expr

Purpose

COALESCE returns the first non-null expr in the expression list. You must specify at least two expressions. If all occurrences of expr evaluate to null, then the function returns null.

Oracle Database uses short-circuit evaluation. The database evaluates each expr value and determines whether it is NULL, rather than evaluating all of the expr values before determining whether any of them is NULL.

If all occurrences of expr are numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type, then Oracle Database determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and "Numeric Precedence" on page 2-16 for information on numeric precedence.

This function is a generalization of the NVL function.

You can also use COALESCE as a variety of the CASE expression. For example,

COALESCE(expr1, expr2)

is equivalent to:

CASE WHEN expr1 IS NOT NULL THEN expr1 ELSE expr2 END

Similarly,

COALESCE(expr1, expr2, ..., exprn)

where n >= 3, is equivalent to:

CASE WHEN expr1 IS NOT NULL THEN expr1
    ELSE COALESCE(expr2, ..., exprn) END

See Also: NVL on page 7-217 and "CASE Expressions" on page 5-5

Examples

The following example uses the sample oe.product_information table to organize a clearance sale of products. It gives a 10% discount to all products with a list price. If there is no list price, then the sale price is the minimum price. If there is no minimum price, then the sale price is "5":

```sql
SELECT product_id, list_price, min_price,
    COALESCE(0.9*list_price, min_price, 5) "Sale"
FROM product_information
WHERE supplier_id = 102050
ORDER BY product_id;
```
<table>
<thead>
<tr>
<th>PRODUCT_ID</th>
<th>LIST_PRICE</th>
<th>MIN_PRICE</th>
<th>Sale</th>
</tr>
</thead>
<tbody>
<tr>
<td>1769</td>
<td>48</td>
<td>43.2</td>
<td></td>
</tr>
<tr>
<td>1770</td>
<td></td>
<td>73</td>
<td>73</td>
</tr>
<tr>
<td>2378</td>
<td>305</td>
<td>247</td>
<td>274.5</td>
</tr>
<tr>
<td>2382</td>
<td>850</td>
<td>731</td>
<td>765</td>
</tr>
<tr>
<td>3355</td>
<td></td>
<td></td>
<td>5</td>
</tr>
</tbody>
</table>
COLLECT

Syntax

```sql
COLLECT
```

Purpose

COLLECT is an aggregate function that takes as its argument a column of any type and creates a nested table of the input type out of the rows selected. To get accurate results from this function you must use it within a CAST function.

If `column` is itself a collection, then the output of `COLLECT` is a nested table of collections. If `column` is of a user-defined type, then `column` must have a MAP or ORDER method defined on it in order for you to use the optional DISTINCT, UNIQUE, and ORDER BY clauses.

**See Also:** `CAST` on page 7-37 and "Aggregate Functions" on page 7-10

Examples

The following example creates a nested table from the varray column of phone numbers in the sample table `oe.customers`. The nested table includes only the phone numbers of customers with an income level of L: 300,000 and above.

```sql
CREATE TYPE phone_book_t AS TABLE OF phone_list_typ;
/
SELECT CAST(COLLECT(phone_numbers) AS phone_book_t) "Income Level L Phone Book"
FROM customers
WHERE income_level = 'L: 300,000 and above';
```

```
Income Level L Phone Book
-----------------------------------------------------------------------------
PHONE_BOOK_T(PHONE_LIST_TYP('+1 414 123 4307'), PHONE_LIST_TYP('+1 608 123 4344' ), PHONE_LIST_TYP('+1 814 123 4696'), PHONE_LIST_TYP('+1 215 123 4721'), PHONE_LIST_TYP('+1 814 123 4755'), PHONE_LIST_TYP('+91 11 012 4817', '+91 11 083 4817'), PHONE_LIST_TYP('+91 172 012 4837'), PHONE_LIST_TYP('+41 31 012 3569', '+41 31 083 3569'))
```

The following example creates a nested table from the column of warehouse names in the sample table `oe.warehouses`. It uses ORDER BY to order the warehouse names.

```sql
CREATE TYPE warehouse_name_t AS TABLE OF VARCHAR2(35);
/
SELECT CAST(COLLECT(warehouse_name ORDER BY warehouse_name) AS warehouse_name_t) "Warehouses"
FROM warehouses;
```

```
Warehouses
-----------------------------------------------------------------------------
WAREHOUSE_NAME_TYP('Beijing', 'Bombay', 'Mexico City', 'New Jersey', 'San Francisco', 'Seattle, Washington', 'Southlake, Texas', 'Sydney', 'Toronto')
```
COMPOSE

Syntax

\( \text{COMPOSE}\left( \text{char} \right) \)

Purpose

COMPOSE takes as its argument a string, or an expression that resolves to a string, in any data type, and returns a Unicode string in the same character set as the input. \textit{char} can be any of the data types \texttt{CHAR}, \texttt{VARCHAR2}, \texttt{NCHAR}, \texttt{NVARCHAR2}, \texttt{CLOB}, or \texttt{NCLOB}. For example, an \( o \) code point qualified by an umlaut code point will be returned as the \( o \)-umlaut code point.

COMPOSE returns the string in NFC normal form. For a more exclusive setting, you can first call \textit{DECOMPOSE} with the \texttt{CANONICAL} setting and then \textit{COMPOSE}. This combination returns the string in NFKC normal form.

\texttt{CLOB} and \texttt{NCLOB} values are supported through implicit conversion. If \textit{char} is a character LOB value, then it is converted to a \texttt{VARCHAR} value before the \textit{COMPOSE} operation. The operation will fail if the size of the LOB value exceeds the supported length of the \texttt{VARCHAR} in the particular development environment.

See Also:

- \textit{Oracle Database Globalization Support Guide} for information on Unicode character sets and character semantics
- \textit{DECOMPOSE} on page 7-94

Examples

The following example returns the \( o \)-umlaut code point:

```sql
SELECT COMPOSE( 'o' || UNISTR('̈') )
FROM DUAL;
```

CO
--
ö

See Also: \texttt{UNISTR} on page 7-391
CON_DBID_TO_ID

Syntax

```sql
CON_DBID_TO_ID (container_dbid)
```

Purpose

`CON_DBID_TO_ID` takes as its argument a container DBID and returns the container ID. For `container_dbid`, specify a `NUMBER` value or any value that can be implicitly converted to `NUMBER`. The function returns a `NUMBER` value.

This function is useful in a multitenant container database (CDB). If you use this function in a non-CDB, then it returns 0.

Example

The following query displays the ID and DBID for all containers in a CDB. The sample output shown is for the purpose of this example.

```sql
SELECT CON_ID, DBID
FROM V$CONTAINERS;

   CON_ID   DBID
-------- --------
     1 1930093401
     2 4054529501
     4 2256797992
```

The following statement returns the ID for the container with DBID 2256797992:

```sql
SELECT CON_DBID_TO_ID(2256797992) "Container ID"
FROM DUAL;

  Container ID
----------
      4
```
**CON_GUID_TO_ID**

**Syntax**

```
CON_GUID_TO_ID(container_guid)
```

**Purpose**

CON_GUID_TO_ID takes as its argument a container GUID (globally unique identifier) and returns the container ID. For `container_guid`, specify a raw value. The function returns a `NUMBER` value.

This function is useful in a multitenant container database (CDB). If you use this function in a non-CDB, then it returns 0.

**Example**

The following query displays the ID and GUID for all containers in a CDB. The GUID is stored as a 16-byte RAW value in the `V$CONTAINERS` view. The query returns the 32-character hexadecimal representation of the GUID. The sample output shown is for the purpose of this example.

```
SELECT CON_ID, GUID
FROM V$CONTAINERS;
```

```
CON_ID GUID
---------- --------------------------------
1 DB0A9F33DF99567FE04305B4F00A667D
2 D990C280C309591EE04305B4F00A593E
4 D990F4BD938865C1E04305B4F00ACA18
```

The following statement returns the ID for the container whose GUID is represented by the hexadecimal value D990F4BD938865C1E04305B4F00ACA18. The `HEXTORAW` function converts the GUID's hexadecimal representation to a raw value.

```
SELECT CON_GUID_TO_ID(HEXTORAW('D990F4BD938865C1E04305B4F00ACA18')) "Container ID"
FROM DUAL;
```

Container ID
------------
4
CON_NAME_TO_ID

Syntax

CON_NAME_TO_ID -> container_name

Purpose

CON_NAME_TO_ID takes as its argument a container name and returns the container ID. For container_name, specify a string, or an expression that resolves to a string, in any data type. The function returns a NUMBER value.

This function is useful in a multitenant container database (CDB). If you use this function in a non-CDB, then it returns 0.

Example

The following query displays the ID and name for all containers in a CDB. The sample output shown is for the purpose of this example.

```
SELECT CON_ID, NAME
FROM V$CONTAINERS;

CON_ID  NAME
-------- --------
  1 CDB$ROOT
  2 PDB$SEED
  4 SALESPDB
```

The following statement returns the ID for the container named SALESPDB:

```
SELECT CON_NAME_TO_ID('SALESPDB') "Container ID"
FROM DUAL;

Container ID
------------
  4
```
CON_UID_TO_ID

Syntax

```sql
CON_UID_TO_ID(container_uid)
```

Purpose

`CON_UID_TO_ID` takes as its argument a container UID (unique identifier) and returns the container ID. For `container_uid`, specify a `NUMBER` value or any value that can be implicitly converted to `NUMBER`. The function returns a `NUMBER` value.

This function is useful in a multitenant container database (CDB). If you use this function in a non-CDB, then it returns 0.

Example

The following query displays the ID and UID for all containers in a CDB. The sample output shown is for the purpose of this example.

```sql
SELECT CON_ID, CON_UID
FROM V$CONTAINERS;
```

<table>
<thead>
<tr>
<th>CON_ID</th>
<th>CON_UID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>4054529501</td>
</tr>
<tr>
<td>4</td>
<td>2256797992</td>
</tr>
</tbody>
</table>

The following query returns the ID for the container with UID 2256797992:

```sql
SELECT CON_UID_TO_ID(2256797992) "Container ID"
FROM DUAL;
```

<table>
<thead>
<tr>
<th>Container ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
</tr>
</tbody>
</table>
CONCAT

Syntax

```
CONCAT(char1, char2)
```

Purpose

CONCAT returns `char1` concatenated with `char2`. Both `char1` and `char2` can be any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB. The string returned is in the same character set as `char1`. Its data type depends on the data types of the arguments.

In concatenations of two different data types, Oracle Database returns the data type that results in a lossless conversion. Therefore, if one of the arguments is a LOB, then the returned value is a LOB. If one of the arguments is a national data type, then the returned value is a national data type. For example:

- `CONCAT(CLOB, NCLOB)` returns NCLOB
- `CONCAT(NCLOB, NCHAR)` returns NCLOB
- `CONCAT(NCLOB, CHAR)` returns NCLOB
- `CONCAT(NCHAR, CLOB)` returns NCLOB

This function is equivalent to the concatenation operator (||).

See Also: "Concatenation Operator" on page 4-3 for information on the CONCAT operator

Examples

This example uses nesting to concatenate three character strings:

```
SELECT CONCAT(CONCAT(last_name, '''s job category is ''), job_id) "Job"
FROM employees
WHERE employee_id = 152;
```

```
Job
-----------------------------
Hall's job category is SA_REP
```
CONVERT

Syntax

CONVERT(char, dest_char_set, source_char_set)

Purpose

CONVERT converts a character string from one character set to another.

- The `char` argument is the value to be converted. It can be any of the data types `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, `CLOB`, or `NCLOB`.
- The `dest_char_set` argument is the name of the character set to which `char` is converted.
- The `source_char_set` argument is the name of the character set in which `char` is stored in the database. The default value is the database character set.

The return value for `CHAR` and `VARCHAR2` is `VARCHAR2`. For `NCHAR` and `NVARCHAR2`, it is `NVARCHAR2`. For `CLOB`, it is `CLOB`, and for `NCLOB`, it is `NCLOB`.

Both the destination and source character set arguments can be either literals or columns containing the name of the character set.

For complete correspondence in character conversion, it is essential that the destination character set contains a representation of all the characters defined in the source character set. Where a character does not exist in the destination character set, a replacement character appears. Replacement characters can be defined as part of a character set definition.

Note: Oracle discourages the use of the `CONVERT` function in the current Oracle Database release. The return value of `CONVERT` has a character data type, so it should be either in the database character set or in the national character set, depending on the data type. Any `dest_char_set` that is not one of these two character sets is unsupported. The `char` argument and the `source_char_set` have the same requirements. Therefore, the only practical use of the function is to correct data that has been stored in a wrong character set.

Values that are in neither the database nor the national character set should be processed and stored as `RAW` or `BLOB`. Procedures in the PL/SQL packages `UTL_RAW` and `UTL_I18N`—for example, `UTL_RAW.CONVERT`—allow limited processing of such values. Procedures accepting a `RAW` argument in the packages `UTL_FILE`, `UTL_TCP`, `UTL_HTTP`, and `UTL_SMTP` can be used to output the processed data.

Examples

The following example illustrates character set conversion by converting a Latin-1 string to ASCII. The result is the same as importing the same string from a WE8ISO8859P1 database to a US7ASCII database.

```sql
SELECT CONVERT('Ä Ê Í Õ Ø A B C D E ', 'US7ASCII', 'WE8ISO8859P1') 
FROM DUAL;

CONVERT('ÄEIØABCDe')
```
You can query the `V$NLS_VALID_VALUES` view to get a listing of valid character sets, as follows:

```
SELECT * FROM V$NLS_VALID_VALUES WHERE parameter = 'CHARACTERSET';
```

**See Also:** Oracle Database Globalization Support Guide for the list of character sets that Oracle Database supports and Oracle Database Reference for information on the `V$NLS_VALID_VALUES` view.
**CORR**

**Syntax**

```
CORR(expr1, expr2) OVER (analytic_clause)
```

**Purpose**

`CORR` returns the coefficient of correlation of a set of number pairs. You can use it as an aggregate or analytic function.

This function takes as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. Oracle determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

**See Also:** "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

**Oracle Database** applies the function to the set of \((\text{expr1}, \text{expr2})\) after eliminating the pairs for which either \(\text{expr1}\) or \(\text{expr2}\) is null. Then Oracle makes the following computation:

\[
\frac{\text{COVAR}_{\text{POP}}(\text{expr1}, \text{expr2})}{\sqrt{\text{STDDEV}_{\text{POP}}(\text{expr1}) \times \text{STDDEV}_{\text{POP}}(\text{expr2})}}
\]

The function returns a value of type `NUMBER`. If the function is applied to an empty set, then it returns `null`.

**Note:** The `CORR` function calculates the Pearson’s correlation coefficient, which requires numeric expressions as arguments. Oracle also provides the `CORR_S` (Spearman’s rho coefficient) and `CORR_K` (Kendall’s tau-b coefficient) functions to support nonparametric or rank correlation.

**See Also:** "Aggregate Functions" on page 7-10, "About SQL Expressions" on page 5-1 for information on valid forms of `expr`, and `CORR_*` on page 7-71 for information on the `CORR_S` and `CORR_K` functions

**Aggregate Example**

The following example calculates the coefficient of correlation between the list prices and minimum prices of products by weight class in the sample table `oe.product_information`:

```sql
SELECT weight_class, CORR(list_price, min_price) "Correlation"
FROM product_information
GROUP BY weight_class
ORDER BY weight_class, "Correlation";
```
Analytic Example

The following example shows the correlation between duration at the company and salary by the employee's position. The result set shows the same correlation for each employee in a given job:

```sql
SELECT employee_id, job_id, 
   TO_CHAR((SYSDATE - hire_date) YEAR TO MONTH ) "Yrs-Mns", salary, 
   CORR(SYSDATE - hire_date, salary) 
OVER(PARTITION BY job_id) AS 'Correlation' 
FROM employees 
WHERE department_id in (50, 80) 
ORDER BY job_id, employee_id;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>JOB_ID</th>
<th>Yrs-Mns</th>
<th>SALARY</th>
<th>Correlation</th>
</tr>

<td>.80436755</td>
</tr>
</tbody>
</table>

...
The CORR_* functions are:

- CORR_S
- CORR_K

**Syntax**

```
correlation ::= 
```

**Purpose**

The CORR function (see CORR on page 7-69) calculates the Pearson's correlation coefficient and requires numeric expressions as input. The CORR_* functions support nonparametric or rank correlation. They let you find correlations between expressions that are ordinal scaled (where ranking of the values is possible). Correlation coefficients take on a value ranging from -1 to 1, where 1 indicates a perfect relationship, -1 a perfect inverse relationship (when one variable increases as the other decreases), and a value close to 0 means no relationship.

These functions takes as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. Oracle Database determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, makes the calculation, and returns NUMBER.

**See Also:** Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and "Numeric Precedence" on page 2-16 for information on numeric precedence

`expr1` and `expr2` are the two variables being analyzed. The third argument is a return value of type VARCHAR2. If you omit the third argument, then the default is COEFFICIENT. The meaning of the return values is shown in the table that follows:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>COEFFICIENT</td>
<td>Coefficient of correlation</td>
</tr>
<tr>
<td>ONE_SIDED_SIG</td>
<td>Positive one-tailed significance of the correlation</td>
</tr>
<tr>
<td>ONE_SIDED_SIG_POS</td>
<td>Same as ONE_SIDED_SIG</td>
</tr>
<tr>
<td>ONE_SIDED_SIG_NEG</td>
<td>Negative one-tailed significance of the correlation</td>
</tr>
<tr>
<td>TWO_SIDED_SIG</td>
<td>Two-tailed significance of the correlation</td>
</tr>
</tbody>
</table>
CORR_S calculates the Spearman’s rho correlation coefficient. The input expressions should be a set of \((x_i, y_i)\) pairs of observations. The function first replaces each value with a rank. Each value of \(x_i\) is replaced with its rank among all the other \(x_i\)s in the sample, and each value of \(y_i\) is replaced with its rank among all the other \(y_i\)s. Thus, each \(x_i\) and \(y_i\) take on a value from 1 to \(n\), where \(n\) is the total number of pairs of values. Ties are assigned the average of the ranks they would have had if their values had been slightly different. Then the function calculates the linear correlation coefficient of the ranks.

**CORR_S Example** Using Spearman’s rho correlation coefficient, the following example derives a coefficient of correlation for each of two different comparisons -- salary and commission_pct, and salary and employee_id:

```sql
SELECT COUNT(*) count,
       CORR_S(salary, commission_pct) commission,
       CORR_S(salary, employee_id) empid
FROM employees;
```

<table>
<thead>
<tr>
<th>COUNT</th>
<th>COMMISSION</th>
<th>EMPID</th>
</tr>
</thead>
<tbody>
<tr>
<td>107</td>
<td>.735837022</td>
<td>-.04473016</td>
</tr>
</tbody>
</table>
**CORR_K**

CORR_K calculates the Kendall's tau-b correlation coefficient. As for CORR_S, the input expressions are a set of \((x_i, y_i)\) pairs of observations. To calculate the coefficient, the function counts the number of concordant and discordant pairs. A pair of observations is concordant if the observation with the larger \(x\) also has a larger value of \(y\). A pair of observations is discordant if the observation with the larger \(x\) has a smaller \(y\).

The significance of tau-b is the probability that the correlation indicated by tau-b was due to chance—a value of 0 to 1. A small value indicates a significant correlation for positive values of tau-b (or anticorrelation for negative values of tau-b).

**CORR_K Example**  Using Kendall's tau-b correlation coefficient, the following example determines whether a correlation exists between an employee's salary and commission percent:

```sql
SELECT CORR_K(salary, commission_pct, 'COEFFICIENT') coefficient,
       CORR_K(salary, commission_pct, 'TWO_SIDED_SIG') two_sided_p_value
FROM employees;
```

<table>
<thead>
<tr>
<th>COEFFICIENT</th>
<th>TWO_SIDED_P_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>.603079768</td>
<td>3.4702E-07</td>
</tr>
</tbody>
</table>
COS

Syntax

\[ \text{COS}(n) \]

Purpose

COS returns the cosine of \( n \) (an angle expressed in radians).

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If the argument is BINARY_FLOAT, then the function returns BINARY_DOUBLE. Otherwise the function returns the same numeric data type as the argument.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

Examples

The following example returns the cosine of 180 degrees:

```
SELECT COS(180 * 3.14159265359/180) "Cosine of 180 degrees"
FROM DUAL;
```

Cosine of 180 degrees
---------------------
-1
COSH

Syntax

\[
\text{COSH}(n)
\]

Purpose

COSH returns the hyperbolic cosine of \( n \).

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If the argument is BINARY_FLOAT, then the function returns BINARY_DOUBLE. Otherwise the function returns the same numeric data type as the argument.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

Examples

The following example returns the hyperbolic cosine of zero:

```
SELECT COSH(0) "Hyperbolic cosine of 0"
FROM DUAL;
```

Hyperbolic cosine of 0
----------------------
1
COUNT

Syntax

```sql
COUNT [DISTINCT] ALL expr
 OVER (analytic_clause)
```

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

COUNT returns the number of rows returned by the query. You can use it as an aggregate or analytic function.

If you specify DISTINCT, then you can specify only the `query_partition_clause` of the `analytic_clause`. The `order_by_clause` and `windowing_clause` are not allowed.

If you specify `expr`, then COUNT returns the number of rows where `expr` is not null. You can count either all rows, or only distinct values of `expr`.

If you specify the asterisk (*), then this function returns all rows, including duplicates and nulls. COUNT never returns null.

See Also: "About SQL Expressions" on page 5-1 for information on valid forms of `expr` and "Aggregate Functions" on page 7-10

Aggregate Examples

The following examples use COUNT as an aggregate function:

```sql
SELECT COUNT(*) 'Total'
 FROM employees;

Total
--------
107

SELECT COUNT(*) 'Allstars'
 FROM employees
 WHERE commission_pct > 0;

Allstars
--------
35

SELECT COUNT(commission_pct) 'Count'
 FROM employees;

Count
--------
35

SELECT COUNT(DISTINCT manager_id) 'Managers'
 FROM employees;
```
Managers
----------

18

**Analytic Example**

The following example calculates, for each employee in the `employees` table, the moving count of employees earning salaries in the range 50 less than through 150 greater than the employee's salary.

```sql
SELECT last_name, salary,
       COUNT(*) OVER (ORDER BY salary RANGE BETWEEN 50 PRECEDING AND 150 FOLLOWING) AS mov_count
FROM employees
ORDER BY salary, last_name;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>SALARY</th>
<th>MOV_COUNT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Olson</td>
<td>2100</td>
<td>3</td>
</tr>
<tr>

<td>2500</td>
<td>10</td>
</tr>
<tr>
<td>Marlow</td>
<td>2500</td>
<td>10</td>
</tr>
<tr>
<td>Patel</td>
<td>2500</td>
<td>10</td>
</tr>
<tr>
<td>. . .</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
COVAR_POP

Syntax

\[
\text{COVAR_POP} (\text{expr1}, \text{expr2}) \over \text{analytic_clause}
\]

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

COVAR_POP returns the population covariance of a set of number pairs. You can use it as an aggregate or analytic function.

This function takes as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. Oracle determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

See Also: Table 2-10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and "Numeric Precedence" on page 2-16 for information on numeric precedence

Oracle Database applies the function to the set of (expr1, expr2) pairs after eliminating all pairs for which either expr1 or expr2 is null. Then Oracle makes the following computation:

\[
\frac{\left(\text{SUM}(\text{expr1} \times \text{expr2}) - \text{SUM}(\text{expr2}) \times \text{SUM}(\text{expr1}) / n\right)}{n}
\]

where \( n \) is the number of (expr1, expr2) pairs where neither expr1 nor expr2 is null. The function returns a value of type NUMBER. If the function is applied to an empty set, then it returns null.

See Also: "About SQL Expressions" on page 5-1 for information on valid forms of expr and "Aggregate Functions" on page 7-10

Aggregate Example

The following example calculates the population covariance and sample covariance for time employed (SYSDATE - hire_date) and salary using the sample table hr.employees:

```
SELECT job_id,
    COVAR_POP(SYSDATE-hire_date, salary) AS covar_pop,
    COVAR_SAMP(SYSDATE-hire_date, salary) AS covar_samp
FROM employees
WHERE department_id in (50, 80)
GROUP BY job_id
ORDER BY job_id, covar_pop, covar_samp;
```

<table>
<thead>
<tr>
<th>JOB_ID</th>
<th>COVAR_POP</th>
<th>COVAR_SAMP</th>
</tr>
</thead>
<tbody>
<tr>

<td>223613.158</td>
</tr>
<tr>
<td>ST_CLERK</td>
<td>176577.25</td>
<td>185870.789</td>
</tr>
</tbody>
</table>
Analytic Example

The following example calculates cumulative sample covariance of the list price and minimum price of the products in the sample schema oe:

```sql
SELECT product_id, supplier_id,
    COVAR_POP(list_price, min_price)
    OVER (ORDER BY product_id, supplier_id) AS CUM_COVP,
    COVAR_SAMP(list_price, min_price)
    OVER (ORDER BY product_id, supplier_id) AS CUM_COVS
FROM product_information p
WHERE category_id = 29
ORDER BY product_id, supplier_id;
```

```
PRODUCT_ID SUPPLIER_ID   CUM_COVP   CUM_COVS
---------- ----------- ---------- ----------
1774      103088          0
1775      103087    1473.25     2946.5
1794      103096  1702.77778 2554.16667
1825      103093    1926.25 2568.33333
2004      103086     1591.4    1989.25
2005      103086     1512.5       1815
2416      103088  1475.97959 1721.97619
```

...
COVAR_SAMP

Syntax

```
COVAR_SAMP(expr1, expr2) OVER (analytic_clause)
```

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

COVAR_SAMP returns the sample covariance of a set of number pairs. You can use it as an aggregate or analytic function.

This function takes as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. Oracle determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and "Numeric Precedence" on page 2-16 for information on numeric precedence

Oracle Database applies the function to the set of (expr1, expr2) pairs after eliminating all pairs for which either expr1 or expr2 is null. Then Oracle makes the following computation:

\[
\frac{\left(\text{SUM}(\text{expr1} \times \text{expr2}) - \text{SUM}(\text{expr1}) \times \text{SUM}(\text{expr2}) / n\right)}{n-1}
\]

where \(n\) is the number of (expr1, expr2) pairs where neither expr1 nor expr2 is null.

The function returns a value of type NUMBER. If the function is applied to an empty set, then it returns null.

See Also: "About SQL Expressions" on page 5-1 for information on valid forms of expr and "Aggregate Functions" on page 7-10

Aggregate Example

Refer to the aggregate example for COVAR_POP on page 7-78.

Analytic Example

Refer to the analytic example for COVAR_POP on page 7-78.
CUBE_TABLE

Syntax

```
CUBE_TABLE(
  'schema.cube'
)
```

Purpose

CUBE_TABLE extracts data from a cube or dimension and returns it in the two-dimensional format of a relational table, which can be used by SQL-based applications.

The function takes a single VARCHAR2 argument. The optional hierarchy clause enables you to specify a dimension hierarchy. A cube can have multiple hierarchy clauses, one for each dimension.

You can generate these different types of tables:

- A cube table contains a key column for each dimension and a column for each measure and calculated measure in the cube. To create a cube table, you can specify the cube with or without a cube hierarchy clause. For a dimension with multiple hierarchies, this clause limits the return values to the dimension members and levels in the specified hierarchy. Without a hierarchy clause, all dimension members and all levels are included.

- A dimension table contains a key column, and a column for each level and each attribute. It also contains a MEMBER_TYPE column, which identifies each member with one of the following codes:
  - **L** - Loaded from a table, view, or synonym
  - **A** - Loaded member and the single root of all hierarchies in the dimension, that is, the "all" aggregate member
  - **C** - Calculated member

  All dimension members and all levels are included in the table. To create a dimension table, specify the dimension without a dimension hierarchy clause.

- A hierarchy table contains all the columns of a dimension table plus a column for the parent member and a column for each source level. It also contains a MEMBER_TYPE column, as described for dimension tables. Any dimension members and levels that are not part of the named hierarchy are excluded from the table. To create a hierarchy table, specify the dimension with a dimension hierarchy clause.

CUBE_TABLE is a table function and is always used in the context of a SELECT statement with this syntax:

```
SELECT ... FROM TABLE(CUBE_TABLE('arg'));
```
See Also: Oracle OLAP User’s Guide for information about dimensional objects and about the tables generated by CUBE_TABLE.

Examples
The following examples require Oracle Database with the OLAP option and the GLOBAL sample schema. Refer to Oracle OLAP User’s Guide for information on downloading and installing the GLOBAL sample schema.

The following SELECT statement generates a dimension table of CHANNEL in the GLOBAL schema.

```
SELECT dim_key, level_name, long_description, channel_total_id as tot_id,
       channel_channel_id as chan_id, channel_long_description as chan_desc,
       total_long_description as tot_desc
FROM TABLE(CUBE_TABLE('global.channel'));
```

```
DIM_KEY          LEVEL_NAME   LONG_DESCRIPTION  TOT_ID  CHAN_ID     CHAN_DESC     TOT_DESC
---------------- ---------- ------------------- ------ ----------- -------------- 
CHANNEL_CAT       CHANNEL      Catalog            TOTAL  CAT        Catalog       Total Channel  
CHANNEL_DIR       CHANNEL      Direct Sales       TOTAL  DIR        Direct Sales Total Channel 
CHANNEL_INT       CHANNEL      Internet           TOTAL  INT        Internet      Total Channel  
TOTAL_TOTAL       TOTAL        Total Channel       TOTAL                      Total Channel 
```

The next statement generates a cube table of UNITS_CUBE. It restricts the table to the MARKET and CALENDAR hierarchies.

```
SELECT sales, units, cost, time, customer, product, channel
FROM TABLE(CUBE_TABLE('global.units_cube HIERARCHY customer market HIERARCHY time calendar'))
WHERE rownum < 20;
```

```
SALES          UNITS        COST        TIME                       CUSTOMER       PRODUCT     CHANNEL
--------------- ---------- ---------- -------------------------- -------------- -----------

...
CUME_DIST

Aggregate Syntax

cume_dist_aggregate::=

Analytic Syntax

cume_dist_analytic::=

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

CUME_DIST calculates the cumulative distribution of a value in a group of values. The range of values returned by CUME_DIST is >0 to <=1. Tie values always evaluate to the same cumulative distribution value.

This function takes as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. Oracle Database determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, makes the calculation, and returns NUMBER.

See Also: Table 2–10,"Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and "Numeric Precedence" on page 2-16 for information on numeric precedence

- As an aggregate function, CUME_DIST calculates, for a hypothetical row r identified by the arguments of the function and a corresponding sort specification, the relative position of row r among the rows in the aggregation group. Oracle makes this calculation as if the hypothetical row r were inserted into the group of rows to be aggregated over. The arguments of the function identify a single hypothetical row within each aggregate group. Therefore, they must all evaluate to constant expressions within each aggregate group. The constant argument expressions and the expressions in the ORDER BY clause of the aggregate match by position. Therefore, the number of arguments must be the same and their types must be compatible.

- As an analytic function, CUME_DIST computes the relative position of a specified value in a group of values. For a row r, assuming ascending ordering, the CUME_
DIST of \( r \) is the number of rows with values lower than or equal to the value of \( r \), divided by the number of rows being evaluated (the entire query result set or a partition).

**Aggregate Example**
The following example calculates the cumulative distribution of a hypothetical employee with a salary of $15,500 and commission rate of 5% among the employees in the sample table `oe.employees`:

```sql
SELECT CUME_DIST(15500, .05) WITHIN GROUP
  (ORDER BY salary, commission_pct) "Cume-Dist of 15500"
FROM employees;
```

Cume-Dist of 15500
--------------------
       .972222222

**Analytic Example**
The following example calculates the salary percentile for each employee in the purchasing division. For example, 40% of clerks have salaries less than or equal to Himuro.

```sql
SELECT job_id, last_name, salary, CUME_DIST() 
  OVER (PARTITION BY job_id ORDER BY salary) AS cume_dist 
FROM employees 
WHERE job_id LIKE 'PU%'
ORDER BY job_id, last_name, salary, cume_dist;
```

<table>
<thead>
<tr>
<th>JOB_ID</th>
<th>LAST_NAME</th>
<th>SALARY</th>
<th>CUME_DIST</th>
</tr>
</thead>
<tbody>
<tr>
<td>PU_CLERK</td>
<td>Baida</td>
<td>2900</td>

<td>1</td>
</tr>
</tbody>
</table>
CURRENT_DATE

Syntax

CURRENT_DATE

Purpose

CURRENT_DATE returns the current date in the session time zone, in a value in the
Gregorian calendar of data type DATE.

Examples

The following example illustrates that CURRENT_DATE is sensitive to the session time
zone:

ALTER SESSION SET TIME_ZONE = '-5:0';
ALTER SESSION SET NLS_DATE_FORMAT = 'DD-MON-YYYY HH24:MI:SS';
SELECT SESSIONTIMEZONE, CURRENT_DATE FROM DUAL;

SESSIONTIMEZONE CURRENT_DATE
--------------- --------------------
-05:00          29-MAY-2000 13:14:03

ALTER SESSION SET TIME_ZONE = '-8:0';
SELECT SESSIONTIMEZONE, CURRENT_DATE FROM DUAL;

SESSIONTIMEZONE CURRENT_DATE
--------------- --------------------
-08:00          29-MAY-2000 10:14:33
**CURRENT_TIMESTAMP**

**Syntax**

```
CURRENT_TIMESTAMP
```

**Purpose**

`CURRENT_TIMESTAMP` returns the current date and time in the session time zone, in a value of data type `TIMESTAMP WITH TIME ZONE`. The time zone offset reflects the current local time of the SQL session. If you omit precision, then the default is 6. The difference between this function and `LOCALTIMESTAMP` is that `CURRENT_TIMESTAMP` returns a `TIMESTAMP WITH TIME ZONE` value while `LOCALTIMESTAMP` returns a `TIMESTAMP` value.

In the optional argument, `precision` specifies the fractional second precision of the time value returned.

**Examples**

The following example illustrates that `CURRENT_TIMESTAMP` is sensitive to the session time zone:

```
ALTER SESSION SET TIME_ZONE = '-5:0';
ALTER SESSION SET NLS_DATE_FORMAT = 'DD-MON-YYYY HH24:MI:SS';
SELECT SESSIONTIMEZONE, CURRENT_TIMESTAMP FROM DUAL;
```

<table>
<thead>
<tr>
<th>SESSIONTIMEZONE</th>
<th>CURRENT_TIMESTAMP</th>
</tr>
</thead>
<tbody>
<tr>
<td>-05:00</td>
<td>04-APR-00 01.17.56.917550 PM -05:00</td>
</tr>
</tbody>
</table>

```
ALTER SESSION SET TIME_ZONE = '-8:0';
SELECT SESSIONTIMEZONE, CURRENT_TIMESTAMP FROM DUAL;
```

<table>
<thead>
<tr>
<th>SESSIONTIMEZONE</th>
<th>CURRENT_TIMESTAMP</th>
</tr>
</thead>
<tbody>
<tr>
<td>-08:00</td>
<td>04-APR-00 10.18.21.366065 AM -08:00</td>
</tr>
</tbody>
</table>

When you use the `CURRENT_TIMESTAMP` with a format mask, take care that the format mask matches the value returned by the function. For example, consider the following table:

```
CREATE TABLE current_test (col1 TIMESTAMP WITH TIME ZONE);
```

The following statement fails because the mask does not include the `TIME ZONE` portion of the type returned by the function:

```
INSERT INTO current_test VALUES
  (TO_TIMESTAMP_TZ(CURRENT_TIMESTAMP, 'DD-MON-RR HH.MI.SSXFF PM'));
```

The following statement uses the correct format mask to match the return type of `CURRENT_TIMESTAMP`:

```
INSERT INTO current_test VALUES
  (TO_TIMESTAMP_TZ(CURRENT_TIMESTAMP, 'DD-MON-RR HH.MI.SSXFF PM TZH:TZM'));
```
CV

Syntax

```
CV[dimension_column]
```

Purpose

The CV function can be used only in the `model_clause` of a SELECT statement and then only on the right-hand side of a model rule. It returns the current value of a dimension column or a partitioning column carried from the left-hand side to the right-hand side of a rule. This function is used in the `model_clause` to provide relative indexing with respect to the dimension column. The return type is that of the data type of the dimension column. If you omit the argument, then it defaults to the dimension column associated with the relative position of the function within the cell reference.

The CV function can be used outside a cell reference. In this case, `dimension_column` is required.

See Also: `model_clause` on page 19-35 and "Model Expressions" on page 5-13 for the syntax and semantics

Examples

The following example assigns the sum of the sales of the product represented by the current value of the dimension column (Mouse Pad or Standard Mouse) for years 1999 and 2000 to the sales of that product for year 2001:

```sql
SELECT country, prod, year, s
FROM sales_view_ref
MODEL
  PARTITION BY {country}
  DIMENSION BY {prod, year}
  MEASURES {sale s}
  IGNORE NAV
  UNIQUE DIMENSION
  RULES UPSERT? SEQUENTIAL ORDER
  {
    s[FOR prod IN ('Mouse Pad', 'Standard Mouse'), 2001] = 
    s[CV( ), 1999] + s[CV( ), 2000]
  }
ORDER BY country, prod, year;
```

<table>
<thead>
<tr>
<th>COUNTRY</th>
<th>PROD</th>
<th>YEAR</th>

16 rows selected.

The preceding example requires the view `sales_view_ref`. Refer to "The MODEL clause: Examples" on page 19-63 to create this view.
DATAOBJ_TO_MAT_PARTITION

Syntax

```
DATAOBJ_TO_MAT_PARTITION (table, partition_id)
```

Purpose

DATAOBJ_TO_MAT_PARTITION is useful only to Data Cartridge developers who are performing data maintenance or query operations on system-partitioned tables that are used to store domain index data. The DML or query operations are triggered by corresponding operations on the base table of the domain index.

This function takes as arguments the name of the base table and the partition ID of the base table partition, both of which are passed to the function by the appropriate ODCIIndex method. The function returns the materialized partition number of the corresponding system-partitioned table, which can be used to perform the operation (DML or query) on that partition of the system-partitioned table.

If the base table is interval partitioned, then Oracle recommends that you use this function instead of the DATAOBJ_TO_PARTITION function. The DATAOBJ_TO_PARTITION function determines the absolute partition number, given the physical partition identifier. However, if the base table is interval partitioned, then there might be holes in the partition numbers corresponding to unmaterialized partitions. Because the system partitioned table only has materialized partitions, DATAOBJ_TO_PARTITION numbers can cause a mis-match between the partitions of the base table and the partitions of the underlying system partitioned index storage tables. The DATAOBJ_TO_MAT_PARTITION function returns the materialized partition number (as opposed to the absolute partition number) and helps keep the two tables in sync. Index types planning to support local domain indexes on interval partitioned tables should migrate to the use of this function.

See Also:

- **DATAOBJ_TO_PARTITION** on page 7-90
- Oracle Database Data Cartridge Developer’s Guide for information on the use of the DATAOBJ_TO_MAT_PARTITION function, including examples
DATAOBJ_TO_PARTITION

Syntax

```
DATAOBJ_TO_PARTITION (table, partition_id)
```

Purpose

DATAOBJ_TO_PARTITION is useful only to Data Cartridge developers who are performing data maintenance or query operations on system-partitioned tables that are used to store domain index data. The DML or query operations are triggered by corresponding operations on the base table of the domain index.

This function takes as arguments the name of the base table and the partition ID of the base table partition, both of which are passed to the function by the appropriate ODCIIndex method. The function returns the absolute partition number of the corresponding system-partitioned table, which can be used to perform the operation (DML or query) on that partition of the system-partitioned table.

**Note:** If the base table is interval partitioned, then Oracle recommends that you instead use the DATAOBJ_TO_MAT_PARTITION function. Refer to DATAOBJ_TO_MAT_PARTITION on page 7-89 for more information.

**See Also:** Oracle Database Data Cartridge Developer’s Guide for information on the use of the DATAOBJ_TO_PARTITION function, including examples
DBTIMEZONE

Syntax

```sql
DBTIMEZONE
```

Purpose

`DBTIMEZONE` returns the value of the database time zone. The return type is a time zone offset (a character type in the format `'[+|-]TZH:TZM'`) or a time zone region name, depending on how the user specified the database time zone value in the most recent `CREATE DATABASE` or `ALTER DATABASE` statement.

Examples

The following example assumes that the database time zone is set to UTC time zone:

```sql
SELECT DBTIMEZONE
FROM DUAL;
```

```
DBTIME
-----
+00:00
```
**DECODE**

**Syntax**

```
DECODE(expr, search, result, default)
```

**Purpose**

DECODE compares `expr` to each `search` value one by one. If `expr` is equal to a `search`, then Oracle Database returns the corresponding `result`. If no match is found, then Oracle returns `default`. If `default` is omitted, then Oracle returns null.

The arguments can be any of the numeric types (`NUMBER`, `BINARY_FLOAT`, or `BINARY_DOUBLE`) or character types.

- If `expr` and `search` are character data, then Oracle compares them using nonpadded comparison semantics. `expr`, `search`, and `result` can be any of the data types `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2`. The string returned is of `VARCHAR2` data type and is in the same character set as the first `result` parameter.

- If the first `search-result` pair are numeric, then Oracle compares all `search-result` expressions and the first `expr` to determine the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

The `search`, `result`, and `default` values can be derived from expressions. Oracle Database uses **short-circuit evaluation**. The database evaluates each `search` value only before comparing it to `expr`, rather than evaluating all `search` values before comparing any of them with `expr`. Consequently, Oracle never evaluates a `search` if a previous `search` is equal to `expr`.

Oracle automatically converts `expr` and each `search` value to the data type of the first `search` value before comparing. Oracle automatically converts the return value to the same data type as the first `result`. If the first `result` has the data type `CHAR` or if the first `result` is null, then Oracle converts the return value to the data type `VARCHAR2`.

In a `DECODE` function, Oracle considers two nulls to be equivalent. If `expr` is null, then Oracle returns the `result` of the first `search` that is also null.

The maximum number of components in the `DECODE` function, including `expr`, `searches`, `results`, and `default`, is 255.

**See Also:**

- "Data Type Comparison Rules" on page 2-39 for information on comparison semantics
- "Data Conversion" on page 2-43 for information on data type conversion in general
- "Floating-Point Numbers" on page 2-15 for information on floating-point comparison semantics
- "Implicit and Explicit Data Conversion" on page 2-43 for information on the drawbacks of implicit conversion
- "COALESCE" on page 7-58 and "CASE Expressions" on page 5-5, which provide functionality similar to that of `DECODE`
Examples

This example decodes the value warehouse_id. If warehouse_id is 1, then the function returns 'Southlake'; if warehouse_id is 2, then it returns 'San Francisco'; and so forth. If warehouse_id is not 1, 2, 3, or 4, then the function returns 'Non domestic'.

```
SELECT product_id,
    DECODE (warehouse_id, 1, 'Southlake',
        2, 'San Francisco',
        3, 'New Jersey',
        4, 'Seattle',
        'Non domestic') "Location"
FROM inventories
WHERE product_id < 1775
ORDER BY product_id, "Location";
```
DECOMPOSE

Syntax

```
DECOMPOSE (string, 'CANONICAL' | 'COMPATIBILITY')
```

Purpose

DECOMPOSE is valid only for Unicode characters. DECOMPOSE takes as its argument a string in any data type and returns a Unicode string after decomposition in the same character set as the input. For example, an o-umlaut code point will be returned as the “o” code point followed by an umlaut code point.

- `string` can be any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB.
- `CANONICAL` causes canonical decomposition, which allows recomposition (for example, with the COMPOSE function) to the original string. This is the default and returns the string in NFD normal form.
- `COMPATIBILITY` causes decomposition in compatibility mode. In this mode, recomposition is not possible. This mode is useful, for example, when decomposing half-width and full-width katakana characters, where recomposition might not be desirable without external formatting or style information. It returns the string in NFKD normal form.

CLOB and NCLOB values are supported through implicit conversion. If `char` is a character LOB value, then it is converted to a VARCHAR value before the COMPOSE operation. The operation will fail if the size of the LOB value exceeds the supported length of the VARCHAR in the particular development environment.

See Also:

- Oracle Database Globalization Support Guide for information on Unicode character sets and character semantics
- COMPOSE on page 7-61

Examples

The following example decomposes the string "Châteaux" into its component code points:

```
SELECT DECOMPOSE ('Châteaux')
FROM DUAL;
```

```
DECOMPOSE
---------
Cha^teaux
```

Note: The results of this example can vary depending on the character set of your operating system.
**DELETEXML**

**Note:** The DELETEXML function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use XQuery Update instead. See Oracle XML DB Developer’s Guide for more information.

**Syntax**

```
DELETEXML( XMLType_instance, XPath_string, namespace_string )
```

**Purpose**

DELETEXML deletes the node or nodes matched by the XPath expression in the target XML.

- `XMLType_instance` is an instance of `XMLType`.
- `XPath_string` is an XPath expression indicating one or more nodes that are to be deleted. You can specify an absolute `XPath_string` with an initial slash or a relative `XPath_string` by omitting the initial slash. If you omit the initial slash, then the context of the relative path defaults to the root node. Any child nodes of the nodes specified by `XPath_string` are also deleted.
- The optional `namespace_string` provides namespace information for the `XPath_string`. This parameter must be of type VARCHAR2.

**See Also:** Oracle XML DB Developer’s Guide for more information about this function

**Examples**

The following example removes the `/Owner` node from the `warehouse_spec` of one of the warehouses modified in the example for APPENDCHILDXML on page 7-22:

```
UPDATE warehouses
  SET warehouse_spec = DELETEXML(warehouse_spec, '/Warehouse/Building/Owner')
WHERE warehouse_id = 2;

SELECT warehouse_id, warehouse_spec
FROM warehouses
WHERE warehouse_id in (2,3);
```

```
  ID WAREHOUSE_SPEC
  ---------- -----------------------------------
   2 <?xml version="1.0"?>
      <Warehouse>
        <Building>Rented</Building>
        <Area>50000</Area>
        <Docks>1</Docks>
        <DockType>Side load</DockType>
        <WaterAccess>Y</WaterAccess>
        <RailAccess>N</RailAccess>
        <Parking>Lot</Parking>
        <VClearance>12 ft</VClearance>
```

Note: The `DELETEXML` function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use XQuery Update instead. See Oracle XML DB Developer’s Guide for more information.
DENSE_RANK

Aggregate Syntax

dense_rank_aggregate ::= 

Analytic Syntax

dense_rank_analytic ::= 

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

DENSE_RANK computes the rank of a row in an ordered group of rows and returns the rank as a NUMBER. The ranks are consecutive integers beginning with 1. The largest rank value is the number of unique values returned by the query. Rank values are not skipped in the event of ties. Rows with equal values for the ranking criteria receive the same rank. This function is useful for top-N and bottom-N reporting.

This function accepts as arguments any numeric data type and returns NUMBER.

As an aggregate function, DENSE_RANK calculates the dense rank of a hypothetical row identified by the arguments of the function with respect to a given sort specification. The arguments of the function must all evaluate to constant expressions within each aggregate group, because they identify a single row within each group. The constant argument expressions and the expressions in the order_by_clause of the aggregate match by position. Therefore, the number of arguments must be the same and types must be compatible.

As an analytic function, DENSE_RANK computes the rank of each row returned from a query with respect to the other rows, based on the values of the value_exprs in the order_by_clause.

Aggregate Example

The following example computes the ranking of a hypothetical employee with the salary $15,500 and a commission of 5% in the sample table oe.employees:

```
SELECT DENSE_RANK(15500, .05) WITHIN GROUP
  (ORDER BY salary DESC, commission_pct) "Dense Rank"
FROM employees;
```
Dense Rank
---------
3

Analytic Example

The following statement ranks the employees in the sample hr schema in department 60 based on their salaries. Identical salary values receive the same rank. However, no rank values are skipped. Compare this example with the analytic example for RANK on page 7-262.

```
SELECT department_id, last_name, salary,
       DENSE_RANK() OVER (PARTITION BY department_id ORDER BY salary) DENSE_RANK
FROM employees WHERE department_id = 60
ORDER BY DENSE_RANK, last_name;
```

```
DEPARTMENT_ID LAST_NAME   SALARY DENSE_RANK
------------- ------------------------ ---------- ----------
       60  Lorentz         4200          1
       60    Austin        4800          2
       60 Pataballa       4800          2
       60    Ernst         6000          3
       60   Hunold         9000          4
```
DEPTH

Syntax

```
DEPTH(correlation_integer)
```

Purpose

DEPTH is an ancillary function used only with the UNDER_PATH and EQUALS_PATH conditions. It returns the number of levels in the path specified by the UNDER_PATH condition with the same correlation variable.

The `correlation_integer` can be any NUMBER integer. Use it to correlate this ancillary function with its primary condition if the statement contains multiple primary conditions. Values less than 1 are treated as 1.

See Also: EQUALS_PATH Condition on page 6-19, UNDER_PATH Condition on page 6-20, and the related function PATH on page 7-225

Examples

The EQUALS_PATH and UNDER_PATH conditions can take two ancillary functions, DEPTH and PATH. The following example shows the use of both ancillary functions. The example assumes the existence of the XMLSchema `warehouses.xsd` (created in "Using XML in SQL Statements" on page F-8).

```sql
SELECT PATH(1), DEPTH(2)
FROM RESOURCE_VIEW
WHERE UNDER_PATH(res, '/sys/schemas/OE', 1)=1
  AND UNDER_PATH(res, '/sys/schemas/OE', 2)=1;
```

<table>
<thead>
<tr>
<th>PATH(1)</th>
<th>DEPTH(2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>. .</td>
<td>. .</td>
</tr>
<tr>
<td><a href="http://www.example.com">www.example.com</a></td>
<td>1</td>
</tr>
<tr>
<td><a href="http://www.example.com/warehouses.xsd">www.example.com/warehouses.xsd</a></td>
<td>2</td>
</tr>
<tr>
<td>. .</td>
<td>. .</td>
</tr>
</tbody>
</table>
DEREF

Syntax

\[ \text{DEREF}(\text{expr}) \]

Purpose

DEREF returns the object reference of argument \( \text{expr} \), where \( \text{expr} \) must return a REF to an object. If you do not use this function in a query, then Oracle Database returns the object ID of the REF instead, as shown in the example that follows.

See Also: MAKE_REF on page 7-189

Examples

The sample schema oe contains an object type cust_address_typ. The "REF Constraint Examples" on page 8-25 create a similar type, cust_address_typ_new, and a table with one column that is a REF to the type. The following example shows how to insert into such a column and how to use DEREF to extract information from the column:

```sql
INSERT INTO address_table VALUES
    ('1 First', 'G45 EU8', 'Paris', 'CA', 'US');

INSERT INTO customer_addresses
    SELECT 999, REF(a) FROM address_table a;

SELECT address
FROM customer_addresses
ORDER BY address;

ADDRESS
--------------------------------------------------------------------------------
000022020876B2245DBE325C5FE03400400B40DCB176E2245DBE305C5FE03400400B40DCB1

SELECT DEREF(address)
FROM customer_addresses;

DEREF(ADDRESS)(STREET_ADDRESS, POSTAL_CODE, CITY, STATE_PROVINCE, COUNTRY_ID)
--------------------------------------------------------------------------------
CUST_ADDRESS_TYP_NEW('1 First', 'G45 EU8', 'Paris', 'CA', 'US')
```
**DUMP**

**Syntax**

```
DUMP(expr, return_fmt, start_position, length)
```

**Purpose**

`DUMP` returns a VARCHAR2 value containing the data type code, length in bytes, and internal representation of `expr`. The returned result is always in the database character set. For the data type corresponding to each code, see Table 2–1, "Built-in Data Type Summary" on page 2-6.

The argument `return_fmt` specifies the format of the return value and can have any of the following values:

- 8 returns result in octal notation.
- 10 returns result in decimal notation.
- 16 returns result in hexadecimal notation.
- 17 returns each byte printed as a character if and only if it can be interpreted as a printable character in the character set of the compiler—typically ASCII or EBCDIC. Some ASCII control characters may be printed in the form ^X as well. Otherwise the character is printed in hexadecimal notation. All NLS parameters are ignored. Do not depend on any particular output format for `DUMP` with `return_fmt` 17.

By default, the return value contains no character set information. To retrieve the character set name of `expr`, add 1000 to any of the preceding format values. For example, a `return_fmt` of 1008 returns the result in octal and provides the character set name of `expr`.

The arguments `start_position` and `length` combine to determine which portion of the internal representation to return. The default is to return the entire internal representation in decimal notation.

If `expr` is null, then this function returns `NULL`.

This function does not support CLOB data directly. However, CLOBs can be passed in as arguments through implicit data conversion.

**Examples**

The following examples show how to extract dump information from a string expression and a column:

```
SELECT DUMP('abc', 1016)
FROM DUAL;
```

```
DUMP('ABC', 1016)
```

```
Typ=96 Len=3 CharacterSet=WE8DEC: 61,62,63
```

**See Also:** "Data Type Comparison Rules" on page 2-39 for more information
SELECT DUMP(last_name, 8, 3, 2) 'OCTAL'
  FROM employees
  WHERE last_name = 'Hunold'
  ORDER BY employee_id;

OCTAL
------------------------------------------------------------
Typ=1 Len=6: 156,157

SELECT DUMP(last_name, 10, 3, 2) 'ASCII'
  FROM employees
  WHERE last_name = 'Hunold'
  ORDER BY employee_id;

ASCII
-----------------------------------------------
Typ=1 Len=6: 110,111
EMTPY_BLOB, EMPTY_CLOB

Syntax

\[
\text{emptyLOB} ::= \\
\begin{cases}
\text{EMPTY_BLOB} \\
\text{EMPTY_CLOB}
\end{cases}
\]

Purpose

\text{EMPTY_BLOB} and \text{EMPTY_CLOB} return an empty LOB locator that can be used to initialize a LOB variable or, in an INSERT or UPDATE statement, to initialize a LOB column or attribute to \text{EMPTY}. \text{EMPTY} means that the LOB is initialized, but not populated with data.

Note: An empty LOB is not the same as a null LOB, and an empty CLOB is not the same as a LOB containing a string of 0 length. For more information, see Oracle Database SecureFiles and Large Objects Developer's Guide.

Restriction on LOB Locators You cannot use the locator returned from this function as a parameter to the \text{DBMS_LOB} package or the OCI.

Examples

The following example initializes the \text{ad_photo} column of the sample \text{pm.print_media} table to \text{EMPTY}:

```
UPDATE print_media
SET ad_photo = EMPTY_BLOB();
```
**EXISTSNODE**

*Note:* The `EXISTSNODE` function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use the `XMLEXISTS` function instead. See `XMLEXISTS` on page 7-419 for more information.

### Syntax

```
EXISTSNODE( XMLType_instance, XPath_string, namespace_string )
```

### Purpose

`EXISTSNODE` determines whether traversal of an XML document using a specified path results in any nodes. It takes as arguments the `XMLType` instance containing an XML document and a `VARCHAR2` XPath string designating a path. The optional `namespace_string` must resolve to a `VARCHAR2` value that specifies a default mapping or namespace mapping for prefixes, which Oracle Database uses when evaluating the XPath expression(s).

The `namespace_string` argument defaults to the namespace of the root element. If you refer to any subelement in `XPath_string`, then you must specify `namespace_string`, and you must specify the "who" prefix in both of these arguments.

**See Also:** "Using XML in SQL Statements" on page F-8 for examples that specify `namespace_string` and use the "who" prefix.

The return value is `NUMBER`:

- 0 if no nodes remain after applying the XPath traversal on the document
- 1 if any nodes remain

### Examples

The following example tests for the existence of the `/Warehouse/Dock` node in the XML path of the `warehouse_spec` column of the sample table `oe.warehouses`:

```sql
SELECT warehouse_id, warehouse_name
FROM warehouses
WHERE EXISTSNODE(warehouse_spec, '/Warehouse/Docks') = 1
ORDER BY warehouse_id;
```

<table>
<thead>
<tr>
<th>WAREHOUSE_ID</th>
<th>WAREHOUSE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Southlake, Texas</td>
</tr>
<tr>
<td>2</td>
<td>San Francisco</td>
</tr>
<tr>
<td>4</td>
<td>Seattle, Washington</td>
</tr>
</tbody>
</table>
**EXP**

**Syntax**

\[ \text{EXP}(n) \]

**Purpose**

`EXP` returns \( e \) raised to the \( n \)th power, where \( e = 2.71828183... \). The function returns a value of the same type as the argument.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If the argument is `BINARY_FLOAT`, then the function returns `BINARY_DOUBLE`. Otherwise the function returns the same numeric data type as the argument.

**See Also:** Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

**Examples**

The following example returns \( e \) to the 4th power:

```
SELECT EXP(4) "e to the 4th power"
FROM DUAL;
```

```
e to the 4th power
------------------
54.59815
```

\[ \text{SELECT } \text{EXP}(4) \text{ " } e \text{ to the } 4th \text{ power" } \text{FROM DUAL; } \]
**EXTRACT (datetime)**

**Syntax**

```
extract_datetime ::=  
```

**Purpose**

EXTRACT extracts and returns the value of a specified datetime field from a datetime or interval expression. The `expr` can be any expression that evaluates to a datetime or interval data type compatible with the requested field:

- If `YEAR` or `MONTH` is requested, then `expr` must evaluate to an expression of data type `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `TIMESTAMP WITH LOCAL TIME ZONE`, or `INTERVAL YEAR TO MONTH`.

- If `DAY` is requested, then `expr` must evaluate to an expression of data type `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `TIMESTAMP WITH LOCAL TIME ZONE`, or `INTERVAL DAY TO SECOND`.

- If `HOUR`, `MINUTE`, or `SECOND` is requested, then `expr` must evaluate to an expression of data type `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `TIMESTAMP WITH LOCAL TIME ZONE`, or `INTERVAL DAY TO SECOND`. `DATE` is not valid here, because Oracle Database treats it as ANSI `DATE` data type, which has no time fields.

- If `TIMEZONE_HOUR`, `TIMEZONE_MINUTE`, `TIMEZONE_ABBR`, `TIMEZONE_REGION`, or `TIMEZONE_OFFSET` is requested, then `expr` must evaluate to an expression of data type `TIMESTAMP WITH TIME ZONE` or `TIMESTAMP WITH LOCAL TIME ZONE`.

EXTRACT interprets `expr` as an ANSI datetime data type. For example, EXTRACT treats `DATE` not as legacy Oracle `DATE` but as ANSI `DATE`, without time elements. Therefore, you can extract only `YEAR`, `MONTH`, and `DAY` from a `DATE` value. Likewise, you can extract `TIMEZONE_HOUR` and `TIMEZONE_MINUTE` only from the `TIMESTAMP WITH TIME ZONE data type`.

When you specify `TIMEZONE_REGION` or `TIMEZONE_ABBR` (abbreviation), the value returned is a VARCHAR2 string containing the appropriate time zone region name or abbreviation. When you specify any of the other datetime fields, the value returned is an integer value of `NUMBER` data type representing the datetime value in the Gregorian calendar. When extracting from a datetime with a time zone value, the value returned...
is in UTC. For a listing of time zone region names and their corresponding abbreviations, query the V$TIMEZONE_NAMES dynamic performance view.

This function can be very useful for manipulating datetime field values in very large tables, as shown in the first example below.

---

**Note:** Time zone region names are needed by the daylight saving feature. These names are stored in two types of time zone files: one large and one small. One of these files is the default file, depending on your environment and the release of Oracle Database you are using. For more information regarding time zone files and names, see *Oracle Database Globalization Support Guide*.

---

Some combinations of datetime field and datetime or interval value expression result in ambiguity. In these cases, Oracle Database returns `UNKNOWN` (see the examples that follow for additional information).

**See Also:**

- Oracle Database Globalization Support Guide for a complete listing of the time zone region names in both files
- "Datetime/Interval Arithmetic" on page 2-22 for a description of `datetime_value_expr` and `interval_value_expr`
- Oracle Database Reference for information on the dynamic performance views

**Examples**

The following example returns from the oe.orders table the number of orders placed in each month:

```sql
SELECT EXTRACT(month FROM order_date) "Month", COUNT(order_date) "No. of Orders"
FROM orders
GROUP BY EXTRACT(month FROM order_date)
ORDER BY "No. of Orders" DESC, "Month";
```

<table>
<thead>
<tr>
<th>Month</th>
<th>No. of Orders</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>15</td>
</tr>
<tr>
<td>6</td>
<td>14</td>
</tr>
<tr>
<td>7</td>
<td>14</td>
</tr>
<tr>
<td>3</td>
<td>11</td>
</tr>
<tr>
<td>5</td>
<td>10</td>
</tr>
<tr>
<td>2</td>
<td>9</td>
</tr>
<tr>
<td>9</td>
<td>9</td>
</tr>
<tr>
<td>8</td>
<td>7</td>
</tr>
<tr>
<td>10</td>
<td>6</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
</tr>
<tr>
<td>12</td>
<td>4</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
</tr>
</tbody>
</table>

12 rows selected.

The following example returns the year 1998.

```sql
SELECT EXTRACT(YEAR FROM '1998-03-07')
FROM DUAL;
```
The following example selects from the sample table hr.employees all employees who were hired after 2007:

```
SELECT last_name, employee_id, hire_date
FROM employees
WHERE EXTRACT(YEAR FROM TO_DATE(hire_date, 'DD-MON-RR')) > 2007
ORDER BY hire_date;
```

```
LAST_NAME  EMPLOYEE_ID HIRE_DATE
---------  ---------  --------
Johnson  179 04-JAN-08
Grant  199 13-JAN-08
Marvins  164 24-JAN-08
...  
```

The following example results in ambiguity, so Oracle returns UNKNOW:

```
SELECT EXTRACT(TIMEZONE_REGION FROM TIMESTAMP '1999-01-01 10:00:00 -08:00')
FROM DUAL;
```

```
EXTRACT(TIMEZONE_REGION FROM TIMESTAMP '1999-01-01 10:00:00 -08:00')
----------------------------------
UNKNOWN
```

The ambiguity arises because the time zone numerical offset is provided in the expression, and that numerical offset may map to more than one time zone region name.
EXTRACT (XML)

Note: The EXTRACT (XML) function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use the XMLQUERY function instead. See XMLQUERY on page 7-425 for more information.

Syntax

extract_xml::=

```
EXTRACT (XMLType_instance, XPath_string, namespace_string)
```

Purpose

EXTRACT (XML) is similar to the EXISTSNODE function. It applies a VARCHAR2 XPath string and returns an XMLType instance containing an XML fragment. You can specify an absolute XPath_string with an initial slash or a relative XPath_string by omitting the initial slash. If you omit the initial slash, then the context of the relative path defaults to the root node. The optional namespace_string is required if the XML you are handling uses a namespace prefix. This argument must resolve to a VARCHAR2 value that specifies a default mapping or namespace mapping for prefixes, which Oracle Database uses when evaluating the XPath expression(s).

Examples

The following example extracts the value of the /Warehouse/Docks node of the XML path of the warehouse_spec column in the sample table oe.warehouses:

```sql
SELECT warehouse_name,
       EXTRACT(warehouse_spec, '/Warehouse/Docks') "Number of Docks"
FROM warehouses
WHERE warehouse_spec IS NOT NULL
ORDER BY warehouse_name;
```

<table>
<thead>
<tr>
<th>WAREHOUSE_NAME</th>
<th>Number of Docks</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Jersey</td>
<td></td>
</tr>
<tr>
<td>San Francisco</td>
<td>&lt;Docks&gt;1&lt;/Docks&gt;</td>
</tr>
<tr>
<td>Seattle, Washington</td>
<td>&lt;Docks&gt;3&lt;/Docks&gt;</td>
</tr>
<tr>
<td>Southlake, Texas</td>
<td>&lt;Docks&gt;2&lt;/Docks&gt;</td>
</tr>
</tbody>
</table>

Compare this example with the example for EXTRACTVALUE on page 7-110, which returns the scalar value of the XML fragment.
The `EXTRACTVALUE` function takes as arguments an `XMLType` instance and an XPath expression and returns a scalar value of the resultant node. The result must be a single node and be either a text node, attribute, or element. If the result is an element, then the element must have a single text node as its child, and it is this value that the function returns. You can specify an absolute `XPath_string` with an initial slash or a relative `XPath_string` by omitting the initial slash. If you omit the initial slash, the context of the relative path defaults to the root node.

If the specified XPath points to a node with more than one child, or if the node pointed to has a non-text node child, then Oracle returns an error. The optional `namespace_string` must resolve to a `VARCHAR2` value that specifies a default mapping or namespace mapping for prefixes, which Oracle uses when evaluating the XPath expression(s).

For documents based on XML schemas, if Oracle can infer the type of the return value, then a scalar value of the appropriate type is returned. Otherwise, the result is of type `VARCHAR2`. For documents that are not based on XML schemas, the return type is always `VARCHAR2`.

### Examples

The following example takes as input the same arguments as the example for `EXTRACT (XML)` on page 7-109. Instead of returning an XML fragment, as does the `EXTRACT` function, it returns the scalar value of the XML fragment:

```sql
SELECT warehouse_name, EXTRACTVALUE(e.warehouse_spec, '/Warehouse/Docks') "Docks"
FROM warehouses e
WHERE warehouse_spec IS NOT NULL
ORDER BY warehouse_name;
```

<table>
<thead>
<tr>
<th>WAREHOUSE_NAME</th>
<th>Docks</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Jersey</td>
<td></td>
</tr>
<tr>
<td>San Francisco</td>
<td>1</td>
</tr>
<tr>
<td>Seattle, Washington</td>
<td>3</td>
</tr>
<tr>
<td>Southlake, Texas</td>
<td>2</td>
</tr>
</tbody>
</table>
FEATURE_DETAILS

Syntax

\[ \text{feature_details} ::= \]

\begin{align*}
\text{FEATURE_DETAILS} & \rightarrow \text{INTO} \hspace{1em} n \\
\text{feature_id} & \rightarrow \text{topN} \\
\text{mining_attribute_clause} & \rightarrow \text{DESC} \hspace{1em} \text{ASC} \hspace{1em} \text{ABS} \\
\text{mining_analytic_clause} & \rightarrow \text{OVER} \hspace{1em} \text{mining_analytic_clause} \\
\text{USING} & \rightarrow \text{schema} \hspace{1em} \text{table} \hspace{1em} \text{AS} \hspace{1em} \text{expr} \hspace{1em} \text{AS} \hspace{1em} \text{alias} \\
\text{query_partition_clause} & \rightarrow \text{order_by_clause} 
\end{align*}

Analytic Syntax

\[ \text{feature_details_analytic} ::= \]

\begin{align*}
\text{FEATUREDETAILS} & \rightarrow \text{INTO} \hspace{1em} n \\
\text{feature_id} & \rightarrow \text{topN} \\
\text{mining_attribute_clause} & \rightarrow \text{DESC} \hspace{1em} \text{ASC} \hspace{1em} \text{ABS} \\
\text{mining_analytic_clause} & \rightarrow \text{OVER} \hspace{1em} \text{mining_analytic_clause} \\
\text{USING} & \rightarrow \text{schema} \hspace{1em} \text{table} \hspace{1em} \text{AS} \hspace{1em} \text{expr} \hspace{1em} \text{AS} \hspace{1em} \text{alias} \\
\text{queryPartitionClause} & \rightarrow \text{order_by_clause} 
\end{align*}

See Also: "Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of mining_analytic_clause
Purpose

FEATURE_DETAILS returns feature details for each row in the selection. The return value is an XML string that describes the attributes of the highest value feature or the specified feature_id.

topN

If you specify a value for topN, the function returns the N attributes that most influence the feature value. If you do not specify topN, the function returns the 5 most influential attributes.

DESC, ASC, or ABS

The returned attributes are ordered by weight. The weight of an attribute expresses its positive or negative impact on the value of the feature. A positive weight indicates a higher feature value. A negative weight indicates a lower feature value.

By default, FEATURE_DETAILS returns the attributes with the highest positive weight (DESC). If you specify ASC, the attributes with the highest negative weight are returned. If you specify ABS, the attributes with the greatest weight, whether negative or positive, are returned. The results are ordered by absolute value from highest to lowest. Attributes with a zero weight are not included in the output.

Syntax Choice

FEATURE_DETAILS can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically mine the data by executing an analytic clause that builds and applies one or more transient mining models. Choose Syntax or Analytic Syntax:

- Syntax — Use the first syntax to score the data with a pre-defined model. Supply the name of a feature extraction model.
- Analytic Syntax — Use the analytic syntax to score the data without a pre-defined model. Include INTO n, where n is the number of features to extract, and mining_analytic_clause, which specifies if the data should be partitioned for multiple model builds. The mining_analytic_clause supports a query_partition_clause and an order_by_clause. (See “analytic_clause:=” on page 7-12.)

mining_attribute_clause

mining_attribute_clause identifies the column attributes to use as predictors for scoring. When the function is invoked with the analytic syntax, these predictors are also used for building the transient models. The mining_attribute_clause behaves as described for the PREDICTION function. (See ”mining_attribute_clause::=” on page 7-237.)

- Oracle Data Mining Concepts for information about feature extraction.

About the Examples:

The following examples are excerpted from the Data Mining sample programs. For more information about the sample programs, see Appendix A in Oracle Data Mining User’s Guide.
### Example

This example uses the feature extraction model `nmf_sh_sample` to score the data. The query returns the three features that best represent customer 100002 and the attributes that most affect those features.

```sql
SELECT S.feature_id fid, value val,
       FEATURE_DETAILS(nmf_sh_sample, S.feature_id, 5 using T.*) det
FROM
  (SELECT v.*, FEATURE_SET(nmf_sh_sample, 3 USING *) fset
   FROM mining_data_apply_v v
   WHERE cust_id = 100002) T,
  TABLE(T.fset) S
ORDER BY 2 DESC;
```

<table>
<thead>
<tr>
<th>FID</th>
<th>VAL</th>
<th>DET</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>3.492</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>1.928</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>.816</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Analytic Example

This example dynamically maps customer attributes into six features and returns the feature mapping for customer 100001.

```sql
SELECT feature_id, value
FROM
  (SELECT cust_id, feature_set(INTO 6 USING *) OVER () fset
   FROM mining_data_apply_v),
  TABLE (fset) S
WHERE cust_id = 100001
ORDER BY feature_id;
```

<table>
<thead>
<tr>
<th>FEATURE_ID</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2.670</td>
</tr>
<tr>
<td>2</td>
<td>0.000</td>
</tr>
<tr>
<td>3</td>
<td>1.792</td>
</tr>
<tr>
<td>4</td>
<td>0.000</td>
</tr>
<tr>
<td>5</td>
<td>0.000</td>
</tr>
<tr>
<td>6</td>
<td>3.379</td>
</tr>
</tbody>
</table>
Syntax

feature_id ::= 

Analytic Syntax

feature_id_analytic ::= 

mining_attribute_clause ::= 

mining_analytic_clause ::=  

See Also: "Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of mining_analytic_clause

Purpose

FEATURE_ID returns the identifier of the highest value feature for each row in the selection. The feature identifier is returned as an Oracle NUMBER.

Syntax Choice

FEATURE_ID can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically mine the data by executing an analytic clause that builds and applies one or more transient mining models. Choose Syntax or Analytic Syntax:

- Syntax — Use the first syntax to score the data with a pre-defined model. Supply the name of a feature extraction model.

- Analytic Syntax — Use the analytic syntax to score the data without a pre-defined model. Include INTO n, where n is the number of features to extract, and mining_analytic_clause, which specifies if the data should be partitioned for multiple model builds. The mining_analytic_clause supports a query_partition_clause and an order_by_clause. (See "analytic_clause::=" on page 7-12.)
mining_attribute_clause

mining_attribute_clause identifies the column attributes to use as predictors for scoring. When the function is invoked with the analytic syntax, these predictors are also used for building the transient models. The mining_attribute_clause behaves as described for the PREDICTION function. (See "mining_attribute_clause::=" on page 7-237.)

About the Example: The following example is excerpted from the Data Mining sample programs. For more information about the sample programs, see Appendix A in Oracle Data Mining User's Guide.

Example

This example lists the features and corresponding count of customers in a data set.

```sql
SELECT FEATURE_ID(nmf_sh_sample USING *) AS feat, COUNT(*) AS cnt
FROM nmf_sh_sample_apply_prepared
GROUP BY FEATURE_ID(nmf_sh_sample USING *)
ORDER BY cnt DESC, feat DESC;
```

<table>
<thead>
<tr>
<th>FEAT</th>
<th>CNT</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>1443</td>
</tr>
<tr>
<td>2</td>
<td>49</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
**FEATURE_SET**

**Syntax**

```plaintext
feature_set ::= 
```

**Analytic Syntax**

```plaintext
feature_set_analytic ::= 
```

**Purpose**

`FEATURE_SET` returns a set of feature ID and feature value pairs for each row in the selection. The return value is a varray of objects with field names `FEATURE_ID` and `VALUE`. The data type of both fields is `NUMBER`.

**topN and cutoff**

You can specify `topN` and `cutoff` to limit the number of features returned by the function. By default, both `topN` and `cutoff` are null and all features are returned.

- `topN` is the N highest value features. If multiple features have the Nth value, then the function chooses one of them.
- `cutoff` is a value threshold. Only features that are greater than or equal to `cutoff` are returned. To filter by `cutoff` only, specify NULL for `topN`.

**See Also:** "Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of `mining_analytic_clause`
To return up to \( N \) features that are greater than or equal to \( \text{cutoff} \), specify both \( \text{topN} \) and \( \text{cutoff} \).

**Syntax Choice**

\( \text{FEATURE\_SET} \) can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically mine the data by executing an analytic clause that builds and applies one or more transient mining models. Choose **Syntax** or **Analytic Syntax**:

- **Syntax** — Use the first syntax to score the data with a pre-defined model. Supply the name of a feature extraction model.

- **Analytic Syntax** — Use the analytic syntax to score the data without a pre-defined model. Include \( \text{INTO} \) \( n \), where \( n \) is the number of features to extract, and \( \text{mining\_analytic\_clause} \), which specifies if the data should be partitioned for multiple model builds. The \( \text{mining\_analytic\_clause} \) supports a \( \text{query\_partition\_clause} \) and an \( \text{order\_by\_clause} \). (See "analytic\_clause::=" on page 7-12.)

**mining\_attribute\_clause**

\( \text{mining\_attribute\_clause} \) identifies the column attributes to use as predictors for scoring. When the function is invoked with the analytic syntax, these predictors are also used for building the transient models. The \( \text{mining\_attribute\_clause} \) behaves as described for the \( \text{PREDICTION} \) function. (See "\( \text{mining\_attribute\_clause::=} \)" on page 7-237.)

**See Also:**

- *Oracle Data Mining User’s Guide* for information about scoring.

- *Oracle Data Mining Concepts* for information about feature extraction.

**About the Example:** The following example is excerpted from the Data Mining sample programs. For more information about the sample programs, see Appendix A in *Oracle Data Mining User’s Guide*.

**Example**

This example lists the top features corresponding to a given customer record and determines the top attributes for each feature (based on coefficient > 0.25).

WITH

\[
\text{feat\_tab AS} \left\{ \right. \\
\text{SELECT F.feature\_id fid,} \\
\text{A.attribute\_name attr,} \\
\text{TO\_CHAR(A.attribute\_value) val,} \\

FEATURE_VALUE

Syntax

\[ \text{feature_value::=} \]

Analytic Syntax

\[ \text{feature_value_analytic::=} \]

\[ \text{mining_attribute_clause::=} \]

See Also: "Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of \text{mining_analytic_clause}

Purpose

\text{FEATURE_VALUE} returns a feature value for each row in the selection. The value refers to the highest value feature or to the specified \text{feature_id}. The feature value is returned as BINARY_DOUBLE.

Syntax Choice

\text{FEATURE_VALUE} can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically mine the data by executing an analytic clause that builds and applies one or more transient mining models. Choose Syntax or Analytic Syntax:

- Syntax — Use the first syntax to score the data with a pre-defined model. Supply the name of a feature extraction model.

- Analytic Syntax — Use the analytic syntax to score the data without a pre-defined model. Include INTO \( n \), where \( n \) is the number of features to extract, and \text{mining_}
analytic_clause, which specifies if the data should be partitioned for multiple model builds. The mining_analytic_clause supports a query_partition_clause and an order_by_clause. (See "analytic_clause::=" on page 7-12.)

mining_attribute_clause

mining_attribute_clause identifies the column attributes to use as predictors for scoring. When the function is invoked with the analytic syntax, this data is also used for building the transient models. The mining_attribute_clause behaves as described for the PREDICTION function. (See "mining_attribute_clause::=" on page 7-237.)

</tbody>
</table>
FIRST

Syntax

\[
\text{first} ::= \text{aggregate-function KEEP} \\
\text{DENSE_RANK FIRST ORDER BY expr DESC ASC NULLS FIRST LAST} \\
\text{OVER (query_partition_clause)}
\]

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions of the ORDER BY clause and OVER clause

Purpose

FIRST and LAST are very similar functions. Both are aggregate and analytic functions that operate on a set of values from a set of rows that rank as the FIRST or LAST with respect to a given sorting specification. If only one row ranks as FIRST or LAST, then the aggregate operates on the set with only one element.

If you omit the OVER clause, then the FIRST and LAST functions are treated as aggregate functions. You can use these functions as analytic functions by specifying the OVER clause. The query_partition_clause is the only part of the OVER clause valid with these functions. If you include the OVER clause but omit the query_partition_clause, then the function is treated as an analytic function, but the window defined for analysis is the entire table.

These functions take as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

When you need a value from the first or last row of a sorted group, but the needed value is not the sort key, the FIRST and LAST functions eliminate the need for self-joins or views and enable better performance.

- The aggregate_function argument is any one of the MIN, MAX, SUM, AVG, COUNT, VARIANCE, or STDDEV functions. It operates on values from the rows that rank either FIRST or LAST. If only one row ranks as FIRST or LAST, then the aggregate operates on a singleton (nonaggregate) set.

- The KEEP keyword is for semantic clarity. It qualifies aggregate_function, indicating that only the FIRST or LAST values of aggregate_function will be returned.

- DENSE_RANK FIRST or DENSE_RANK LAST indicates that Oracle Database will aggregate over only those rows with the minimum (FIRST) or the maximum (LAST) dense rank (also called olympic rank).
Aggregate Example

The following example returns, within each department of the sample table hr.employees, the minimum salary among the employees who make the lowest commission and the maximum salary among the employees who make the highest commission:

```sql
SELECT department_id,
       MIN(salary) KEEP (DENSE_RANK FIRST ORDER BY commission_pct) "Worst",
       MAX(salary) KEEP (DENSE_RANK LAST ORDER BY commission_pct) "Best"
FROM employees
GROUP BY department_id
ORDER BY department_id;
```

<table>

<td>7000</td>
<td>7000</td>
</tr>
</tbody>
</table>

See Also: Table 2-10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and LAST on page 7-170
**FIRST_VALUE**

**Syntax**

```
FIRST_VALUE(expr)
```

**Purpose**

FIRST_VALUE is an analytic function. It returns the first value in an ordered set of values. If the first value in the set is null, then the function returns NULL unless you specify IGNORE NULLS. This setting is useful for data densification.

```
{RESPECT | IGNORE} NULLS
determines whether null values of expr are included in or eliminated from the calculation. The default is RESPECT NULLS. If you specify IGNORE NULLS, then FIRST_VALUE returns the first non-null value in the set, or NULL if all values are null. Refer to "Using Partitioned Outer Joins: Examples" on page 19-71 for an example of data densification.
```

**Examples**

The following example selects, for each employee in Department 90, the name of the employee with the lowest salary:

```
SELECT employee_id, last_name, salary, hire_date,
       FIRST_VALUE(last_name)
OVER (ORDER BY salary ASC ROWS UNBOUNDED PRECEDING) AS fv
FROM (SELECT * FROM employees
       WHERE department_id = 90
       ORDER BY hire_date);
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>SALARY</th>
<th>HIRE_DATE</th>
<th>FV</th>
</tr>
</thead>
<tbody>
<tr>
<td>102</td>
<td>De Haan</td>
<td>17000</td>
<td>13-JAN-01 De Haan</td>
<td></td>
</tr>
<tr>
<td>101</td>
<td>Kochhar</td>
<td>17000</td>
<td>21-SEP-05 De Haan</td>
<td></td>
</tr>
<tr>
<td>100</td>
<td>King</td>
<td>24000</td>
<td>17-JUN-03 De Haan</td>
<td></td>
</tr>
</tbody>
</table>

**See Also:** "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions, including valid forms of expr

**Note:** The two forms of this syntax have the same behavior. The top branch is the ANSI format, which Oracle recommends for ANSI compatibility.

The two forms of this syntax have the same behavior. The top branch is the ANSI format, which Oracle recommends for ANSI compatibility.
The example illustrates the nondeterministic nature of the `FIRST_VALUE` function. Kochhar and DeHaan have the same salary, so are in adjacent rows. Kochhar appears first because the rows returned by the subquery are ordered by `hire_date`. However, if the rows returned by the subquery are ordered by `hire_date` in descending order, as in the next example, then the function returns a different value:

```sql
SELECT employee_id, last_name, salary, hire_date,
       FIRST_VALUE(last_name) OVER (ORDER BY salary ASC ROWS UNBOUNDED PRECEDING) AS fv
FROM (SELECT * FROM employees
       WHERE department_id = 90
       ORDER by hire_date DESC);
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>SALARY</th>
<th>HIRE_DATE</th>
<th>FV</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>Kochhar</td>
<td>17000</td>
<td>21-SEP-05</td>
<td>Kochhar</td>
</tr>
<tr>
<td>102</td>
<td>De Haan</td>
<td>17000</td>
<td>13-JAN-01</td>
<td>Kochhar</td>
</tr>
<tr>
<td>100</td>
<td>King</td>
<td>24000</td>
<td>17-JUN-03</td>
<td>Kochhar</td>
</tr>
</tbody>
</table>

The following two examples show how to make the `FIRST_VALUE` function deterministic by ordering on a unique key. By ordering within the function by both `salary` and the unique key `employee_id`, you can ensure the same result regardless of the ordering in the subquery.

```sql
SELECT employee_id, last_name, salary, hire_date,
       FIRST_VALUE(last_name) OVER (ORDER BY salary ASC, employee_id ROWS UNBOUNDED PRECEDING) AS fv
FROM (SELECT * FROM employees
       WHERE department_id = 90
       ORDER by hire_date);
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>SALARY</th>
<th>HIRE_DATE</th>
<th>FV</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>Kochhar</td>
<td>17000</td>
<td>21-SEP-05</td>
<td>Kochhar</td>
</tr>
<tr>
<td>102</td>
<td>De Haan</td>
<td>17000</td>
<td>13-JAN-01</td>
<td>Kochhar</td>
</tr>
<tr>
<td>100</td>
<td>King</td>
<td>24000</td>
<td>17-JUN-03</td>
<td>Kochhar</td>
</tr>
</tbody>
</table>

```sql
SELECT employee_id, last_name, salary, hire_date,
       FIRST_VALUE(last_name) OVER (ORDER BY salary ASC RANGE UNBOUNDED PRECEDING) AS fv
FROM (SELECT * FROM employees
       WHERE department_id = 90
       ORDER by hire_date DESC);
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>SALARY</th>
<th>HIRE_DATE</th>
<th>FV</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>Kochhar</td>
<td>17000</td>
<td>21-SEP-05</td>
<td>Kochhar</td>
</tr>
<tr>
<td>102</td>
<td>De Haan</td>
<td>17000</td>
<td>13-JAN-01</td>
<td>Kochhar</td>
</tr>
<tr>
<td>100</td>
<td>King</td>
<td>24000</td>
<td>17-JUN-03</td>
<td>Kochhar</td>
</tr>
</tbody>
</table>

The following two examples show that the `FIRST_VALUE` function is deterministic when you use a logical offset (`RANGE` instead of `ROWS`). When duplicates are found for the `ORDER BY` expression, the `FIRST_VALUE` is the lowest value of `expr`:

```sql
SELECT employee_id, last_name, salary, hire_date,
       FIRST_VALUE(last_name) OVER (ORDER BY salary ASC RANGE UNBOUNDED PRECEDING) AS fv
FROM (SELECT * FROM employees
       WHERE department_id = 90
       ORDER by hire_date);
```
<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>SALARY</th>
<th>HIRE_DATE</th>
<th>FV</th>
</tr>
</thead>
<tbody>
<tr>
<td>102</td>
<td>De Haan</td>
<td>17000</td>
<td>13-JAN-01 De Haan</td>
<td></td>
</tr>
<tr>
<td>101</td>
<td>Kochhar</td>
<td>17000</td>
<td>21-SEP-05 De Haan</td>
<td></td>
</tr>
<tr>
<td>100</td>
<td>King</td>
<td>24000</td>
<td>17-JUN-03 De Haan</td>
<td></td>
</tr>
</tbody>
</table>

```sql
SELECT employee_id, last_name, salary, hire_date,
    FIRST_VALUE(last_name)
OVER (ORDER BY salary ASC RANGE UNBOUNDED PRECEDING) AS fv
FROM (SELECT * FROM employees
    WHERE department_id = 90
    ORDER BY hire_date DESC);
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>SALARY</th>
<th>HIRE_DATE</th>
<th>FV</th>
</tr>
</thead>
<tbody>
<tr>
<td>102</td>
<td>De Haan</td>
<td>17000</td>
<td>13-JAN-01 De Haan</td>
<td></td>
</tr>
<tr>
<td>101</td>
<td>Kochhar</td>
<td>17000</td>
<td>21-SEP-05 De Haan</td>
<td></td>
</tr>
<tr>
<td>100</td>
<td>King</td>
<td>24000</td>
<td>17-JUN-03 De Haan</td>
<td></td>
</tr>
</tbody>
</table>
FLOOR

Syntax

\[ \text{FLOOR}(n) \]

Purpose

FLOOR returns the largest integer equal to or less than \( n \). The number \( n \) can always be written as the sum of an integer \( k \) and a positive fraction \( f \) such that \( 0 \leq f < 1 \) and \( n = k + f \). The value of FLOOR is the integer \( k \). Thus, the value of FLOOR is \( n \) itself if and only if \( n \) is precisely an integer.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and CEIL on page 7-40

Examples

The following example returns the largest integer equal to or less than 15.7:

```sql
SELECT FLOOR(15.7) "Floor"
FROM DUAL;
```

```
Floor
15
```
FROM_TZ

Syntax

```
FROM_TZ (timestamp_value, time_zone_value)
```

Purpose

FROM_TZ converts a timestamp value and a time zone to a `TIMESTAMP WITH TIME ZONE` value. `time_zone_value` is a character string in the format `TZH:TZM` or a character expression that returns a string in TZR with optional TZD format.

Examples

The following example returns a timestamp value to `TIMESTAMP WITH TIME ZONE`:

```
SELECT FROM_TZ_TIMESTAMP '2000-03-28 08:00:00', '3:00')
FROM DUAL;
```

```
FROM_TZ(TIMESTAMP'2000-03-28T08:00:00','3:00')
```

-----------------------------------------------
28-MAR-00 08.00.000000000 AM +03:00
GREATEST

Syntax

GREATEST( expr )

Purpose

GREATEST returns the greatest of a list of one or more expressions. Oracle Database uses the first expr to determine the return type. If the first expr is numeric, then Oracle determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type before the comparison, and returns that data type. If the first expr is not numeric, then each expr after the first is implicitly converted to the data type of the first expr before the comparison.

Oracle Database compares each expr using nonpadded comparison semantics. The comparison is binary by default and is linguistic if the NLS_COMP parameter is set to LINGUISTIC and the NLS_SORT parameter has a setting other than BINARY. Character comparison is based on the numerical codes of the characters in the database character set and is performed on whole strings treated as one sequence of bytes, rather than character by character. If the value returned by this function is character data, then its data type is VARCHAR2 if the first expr is a character data type and NVARCHAR2 if the first expr is a national character data type.

See Also:

- "Data Type Comparison Rules" on page 2-39 for more information on character comparison
- Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and "Floating-Point Numbers" on page 2-15 for information on binary-float comparison semantics
- "LEAST" on page 7-177, which returns the least of a list of one or more expressions

Examples

The following statement selects the string with the greatest value:

```sql
SELECT GREATEST('HARRY', 'HARRIOT', 'HAROLD') "Greatest"
FROM DUAL;
```

```
Greatest
--------
HARRY
```

In the following statement, the first argument is numeric. Oracle Database determines that the argument with the highest numeric precedence is the second argument, converts the remaining arguments to the data type of the second argument, and returns the greatest value as that data type:

```sql
SELECT GREATEST (1, '3.925', '2.4') "Greatest"
FROM DUAL;
```

```
Greatest
--------
3.925
```
GROUP_ID

Syntax

\[
\text{GROUP_ID} \rightarrow 1 \rightarrow 1
\]

Purpose

GROUP_ID distinguishes duplicate groups resulting from a GROUP BY specification. It is useful in filtering out duplicate groupings from the query result. It returns an Oracle NUMBER to uniquely identify duplicate groups. This function is applicable only in a SELECT statement that contains a GROUP BY clause.

If \( n \) duplicates exist for a particular grouping, then GROUP_ID returns numbers in the range 0 to \( n-1 \).

Examples

The following example assigns the value 1 to the duplicate \( \text{co.country_region} \) grouping from a query on the sample tables \( \text{sh.countries} \) and \( \text{sh.sales} \):

```sql
SELECT co.country_region, co.country_subregion,
       SUM(s.amount_sold) 'Revenue', GROUP_ID() g
FROM sales s, customers c, countries co
WHERE s.cust_id = c.cust_id
AND c.country_id = co.country_id
AND s.time_id = '1-JAN-00'
AND co.country_region IN ('Americas', 'Europe')
GROUP BY GROUPING SETS ( (co.country_region, co.country_subregion),
                           (co.country_region, co.country_subregion) )
ORDER BY co.country_region, co.country_subregion, "Revenue", g;
```

<table>
<thead>
<tr>
<th>COUNTRY_REGION</th>
<th>COUNTRY_SUBREGION</th>
<th>Revenue</th>
<th>G</th>
</tr>
</thead>
<tbody>
<tr>
<td>Americas</td>
<td>Northern America</td>
<td>944.6</td>
<td>0</td>
</tr>
<tr>
<td>Americas</td>
<td>Northern America</td>
<td>944.6</td>
<td>1</td>
</tr>
<tr>
<td>Europe</td>
<td>Western Europe</td>
<td>566.39</td>
<td>0</td>
</tr>
<tr>
<td>Europe</td>
<td>Western Europe</td>
<td>566.39</td>
<td>1</td>
</tr>
</tbody>
</table>

To ensure that only rows with GROUP_ID < 1 are returned, add the following HAVING clause to the end of the statement:

```
HAVING GROUP_ID() < 1
```
GROUPING

Syntax

\[ \text{GROUPING}(\text{expr}) \]

Purpose

GROUPING distinguishes superaggregate rows from regular grouped rows. GROUP BY extensions such as ROLLUP and CUBE produce superaggregate rows where the set of all values is represented by null. Using the GROUPING function, you can distinguish a null representing the set of all values in a superaggregate row from a null in a regular row.

The \text{expr} in the GROUPING function must match one of the expressions in the \text{GROUP BY} clause. The function returns a value of 1 if the value of \text{expr} in the row is a null representing the set of all values. Otherwise, it returns zero. The data type of the value returned by the GROUPING function is Oracle NUMBER. Refer to the \text{SELECT group_by_clause} on page 19-34 for a discussion of these terms.

Examples

In the following example, which uses the sample tables \text{hr.departments} and \text{hr.employees}, if the GROUPING function returns 1 (indicating a superaggregate row rather than a regular row from the table), then the string "All Jobs" appears in the "JOB" column instead of the null that would otherwise appear:

```sql
SELECT DECODE(GROUPING(department_name), 1, 'ALL DEPARTMENTS', department_name) AS department,
       DECODE(GROUPING(job_id), 1, 'All Jobs', job_id) AS job,
       COUNT(*) "Total Empl",
       AVG(salary) * 12 "Average Sal"
FROM employees e, departments d
WHERE d.department_id = e.department_id
GROUP BY ROLLUP (department_name, job_id)
ORDER BY department, job;
```

<table>
<thead>
<tr>
<th>DEPARTMENT</th>
<th>JOB</th>
<th>Total Empl</th>
<th>Average Sal</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL DEPARTMENTS</td>
<td>All Jobs</td>
<td>106</td>
<td>77481.0566</td>
</tr>
<tr>
<td>Accounting</td>
<td>AC_ACCOUNT</td>
<td>1</td>
<td>99600</td>
</tr>
<tr>

<td>FI_ACCOUNT</td>
<td>5</td>
<td>95040</td>
</tr>
</tbody>
</table>
```

GROUPING
GROUPING_ID

Syntax

```
GROUPING_ID(expr)
```

Purpose

GROUPING_ID returns a number corresponding to the GROUPING bit vector associated with a row. GROUPING_ID is applicable only in a SELECT statement that contains a GROUP BY extension, such as ROLLUP or CUBE, and a GROUPING function. In queries with many GROUP BY expressions, determining the GROUP BY level of a particular row requires many GROUPING functions, which leads to cumbersome SQL. GROUPING_ID is useful in these cases.

GROUPING_ID is functionally equivalent to taking the results of multiple GROUPING functions and concatenating them into a bit vector (a string of ones and zeros). By using GROUPING_ID you can avoid the need for multiple GROUPING functions and make row filtering conditions easier to express. Row filtering is easier with GROUPING_ID because the desired rows can be identified with a single condition of GROUPING_ID = n. The function is especially useful when storing multiple levels of aggregation in a single table.

Examples

The following example shows how to extract grouping IDs from a query of the sample table sh.sales:

```sql
SELECT channel_id, promo_id, sum(amount_sold) s_sales,
       GROUPING(channel_id) gc,
       GROUPING(promo_id) gp,
       GROUPING_ID(channel_id, promo_id) gcp,
       GROUPING_ID(promo_id, channel_id) gpc
FROM sales
WHERE promo_id > 496
GROUP BY CUBE(channel_id, promo_id)
ORDER BY channel_id, promo_id, s_sales, gc;
```

<table>
<thead>
<tr>
<th>CHANNEL_ID</th>
<th>PROMO_ID</th>
<th>S_SALES</th>
<th>GC</th>
<th>GP</th>
<th>GCP</th>
<th>GPC</th>
</tr>

</tr>
</tbody>
</table>
HEXTORAW

Syntax

```sql
HEXTORAW (char)
```

Purpose

HEXTORAW converts char containing hexadecimal digits in the CHAR, VARCHAR2, NCHAR, or NVARCHAR2 data type to a raw value.

This function does not support CLOB data directly. However, CLOBs can be passed in as arguments through implicit data conversion.

See Also: "Data Type Comparison Rules" on page 2-39 for more information.

Examples

The following example creates a simple table with a raw column, and inserts a hexadecimal value that has been converted to RAW:

```sql
CREATE TABLE test (raw_col RAW(10));

INSERT INTO test VALUES (HEXTORAW('7D'));
```

The following example converts hexadecimal digits to a raw value and casts the raw value to VARCHAR2:

```sql
SELECT UTL_RAW.CAST_TO_VARCHAR2(HEXTORAW('4041424344')) FROM DUAL;
```

```
UTL_RAW.CAST_TO_VARCHAR2(HEXTORAW('4041424344'))
-----------------------------------------------
@ABCD
```

See Also: "RAW and LONG RAW Data Types" on page 2-26 and RAWTOHEX on page 7-265
INITCAP

Syntax

```
INITCAP ( char )
```

Purpose

INITCAP returns char, with the first letter of each word in uppercase, all other letters in lowercase. Words are delimited by white space or characters that are not alphanumeric.

char can be of any of the data types CHAR, VARCHAR2, NCHAR, or NVARCHAR2. The return value is the same data type as char. The database sets the case of the initial characters based on the binary mapping defined for the underlying character set. For linguistic-sensitive uppercase and lowercase, refer to NLS_INITCAP on page 7-205.

This function does not support CLOB data directly. However, CLOBs can be passed in as arguments through implicit data conversion.

See Also: "Data Type Comparison Rules" on page 2-39 for more information.

Examples

The following example capitalizes each word in the string:

```sql
SELECT INITCAP('the soap') 'Capitals'
FROM DUAL;
```

Capitals
---------
The Soap
**INSETCHILDXML**

- **Syntax**

  ```sql
  INSETCHILDXML
  (XMLType_instance, XPath_string, child_expr, value_expr, namespace_string)
  ```

- **Purpose**

  INSETCHILDXML inserts a user-supplied value into the target XML at the node indicated by the XPath expression. Compare this function with INSETXMLBEFORE on page 7-142.

  - `XMLType_instance` is an instance of `XMLType`.
  - `XPath_string` is an XPath expression indicating one or more nodes into which the one or more child nodes are to be inserted. You can specify an absolute `XPath_string` with an initial slash or a relative `XPath_string` by omitting the initial slash. If you omit the initial slash, then the context of the relative path defaults to the root node.
  - `child_expr` specifies the one or more element or attribute nodes to be inserted.
  - `value_expr` is an fragment of `XMLType` that specifies one or more nodes being inserted. It must resolve to a string.
  - The optional `namespace_string` provides namespace information for the `XPath_string`. This parameter must be of type `VARCHAR2`.

- **Examples**

  The following example adds a second `/Owner` node to the `warehouse_spec` of one of the warehouses updated in the example for APPENDCHILDXML on page 7-22:

  ```sql
  UPDATE warehouses
  SET warehouse_spec = INSETCHILDXML(warehouse_spec, '/Warehouse/Building',
    '<Owner>', XMLType('<Owner>LesserCo</Owner>'))
  WHERE warehouse_id = 3;
  
  SELECT warehouse_spec
  FROM warehouses
  WHERE warehouse_id = 3;
  ```

  **Note:** The `INSETCHILDXML` function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use XQuery Update instead. See Oracle XML DB Developer’s Guide for more information.

  **See Also:** Oracle XML DB Developer’s Guide for more information about this function.
<Warehouse>
  <Building>Rented
    <Owner>Grandco</Owner>
    <Owner>LesserCo</Owner>
  </Building>
  <Area>85700</Area>
  <DockType/>
  <WaterAccess>N</WaterAccess>
  <RailAccess>N</RailAccess>
  <Parking>Street</Parking>
  <VClearance>11.5 ft</VClearance>
</Warehouse>
INSERTCHILDXMLAFTER

**Note:** The `INSERTCHILDXMLAFTER` function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use XQuery Update instead. See Oracle XML DB Developer’s Guide for more information.

**Syntax**

```sql
INSERTCHILDXMLAFTER(
    XMLType_instance,  
    XPath_string,      
    child_expr,        
    value_expr,        
    namespace_string   
)
```

**Purpose**

`INSERTCHILDXMLAFTER` inserts one or more collection elements as children of target parent elements. The insertion for each target occurs immediately after a specified existing collection element. The existing XML document that is the target of the insertion can be schema-based or non-schema-based.

- `XMLType_instance` identifies the XML data that is the target of the insertion.
- `XPath_string` locates the parent elements within target-data; child-data is inserted under each parent element.
- `child_expr` is a relative XPath 1.0 expression that locates the existing child that will precede the inserted child-data. It must name a child element of the element indicated by parent-xpath, and it can include a predicate.
- `value_expr` is the XMLType child element data to insert. Each top-level element node in this argument must have the same data type as the element indicated by `child_expr`.
- The optional `namespace_string` specifies the namespace for the parent elements, existing child element, and child element XML data to be inserted.

**Examples**

The following example is similar to that for `INSERTCHILDXML`, but it adds a third `/Owner` node after the `/Owner` node added in the other example. The output of the query has been formatted for readability.

```sql
UPDATE warehouses
SET warehouse_spec = INSERTCHILDXMLAFTER(warehouse_spec, '/Warehouse/Building',  
'Owner[2]', XMLType('<Owner>ThirdOwner</Owner>'))  
WHERE warehouse_id = 3;
```

```sql
SELECT warehouse_name,  
EXTRACT(warehouse_spec, '/Warehouse/Building/Owner') "Owners"  
FROM warehouses  
WHERE warehouse_id = 3;
```
<table>
<thead>
<tr>
<th>WAREHOUSE_NAME</th>
<th>Owners</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Jersey</td>
<td>&lt;Owner&gt;GrandCo&lt;/Owner&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;Owner&gt;LesserCo&lt;/Owner&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;Owner&gt;ThirdOwner&lt;/Owner&gt;</td>
</tr>
</tbody>
</table>
INSERTCHILDXMLBEFORE

Note: The INSERTCHILDXMLBEFORE function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use XQuery Update instead. See Oracle XML DB Developer’s Guide for more information.

Syntax

```
INSERTCHILDXMLBEFORE(
  XMLType_instance, XPath_string, child_expr, value_expr, namespace_string)
```

Purpose

INSERTCHILDXMLBEFORE inserts one or more collection elements as children of target parent elements. The insertion for each target occurs immediately before a specified existing collection element. The existing XML document that is the target of the insertion can be schema-based or non-schema-based.

- **XMLType_instance** identifies the XML data that is the target of the insertion.
- **XPath_string** locates the parent elements within target-data; child-data is inserted under each parent element.
- **child_expr** is a relative XPath 1.0 expression that locates the existing child that will follow the inserted child-data. It must name a child element of the element indicated by parent-xpath, and it can include a predicate.
- **value_expr** is the XMLType child element data to insert. Each top-level element node in this argument must have the same data type as the element indicated by child_expr.
- The optional **namespace_string** specifies the namespace for the parent elements, existing child element, and child element XML data to be inserted.

See Also: Oracle XML DB Developer’s Guide for more information about this function.

Examples

The following example is similar to that for INSERTCHILDXML, but it adds a third /Owner node before the /Owner node added in the other example. The output of the query has been formatted for readability.

```sql
UPDATE warehouses
SET warehouse_spec = INSERTCHILDXMLBEFORE(warehouse_spec, '/Warehouse/Building', '
  Owner[2]', XMLType('<Owner>ThirdOwner</Owner>'))
WHERE warehouse_id = 3;

SELECT warehouse_name,
       EXTRACT(warehouse_spec, '/Warehouse/Building/Owner') "Owners"
FROM warehouses
WHERE warehouse_id = 3;
```
<table>
<thead>
<tr>
<th>WAREHOUSE_NAME</th>
<th>Owners</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Jersey</td>
<td>&lt;Owner&gt;GrandCo&lt;/Owner&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;Owner&gt;ThirdOwner&lt;/Owner&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;Owner&gt;LesserCo&lt;/Owner&gt;</td>
</tr>
</tbody>
</table>
INSERTXMLAFTER

Syntax

```
INSERTXMLAFTER (XMLType_instance, XPath_string, value_expr, namespace_string)
```

Purpose

INSERTXMLAFTER inserts one or more nodes of any kind immediately after a target node that is not an attribute node. The XML document that is the target of the insertion can be schema-based or non-schema-based. This function is similar to insertXMLbefore, but it inserts after, not before, the target node.

- `XMLType_instance` specifies the target node of the insertion.
- `XPath_string` is an XPath 1.0 expression that locates in the target node zero or more nodes of any kind except attribute nodes. XML-data is inserted immediately after each of these nodes; that is, each node specified becomes the preceding sibling node of a node specified in `value_expr`.
- `value_expr` is the XML data to be inserted. You can specify one or more nodes of any kind. The order of the nodes is preserved after the insertion.
- The optional `namespace_string` is the namespace for the target node.

See Also: Oracle XML DB Developer’s Guide for more information about this function

Examples

The following example is similar to that for INSERTCHILDXML, but it adds a third `/Owner` node after the `/Owner` node added in the other example. The output of the query has been formatted for readability.

```sql
UPDATE warehouses
SET warehouse_spec = INSERTXMLAFTER(warehouse_spec,
                                   '/Warehouse/Building/Owner[1]', XMLType('<Owner>SecondOwner</Owner>'))
WHERE warehouse_id = 3;

SELECT warehouse_name,
       EXTRACT(warehouse_spec, '/Warehouse/Building/Owner') "Owners"
FROM warehouses
WHERE warehouse_id = 3;

WAREHOUSE_NAME Owners
----------------------- -----------------------------------------------
New Jersey             <Owner>GrandCo</Owner>
                        <Owner>SecondOwner</Owner>
                        <Owner>LesserCo</Owner>
```

Note: The INSERTXMLAFTER function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use XQuery Update instead. See Oracle XML DB Developer’s Guide for more information.
**Syntax**

```
INSERTXMLBEFORE(XMLType_instance, XPath_string, value_expr, namespace_string)
```

**Purpose**

`INSERTXMLBEFORE` inserts a user-supplied value into the target XML before the node indicated by the XPath expression. This function is similar to `INSERTXMLAFTER`, but it inserts before, not after, the target node. Compare this function with `INSERTCHILDXML` on page 7-135.

- **XMLType_instance** is an instance of `XMLType`.
- **XPath_string** is an XPath expression indicating one or more nodes into which one or more child nodes are to be inserted. You can specify an absolute `XPath_string` with an initial slash or a relative `XPath_string` by omitting the initial slash. If you omit the initial slash, then the context of the relative path defaults to the root node.
- **value_expr** is a fragment of `XMLType` that defines one or more nodes being inserted and their position within the parent node. It must resolve to a string.
- The optional **namespace_string** provides namespace information for the `XPath_string`. This parameter must be of type `VARCHAR2`.

**Examples**

The following example is similar to that for `INSERTCHILDXML` on page 7-135, but it adds a third `/Owner` node before the `/Owner` node added in the other example. The output of the query has been formatted for readability.

```
UPDATE warehouses
SET warehouse_spec = INSERTXMLBEFORE(warehouse_spec,
                                         '/Warehouse/Building/Owner[2]', XMLType('<Owner>ThirdOwner</Owner>'))
WHERE warehouse_id = 3;

SELECT warehouse_name,
       EXTRACT(warehouse_spec, '/Warehouse/Building/Owner') "Owners"
FROM warehouses
WHERE warehouse_id = 3;
```

<table>
<thead>
<tr>
<th>WAREHOUSE_NAME</th>
<th>Owners</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Jersey</td>
<td>&lt;Owner&gt;GrandCo&lt;/Owner&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;Owner&gt;ThirdOwner&lt;/Owner&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;Owner&gt;LesserCo&lt;/Owner&gt;</td>
</tr>
</tbody>
</table>

**Note:** The `INSERTXMLBEFORE` function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use XQuery Update instead. See Oracle XML DB Developer’s Guide for more information.

**See Also:** Oracle XML DB Developer’s Guide for more information about this function.
INSTR

Syntax

```
INSTR (string, substring, position, occurrence)
INSTRB (string, substring, position, occurrence)
INSTRC (string, substring, position, occurrence)
INSTR2 (string, substring, position, occurrence)
INSTR4 (string, substring, position, occurrence)
```

Purpose

The INSTR functions search `string` for `substring`. The search operation is defined as comparing the `substring` argument with substrings of `string` of the same length for equality until a match is found or there are no more substrings left. Each consecutive compared substring of `string` begins one character to the right (for forward searches) or one character to the left (for backward searches) from the first character of the previous compared substring. If a substring that is equal to `substring` is found, then the function returns an integer indicating the position of the first character of this substring. If no such substring is found, then the function returns zero.

- `position` is an nonzero integer indicating the character of `string` where Oracle Database begins the search—that is, the position of the first character of the first substring to compare with `substring`. If `position` is negative, then Oracle counts backward from the end of `string` and then searches backward from the resulting position.

- `occurrence` is an integer indicating which occurrence of `substring` in `string` Oracle should search for. The value of `occurrence` must be positive. If `occurrence` is greater than 1, then the database does not return on the first match but continues comparing consecutive substrings of `string`, as described above, until match number `occurrence` has been found.

INSTR accepts and returns positions in characters as defined by the input character set, with the first character of string having position 1. INSTRB uses bytes instead of characters. INSTRC uses Unicode complete characters. INSTR2 uses UCS2 code points. INSTR4 uses UCS4 code points.

`string` can be any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB. The exceptions are INSTRC, INSTR2, and INSTR4, which do not allow `string` to be a CLOB or NCLOB.

`substring` can be any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB.

The value returned is of NUMBER data type.

Both `position` and `occurrence` must be of data type NUMBER, or any data type that can be implicitly converted to NUMBER, and must resolve to an integer. The default values of both `position` and `occurrence` are 1, meaning Oracle begins searching at the first character of `string` for the first occurrence of `substring`. The return value is relative to the beginning of `string`, regardless of the value of `position`.

See Also: Table 2-10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion.
Examples

The following example searches the string CORPORATE FLOOR, beginning with the third character, for the string "OR". It returns the position in CORPORATE FLOOR at which the second occurrence of "OR" begins:

```sql
SELECT INSTR('CORPORATE FLOOR','OR', 3, 2) "Instring"
FROM DUAL;
```

```
Instring
----------
14
```

In the next example, Oracle counts backward from the last character to the third character from the end, which is the first O in FLOOR. Oracle then searches backward for the second occurrence of OR, and finds that this second occurrence begins with the second character in the search string:

```sql
SELECT INSTR('CORPORATE FLOOR','OR', -3, 2) "Reversed Instring"
FROM DUAL;
```

```
Reversed Instring
-----------------  
2
```

The next example assumes a double-byte database character set.

```sql
SELECT INSTRB('CORPORATE FLOOR','OR',5,2) "Instring in bytes"
FROM DUAL;
```

```
Instring in bytes
-----------------  
27
```
ITERATION_NUMBER

Syntax

ITERATION_NUMBER

Purpose

The ITERATION_NUMBER function can be used only in the model_clause of the SELECT statement and then only when ITERATE(number) is specified in the model_rules_clause. It returns an integer representing the completed iteration through the model rules. The ITERATION_NUMBER function returns 0 during the first iteration. For each subsequent iteration, the ITERATION_NUMBER function returns the equivalent of iteration_number plus one.

See Also: model_clause on page 19-35 and "Model Expressions" on page 5-13 for the syntax and semantics

Examples

The following example assigns the sales of the Mouse Pad for the years 1998 and 1999 to the sales of the Mouse Pad for the years 2001 and 2002 respectively:

```
SELECT country, prod, year, s
FROM sales_view_ref
MODEL
  PARTITION BY (country)
  DIMENSION BY (prod, year)
  MEASURES (sale s)
  IGNORE NAV
  UNIQUE DIMENSION
  RULES UPSERT SEQUENTIAL ORDER ITERATE(2)
  {
    s['Mouse Pad', 2001 + ITERATION_NUMBER] =
    s['Mouse Pad', 1998 + ITERATION_NUMBER]
  }
ORDER BY country, prod, year;
```

<table>
<thead>
<tr>

The preceding example requires the view `sales_view_ref`. Refer to "The MODEL clause: Examples" on page 19-63 to create this view.
Note: The JSON_QUERY function is available starting with Oracle Database 12c Release 1 (12.1.0.2).

Syntax

JSON_QUERY(expr, JSON, JSON_path_expression, JSON_query_returning_clause, JSON_query_wrapper_clause, JSON_query_on_error_clause)

JSON_path_expression ::= object_step | array_step

object_step ::= simple_name | complex_name

array_step ::= integer | integer TO integer

JSON_query_returning_clause ::= RETURNING JSON_query_return_type PRETTY ASCII

JSON_query_return_type ::= VARCHAR2 size | BYTE | CHAR
**Purpose**

`JSON_QUERY` finds one or more specified JSON values in JSON data and returns the values in a character string.

**expr**

Use this clause to specify the JSON data to be evaluated. For `expr`, specify an expression that evaluates to a text literal. If `expr` is a column, then the column must be of data type `VARCHAR2`, `CLOB`, or `BLOB`. If `expr` is null, then the function returns null.

If `expr` is not a text literal of well-formed JSON data using strict or lax syntax, then the function returns null by default. You can use the `JSON_query_on_error_clause` to override this default behavior. Refer to `JSON_query_on_error_clause` on page 7-150.

**FORMAT JSON**

You must specify `FORMAT JSON` if `expr` is a column of data type `BLOB`.

**JSON_path_expression**

Use this clause to specify a JSON path expression. The function uses the path expression to evaluate `expr` and find one or more JSON values that match, or satisfy, the path expression. The path expression must be a text literal.

The path expression must begin with a dollar sign (`$`), which represents the context item, that is, the expression specified by `expr`. The dollar sign is followed by zero or more steps, each of which can be an object step or an array step.

The function attempts to match the first step in the path expression to the context item. If the first step results in a match, then the function attempts to match the second step to the JSON value(s) that matched the first step. If the second step results in a match, then the function attempts to match the third step to the JSON value(s) that matched the second step, and so on. The function returns the value(s) matched in the final step as a comma-separated sequence of values in a character string. The order of the sequence is nondeterministic. All values are returned using strict JSON syntax, regardless of whether the original JSON data used strict or lax JSON syntax. A path expression that consists of a dollar sign followed by zero steps (`'='$`) matches the entire context item.

You can specify the `JSON_query_returning_clause` to control the data type and format of the return character string. Refer to the `JSON_query_returning_clause` on page 7-149.
If multiple values match the path expression, or if only one scalar value matches the path expression, then you must wrap the value(s) in an array wrapper. Refer to the JSON_query_wrapper_clause on page 7-150.

If any step in the path expression does not result in a match, then the function returns null by default. You can use the JSON_query_on_error_clause to override this default behavior. Refer to the JSON_query_on_error_clause on page 7-150.

**object_step** Use this clause to specify an object step.

- Use simple_name or complex_name to specify a property name. If a member with that property name exists in the JSON object being evaluated, then the object step results in a match to the property value of that member. Otherwise, the object step does not result in a match. Both types of names are case-sensitive. Therefore, a match will result only if the alphabetic character cases match in the object step and the JSON data.

  A simple_name can contain only alphanumeric characters and must begin with an alphabetic character. A complex_name can contain only alphanumeric characters and spaces, and must begin with an alphanumeric character. A complex_name must be enclosed in double quotation marks.

- Use the asterisk wildcard symbol (*) to specify all property names. If the JSON object being evaluated contains at least one member, then the object step results in a match to the values of all members. Otherwise, the object step does not result in a match.

If you apply an object step to a JSON array, then the array is implicitly unwrapped and the elements of the array are evaluated using the object step. This is called JSON path expression relaxation. Refer to Oracle XML DB Developer’s Guide for more information.

If the JSON data being evaluated is not a JSON object, then the object step does not result in a match.

**array_step** Use this clause to specify an array step.

- Use integer to specify the element at index integer in a JSON array. Use integer TO integer to specify the range of elements between the two index integer values, inclusive. If the specified elements exist in the JSON array being evaluated, then the array step results in a match to those elements. Otherwise, the array step does not result in a match. The first element in a JSON array had index 0.

- Use the asterisk wildcard symbol (*) to specify all elements in a JSON array. If the JSON array being evaluated contains at least one element, then the array step results in a match to all elements in the JSON array. Otherwise, the array step does not result in a match.

If the JSON data being evaluated is not a JSON array, then the data is implicitly wrapped in an array and then evaluated using the array step. This is called JSON path expression relaxation. Refer to Oracle XML DB Developer’s Guide for more information.

**JSON_query_returning_clause**

Use this clause to specify the data type and format of the character string returned by this function.

**RETURNING** Use the RETURNING clause to specify the data type of the character string. If you omit this clause, then JSON_QUERY returns a character string of type VARCHAR2(4000).

You can use the JSON_return_type_clause to specify the following data type:
When specifying the `VARCHAR2` data type elsewhere in SQL, you are required to specify a size. However, in this clause you can omit the size. In this case, `JSON_QUERY` returns a character string of type `VARCHAR2(4000)`.

Refer to "VARCHAR2 Data Type" on page 2-10 for more information.

If the data type is not large enough to hold the return character string, then this function returns null by default. You can use the `JSON_query_on_error_clause` to override this default behavior. Refer to the `JSON_query_on_error_clause` on page 7-150.

**PRETTY** Specify `PRETTY` to pretty-print the return character string by inserting newline characters and indenting.

**ASCII** Specify `ASCII` to automatically escape any non-ASCII Unicode characters in the return character string, using standard ASCII Unicode escape sequences.

**JSON_query_wrapper_clause**

Use this clause to control whether this function wraps the values matched by the path expression in an array wrapper—that is, encloses the sequence of values in square brackets ([]).

- Specify `WITHOUT WRAPPER` to omit the array wrapper. You can specify this clause only if the path expression matches a single JSON object or JSON array. This is the default.
- Specify `WITH WRAPPER` to include the array wrapper. You must specify this clause if the path expression matches a single scalar value (a value that is not a JSON object or JSON array) or multiple values of any type.
- Specifying the `WITH UNCONDITIONAL WRAPPER` clause is equivalent to specifying the `WITH WRAPPER` clause. The `UNCONDITIONAL` keyword is provided for semantic clarity.
- Specify `WITH CONDITIONAL WRAPPER` to include the array wrapper only if the path expression matches a single scalar value or multiple values of any type. If the path expression matches a single JSON object or JSON array, then the array wrapper is omitted.

The `ARRAY` keyword is optional and is provided for semantic clarity.

If the function returns a single scalar value, or multiple values of any type, and you do not specify `WITH [UNCONDITIONAL | CONDITIONAL] WRAPPER`, then the function returns null by default. You can use the `JSON_query_on_error_clause` to override this default behavior. Refer to the `JSON_query_on_error_clause` on page 7-150.

**JSON_query_on_error_clause**

Use this clause to specify the value returned by this function when any of the following errors occur:

- `expr` is not well-formed JSON data using strict or lax JSON syntax
- No match is found when the JSON data is evaluated using the JSON path expression
- The return value data type is not large enough to hold the return character string
- The function matches a single scalar value or, multiple values of any type, and the `WITH [UNCONDITIONAL | CONDITIONAL] WRAPPER` clause is not specified

You can specify the following clauses:
- **NULL ON ERROR** - Returns null when an error occurs. This is the default.
- **ERROR ON ERROR** - Returns the appropriate Oracle error when an error occurs.
- **EMPTY ON ERROR** - Returns an empty JSON array (``[]``) when an error occurs.

**Examples**

The following query returns the context item, or the specified string of JSON data. The path expression matches a single JSON object, which does not require an array wrapper. Note that the JSON data is converted to strict JSON syntax in the returned value—that is, the object property names are enclosed in double quotation marks.

```sql
SELECT JSON_QUERY('{a:100, b:200, c:300}', '$') AS value
FROM DUAL;
```

**VALUE**

```
{"a":100,"b":200,"c":300}
```

The following query returns the value of the member with property name `a`. The path expression matches a scalar value, which must be enclosed in an array wrapper. Therefore, the WITH WRAPPER clause is specified.

```sql
SELECT JSON_QUERY('{a:100, b:200, c:300}', '$.a' WITH WRAPPER) AS value
FROM DUAL;
```

**VALUE**

```
[100]
```

The following query returns the values of all object members. The path expression matches multiple values, which together must be enclosed in an array wrapper. Therefore, the WITH WRAPPER clause is specified.

```sql
SELECT JSON_QUERY('{a:100, b:200, c:300}', '$.*' WITH WRAPPER) AS value
FROM DUAL;
```

**VALUE**

```
[100,200,300]
```

The following query returns the context item, or the specified string of JSON data. The path expression matches a single JSON array, which does not require an array wrapper.

```sql
SELECT JSON_QUERY('[0,1,2,3,4]', '$') AS value
FROM DUAL;
```

**VALUE**

```
[0,1,2,3,4]
```

The following query is similar to the previous query, except the WITH WRAPPER clause is specified. Therefore, the JSON array is wrapped in an array wrapper.

```sql
SELECT JSON_QUERY('[0,1,2,3,4]', '$' WITH WRAPPER) AS value
FROM DUAL;
```

**VALUE**

```
[[0,1,2,3,4]]
```
The following query returns all elements in a JSON array. The path expression matches multiple values, which together must be enclosed in an array wrapper. Therefore, the WITH WRAPPER clause is specified.

```
SELECT JSON_QUERY('[0,1,2,3,4]', '$[*]' WITH WRAPPER) AS value
FROM DUAL;
```

```
VALUE
[0,1,2,3,4]
```

The following query returns the elements at indexes 0, 3 through 5, and 7 in a JSON array. The path expression matches multiple values, which together must be enclosed in an array wrapper. Therefore, the WITH WRAPPER clause is specified.

```
SELECT JSON_QUERY('[0,1,2,3,4,5,6,7,8]', '$[0, 3 TO 5, 7]' WITH WRAPPER) AS value
FROM DUAL;
```

```
VALUE
[0,3,4,5,7]
```

The following query returns the fourth element in a JSON array. The path expression matches a scalar value, which must be enclosed in an array wrapper. Therefore, the WITH WRAPPER clause is specified.

```
SELECT JSON_QUERY('[0,1,2,3,4]', '$[3]' WITH WRAPPER) AS value
FROM DUAL;
```

```
VALUE
[3]
```

The following query returns the first element in a JSON array. The WITH CONDITIONAL WRAPPER clause is specified and the path expression matches a single JSON object. Therefore, the value returned is not wrapped in an array. Note that the JSON data is converted to strict JSON syntax in the returned value—that is, the object property name is enclosed in double quotation marks.

```
SELECT JSON_QUERY('[{a:100},{b:200},{c:300}]', '$[0]' WITH CONDITIONAL WRAPPER) AS value
FROM DUAL;
```

```
VALUE
{"a":100}
```

The following query returns all elements in a JSON array. The WITH CONDITIONAL WRAPPER clause is specified and the path expression matches multiple JSON objects. Therefore, the value returned is wrapped in an array.

```
SELECT JSON_QUERY('[{“a”:100},{‘b‘:200},{“c“:300}]', ‘$[*]’ WITH CONDITIONAL WRAPPER) AS value
FROM DUAL;
```

```
VALUE
[{"a":100},{“b“:200},{“c“:300}]```
The following query is similar to the previous query, except that the value returned is of data type VARCHAR2(100).

```sql
SELECT JSON_QUERY('['${"a":100},'${"b":200},'${"c":300}'], '"$"[*]'
    RETURNING VARCHAR2(100) WITH CONDITIONAL WRAPPER) AS value
FROM DUAL;
VALUE
--------------------------------------------------------------------------------
[{'a':100},{'b':200},{'c':300}]
```

The following query returns the fourth element in a JSON array. However, the supplied JSON array does not contain a fourth element, which results in an error. The EMPTY ON ERROR clause is specified. Therefore, the query returns an empty JSON array.

```sql
SELECT JSON_QUERY('['${"a":100},'${"b":200},'${"c":300}'], '"$[3]'
    EMPTY ON ERROR) AS value
FROM DUAL;
VALUE
--------------------------------------------------------------------------------
[]
```
**Note:** The `JSON_TABLE` function is available starting with Oracle Database 12c Release 1 (12.1.0.2).

### Syntax

```
JSON_TABLE ( expr FORMAT JSON, JSON_path_expression JSON_table_on_error_clause JSON_columns_clause )
```

( `JSON_path_expression::=` on page 7-154, `JSON_table_on_error_clause::=` on page 7-154, `JSON_columns_clause::=` on page 7-155)

ordinality_column ::= 

| column_name | FOR | ORDINALITY |

Purpose

JSON_TABLE creates a relational view of JSON data. It maps the result of a JSON data evaluation into relational rows and columns. You can query the result returned by the function as a virtual relational table using SQL. The main purpose of JSON_TABLE is to create a row of relational data for each object inside a JSON array and output JSON values from within that object as individual SQL column values.

You can specify JSON_TABLE only in the FROM clause of a SELECT statement. The function first applies a JSON path expression, called a row path expression, to the supplied JSON data. The JSON value that matches the row path expression is called a row source in that it generates a row of relational data. The COLUMNS clause evaluates the row source, finds specific JSON values within the row source, and returns those JSON values as SQL values in individual columns of a row of relational data.

The COLUMNS clause enables you to search for JSON values in different ways by using the following clauses:

- JSON_exists_column - Evaluates JSON data in the same manner as the JSON_EXISTS condition, that is, determines if a specified JSON value exists, and returns either a VARCHAR2 column of values 'true' or 'false', or a NUMBER column of values 1 or 0.

- JSON_query_column - Evaluates JSON data in the same manner as the JSON_QUERY function, that is, finds one or more specified JSON values, and returns a column of character strings that contain those JSON values.

- JSON_value_column - Evaluates JSON data in the same manner as the JSON_VALUE function, that is, finds a specified scalar JSON value, and returns a column of those JSON values as SQL values.

- JSON_nested_path - Allows you to flatten JSON values in a nested JSON object or JSON array into individual columns in a single row along with JSON values from the parent object or array. You can use this clause recursively to project data from multiple layers of nested objects or arrays into a single row.

- ordinality_column - Returns a column of generated row numbers.

The column definition clauses allow you to specify a name for each column of data that they return. You can reference these column names elsewhere in the SELECT statement, such as in the SELECT list and the WHERE clause.

expr

Use this clause to specify the JSON data to be evaluated. For expr, specify an expression that evaluates to a text literal. If expr is a column, then the column must be of data type VARCHAR2, CLOB, or BLOB. If expr is null, then the function returns null.

If expr is not a text literal of well-formed JSON data using strict or lax syntax, then the function returns null by default. You can use the JSON_table_on_error_clause to override this default behavior. Refer to JSON_table_on_error_clause on page 7-157.

FORMAT JSON

You must specify FORMAT JSON if expr is a column of data type BLOB.
**JSON_path_expression**
Use this clause to specify the row path expression. The function uses the row path expression to evaluate `expr` and find the a JSON value, called the row source, that matches, or satisfy, the path expression. This row source is then evaluated by the `COLUMNS` clause. The path expression must be a text literal.

The `JSON_path_expression` clause has the same semantics for `JSON_TABLE` and `JSON_QUERY`. For the full semantics of this clause, refer to `JSON_path_expression` on page 7-148 in the documentation on `JSON_QUERY`.

**JSON_table_on_error_clause**
Use this clause to specify the value returned by this function when the following errors occur:

- `expr` is not well-formed JSON data using strict or lax JSON syntax
- No match is found when the JSON data is evaluated using the row path expression

You can specify the following clauses:

- `NULL ON ERROR` - Returns null when an error occurs. This is the default.
- `ERROR ON ERROR` - Returns the appropriate Oracle error when an error occurs.
- `DEFAULT literal ON ERROR` - Returns `literal` when an error occurs. If the data type of the value returned by this function is `VARCHAR2`, then you must specify a text literal. If the data type is `NUMBER`, then you must specify a numeric literal.

**JSON_columns_clause**
Use the `COLUMNS` clause to define the columns in the virtual relational table returned by the `JSON_TABLE` function.

**JSON_exists_column** This clause evaluates JSON data in the same manner as the `JSON_EXISTS` condition, that is, it determines if a specified JSON value exists. It returns either a `VARCHAR2` column of values 'true' or 'false', or a `NUMBER` column of values 1 or 0. A value of 'true' or 1 indicates that the JSON value exists and a value of 'false' or 0 indicates that the JSON value does not exist.

You can use the `JSON_value_return_type` clause to control the data type of the returned column. If you omit this clause, then the data type is `VARCHAR2(4000)`. Use `column_name` to specify the name of the returned column. The rest of the clauses of `JSON_exists_column` have the same semantics here as they have for the `JSON_EXISTS` condition. For full information on these clauses, refer to "Using JSON_exists_column: Examples" on page 7-160 for an example.

**JSON_query_column** This clause evaluates JSON data in the same manner as the `JSON_QUERY` function, that is, it finds one or more specified JSON values, and returns a column of character strings that contain those JSON values.

Use `column_name` to specify the name of the returned column. The rest of the clauses of `JSON_query_column` have the same semantics here as they have for the `JSON_QUERY` function. For full information on these clauses, refer to `JSON_QUERY` on page 7-147. Also see "Using JSON_query_column: Example" on page 7-159 for an example.

**JSON_value_column** This clause evaluates JSON data in the same manner as the `JSON_VALUE` function, that is, it finds a specified scalar JSON value, and returns a column of those JSON values as SQL values.
Use column_name to specify the name of the returned column. The rest of the clauses of JSON_value_column have the same semantics here as they have for the JSON_VALUE function. For full information on these clauses, refer to JSON_VALUE on page 7-162. Also see "Using JSON_value_column: Example" on page 7-159 for an example.

JSON_nested_path Use this clause to flatten JSON values in a nested JSON object or JSON array into individual columns in a single row along with JSON values from the parent object or array. You can use this clause recursively to project data from multiple layers of nested objects or arrays into a single row.

Specify the JSON_path_expression clause to match the nested object or array. This path expression is relative to the row path expression specified in the JSON_TABLE function.

Use the COLUMNS clause to define the columns of the nested object or array to be returned. This clause is recursive—you can specify the JSON_nested_path clause within another JSON_nested_path clause. Also see "Using JSON_nested_path: Examples" on page 7-160 for an example.

ordinality_column This clause returns a column of generated row numbers of data type NUMBER. You can specify at most one ordinality_column. Also see "Using JSON_value_column: Example" on page 7-159 for an example of using the ordinality_column clause.

Examples

Creating a Table That Contains a JSON Document: Example This example shows how to create and populate table j_purchaseorder, which is used in the rest of the JSON_TABLE examples in this section.

The following statement creates table j_purchaseorder. Column po_document is for storing JSON data and, therefore, has an IS JSON check constraint to ensure that only well-formed JSON is stored in the column.

CREATE TABLE j_purchaseorder
(id RAW (16) NOT NULL,
 date_loaded TIMESTAMP(6) WITH TIME ZONE,
 po_document CLOB CONSTRAINT ensure_json CHECK (po_document IS JSON));

The following statement inserts one row, or one JSON document, into table j_purchaseorder:

INSERT INTO j_purchaseorder
VALUES (SYS_GUID(), SYSTIMESTAMP,
   '{"PONumber" : 1600,
    "Reference" : "ABULL-20140421",
    "Requestor" : "Alexis Bull",
    "User" : "ABULL",
    "CostCenter" : "A50",
    "ShippingInstructions" : {'name' : 'Alexis Bull',
        'Address': {'street' : "200 Sporting Green",
                  'city' : "South San Francisco",
                  'state' : "CA",
                  'zipCode' : 99236,
                  'country' : "United States of America"},
        'Phone' : [{'type' : "Office", "number" : "909-555-7307"},
                   {'type' : "Mobile", "number" : "415-555-1234"}]},
   'PONumber' : 1600,
   "Reference" : "ABULL-20140421",
   "Requestor" : "Alexis Bull",
   "User" : "ABULL",
   "CostCenter" : "A50",
   "ShippingInstructions" : {'name' : 'Alexis Bull',
        'Address': {'street' : "200 Sporting Green",
                  'city' : "South San Francisco",
                "state" : "CA",
                  'zipCode' : 99236,
                  'country' : "United States of America"},
        'Phone' : [{'type' : "Office", "number" : "909-555-7307"},
                   {'type' : "Mobile", "number" : "415-555-1234"}]},
   SYS_GUID(), SYSTIMESTAMP,
   '{"PONumber" : 1600,
    "Reference" : "ABULL-20140421",
    "Requestor" : "Alexis Bull",
    "User" : "ABULL",
    "CostCenter" : "A50",
    "ShippingInstructions" : {'name' : 'Alexis Bull',
        'Address': {'street' : "200 Sporting Green",
                  'city' : "South San Francisco",
                "state" : "CA",
                  'zipCode' : 99236,
                  'country' : "United States of America"},
        'Phone' : [{'type' : "Office", "number" : "909-555-7307"},
                   {'type' : "Mobile", "number" : "415-555-1234"}]);
Using JSON_query_column: Example  The statement in this example queries JSON data for a specific JSON property using the JSON_query_column clause, and returns the property value in a column.

The statement first applies a row path expression to column po_document, which results in a match to the ShippingInstructions property. The COLUMNS clause then uses the JSON_query_column clause to return the Phone property value in a VARCHAR2(100) column.

```sql
SELECT jt.phones
FROM j_purchaseorder,
JSON_TABLE(po_document, '$.ShippingInstructions'
COLUMNS
(phones VARCHAR2(100) FORMAT JSON PATH '$.Phone')) AS jt;
```

<table>
<thead>
<tr>
<th>PHONES</th>
</tr>
</thead>
<tbody>
<tr>
<td>[&quot;type&quot;:&quot;Office&quot;,&quot;number&quot;:&quot;909-555-7307&quot;],(&quot;type&quot;:&quot;Mobile&quot;,&quot;number&quot;:&quot;415-555-1234&quot;)</td>
</tr>
</tbody>
</table>

Using JSON_value_column: Example  The statement in this example refines the statement in the previous example by querying JSON data for specific JSON values using the JSON_value_column clause, and returns the JSON values as SQL values in relational rows and columns.

The statement first applies a row path expression to column po_document, which results in a match to the elements in the JSON array Phone. These elements are JSON objects that contain two members named type and number. The statement uses the COLUMNS clause to return the type value for each object in a VARCHAR2(10) column called phone_type, and the number value for each object in a VARCHAR2(20) column called phone_num. The statement also returns an ordinal column named row_number.

```sql
SELECT jt.*
FROM j_purchaseorder,
JSON_TABLE(po_document, '$.ShippingInstructions.Phone[*]'
COLUMNS
(row_number FOR ORDINALITY,
 phone_type VARCHAR2(10) PATH '$.type',
 phone_num VARCHAR2(20) PATH '$.number'))
AS jt;
```

<table>
<thead>
<tr>
<th>ROW_NUMBER</th>
<th>PHONE_TYPE</th>
<th>PHONE_NUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Office</td>
<td>909-555-7307</td>
</tr>
<tr>
<td>2</td>
<td>Mobile</td>
<td>415-555-1234</td>
</tr>
</tbody>
</table>
Using JSON_exists_column: Examples  The statements in this example test whether a JSON value exists in JSON data using the JSON_exists_column clause. The first example returns the result of the test as a 'true' or 'false' value in a column. The second example uses the result of the test in the WHERE clause.

The following statement first applies a row path expression to column po_document, which results in a match to the entire context item, or JSON document. It then uses the COLUMNS clause to return the requestor's name and a string value of 'true' or 'false' indicating whether the JSON data for that requestor contains a zip code. The COLUMNS clause first uses the JSON_value_column clause to return the Requestor value in a VARCHAR2(32) column called requestor. It then uses the JSON_exists_column clause to determine if the zipCode object exists and returns the result in a VARCHAR2(5) column called has_zip.

```
SELECT requestor, has_zip
FROM j_purchaseorder,
JSON_TABLE(po_document, '$'
COLUMNS
  (requestor VARCHAR2(32) PATH '$.Requestor',
   has_zip VARCHAR2(5) EXISTS PATH '$.ShippingInstructions.Address.zipCode'));
```

<table>
<thead>
<tr>
<th>REQUESTOR</th>
<th>HAS_ZIP</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alexis Bull</td>
<td>true</td>
</tr>
</tbody>
</table>

The following statement is similar to the previous statement, except that it uses the value of has_zip in the WHERE clause to determine whether to return the Requestor value:

```
SELECT requestor
FROM j_purchaseorder,
JSON_TABLE(po_document, '$'
COLUMNS
  (requestor VARCHAR2(32) PATH '$.Requestor',
   has_zip VARCHAR2(5) EXISTS PATH '$.ShippingInstructions.Address.zipCode'))
WHERE (has_zip = 'true');
```

<table>
<thead>
<tr>
<th>REQUESTOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alexis Bull</td>
</tr>
</tbody>
</table>

Using JSON_nested_path: Examples  The following two simple statements demonstrate the functionality of the JSON_nested_path clause. They operate on a simple JSON array that contains three elements. The first two elements are numbers. The third element is a nested JSON array that contains two string value elements.

The following statement does not use the JSON_nested_path clause. It returns the three elements in the array in a single row. The nested array is returned in its entirety.

```
SELECT *
FROM JSON_TABLE('[1,2,["a","b"]]', '$'
COLUMNS (outer_value_0 NUMBER PATH '$[0]',
          outer_value_1 NUMBER PATH '$[1]',
          outer_value_2 VARCHAR2(20) FORMAT JSON PATH '$[2]'));
```

<table>
<thead>
<tr>
<th>OUTER_VALUE_0</th>
<th>OUTER_VALUE_1</th>
<th>OUTER_VALUE_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>['a','b']</td>
</tr>
</tbody>
</table>
The following statement is different from the previous statement because it uses the `JSON_nested_path` clause to return the individual elements of the nested array in individual columns in a single row along with the parent array elements.

```
SELECT *
FROM JSON_TABLE('[1,2,["a","b"]]', '$'
COLUMNS (outer_value_0 NUMBER PATH '$[0]',
          outer_value_1 NUMBER PATH '$[1]',
          NESTED PATH '$[2]'
          COLUMNS (nested_value_0 VARCHAR2(1) PATH '$[0]',
                   nested_value_1 VARCHAR2(1) PATH '$[1]')));
```

```
OUTER_VALUE_0 OUTER_VALUE_1 NESTED_VALUE_0 NESTED_VALUE_1
------------- ------------- -------------- --------------
1             2 a              b
```

The previous example shows how to use `JSON_nested_path` with a nested JSON array. The following example shows how to use the `JSON_nested_path` clause with a nested JSON object by returning the individual elements of the nested object in individual columns in a single row along with the parent object elements.

```
SELECT *
FROM JSON_TABLE('{a:100, b:200, c:{d:300, e:400}}', '$'
COLUMNS (outer_value_0 NUMBER PATH '$.a',
          outer_value_1 NUMBER PATH '$.b',
          NESTED PATH '$.c'
          COLUMNS (nested_value_0 NUMBER PATH '$.d',
                   nested_value_1 NUMBER PATH '$.e')));
```

```
OUTER_VALUE_0 OUTER_VALUE_1 NESTED_VALUE_0 NESTED_VALUE_1
------------- ------------- -------------- --------------
100           200            300            400
```

The following statement uses the `JSON_nested_path` clause when querying the `j_purchaseorder` table. It first applies a row path expression to column `po_document`, which results in a match to the entire context item, or JSON document. It then uses the `COLUMNS` clause to return the `Requestor` value in a `VARCHAR2(32)` column called `requestor`. It then uses the `JSON_nested_path` clause to return the property values of the individual objects in each member of the nested `Phone` array. Note that a row is generated for each member of the nested array, and each row contains the corresponding `Requestor` value.

```
SELECT jt.*
FROM j_purchaseorder,
JSON_TABLE(po_document, '$'
COLUMNS
  (requestor VARCHAR2(32) PATH '.$.Requestor',
   NESTED PATH '.$.ShippingInstructions.Phone[*]'
   COLUMNS (phone_type VARCHAR2(32) PATH '.$.type',
                        phone_num VARCHAR2(20) PATH '.$.number')))
AS jt;
```

```
REQUESTOR            PHONE_TYPE           PHONE_NUM
-------------------- -------------------- ---------------
Alexis Bull          Office               909-555-7307
Alexis Bull          Mobile               415-555-1234
```
Note: The JSON.VALUE function is available starting with Oracle Database 12c Release 1 (12.1.0.2).

Syntax

**JSON_PATH_EXPRESSION::=**

**OBJECT_STEP::=**

**ARRAY_STEP::=**

**JSON_VALUE_RETURNING_CLAUSE::=**
**Purpose**

`JSON_VALUE` finds a specified scalar JSON value in JSON data and returns it as a SQL value.

**expr**

Use this clause to specify the JSON data to be evaluated. For `expr`, specify an expression that evaluates to a text literal. If `expr` is a column, then the column must be of data type `VARCHAR2`, `CLOB`, or `BLOB`. If `expr` is null, then the function returns null.

If `expr` is not a text literal of well-formed JSON data using strict or lax syntax, then the function returns null by default. You can use the `JSON_value_on_error_clause` to override this default behavior. Refer to the `JSON_value_on_error_clause` on page 7-165.

**FORMAT JSON**

You must specify `FORMAT JSON` if `expr` is a column of data type `BLOB`.

**JSON_path_expression**

Use this clause to specify a JSON path expression. The function uses the path expression to evaluate `expr` and find a scalar JSON value that matches, or satisfies, the path expression. The path expression must be a text literal.

The path expression must begin with a dollar sign ($), which represents the context item, that is, the expression specified by `expr`. The dollar sign is followed by zero or more steps, each of which can be an object step or an array step.

The function attempts to match the first step in the path expression to the context item. If the first step results in a match, then the function attempts to match the second step to the JSON value(s) that matched the first step. If the second step results in a match, then the function attempts to match the third step to the JSON value(s) that matched the second step, and so on. If the final step matches a scalar JSON value, then the function returns that value as a SQL value. A path expression that consists of a dollar sign followed by zero steps ("\$") matches the entire context item.

You can specify the `JSON_value_returning_clause` to control the data type and format of the returned SQL value. Refer to the `JSON_value_returning_clause` on page 7-164.

If any step in the path expression does not result in a match, or if the final step matches a nonscalar value, then the function returns null by default. You can use the `JSON_`
value_on_error_clause to override this default behavior. Refer to the JSON_value_on_error_clause on page 7-165.

**object_step** Use this clause to specify an object step.

- Use `simple_name` or `complex_name` to specify a property name. If a member with that property name exists in the JSON object being evaluated, then the object step results in a match to the property value of that member. Otherwise, the object step does not result in a match. Both types of names are case-sensitive. Therefore, a match will result only if the alphabetic character cases match in the object step and the JSON data.

  A `simple_name` can contain only alphanumeric characters and must begin with an alphabetic character. A `complex_name` can contain only alphanumeric characters and spaces, and must begin with an alphanumeric character. A `complex_name` must be enclosed in double quotation marks.

- Use the asterisk wildcard symbol (*) to specify all property names. If the JSON object being evaluated contains at least one member, then the object step results in a match to the values of all members. Otherwise, the object step does not result in a match.

If you apply an object step to a JSON array, then the array is implicitly unwrapped and the elements of the array are evaluated using the object step. This is called JSON path expression relaxation. Refer to Oracle XML DB Developer’s Guide for more information.

If the JSON value being evaluated is not a JSON object, then the object step does not result in a match.

**array_step** Use this clause to specify an array step.

- Use `integer` to specify the element at index `integer` in a JSON array. Use `integer TO integer` to specify the range of elements between the two index `integer` values, inclusive. If the specified elements exist in the JSON array being evaluated, then the array step results in a match to those elements. Otherwise, the array step does not result in a match. The first element in a JSON array has index 0.

- Use the asterisk wildcard symbol (*) to specify all elements in a JSON array. If the JSON array being evaluated contains at least one element, then the array step results in a match to all elements in the JSON array. Otherwise, the array step does not result in a match.

If the JSON data being evaluated is not a JSON array, then the data is implicitly wrapped in an array and then evaluated using the array step. This is called JSON path expression relaxation. Refer to Oracle XML DB Developer’s Guide for more information.

**JSON_value_returning_clause**

Use this clause to specify the data type and format of the value returned by this function.

**RETURNING** Use the RETURNING clause to specify the data type of the return value. If you omit this clause, then JSON_VALUE returns a value of type VARCHAR2(4000).

You can use JSON_value_return_type to specify the following data types:

- `VARCHAR2[size [BYTE,CHAR]]`

  If you specify this data type, then the scalar value returned by this function can be a character or number value. A number value will be implicitly converted to a VARCHAR2. When specifying the VARCHAR2 data type elsewhere in SQL, you are
required to specify a size. However, in this clause you can omit the size. In this case, JSON_VALUE returns a value of type VARCHAR2 (4000).

Refer to "VARCHAR2 Data Type" on page 2-10 for more information.

- **NUMBER[(precision [, scale])]**
  
  If you specify this data type, then the scalar value returned by this function must be a number value.
  
  Refer to "NUMBER Data Type" on page 2-12 for more information.

If the data type is not large enough to hold the return value, then this function returns null by default. You can use the JSON_value_on_error_clause to override this default behavior. Refer to the JSON_value_on_error_clause on page 7-165.

ASCII  Specify ASCII to automatically escape any non-ASCII Unicode characters in the return value, using standard ASCII Unicode escape sequences.

**JSON_value_on_error_clause**

Use this clause to specify the value returned by this function when any of the following errors occur:

- expr is not well-formed JSON data using strict or lax JSON syntax
- A nonscalar value or no match is found when the JSON data is evaluated using the JSON path expression
- The return value data type is not large enough to hold the return value

You can specify the following clauses:

- **NULL ON ERROR** - Returns null when an error occurs. This is the default.
- **ERROR ON ERROR** - Returns the appropriate Oracle error when an error occurs.
- **DEFAULT literal ON ERROR** - Returns literal when an error occurs. If the data type of the value returned by this function is VARCHAR2, then you must specify a text literal. If the data type is NUMBER, then you must specify a numeric literal.

**Examples**

The following query returns the value of the member with property name a. Because the RETURNING clause is not specified, the value is returned as a VARCHAR2 (4000) data type:

```
SELECT JSON_VALUE('{a:100}', '$.a') AS value
FROM DUAL;
```

```
VALUE
------
100
```

The following query returns the value of the member with property name a. Because the RETURNING NUMBER clause is specified, the value is returned as a NUMBER data type:

```
SELECT JSON_VALUE('{a:100}', '$.a' RETURNING NUMBER) AS value
FROM DUAL;
```

```
VALUE
-------
100
```
The following query returns the value of the member with property name \( b \), which is in the value of the member with property name \( a \):

```sql
SELECT JSON_VALUE('{a:{b:100}}', '$.a.b') AS value
FROM DUAL;
```

```
VALUE
-----
100
```

The following query returns the value of the member with property name \( d \) in any object:

```sql
SELECT JSON_VALUE('{a:{b:100}, c:{d:200}, e:{f:300}}', '$.*.d') AS value
FROM DUAL;
```

```
VALUE
-----
200
```

The following query returns the value of the first element in an array:

```sql
SELECT JSON_VALUE('[0, 1, 2, 3]', '$[0]') AS value
FROM DUAL;
```

```
VALUE
-----
0
```

The following query returns the value of the third element in an array. The array is the value of the member with property name \( a \):

```sql
SELECT JSON_VALUE('{a:[5, 10, 15, 20]}', '$.a[2]') AS value
FROM DUAL;
```

```
VALUE
-----
15
```

The following query returns the value of the member with property name \( a \) in the second object in an array:

```sql
SELECT JSON_VALUE('[[a:100], {a:200}, {a:300}]', '${1}.a') AS value
FROM DUAL;
```

```
VALUE
-----
200
```

The following query returns the value of the member with property name \( c \) in any object in an array:

```sql
SELECT JSON_VALUE('[[a:100], {b:200}, {c:300}]', '${*}.c') AS value
FROM DUAL;
```

```
VALUE
-----
300
```

The following query attempts to return the value of the member that has property name \( lastname \). However, such a member does not exist in the specified JSON data,
resulting in no match. Because the ON ERROR clause is not specified, the statement uses the default NULL ON ERROR and returns null.

```sql
SELECT JSON_VALUE('{firstname:"John"}', '$.lastname') AS "Last Name"
FROM DUAL;
```

```
Last Name
---------

No last name found
```

The following query results in an error because it attempts to return the value of the member with property name lastname, which does not exist in the specified JSON. Because the ON ERROR clause is specified, the statement returns the specified text literal.

```sql
SELECT JSON_VALUE('{firstname:"John"}', '$.lastname'
                    DEFAULT 'No last name found' ON ERROR) AS "Last Name"
FROM DUAL;
```

```
Last Name
---------

No last name found
```
LAG

Syntax

\[
\text{LAG} \left( \text{value_expr}, \text{offset}, \text{default} \right) \text{ OVER} \left( \text{query_partition_clause ORDER BY clause} \right)
\]

Purpose

LAG is an analytic function. It provides access to more than one row of a table at the same time without a self join. Given a series of rows returned from a query and a position of the cursor, LAG provides access to a row at a given physical offset prior to that position.

For the optional offset argument, specify an integer that is greater than zero. If you do not specify offset, then its default is 1. The optional default value is returned if the offset goes beyond the scope of the window. If you do not specify default, then its default is null.

\{RESPECT | IGNORE\} NULLS determines whether null values of value_expr are included in or eliminated from the calculation. The default is RESPECT NULLS.

You cannot nest analytic functions by using LAG or any other analytic function for value_expr. However, you can use other built-in function expressions for value_expr.

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions, including valid forms of value_expr

See Also: "About SQL Expressions" on page 5-1 for information on valid forms of expr and LEAD on page 7-175

Examples

The following example provides, for each purchasing clerk in the employees table, the salary of the employee hired just before:

```
SELECT hire_date, last_name, salary,
       LAG(salary, 1, 0) OVER (ORDER BY hire_date) AS prev_sal
FROM employees
WHERE job_id = 'PU_CLERK'
ORDER BY hire_date;
```

<table>
<thead>
<tr>
<th>HIRE_DATE</th>
<th>LAST_NAME</th>
<th>SALARY</th>
<th>PREV_SAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>18-MAY-03</td>
<td>Khoo</td>
<td>3100</td>
<td>0</td>
</tr>
<tr>
<td>24-JUL-05</td>
<td>Tobias</td>
<td>2800</td>
<td>3100</td>
</tr>
<tr>
<td>24-DEC-05</td>
<td>Baida</td>
<td>2900</td>
<td>2800</td>
</tr>
<tr>
<td>15-NOV-06</td>
<td>Himuro</td>
<td>2600</td>
<td>2900</td>
</tr>
<tr>
<td>Date</td>
<td>Customer</td>
<td>Quantity 1</td>
<td>Quantity 2</td>
</tr>
<tr>
<td>------------</td>
<td>--------------</td>
<td>------------</td>
<td>------------</td>
</tr>
<tr>
<td>10-AUG-07</td>
<td>Colmenares</td>
<td>2500</td>
<td>2600</td>
</tr>
</tbody>
</table>
LAST

Syntax

\[
\text{last}: =
\]

\[
\begin{align*}
&\text{aggregate\_function} & \text{KEEP} \\
&\text{DENSE\_RANK} & \text{LAST} & \text{ORDER} & \text{BY} & \text{expr} & \text{DESC} & \text{ASC} & \text{NULLS} & \text{FIRST} & \text{LAST} \\
&\text{OVER} & \text{query\_partition\_clause}
\end{align*}
\]

See Also:  "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions of the query_partitioning_clause

Purpose

FIRST and LAST are very similar functions. Both are aggregate and analytic functions that operate on a set of values from a set of rows that rank as the FIRST or LAST with respect to a given sorting specification. If only one row ranks as FIRST or LAST, then the aggregate operates on the set with only one element.

Refer to FIRST on page 7-121 for complete information on this function and for examples of its use.
LAST_DAY

Syntax

```
LAST_DAY(date)
```

Purpose

LAST_DAY returns the date of the last day of the month that contains `date`. The last day of the month is defined by the session parameter `NLS_CALENDAR`. The return type is always `DATE`, regardless of the data type of `date`.

Examples

The following statement determines how many days are left in the current month.

```sql
SELECT SYSDATE,
       LAST_DAY(SYSDATE) "Last",
       LAST_DAY(SYSDATE) - SYSDATE "Days Left"
FROM DUAL;
```

```
SYSDATE Last Days Left
--------- --------- ----------
30-MAY-09 31-MAY-09          1
```

The following example adds 5 months to the hire date of each employee to give an evaluation date:

```sql
SELECT last_name, hire_date,
       TO_CHAR(ADD_MONTHS(LAST_DAY(hire_date), 5)) "Eval Date"
FROM employees
ORDER BY last_name, hire_date;
```

```
LAST_NAME                 HIRE_DATE Eval Date
------------------------- --------- ---------
Abel                      11-MAY-04 31-OCT-04
Ande                      24-MAR-08 31-AUG-08
Atkinson                  30-OCT-05 31-MAR-06
Austin                    25-JUN-05 30-NOV-05
Baer                      07-JUN-02 30-NOV-02
Baida                     24-DEC-05 31-MAY-06
Banda                     21-APR-08 30-SEP-08
Bates                     24-MAR-07 31-AUG-07
. . .
LAST_VALUE

Syntax

LAST_VALUE(expr) RESPECT | IGNORE NULLS

OVER (analytic_clause)

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions, including valid forms of expr.

Purpose

LAST_VALUE is an analytic function that is useful for data densification. It returns the last value in an ordered set of values.

Note: The two forms of this syntax have the same behavior. The top branch is the ANSI format, which Oracle recommends for ANSI compatibility.

{RESPECT | IGNORE} NULLS determines whether null values of expr are included in or eliminated from the calculation. The default is RESPECT NULLS. If the last value in the set is null, then the function returns NULL unless you specify IGNORE NULLS. If you specify IGNORE NULLS, then LAST_VALUE returns the last non-null value in the set, or NULL if all values are null. Refer to "Using Partitioned Outer Joins: Examples" on page 19-71 for an example of data densification.

You cannot nest analytic functions by using LAST_VALUE or any other analytic function for expr. However, you can use other built-in function expressions for expr. Refer to "About SQL Expressions" on page 5-1 for information on valid forms of expr.

If you omit the windowing_clause of the analytic_clause, it defaults to RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW. This default sometimes returns an unexpected value, because the last value in the window is at the bottom of the window, which is not fixed. It keeps changing as the current row changes. For expected results, specify the windowing_clause as RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING. Alternatively, you can specify the windowing_clause as RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING.

Examples

The following example returns, for each row, the hire date of the employee earning the lowest salary:

```
SELECT employee_id, last_name, salary, hire_date,
    LAST_VALUE(hire_date)
OVER (ORDER BY salary DESC ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS lv
FROM (SELECT * FROM employees
WHERE department_id = 90
```
This example illustrates the nondeterministic nature of the `LAST_VALUE` function. Kochhar and De Haan have the same salary, so they are in adjacent rows. Kochhar appears first because the rows in the subquery are ordered by `hire_date`. However, if the rows are ordered by `hire_date` in descending order, as in the next example, then the function returns a different value:

```sql
SELECT employee_id, last_name, salary, hire_date,
       LAST_VALUE(hire_date)
OVER (ORDER BY salary DESC ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS lv
FROM (SELECT * FROM employees
      WHERE department_id = 90
      ORDER BY hire_date DESC);
```

The following two examples show how to make the `LAST_VALUE` function deterministic by ordering on a unique key. By ordering within the function by both `salary` and the unique key `employee_id`, you can ensure the same result regardless of the ordering in the subquery.

```sql
SELECT employee_id, last_name, salary, hire_date,
       LAST_VALUE(hire_date)
OVER (ORDER BY salary DESC, employee_id ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS lv
FROM (SELECT * FROM employees
      WHERE department_id = 90
      ORDER BY hire_date);
```

```sql
SELECT employee_id, last_name, salary, hire_date,
       LAST_VALUE(hire_date)
OVER (ORDER BY salary DESC, employee_id ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS lv
FROM (SELECT * FROM employees
      WHERE department_id = 90
      ORDER BY hire_date DESC);
```
The following two examples show that the \texttt{LAST_VALUE} function is deterministic when you use a logical offset (\texttt{RANGE} instead of \texttt{ROWS}). When duplicates are found for the \texttt{ORDER BY} expression, the \texttt{LAST_VALUE} is the highest value of \texttt{expr}:

\begin{verbatim}
SELECT employee_id, last_name, salary, hire_date,
      \texttt{LAST_VALUE(hire_date)}
OVER (ORDER BY salary DESC
      \texttt{RANGE} BETWEEN UNBOUNDED PRECEDING AND
      UNBOUNDED FOLLOWING) AS \texttt{lv}
FROM (SELECT * FROM employees
      WHERE department_id = 90
      ORDER BY hire_date);
\end{verbatim}

\begin{tabular}{lllll}
 EMPLOYEE_ID & LAST_NAME     & SALARY & HIRE_DATE & LV    \\
------------- & -------------- & ------- & ---------- & ----- \\
 100 King     & --------------- & 24000   & 17-JUN-03 & 21-SEP-05 \\
 102 De Haan  & 17000          & 13-JAN-01 & 21-SEP-05 & \\
 101 Kochhar  & 17000          & 21-SEP-05 & 21-SEP-05 & \\
\end{tabular}

\begin{verbatim}
SELECT employee_id, last_name, salary, hire_date,
      \texttt{LAST_VALUE(hire_date)}
OVER (ORDER BY salary DESC
      \texttt{RANGE} BETWEEN UNBOUNDED PRECEDING AND
      UNBOUNDED FOLLOWING) AS \texttt{lv}
FROM (SELECT * FROM employees
      WHERE department_id = 90
      ORDER BY hire_date \texttt{DESC});
\end{verbatim}

\begin{tabular}{lllll}
 EMPLOYEE_ID & LAST_NAME     & SALARY & HIRE_DATE & LV    \\
------------- & -------------- & ------- & ---------- & ----- \\
 100 King     & --------------- & 24000   & 17-JUN-03 & 21-SEP-05 \\
 102 De Haan  & 17000          & 13-JAN-01 & 21-SEP-05 & \\
 101 Kochhar  & 17000          & 21-SEP-05 & 21-SEP-05 & \\
\end{tabular}
LEAD

Syntax

\[
\text{LEAD} \left( \text{valueExpr}, \text{offset}, \text{default} \right) \text{ OVER (query_partition_clause order_by_clause)}
\]

**Purpose**

LEAD is an analytic function. It provides access to more than one row of a table at the same time without a self join. Given a series of rows returned from a query and a position of the cursor, LEAD provides access to a row at a given physical offset beyond that position.

If you do not specify `offset`, then its default is 1. The optional `default` value is returned if the offset goes beyond the scope of the table. If you do not specify `default`, then its default value is null.

\{RESPECT | IGNORE\} NULLS determines whether null values of `valueExpr` are included in or eliminated from the calculation. The default is RESPECT NULLS.

You cannot nest analytic functions by using LEAD or any other analytic function for `valueExpr`. However, you can use other built-in function expressions for `valueExpr`.

**Examples**

The following example provides, for each employee in Department 30 in the employees table, the hire date of the employee hired just after:

```
SELECT hire_date, last_name,
    LEAD(hire_date, 1) OVER (ORDER BY hire_date) AS "NextHired"
FROM employees
WHERE department_id = 30
ORDER BY hire_date;
```

<table>
<thead>
<tr>
<th>HIRE_DATE</th>
<th>LAST_NAME</th>
<th>Next Hired</th>
</tr>
</thead>
<tbody>
<tr>
<td>07-DEC-02</td>
<td>Raphaely</td>
<td>18-MAY-03</td>
</tr>
<tr>
<td>18-MAY-03</td>
<td>Khoo</td>
<td>24-JUL-05</td>
</tr>
<tr>
<td>24-JUL-05</td>
<td>Tobias</td>
<td>24-DEC-05</td>
</tr>
<tr>
<td>24-DEC-05</td>
<td>Baida</td>
<td>15-NOV-06</td>
</tr>
<tr>
<td>15-NOV-06</td>
<td>Himuro</td>
<td>10-AUG-07</td>
</tr>
</tbody>
</table>

**See Also:** [“Analytic Functions”](#) on page 7-12 for information on syntax, semantics, and restrictions, including valid forms of `valueExpr`.

**See Also:** [“About SQL Expressions”](#) on page 5-1 for information on valid forms of `expr` and LAG on page 7-168.
LEAST

Syntax

\[
\text{LEAST}(\text{expr}_1, \text{expr}_2, \ldots, \text{expr}_n)
\]

Purpose

LEAST returns the least of a list of one or more expressions. Oracle Database uses the first \text{expr} to determine the return type. If the first \text{expr} is numeric, then Oracle determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type before the comparison, and returns that data type. If the first \text{expr} is not numeric, then each \text{expr} after the first is implicitly converted to the data type of the first \text{expr} before the comparison.

Oracle Database compares each \text{expr} using nonpadded comparison semantics. The comparison is binary by default and is linguistic if the \text{NLS_COMP} parameter is set to \text{LINGUISTIC} and the \text{NLS_SORT} parameter has a setting other than \text{BINARY}. Character comparison is based on the numerical codes of the characters in the database character set and is performed on whole strings treated as one sequence of bytes, rather than character by character. If the value returned by this function is character data, then its data type is VARCHAR2 if the first \text{expr} is a character data type and NVARCHAR2 if the first \text{expr} is a national character data type.

See Also:

- "Data Type Comparison Rules" on page 2-39 for more information on character comparison
- Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and "Floating-Point Numbers" on page 2-15 for information on binary-float comparison semantics
- "GREATEST" on page 7-128, which returns the greatest of a list of one or more expressions

Examples

The following statement selects the string with the least value:

```sql
SELECT LEAST('HARRY', 'HARRIOT', 'HAROLD') "Least"
FROM DUAL;

Least
------
HAROLD
```

In the following statement, the first argument is numeric. Oracle Database determines that the argument with the highest numeric precedence is the third argument, converts the remaining arguments to the data type of the third argument, and returns the least value as that data type:

```sql
SELECT LEAST (1, '2.1', '.000832') "Least"
FROM DUAL;

Least
```
**LENGTH**

**Syntax**

\[
\text{length} ::= \\
\text{LENGTH} \\
\text{LENGTHB} \\
\text{LENGTHC} \\
\text{LENGTH2} \\
\text{LENGTH4}
\]

**Purpose**

The `LENGTH` functions return the length of `char`. `LENGTH` calculates length using characters as defined by the input character set. `LENGTHB` uses bytes instead of characters. `LENGTHC` uses Unicode complete characters. `LENGTH2` uses UCS2 code points. `LENGTH4` uses UCS4 code points.

`char` can be any of the data types `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, `CLOB`, or `NCLOB`. The exceptions are `LENGTHC`, `LENGTH2`, and `LENGTH4`, which do not allow `char` to be a `CLOB` or `NCLOB`. The return value is of data type `NUMBER`. If `char` has data type `CHAR`, then the length includes all trailing blanks. If `char` is null, then this function returns null.

**Restriction on LENGTHB** The `LENGTHB` function is supported for single-byte LOBs only. It cannot be used with `CLOB` and `NCLOB` data in a multibyte character set.

**Examples**

The following example uses the `LENGTH` function using a single-byte database character set:

```sql
SELECT LENGTH('CANDIDE') "Length in characters"
FROM DUAL;
```

Length in characters
---------------------
7

The next example assumes a double-byte database character set.

```sql
SELECT LENGTHB ('CANDIDE') "Length in bytes"
FROM DUAL;
```

Length in bytes
----------------
14
LISTAGG

Syntax

\[
\text{LISTAGG} \quad \text{measure\_expr} \quad \text{delimiter} \quad \text{WITHIN} \quad \text{GROUP} \quad \text{order\_by\_clause} \quad \text{OVER} \quad \text{query\_partition\_clause}
\]

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions of the ORDER BY clause and OVER clause

Purpose

For a specified measure, LISTAGG orders data within each group specified in the ORDER BY clause and then concatenates the values of the measure column.

- As a single-set aggregate function, LISTAGG operates on all rows and returns a single output row.
- As a group-set aggregate, the function operates on and returns an output row for each group defined by the GROUP BY clause.
- As an analytic function, LISTAGG partitions the query result set into groups based on one or more expression in the query_partition_clause.

The arguments to the function are subject to the following rules:

- The measure_expr can be any expression. Null values in the measure column are ignored.
- The delimiter_expr designates the string that is to separate the measure values. This clause is optional and defaults to NULL.
- The order_by_clause determines the order in which the concatenated values are returned. The function is deterministic only if the ORDER BY column list achieved unique ordering.

The return data type is RAW if the measure column is RAW; otherwise the return value is VARCHAR2.

Aggregate Examples

The following single-set aggregate example lists all of the employees in Department 30 in the hr.employees table, ordered by hire date and last name:

```sql
SELECT LISTAGG(last_name, '; ') WITHIN GROUP (ORDER BY hire_date, last_name) "Emp_list",
       MIN(hire_date) 'Earliest'
FROM employees
WHERE department_id = 30;
```

<table>
<thead>
<tr>
<th>Emp_list</th>
<th>Earliest</th>
</tr>
</thead>
<tbody>
<tr>
<td>Raphaely; Khoo; Tobias; Baida; Himuro; Colmenares</td>
<td>07-DEC-02</td>
</tr>
</tbody>
</table>

The following group-set aggregate example lists, for each department ID in the hr.employees table, the employees in that department in order of their hire date:
SELECT department_id "Dept.",
    LISTAGG(last_name, '; ') WITHIN GROUP (ORDER BY hire_date) "Employees"
FROM employees
GROUP BY department_id
ORDER BY department_id;

Dept. Employees
--- -------------------------------------------------------------
10 Whalen
20 Hartstein; Fay
30 Raphaely; Khoo; Tobias; Baida; Himuro; Colmenares
40 Mavris
50 Kaufling; Ladwig; Rajs; Sarchand; Bell; Mallin; Weiss; Davie;
    Marlow; Bull; Everett; Fripp; Chung; Nayer; Dilly; Bissot;
    Vollman; Stiles; Atkinson; Taylor; Seo; Pleaur; Matos; Pat;
    el; Walsh; Feeney; Dellinger; McCain; Vargas; Gates; Rogers;
    Mikkileni; Landry; Cabrio; Jones; Olson; O'Connell; Sullivan;
    an; Mourgos; Gee; Perkins; Grant; Geoni; Philtanker; Markle
60 Austin; Hunold; Pataballa; Lorentz; Ernst
70 Baer
...

Analytic Example
The following analytic example shows, for each employee hired earlier than
September 1, 2003, the employee's department, hire date, and all other employees in
that department also hired before September 1, 2003:

SELECT department_id "Dept", hire_date "Date", last_name "Name",
    LISTAGG(last_name, '; ') OVER (PARTITION BY department_id) as "Emp_list"
FROM employees
WHERE hire_date < '01-SEP-2003'
ORDER BY "Dept", "Date", "Name";

Dept Date Name Emp_list
----- --------- --------------- ---------------------------------------------
30 07-DEC-02 Raphaely Raphaely; Khoo
30 08-MAY-03 Khoo Raphaely; Khoo
40 07-JUN-02 Mavris Mavris
50 01-MAY-03 Kaufling Kaufling; Ladwig
50 14-JUL-03 Ladwig Kaufling; Ladwig
70 07-JUN-02 Baer Baer
90 13-JAN-01 De Haan De Haan; King
90 17-JUN-03 King De Haan; King
100 16-AUG-02 Faviet Faviet; Greenberg
100 17-AUG-02 Greenberg Faviet; Greenberg
110 07-JUN-02 Gietz Gietz; Higgins
110 07-JUN-02 Higgins Gietz; Higgins
LN

Syntax

\[ \text{LN}(n) \]

Purpose

LN returns the natural logarithm of \( n \), where \( n \) is greater than 0.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If the argument is BINARY_FLOAT, then the function returns BINARY_DOUBLE. Otherwise the function returns the same numeric data type as the argument.

See Also:  Table 2–10, ”Implicit Type Conversion Matrix” on page 2-43 for more information on implicit conversion

Examples

The following example returns the natural logarithm of 95:

```sql
SELECT LN(95) "Natural log of 95"
FROM DUAL;
```

<table>
<thead>
<tr>
<th>Natural log of 95</th>
</tr>
</thead>
<tbody>
<tr>
<td>4.55387689</td>
</tr>
</tbody>
</table>
**Syntax**

```
LNNVL(condition)
```

**Purpose**

`LNNVL` provides a concise way to evaluate a condition when one or both operands of the condition may be null. The function can be used in the `WHERE` clause of a query, or as the `WHEN` condition in a searched `CASE` expression. It takes as an argument a condition and returns `TRUE` if the condition is `FALSE` or `UNKNOWN` and `FALSE` if the condition is `TRUE`. `LNNVL` can be used anywhere a scalar expression can appear, even in contexts where the `IS [NOT] NULL`, `AND`, or `OR` conditions are not valid but would otherwise be required to account for potential nulls.

Oracle Database sometimes uses the `LNNVL` function internally in this way to rewrite `NOT IN` conditions as `NOT EXISTS` conditions. In such cases, output from EXPLAIN PLAN shows this operation in the plan table output. The `condition` can evaluate any scalar values but cannot be a compound condition containing `AND`, `OR`, or `BETWEEN`.

The table that follows shows what `LNNVL` returns given that `a = 2` and `b` is null.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Truth of Condition</th>
<th>LNNVL Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a = 1</code></td>
<td><code>FALSE</code></td>
<td><code>TRUE</code></td>
</tr>
<tr>
<td><code>a = 2</code></td>
<td><code>TRUE</code></td>
<td><code>FALSE</code></td>
</tr>
<tr>
<td><code>a IS NULL</code></td>
<td><code>FALSE</code></td>
<td><code>TRUE</code></td>
</tr>
<tr>
<td><code>b = 1</code></td>
<td><code>UNKNOWN</code></td>
<td><code>TRUE</code></td>
</tr>
<tr>
<td><code>b IS NULL</code></td>
<td><code>TRUE</code></td>
<td><code>FALSE</code></td>
</tr>
<tr>
<td><code>a = b</code></td>
<td><code>UNKNOWN</code></td>
<td><code>TRUE</code></td>
</tr>
</tbody>
</table>

**Examples**

Suppose that you want to know the number of employees with commission rates of less than 20%, including employees who do not receive commissions. The following query returns only employees who actually receive a commission of less than 20%:

```sql
SELECT COUNT(*)
  FROM employees
  WHERE commission_pct < .2;
```

```
COUNT(*)
----------
  11
```

To include the 72 employees who receive no commission at all, you could rewrite the query using the `LNNVL` function as follows:

```sql
SELECT COUNT(*)
  FROM employees
  WHERE LNNVL(commission_pct >= .2);
```

```
COUNT(*)
----------
  83
```
LOCALTIMESTAMP

Syntax

```
LOCALTIMESTAMP [ ( timestamp_precision ) ]
```

Purpose

LOCALTIMESTAMP returns the current date and time in the session time zone in a value of data type TIMESTAMP. The difference between this function and CURRENT_TIMESTAMP is that LOCALTIMESTAMP returns a TIMESTAMP value while CURRENT_TIMESTAMP returns a TIMESTAMP WITH TIME ZONE value.

The optional argument `timestamp_precision` specifies the fractional second precision of the time value returned.

See Also: CURRENT_TIMESTAMP on page 7-86, "TIMESTAMP Data Type" on page 2-20, and "TIMESTAMP WITH TIME ZONE Data Type" on page 2-20

Examples

This example illustrates the difference between LOCALTIMESTAMP and CURRENT_TIMESTAMP:

```
ALTER SESSION SET TIME_ZONE = '-5:00';
SELECT CURRENT_TIMESTAMP, LOCALTIMESTAMP FROM DUAL;

CURRENT_TIMESTAMP                    LOCALTIMESTAMP
-----------------------------------  ------------------------------
04-APR-00 01.27.18.999220 PM -05:00  04-APR-00 01.27.19 PM

ALTER SESSION SET TIME_ZONE = '-8:00';
SELECT CURRENT_TIMESTAMP, LOCALTIMESTAMP FROM DUAL;

CURRENT_TIMESTAMP                    LOCALTIMESTAMP
-----------------------------------  ------------------------------
04-APR-00 10.27.45.132474 AM -08:00  04-APR-00 10.27.451 AM
```

When you use the LOCALTIMESTAMP with a format mask, take care that the format mask matches the value returned by the function. For example, consider the following table:

```
CREATE TABLE local_test (col1 TIMESTAMP WITH LOCAL TIME ZONE);
```

The following statement fails because the mask does not include the TIME ZONE portion of the return type of the function:

```
INSERT INTO local_test
VALUES (TO_TIMESTAMP(LOCALTIMESTAMP, 'DD-MON-RR HH.MI.SSXFF'));
```

The following statement uses the correct format mask to match the return type of LOCALTIMESTAMP:

```
INSERT INTO local_test
VALUES (TO_TIMESTAMP(LOCALTIMESTAMP, 'DD-MON-RR HH.MI.SSXFF PM'));
```
LOG

Syntax

\[ \text{LOG}(n_2, n_1) \]

Purpose

\text{LOG} returns the logarithm, base } n_2, \text{ of } n_1. \text{ The base } n_2 \text{ can be any positive value other than 0 or 1 and } n_1 \text{ can be any positive value.}

This function takes as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If any argument is \text{BINARY_FLOAT} or \text{BINARY_DOUBLE}, then the function returns \text{BINARY_DOUBLE}. Otherwise the function returns \text{NUMBER}.

\textbf{See Also:} \hspace{1em} \text{Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion}

Examples

The following example returns the log of 100:

\begin{verbatim}
SELECT LOG(10,100) "Log base 10 of 100"
  FROM DUAL;
\end{verbatim}

\begin{verbatim}
Log base 10 of 100
------------------
2
\end{verbatim}
LOWER

Syntax

\[ \text{LOWER}(\text{char}) \]

Purpose

\text{LOWER} returns \text{char}, with all letters lowercase. \text{char} can be any of the data types \text{CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB}. The return value is the same data type as \text{char}. The database sets the case of the characters based on the binary mapping defined for the underlying character set. For linguistic-sensitive lowercase, refer to \text{NLS_LOWER} on page 7-206.

Examples

The following example returns a string in lowercase:

\[
\begin{align*}
\text{SELECT LOWER('MR. SCOTT McMILLAN')} & \quad \text{'Lowercase'} \\
& \text{FROM DUAL;}
\end{align*}
\]

\[
\begin{align*}
\text{Lowercase} \\
\text{-------------------} \\
\text{mr. scott mcmillan}
\end{align*}
\]
LPAD

Syntax

```
LPAD(expr1, n, expr2)
```

Purpose

LPAD returns `expr1`, left-padded to length `n` characters with the sequence of characters in `expr2`. This function is useful for formatting the output of a query.

Both `expr1` and `expr2` can be any of the data types `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, `CLOB`, or `NCLOB`. The string returned is of `VARCHAR2` data type if `expr1` is a character data type, `NVARCHAR2` if `expr1` is a national character data type, and a LOB if `expr1` is a LOB data type. The string returned is in the same character set as `expr1`. The argument `n` must be a `NUMBER` integer or a value that can be implicitly converted to a `NUMBER` integer.

If you do not specify `expr2`, then the default is a single blank. If `expr1` is longer than `n`, then this function returns the portion of `expr1` that fits in `n`.

The argument `n` is the total length of the return value as it is displayed on your terminal screen. In most character sets, this is also the number of characters in the return value. However, in some multibyte character sets, the display length of a character string can differ from the number of characters in the string.

Examples

The following example left-pads a string with the asterisk (*) and period (.) characters:

```
SELECT LPAD('Page 1',15,'*.') "LPAD example"
FROM DUAL;
```

```
LPAD example
---------------
*.*.*.*.Page 1
```
**LTRIM**

**Syntax**

\[
\text{LTRIM}\left(\text{char}, \text{set}\right)
\]

**Purpose**

LTRIM removes from the left end of char all of the characters contained in set. If you do not specify set, then it defaults to a single blank. Oracle Database begins scanning char from its first character and removes all characters that appear in set until reaching a character not in set and then returns the result.

Both char and set can be any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB. The string returned is of VARCHAR2 data type if char is a character data type, NVARCHAR2 if char is a national character data type, and a LOB if char is a LOB data type.

**See Also:**  RTRIM on page 7-294

**Examples**

The following example trims all the left-most occurrences of less than sign (<), greater than sign (>), and equal sign (=) from a string:

```
SELECT LTRIM('<======BROWNING======>', '<=>=') "LTRIM Example"
  FROM DUAL;
```

LTRIM Example
-------------
BROWNING<====>
MAKE_REF

Syntax

```
MAKE_REF (table view, key)
```

Purpose

MAKE_REF creates a REF to a row of an object view or a row in an object table whose object identifier is primary key based. This function is useful, for example, if you are creating an object view.

See Also: Oracle Database Object-Relational Developer’s Guide for more information about object views and DEREF on page 7-100

Examples

The sample schema oe contains an object view oc_inventories based on inventory_typ. The object identifier is product_id. The following example creates a REF to the row in the oc_inventories object view with a product_id of 3003:

```
SELECT MAKE_REF (oc_inventories, 3003)
FROM DUAL;
```

```
MAKE_REF(OC_INVENTORIES,3003)
```

```
00004A038A0046857C14617141109EE0340800208254360000014260100010001
00290090606002A00078401FE0000000B03C21F04000000000000000000000000
0000000000
```
MAX

Syntax

```
MAX(expr) [DISTINCT | ALL] OVER (analytic_clause)
```

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

MAX returns maximum value of `expr`. You can use it as an aggregate or analytic function.

See Also: "About SQL Expressions" on page 5-1 for information on valid forms of `expr`, "Floating-Point Numbers" on page 2-15 for information on binary-float comparison semantics, and "Aggregate Functions" on page 7-10

Aggregate Example

The following example determines the highest salary in the `hr.employees` table:

```
SELECT MAX(salary) "Maximum"
FROM employees;
```

```
Maximum
----------
24000
```

Analytic Examples

The following example calculates, for each employee, the highest salary of the employees reporting to the same manager as the employee.

```
SELECT manager_id, last_name, salary,
      MAX(salary) OVER (PARTITION BY manager_id) AS mgr_max
FROM employees
ORDER BY manager_id, last_name, salary;
```

```
MANAGER_ID LAST_NAME                     SALARY    MGR_MAX
---------- ------------------------- ---------- ----------
100 Cambrault                      11000      17000
100 De Haan                        17000      17000
100 Errazuriz                      12000      17000
100 Fripp                           8200      17000
100 Hartstein                      13000      17000
100 Kaufling                        7900      17000
100 Kochhar                        17000      17000
....
```

If you enclose this query in the parent query with a predicate, then you can determine the employee who makes the highest salary in each department:

```
SELECT manager_id, last_name, salary
FROM (SELECT manager_id, last_name, salary,
```
MAX(salary) OVER (PARTITION BY manager_id) AS rmax_sal
FROM employees)
WHERE salary = rmax_sal
ORDER BY manager_id, last_name, salary;

<table>
<thead>
<tr>
<th>MANAGER_ID</th>

<td>8300</td>
</tr>
<tr>
<td>King</td>
<td></td>
<td>24000</td>
</tr>
</tbody>
</table>
```

22 rows selected.
**Syntax**

```sql
MEDIAN(expr) OVER(query_partition_clause)
```

**Purpose**

`MEDIAN` is an inverse distribution function that assumes a continuous distribution model. It takes a numeric or datetime value and returns the middle value or an interpolated value that would be the middle value once the values are sorted. Nulls are ignored in the calculation.

This function takes as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If you specify only `expr`, then the function returns the same data type as the numeric data type of the argument. If you specify the `OVER` clause, then Oracle Database determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

**See Also:** Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and "Numeric Precedence" on page 2-16 for information on numeric precedence

The result of `MEDIAN` is computed by first ordering the rows. Using \( N \) as the number of rows in the group, Oracle calculates the row number \( RN \) of interest with the formula \( RN = (1 + (0.5 \times (N - 1))) \). The final result of the aggregate function is computed by linear interpolation between the values from rows at row numbers \( CRN = \text{CEILING}(RN) \) and \( FRN = \text{FLOOR}(RN) \).

The final result will be:

```sql
if (CRN = FRN = RN) then
  (value of expression from row at RN)
else
  (CRN - RN) * (value of expression for row at FRN) +
  (RN - FRN) * (value of expression for row at CRN)
```

You can use `MEDIAN` as an analytic function. You can specify only the `query_partition_clause` in its `OVER` clause. It returns, for each row, the value that would fall in the middle among a set of values within each partition.

Compare this function with these functions:

- `PERCENTILE_CONT` on page 7-228, which returns, for a given percentile, the value that corresponds to that percentile by way of interpolation. `MEDIAN` is the specific case of `PERCENTILE_CONT` where the percentile value defaults to 0.5.
- `PERCENTILE_DISC` on page 7-231, which is useful for finding values for a given percentile without interpolation.
### Aggregate Example

The following query returns the median salary for each department in the hr.employees table:

```sql
SELECT department_id, MEDIAN(salary)
FROM employees
GROUP BY department_id
ORDER BY department_id;
```

<table>
<thead>
<tr>
<th>DEPARTMENT_ID</th>
<th>MEDIAN(SALARY)</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>4400</td>
</tr>
<tr>
<td>20</td>
<td>9500</td>
</tr>
<tr>
<td>30</td>
<td>2850</td>
</tr>
<tr>
<td>40</td>
<td>6500</td>
</tr>
<tr>
<td>50</td>
<td>3100</td>
</tr>
<tr>
<td>60</td>
<td>4800</td>
</tr>
<tr>
<td>70</td>
<td>10000</td>
</tr>
<tr>
<td>80</td>
<td>8900</td>
</tr>
<tr>
<td>90</td>
<td>17000</td>
</tr>
<tr>
<td>100</td>
<td>8000</td>
</tr>
<tr>
<td>110</td>
<td>10154</td>
</tr>
</tbody>
</table>

### Analytic Example

The following query returns the median salary for each manager in a subset of departments in the hr.employees table:

```sql
SELECT manager_id, employee_id, salary,
    MEDIAN(salary) OVER (PARTITION BY manager_id) "Median by Mgr"
FROM employees
WHERE department_id > 60
ORDER BY manager_id, employee_id;
```

<table>
<thead>
<tr>
<th>MANAGER_ID</th>
<th>EMPLOYEE_ID</th>
<th>SALARY</th>
<th>Median by Mgr</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>101</td>
<td>17000</td>
<td>13500</td>
</tr>
<tr>
<td>100</td>
<td>102</td>
<td>17000</td>
<td>13500</td>
</tr>
<tr>
<td>100</td>
<td>145</td>
<td>14000</td>
<td>13500</td>
</tr>
<tr>
<td>100</td>
<td>146</td>
<td>13500</td>
<td>13500</td>
</tr>
<tr>

<td>8500</td>
</tr>
<tr>
<td>145</td>
<td>151</td>
<td>9500</td>
<td>8500</td>
</tr>
<tr>
<td>145</td>
<td>152</td>
<td>9000</td>
<td>8500</td>
</tr>
</tbody>
</table>

...
MIN

Syntax

\[
\text{MIN} \quad \begin{cases} \\
\text{DISTINCT} \\
\text{ALL} \\
\text{expr} \\
\text{OVER} \quad \text{analytic_clause} \\
\end{cases}
\]

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

MIN returns minimum value of expr. You can use it as an aggregate or analytic function.

See Also: "About SQL Expressions" on page 5-1 for information on valid forms of expr, "Floating-Point Numbers" on page 2-15 for information on binary-float comparison semantics, and "Aggregate Functions" on page 7-10

Aggregate Example

The following statement returns the earliest hire date in the hr.employees table:

```sql
SELECT MIN(hire_date) 'Earliest'
FROM employees;

Earliest
---------
13-JAN-01
```

Analytic Example

The following example determines, for each employee, the employees who were hired on or before the same date as the employee. It then determines the subset of employees reporting to the same manager as the employee, and returns the lowest salary in that subset.

```sql
SELECT manager_id, last_name, hire_date, salary,
       MIN(salary) OVER(PARTITION BY manager_id ORDER BY hire_date
                     RANGE UNBOUNDED PRECEDING) AS p_cmin
FROM employees
ORDER BY manager_id, last_name, hire_date, salary;
```

<table>
<thead>
<tr>
<th>MANAGER_ID</th>
<th>LAST_NAME</th>
<th>HIRE_DATE</th>
<th>SALARY</th>
<th>P_CMIN</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>Cambrault</td>
<td>15-OCT-07</td>
<td>11000</td>
<td>6500</td>
</tr>
<tr>
<td>100</td>

<td>07-DEC-02</td>
<td>11000</td>
<td>11000</td>
</tr>
<tr>
<td>100</td>
<td>Russell</td>
<td>01-OCT-04</td>
<td>14000</td>
<td>7900</td>
</tr>
</tbody>
</table>
MOD

Syntax

\[ \text{MOD}(n2, n1) \]

Purpose

\text{MOD} returns the remainder of \( n2 \) divided by \( n1 \). Returns \( n2 \) if \( n1 \) is 0.

This function takes as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. Oracle determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and "Numeric Precedence" on page 2-16 for information on numeric precedence.

Examples

The following example returns the remainder of 11 divided by 4:

\begin{verbatim}
SELECT MOD(11,4) "Modulus"
FROM DUAL;
\end{verbatim}

\begin{verbatim}
Modulus
----------
3
\end{verbatim}

This function behaves differently from the classical mathematical modulus function when \( m \) is negative. The classical modulus can be expressed using the \text{MOD} function with this formula:

\[ n2 - n1 \times \text{FLOOR}(n2/n1) \]

The following table illustrates the difference between the \text{MOD} function and the classical modulus:

<table>
<thead>
<tr>
<th>n2</th>
<th>n1</th>
<th>MOD(n2,n1)</th>
<th>Classical Modulus</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>4</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>11</td>
<td>-4</td>
<td>3</td>
<td>-1</td>
</tr>
<tr>
<td>-11</td>
<td>4</td>
<td>-3</td>
<td>1</td>
</tr>
<tr>
<td>-11</td>
<td>-4</td>
<td>-3</td>
<td>-3</td>
</tr>
</tbody>
</table>

See Also: \text{FLOOR} on page 7-126 and \text{REMAINDER} on page 7-284, which is similar to \text{MOD}, but uses \text{ROUND} in its formula instead of \text{FLOOR}. 

---

7-196  Oracle Database SQL Language Reference
MONTHS_BETWEEN

Syntax

\[
\text{MONTHS\_BETWEEN}(\text{date1}, \text{date2})
\]

Purpose

MONTHS_BETWEEN returns number of months between dates \text{date1} and \text{date2}. The month and the last day of the month are defined by the parameter NLS_CALENDAR. If \text{date1} is later than \text{date2}, then the result is positive. If \text{date1} is earlier than \text{date2}, then the result is negative. If \text{date1} and \text{date2} are either the same days of the month or both last days of months, then the result is always an integer. Otherwise Oracle Database calculates the fractional portion of the result based on a 31-day month and considers the difference in time components \text{date1} and \text{date2}.

Examples

The following example calculates the months between two dates:

```
SELECT MONTHS_BETWEEN
    (TO_DATE('02-02-1995','MM-DD-YYYY'),
     TO_DATE('01-01-1995','MM-DD-YYYY')) "Months"
FROM DUAL;

Months
--------
1.03225806
```
NANVL

Syntax

```
NANVL(n2, n1)
```

Purpose

The `NANVL` function is useful only for floating-point numbers of type `BINARY_FLOAT` or `BINARY_DOUBLE`. It instructs Oracle Database to return an alternative value `n1` if the input value `n2` is NaN (not a number). If `n2` is not NaN, then Oracle returns `n2`.

This function takes as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. Oracle determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

See Also:  Table 2–10, ”Implicit Type Conversion Matrix” on page 2-43 for more information on implicit conversion, ”Floating-Point Numbers” on page 2-15 for information on binary-float comparison semantics, and ”Numeric Precedence” on page 2-16 for information on numeric precedence

Examples

Using table `float_point_demo` created for `TO_BINARY_DOUBLE` on page 7-354, insert a second entry into the table:

```
INSERT INTO float_point_demo
VALUES (0,'NaN','NaN');
```

```
SELECT *
FROM float_point_demo;
```

```
DEC_NUM BIN_DOUBLE BIN_FLOAT
---------- ---------- ----------
1234.56 1.235E+003 1.235E+003
0 Nan Nan
```

The following example returns `bin_float` if it is a number. Otherwise, 0 is returned.

```
SELECT bin_float, NANVL(bin_float,0)
FROM float_point_demo;
```

```
BIN_FLOAT NANVL(BIN_FLOAT,0)
---------- ---------------
1.235E+003 1.235E+003
Nan 0
```
NCHR

Syntax

```
NCHR(number)
```

Purpose

NCHR returns the character having the binary equivalent to `number` in the national character set. The value returned is always NVARCHAR2. This function is equivalent to using the CHR function with the USING NCHAR_CS clause.

This function takes as an argument a NUMBER value, or any value that can be implicitly converted to NUMBER, and returns a character.

See Also: CHR on page 7-42

Examples

The following examples return the nchar character 187:

```
SELECT NCHR(187)
    FROM DUAL;

N
```

```
SELECT CHR(187 USING NCHAR_CS)
    FROM DUAL;

C
```

NEW_TIME

Syntax

```
NEW_TIME ( date, timezone1, timezone2 )
```

Purpose

`NEW_TIME` returns the date and time in time zone `timezone2` when date and time in time zone `timezone1` are `date`. Before using this function, you must set the `NLS_DATE_FORMAT` parameter to display 24-hour time. The return type is always `DATE`, regardless of the data type of `date`.

**Note:** This function takes as input only a limited number of time zones. You can have access to a much greater number of time zones by combining the `FROM_TZ` function and the datetime expression. See `FROM_TZ` on page 7-127 and the example for "Datetime Expressions" on page 5-9.

The arguments `timezone1` and `timezone2` can be any of these text strings:

- AST, ADT: Atlantic Standard or Daylight Time
- BST, BDT: Bering Standard or Daylight Time
- CST, CDT: Central Standard or Daylight Time
- EST, EDT: Eastern Standard or Daylight Time
- GMT: Greenwich Mean Time
- HST, HDT: Alaska-Hawaii Standard Time or Daylight Time.
- MST, MDT: Mountain Standard or Daylight Time
- NST: Newfoundland Standard Time
- PST, PDT: Pacific Standard or Daylight Time
- YST, YDT: Yukon Standard or Daylight Time

Examples

The following example returns an Atlantic Standard time, given the Pacific Standard time equivalent:

```
ALTER SESSION SET NLS_DATE_FORMAT = 'DD-MON-YYYY HH24:MI:SS';

SELECT NEW_TIME(TO_DATE('11-10-09 01:23:45', 'MM-DD-YY HH24:MI:SS'), 'AST', 'PST')
   "New Date and Time"
FROM DUAL;
```

New Date and Time
-----------------
09-NOV-2009 21:23:45
NEXT_DAY

Syntax

```
NEXT_DAY(date, char)
```

Purpose

`NEXT_DAY` returns the date of the first weekday named by `char` that is later than the date `date`. The return type is always `DATE`, regardless of the data type of `date`. The argument `char` must be a day of the week in the date language of your session, either the full name or the abbreviation. The minimum number of letters required is the number of letters in the abbreviated version. Any characters immediately following the valid abbreviation are ignored. The return value has the same hours, minutes, and seconds component as the argument `date`.

Examples

This example returns the date of the next Tuesday after October 15, 2009:

```
SELECT NEXT_DAY('15-OCT-2009', 'TUESDAY') "NEXT DAY"
FROM DUAL;

NEXT DAY
-------------------
20-OCT-2009 00:00:00
```
NLS_CHARSET_DECL_LEN

Syntax

```
NLS_CHARSET_DECL_LEN (byte_count, char_set_id)
```

Purpose

NLS_CHARSET_DECL_LEN returns the declaration length (in number of characters) of an
NCHAR column. The `byte_count` argument is the width of the column. The `char_set_id`
argument is the character set ID of the column.

Examples

The following example returns the number of characters that are in a 200-byte column
when you are using a multibyte character set:

```
SELECT NLS_CHARSET_DECL_LEN(200, nls_charset_id('ja16eucfixed'))
FROM DUAL;
```

```
NLS_CHARSET_DECL_LEN(200, NLS_CHARSET_ID('JA16EUCFIXED'))
--------------------------------------------------------
100
```
NLS_CHARSET_ID

Syntax

```
NLS_CHARSET_ID(string)
```

Purpose

`NLS_CHARSET_ID` returns the character set ID number corresponding to character set name `string`. The `string` argument is a run-time `VARCHAR2` value. The `string` value 'CHAR_CS' returns the database character set ID number of the server. The `string` value 'NCHAR_CS' returns the national character set ID number of the server.

Invalid character set names return null.

Examples

The following example returns the character set ID of a character set:

```
SELECT NLS_CHARSET_ID('ja16euc')
FROM DUAL;
```

```
NLS_CHARSET_ID('JA16EUC')
-------------------------
     830
```

See Also: `Oracle Database Globalization Support Guide` for a list of character sets
**NLS_CHARSET_NAME**

**Syntax**

```
NLS_CHARSET_NAME(number1)
```

**Purpose**

`NLS_CHARSET_NAME` returns the name of the character set corresponding to ID number `number`. The character set name is returned as a `VARCHAR2` value in the database character set.

If `number` is not recognized as a valid character set ID, then this function returns null.

**Examples**

The following example returns the character set corresponding to character set ID number 2:

```
SELECT NLS_CHARSET_NAME(2)
FROM DUAL;
```

```
NLS_CH
------
WE8DEC
```
NLS_INITCAP

Syntax

```
NLS_INITCAP (char, 'nlsparam')
```

Purpose

NLS_INITCAP returns `char`, with the first letter of each word in uppercase, all other letters in lowercase. Words are delimited by white space or characters that are not alphanumeric.

Both `char` and `nlsparam` can be any of the data types `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2`. The string returned is of `VARCHAR2` data type and is in the same character set as `char`.

The value of `nlsparam` can have this form:

`'NLS_SORT = sort'`

where `sort` is either a linguistic sort sequence or `BINARY`. The linguistic sort sequence handles special linguistic requirements for case conversions. These requirements can result in a return value of a different length than the `char`. If you omit `nlsparam`, then this function uses the default sort sequence for your session.

This function does not support `CLOB` data directly. However, `CLOBs` can be passed in as arguments through implicit data conversion.

See Also: "Data Type Comparison Rules" on page 2-39 for more information.

Examples

The following examples show how the linguistic sort sequence results in a different return value from the function:

```
SELECT NLS_INITCAP('ijsland') "InitCap"
FROM DUAL;
InitCap
-------
Ijsland

SELECT NLS_INITCAP('ijsland', 'NLS_SORT = XDutch') "InitCap"
FROM DUAL;
InitCap
-------
IJsland
```

See Also: Oracle Database Globalization Support Guide for information on sort sequences
NLS_LOWER

Syntax

\[ \text{NLS}\_\text{LOWER}(\text{char}, \text{nlsparam}) \]

Purpose

NLS_LOWER returns char, with all letters lowercase.

Both char and nlsparam can be any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB. The string returned is of VARCHAR2 data type if char is a character data type and a LOB if char is a LOB data type. The return string is in the same character set as char.

The nlsparam can have the same form and serve the same purpose as in the NLS_INITCAP function.

Examples

The following statement returns the lowercase form of the character string 'NOKTASINDA' using the XTurkish linguistic sort sequence. The Turkish uppercase I becoming a small, dotless i.

```sql
SELECT NLS_LOWER('NOKTASINDA', 'NLS_SORT = XTurkish') "Lowercase"
FROM DUAL;
```
NLS_UPPER

Syntax

```
NLS_UPPER(char, nlsparam)
```

Purpose

NLS_UPPER returns `char`, with all letters uppercase.

Both `char` and `nlsparam` can be any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB. The string returned is of VARCHAR2 data type if `char` is a character data type and a LOB if `char` is a LOB data type. The return string is in the same character set as `char`.

The `nlsparam` can have the same form and serve the same purpose as in the NLS_INITCAP function.

Examples

The following example returns a string with all the letters converted to uppercase:

```
SELECT NLS_UPPER('große') "Uppercase"
FROM DUAL;
```

```
Upper
-----
GROßE
```

```
SELECT NLS_UPPER('große', 'NLS_SORT = XGerman') "Uppercase"
FROM DUAL;
```

```
Upperc
-----
GROßE
```

See Also:  
NLS_INITCAP on page 7-205
NLSSORT

Syntax

[Diagram: NLSSORT( char nlsparam )]

Purpose

NLSSORT returns a collation key for the character value char and an explicitly or implicitly specified collation. A collation key is a string of bytes used to sort char according to the specified collation. The property of the collation keys is that mutual ordering of two such keys generated for the given collation when compared according to their binary order is the same as mutual ordering of the source character values when compared according to the given collation.

Both char and 'nlsparam' can be any of the data types CHAR, VARCHAR2, NCHAR, or NVARCHAR2.

The value of 'nlsparam' must have the form

'NLS_SORT = collation'

where collation is the name of a linguistic collation or BINARY. NLSSORT uses the specified collation to generate the collation key. If you omit 'nlsparam', then this function uses the default collation for your session, which is specified in the session parameter NLS_SORT. If you specify BINARY, then this function returns the char value itself cast to RAW and possibly truncated as described below.

If you specify 'nlsparam', then you can append to the linguistic collation name the suffix _ai to request an accent-insensitive collation or _ci to request a case-insensitive collation. Refer to Oracle Database Globalization Support Guide for more information on accent- and case-insensitive sorting. Using accent-insensitive or case-insensitive collations with the ORDER BY query clause is not recommended as it leads to a nondeterministic sort order.

The returned collation key is of RAW data type. The length of the collation key resulting from a given char value for a given collation may exceed the maximum length of the RAW value returned by NLSSORT. In this case, the behavior of NLSSORT depends on the value of the initialization parameter MAX_STRING_SIZE. If MAX_STRING_SIZE = EXTENDED, then the maximum length of the return value is 32767 bytes. If the collation key exceeds this limit, then the function fails with the error "ORA-12742: unable to create the collation key". This error may also be reported for short input strings if they contain a high percentage of Unicode characters with very high decomposition ratios.

If MAX_STRING_SIZE = STANDARD, then the maximum length of the return value is 2000 bytes. If the value to be returned exceeds the limit, then NLSSORT calculates the collation key for a maximum prefix, or initial substring, of char so that the calculated result does not exceed the maximum length. For monolingual collations, for example FRENCH, the prefix length is typically 1000 characters. For multilingual collations, for example GENERIC_M, the prefix is typically 500 characters. For Unicode Collation Algorithm (UCA) collations, for example UCA0610_DUCET, the prefix is typically 285 characters. The exact length may be lower or higher depending on the collation and the characters contained in char.

The behavior when MAX_STRING_SIZE = STANDARD implies that two character values whose collation keys (NLSSORT results) are compared to find the linguistic ordering are considered equal if they do not differ in the prefix even though they may differ at
some further character position. Because the `NLSSORT` function is used implicitly to find linguistic ordering for comparison conditions, the `BETWEEN` condition, the `IN` condition, `ORDER BY`, `GROUP BY`, and `COUNT(DISTINCT)`, those operations may return results that are only approximate for long character values. If you want guarantee that the results of those operations are exact, then migrate your database to use `MAX_STRING_SIZE = EXTENDED`.

Refer to "Extended Data Types" on page 2-29 for more information on the `MAX_STRING_SIZE` initialization parameter.

This function does not support `CLOB` data directly. However, `CLOB`s can be passed in as arguments through implicit data conversion.

See Also: "Data Type Comparison Rules" on page 2-39 for more information.

Examples
This function can be used to specify sorting and comparison operations based on a linguistic sort sequence rather than on the binary value of a string. The following example creates a test table containing two values and shows how the values returned can be ordered by the `NLSSORT` function:

```sql
CREATE TABLE test (name VARCHAR2(15));
INSERT INTO test VALUES ('Gaardiner');
INSERT INTO test VALUES ('Gaberd');
INSERT INTO test VALUES ('Gaasten');

SELECT *
FROM test
ORDER BY name;

NAME
---------------
Gaardiner
Gaasten
Gaberd

SELECT *
FROM test
ORDER BY NLSSORT(name, 'NLS_SORT = XDanish');

NAME
---------------
Gaberd
Gaardiner
Gaasten
```

The following example shows how to use the `NLSSORT` function in comparison operations:

```sql
SELECT *
FROM test
WHERE name > 'Gaberd'
ORDER BY name;
no rows selected

SELECT *
FROM test
WHERE NLSSORT(name, 'NLS_SORT = XDanish') >
NLSSORT('Gaberd', 'NLS_SORT = XDanish')
ORDER BY name;

<table>
<thead>
<tr>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gaardiner</td>
</tr>
<tr>
<td>Gaasten</td>
</tr>
</tbody>
</table>

If you frequently use NLSSORT in comparison operations with the same linguistic sort sequence, then consider this more efficient alternative: Set the NLS_COMP parameter (either for the database or for the current session) to LINGUISTIC, and set the NLS_SORT parameter for the session to the desired sort sequence. Oracle Database will use that sort sequence by default for all sorting and comparison operations during the current session:

```sql
ALTER SESSION SET NLS_COMP = 'LINGUISTIC';
ALTER SESSION SET NLS_SORT = 'XDanish';
```

```sql
SELECT * FROM test WHERE name > 'Gaberd' ORDER BY name;
```

<table>
<thead>
<tr>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gaardiner</td>
</tr>
<tr>
<td>Gaasten</td>
</tr>
</tbody>
</table>

See Also: Oracle Database Globalization Support Guide for information on sort sequences
**NTH_VALUE**

**Syntax**

```
NTH_VALUE (measure_expr, n) OVER (analytic_clause)
```

**Purpose**

NTH_VALUE returns the measure_expr value of the n-th row in the window defined by the analytic_clause. The returned value has the data type of the measure_expr.

- `[RESPECT | IGNORE] NULLS` determines whether null values of measure_expr are included in or eliminated from the calculation. The default is RESPECT NULLS.

- `n` determines the n-th row for which the measure value is to be returned. n can be a constant, bind variable, column, or an expression involving them, as long as it resolves to a positive integer. The function returns NULL if the data source window has fewer than `n` rows. If `n` is null, then the function returns an error.

- `FROM [FIRST | LAST]` determines whether the calculation begins at the first or last row of the window. The default is FROM FIRST.

If you omit the windowing_clause of the analytic_clause, it defaults to RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW. This default sometimes returns an unexpected value for NTH_VALUE ... FROM LAST ..., because the last value in the window is at the bottom of the window, which is not fixed. It keeps changing as the current row changes. For expected results, specify the windowing_clause as RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING. Alternatively, you can specify the windowing_clause as RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING.

**See Also:** "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions of the analytic_clause

**Examples**

The following example shows the minimum amount_sold value for the second channel_id in ascending order for each prod_id between 13 and 16:

```sql
SELECT prod_id, channel_id, MIN(amount_sold),
       NTH_VALUE(MIN(amount_sold), 2) OVER (PARTITION BY prod_id ORDER BY channel_id
       ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) nv
FROM sales
WHERE prod_id BETWEEN 13 and 16
GROUP BY prod_id, channel_id;
```

<table>

</table>

13 rows selected.
NTILE

Syntax

```
NTILE(expr) OVER (query_partition_clause order_by_clause)
```

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions, including valid forms of `expr`

Purpose

NTILE is an analytic function. It divides an ordered data set into a number of buckets indicated by `expr` and assigns the appropriate bucket number to each row. The buckets are numbered 1 through `expr`. The `expr` value must resolve to a positive constant for each partition. Oracle Database expects an integer, and if `expr` is a noninteger constant, then Oracle truncates the value to an integer. The return value is NUMBER.

The number of rows in the buckets can differ by at most 1. The remainder values (the remainder of number of rows divided by buckets) are distributed one for each bucket, starting with bucket 1.

If `expr` is greater than the number of rows, then a number of buckets equal to the number of rows will be filled, and the remaining buckets will be empty.

You cannot nest analytic functions by using NTILE or any other analytic function for `expr`. However, you can use other built-in function expressions for `expr`.

See Also: "About SQL Expressions" on page 5-1 for information on valid forms of `expr` and Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

Examples

The following example divides into 4 buckets the values in the salary column of the oe.employees table from Department 100. The salary column has 6 values in this department, so the two extra values (the remainder of 6 / 4) are allocated to buckets 1 and 2, which therefore have one more value than buckets 3 or 4.

```sql
SELECT last_name, salary, NTILE(4) OVER (ORDER BY salary DESC) AS quartile
FROM employees
WHERE department_id = 100
ORDER BY last_name, salary, quartile;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>SALARY</th>
<th>QUARTILE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chen</td>
<td>8200</td>
<td>2</td>
</tr>
<tr>
<td>Faviet</td>
<td>9000</td>
<td>1</td>

<td>4</td>
</tr>
<tr>
<td>Sciarra</td>
<td>7700</td>
<td>3</td>
</tr>
<tr>
<td>Urman</td>
<td>7800</td>
<td>2</td>
</tr>
</tbody>
</table>
**NULLIF**

**Syntax**

```
NULLIF(expr1, expr2)
```

**Purpose**

NULLIF compares `expr1` and `expr2`. If they are equal, then the function returns null. If they are not equal, then the function returns `expr1`. You cannot specify the literal `NULL` for `expr1`.

If both arguments are numeric data types, then Oracle Database determines the argument with the higher numeric precedence, implicitly converts the other argument to that data type, and returns that data type. If the arguments are not numeric, then they must be of the same data type, or Oracle returns an error.

The NULLIF function is logically equivalent to the following CASE expression:

```
CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END
```

**Examples**

The following example selects those employees from the sample schema `hr` who have changed jobs since they were hired, as indicated by a `job_id` in the `job_history` table different from the current `job_id` in the `employees` table:

```sql
SELECT e.last_name, NULLIF(j.job_id, e.job_id) "Old Job ID"
FROM employees e, job_history j
WHERE e.employee_id = j.employee_id
ORDER BY last_name, "Old Job ID";
```

<table>

</tbody>
</table>
NUMTODSINTERVAL

Syntax

```
NUMTODSINTERVAL ( n interval_unit )
```

Purpose

NUMTODSINTERVAL converts \( n \) to an INTERVAL DAY TO SECOND literal. The argument \( n \) can be any NUMBER value or an expression that can be implicitly converted to a NUMBER value. The argument \( interval_unit \) can be of CHAR, VARCHAR2, NCHAR, or NVARCHAR2 data type. The value for \( interval_unit \) specifies the unit of \( n \) and must resolve to one of the following string values:

- 'DAY'
- 'HOUR'
- 'MINUTE'
- 'SECOND'

\( interval_unit \) is case insensitive. Leading and trailing values within the parentheses are ignored. By default, the precision of the return is 9.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion.

Examples

The following example uses NUMTODSINTERVAL in a COUNT analytic function to calculate, for each employee, the number of employees hired by the same manager within the past 100 days from his or her hire date. Refer to "Analytic Functions" on page 7-12 for more information on the syntax of the analytic functions.

```
SELECT manager_id, last_name, hire_date,
       COUNT(*) OVER (PARTITION BY manager_id ORDER BY hire_date
                     RANGE NUMTODSINTERVAL(100, 'day') PRECEDING) AS t_count
FROM employees
ORDER BY last_name, hire_date;
```

<table>

NUMTOYMINTERVAL

Syntax

```sql
NUMTOYMINTERVAL(n, interval_unit)
```

Purpose

NUMTOYMINTERVAL converts number `n` to an INTERVAL YEAR TO MONTH literal. The argument `n` can be any NUMBER value or an expression that can be implicitly converted to a NUMBER value. The argument `interval_unit` can be of CHAR, VARCHAR2, NCHAR, or NVARCHAR2 data type. The value for `interval_unit` specifies the unit of `n` and must resolve to one of the following string values:

- 'YEAR'
- 'MONTH'

`interval_unit` is case insensitive. Leading and trailing values within the parentheses are ignored. By default, the precision of the return is 9.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion.

Examples

The following example uses NUMTOYMINTERVAL in a SUM analytic function to calculate, for each employee, the total salary of employees hired in the past one year from his or her hire date. Refer to "Analytic Functions" on page 7-12 for more information on the syntax of the analytic functions.

```sql
SELECT last_name, hire_date, salary,
       SUM(salary) OVER (ORDER BY hire_date
                       RANGE NUMTOYMINTERVAL(1,'year') PRECEDING) AS t_sal
FROM employees
ORDER BY last_name, hire_date;
```

<table>

<td>119000</td>
</tr>
</tbody>
</table>

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion.
NVL

Syntax

```
NVL(expr1, expr2)
```

Purpose

NVL lets you replace null (returned as a blank) with a string in the results of a query. If `expr1` is null, then `NVL` returns `expr2`. If `expr1` is not null, then `NVL` returns `expr1`.

The arguments `expr1` and `expr2` can have any data type. If their data types are different, then Oracle Database implicitly converts one to the other. If they cannot be converted implicitly, then the database returns an error. The implicit conversion is implemented as follows:

- If `expr1` is character data, then Oracle Database converts `expr2` to the data type of `expr1` before comparing them and returns `VARCHAR2` in the character set of `expr1`.
- If `expr1` is numeric, then Oracle Database determines which argument has the highest numeric precedence, implicitly converts the other argument to that data type, and returns that data type.

See Also:

- Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and "Numeric Precedence" on page 2-16 for information on numeric precedence
- "COALESCE" on page 7-58 and "CASE Expressions" on page 5-5, which provide functionality similar to that of `NVL`

Examples

The following example returns a list of employee names and commissions, substituting "Not Applicable" if the employee receives no commission:

```
SELECT last_name, NVL(TO_CHAR(commission_pct), 'Not Applicable') commission
FROM employees
WHERE last_name LIKE 'B%'
ORDER BY last_name;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>COMMISSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Baer</td>
<td>Not Applicable</td>
</tr>
<tr>
<td>Baida</td>
<td>Not Applicable</td>
</tr>
<tr>
<td>Banda</td>
<td>.1</td>
</tr>
<tr>
<td>Bates</td>
<td>.15</td>
</tr>
<tr>
<td>Bell</td>
<td>Not Applicable</td>
</tr>
<tr>
<td>Bernstein</td>
<td>.25</td>
</tr>
<tr>
<td>Bissot</td>
<td>Not Applicable</td>
</tr>
<tr>
<td>Bloom</td>
<td>.2</td>
</tr>
<tr>
<td>Bull</td>
<td>Not Applicable</td>
</tr>
</tbody>
</table>
NVL2

Syntax

```
NVL2(expr1, expr2, expr3)
```

Purpose

NVL2 lets you determine the value returned by a query based on whether a specified expression is null or not null. If `expr1` is not null, then NVL2 returns `expr2`. If `expr1` is null, then NVL2 returns `expr3`.

The argument `expr1` can have any data type. The arguments `expr2` and `expr3` can have any data types except LONG.

If the data types of `expr2` and `expr3` are different, then Oracle Database implicitly converts one to the other. If they cannot be converted implicitly, then the database returns an error. If `expr2` is character or numeric data, then the implicit conversion is implemented as follows:

- If `expr2` is character data, then Oracle Database converts `expr3` to the data type of `expr2` before returning a value unless `expr3` is a null constant. In that case, a data type conversion is not necessary, and the database returns VARCHAR2 in the character set of `expr2`.
- If `expr2` is numeric data, then Oracle Database determines which argument has the highest numeric precedence, implicitly converts the other argument to that data type, and returns that data type.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and "Numeric Precedence" on page 2-16 for information on numeric precedence

Examples

The following example shows whether the income of some employees is made up of salary plus commission, or just salary, depending on whether the `commission_pct` column of employees is null or not.

```
SELECT last_name, salary,
       NVL2(commission_pct, salary + (salary * commission_pct), salary) income
FROM employees
WHERE last_name like 'B%'
ORDER BY last_name;
```

<table>
<thead>

</table>
ORA_DST_AFFECTED

Syntax

```ora_dst_affected```

Purpose

ORA_DST_AFFECTED is useful when you are changing the time zone data file for your database. The function takes as an argument a datetime expression that resolves to a `TIMESTAMP WITH TIME ZONE` value or a VARRAY object that contains `TIMESTAMP WITH TIME ZONE` values. The function returns 1 if the datetime value is affected by or will result in a “nonexisting time” or “duplicate time” error with the new time zone data. Otherwise, it returns 0.

This function can be issued only when changing the time zone data file of the database and upgrading the timestamp with the time zone data, and only between the execution of the `DBMS_DST.BEGIN_PREPARE` and the `DBMS_DST.END_PREPARE` procedures or between the execution of the `DBMS_DST.BEGIN_UPGRADE` and the `DBMS_DST.END_UPGRADE` procedures.

See Also: Oracle Database Globalization Support Guide for more information on time zone data files and on how Oracle Database handles daylight saving time, and Oracle Database PL/SQL Packages and Types Reference for information on the `DBMS_DST` package.
ORA_DST_CONVERT

Syntax

Syntax diagram:

```
ORA_DST_CONVERT (datetime_expr, integer, integer)
```

Purpose

ORA_DST_CONVERT is useful when you are changing the time zone data file for your database. The function lets you specify error handling for a specified datetime expression.

- For `datetime_expr`, specify a datetime expression that resolves to a `TIMESTAMP WITH TIME ZONE` value or a `VARRAY` object that contains `TIMESTAMP WITH TIME ZONE` values.
- The optional second argument specifies handling of "duplicate time" errors. Specify 0 (false) to suppress the error by returning the source datetime value. This is the default. Specify 1 (true) to allow the database to return the duplicate time error.
- The optional third argument specifies handling of "nonexisting time" errors. Specify 0 (false) to suppress the error by returning the source datetime value. This is the default. Specify 1 (true) to allow the database to return the nonexisting time error.

If no error occurs, this function returns a value of the same data type as `datetime_expr` (a `TIMESTAMP WITH TIME ZONE` value or a `VARRAY` object that contains `TIMESTAMP WITH TIME ZONE` values). The returned datetime value when interpreted with the new time zone file corresponds to `datetime_expr` interpreted with the old time zone file.

This function can be issued only when changing the time zone data file of the database and upgrading the timestamp with the time zone data, and only between the execution of the `DBMS_DST.BEGIN_UPGRADE` and the `DBMS_DST.END_UPGRADE` procedures.

See Also: Oracle Database Globalization Support Guide for more information on time zone data files and on how Oracle Database handles daylight saving time, and Oracle Database PL/SQL Packages and Types Reference for information on the `DBMS_DST` package
ORA_DST_ERROR

Syntax

ORA_DST_ERROR (datetime_expr)

Purpose

ORA_DST_ERROR is useful when you are changing the time zone data file for your database. The function takes as an argument a datetime expression that resolves to a TIMESTAMP WITH TIME ZONE value or a VARRAY object that contains TIMESTAMP WITH TIME ZONE values, and indicates whether the datetime value will result in an error with the new time zone data. The return values are:

- 0: the datetime value does not result in an error with the new time zone data.
- 1878: the datetime value results in a "nonexisting time" error.
- 1883: the datetime value results in a "duplicate time" error.

This function can be issued only when changing the time zone data file of the database and upgrading the timestamp with the time zone data, and only between the execution of the DBMS_DST.BEGIN_PREPARE and the DBMS_DST.END_PREPARE procedures or between the execution of the DBMS_DST.BEGIN_UPGRADE and the DBMS_DST.END_UPGRADE procedures.

See Also:  Oracle Database Globalization Support Guide for more information on time zone data files and on how Oracle Database handles daylight saving time, and Oracle Database PL/SQL Packages and Types Reference for information on the DBMS_DST package.
ORA_HASH

Syntax

```
ORA_HASH(expr, max_bucket, seed_value)
```

Purpose

ORA_HASH is a function that computes a hash value for a given expression. This function is useful for operations such as analyzing a subset of data and generating a random sample.

- The `expr` argument determines the data for which you want Oracle Database to compute a hash value. There are no restrictions on the length of data represented by `expr`, which commonly resolves to a column name. The `expr` cannot be a `LONG` or LOB type. It cannot be a user-defined object type unless it is a nested table type. The hash value for nested table types does not depend on the order of elements in the collection. All other data types are supported for `expr`.

- The optional `max_bucket` argument determines the maximum bucket value returned by the hash function. You can specify any value between 0 and 4294967295. The default is 4294967295.

- The optional `seed_value` argument enables Oracle to produce many different results for the same set of data. Oracle applies the hash function to the combination of `expr` and `seed_value`. You can specify any value between 0 and 4294967295. The default is 0.

The function returns a `NUMBER` value.

Examples

The following example creates a hash value for each combination of customer ID and product ID in the `sh.sales` table, divides the hash values into a maximum of 100 buckets, and returns the sum of the `amount_sold` values in the first bucket (bucket 0). The third argument (5) provides a seed value for the hash function. You can obtain different hash results for the same query by changing the seed value.

```sql
SELECT SUM(amount_sold) FROM sales WHERE ORA_HASH(CONCAT(cust_id, prod_id), 99, 5) = 0;
```

```
SUM(AMOUNT_SOLD)-------------------989431.14
```
ORA_INVOKING_USER

Syntax

ORA_INVOKING_USER

Purpose

ORA_INVOKING_USER returns the name of the database user who invoked the current statement or view. This function takes into account the BEQUEATH property of intervening views referenced in the statement. If this function is invoked from within a definer’s rights context, then it returns the name of the owner of the definer’s rights object. If the invoking user is a Real Application Security user, then it returns user XS$NULL.

This function returns a VARCHAR2 value.

See Also:

- BEQUEATH clause of the CREATE VIEW statement on page 17-21
- Oracle Database 2 Day + Security Guide for more information on user XS$NULL

Examples

The following example returns the name of the database user who invoked the statement:

```
SELECT ORA_INVOKING_USER FROM DUAL;
```
ORA_INVOKING_USERID

Syntax

ORA_INVOKING_USERID

Purpose

ORA_INVOKING_USERID returns the identifier of the database user who invoked the current statement or view. This function takes into account the BEQUEATH property of intervening views referenced in the statement.

This function returns a NUMBER value.

See Also:

- ORA_INVOKING_USER on page 7-223 to learn how Oracle Database determines the database user who invoked the current statement or view
- BEQUEATH clause of the CREATE VIEW statement on page 17-21

Examples

The following example returns the identifier of the database user who invoked the statement:

SELECT ORA_INVOKING_USERID FROM DUAL;
Syntax

\[ \text{PATH}(\text{correlation\_integer}) \]

**Purpose**

\( \text{PATH} \) is an ancillary function used only with the \texttt{UNDER\_PATH} and \texttt{EQUALS\_PATH} conditions. It returns the relative path that leads to the resource specified in the parent condition.

The \textit{correlation\_integer} can be any \texttt{NUMBER} integer and is used to correlate this ancillary function with its primary condition. Values less than 1 are treated as 1.

See Also: \texttt{EQUALS\_PATH Condition} on page 6-19 and \texttt{UNDER\_PATH Condition} on page 6-20

**Examples**

Refer to the related function \texttt{DEPTH} on page 7-99 for an example using both of these ancillary functions of the \texttt{EQUALS\_PATH} and \texttt{UNDER\_PATH} conditions.
**PERCENT_RANK**

**Aggregate Syntax**

\[
\text{percent_rank_aggregate} := \\
\text{PERCENT_RANK} (\text{expr}) \text{ WITHIN GROUP} \\
\text{ORDER BY} \text{expr} \text{ASC DESC NULLS FIRST LAST}
\]

**Analytic Syntax**

\[
\text{percent_rank_analytic} := \\
\text{PERCENT_RANK} (\text{expr}) \text{ OVER} \text{query_partition_clause} \text{order_by_clause}
\]

**See Also:** "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

**Purpose**

PERCENT_RANK is similar to the CUME_DIST (cumulative distribution) function. The range of values returned by PERCENT_RANK is 0 to 1, inclusive. The first row in any set has a PERCENT_RANK of 0. The return value is NUMBER.

**See Also:** Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

- As an aggregate function, PERCENT_RANK calculates, for a hypothetical row \( r \) identified by the arguments of the function and a corresponding sort specification, the rank of row \( r \) minus 1 divided by the number of rows in the aggregate group. This calculation is made as if the hypothetical row \( r \) were inserted into the group of rows over which Oracle Database is to aggregate.

  The arguments of the function identify a single hypothetical row within each aggregate group. Therefore, they must all evaluate to constant expressions within each aggregate group. The constant argument expressions and the expressions in the ORDER BY clause of the aggregate match by position. Therefore the number of arguments must be the same and their types must be compatible.

- As an analytic function, for a row \( r \), PERCENT_RANK calculates the rank of \( r \) minus 1, divided by 1 less than the number of rows being evaluated (the entire query result set or a partition).
Aggregate Example
The following example calculates the percent rank of a hypothetical employee in the sample table hr.employees with a salary of $15,500 and a commission of 5%:

```
SELECT PERCENT_RANK(15000, .05) WITHIN GROUP
    (ORDER BY salary, commission_pct) "Percent-Rank"
FROM employees;
```

Percent-Rank
------------
       .971962617

Analytic Example
The following example calculates, for each employee, the percent rank of the employee's salary within the department:

```
SELECT department_id, last_name, salary, PERCENT_RANK()
    OVER (PARTITION BY department_id ORDER BY salary DESC) AS pr
FROM employees
ORDER BY pr, salary, last_name;
```

</tr>
</tbody>
</table>
PERCENTILE_CONT

Syntax

```
PERCENTILE_CONT ( expr )
          WITHIN GROUP ( ORDER BY expr )
```

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions of the `OVER` clause

Purpose

`PERCENTILE_CONT` is an inverse distribution function that assumes a continuous distribution model. It takes a percentile value and a sort specification, and returns an interpolated value that would fall into that percentile value with respect to the sort specification. Nulls are ignored in the calculation.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

The first `expr` must evaluate to a numeric value between 0 and 1, because it is a percentile value. This `expr` must be constant within each aggregation group. The `ORDER BY` clause takes a single expression that must be a numeric or datetime value, as these are the types over which Oracle can perform interpolation.

The result of `PERCENTILE_CONT` is computed by linear interpolation between values after ordering them. Using the percentile value (P) and the number of rows (N) in the aggregation group, you can compute the row number you are interested in after ordering the rows with respect to the sort specification. This row number (RN) is computed according to the formula

```
RN = 1 + (P * (N - 1))
```

The final result of the aggregate function is computed by linear interpolation between the values from rows at row numbers `CRN = CEILING(RN)` and `FRN = FLOOR(RN)`.

The final result will be:

If `(CRN = FRN = RN)` then the result is

(value of expression from row at RN)

Otherwise the result is

```
(CRN - RN) * (value of expression for row at FRN) +
(RN - FRN) * (value of expression for row at CRN)
```

You can use the `PERCENTILE_CONT` function as an analytic function. You can specify only the `query_partitioning_clause` in its `OVER` clause. It returns, for each row, the value that would fall into the specified percentile among a set of values within each partition.

The `MEDIAN` function is a specific case of `PERCENTILE_CONT` where the percentile value defaults to 0.5. For more information, refer to `MEDIAN` on page 7-192.
Aggregate Example
The following example computes the median salary in each department:

```sql
SELECT department_id,
       PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY salary DESC) "Median cont",
       PERCENTILE_DISC(0.5) WITHIN GROUP (ORDER BY salary DESC) "Median disc"
FROM employees
GROUP BY department_id
ORDER BY department_id;
```

<table>
<thead>
<tr>
<th>DEPARTMENT_ID</th>
<th>Median cont</th>
<th>Median disc</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>4400</td>
<td>4400</td>
</tr>
<tr>
<td>20</td>
<td>9500</td>
<td>13000</td>
</tr>
<tr>
<td>30</td>
<td>2850</td>
<td>2900</td>
</tr>
<tr>
<td>40</td>
<td>6500</td>
<td>6500</td>
</tr>
<tr>
<td>50</td>
<td>3100</td>
<td>3100</td>
</tr>
<tr>
<td>60</td>
<td>4800</td>
<td>4800</td>
</tr>
<tr>
<td>70</td>
<td>10000</td>
<td>10000</td>
</tr>
<tr>
<td>80</td>
<td>8900</td>
<td>9000</td>
</tr>
<tr>
<td>90</td>
<td>17000</td>
<td>17000</td>
</tr>
<tr>
<td>100</td>
<td>8000</td>
<td>8200</td>
</tr>
<tr>
<td>110</td>
<td>10154</td>
<td>12008</td>
</tr>
<tr>
<td>7000</td>
<td>7000</td>
<td>7000</td>
</tr>
</tbody>
</table>

PERCENTILE_CONT and PERCENTILE_DISC may return different results. PERCENTILE_CONT returns a computed result after doing linear interpolation. PERCENTILE_DISC simply returns a value from the set of values that are aggregated over. When the percentile value is 0.5, as in this example, PERCENTILE_CONT returns the average of the two middle values for groups with even number of elements, whereas PERCENTILE_DISC returns the value of the first one among the two middle values. For aggregate groups with an odd number of elements, both functions return the value of the middle element.

Analytic Example
In the following example, the median for Department 60 is 4800, which has a corresponding percentile (Percent_Rank) of 0.5. None of the salaries in Department 30 have a percentile of 0.5, so the median value must be interpolated between 2900 (percentile 0.4) and 2800 (percentile 0.6), which evaluates to 2850.

```sql
SELECT last_name, salary, department_id,
       PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY salary DESC) OVER (PARTITION BY department_id) "Percentile_Cont",
       PERCENT_RANK() OVER (PARTITION BY department_id ORDER BY salary DESC) "Percent_Rank"
FROM employees
WHERE department_id IN (30, 60)
ORDER BY last_name, salary, department_id;
```

<table>
<thead>
<tr>

</tbody>
</table>
PERCENTILE_DISC

Syntax

```sql
PERCENTILE_DISC(expr) WITHIN GROUP (ORDER BY expr) OVER (query_partition_clause)
```

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions of the OVER clause

Purpose

PERCENTILE_DISC is an inverse distribution function that assumes a discrete distribution model. It takes a percentile value and a sort specification and returns an element from the set. Nulls are ignored in the calculation.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

The first `expr` must evaluate to a numeric value between 0 and 1, because it is a percentile value. This expression must be constant within each aggregate group. The `ORDER BY` clause takes a single expression that can be of any type that can be sorted.

For a given percentile value `P`, PERCENTILE_DISC sorts the values of the expression in the `ORDER BY` clause and returns the value with the smallest `CUME_DIST` value (with respect to the same sort specification) that is greater than or equal to `P`.

Aggregate Example

See aggregate example for PERCENTILE_CONT on page 7-228.

Analytic Example

The following example calculates the median discrete percentile of the salary of each employee in the sample table `hr.employees`:

```sql
SELECT last_name, salary, department_id,
    PERCENTILE_DISC(0.5) WITHIN GROUP (ORDER BY salary DESC)
    OVER (PARTITION BY department_id) "Percentile_Disc",
    CUME_DIST() OVER (PARTITION BY department_id ORDER BY salary DESC) "Cume_Dist"
FROM employees
WHERE department_id in (30, 60)
ORDER BY last_name, salary, department_id;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>SALARY</th>
<th>DEPARTMENT_ID</th>
<th>Percentile_Disc</th>
<th>Cume_Dist</th>
</tr>
</thead>
<tbody>
<tr>
<td>Austin</td>
<td>4800</td>
<td>60</td>
<td>4800</td>
<td>.8</td>
</tr>
<tr>
<td>Baida</td>
<td>2900</td>
<td>30</td>
<td>2900</td>
<td>.5</td>
</tr>
</tbody>
</table>

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion
<table>
<thead>
<tr>
<th>Name</th>
<th>Salary</th>
<th>Service</th>
<th>Value</th>
<th>Percentile</th>
</tr>
</thead>
<tbody>
<tr>
<td>Colmenares</td>
<td>2500</td>
<td>30</td>
<td>2900</td>
<td>1</td>
</tr>
<tr>
<td>Ernst</td>
<td>6000</td>
<td>60</td>
<td>4800</td>
<td>0.4</td>
</tr>
<tr>
<td>Himuro</td>
<td>2600</td>
<td>30</td>
<td>2900</td>
<td>0.833333333</td>
</tr>
<tr>
<td>Hunold</td>
<td>9000</td>
<td>60</td>
<td>4800</td>
<td>0.2</td>
</tr>
<tr>
<td>Khoo</td>
<td>3100</td>
<td>30</td>
<td>2900</td>
<td>0.333333333</td>
</tr>
<tr>
<td>Lorentz</td>
<td>4200</td>
<td>60</td>
<td>4800</td>
<td>1</td>
</tr>
<tr>
<td>Pataballa</td>
<td>4800</td>
<td>60</td>
<td>4800</td>
<td>0.8</td>
</tr>
<tr>
<td>Raphaely</td>
<td>11000</td>
<td>30</td>
<td>2900</td>
<td>0.166666667</td>
</tr>
<tr>
<td>Tobias</td>
<td>2800</td>
<td>30</td>
<td>2900</td>
<td>0.666666667</td>
</tr>
</tbody>
</table>

The median value for Department 30 is 2900, which is the value whose corresponding percentile (Cume_Dist) is the smallest value greater than or equal to 0.5. The median value for Department 60 is 4800, which is the value whose corresponding percentile is the smallest value greater than or equal to 0.5.
POWER

Syntax

\[
\text{POWER}(n_2, n_1)
\]

Purpose

POWER returns \( n_2 \) raised to the \( n_1 \) power. The base \( n_2 \) and the exponent \( n_1 \) can be any numbers, but if \( n_2 \) is negative, then \( n_1 \) must be an integer.

This function takes as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If any argument is BINARY_FLOAT or BINARY_DOUBLE, then the function returns BINARY_DOUBLE. Otherwise, the function returns NUMBER.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

Examples

The following example returns 3 squared:

```
SELECT POWER(3,2) "Raised"
FROM DUAL;

Raised
-------
9
```
POWERMULTISET

Syntax

```
POWERMULTISET (expr)
```

Purpose

POWERMULTISET takes as input a nested table and returns a nested table of nested tables containing all nonempty subsets (called submultisets) of the input nested table.

- `expr` can be any expression that evaluates to a nested table.
- If `expr` resolves to null, then Oracle Database returns `NULL`.
- If `expr` resolves to a nested table that is empty, then Oracle returns an error.
- The element types of the nested table must be comparable. Refer to "Comparison Conditions" on page 6-4 for information on the comparability of nonscalar types.

Note: This function is not supported in PL/SQL.

Examples

First, create a data type that is a nested table of the `cust_address_tab_type` data type:

```sql
CREATE TYPE cust_address_tab_tab_typ AS TABLE OF cust_address_tab_typ;
/
```

Now, select the nested table column `cust_address_ntab` from the `customers_demo` table using the POWERMULTISET function:

```sql
SELECT CAST(POWERMULTISET(cust_address_ntab) AS cust_address_tab_tab_typ)
FROM customers_demo;
```

```
CAST(POWERMULTISET(CUST_ADDRESS_NTAB) AS CUST_ADDRESS_TAB_TAB_TYP)
(STREET_ADDRESS, POSTAL_CODE, CITY, STATE_PROVINCE, COUNTRY_ID)
------------------------------------------------------------------
CUST_ADDRESS_TAB_TAB_TYP(CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP
('514 W Superior St', '46901', 'Kokomo', 'IN', 'US')))
CUST_ADDRESS_TAB_TAB_TYP(CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP
('2515 Boyd Ave', '46218', 'Indianapolis', 'IN', 'US')))
CUST_ADDRESS_TAB_TAB_TYP(CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP
('8768 N State Rd 37', '47404', 'Bloomington', 'IN', 'US')))
CUST_ADDRESS_TAB_TAB_TYP(CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP
('645 Bay Harbor Ln', '46254', 'Indianapolis', 'IN', 'US')))
... 
```

The preceding example requires the `customers_demo` table and a nested table column containing data. Refer to "Multiset Operators" on page 4-5 to create this table and nested table columns.
POWERMULTISET_BY_CARDINALITY

Syntax

POWERMULTISET_BY_CARDINALITY(expr, cardinality)

Purpose

POWERMULTISET_BY_CARDINALITY takes as input a nested table and a cardinality and returns a nested table of nested tables containing all nonempty subsets (called submultisets) of the nested table of the specified cardinality.

- expr can be any expression that evaluates to a nested table.
- cardinality can be any positive integer.
- If expr resolves to null, then Oracle Database returns NULL.
- If expr resolves to a nested table that is empty, then Oracle returns an error.
- The element types of the nested table must be comparable. Refer to "Comparison Conditions" on page 6-4 for information on the comparability of nonscalar types.

Examples

First, create a data type that is a nested table of the cust_address_tab_type data type:

CREATE TYPE cust_address_tab_tab_typ AS TABLE OF cust_address_tab_typ;
/

Next, duplicate the elements in all the nested table rows to increase the cardinality of the nested table rows to 2:

UPDATE customers_demo
    SET cust_address_ntab = cust_address_ntab MULTISET UNION cust_address_ntab;

Now, select the nested table column cust_address_ntab from the customers_demo table using the POWERMULTISET_BY_CARDINALITY function:

SELECT CAST(POWERMULTISET_BY_CARDINALITY(cust_address_ntab, 2) AS cust_address_tab_tab_typ)
FROM customers_demo;

Note: This function is not supported in PL/SQL.
The preceding example requires the `customers_demo` table and a nested table column containing data. Refer to "Multiset Operators" on page 4-5 to create this table and nested table columns.
Syntax

\[ prediction::= \]

Analytic Syntax

\[ prediction_analytic::= \]

\[ cost_matrix_clause::= \]

\[ mining_attribute_clause::= \]

\[ mining_analytic_clause::= \]

See Also: "Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of \texttt{mining_analytic_clause}

Purpose

\texttt{PREDICTION} returns a prediction for each row in the selection. The data type of the returned prediction depends on whether the function performs regression, classification, or anomaly detection.
Regression — Returns the expected target value for each row. The data type of the return value is the data type of the target.

Classification — Returns the most probable target class (or lowest cost target class, if costs are specified) for each row. The data type of the return value is the data type of the target.

Anomaly Detection — Returns 1 or 0 for each row. Typical rows are classified as 1. Rows that differ significantly from the rest of the data are classified as 0.

cost_matrix_clause
Costs are a biasing factor for minimizing the most harmful kinds of misclassifications. You can specify cost_matrix_clause for classification or anomaly detection. Costs are not relevant for regression. The cost_matrix_clause behaves as described for "PREDICTION_COST" on page 7-243.

Syntax Choice
PREDICTION can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically score the data by executing an analytic clause that builds and applies one or more transient mining models. Choose Syntax or Analytic Syntax:

Syntax — Use the first syntax to score the data with a pre-defined model. Supply the name of a model that performs classification, regression, or anomaly detection.

Analytic Syntax — Use the analytic syntax to score the data without a pre-defined model. The analytic syntax uses mining_analytic_clause, which specifies if the data should be partitioned for multiple model builds. The mining_analytic_clause supports a query_partition_clause and an order_by_clause. (See "analytic_clause::=" on page 7-12.)

– For regression, specify FOR expr, where expr is an expression that identifies a target column that has a numeric data type.

– For classification, specify FOR expr, where expr is an expression that identifies a target column that has a character data type.

– For anomaly detection, specify the keywords OF ANOMALY.

mining_attribute_clause
mining_attribute_clause identifies the column attributes to use as predictors for scoring.

– If you specify USING *, all the relevant attributes present in the input row are used.

– If you invoke the function with the analytic syntax, the mining_attribute_clause is used both for building the transient models and for scoring.

– If you invoke the function with a pre-defined model, the mining_attribute_clause should include all or some of the attributes that were used to create the model. The following conditions apply:

  – If mining_attribute_clause includes an attribute with the same name but a different data type from the one that was used to create the model, then the data type is converted to the type expected by the model.

  – If you specify more attributes for scoring than were used to create the model, then the extra attributes are silently ignored.

  – If you specify fewer attributes for scoring than were used to create the model, then scoring is performed on a best-effort basis.
Example
In this example, the model dt_sh_clas_sample predicts the gender and age of customers who are most likely to use an affinity card (target = 1). The PREDICTION function takes into account the cost matrix associated with the model and uses marital status, education, and household size as predictors.

```sql
SELECT cust_gender, COUNT(*) AS cnt, ROUND(AVG(age)) AS avg_age
FROM mining_data_apply_v
WHERE PREDICTION(dt_sh_clas_sample COST MODEL USING cust_marital_status, education, household_size) = 1
GROUP BY cust_gender
ORDER BY cust_gender;
```

<table>
<thead>
<tr>
<th>CUST_GENDER</th>
<th>CNT</th>
<th>AVG_AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>170</td>
<td>38</td>
</tr>
<tr>
<td>M</td>
<td>685</td>
<td>42</td>
</tr>
</tbody>
</table>

The cost matrix associated with the model dt_sh_clas_sample is stored in the table dt_sh_sample_costs. The cost matrix specifies that the misclassification of 1 is 8 times more costly than the misclassification of 0.

```sql
SQL> select * from dt_sh_sample_cost;
```

<table>
<thead>
<tr>
<th>ACTUAL_TARGET_VALUE</th>
<th>PREDICTED_TARGET_VALUE</th>
<th>COST</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0.000000000</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1.000000000</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>8.000000000</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0.000000000</td>
</tr>
</tbody>
</table>

Analytic Example
In this example, dynamic regression is used to predict the age of customers who are likely to use an affinity card. The query returns the 3 customers whose predicted age is most different from the actual. The query includes information about the predictors that have the greatest influence on the prediction.

```sql
SELECT cust_id, age, pred_age, age-pred_age age_diff, pred_det
FROM
(SELECT cust_id, age, pred_age, age_diff, pred_det FROM
 (SELECT cust_id, age, pred_age, age_diff, pred_det, RANK() OVER (ORDER BY ABS(age-pred_age) desc) rnk FROM
 (SELECT cust_id, age, PREDICTION(FOR age USING *) OVER () pred_age, PREDICTION_DETAILS(FOR age ABS USING *) OVER () pred_det FROM mining_data_apply_v))
WHERE rnk <= 3;
```

PREDICTION_BOUNDS

Syntax

```
PREDICTION_BOUNDS( schema.model, confidence_level, class_value, mining_attribute_clause )
```

**Purpose**

PREDICTION_BOUNDS applies a Generalized Linear Model (GLM) to predict a class or a value for each row in the selection. The function returns the upper and lower bounds of each prediction in a varray of objects with fields `UPPER` and `LOWER`.

GLM can perform either regression or binary classification:

- The bounds for regression refer to the predicted target value. The data type of `UPPER` and `LOWER` is the data type of the target.
- The bounds for binary classification refer to the probability of either the predicted target class or the specified `class_value`. The data type of `UPPER` and `LOWER` is `BINARY_DOUBLE`.

If the model was built using ridge regression, or if the covariance matrix is found to be singular during the build, then PREDICTION_BOUNDS returns `NULL` for both bounds.

`confidence_level` is a number in the range (0,1). The default value is 0.95. You can specify `class_value` while leaving `confidence_level` at its default by specifying `NULL` for `confidence_level`.

**mining_attribute_clause**

`mining_attribute_clause` identifies the column attributes to use as predictors for scoring. This clause behaves as described for the PREDICTION function. (Note that the reference to analytic syntax does not apply.) See "mining_attribute_clause::=" on page 7-237.

**See Also:**

- *Oracle Data Mining User’s Guide* for information about scoring
- *Oracle Data Mining Concepts* for information about Generalized Linear Models
About the Example: The following example is excerpted from the Data Mining sample programs. For more information about the sample programs, see Appendix A in Oracle Data Mining User's Guide.

Example
The following example returns the distribution of customers whose ages are predicted with 98% confidence to be greater than 24 and less than 46.

```sql
SELECT count(cust_id) cust_count, cust_marital_status
FROM (SELECT cust_id, cust_marital_status
     FROM mining_data_apply_v
     WHERE PREDICTION_BOUNDS(glmr_sh_regr_sample,0.98 USING *).LOWER > 24 AND
           PREDICTION_BOUNDS(glmr_sh_regr_sample,0.98 USING *).UPPER < 46)
GROUP BY cust_marital_status;
```

<table>
<thead>
<tr>
<th>CUST_COUNT</th>
<th>CUST_MARITAL_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>46</td>
<td>NeverM</td>
</tr>
<tr>
<td>7</td>
<td>Mabsent</td>
</tr>
<tr>
<td>5</td>
<td>Separ.</td>
</tr>
<tr>
<td>35</td>
<td>Divorc.</td>
</tr>
<tr>
<td>72</td>
<td>Married</td>
</tr>
</tbody>
</table>
Purpose

`PREDICTION_COST` returns a cost for each row in the selection. The cost refers to the lowest cost class or to the specified `class`. The cost is returned as `BINARY_DOUBLE`.

See Also: "Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of `mining_analytic_clause`
**PREDICTION_COST** can perform classification or anomaly detection. For classification, the returned cost refers to a predicted target class. For anomaly detection, the returned cost refers to a classification of 1 (for typical rows) or 0 (for anomalous rows).

You can use **PREDICTION_COST** in conjunction with the **PREDICTION** function to obtain the prediction and the cost of the prediction.

**cost_matrix_clause**
Costs are a biasing factor for minimizing the most harmful kinds of misclassifications. For example, false positives might be considered more costly than false negatives. Costs are specified in a cost matrix that can be associated with the model or defined in a **VALUES** clause. All classification algorithms can use costs to influence scoring.

Decision Tree is the only algorithm that can use costs to influence the model build. The cost matrix used to build a Decision Tree model is also the default scoring cost matrix for the model.

The following cost matrix table specifies that the misclassification of 1 is five times more costly than the misclassification of 0.

<table>
<thead>
<tr>
<th>ACTUAL_TARGET_VALUE</th>
<th>PREDICTED_TARGET_VALUE</th>
<th>COST</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>5</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

In **cost_matrix_clause**:

- **COST MODEL** indicates that scoring should be performed by taking into account the scoring cost matrix associated with the model. If the cost matrix does not exist, then the function returns an error.

- **COST MODEL AUTO** indicates that the existence of a cost matrix is unknown. If a cost matrix exists, then the function uses it to return the lowest cost prediction. Otherwise the function returns the highest probability prediction.

- The **VALUES** clause specifies an inline cost matrix for **class_value**. For example, you could specify that the misclassification of 1 is five times more costly than the misclassification of 0 as follows:

```sql
PREDICTION (nb_model COST (0,1) VALUES ((0, 1),(1, 5)) USING *)
```

If a model that has a scoring cost matrix is invoked with an inline cost matrix, then the inline costs are used.

**See Also**: Oracle Data Mining User’s Guide for more information about cost-sensitive prediction.

**Syntax Choice**
**PREDICTION_COST** can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically mine the data by executing an analytic clause that builds and applies one or more transient mining models. Choose **Syntax** or **Analytic Syntax**:

- **Syntax** — Use the first syntax to score the data with a pre-defined model. Supply the name of a model that performs classification or anomaly detection.
Analytic Syntax — Use the analytic syntax to score the data without a pre-defined model. The analytic syntax uses mining_analytic_clause, which specifies if the data should be partitioned for multiple model builds. The mining_analytic_clause supports a query_partition_clause and an order_by_clause. (See "analytic_clause::=" on page 7-12.)

- For classification, specify FOR expr, where expr is an expression that identifies a target column that has a character data type.
- For anomaly detection, specify the keywords OF ANOMALY.

mining_attribute_clause

mining_attribute_clause identifies the column attributes to use as predictors for scoring. When the function is invoked with the analytic syntax, these predictors are also used for building the transient models. The mining_attribute_clause behaves as described for the PREDICTION function. (See "mining_attribute_clause::=" on page 7-237.)

Example

This example predicts the ten customers in Italy who would respond to the least expensive sales campaign (offering an affinity card).

```
SELECT cust_id
FROM (SELECT cust_id,rank()
      OVER (ORDER BY PREDICTION_COST(DT_SH_Clas_sample, 1 COST MODEL USING *)
              ASC, cust_id) rnk
      FROM mining_data_apply_v
      WHERE country_name = 'Italy')
WHERE rnk <= 10
ORDER BY rnk;
```

CUST_ID
----------
100081
100179
100185
100324
100344
100554
100662
100733
101250
101306

mining_attribute_clause::=

USING

+

schema . . table AS alias +

expr

mining_analytic_clause::=

See Also: "Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of mining_analytic_clause

Purpose

PREDICTION_DETAILS returns prediction details for each row in the selection. The return value is an XML string that describes the attributes of the prediction.
For regression, the returned details refer to the predicted target value. For classification and anomaly detection, the returned details refer to the highest probability class or the specified `class_value`.

**topN**
If you specify a value for `topN`, the function returns the `N` attributes that have the most influence on the prediction (the score). If you do not specify `topN`, the function returns the 5 most influential attributes.

**DESC, ASC, or ABS**
The returned attributes are ordered by weight. The weight of an attribute expresses its positive or negative impact on the prediction. For regression, a positive weight indicates a higher value prediction; a negative weight indicates a lower value prediction. For classification and anomaly detection, a positive weight indicates a higher probability prediction; a negative weight indicates a lower probability prediction.

By default, `PREDICTION_DETAILS` returns the attributes with the highest positive weight (DESC). If you specify ASC, the attributes with the highest negative weight are returned. If you specify ABS, the attributes with the greatest weight, whether negative or positive, are returned. The results are ordered by absolute value from highest to lowest. Attributes with a zero weight are not included in the output.

**Syntax Choice**
`PREDICTION_DETAILS` can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically mine the data by executing an analytic clause that builds and applies one or more transient mining models. Choose **Syntax** or **Analytic Syntax**:

- **Syntax** — Use the first syntax to score the data with a pre-defined model. Supply the name of a model that performs classification, regression, or anomaly detection.

- **Analytic Syntax** — Use the analytic syntax to score the data without a pre-defined model. The analytic syntax uses `mining_analytic_clause`, which specifies if the data should be partitioned for multiple model builds. The `mining_analytic_clause` supports a `query_partition_clause` and an `order_by_clause`. (See “analytic_clause::=” on page 7-12.)
  - For classification, specify `FOR expr`, where `expr` is an expression that identifies a target column that has a character data type.
  - For regression, specify `FOR expr`, where `expr` is an expression that identifies a target column that has a numeric data type.
  - For anomaly detection, specify the keywords **OF ANOMALY**.

**mining_attribute_clause**
`mining_attribute_clause` identifies the column attributes to use as predictors for scoring. When the function is invoked with the analytic syntax, these predictors are also used for building the transient models. The `mining_attribute_clause` behaves as described for the `PREDICTION` function. (See ”mining_attribute_clause::=” on page 7-237.)
Example
This example uses the model `svmr_sh_regr_sample` to score the data. The query returns the three attributes that have the greatest influence on predicting a higher value for customer age.

```sql
SELECT PREDICTION_DETAILS(svmr_sh_regr_sample, null, 3 USING *) prediction_details
FROM mining_data_apply_v
WHERE cust_id = 100001;
```

PREDICTION_DETAILS
-------------------------------------------------------------------------------
<Details algorithm="Support Vector Machines">
<Attribute name="CUST_MARITAL_STATUS" actualValue="Widowed" weight=".361" rank="1"/>
<Attribute name="CUST_GENDER" actualValue="F" weight=".14" rank="2"/>
<Attribute name="HOME_THEATER_PACKAGE" actualValue="1" weight=".135" rank="3"/>
</Details>

Analytic Syntax
This example dynamically identifies customers whose age is not typical for the data. The query returns the attributes that predict or detract from a typical age.

```sql
SELECT cust_id, age, pred_age, age-pred_age age_diff, pred_det
FROM (SELECT cust_id, age, PREDICTION(FOR age USING *) OVER () pred_age,
      PREDICTION_DETAILS(FOR age ABS USING *) OVER () pred_det
      FROM mining_data_apply_v)
WHERE rnk <= 5;
```

</Details>
PREDICTION_PROBABILITY

Syntax

\[
prediction\_probability::=
\]

Analytic Syntax

\[
prediction\_prob\_analytic::=
\]

**Purpose**

PREDICTION_PROBABILITY returns a probability for each row in the selection. The probability refers to the highest probability class or to the specified `class`. The data type of the returned probability is `BINARY_DOUBLE`.

PREDICTION_PROBABILITY can perform classification or anomaly detection. For classification, the returned probability refers to a predicted target class. For anomaly detection, the returned probability refers to a classification of 1 (for typical rows) or 0 (for anomalous rows).

You can use PREDICTION_PROBABILITY in conjunction with the PREDICTION function to obtain the prediction and the probability of the prediction.

See Also:
"Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of `mining_analytic_clause`
Syntax Choice

PREDICTION_PROBABILITY can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically mine the data by executing an analytic clause that builds and applies one or more transient mining models. Choose Syntax or Analytic Syntax:

- **Syntax** — Use the first syntax to score the data with a pre-defined model. Supply the name of a model that performs classification or anomaly detection.
- **Analytic Syntax** — Use the analytic syntax to score the data without a pre-defined model. The analytic syntax uses `mining_analytic_clause`, which specifies if the data should be partitioned for multiple model builds. The `mining_analytic_clause` supports a `query_partition_clause` and an `order_by_clause`. (See “analytic_clause::=” on page 7-12.)
  - For classification, specify `FOR expr`, where `expr` is an expression that identifies a target column that has a character data type.
  - For anomaly detection, specify the keywords `OF ANOMALY`.

**mining_attribute_clause**

`mining_attribute_clause` identifies the column attributes to use as predictors for scoring. When the function is invoked with the analytic syntax, these predictors are also used for building the transient models. The `mining_attribute_clause` behaves as described for the `PREDICTION` function. (See ”`mining_attribute_clause::=”` on page 7-237.)

**About the Examples:** The following examples are excerpted from the Data Mining sample programs. For information about the sample programs, see Appendix A in *Oracle Data Mining User’s Guide*.

**Example**

The following example returns the 10 customers living in Italy who are most likely to use an affinity card.

```sql
SELECT cust_id FROM {
    SELECT cust_id
    FROM mining_data_apply_v
    WHERE country_name = 'Italy'
    ORDER BY PREDICTION_PROBABILITY(DT_SH_Clas_sample, 1 USING *)
        DESC, cust_id)
WHERE rownum < 11;
```

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>100081</td>
</tr>
<tr>
<td>100179</td>
</tr>
<tr>
<td>100185</td>
</tr>
<tr>
<td>100324</td>
</tr>
<tr>
<td>100344</td>
</tr>
<tr>
<td>100554</td>
</tr>
</tbody>
</table>
Analytic Example

This example identifies rows that are most atypical in the data in mining_data_one_class_v. Each type of marital status is considered separately so that the most anomalous rows per marital status group are returned.

The query returns three attributes that have the most influence on the determination of anomalous rows. The PARTITION BY clause causes separate models to be built and applied for each marital status. Because there is only one record with status Mabsent, no model is created for that partition (and no details are provided).

```
SELECT cust_id, cust_marital_status, rank_anom, anom_det FROM
(SELECT cust_id, cust_marital_status, anom_det,

PREDICTION_SET

Syntax

\[ \text{prediction_set} := \]

Analytic Syntax

\[ \text{prediction_set_analytic} := \]

\[ \text{cost_matrix_clause} := \]

\[ \text{mining_attribute_clause} := \]

\[ \text{mining_analytic_clause} := \]
See Also: "Analytic Functions" on page 7-12 for information on the syntax, semantics, and restrictions of mining_analytic_clause

Purpose
PREDICTION_SET returns a set of predictions with either probabilities or costs for each row in the selection. The return value is a varray of objects with field names PREDICTION_ID and PROBABILITY or COST. The prediction identifier is an Oracle NUMBER; the probability and cost fields are BINARY_DOUBLE.

PREDICTION_SET can perform classification or anomaly detection. For classification, the return value refers to a predicted target class. For anomaly detection, the return value refers to a classification of 1 (for typical rows) or 0 (for anomalous rows).

cost_matrix_clause
You can specify cost_matrix_clause as a biasing factor for minimizing the most harmful kinds of misclassifications. cost_matrix_clause behaves as described for "PREDICTION_COST" on page 7-243.

Syntax Choice
PREDICTION_SET can score the data in one of two ways: It can apply a mining model object to the data, or it can dynamically mine the data by executing an analytic clause that builds and applies one or more transient mining models. Choose Syntax or Analytic Syntax:

- Syntax — Use the first syntax to score the data with a pre-defined model. Supply the name of a model that performs classification or anomaly detection.

- Analytic Syntax — Use the analytic syntax to score the data without a pre-defined model. The analytic syntax uses mining_analytic_clause, which specifies if the data should be partitioned for multiple model builds. The mining_analytic_clause supports a query_partition_clause and an order_by_clause. (See "analytic_clause::=" on page 7-12.)
  - For classification, specify FOR expr, where expr is an expression that identifies a target column that has a character data type.
  - For anomaly detection, specify the keywords OF ANOMALY.

bestN and cutoff
You can specify bestN and cutoff to limit the number of predictions returned by the function. By default, both bestN and cutoff are null and all predictions are returned.

- bestN is the N predictions that are either the most probable or the least costly. If multiple predictions share the Mth probability or cost, then the function chooses one of them.

- cutoff is a value threshold. Only predictions with probability greater than or equal to cutoff, or with cost less than or equal to cutoff, are returned. To filter by cutoff only, specify NULL for bestN. If the function uses a cost_matrix_clause with COST MODEL AUTO, then cutoff is ignored.

You can specify bestN with cutoff to return up to the N most probable predictions that are greater than or equal to cutoff. If costs are used, specify bestN with cutoff to return up to the N least costly predictions that are less than or equal to cutoff.
mining_attribute_clause

`mining_attribute_clause` identifies the column attributes to use as predictors for scoring. When the function is invoked with the analytic syntax, these predictors are also used for building the transient models. The `mining_attribute_clause` behaves as described for the `PREDICTION` function. (See "mining_attribute_clause::=" on page 7-237.)

**See Also:**

**About the Example:** The following example is excerpted from the Data Mining sample programs. For more information about the sample programs, see Appendix A in *Oracle Data Mining User’s Guide*.

**Example**

This example lists the probability and cost that customers with ID less than 100006 will use an affinity card. This example has a binary target, but such a query is also useful for multiclass classification such as low, medium, and high.

```sql
SELECT T.cust_id, S.prediction, S.probability, S.cost
FROM (SELECT cust_id,
       PREDICTION_SET(dt_sh_clas_sample COST MODEL USING *) pset
FROM mining_data_apply_v
WHERE cust_id < 100006) T,
    TABLE(T.pset) S
ORDER BY cust_id, S.prediction;
```

PRESENTNNV

Syntax

\[
\text{PRESENTNNV}(\text{cell_reference}, \text{expr1}, \text{expr2})
\]

Purpose

The PRESENTNNV function can be used only in the `model_clause` of the `SELECT` statement and then only on the right-hand side of a model rule. It returns `expr1` when `cell_reference` exists prior to the execution of the `model_clause` and is not null when `PRESENTNNV` is evaluated. Otherwise it returns `expr2`. This function differs from `NVL2` in that `NVL2` evaluates the data at the time it is executed, rather than evaluating the data as it was prior to the execution of the `model_clause`.

See Also:

- `model_clause` on page 19-35 and "Model Expressions" on page 5-13 for the syntax and semantics
- `NVL2` on page 7-218 for comparison

Examples

In the following example, if a row containing sales for the Mouse Pad for the year 2002 exists, and the sales value is not null, then the sales value remains unchanged. If the row exists and the sales value is null, then the sales value is set to 10. If the row does not exist, then the row is created with the sales value set to 10.

```sql
SELECT country, prod, year, s
FROM sales_view_ref
MODEL
  PARTITION BY (country)
  DIMENSION BY (prod, year)
  MEASURES (sale s)
  IGNORE NAV
  UNIQUE DIMENSION
  RULES UPSERT SEQUENTIAL ORDER
  ( s['Mouse Pad', 2002] = PRESENTNNV(s['Mouse Pad', 2002], s['Mouse Pad', 2002], 10) )
ORDER BY country, prod, year;
```

COUNTRY | PROD       | YEAR | S
---------|------------|------|---------
France   | Mouse Pad  | 1998 | 2509.42 |
France   | Mouse Pad  | 1999 | 3678.69 |
France   | Mouse Pad  | 2000 | 3000.72 |
France   | Mouse Pad  | 2001 | 3269.09 |
France   | Mouse Pad  | 2002 | 10      |
France   | Standard Mouse | 1998 | 2390.83 |
France   | Standard Mouse | 1999 | 2280.45 |
France   | Standard Mouse | 2000 | 1274.31 |
France   | Standard Mouse | 2001 | 2164.54 |
Germany  | Mouse Pad  | 1998 | 5827.87 |
Germany  | Mouse Pad  | 1999 | 8346.44 |
Germany  | Mouse Pad  | 2000 | 7375.46 |
Germany  | Mouse Pad  | 2001 | 9535.08 |
Germany  | Mouse Pad  | 2002 | 10      |
<table>
<thead>
<tr>

PRESENTV

Syntax

\[
\text{PRESENTV}(cell\_reference, expr1, expr2)
\]

Purpose

The PRESENTV function can be used only within the model_clause of the SELECT statement and then only on the right-hand side of a model rule. It returns \( expr1 \) when, prior to the execution of the model_clause, cell_reference exists. Otherwise it returns \( expr2 \).

See Also: model_clause on page 19-35 and "Model Expressions" on page 5-13 for the syntax and semantics

Examples

In the following example, if a row containing sales for the Mouse Pad for the year 2000 exists, then the sales value for the Mouse Pad for the year 2001 is set to the sales value for the Mouse Pad for the year 2000. If the row does not exist, then a row is created with the sales value for the Mouse Pad for year 2000 set to 0.

```sql
SELECT country, prod, year, s
FROM sales_view_ref
MODEL
PARTITION BY (country)
DIMENSION BY (prod, year)
MEASURES (sale s)
IGNORE NAV
UNIQUE DIMENSION
RULES UPSERT SEQUENTIAL ORDER
{
  s['Mouse Pad', 2001] = 
  PRESENTV(s['Mouse Pad', 2000], s['Mouse Pad', 2000], 0)
}
ORDER BY country, prod, year;
```

</tr>
</tbody>
</table>

16 rows selected.
The preceding example requires the view `sales_view_ref`. Refer to "The MODEL clause: Examples" on page 19-63 to create this view.
The `PREVIOUS` function can be used only in the `model_clause` of the `SELECT` statement and then only in the `ITERATE ... [ UNTIL ]` clause of the `model_rules_clause`. It returns the value of `cell_reference` at the beginning of each iteration.

**Examples**

The following example repeats the rules, up to 1000 times, until the difference between the values of `cur_val` at the beginning and at the end of an iteration is less than one:

```sql
SELECT dim_col, cur_val, num_of_iterations
FROM (SELECT 1 AS dim_col, 10 AS cur_val FROM dual)
MODEL
  DIMENSION BY (dim_col)
  MEASURES (cur_val, 0 num_of_iterations)
  IGNORE NAV
  UNIQUE DIMENSION
  RULES ITERATE (1000) UNTIL (PREVIOUS(cur_val[1]) - cur_val[1] < 1)
  {
    cur_val[1] = cur_val[1]/2,
  );

DIM_COL CUR_VAL NUM_OF_ITERATIONS
---------- ---------- -----------------
  1       .625                 4
```

See Also: `model_clause` on page 19-35 and "Model Expressions" on page 5-13 for the syntax and semantics.
RANK

Aggregate Syntax

\[
\text{rank\_aggregate ::= RANK (expr) WITHIN GROUP} \]

Analytic Syntax

\[
\text{rank\_analytic ::= RANK (expr) OVER (query\_partition\_clause order\_by\_clause)} \\
\]

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

RANK calculates the rank of a value in a group of values. The return type is NUMBER.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and "Numeric Precedence" on page 2-16 for information on numeric precedence

Rows with equal values for the ranking criteria receive the same rank. Oracle Database then adds the number of tied rows to the tied rank to calculate the next rank. Therefore, the ranks may not be consecutive numbers. This function is useful for top-N and bottom-N reporting.

- As an aggregate function, RANK calculates the rank of a hypothetical row identified by the arguments of the function with respect to a given sort specification. The arguments of the function must all evaluate to constant expressions within each aggregate group, because they identify a single row within each group. The constant argument expressions and the expressions in the ORDER BY clause of the aggregate match by position. Therefore, the number of arguments must be the same and their types must be compatible.

- As an analytic function, RANK computes the rank of each row returned from a query with respect to the other rows returned by the query, based on the values of the value_exprs in the order_by_clause.
Aggregate Example
The following example calculates the rank of a hypothetical employee in the sample table hr.employees with a salary of $15,500 and a commission of 5%:

```
SELECT RANK(15500, .05) WITHIN GROUP
  (ORDER BY salary, commission_pct) "Rank"
FROM employees;
```

```
Rank
----------
105
```

Similarly, the following query returns the rank for a $15,500 salary among the employee salaries:

```
SELECT RANK(15500) WITHIN GROUP
  (ORDER BY salary DESC) "Rank of 15500"
FROM employees;
```

```
Rank of 15500
-------------
4
```

Analytic Example
The following statement ranks the employees in the sample hr schema in department 60 based on their salaries. Identical salary values receive the same rank and cause nonconsecutive ranks. Compare this example with the analytic example for DENSE_RANK on page 7-97.

```
SELECT department_id, last_name, salary,
  RANK() OVER (PARTITION BY department_id ORDER BY salary) RANK
FROM employees WHERE department_id = 60
ORDER BY RANK, last_name;
```

```
DEPARTMENT_ID LAST_NAME             SALARY   RANK
------------- ------------------------- ---------- ----------
     60 Lorentz                         4200     1
     60 Austin                          4800     2
     60 Pataballa                       4800     2
     60 Ernst                           6000     4
     60 Hunold                          9000     5
```
RATIO_TO_REPORT

Syntax

```
RATIO_TO_REPORT(expr) OVER (query_partition_clause)
```

See Also:  "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions, including valid forms of `expr`

Purpose

RATIO_TO_REPORT is an analytic function. It computes the ratio of a value to the sum of a set of values. If `expr` evaluates to null, then the ratio-to-report value also evaluates to null.

The set of values is determined by the `query_partition_clause`. If you omit that clause, then the ratio-to-report is computed over all rows returned by the query.

You cannot nest analytic functions by using `RATIO_TO_REPORT` or any other analytic function for `expr`. However, you can use other built-in function expressions for `expr`. Refer to "About SQL Expressions" on page 5-1 for information on valid forms of `expr`.

Examples

The following example calculates the ratio-to-report value of each purchasing clerk's salary to the total of all purchasing clerks' salaries:

```
SELECT last_name, salary, RATIO_TO_REPORT(salary) OVER () AS rr
FROM employees
WHERE job_id = 'PU_CLERK'
ORDER BY last_name, salary, rr;
```

```
LAST_NAME                     SALARY         RR
------------------------- ---------- ----------
Baida                           2900 .208633094
Colmenares                      2500 .179856115
Himuro                          2600 .18705036
Khoo                            3100 .223021583
Tobias                          2800 .201438849
```
RAWTOHEX

Syntax

RAWTOHEX (raw)

Purpose

RAWTOHEX converts raw to a character value containing its hexadecimal representation. As a SQL built-in function, RAWTOHEX accepts an argument of any scalar data type other than LONG, LONG RAW, CLOB, NCLB, BLOB, or BFILE. If the argument is of a data type other than RAW, then this function converts the argument value, which is represented using some number of data bytes, into a RAW value with the same number of data bytes. The data itself is not modified in any way, but the data type is recast to a RAW data type.

This function returns a VARCHAR2 value with the hexadecimal representation of bytes that make up the value of raw. Each byte is represented by two hexadecimal digits.

Note: RAWTOHEX functions differently when used as a PL/SQL built-in function. Refer to Oracle Database Development Guide for more information.

Examples

The following hypothetical example returns the hexadecimal equivalent of a RAW column value:

SELECT RAWTOHEX(raw_column) "Graphics"
FROM graphics;

Graphics
--------
7D

See Also: "RAW and LONG RAW Data Types" on page 2-26 and HEXTORAW on page 7-133
RAWTONHEX

Syntax

```
RAWTONHEX(raw)
```

Purpose

RAWTONHEX converts raw to a character value containing its hexadecimal representation. RAWTONHEX(raw) is equivalent to TO_NCHAR(RAWTOHEX(raw)). The value returned is always in the national character set.

---

**Note:** RAWTONHEX functions differently when used as a PL/SQL built-in function. Refer to Oracle Database Development Guide for more information.

---

Examples

The following hypothetical example returns the hexadecimal equivalent of a RAW column value:

```
SELECT RAWTONHEX(raw_column),
       DUMP (RAWTONHEX(raw_column)) "DUMP"
FROM graphics;
```

<table>
<thead>
<tr>
<th>RAWTONHEX(RA)</th>
<th>DUMP</th>
</tr>
</thead>
<tbody>
<tr>
<td>7D</td>
<td>Typ=1 Len=4: 0,55,0,68</td>
</tr>
</tbody>
</table>
REF

Syntax

\[ \text{REF}(\text{correlation\_variable}) \]

Purpose

REF takes as its argument a correlation variable (table alias) associated with a row of an object table or an object view. A REF value is returned for the object instance that is bound to the variable or row.

Examples

The sample schema oe contains a type called cust_address_typ, described as follows:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>STREET_ADDRESS</td>
<td>VARCHAR2(40)</td>
</tr>
<tr>
<td>POSTAL_CODE</td>
<td>VARCHAR2(10)</td>
</tr>
<tr>
<td>CITY</td>
<td>VARCHAR2(30)</td>
</tr>
<tr>
<td>STATE_PROVINCE</td>
<td>VARCHAR2(10)</td>
</tr>
<tr>
<td>COUNTRY_ID</td>
<td>CHAR(2)</td>
</tr>
</tbody>
</table>

The following example creates a table based on the sample type oe.cust_address_typ, inserts a row into the table, and retrieves a REF value for the object instance of the type in the addresses table:

CREATE TABLE addresses OF cust_address_typ;

INSERT INTO addresses VALUES ('123 First Street', '4GF H1J', 'Our Town', 'Ourcounty', 'US');

SELECT REF(e) FROM addresses e;

REF(E)

See Also: Oracle Database Object-Relational Developer's Guide for information on REFs
REFTOHEX

Syntax

```
REFTOHEX(expr)
```

Purpose

REFTOHEX converts argument `expr` to a character value containing its hexadecimal equivalent. `expr` must return a REF.

Examples

The sample schema `oe` contains a `warehouse_typ`. The following example builds on that type to illustrate how to convert the REF value of a column to a character value containing its hexadecimal equivalent:

```sql
CREATE TABLE warehouse_table OF warehouse_typ
   (PRIMARY KEY (warehouse_id));

CREATE TABLE location_table
   (location_number NUMBER, building REF warehouse_typ
    SCOPE IS warehouse_table);

INSERT INTO warehouse_table VALUES (1, 'Downtown', 99);

INSERT INTO location_table SELECT 10, REF(w) FROM warehouse_table w;

SELECT REFTOHEX(building) FROM location_table;

REFTOHEX(BUILDING)
```

```
0000220208859B5E9255C31760E034080020825436859B5E9255C21760E034080020825436
```
REGEXP_COUNT

Syntax

```
REGEXP_COUNT(source_char, pattern, position, match_param)
```

Purpose

REGEXP_COUNT complements the functionality of the REGEXP_INSTR function by returning the number of times a pattern occurs in a source string. The function evaluates strings using characters as defined by the input character set. It returns an integer indicating the number of occurrences of pattern. If no match is found, then the function returns 0.

- `source_char` is a character column and can be of any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB.
- `pattern` is the regular expression. It is usually a text literal and can be of any of the data types CHAR, VARCHAR2, NCHAR, or NVARCHAR2. It can contain up to 512 bytes. If the data type of `pattern` is different from the data type of `source_char`, then Oracle Database converts `pattern` to the data type of `source_char`.
- `position` is a positive integer indicating the character of `source_char` where Oracle should begin the search. The default is 1, meaning that Oracle begins the search at the first character of `source_char`. After finding the first occurrence of `pattern`, the database searches for a second occurrence beginning with the first character following the first occurrence.
- `match_param` is a text literal that lets you change the default matching behavior of the function. You can specify one or more of the following values for `match_param`:
  - `'i'` specifies case-insensitive matching.
  - `'c'` specifies case-sensitive matching.
  - `'n'` allows the period (.), which is the match-any-character character, to match the newline character. If you omit this parameter, then the period does not match the newline character.
  - `'m'` treats the source string as multiple lines. Oracle interprets the caret (^) and dollar sign ($) as the start and end, respectively, of any line anywhere in the source string, rather than only at the start or end of the entire source string. If you omit this parameter, then Oracle treats the source string as a single line.
  - `'x'` ignores whitespace characters. By default, whitespace characters match themselves.

If you specify multiple contradictory values, then Oracle uses the last value. For example, if you specify `'ic'`, then Oracle uses case-sensitive matching. If you specify a character other than those shown above, then Oracle returns an error.

If you omit `match_param`, then:
- The default case sensitivity is determined by the value of the NLS_SORT parameter.
- A period (.) does not match the newline character.
- The source string is treated as a single line.

**Examples**
The following example shows that subexpressions parentheses in pattern are ignored:

```sql
SELECT REGEXP_COUNT('123123123123123', '(12)3', 1, 'i') FROM DUAL;
```

```
REGEXP_COUNT
------------
    5
```

In the following example, the function begins to evaluate the source string at the third character, so skips over the first occurrence of pattern:

```sql
SELECT REGEXP_COUNT('123123123123', '123', 3, 'i') FROM DUAL;
```

```
COUNT
--------
    3
```
REGEXP_INSTR

Syntax

```sql
REGEXP_INSTR(source_char, pattern, position, occurrence, return_option, match_param, subexpr)
```

Purpose

REGEXP_INSTR extends the functionality of the INSTR function by letting you search a string for a regular expression pattern. The function evaluates strings using characters as defined by the input character set. It returns an integer indicating the beginning or ending position of the matched substring, depending on the value of the `return_option` argument. If no match is found, then the function returns 0.

This function complies with the POSIX regular expression standard and the Unicode Regular Expression Guidelines. For more information, refer to Appendix D, "Oracle Regular Expression Support".

- `source_char` is a character expression that serves as the search value. It is commonly a character column and can be of any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB.

- `pattern` is the regular expression. It is usually a text literal and can be of any of the data types CHAR, VARCHAR2, NCHAR, or NVARCHAR2. It can contain up to 512 bytes. If the data type of `pattern` is different from the data type of `source_char`, then Oracle Database converts `pattern` to the data type of `source_char`. For a listing of the operators you can specify in `pattern`, refer to Appendix D, "Oracle Regular Expression Support".

- `position` is a positive integer indicating the character of `source_char` where Oracle should begin the search. The default is 1, meaning that Oracle begins the search at the first character of `source_char`.

- `occurrence` is a positive integer indicating which occurrence of `pattern` in `source_char` Oracle should search for. The default is 1, meaning that Oracle searches for the first occurrence of `pattern`. If `occurrence` is greater than 1, then the database searches for the second occurrence beginning with the first character following the first occurrence of `pattern`, and so forth. This behavior is different from the INSTR function, which begins its search for the second occurrence at the second character of the first occurrence.

- `return_option` lets you specify what Oracle should return in relation to the occurrence:
  - If you specify 0, then Oracle returns the position of the first character of the occurrence. This is the default.
  - If you specify 1, then Oracle returns the position of the character following the occurrence.
**match_parameter** is a text literal that lets you change the default matching behavior of the function. The behavior of this parameter is the same for this function as for **REGEXP_COUNT**. Refer to **REGEXP_COUNT** on page 7-269 for detailed information.

For a **pattern** with subexpressions, **subexpr** is an integer from 0 to 9 indicating which subexpression in **pattern** is the target of the function. The **subexpr** is a fragment of pattern enclosed in parentheses. Subexpressions can be nested. Subexpressions are numbered in order in which their left parentheses appear in pattern. For example, consider the following expression:

```
0123(((abc)(def)ghi)45(678))
```

This expression has five subexpressions in the following order: "abcdefg" followed by "abcdef", "abc", "de" and "678".

If **subexpr** is zero, then the position of the entire substring that matches the **pattern** is returned. If **subexpr** is greater than zero, then the position of the substring fragment that corresponds to subexpression number **subexpr** in the matched substring is returned. If **pattern** does not have at least **subexpr** subexpressions, the function returns zero. A null **subexpr** value returns **NULL**. The default value for **subexpr** is zero.

**See Also:**

- **INSTR** on page 7-143 and **REGEXP_SUBSTR** on page 7-277
- **REGEXP_REPLACE** on page 7-274 and **REGEXP_LIKE Condition** on page 6-17

**Examples**

The following example examines the string, looking for occurrences of one or more non-blank characters. Oracle begins searching at the first character in the string and returns the starting position (default) of the sixth occurrence of one or more non-blank characters.

```
SELECT REGEXP_INSTR('500 Oracle Parkway, Redwood Shores, CA', '[^ \n]+', 1, 6) "REGEXP_INSTR"
FROM DUAL;
```

<table>
<thead>
<tr>
<th>REGEXP_INSTR</th>
</tr>
</thead>
<tbody>
<tr>
<td>37</td>
</tr>
</tbody>
</table>

The following example examines the string, looking for occurrences of words beginning with **s**, **r**, or **p**, regardless of case, followed by any six alphabetic characters. Oracle begins searching at the third character in the string and returns the position in the string of the character following the second occurrence of a seven-letter word beginning with **s**, **r**, or **p**, regardless of case.

```
SELECT REGEXP_INSTR('500 Oracle Parkway, Redwood Shores, CA', '[s|r|p][[:alpha:]]{6}', 3, 2, 1, 'i') "REGEXP_INSTR"
FROM DUAL;
```

<table>
<thead>
<tr>
<th>REGEXP_INSTR</th>
</tr>
</thead>
<tbody>
<tr>
<td>28</td>
</tr>
</tbody>
</table>
The following examples use the `subexpr` argument to search for a particular subexpression in `pattern`. The first statement returns the position in the source string of the first character in the first subexpression, which is '123':

```
SELECT REGEXP_INSTR('1234567890', '(123)(4(56)(78))', 1, 1, 0, 'i', 1) *REGEXP_INSTR* FROM DUAL;
```

REGEXP_INSTR
--------------
1

The next statement returns the position in the source string of the first character in the second subexpression, which is '45678':

```
SELECT REGEXP_INSTR('1234567890', '(123)(4(56)(78))', 1, 1, 0, 'i', 2) *REGEXP_INSTR* FROM DUAL;
```

REGEXP_INSTR
--------------
4

The next statement returns the position in the source string of the first character in the fourth subexpression, which is '78':

```
SELECT REGEXP_INSTR('1234567890', '(123)(4(56)(78))', 1, 1, 0, 'i', 4) *REGEXP_INSTR* FROM DUAL;
```

REGEXP_INSTR
--------------
7
REGEXP_REPLACE extends the functionality of the REPLACE function by letting you search a string for a regular expression pattern. By default, the function returns source_char with every occurrence of the regular expression pattern replaced with replace_string. The string returned is in the same character set as source_char. The function returns VARCHAR2 if the first argument is not a LOB and returns CLOB if the first argument is a LOB.

This function complies with the POSIX regular expression standard and the Unicode Regular Expression Guidelines. For more information, refer to Appendix D, "Oracle Regular Expression Support".

- source_char is a character expression that serves as the search value. It is commonly a character column and can be of any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB or NCLOB.

- pattern is the regular expression. It is usually a text literal and can be of any of the data types CHAR, VARCHAR2, NCHAR, or NVARCHAR2. It can contain up to 512 bytes. If the data type of pattern is different from the data type of source_char, then Oracle Database converts pattern to the data type of source_char. For a listing of the operators you can specify in pattern, refer to Appendix D, "Oracle Regular Expression Support".

- replace_string can be of any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB. If replace_string is a CLOB or NCLOB, then Oracle truncates replace_string to 32K. The replace_string can contain up to 500 backreferences to subexpressions in the form \n, where n is a number from 1 to 9. If you want to include a backslash (\) in replace_string, then you must precede it with the escape character, which is also a backslash. For example, to replace \2 you would enter \\2. For more information on backreference expressions, refer to the notes to "Oracle Regular Expression Support", Table D–1 on page D-1.

- position is a positive integer indicating the character of source_char where Oracle should begin the search. The default is 1, meaning that Oracle begins the search at the first character of source_char.

- occurrence is a nonnegative integer indicating the occurrence of the replace operation:
  - If you specify 0, then Oracle replaces all occurrences of the match.
  - If you specify a positive integer n, then Oracle replaces the n

If occurrence is greater than 1, then the database searches for the second occurrence beginning with the first character following the first occurrence of
pattern, and so forth. This behavior is different from the INSTR function, which begins its search for the second occurrence at the second character of the first occurrence.

- **match_parameter** is a text literal that lets you change the default matching behavior of the function. The behavior of this parameter is the same for this function as for REGEXP_COUNT. Refer to REGEXP_COUNT on page 7-269 for detailed information.

**Examples**

The following example examines `phone_number`, looking for the pattern `xxx.xxx.xxxx`. Oracle reformats this pattern with `(xxx) xxx-xxxx`.

```sql
SELECT REGEXP_REPLACE(phone_number,
    '([[:digit:]]{3})\.(\[[:digit:]]{3})\.(\[[:digit:]]{4})',
    '(\1) \2-\3') "REGEXP_REPLACE"
FROM employees
ORDER BY "REGEXP_REPLACE";
```

<table>
<thead>
<tr>
<th>REGEXP_REPLACE</th>
</tr>
</thead>
<tbody>
<tr>
<td>(515) 123-4444</td>
</tr>
<tr>
<td>(515) 123-4567</td>
</tr>
<tr>
<td>(515) 123-4568</td>
</tr>
<tr>
<td>(515) 123-4569</td>
</tr>
<tr>
<td>(515) 123-5555</td>
</tr>
<tr>
<td>. . .</td>
</tr>
</tbody>
</table>

The following example examines `country_name`. Oracle puts a space after each non-null character in the string.

```sql
SELECT REGEXP_REPLACE(country_name, '(.)', '\1 ') "REGEXP_REPLACE"
FROM countries;
```

<table>
<thead>
<tr>
<th>REGEXP_REPLACE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Argentina</td>
</tr>
<tr>
<td>Australia</td>
</tr>
<tr>
<td>Belgium</td>
</tr>
<tr>
<td>Brazil</td>
</tr>
<tr>
<td>Canada</td>
</tr>
<tr>
<td>. . .</td>
</tr>
</tbody>
</table>

The following example examines the string, looking for two or more spaces. Oracle replaces each occurrence of two or more spaces with a single space.

```sql
SELECT REGEXP_REPLACE('500 Oracle Parkway, Redwood Shores, CA', '( ){2,}', ' ') "REGEXP_REPLACE"
FROM DUAL;
```

<table>
<thead>
<tr>
<th>REGEXP_REPLACE</th>
</tr>
</thead>
<tbody>
<tr>
<td>500 Oracle</td>
</tr>
<tr>
<td>Parkway, Redwood Shores, CA</td>
</tr>
</tbody>
</table>
REGEXP_SUBSTR

Syntax

```
REGEXP_SUBSTR(source_char, pattern
  position, occurrence, match_param
  subexpr)
```

Purpose

REGEXP_SUBSTR extends the functionality of the SUBSTR function by letting you search a string for a regular expression pattern. It is also similar to REGEXP_INSTR, but instead of returning the position of the substring, it returns the substring itself. This function is useful if you need the contents of a match string but not its position in the source string. The function returns the string as VARCHAR2 or CLOB data in the same character set as source_char.

This function complies with the POSIX regular expression standard and the Unicode Regular Expression Guidelines. For more information, refer to Appendix D, "Oracle Regular Expression Support".

- **source_char** is a character expression that serves as the search value. It is commonly a character column and can be of any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NLOB.

- **pattern** is the regular expression. It is usually a text literal and can be of any of the data types CHAR, VARCHAR2, NCHAR, or NVARCHAR2. It can contain up to 512 bytes. If the data type of pattern is different from the data type of source_char, then Oracle Database converts pattern to the data type of source_char. For a listing of the operators you can specify in pattern, refer to Appendix D, "Oracle Regular Expression Support".

- **position** is a positive integer indicating the character of source_char where Oracle should begin the search. The default is 1, meaning that Oracle begins the search at the first character of source_char.

- **occurrence** is a positive integer indicating which occurrence of pattern in source_char Oracle should search for. The default is 1, meaning that Oracle searches for the first occurrence of pattern.

  If occurrence is greater than 1, then the database searches for the second occurrence beginning with the first character following the first occurrence of pattern, and so forth. This behavior is different from the SUBSTR function, which begins its search for the second occurrence at the second character of the first occurrence.

- **match_parameter** is a text literal that lets you change the default matching behavior of the function. The behavior of this parameter is the same for this function as for REGEXP_COUNT. Refer to REGEXP_COUNT on page 7-269 for detailed information.

- For a pattern with subexpressions, **subexpr** is a nonnegative integer from 0 to 9 indicating which subexpression in pattern is to be returned by the function. This
parameter has the same semantics that it has for the REGEXP_INSTR function. Refer to REGEXP_INSTR on page 7-271 for more information.

**See Also:**
- SUBSTR on page 7-329 and REGEXP_INSTR on page 7-271
- REGEXP_REPLACE on page 7-274, and REGEXP_LIKE Condition on page 6-17

**Examples**
The following example examines the string, looking for the first substring bounded by commas. Oracle Database searches for a comma followed by one or more occurrences of non-comma characters followed by a comma. Oracle returns the substring, including the leading and trailing commas.

```
SELECT
  REGEXP_SUBSTR('500 Oracle Parkway, Redwood Shores, CA', ',[^,]+,' 'REGEXPR_SUBSTR'
FROM DUAL;
REGEXPR_SUBSTR
-------------
, Redwood Shores,
```

The following example examines the string, looking for http:// followed by a substring of one or more alphanumeric characters and optionally, a period (.). Oracle searches for a minimum of three and a maximum of four occurrences of this substring between http:// and either a slash (/) or the end of the string.

```
SELECT
  REGEXP_SUBSTR('http://www.example.com/products', 'http://([^[:alnum:]]+\.?){3,4}/?') 'REGEXP_SUBSTR'
FROM DUAL;
REGEXP_SUBSTR
----------------------
http://www.example.com/
```

The next two examples use the subexpr argument to return a specific subexpression of pattern. The first statement returns the first subexpression in pattern:

```
SELECT REGEXP_SUBSTR('1234567890', '(123)(4(56)(78))', 1, 1, 'i', 1) "REGEXP_SUBSTR" FROM DUAL;
REGEXP_SUBSTR
-------------------
123
```

The next statement returns the fourth subexpression in pattern:

```
SELECT REGEXP_SUBSTR('1234567890', '(123)(4(56)(78))', 1, 1, 'i', 4) "REGEXP_SUBSTR" FROM DUAL;
REGEXP_SUBSTR
-------------------
78
```
REGR_ (Linear Regression) Functions

The linear regression functions are:

- REGR_SLOPE
- REGR_INTERCEPT
- REGR_COUNT
- REGR_R2
- REGR_AVGX
- REGR_AVGY
- REGR_SXX
- REGR_SYY
- REGR_SXY

**Syntax**

```sql
linear_regr ::= REGR_SLOPE
            | REGR_INTERCEPT
            | REGR_COUNT
            | REGR_R2
            | REGR_AVGX
            | REGR_AVGY
            | REGR_SXX
            | REGR_SYY
            | REGR_SXY

(expr1, expr2) OVER (analytic_clause)
```

**See Also:** "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

**Purpose**

The linear regression functions fit an ordinary-least-squares regression line to a set of number pairs. You can use them as both aggregate and analytic functions.

**See Also:** "Aggregate Functions" on page 7-10 and "About SQL Expressions" on page 5-1 for information on valid forms of `expr`

These functions take as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. Oracle determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.
REGR_ (Linear Regression) Functions

Oracle applies the function to the set of \((\text{expr1}, \text{expr2})\) pairs after eliminating all pairs for which either \text{expr1} or \text{expr2} is null. Oracle computes all the regression functions simultaneously during a single pass through the data.

\text{expr1} is interpreted as a value of the dependent variable (a \(y\) value), and \text{expr2} is interpreted as a value of the independent variable (an \(x\) value).

- **REGR_SLOPE** returns the slope of the line. The return value is a numeric data type and can be null. After the elimination of null \((\text{expr1}, \text{expr2})\) pairs, it makes the following computation:
  
  \[
  \frac{\text{COVARPOP}(\text{expr1}, \text{expr2})}{\text{VARPOP}(\text{expr2})}
  \]

- **REGR_INTERCEPT** returns the \(y\)-intercept of the regression line. The return value is a numeric data type and can be null. After the elimination of null \((\text{expr1}, \text{expr2})\) pairs, it makes the following computation:
  
  \[
  \text{AVG}(\text{expr1}) - \text{REGR_SLOPE}(\text{expr1}, \text{expr2}) \times \text{AVG}(\text{expr2})
  \]

- **REGR_COUNT** returns an integer that is the number of non-null number pairs used to fit the regression line.

- **REGR_R2** returns the coefficient of determination (also called R-squared or goodness of fit) for the regression. The return value is a numeric data type and can be null. \(\text{VARPOP}(\text{expr1})\) and \(\text{VARPOP}(\text{expr2})\) are evaluated after the elimination of null pairs. The return values are:
  
  - \(\text{NULL}\) if \(\text{VARPOP}(\text{expr2}) = 0\)
  - \(1\) if \(\text{VARPOP}(\text{expr1}) = 0\) and \(\text{VARPOP}(\text{expr2}) \neq 0\)
  - \(\text{POWER}(\text{CORR}(\text{expr1}, \text{expr2}), 2)\) if \(\text{VARPOP}(\text{expr1}) > 0\) and \(\text{VARPOP}(\text{expr2}) \neq 0\)

All of the remaining regression functions return a numeric data type and can be null:

- **REGR_AVGX** evaluates the average of the independent variable \((\text{expr2})\) of the regression line. It makes the following computation after the elimination of null \((\text{expr1}, \text{expr2})\) pairs:
  
  \[
  \text{AVG}(\text{expr2})
  \]

- **REGR_AVGY** evaluates the average of the dependent variable \((\text{expr1})\) of the regression line. It makes the following computation after the elimination of null \((\text{expr1}, \text{expr2})\) pairs:
  
  \[
  \text{AVG}(\text{expr1})
  \]

**REGR_SXY**, **REGR_SXX**, **REGR_SYY** are auxiliary functions that are used to compute various diagnostic statistics.

- **REGR_SXX** makes the following computation after the elimination of null \((\text{expr1}, \text{expr2})\) pairs:
  
  \[
  \text{REGR_COUNT}(\text{expr1}, \text{expr2}) \times \text{VARPOP}(\text{expr2})
  \]
- **REGR_SYY** makes the following computation after the elimination of null \((\text{expr1}, \text{expr2})\) pairs:
  \[
  \text{REGR_COUNT(\text{expr1}, \text{expr2})} \cdot \text{VAR_POP(\text{expr1})}
  \]
- **REGR_SXY** makes the following computation after the elimination of null \((\text{expr1}, \text{expr2})\) pairs:
  \[
  \text{REGR_COUNT(\text{expr1}, \text{expr2})} \cdot \text{COVAR_POP(\text{expr1}, \text{expr2})}
  \]

The following examples are based on the sample tables `sh.sales` and `sh.products`.

### General Linear Regression Example

The following example provides a comparison of the various linear regression functions used in their analytic form. The analytic form of these functions can be useful when you want to use regression statistics for calculations such as finding the salary predicted for each employee by the model. The sections that follow on the individual linear regression functions contain examples of the aggregate form of these functions.

```sql
SELECT job_id, employee_id ID, salary,
       REGR_SLOPE(SYSDATE-hire_date, salary)
       OVER (PARTITION BY job_id) slope,
       REGR_INTERCEPT(SYSDATE-hire_date, salary)
       OVER (PARTITION BY job_id) intcpt,
       REGR_R2(SYSDATE-hire_date, salary)
       OVER (PARTITION BY job_id) rsqr,
       REGR_COUNT(SYSDATE-hire_date, salary)
       OVER (PARTITION BY job_id) count,
       REGR_AVGX(SYSDATE-hire_date, salary)
       OVER (PARTITION BY job_id) avgx,
       REGR_AVGY(SYSDATE-hire_date, salary)
       OVER (PARTITION BY job_id) avgy
FROM employees
WHERE department_id in (50, 80)
ORDER BY job_id, employee_id;
```

```

### REGR_SLOPE and REGR_INTERCEPT Examples

The following example calculates the slope and regression of the linear regression model for time employed \((\text{SYSDATE} - \text{hire_date})\) and salary using the sample table `hr.employees`. Results are grouped by `job_id`.

```sql
SELECT job_id,
       REGR_SLOPE(SYSDATE-hire_date, salary) slope,
FROM hr.employees
WHERE department_id in (50, 80)
ORDER BY job_id,
```
REGR_INTERCEPT(SYSDATE-hire_date, salary) intercept
FROM employees
WHERE department_id in (50, 80)
GROUP BY job_id
ORDER BY job_id;

<table>
<thead>
<tr>

REGR_COUNT Examples
The following example calculates the count of by job_id for time employed (SYSDATE - hire_date) and salary using the sample table hr.employees. Results are grouped by job_id.

SELECT job_id,
REGR_COUNT(SYSDATE-hire_date, salary) count
FROM employees
WHERE department_id in (30, 50)
GROUP BY job_id
ORDER BY job_id, count;

<table>
<thead>
<tr>

</table>
REMAINDER

Syntax

```plaintext
REMAINDER(n2, n1)
```

Purpose

REMAINDER returns the remainder of \( n2 \) divided by \( n1 \).

This function takes as arguments any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. Oracle determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

The `MOD` function is similar to `REMAINDER` except that it uses `FLOOR` in its formula, whereas `REMAINDER` uses `ROUND`. Refer to `MOD` on page 7-196.

- If \( n1 \) = 0 or \( n2 \) = infinity, then Oracle returns
  - An error if the arguments are of type `NUMBER`
  - `NaN` if the arguments are `BINARY_FLOAT` or `BINARY_DOUBLE`.
- If \( n1 \) != 0, then the remainder is \( n2 - (n1 \times N) \) where \( N \) is the integer nearest \( n2/n1 \). If \( n2/n1 \) equals \( x.5 \), then \( N \) is the nearest even integer.
- If \( n2 \) is a floating-point number, and if the remainder is 0, then the sign of the remainder is the sign of \( n2 \). Remainders of 0 are unsigned for `NUMBER` values.

Examples

Using table `float_point_demo`, created for the TO_BINARY_DOUBLE "Examples" on page 7-354, the following example divides two floating-point numbers and returns the remainder of that operation:

```sql
SELECT bin_float, bin_double, REMAINDER(bin_float, bin_double)
FROM float_point_demo;
```

```
BIN_FLOAT  BIN_DOUBLE  REMAINDER(BIN_FLOAT, BIN_DOUBLE)
----------  ----------  -------------------------------
1.235E+003  1.235E+003                        5.859E-005
```

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion and "Numeric Precedence" on page 2-16 for information on numeric precedence.
REPLACE

Syntax

```
REPLACE (char, search_string, replacement_string)
```

Purpose

REPLACE returns char with every occurrence of search_string replaced with replacement_string. If replacement_string is omitted or null, then all occurrences of search_string are removed. If search_string is null, then char is returned.

Both search_string and replacement_string, as well as char, can be any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB. The string returned is in the same character set as char. The function returns VARCHAR2 if the first argument is not a LOB and returns CLOB if the first argument is a LOB.

REPLACE provides functionality related to that provided by the TRANSLATE function. TRANSLATE provides single-character, one-to-one substitution. REPLACE lets you substitute one string for another as well as to remove character strings.

See Also: TRANSLATE on page 7-382

Examples

The following example replaces occurrences of J with BL:

```
SELECT REPLACE('JACK and JUE','J','BL') "Changes"
FROM DUAL;
```

Changes

-------------
BLACK and BLUE
ROUND (date)

Syntax

\[ \text{round\_date} ::= \]

\[ \text{ROUND} \rightarrow \text{date} \rightarrow \text{fmt} \rightarrow \text{date} \rightarrow \]

Purpose

ROUND returns \textit{date} rounded to the unit specified by the format model \textit{fmt}. This function is not sensitive to the NLS_CALENDAR session parameter. It operates according to the rules of the Gregorian calendar. The value returned is always of data type DATE, even if you specify a different datetime data type for \textit{date}. If you omit \textit{fmt}, then \textit{date} is rounded to the nearest day. The \textit{date} expression must resolve to a DATE value.

\[ \text{See Also: } \text{"ROUND and TRUNC Date Functions" on page 7-437 for the permitted format models to use in fmt} \]

Examples

The following example rounds a date to the first day of the following year:

```
SELECT ROUND (TO_DATE ('27-OCT-00') , 'YEAR')
    'New Year' FROM DUAL;
```

New Year
---------
01-JAN-01
ROUND (number)

Syntax

\[ \text{round\_number ::= \text{ROUND} (n, \text{integer})} \]

Purpose

ROUND returns \( n \) rounded to \( \text{integer} \) places to the right of the decimal point. If you omit \( \text{integer} \), then \( n \) is rounded to zero places. If \( \text{integer} \) is negative, then \( n \) is rounded off to the left of the decimal point.

\( n \) can be any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If you omit \( \text{integer} \), then the function returns the value \( \text{ROUND}(n, 0) \) in the same data type as the numeric data type of \( n \). If you include \( \text{integer} \), then the function returns \( \text{NUMBER} \).

ROUND is implemented using the following rules:

1. If \( n \) is 0, then \( \text{ROUND} \) always returns 0 regardless of \( \text{integer} \).
2. If \( n \) is negative, then \( \text{ROUND}(n, \text{integer}) \) returns -\( \text{ROUND}(-n, \text{integer}) \).
3. If \( n \) is positive, then

\[
\text{ROUND}(n, \text{integer}) = \text{FLOOR}(n \times \text{POWER}(10, \text{integer}) + 0.5) \times \text{POWER}(10, -\text{integer})
\]

ROUND applied to a \( \text{NUMBER} \) value may give a slightly different result from \( \text{ROUND} \) applied to the same value expressed in floating-point. The different results arise from differences in internal representations of \( \text{NUMBER} \) and floating point values. The difference will be \( 1 \) in the rounded digit if a difference occurs.

See Also:

- Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion
- "Floating-Point Numbers" on page 2-15 for more information on how Oracle Database handles \( \text{BINARY\_FLOAT} \) and \( \text{BINARY\_DOUBLE} \) values
- \( \text{FLOOR} \) on page 7-126 and \( \text{CEIL} \) on page 7-40, \( \text{TRUNC (number)} \) on page 7-388 and \( \text{MOD} \) on page 7-196 for information on functions that perform related operations

Examples

The following example rounds a number to one decimal point:

```sql
SELECT ROUND(15.193,1) "Round" FROM DUAL;
```

```
Round
-------
15.2
```

The following example rounds a number one digit to the left of the decimal point:

```sql
SELECT ROUND(15.193,-1) "Round" FROM DUAL;
```
ROUND (number)

Round
--------
  20
**ROW_NUMBER**

Syntax

```
ROW_NUMBER { OVER (query_partition_clause) order_by_clause }
```

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

**Purpose**

`ROW_NUMBER` is an analytic function. It assigns a unique number to each row to which it is applied (either each row in the partition or each row returned by the query), in the ordered sequence of rows specified in the `order_by_clause`, beginning with 1.

By nesting a subquery using `ROW_NUMBER` inside a query that retrieves the `ROW_NUMBER` values for a specified range, you can find a precise subset of rows from the results of the inner query. This use of the function lets you implement top-N, bottom-N, and inner-N reporting. For consistent results, the query must ensure a deterministic sort order.

**Examples**

The following example finds the three highest paid employees in each department in the `hr.employees` table. Fewer than three rows are returned for departments with fewer than three employees.

```
SELECT department_id, first_name, last_name, salary
FROM

(SELECT department_id, first_name, last_name, salary,
     ROW_NUMBER() OVER (PARTITION BY department_id ORDER BY salary desc) rn
  FROM employees
) WHERE rn <= 3
ORDER BY department_id, salary DESC, last_name;
```

The following example is a join query on the `sh.sales` table. It finds the sales amounts in 2000 of the five top-selling products in 1999 and compares the difference between 2000 and 1999. The ten top-selling products are calculated within each distribution channel.

```
SELECT sales_2000.channel_desc, sales_2000.prod_name,
      sales_2000.amt  amt_2000, top_5_prods_1999_year.amt  amt_1999,
      sales_2000.amt  - top_5_prods_1999_year.amt  amt_diff
FROM

/* The first subquery finds the 5 top-selling products per channel in year 1999. */
(SELECT channel_desc, prod_name, amt
  FROM

  (SELECT channel_desc, prod_name, sum(amount_sold) amt,
   ROW_NUMBER() OVER (PARTITION BY channel_desc
                       ORDER BY SUM(amount_sold) DESC) rn
  FROM sales, times, channels, products
  WHERE sales.time_id = times.time_id
  AND times.calendar_year = 1999
  GROUP BY channel_desc, prod_name)
  WHERE rn <= 5
) AS top_5_prods_1999_year
JOIN sales_2000
  ON top_5_prods_1999_year.prod_name = sales_2000.prod_name
  AND top_5_prods_1999_year.channel_desc = sales_2000.channel_desc
ORDER BY sales_2000.channel_desc, sales_2000.prod_name;
```
AND channels.channel_id = sales.channel_id
AND products.prod_id = sales.prod_id
GROUP BY channel_desc, prod_name
)
WHERE rn <= 5
) top_5_prods_1999_year,
/* The next subquery finds sales per product and per channel in 2000. */
(SELECT channel_desc, prod_name, sum(amount_sold) amt
FROM sales, times, channels, products
WHERE sales.time_id = times.time_id
AND times.calendar_year = 2000
AND channels.channel_id = sales.channel_id
AND products.prod_id = sales.prod_id
GROUP BY channel_desc, prod_name
) sales_2000
WHERE sales_2000.channel_desc = top_5_prods_1999_year.channel_desc
AND sales_2000.prod_name = top_5_prods_1999_year.prod_name
ORDER BY sales_2000.channel_desc, sales_2000.prod_name
;

ROWIDTOCHAR

Syntax

```
ROWIDTOCHAR(rowid)
```

Purpose

`ROWIDTOCHAR` converts a rowid value to `VARCHAR2` data type. The result of this conversion is always 18 characters long.

Examples

The following example converts a rowid value in the `employees` table to a character value. (Results vary for each build of the sample database.)

```sql
SELECT ROWID FROM employees
  WHERE ROWIDTOCHAR(ROWID) LIKE '%JAAB%
  ORDER BY ROWID;
```

<table>
<thead>
<tr>
<th>ROWID</th>
</tr>
</thead>
<tbody>
<tr>
<td>AAAFFIAAPAAAABSAAAb</td>
</tr>
</tbody>
</table>
ROWIDTONCHAR

Syntax

```
ROWIDTONCHAR ( rowid )
```

Purpose

`ROWIDTONCHAR` converts a rowid value to `NVARCHAR2` data type. The result of this conversion is always in the national character set and is 18 characters long.

Examples

The following example converts a rowid value to an `NVARCHAR2` string:

```
SELECT LENGTH( ROWIDTONCHAR(ROWID) ) Length, ROWIDTONCHAR(ROWID)
FROM employees
ORDER BY length;
```

```
<table>
<thead>
<tr>
<th>Length</th>
<th>ROWIDTONCHAR(ROWID)</th>

</thead>
<tbody>
<tr>
<td>36</td>
<td>AAAL52AFAAAABSABD</td>
</tr>
<tr>
<td>36</td>
<td>AAAL52AFAAAABSABV</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>
```
RPAD

Syntax

```
RPAD(expr1, n, expr2)
```

Purpose

RPAD returns `expr1`, right-padded to length `n` characters with `expr2`, replicated as many times as necessary. This function is useful for formatting the output of a query.

Both `expr1` and `expr2` can be any of the data types `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, `CLOB`, or `NCLOB`. The string returned is of `VARCHAR2` data type if `expr1` is a character data type, `NVARCHAR2` if `expr1` is a national character data type, and a LOB if `expr1` is a LOB data type. The string returned is in the same character set as `expr1`. The argument `n` must be a `NUMBER` integer or a value that can be implicitly converted to a `NUMBER` integer.

`expr1` cannot be null. If you do not specify `expr2`, then it defaults to a single blank. If `expr1` is longer than `n`, then this function returns the portion of `expr1` that fits in `n`.

The argument `n` is the total length of the return value as it is displayed on your terminal screen. In most character sets, this is also the number of characters in the return value. However, in some multibyte character sets, the display length of a character string can differ from the number of characters in the string.

Examples

The following example creates a simple chart of salary amounts by padding a single space with asterisks:

```
SELECT last_name, RPAD(' ', salary/1000/1, '*') "Salary"
FROM employees
WHERE department_id = 80
ORDER BY last_name, "Salary";
```

```
LAST_NAME  Salary
-----------  --------

Ande        *****
Banda       *****
Bates       *****
Bernstein   ********
Bloom       ********
Cambrault   *********
Cambrault   *****
Doran       *****
Errazuriz   *********
Fox         ********
Greene      ********
Hall        ********
Hutton      ********
Johnson     *****
King        ********
...          
```
RTRIM

Syntax

```
RTRIM(char, set)
```

Purpose

RTRIM removes from the right end of char all of the characters that appear in set. This function is useful for formatting the output of a query.

If you do not specify set, then it defaults to a single blank. RTRIM works similarly to LTRIM.

Both char and set can be any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB. The string returned is of VARCHAR2 data type if char is a character data type, NVARCHAR2 if char is a national character data type, and a LOB if char is a LOB data type.

See Also: LTRIM on page 7-188

Examples

The following example trims all the right-most occurrences of less than sign (<), greater than sign (>), and equal sign (=) from a string:

```
SELECT RTRIM('<<<<>BROWNING<<<<>', '<=>') "RTRIM Example"
 FROM DUAL;
```

RTRIM Example

```
<<<<>BROWNING
```
SCN_TO_TIMESTAMP

Syntax

\[
\text{SCN\_TO\_TIMESTAMP}(\text{number})
\]

Purpose

SCN_TO_TIMESTAMP takes as an argument a number that evaluates to a system change number (SCN), and returns the approximate timestamp associated with that SCN. The returned value is of TIMESTMP data type. This function is useful any time you want to know the timestamp associated with an SCN. For example, it can be used in conjunction with the ORA\_ROWSCN pseudocolumn to associate a timestamp with the most recent change to a row.

Notes:

- The usual precision of the result value is 3 seconds.
- The association between an SCN and a timestamp when the SCN is generated is remembered by the database for a limited period of time. This period is the maximum of the auto-tuned undo retention period, if the database runs in the Automatic Undo Management mode, and the retention times of all flashback archives in the database, but no less than 120 hours. The time for the association to become obsolete elapses only when the database is open. An error is returned if the SCN specified for the argument to SCN\_TO\_TIMESTAMP is too old.

See Also: ORA\_ROWSCN Pseudocolumn on page 3-8 and TIMESTAMP\_TO\_SCN on page 7-353

Examples

The following example uses the ORA\_ROWSCN pseudocolumn to determine the system change number of the last update to a row and uses SCN\_TO\_TIMESTAMP to convert that SCN to a timestamp:

```sql
SELECT SCN_TO_TIMESTAMP(ORA_ROWSCN) FROM employees
WHERE employee_id = 188;
```

You could use such a query to convert a system change number to a timestamp for use in an Oracle Flashback Query:

```sql
SELECT salary FROM employees WHERE employee_id = 188;
  SALARY
  --------
  3800

UPDATE employees SET salary = salary*10 WHERE employee_id = 188;
COMMIT;

SELECT salary FROM employees WHERE employee_id = 188;
  SALARY
  --------
  38000

SELECT SCN_TO_TIMESTAMP(ORA_ROWSCN) FROM employees
```

```
WHERE employee_id = 188;
SCN_TO_TIMESTAMP(ORA_ROWSCN)

28-AUG-03 01.58.01.000000000 PM

FLASHBACK TABLE employees TO TIMESTAMP
   TO_TIMESTAMP('28-AUG-03 01.00.00.000000000 PM');

SELECT salary FROM employees WHERE employee_id = 188;
  SALARY
     ----
      3800
SESSIONTIMEZONE

Syntax

SESSIONTIMEZONE

Purpose

SESSIONTIMEZONE returns the time zone of the current session. The return type is a time zone offset (a character type in the format ' [+|−]TZH:TZM') or a time zone region name, depending on how the user specified the session time zone value in the most recent ALTER SESSION statement.

Note: The default client session time zone is an offset even if the client operating system uses a named time zone. If you want the default session time zone to use a named time zone, then set the ORA_SDTZ variable in the client environment to an Oracle time zone region name. Refer to Oracle Database Globalization Support Guide for more information on this variable.

Examples

The following example returns the time zone of the current session:

SELECT SESSIONTIMEZONE FROM DUAL;

SESSION
-------
-08:00
SET

Syntax

```
SET (nested_table) 
```

Purpose

SET converts a nested table into a set by eliminating duplicates. The function returns a nested table whose elements are distinct from one another. The returned nested table is of the same type as the input nested table.

The element types of the nested table must be comparable. Refer to "Comparison Conditions" on page 6-4 for information on the comparability of nonscalar types.

Examples

The following example selects from the customers_demo table the unique elements of the cust_address_ntab nested table column:

```
SELECT customer_id, SET(cust_address_ntab) address
FROM customers_demo
ORDER BY customer_id;
```

<table>
<thead>

<td>CUST_ADDRESS_TAB_TYP(CUST_ADDRESS_TYP('4819 W 3rd St', '47404', 'Bloomington', 'IN', 'US'))</td>
</tr>
</tbody>
</table>

The preceding example requires the table customers_demo and a nested table column containing data. Refer to "Multiset Operators" on page 4-1 to create this table and nested table column.
SIGN

Syntax

\[ \text{SIGN}( \text{n} ) \]

Purpose

SIGN returns the sign of \( n \). This function takes as an argument any numeric data type, or any nonnumeric data type that can be implicitly converted to NUMBER, and returns NUMBER.

For value of NUMBER type, the sign is:
- -1 if \( n < 0 \)
- 0 if \( n = 0 \)
- 1 if \( n > 0 \)

For binary floating-point numbers (BINARY_FLOAT and BINARY_DOUBLE), this function returns the sign bit of the number. The sign bit is:
- -1 if \( n < 0 \)
- +1 if \( n \geq 0 \) or \( n = \text{NaN} \)

Examples

The following example indicates that the argument of the function (-15) is <0:

```
SELECT SIGN(-15) "Sign" FROM DUAL;
```

```
Sign
-------
-1
```
SIN

Syntax

\[
\text{SIN}(n)
\]

Purpose

\(\text{SIN}\) returns the sine of \(n\) (an angle expressed in radians).

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If the argument is \texttt{BINARY_FLOAT}, then the function returns \texttt{BINARY_DOUBLE}. Otherwise the function returns the same numeric data type as the argument.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

Examples

The following example returns the sine of 30 degrees:

```
SELECT \text{SIN}(30 * 3.14159265359/180)
'Sine of 30 degrees' FROM DUAL;
```

Sine of 30 degrees
------------------
.5
SINH

Syntax

\[ \text{SINH}(n) \]

Purpose

SINH returns the hyperbolic sine of \( n \).

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If the argument is \texttt{BINARY\_FLOAT}, then the function returns \texttt{BINARY\_DOUBLE}. Otherwise the function returns the same numeric data type as the argument.

**See Also:** Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

Examples

The following example returns the hyperbolic sine of 1:

```sql
SELECT SINH(1) 'Hyperbolic sine of 1' FROM DUAL;
```

Hyperbolic sine of 1
---------------------
1.17520119
SOUNDEX

Syntax

```sql
SOUNDEX(char)
```

Purpose

SOUNDEX returns a character string containing the phonetic representation of `char`. This function lets you compare words that are spelled differently, but sound alike in English.

The phonetic representation is defined in *The Art of Computer Programming*, Volume 3: Sorting and Searching, by Donald E. Knuth, as follows:

1. Retain the first letter of the string and remove all other occurrences of the following letters: a, e, h, i, o, u, w, y.
2. Assign numbers to the remaining letters (after the first) as follows:
   - b, f, p, v = 1
   - c, g, j, k, q, s, x, z = 2
   - d, t = 3
   - l = 4
   - m, n = 5
   - r = 6
3. If two or more letters with the same number were adjacent in the original name (before step 1), or adjacent except for any intervening h and w, then retain the first letter and omit rest of all the adjacent letters with same number.
4. Return the first four bytes padded with 0.

`char` can be of any of the data types `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2`. The return value is the same data type as `char`.

This function does not support `CLOB` data directly. However, `CLOBs` can be passed in as arguments through implicit data conversion.

See Also: "Data Type Comparison Rules" on page 2-39 for more information.

Examples

The following example returns the employees whose last names are a phonetic representation of "Smyth":

```sql
SELECT last_name, first_name
FROM hr.employees
WHERE SOUNDEX(last_name) = SOUNDEX('SMYTHE')
ORDER BY last_name, first_name;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>FIRST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Smith</td>
<td>Lindsey</td>
</tr>
<tr>
<td>Smith</td>
<td>William</td>
</tr>
</tbody>
</table>
SQRT

Syntax

\[ \text{SQRT} \rightarrow \text{n} \]

Purpose

\text{SQRT} \text{ returns the square root of } n. 

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

- If \( n \) resolves to a \text{NUMBER}, then the value \( n \) cannot be negative. \text{SQRT} \text{ returns a real number.}
- If \( n \) resolves to a binary floating-point number (\text{BINARY_FLOAT} or \text{BINARY_DOUBLE}): 
  - If \( n \geq 0 \), then the result is positive.
  - If \( n = -0 \), then the result is -0.
  - If \( n < 0 \), then the result is \text{NaN}.

Examples

The following example returns the square root of 26:

```sql
SELECT SQRT(26) "Square root" FROM DUAL;
```

<table>
<thead>
<tr>
<th>Square root</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.09901951</td>
</tr>
</tbody>
</table>
STANDARD_HASH

Syntax

```
STANDARD_HASH(expr, 'method')
```

Purpose

STANDARD_HASH computes a hash value for a given expression using one of several hash algorithms that are defined and standardized by the National Institute of Standards and Technology. This function is useful for performing authentication and maintaining data integrity in security applications such as digital signatures, checksums, and fingerprinting.

You can use the STANDARD_HASH function to create an index on an extended data type column. Refer to "Creating an Index on an Extended Data Type Column" on page 14-83 for more information.

- The `expr` argument determines the data for which you want Oracle Database to compute a hash value. There are no restrictions on the length of data represented by `expr`, which commonly resolves to a column name. The `expr` cannot be a LONG or LOB type. It cannot be a user-defined object type. All other data types are supported for `expr`.

- The optional `method` argument lets you specify the name of the hash algorithm to be used. Valid algorithms are SHA1, SHA256, SHA384, SHA512, and MD5. If you omit this argument, then SHA1 is used.

The function returns a RAW value.

---

**Note:** The STANDARD_HASH function is not identical to the one used internally by Oracle Database for hash partitioning.
STATS_BINOMIAL_TEST

Syntax

```sql
STATS_BINOMIAL_TEST(expr1, expr2, p, return_value)
```

Purpose

`STATS_BINOMIAL_TEST` is an exact probability test used for dichotomous variables, where only two possible values exist. It tests the difference between a sample proportion and a given proportion. The sample size in such tests is usually small.

This function takes three required arguments: `expr1` is the sample being examined, `expr2` contains the values for which the proportion is expected to be, and `p` is a proportion to test against. The optional fourth argument lets you specify the meaning of the NUMBER value returned by this function, as shown in Table 7–3. For this argument, you can specify a text literal, or a bind variable or expression that evaluates to a constant character value. If you omit the fourth argument, then the default is 'TWO_SIDED_PROB'.

Table 7–3 STATS_BINOMIAL Return Values

<table>
<thead>
<tr>
<th>Argument</th>
<th>Return Value Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'TWO_SIDED_PROB'</td>
<td>The probability that the given population proportion, ( p ), could result in the observed proportion or a more extreme one.</td>
</tr>
<tr>
<td>'EXACT_PROB'</td>
<td>The probability that the given population proportion, ( p ), could result in exactly the observed proportion.</td>
</tr>
<tr>
<td>'ONE_SIDED_PROB_OR_MORE'</td>
<td>The probability that the given population proportion, ( p ), could result in the observed proportion or a larger one.</td>
</tr>
<tr>
<td>'ONE_SIDED_PROB_OR_LESS'</td>
<td>The probability that the given population proportion, ( p ), could result in the observed proportion or a smaller one.</td>
</tr>
</tbody>
</table>

'EXACT_PROB' gives the probability of getting exactly proportion \( p \). In cases where you want to test whether the proportion found in the sample is significantly different from a 50-50 split, \( p \) would normally be 0.50. If you want to test only whether the proportion is different, then use the return value 'TWO_SIDED_PROB'. If your test is whether the proportion is more than the value of `expr2`, then use the return value 'ONE_SIDED_PROB_OR_MORE'. If the test is to determine whether the proportion of `expr2` is less, then use the return value 'ONE_SIDED_PROB_OR_LESS'.

STATS_BINOMIAL_TEST Example

The following example determines the probability that reality exactly matches the number of men observed under the assumption that 69% of the population is composed of men:

```sql
SELECT AVG(DECODE(cust_gender, 'M', 1, 0)) real_proportion,
       STATS_BINOMIAL_TEST(cust_gender, 'M', 0.68, 'EXACT_PROB') exact;
```
(cust_gender, 'M', 0.68, 'ONE_SIDED_PROB_OR_LESS') prob_or_less
FROM sh.customers;
Crosstabulation (commonly called crosstab) is a method used to analyze two nominal variables. The `STATS_CROSSTAB` function takes two required arguments: `expr1` and `expr2` are the two variables being analyzed. The optional third argument lets you specify the meaning of the NUMBER value returned by this function, as shown in Table 7–4. For this argument, you can specify a text literal, or a bind variable or expression that evaluates to a constant character value. If you omit the third argument, then the default is 'CHISQ_SIG'.

### Table 7–4  `STATS_CROSSTAB` Return Values

<table>
<thead>
<tr>
<th>Argument</th>
<th>Return Value Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'CHISQ_OBS'</td>
<td>Observed value of chi-squared</td>
</tr>
<tr>
<td>'CHISQ_SIG'</td>
<td>Significance of observed chi-squared</td>
</tr>
<tr>
<td>'CHISQ_DF'</td>
<td>Degree of freedom for chi-squared</td>
</tr>
<tr>
<td>'PHI_COEFFICIENT'</td>
<td>Phi coefficient</td>
</tr>
<tr>
<td>'CRAMERS_V'</td>
<td>Cramer's V statistic</td>
</tr>
<tr>
<td>'CONT_COEFFICIENT'</td>
<td>Contingency coefficient</td>
</tr>
<tr>
<td>'COHENS_K'</td>
<td>Cohen's kappa</td>
</tr>
</tbody>
</table>

### `STATS_CROSSTAB` Example

The following example determines the strength of the association between gender and income level:

```sql
SELECT STATS_CROSSTAB
  (cust_gender, cust_income_level, 'CHISQ_OBS') chi_squared,
  STATS_CROSSTAB
  (cust_gender, cust_income_level, 'CHISQ_SIG') p_value,
  STATS_CROSSTAB
  (cust_gender, cust_income_level, 'PHI_COEFFICIENT') phi_coefficient
FROM sh.customers;
```

<table>
<thead>
<tr>
<th>CHI_SQUARED</th>
<th>P_VALUE</th>
<th>PHI_COEFFICIENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>251.690705</td>
<td>1.2364E-47</td>
<td>0.067367056</td>
</tr>
</tbody>
</table>
**STATS_F_TEST**

**Syntax**

```
STATS_F_TEST(expr1, expr2, 'STATISTIC', expr3)
```

**Purpose**

`STATS_F_TEST` tests whether two variances are significantly different. The observed value of $f$ is the ratio of one variance to the other, so values very different from 1 usually indicate significant differences.

This function takes two required arguments: `expr1` is the grouping or independent variable and `expr2` is the sample of values. The optional third argument lets you specify the meaning of the NUMBER value returned by this function, as shown in Table 7-5. For this argument, you can specify a text literal, or a bind variable or expression that evaluates to a constant character value. If you omit the third argument, then the default is 'TWO_SIDED_SIG'.

**Table 7-5  STATS_F_TEST Return Values**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Return Value Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'STATISTIC'</td>
<td>The observed value of $f$</td>
</tr>
<tr>
<td>'DF_NUM'</td>
<td>Degree of freedom for the numerator</td>
</tr>
<tr>
<td>'DF_DEN'</td>
<td>Degree of freedom for the denominator</td>
</tr>
<tr>
<td>'ONE_SIDED_SIG'</td>
<td>One-tailed significance of $f$</td>
</tr>
<tr>
<td>'TWO_SIDED_SIG'</td>
<td>Two-tailed significance of $f$</td>
</tr>
</tbody>
</table>

The one-tailed significance is always in relation to the upper tail. The final argument, `expr3`, indicates which of the two groups specified by `expr1` is the high value or numerator (the value whose rejection region is the upper tail).

The observed value of $f$ is the ratio of the variance of one group to the variance of the second group. The significance of the observed value of $f$ is the probability that the variances are different just by chance—a number between 0 and 1. A small value for the significance indicates that the variances are significantly different. The degree of freedom for each of the variances is the number of observations in the sample minus 1.

**STATS_F_TEST Example** The following example determines whether the variance in credit limit between men and women is significantly different. The results, a p_value not close to zero, and an f_statistic close to 1, indicate that the difference between credit limits for men and women are not significant.

```sql
SELECT VARIANCE(DECODE(cust_gender, 'M', cust_credit_limit, null)) var_men,
       VARIANCE(DECODE(cust_gender, 'F', cust_credit_limit, null)) var_women,
       STATS_F_TEST(cust_gender, cust_credit_limit, 'STATISTIC', 'F') f_statistic,
       STATS_F_TEST(cust_gender, cust_credit_limit) two_sided_p_value
```

---

7-308  Oracle Database SQL Language Reference

<td>13046865</td>
<td>1.01296348</td>
<td>.311928071</td>
</tr>
</tbody>
</table>
STATS_KS_TEST

Syntax

```
STATS_KS_TEST (expr1, expr2, 'STATISTIC' | 'SIG')
```

Purpose

STATS_KS_TEST is a Kolmogorov-Smirnov function that compares two samples to test whether they are from the same population or from populations that have the same distribution. It does not assume that the population from which the samples were taken is normally distributed.

This function takes two required arguments: `expr1` classifies the data into the two samples and `expr2` contains the values for each of the samples. If `expr1` classifies the data into only one sample or into more than two samples, then an error is raised. The optional third argument lets you specify the meaning of the `NUMBER` value returned by this function, as shown in Table 7–6. For this argument, you can specify a text literal, or a bind variable or expression that evaluates to a constant character value. If you omit the third argument, then the default is `'SIG'`.

Table 7–6  STATS_KS_TEST Return Values

<table>
<thead>
<tr>
<th>Argument</th>
<th>Return Value Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'STATISTIC'</code></td>
<td>Observed value of $D$</td>
</tr>
<tr>
<td><code>'SIG'</code></td>
<td>Significance of $D$</td>
</tr>
</tbody>
</table>

STATS_KS_TEST Example  Using the Kolmogorov Smirnov test, the following example determines whether the distribution of sales between men and women is due to chance:

```
SELECT stats_ks_test(cust_gender, amount_sold, 'STATISTIC') ks_statistic,
       stats_ks_test(cust_gender, amount_sold) p_value
FROM sh.customers c, sh.sales s
WHERE c.cust_id = s.cust_id;
```

<table>
<thead>
<tr>
<th>KS_STATISTIC</th>
<th>P_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>.003841396</td>
<td>.004080006</td>
</tr>
</tbody>
</table>
STATS_MODE

Syntax

```
STATS_MODE(expr)
```

Purpose

STATS_MODE takes as its argument a set of values and returns the value that occurs with the greatest frequency. If more than one mode exists, then Oracle Database chooses one and returns only that one value.

To obtain multiple modes (if multiple modes exist), you must use a combination of other functions, as shown in the hypothetical query:

```
SELECT x FROM (SELECT x, COUNT(x) AS cnt1
    FROM t GROUP BY x)
WHERE cnt1 =
    (SELECT MAX(cnt2) FROM (SELECT COUNT(x) AS cnt2 FROM t GROUP BY x));
```

Examples

The following example returns the mode of salary per department in the hr.employees table:

```
SELECT department_id, STATS_MODE(salary) FROM employees
    GROUP BY department_id
    ORDER BY department_id, stats_mode(salary);
```

Example 1

<table>
<thead>
<tr>
<th>DEPARTMENT_ID</th>
<th>STATS_MODE(SALARY)</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>4400</td>
</tr>
<tr>
<td>20</td>
<td>6000</td>
</tr>
<tr>
<td>30</td>
<td>2500</td>
</tr>
<tr>
<td>40</td>
<td>6500</td>
</tr>
<tr>
<td>50</td>
<td>2500</td>
</tr>
<tr>
<td>60</td>
<td>4800</td>
</tr>
<tr>
<td>70</td>
<td>10000</td>
</tr>
<tr>
<td>80</td>
<td>9500</td>
</tr>
<tr>
<td>90</td>
<td>17000</td>
</tr>
<tr>
<td>100</td>
<td>6900</td>
</tr>
<tr>
<td>110</td>
<td>8300</td>
</tr>
<tr>
<td>7000</td>
<td></td>
</tr>
</tbody>
</table>

If you need to retrieve all of the modes (in cases with multiple modes), you can do so using a combination of other functions, as shown in the next example:

```
SELECT commission_pct FROM
    (SELECT commission_pct, COUNT(commission_pct) AS cnt1 FROM employees
        GROUP BY commission_pct)
WHERE cnt1 =
    (SELECT MAX(cnt2) FROM
        (SELECT COUNT(commission_pct) AS cnt2 FROM employees GROUP BY commission_pct))
ORDER BY commission_pct;
```

Example 2

<table>
<thead>
<tr>
<th>COMMISSION_PCT</th>
</tr>
</thead>
<tbody>
<tr>
<td>.2</td>
</tr>
<tr>
<td>.3</td>
</tr>
</tbody>
</table>
Syntax

Purpose
A Mann Whitney test compares two independent samples to test the null hypothesis that two populations have the same distribution function against the alternative hypothesis that the two distribution functions are different.

The `STATS_MW_TEST` does not assume that the differences between the samples are normally distributed, as do the `STATS_T_TEST_*` functions. This function takes two required arguments: `expr1` classifies the data into groups and `expr2` contains the values for each of the groups. The optional third argument lets you specify the meaning of the `NUMBER` value returned by this function, as shown in Table 7–7. For this argument, you can specify a text literal, or a bind variable or expression that evaluates to a constant character value. If you omit the third argument, then the default is `'TWO_SIDED_SIG'`.

The significance of the observed value of \( Z \) or \( U \) is the probability that the variances are different just by chance—a number between 0 and 1. A small value for the significance indicates that the variances are significantly different. The degree of freedom for each of the variances is the number of observations in the sample minus 1.

The one-tailed significance is always in relation to the upper tail. The final argument, `expr3`, indicates which of the two groups specified by `expr1` is the high value (the value whose rejection region is the upper tail).

`STATS_MW_TEST` computes the probability that the samples are from the same distribution by checking the differences in the sums of the ranks of the values. If the samples come from the same distribution, then the sums should be close in value.

**STATS_MW_TEST Example** Using the Mann Whitney test, the following example determines whether the distribution of sales between men and women is due to chance:

```sql
SELECT STATS_MW_TEST
    (cust_gender, amount_sold, 'STATISTIC') z_statistic,
    STATS_MW_TEST
```
(cust_gender, amount_sold, 'ONE_SIDED_SIG', 'F') one_sided_p_value
FROM sh.customers c, sh.sales s
WHERE c.cust_id = s.cust_id;

Z_STATISTIC ONE_SIDED_P_VALUE
-----------------------------
-1.4011509        .080584471
STATS_ONE_WAY_ANOVA

Syntax

The one-way analysis of variance function (\texttt{STATS_ONE_WAY_ANOVA}) tests differences in means (for groups or variables) for statistical significance by comparing two different estimates of variance. One estimate is based on the variances within each group or category. This is known as the mean squares within or mean square error. The other estimate is based on the variances among the means of the groups. This is known as the mean squares between. If the means of the groups are significantly different, then the mean squares between will be larger than expected and will not match the mean squares within. If the mean squares of the groups are consistent, then the two variance estimates will be about the same.

\texttt{STATS_ONE_WAY_ANOVA} takes two required arguments: \texttt{expr1} is an independent or grouping variable that divides the data into a set of groups and \texttt{expr2} is a dependent variable (a numeric expression) containing the values corresponding to each member of a group. The optional third argument lets you specify the meaning of the \texttt{NUMBER} value returned by this function, as shown in Table 7-8. For this argument, you can specify a text literal, or a bind variable or expression that evaluates to a constant character value. If you omit the third argument, then the default is \texttt{''SIG''}.

Table 7-8 \texttt{STATS_ONE_WAY_ANOVA} Return Values

<table>
<thead>
<tr>
<th>Argument</th>
<th>Return Value Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'SUM_SQUARES_BETWEEN'</td>
<td>Sum of squares between groups</td>
</tr>
<tr>
<td>'SUM_SQUARES_WITHIN'</td>
<td>Sum of squares within groups</td>
</tr>
<tr>
<td>'DF_BETWEEN'</td>
<td>Degree of freedom between groups</td>
</tr>
<tr>
<td>'DF_WITHIN'</td>
<td>Degree of freedom within groups</td>
</tr>
<tr>
<td>'MEAN_SQUARES_BETWEEN'</td>
<td>Mean squares between groups</td>
</tr>
<tr>
<td>'MEAN_SQUARES_WITHIN'</td>
<td>Mean squares within groups</td>
</tr>
<tr>
<td>'F_RATIO'</td>
<td>Ratio of the mean squares between to the mean squares within (MSB/MSW)</td>
</tr>
<tr>
<td>'SIG'</td>
<td>Significance</td>
</tr>
</tbody>
</table>
The significance of one-way analysis of variance is determined by obtaining the one-tailed significance of an $f$-test on the ratio of the mean squares between and the mean squares within. The $f$-test should use one-tailed significance, because the mean squares between can be only equal to or larger than the mean squares within. Therefore, the significance returned by `STATS_ONE_WAY_ANOVA` is the probability that the differences between the groups happened by chance—a number between 0 and 1. The smaller the number, the greater the significance of the difference between the groups. Refer to the `STATS_F_TEST` on page 7-308 for information on performing an $f$-test.

**STATS_ONE_WAY_ANOVA Example**  The following example determines the significance of the differences in mean sales within an income level and differences in mean sales between income levels. The results, $p$ values close to zero, indicate that, for both men and women, the difference in the amount of goods sold across different income levels is significant.

```
SELECT cust_gender,
       STATS_ONE_WAY_ANOVA(cust_income_level, amount_sold, 'F_RATIO') f_ratio,
       STATS_ONE_WAY_ANOVA(cust_income_level, amount_sold, 'SIG') p_value
FROM sh.customers c, sh.sales s
WHERE c.cust_id = s.cust_id
GROUP BY cust_gender
ORDER BY cust_gender;
```

<table>
<thead>
<tr>
<th></th>
<th>F_RATIO</th>
<th>P_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>5.59536943</td>
<td>4.7840E-09</td>
</tr>
<tr>
<td>F</td>
<td>9.2865001</td>
<td>6.7139E-17</td>
</tr>
</tbody>
</table>

The meaning of the output: The results show that there is a significant difference in sales between income levels for both men and women, with the differences being more pronounced for women.
The *t*-test functions are:

- **STATS_T_TEST_ONE**: A one-sample *t*-test
- **STATS_T_TEST_PAIRED**: A two-sample, paired *t*-test (also known as a crossed *t*-test)
- **STATS_T_TEST_INDEP**: A *t*-test of two independent groups with the same variance (pooled variances)
- **STATS_T_TEST_INDEPU**: A *t*-test of two independent groups with unequal variance (unpooled variances)

**Syntax**

```sql
stats_t_test ::= ...
```

**Purpose**

The *t*-test measures the significance of a difference of means. You can use it to compare the means of two groups or the means of one group with a constant. Each *t*-test function takes two expression arguments, although the second expression is optional for the one-sample function (**STATS_T_TEST_ONE**). Each *t*-test function takes an optional third argument, which lets you specify the meaning of the NUMBER value returned by the function, as shown in Table 7–9. For this argument, you can specify a text literal, or a bind variable or expression that evaluates to a constant character value. If you omit the third argument, then the default is **'TWO_SIDED_SIG'**.

**Table 7–9  **STATS_T_TEST_** Return Values**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Return Value Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'STATISTIC'</td>
<td>The observed value of <em>t</em></td>
</tr>
<tr>
<td>'DF'</td>
<td>Degree of freedom</td>
</tr>
<tr>
<td>'ONE_SIDED_SIG'</td>
<td>One-tailed significance of <em>t</em></td>
</tr>
<tr>
<td>'TWO_SIDED_SIG'</td>
<td>Two-tailed significance of <em>t</em></td>
</tr>
</tbody>
</table>

The two independent **STATS_T_TEST_** functions can take a fourth argument (**expr3**) if the third argument is specified as **'STATISTIC'** or **'ONE_SIDED_SIG'**. In this case, **expr3** indicates which value of **expr1** is the high value, or the value whose rejection region is the upper tail.

The significance of the observed value of *t* is the probability that the value of *t* would have been obtained by chance—a number between 0 and 1. The smaller the value, the
more significant the difference between the means. One-sided significance is always respect to the upper tail. For one-sample and paired $t$-test, the high value is the first expression. For independent $t$-test, the high value is the one specified by $expr3$.

The degree of freedom depends on the type of $t$-test that resulted in the observed value of $t$. For example, for a one-sample $t$-test ($\text{STATS\_T\_TEST\_ONE}$), the degree of freedom is the number of observations in the sample minus 1.
In the `STATS_T_TEST_ONE` function, `expr1` is the sample and `expr2` is the constant mean against which the sample mean is compared. For this t-test only, `expr2` is optional; the constant mean defaults to 0. This function obtains the value of `t` by dividing the difference between the sample mean and the known mean by the standard error of the mean (rather than the standard error of the difference of the means, as for `STATS_T_TEST_PAIRED`).

**STATS_T_TEST_ONE Example**  The following example determines the significance of the difference between the average list price and the constant value 60:

```sql
SELECT AVG(prod_list_price) group_mean,
       STATS_T_TEST_ONE(prod_list_price, 60, 'STATISTIC') t_observed,
       STATS_T_TEST_ONE(prod_list_price, 60) two_sided_p_value
FROM sh.products;
```

```
GROUP MEAN T_OBSERVED TWO_SIDED_P_VALUE
---------- ---------- -----------------
139.545556 2.32107746        .023158537
```
STATS_T_TEST_PAIRED

In the STATS_T_TEST_PAIRED function, expr1 and expr2 are the two samples whose means are being compared. This function obtains the value of \( t \) by dividing the difference between the sample means by the standard error of the difference of the means (rather than the standard error of the mean, as for STATS_T_TEST_ONE).
In the `STATS_T_TEST_INDEP` and `STATS_T_TEST_INDEPU` functions, `expr1` is the grouping column and `expr2` is the sample of values. The pooled variances version (`STATS_T_TEST_INDEP`) tests whether the means are the same or different for two distributions that have similar variances. The unpooled variances version (`STATS_T_TEST_INDEPU`) tests whether the means are the same or different even if the two distributions are known to have significantly different variances.

Before using these functions, it is advisable to determine whether the variances of the samples are significantly different. If they are, then the data may come from distributions with different shapes, and the difference of the means may not be very useful. You can perform an *f*-test to determine the difference of the variances. If they are not significantly different, use `STATS_T_TEST_INDEP`. If they are significantly different, use `STATS_T_TEST_INDEPU`. Refer to `STATS_F_TEST` on page 7-308 for information on performing an *f*-test.

**STATS_T_TEST_INDEP Example**
The following example determines the significance of the difference between the average sales to men and women where the distributions are assumed to have similar (pooled) variances:

```sql
SELECT SUBSTR(cust_income_level, 1, 22) income_level,
       AVG(DECODE(cust_gender, 'M', amount_sold, null)) sold_to_men,
       AVG(DECODE(cust_gender, 'F', amount_sold, null)) sold_to_women,
       STATS_T_TEST_INDEP(cust_gender, amount_sold, 'STATISTIC', 'F') t_observed,
       STATS_T_TEST_INDEP(cust_gender, amount_sold) two_sided_p_value
FROM sh.customers c, sh.sales s
WHERE c.cust_id = s.cust_id
GROUP BY ROLLUP(cust_income_level)
ORDER BY income_level, sold_to_men, sold_to_women, t_observed;
```

<table>

14 rows selected.

**STATS_T_TEST_INDEPU Example**
The following example determines the significance of the difference between the average sales to men and women where the distributions are known to have significantly different (unpooled) variances:

```sql
SELECT SUBSTR(cust_income_level, 1, 22) income_level,
       AVG(DECODE(cust_gender, 'M', amount_sold, null)) sold_to_men,
       AVG(DECODE(cust_gender, 'F', amount_sold, null)) sold_to_women,
       STATS_T_TEST_INDEPU(cust_gender, amount_sold, 'STATISTIC', 'F') t_observed,
       STATS_T_TEST_INDEPU(cust_gender, amount_sold) two_sided_p_value
FROM sh.customers c, sh.sales s
```
WHERE c.cust_id = s.cust_id
GROUP BY ROLLUP(cust_income_level)
ORDER BY income_level, sold_to_men, sold_to_women, t_observed;

14 rows selected.
Syntax

```
STATS_WSR_TEST(expr1, expr2, 'STATISTIC' | 'ONE_SIDED_SIG' | 'TWO_SIDED_SIG')
```

Purpose

`STATS_WSR_TEST` is a Wilcoxon Signed Ranks test of paired samples to determine whether the median of the differences between the samples is significantly different from zero. The absolute values of the differences are ordered and assigned ranks. Then the null hypothesis states that the sum of the ranks of the positive differences is equal to the sum of the ranks of the negative differences.

This function takes two required arguments: `expr1` and `expr2` are the two samples being analyzed. The optional third argument lets you specify the meaning of the `NUMBER` value returned by this function, as shown in Table 7–10. For this argument, you can specify a text literal, or a bind variable or expression that evaluates to a constant character value. If you omit the third argument, then the default is `'TWO_SIDED_SIG'`.

Table 7–10  STATS_WSR_TEST * Return Values

<table>
<thead>
<tr>
<th>Argument</th>
<th>Return Value Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'STATISTIC'</td>
<td>The observed value of Z</td>
</tr>
<tr>
<td>'ONE_SIDED_SIG'</td>
<td>One-tailed significance of Z</td>
</tr>
<tr>
<td>'TWO_SIDED_SIG'</td>
<td>Two-tailed significance of Z</td>
</tr>
</tbody>
</table>

One-sided significance is always with respect to the upper tail. The high value (the value whose rejection region is the upper tail) is `expr1`. 
STDDEV

Syntax

```
STDDEV(expr) [OVER (analytic_clause)]
```

**See Also:** "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

`STDDEV` returns the sample standard deviation of `expr`, a set of numbers. You can use it as both an aggregate and analytic function. It differs from `STDDEV_SAMP` in that `STDDEV` returns zero when it has only 1 row of input data, whereas `STDDEV_SAMP` returns null.

Oracle Database calculates the standard deviation as the square root of the variance defined for the `VARIANCE` aggregate function.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

**See Also:** Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

If you specify `DISTINCT`, then you can specify only the `query_partition_clause` of the `analytic_clause`. The `order_by_clause` and `windowing_clause` are not allowed.

**See Also:**
- "Aggregate Functions" on page 7-10, `VARIANCE` on page 7-402, and `STDDEV_SAMP` on page 7-327
- "About SQL Expressions" on page 5-1 for information on valid forms of `expr`

Aggregate Examples

The following example returns the standard deviation of the salaries in the sample `hr.employees` table:

```sql
SELECT STDDEV(salary) "Deviation"
FROM employees;
```

```
Deviation
----------
3909.36575
```

Analytic Examples

The query in the following example returns the cumulative standard deviation of the salaries in Department 80 in the sample table `hr.employees`, ordered by `hire_date`:

```sql
SELECT last_name, salary,
       STDDEV(salary) OVER (ORDER BY hire_date) "StdDev"
FROM employees
WHERE department_id = 30
```
ORDER BY last_name, salary, 'StdDev';

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>SALARY</th>
<th>StdDev</th>
</tr>
</thead>
<tbody>
<tr>
<td>Baida</td>

<td>4650.0896</td>
</tr>
</tbody>
</table>
STDDEV_POP

Syntax

\[
\text{STDDEV\_POP}(\text{expr}) \text{ OVER} \{\text{analytic\_clause}\}
\]

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

STDDEV_POP computes the population standard deviation and returns the square root of the population variance. You can use it as both an aggregate and analytic function.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

See Also: Table 2-10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

This function is the same as the square root of the \text{VAR}\_POP function. When \text{VAR}\_POP returns null, this function returns null.

See Also:
- "Aggregate Functions" on page 7-10 and \text{VAR}\_POP on page 7-399
- "About SQL Expressions" on page 5-1 for information on valid forms of \text{expr}

Aggregate Example

The following example returns the population and sample standard deviations of the amount of sales in the sample table \text{sh.sales}:

```sql
SELECT STDDEV_POP(amount_sold) "Pop",
       STDDEV_SAMP(amount_sold) "Samp"
FROM sales;
```

<table>
<thead>
<tr>
<th>Pop</th>
<th>Samp</th>
</tr>
</thead>
<tbody>
<tr>
<td>896.355151</td>
<td>896.355592</td>
</tr>
</tbody>
</table>

Analytic Example

The following example returns the population standard deviations of salaries in the sample \text{hr.employees} table by department:

```sql
SELECT department_id, last_name, salary,
       STDDEV_POP(salary) OVER (PARTITION BY department_id) AS pop_std
FROM employees
ORDER BY department_id, last_name, salary, pop_std;
```

<table>
<thead>
<tr>
<th>DEPARTMENT_ID</th>
<th>LAST_NAME</th>
<th>SALARY</th>
<th>POP_STD</th>

</tbody>
</table>
STDDEV_SAMP

Syntax

```
STDDEV_SAMP(expr) OVER (analytic_clause)
```

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

STDDEV_SAMP computes the cumulative sample standard deviation and returns the square root of the sample variance. You can use it as both an aggregate and analytic function.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

This function is same as the square root of the VAR_SAMP function. When VAR_SAMP returns null, this function returns null.

See Also:
- "Aggregate Functions" on page 7-10 and VAR_SAMP on page 7-401
- "About SQL Expressions" on page 5-1 for information on valid forms of expr

Aggregate Example

Refer to the aggregate example for STDDEV_POP on page 7-325.

Analytic Example

The following example returns the sample standard deviation of salaries in the employees table by department:

```
SELECT department_id, last_name, hire_date, salary,
     STDDEV_SAMP(salary) OVER (PARTITION BY department_id
         ORDER BY hire_date
         ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW) AS cum_sdev
FROM employees
ORDER BY department_id, last_name, hire_date, salary, cum_sdev;
```

</table>
SUBSTR

Syntax

```
substr::=
```

Purpose

The `SUBSTR` functions return a portion of `char`, beginning at character `position`, `substring_length` characters long. `SUBSTR` calculates lengths using characters as defined by the input character set. `SUBSTRB` uses bytes instead of characters. `SUBSTRC` uses Unicode complete characters. `SUBSTR2` uses UCS2 code points. `SUBSTR4` uses UCS4 code points.

■ If `position` is 0, then it is treated as 1.
■ If `position` is positive, then Oracle Database counts from the beginning of `char` to find the first character.
■ If `position` is negative, then Oracle counts backward from the end of `char`.
■ If `substring_length` is omitted, then Oracle returns all characters to the end of `char`. If `substring_length` is less than 1, then Oracle returns null.

`char` can be any of the data types `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, `CLOB`, or `NCLOB`. The exceptions are `SUBSTRC`, `SUBSTR2`, and `SUBSTR4`, which do not allow `char` to be a `CLOB` or `NCLOB`. Both `position` and `substring_length` must be of data type `NUMBER`, or any data type that can be implicitly converted to `NUMBER`, and must resolve to an integer. The return value is the same data type as `char`. Floating-point numbers passed as arguments to `SUBSTR` are automatically converted to integers.

See Also: Oracle Database Globalization Support Guide for more information about `SUBSTR` functions and length semantics in different locales.

Examples

The following example returns several specified substrings of "ABCDEFG":

```
SELECT SUBSTR('ABCDEFG',3,4) "Substring"
FROM DUAL;

Substring
---------
CDEF

SELECT SUBSTR('ABCDEFG',-5,4) "Substring"
FROM DUAL;

Substring
---------
DEFG
```
--------
CDEF

Assume a double-byte database character set:

```sql
SELECT SUBSTRB('ABCDEFG',5,4.2) "Substring with bytes"
FROM DUAL;
```

Substring with bytes
---------------------
CD
SUM

Syntax

```
SUM(expr) [DISTINCT | ALL] OVER (analytic_clause)
```

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

`SUM` returns the sum of values of `expr`. You can use it as an aggregate or analytic function.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

If you specify `DISTINCT`, then you can specify only the `query_partition_clause` of the `analytic_clause`. The `order_by_clause` and `windowing_clause` are not allowed.

See Also: "About SQL Expressions" on page 5-1 for information on valid forms of `expr` and "Aggregate Functions" on page 7-10

Aggregate Example

The following example calculates the sum of all salaries in the sample `hr.employees` table:

```
SELECT SUM(salary) "Total"
FROM employees;
```

```
Total
----------
691400
```

Analytic Example

The following example calculates, for each manager in the sample table `hr.employees`, a cumulative total of salaries of employees who answer to that manager that are equal to or less than the current salary. You can see that Raphaely and Cambrault have the same cumulative total. This is because Raphaely and Cambrault have the identical salaries, so Oracle Database adds together their salary values and applies the same cumulative total to both rows.

```
SELECT manager_id, last_name, salary,
       SUM(salary) OVER (PARTITION BY manager_id ORDER BY salary
                       RANGE UNBOUNDED PRECEDING) l_csum
FROM employees
ORDER BY manager_id, last_name, salary, l_csum;
```

```
MANAGER_ID LAST_NAME   SALARY     L_CSUM
--------------- ------- ------- -------
```

...
SYS_CONNECT_BY_PATH

Syntax

```sql
SYS_CONNECT_BY_PATH(column(char))
```

Purpose

SYS_CONNECT_BY_PATH is valid only in hierarchical queries. It returns the path of a column value from root to node, with column values separated by `char` for each row returned by `CONNECT BY` condition.

Both `column` and `char` can be any of the data types `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2`. The string returned is of `VARCHAR2` data type and is in the same character set as `column`.

See Also: "Hierarchical Queries" on page 9-3 for more information about hierarchical queries and `CONNECT BY` conditions

Examples

The following example returns the path of employee names from employee Kochhar to all employees of Kochhar (and their employees):

```sql
SELECT LPAD(' ', 2*level-1) || SYS_CONNECT_BY_PATH(last_name, '/') "Path"
FROM employees
START WITH last_name = 'Kochhar'
CONNECT BY PRIOR employee_id = manager_id;
```

Path

```
/Kochhar/Greenberg/Chen
/Kochhar/Greenberg/Faviet
/Kochhar/Greenberg/Popp
/Kochhar/Greenberg/Sciarra
/Kochhar/Greenberg/Urman
/Kochhar/Higgins/Gietz
/Kochhar/Baer
/Kochhar/Greenberg
/Kochhar/Higgins
/Kochhar/Mavris
/Kochhar/Whalen
/Kochhar
```
SYS_CONTEXT

Syntax

```
SYS_CONTEXT('namespace', 'parameter') [length]
```

Purpose

SYS_CONTEXT returns the value of parameter associated with the context namespace at the current instant. You can use this function in both SQL and PL/SQL statements. SYS_CONTEXT must be executed locally.

For namespace and parameter, you can specify either a string or an expression that resolves to a string designating a namespace or an attribute. If you specify literal arguments for namespace and parameter, and you are using SYS_CONTEXT explicitly in a SQL statement—rather than in a PL/SQL function that in turn is mentioned in a SQL statement—then Oracle Database evaluates SYS_CONTEXT only once per SQL statement execution for each call site that invokes the SYS_CONTEXT function.

The context namespace must already have been created, and the associated parameter and its value must also have been set using the DBMS_SESSION.set_context procedure. The namespace must be a valid SQL identifier. The parameter name can be any string. It is not case sensitive, but it cannot exceed 30 bytes in length.

The data type of the return value is VARCHAR2. The default maximum size of the return value is 256 bytes. You can override this default by specifying the optional length parameter, which must be a NUMBER or a value that can be implicitly converted to NUMBER. The valid range of values is 1 to 4000 bytes. If you specify an invalid value, then Oracle Database ignores it and uses the default.

Oracle provides the following built-in namespaces:

- **USERENV** - Describes the current session. The predefined parameters of namespace USERENV are listed in Table 7–11 on page 7-336.

- **SYS_SESSION_ROLES** - Indicates whether a specified role is currently enabled for the session.

See Also:

- Oracle Database Security Guide for information on using the application context feature in your application development
- CREATE CONTEXT on page 14-19 for information on creating user-defined context namespaces
- Oracle Database PL/SQL Packages and Types Reference for information on the DBMS_SESSION.set_context procedure

Examples

The following statement returns the name of the user who logged onto the database:

```sql
CONNECT OE
Enter password: password

SELECT SYS_CONTEXT ('USERENV', 'SESSION_USER')
FROM DUAL;
```
SYS_CONTEXT ('USERENV', 'SESSION_USER')
---------------------------------------
OE

The following example queries the SESSION_ROLES data dictionary view to show that RESOURCE is the only role currently enabled for the session. It then uses the SYS_CONTEXT function to show that the RESOURCE role is currently enabled for the session and the DBA role is not.

CONNECT OE
Enter password: password

SELECT role FROM session_roles;
ROLE
-------
RESOURCE

SELECT SYS_CONTEXT('SYS_SESSION_ROLES', 'RESOURCE')
FROM DUAL;

SYS_CONTEXT('SYS_SESSION_ROLES', 'RESOURCE')
--------------------------------------
TRUE

SELECT SYS_CONTEXT('SYS_SESSION_ROLES', 'DBA')
FROM DUAL;

SYS_CONTEXT('SYS_SESSION_ROLES', 'DBA')
--------------------------------------
FALSE

Note: For simplicity in demonstrating this feature, these examples do not perform the password management techniques that a deployed system normally uses. In a production environment, follow the Oracle Database password management guidelines, and disable any sample accounts. See Oracle Database Security Guide for password management guidelines and other security recommendations.

The following hypothetical example returns the group number that was set as the value for the attribute group_no in the PL/SQL package that was associated with the context hr_apps when hr_apps was created:

SELECT SYS_CONTEXT ('hr_apps', 'group_no') "User Group"
FROM DUAL;
# Table 7–11 Predefined Parameters of Namespace USERENV

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Return Value</th>

<td>■ Parallel Query Slave process: PQ_SLAVE</td>
</tr>
<tr>
<td></td>
<td>You can use IDENTIFICATION_TYPE to distinguish between external and enterprise users when the authentication method is Password, Kerberos, or SSL.</td>
</tr>
<tr>
<td><strong>BG_JOB_ID</strong></td>
<td>Job ID of the current session if it was established by an Oracle Database background process. Null if the session was not established by a background process.</td>
</tr>
</tbody>
</table>
### Table 7–11 (Cont.) Predefined Parameters of Namespace USERENV

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CDB_NAME</td>
<td>If queried while connected to a multitenant container database (CDB), returns the name of the CDB. Otherwise, returns null.</td>
</tr>
<tr>
<td>CLIENT_IDENTIFIER</td>
<td>Returns an identifier that is set by the application through the DBMS_SESSION.SET_IDENTIFIER procedure, the OCI attribute OCI_ATTR_CLIENT_IDENTIFIER, or Oracle Dynamic Monitoring Service (DMS). This attribute is used by various database components to identify lightweight application users who authenticate as the same database user.</td>
</tr>
<tr>
<td>CLIENT_INFO</td>
<td>Returns up to 64 bytes of user session information that can be stored by an application using the DBMS_APPLICATION_INFO package.</td>
</tr>
<tr>
<td>CLIENT_PROGRAM_NAME</td>
<td>The name of the program used for the database session.</td>
</tr>
<tr>
<td>CON_ID</td>
<td>If queried while connected to a CDB, returns the current container ID. Otherwise, returns 0.</td>
</tr>
<tr>
<td>CON_NAME</td>
<td>If queried while connected to a CDB, returns the current container name. Otherwise, returns the name of the database as specified in the DB_NAME initialization parameter.</td>
</tr>
<tr>
<td>CURRENT_BIND</td>
<td>The bind variables for fine-grained auditing. You can specify this attribute only inside the event handler for the fine-grained auditing feature.</td>
</tr>
<tr>
<td>CURRENT_EDITION_ID</td>
<td>The identifier of the current edition.</td>
</tr>
<tr>
<td>CURRENT_EDITION_NAME</td>
<td>The name of the current edition.</td>
</tr>
</tbody>
</table>
| CURRENT_SCHEMA    | The name of the currently active default schema. This value may change during the duration of a session through use of an ALTER SESSION SET CURRENT_SCHEMA statement. This may also change during the duration of a session to reflect the owner of any active definer’s rights object. When used directly in the body of a view definition, this returns the default schema used when executing the cursor that is using the view; it does not respect views used in the cursor as being definer’s rights.  

**Note:** Oracle recommends against issuing the SQL statement ALTER SESSION SET CURRENT_SCHEMA from within all types of stored PL/SQL units except logon triggers. |
| CURRENT_SCHEMAID  | Identifier of the currently active default schema.                                                                                                                                                           |
| CURRENT_SQL       | CURRENT_SQL returns the first 4K bytes of the current SQL that triggered the fine-grained auditing event. The CURRENT_SQL attributes return subsequent 4K-byte increments, where \( n \) can be an integer from 1 to 7, inclusive. CURRENT_SQL1 returns bytes 4K to 8K; CURRENT_SQL2 returns bytes 8K to 12K, and so forth. You can specify these attributes only inside the event handler for the fine-grained auditing feature. |
| CURRENT_SQLn      | CURRENT_SQLn returns bytes 4K to 8K, CURRENT_SQL2 returns bytes 8K to 12K, and so forth. You can specify these attributes only inside the event handler for the fine-grained auditing feature.                             |
| CURRENT_SQL_LENGTH | The length of the current SQL statement that triggers fine-grained audit or row-level security (RLS) policy functions or event handlers. You can specify this attribute only inside the event handler for the fine-grained auditing feature. |
| CURRENT_USER      | The name of the database user whose privileges are currently active. This may change during the duration of a database session as Real Application Security sessions are attached or detached, or to reflect the owner of any active definer’s rights object. When no definer’s rights object is active, CURRENT_USER returns the same value as SESSION_USER. When used directly in the body of a view definition, this returns the user that is executing the cursor that is using the view; it does not respect views used in the cursor as being definer’s rights. For enterprise users, returns schema. If a Real Application Security user is currently active, returns user XS$NULL. |

**See Also:** Oracle Database 2 Day + Security Guide for more information on user XS$NULL. |
| CURRENT_USERID    | The identifier of the database user whose privileges are currently active.                                                                                                                                   |
## Table 7–11 (Cont.) Predefined Parameters of Namespace USERENV

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATABASE_ROLE</td>
<td>The database role using the <code>SYS_CONTEXT</code> function with the <code>USERENV</code> namespace. The role is one of the following: PRIMARY, PHYSICAL_STANDBY, LOGICAL_STANDBY, SNAPSHOT_STANDBY.</td>
</tr>
<tr>
<td>DB_DOMAIN</td>
<td>Domain of the database as specified in the <code>DB_DOMAIN</code> initialization parameter.</td>
</tr>
<tr>
<td>DB_NAME</td>
<td>Name of the database as specified in the <code>DB_NAME</code> initialization parameter.</td>
</tr>
<tr>
<td>DB_SUPPLEMENTAL_LOG_LEVEL</td>
<td>If supplemental logging is enabled, returns a string containing the list of enabled supplemental logging levels. Possible values are: ALL_COLUMN, FOREIGN_KEY, MINIMAL, PRIMARY_KEY, PROCEDURAL, and UNIQUE_INDEX. If supplemental logging is not enabled, returns null.</td>
</tr>
<tr>
<td>DB_UNIQUE_NAME</td>
<td>Name of the database as specified in the <code>DB_UNIQUE_NAME</code> initialization parameter.</td>
</tr>
</tbody>
</table>
| DBLINK_INFO          | Returns the source of a database link session. Specifically, it returns a string of the form:  
|                      | `SOURCE_GLOBAL_NAME=dblink_src_global_name`, `DBLINK_NAME=dblink_name`, `SOURCE_AUDIT_SESSIONID=dblink_src_audit_sessionid`  
|                      | where:  
|                      | ▪ `dblink_src_global_name` is the unique global name of the source database  
|                      | ▪ `dblink_name` is the name of the database link on the source database  
|                      | ▪ `dblink_src_audit_sessionid` is the audit session ID of the session on the source database that initiated the connection to the remote database using `dblink_name` |
| ENTRYID              | The current audit entry number. The audit entryid sequence is shared between fine-grained audit records and regular audit records. You cannot use this attribute in distributed SQL statements. The correct auditing entry identifier can be seen only through an audit handler for standard or fine-grained audit. |
| ENTERPRISE.IDENTITY  | Returns the user’s enterprise-wide identity:  
|                      | ▪ For enterprise users: the Oracle Internet Directory DN.  
|                      | ▪ For external users: the external identity (Kerberos principal name, Radius schema names, OS user name, Certificate DN).  
|                      | ▪ For local users and SYSDBA/SYSOPER logins: `NULL`.  
|                      | The value of the attribute differs by proxy method:  
|                      | ▪ For a proxy with DN: the Oracle Internet Directory DN of the client  
|                      | ▪ For a proxy with certificate: the certificate DN of the client for external users; the Oracle Internet Directory DN for global users  
|                      | ▪ For a proxy with username: the Oracle Internet Directory DN if the client is an enterprise users; Null if the client is a local database user. |
| FG_JOB_ID            | If queried from within a job that was created using the `DBMS_JOB` package: Returns the job ID of the current session if it was established by a client foreground process. Null if the session was not established by a foreground process. Otherwise: Returns 0. |
| GLOBAL_CONTEXT_MEMORY | Returns the number being used in the System Global Area by the globally accessed context.                                                   |
| GLOBAL_UID           | Returns the global user ID from Oracle Internet Directory for Enterprise User Security (EUS) logins; returns null for all other logins.             |
| HOST                 | Name of the host machine from which the client has connected.                                                                              |
Table 7–11 (Cont.) Predefined Parameters of Namespace USERENV

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDENTIFICATION_TYPE</td>
<td>Returns the way the user’s schema was created in the database. Specifically, it reflects the IDENTIFIED clause in the CREATE/ALTER USER syntax. In the list that follows, the syntax used during schema creation is followed by the identification type returned:</td>
</tr>
<tr>
<td></td>
<td>- IDENTIFIED BY password LOCAL</td>
</tr>
<tr>
<td></td>
<td>- IDENTIFIED EXTERNALLY: EXTERNAL</td>
</tr>
<tr>
<td></td>
<td>- IDENTIFIED GLOBALLY: GLOBAL SHARED</td>
</tr>
<tr>
<td></td>
<td>- IDENTIFIED GLOBALLY AS DN GLOBAL PRIVATE</td>
</tr>
<tr>
<td>INSTANCE</td>
<td>The instance identification number of the current instance.</td>
</tr>
<tr>
<td>INSTANCE_NAME</td>
<td>The name of the instance.</td>
</tr>
<tr>
<td>IP_ADDRESS</td>
<td>IP address of the machine from which the client is connected. If the client and server are on the same machine and the connection uses IPv6 addressing, then ::1 is returned.</td>
</tr>
<tr>
<td>IS_APPLY_SERVER</td>
<td>Returns TRUE if queried from within a SQL Apply server in a logical standby database. Otherwise, returns FALSE.</td>
</tr>
<tr>
<td>IS_DG_ROLLING_UPGRADE</td>
<td>Returns TRUE if a rolling upgrade of the database software in a Data Guard configuration, initiated by way of the DBMS_ROLLING package, is active. Otherwise, returns FALSE.</td>
</tr>
<tr>
<td>ISDBA</td>
<td>Returns TRUE if the user has been authenticated as having DBA privileges either through the operating system or through a password file.</td>
</tr>
<tr>
<td>LANG</td>
<td>The abbreviated name for the language, a shorter form than the existing 'LANGUAGE' parameter.</td>
</tr>
<tr>
<td>LANGUAGE</td>
<td>The language and territory currently used by your session, along with the database character set, in this form:</td>
</tr>
<tr>
<td></td>
<td>language_territory.charsetset</td>
</tr>
<tr>
<td>MODULE</td>
<td>The application name (module) set through the DBMS_APPLICATION_INFO package or OCI.</td>
</tr>
<tr>
<td>NETWORK_PROTOCOL</td>
<td>Network protocol being used for communication, as specified in the 'PROTOCOL=protocol' portion of the connect string.</td>
</tr>
<tr>
<td>NLSCALENDAR</td>
<td>The current calendar of the current session.</td>
</tr>
<tr>
<td>NLS_CURRENCY</td>
<td>The currency of the current session.</td>
</tr>
<tr>
<td>NLS_DATE_FORMAT</td>
<td>The date format for the session.</td>
</tr>
<tr>
<td>NLS_DATE_LANGUAGE</td>
<td>The language used for expressing dates.</td>
</tr>
<tr>
<td>NLS_SORT</td>
<td>BINARY or the linguistic sort basis.</td>
</tr>
<tr>
<td>NLS_TERRITORY</td>
<td>The territory of the current session.</td>
</tr>
<tr>
<td>ORACLE_HOME</td>
<td>The full path name for the Oracle home directory.</td>
</tr>
<tr>
<td>OS_USER</td>
<td>Operating system user name of the client process that initiated the database session.</td>
</tr>
<tr>
<td>PLATFORM_SLASH</td>
<td>The slash character that is used as the file path delimiter for your platform.</td>
</tr>
<tr>
<td>POLICY_INVOKER</td>
<td>The invoker of row-level security (RLS) policy functions.</td>
</tr>
<tr>
<td>PROXY_ENTERPRISE_IDENTITY</td>
<td>Returns the Oracle Internet Directory DN when the proxy user is an enterprise user.</td>
</tr>
<tr>
<td>PROXY_USER</td>
<td>Name of the database user who opened the current session on behalf of SESSION_USER.</td>
</tr>
</tbody>
</table>
### Table 7–11  (Cont.) Predefined Parameters of Namespace USERENV

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROXY_USERID</td>
<td>Identifier of the database user who opened the current session on behalf of SESSION_USER.</td>
</tr>
<tr>
<td>SCHEDULER_JOB</td>
<td>Returns Y if the current session belongs to a foreground job or background job. Otherwise, returns N.</td>
</tr>
<tr>
<td>SERVER_HOST</td>
<td>The host name of the machine on which the instance is running.</td>
</tr>
<tr>
<td>SERVICE_NAME</td>
<td>The name of the service to which a given session is connected.</td>
</tr>
<tr>
<td>SESSION_EDITION_ID</td>
<td>The identifier of the session edition.</td>
</tr>
<tr>
<td>SESSION_EDITION_NAME</td>
<td>The name of the session edition.</td>
</tr>
</tbody>
</table>
| SESSION_USER           | The name of the session user (the user who logged on). This may change during the duration of a database session as Real Application Security sessions are attached or detached. For enterprise users, returns the schema. For other users, returns the database user name. If a Real Application Security session is currently attached to the database session, returns user XS$NULL.  

**See Also:** Oracle Database 2 Day + Security Guide for more information on user XS$NULL. |
| SESSION_USERID         | The identifier of the session user (the user who logged on).                                                                                 |
| SESSIONID              | The auditing session identifier. You cannot use this attribute in distributed SQL statements.                                                |
| SID                    | The session ID.                                                                                                                            |
| STATEMENTID            | The auditing statement identifier. STATEMENTID represents the number of SQL statements audited in a given session. You cannot use this attribute in distributed SQL statements. The correct auditing statement identifier can be seen only through an audit handler for standard or fine-grained audit. |
| TERMINAL               | The operating system identifier for the client of the current session. In distributed SQL statements, this attribute returns the identifier for your local session. In a distributed environment, this is supported only for remote SELECT statements, not for remote INSERT, UPDATE, or DELETE operations. (The return length of this parameter may vary by operating system.) |
| UNIFIED_AUDIT_SESSIONID| If queried while connected to a database that uses unified auditing or mixed mode auditing, returns the unified audit session ID.  
If queried while connected to a database that uses traditional auditing, returns null.  

**Note:** This parameter is available starting with Oracle Database 12c: Release 1 (12.1.0.2). |
SYS_DBURIGEN

Syntax

SYS_DBURIGEN takes as its argument one or more columns or attributes, and optionally a rowid, and generates a URL of data type DBURI_Type to a particular column or row object. You can then use the URL to retrieve an XML document from the database.

All columns or attributes referenced must reside in the same table. They must perform the function of a primary key. They need not actually match the primary key of the table, but they must reference a unique value. If you specify multiple columns, then all but the final column identify the row in the database, and the last column specified identifies the column within the row.

By default the URL points to a formatted XML document. If you want the URL to point only to the text of the document, then specify the optional 'text()'.

Note: In this XML context, the lowercase text is a keyword, not a syntactic placeholder.

If the table or view containing the columns or attributes does not have a schema specified in the context of the query, then Oracle Database interprets the table or view name as a public synonym.

See Also: Oracle XML DB Developer’s Guide for information on the DBURI_Type data type and XML documents in the database.

Examples

The following example uses the SYS_DBURIGen function to generate a URL of data type DBURI_Type to the email column of the row in the sample table hr.employees where the employee_id = 206:

```
SELECT SYS_DBURIGEN(employee_id, email)
    FROM employees
    WHERE employee_id = 206;
```

```
SYS_DBURIGEN(EMPLOYEE_ID,EMAIL) (URL, SPARE)
--------------------------------------------------------------------
DBURITYPE('/PUBLIC/EMPLOYEES/ROW[EMPLOYEE_ID=''206'']/EMAIL', NULL)
```
SYS_EXTRACT_UTC

Syntax

```
SYS_EXTRACT_UTC(datetime_with_timezone)
```

Purpose

`SYS_EXTRACT_UTC` extracts the UTC (Coordinated Universal Time—formerly Greenwich Mean Time) from a datetime value with time zone offset or time zone region name. If a time zone is not specified, then the datetime is associated with the session time zone.

Examples

The following example extracts the UTC from a specified datetime:

```
SELECT SYS_EXTRACT_UTC(TIMESTAMP '2000-03-28 11:30:00.00 -08:00')
FROM DUAL;
```

```
SYS_EXTRACT_UTC(TIMESTAMP '2000-03-28 11:30:00.00 -08:00')
```

-----------------------------------------------------------------

```
28-MAR-00 07.30.00 PM
```

---

7-342  Oracle Database SQL Language Reference
SYS_GUID

Syntax

```
SYS_GUID
```

Purpose

SYS_GUID generates and returns a globally unique identifier (RAW value) made up of 16 bytes. On most platforms, the generated identifier consists of a host identifier, a process or thread identifier of the process or thread invoking the function, and a nonrepeating value (sequence of bytes) for that process or thread.

Examples

The following example adds a column to the sample table hr.locations, inserts unique identifiers into each row, and returns the 32-character hexadecimal representation of the 16-byte RAW value of the global unique identifier:

```
ALTER TABLE locations ADD (uid_col RAW(16));

UPDATE locations SET uid_col = SYS_GUID();

SELECT location_id, uid_col FROM locations
ORDER BY location_id, uid_col;
```

```
LOCATION_ID UID_COL
------------- --------------------------------------------------------
1000 09F686761827CF8AE040578CB20B7491

...
SYS_OP_ZONE_ID

Note: The SYS_OP_ZONE_ID function is available starting with Oracle Database 12c Release 1 (12.1.0.2).

Syntax

```
SYS_OP_ZONE_ID (schema | table | t_alias | rowid, scale)
```

Purpose

SYS_OP_ZONE_ID takes as its argument a rowid and returns a zone ID. The rowid identifies a row in a table. The zone ID identifies the set of contiguous disk blocks, called the zone, that contains the row. The function returns a NUMBER value.

The SYS_OP_ZONE_ID function is used when creating a zone map with the CREATE MATERIALIZED ZONEMAP statement. You must specify SYS_OP_ZONE_ID in the SELECT and GROUP BY clauses of the defining subquery of the zone map.

For rowid, specify the ROWID pseudocolumn of the fact table of the zone map.

Use schema and table to specify the schema and name of the fact table, or t_alias to specify the table alias for the fact table. The specification of these parameters depends on the FROM clause in the defining subquery of the zone map:

- If the FROM clause specifies a table alias for the fact table, then you must also specify the table alias (t_alias) in SYS_OP_ZONE_ID.
- If the FROM clause does not specify a table alias for the fact table, then use table to specify the name of the fact table. You can use the schema qualifier if the fact table is in a schema other than your own. If you omit schema, then the database assumes the fact table is in your own schema. If the FROM clause specifies only one table (the fact table) then you need not specify schema or table.

The optional scale parameter represents the scale of the zone map. It is not necessary to specify this parameter because, by default, SYS_OP_ZONE_ID uses the scale of the zone map being created. If you do specify scale, then it must match the scale of the zone map being created. Refer to the SCALE clause of CREATE MATERIALIZED ZONEMAP on page 15-45 for information on specifying the scale of a zone map.

See Also: CREATE MATERIALIZED ZONEMAP on page 15-41 for more information on creating zone maps

Examples

The following example uses the SYS_OP_ZONE_ID function when creating a basic zone map that tracks the column time_id of the fact table sales. The scale of the zone map is the default value of 10. Therefore, the SYS_OP_ZONE_ID function will default to a scale value of 10.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
AS
SELECT SYS_OP_ZONE_ID(rowid), MIN(time_id), MAX(time_id)
```
FROM sales
GROUP BY SYS_OP_ZONE_ID(rowid);

The following example is similar to the previous example, except that the scale of the zone map being created is specified as 8. Therefore, the SYS_OP_ZONE_ID function will default to a scale value of 8.

CREATE MATERIALIZED ZONEMAP sales_zmap
SCALE 8
AS
  SELECT SYS_OP_ZONE_ID(rowid), MIN(time_id), MAX(time_id)
  FROM sales
  GROUP BY SYS_OP_ZONE_ID(rowid);

The following example returns an error because the scale of the zone map being created is specified as 8, which does not match the scale argument of 12 specified in the SYS_OP_ZONE_ID function.

CREATE MATERIALIZED ZONEMAP sales_zmap
SCALE 8
AS
  SELECT SYS_OP_ZONE_ID(rowid,12), MIN(time_id), MAX(time_id)
  FROM sales
  GROUP BY SYS_OP_ZONE_ID(rowid,12);

The following example creates a join zone map. The fact table is sales and the dimension tables are products and customers. Because the table alias s is specified for the fact table in the FROM clause, the table alias s is also specified in the SYS_OP_ZONE_ID function.

CREATE MATERIALIZED ZONEMAP sales_zmap
AS
  SELECT SYS_OP_ZONE_ID(s.rowid),
             MIN(prod_category), MAX(prod_category),
             MIN(country_id), MAX(country_id)
  FROM sales s, products p, customers c
  WHERE s.prod_id = p.prod_id(+) AND
        s.cust_id = c.cust_id(+)
  GROUP BY SYS_OP_ZONE_ID(s.rowid);
SYS_TYPEID

Syntax

\[
\text{SYS\_TYPEID}(\text{object\_type\_value})
\]

Purpose

SYS_TYPEID returns the typeid of the most specific type of the operand. This value is used primarily to identify the type-discriminant column underlying a substitutable column. For example, you can use the value returned by SYS_TYPEID to build an index on the type-discriminant column.

You can use this function only on object type operands. All final root object types—final types not belonging to a type hierarchy—have a null typeid. Oracle Database assigns to all types belonging to a type hierarchy a unique non-null typeid.

See Also: Oracle Database Object-Relational Developer’s Guide for more information on typeids

Examples

The following examples use the tables persons and books, which are created in "Substitutable Table and Column Examples" on page 16-91. The first query returns the most specific types of the object instances stored in the persons table.

```
SELECT name, SYS_TYPEID(VALUE(p)) "Type_id" FROM persons p;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>Type_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bob</td>
<td>01</td>
</tr>
<tr>
<td>Joe</td>
<td>02</td>
</tr>
<tr>
<td>Tim</td>
<td>03</td>
</tr>
</tbody>
</table>

The next query returns the most specific types of authors stored in the table books:

```
SELECT b.title, b.author.name, SYS_TYPEID(author) "Type_ID" FROM books b;
```

<table>
<thead>
<tr>
<th>TITLE</th>
<th>AUTHOR_NAME</th>
<th>Type_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>An Autobiography</td>
<td>Bob</td>
<td>01</td>
</tr>
<tr>
<td>Business Rules</td>
<td>Joe</td>
<td>02</td>
</tr>
<tr>
<td>Mixing School and Work</td>
<td>Tim</td>
<td>03</td>
</tr>
</tbody>
</table>

You can use the SYS_TYPEID function to create an index on the type-discriminant column of a table. For an example, see "Indexing on Substitutable Columns: Examples" on page 14-102.
SYS_XMLAGG

Syntax

SYS_XMLAGG(expr, fmt)

Purpose

SYS_XMLAgg aggregates all of the XML documents or fragments represented by expr and produces a single XML document. It adds a new enclosing element with a default name ROWSET. If you want to format the XML document differently, then specify fmt, which is an instance of the XMLFormat object.

EXAMPLES

The following example uses the SYS_XMLGen function to generate an XML document for each row of the sample table employees where the employee’s last name begins with the letter R, and then aggregates all of the rows into a single XML document in the default enclosing element ROWSET:

```sql
SELECT SYS_XMLAGG(SYS_XMLGEN(last_name)) XMLAGG
FROM employees
WHERE last_name LIKE 'R%'
ORDER BY xmlagg;
```

XMLAGG

```xml
<ROWSET>
  <LAST_NAME>Rajs</LAST_NAME>
  <LAST_NAME>Raphaely</LAST_NAME>
  <LAST_NAME>Rogers</LAST_NAME>
  <LAST_NAME>Russell</LAST_NAME>
</ROWSET>
```

See Also:  SYS_XMLGEN on page 7-348 and ”XML Format Model” on page 2-73 for using the attributes of the XMLFormat type to format SYS_XMLAgg results

Examples

The following example uses the SYS_XMLGen function to generate an XML document for each row of the sample table employees where the employee’s last name begins with the letter R, and then aggregates all of the rows into a single XML document in the default enclosing element ROWSET:

```sql
SELECT SYS_XMLAGG(SYS_XMLGEN(last_name)) XMLAGG
FROM employees
WHERE last_name LIKE 'R%'
ORDER BY xmlagg;
```

XMLAGG

```xml
<ROWSET>
  <LAST_NAME>Rajs</LAST_NAME>
  <LAST_NAME>Raphaely</LAST_NAME>
  <LAST_NAME>Rogers</LAST_NAME>
  <LAST_NAME>Russell</LAST_NAME>
</ROWSET>
```
SYS_XMLGEN

Note: The SYS_XMLGen function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use the SQL/XML generation functions instead. See Oracle XML DB Developer’s Guide for more information.

Syntax

SYS_XMLGEN(expr, fmt)

Purpose

SYS_XMLGen takes an expression that evaluates to a particular row and column of the database, and returns an instance of type XMLType containing an XML document. The expr can be a scalar value, a user-defined type, or an XMLType instance.

- If expr is a scalar value, then the function returns an XML element containing the scalar value.
- If expr is a type, then the function maps the user-defined type attributes to XML elements.
- If expr is an XMLType instance, then the function encloses the document in an XML element whose default tag name is ROW.

By default the elements of the XML document match the elements of expr. For example, if expr resolves to a column name, then the enclosing XML element will be the same column name. If you want to format the XML document differently, then specify fmt, which is an instance of the XMLFormat object.

See Also: "XML Format Model" on page 2-73 for a description of the XMLFormat type and how to use its attributes to format SYS_XMLGen results

Examples

The following example retrieves the employee email ID from the sample table oe.employees where the employee_id value is 205, and generates an instance of an XMLType containing an XML document with an EMAIL element.

SELECT SYS_XMLGEN(email)
FROM employees
WHERE employee_id = 205;

SYS_XMLGEN(EMAIL)
-------------------------------------------------------------------
<?xml version="1.0"?>
<EMAIL>SHIGGINS</EMAIL>
## SYSDATE

### Syntax

```sql
SYSDATE
```

### Purpose

`SYSDATE` returns the current date and time set for the operating system on which the database server resides. The data type of the returned value is `DATE`, and the format returned depends on the value of the `NLS_DATE_FORMAT` initialization parameter. The function requires no arguments. In distributed SQL statements, this function returns the date and time set for the operating system of your local database. You cannot use this function in the condition of a `CHECK` constraint.

### Note:
The `FIXED_DATE` initialization parameter enables you to set a constant date and time that `SYSDATE` will always return instead of the current date and time. This parameter is useful primarily for testing. Refer to *Oracle Database Reference* for more information on the `FIXED_DATE` initialization parameter.

### Examples

The following example returns the current operating system date and time:

```sql
SELECT TO_CHAR(SYSDATE, 'MM-DD-YYYY HH24:MI:SS') "NOW"
FROM DUAL;
```

```
NOW
-------------------
04-13-2001 09:45:51
```
SYSTIMESTAMP

Syntax

SYSTIMESTAMP

Purpose

SYSTIMESTAMP returns the system date, including fractional seconds and time zone, of the system on which the database resides. The return type is TIMESTAMP WITH TIME ZONE.

Examples

The following example returns the system timestamp:

SELECT SYSTIMESTAMP FROM DUAL;

SYSTIMESTAMP
------------------------------------------------------------------
28-MAR-00 12.38.55.538741 PM -08:00

The following example shows how to explicitly specify fractional seconds:

SELECT TO_CHAR(SYSTIMESTAMP, 'SSSSS.FF') FROM DUAL;

TO_CHAR(SYSTIMESTAMP, 'SSSSS.FF')
-----------------------------
55615.449255

The following example returns the current timestamp in a specified time zone:

SELECT SYSTIMESTAMP AT TIME ZONE 'UTC' FROM DUAL;

SYSTIMESTAMPATTIMEZONE'UTC'
---------------------------------------------------------------------------
08-07-21 20:39:52,743557 UTC

The output format in this example depends on the NLS_TIMESTAMP_TZ_FORMAT for the session.
TAN

Syntax

\[ \text{TAN}(n) \]

Purpose

TAN returns the tangent of \( n \) (an angle expressed in radians).

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If the argument is BINARY_FLOAT, then the function returns BINARY_DOUBLE. Otherwise the function returns the same numeric data type as the argument.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

Examples

The following example returns the tangent of 135 degrees:

```sql
SELECT TAN(135 * 3.14159265359/180) "Tangent of 135 degrees" FROM DUAL;
```

Tangent of 135 degrees

----------------------

-1
**TANH**

**Syntax**

```
TANH(n)
```

**Purpose**

TANH returns the hyperbolic tangent of n.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If the argument is `BINARY_FLOAT`, then the function returns `BINARY_DOUBLE`. Otherwise the function returns the same numeric data type as the argument.

**See Also:** Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

**Examples**

The following example returns the hyperbolic tangent of .5:

```
SELECT TANH(.5) "Hyperbolic tangent of .5"
FROM DUAL;
```

```
Hyperbolic tangent of .5
------------------------
.462117157
```
TIMESTAMP_TO_SCN

Syntax

\[
\text{TIMESTAMP\_TO\_SCN}(\text{timestamp})
\]

Purpose

TIMESTAMP_TO_SCN takes as an argument a timestamp value and returns the approximate system change number (SCN) associated with that timestamp. The returned value is of data type NUMBER. This function is useful any time you want to know the SCN associated with a particular timestamp.

**Note:** The association between an SCN and a timestamp when the SCN is generated is remembered by the database for a limited period of time. This period is the maximum of the auto-tuned undo retention period, if the database runs in the Automatic Undo Management mode, and the retention times of all flashback archives in the database, but no less than 120 hours. The time for the association to become obsolete elapses only when the database is open. An error is returned if the timestamp specified for the argument to TIMESTAMP_TO_SCN is too old.

**See Also:** SCN_TO_TIMESTAMP on page 7-295 for information on converting SCNs to timestamp

Examples

The following example inserts a row into the oe.orders table and then uses the function to determine the system change number of the insert operation. (The actual SCN returned will differ on each system.)

```sql
INSERT INTO orders (order_id, order_date, customer_id, order_total)
VALUES (5000, SYSTIMESTAMP, 188, 2345);
```

1 row created.

```sql
COMMIT;
```

Commit complete.

```sql
SELECT TIMESTAMP_TO_SCN(order_date) FROM orders
WHERE order_id = 5000;
```

```
TIMESTAMP_TO_SCN(ORDER_DATE)
-----------------------------
574100
```
**TO_BINARY_DOUBLE**

**Syntax**

```sql
TO_BINARY_DOUBLE(expr, fmt, 'nlsparam')
```

**Purpose**

`TO_BINARY_DOUBLE` returns a double-precision floating-point number.

- `expr` can be a character string or a numeric value of type `NUMBER`, `BINARY_FLOAT`, or `BINARY_DOUBLE`. If `expr` is `BINARY_DOUBLE`, then the function returns `expr`.
- The optional `fmt` and `nlsparam` arguments are valid only if `expr` is a character string. They serve the same purpose as for the `TO_CHAR` (number) function.
  - The case-insensitive string 'INF' is converted to positive infinity.
  - The case-insensitive string '-INF' is converted to negative identity.
  - The case-insensitive string 'NaN' is converted to NaN (not a number).

You cannot use a floating-point number format element (`F`, `f`, `D`, or `d`) in a character string `expr`.

Conversions from character strings or `NUMBER` to `BINARY_DOUBLE` can be inexact, because the `NUMBER` and character types use decimal precision to represent the numeric value, and `BINARY_DOUBLE` uses binary precision.

Conversions from `BINARY_FLOAT` to `BINARY_DOUBLE` are exact.

**See Also:** `TO_CHAR (number)` on page 7-362 and "Floating-Point Numbers" on page 2-15

**Examples**

The examples that follow are based on a table with three columns, each with a different numeric data type:

```sql
CREATE TABLE float_point_demo
  (dec_num NUMBER(10,2), bin_double BINARY_DOUBLE, bin_float BINARY_FLOAT);

INSERT INTO float_point_demo
  VALUES (1234.56,1234.56,1234.56);

SELECT * FROM float_point_demo;
```

<table>
<thead>
<tr>
<th>DEC_NUM</th>
<th>BIN_DOUBLE</th>
<th>BIN_FLOAT</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234.56</td>
<td>1.235E+003</td>
<td>1.235E+003</td>
</tr>
</tbody>
</table>

The following example converts a value of data type `NUMBER` to a value of data type `BINARY_DOUBLE`:

```sql
SELECT dec_num, TO_BINARY_DOUBLE(dec_num)
FROM float_point_demo;
```

<table>
<thead>
<tr>
<th>DEC_NUM</th>
<th>TO_BINARY_DOUBLE(DEC_NUM)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234.56</td>
<td>1.235E+003</td>
</tr>
</tbody>
</table>
1234.56                  1.235E+003

The following example compares extracted dump information from the `dec_num` and `bin_double` columns:

```sql
SELECT DUMP(dec_num) "Decimal",
       DUMP(bin_double) "Double"
FROM float_point_demo;
```

<table>
<thead>
<tr>
<th>Decimal</th>
<th>Double</th>
</tr>
</thead>
<tbody>
<tr>
<td>Typ=2 Len=4: 194,13,35,57</td>
<td>Typ=101 Len=8: 192,147,74,61,112,163,215,10</td>
</tr>
</tbody>
</table>
**TO_BINARY_FLOAT**

**Syntax**

```
TO_BINARY_FLOAT(expr, fmt, 'nlsparam')
```

**Purpose**

`TO_BINARY_FLOAT` returns a single-precision floating-point number.

- `expr` can be a character string or a numeric value of type `NUMBER`, `BINARY_FLOAT`, or `BINARY_DOUBLE`. If `expr` is `BINARY_FLOAT`, then the function returns ` expr`.
- The optional `fmt` and `nlsparam` arguments are valid only if `expr` is a character string. They serve the same purpose as for the `TO_CHAR` (number) function.
  - The incase-sensitive string `"INF"` is converted to positive infinity.
  - The incase-sensitive string `"-INF"` is converted to negative identity.
  - The incase-sensitive string `"NaN"` is converted to `NaN` (not a number).

You cannot use a floating-point number format element (`F`, `f`, `D`, or `d`) in a character string `expr`.

Conversions from character strings or `NUMBER` to `BINARY_FLOAT` can be inexact, because the `NUMBER` and character types use decimal precision to represent the numeric value and `BINARY_FLOAT` uses binary precision.

Conversions from `BINARY_DOUBLE` to `BINARY_FLOAT` are inexact if the `BINARY_DOUBLE` value uses more bits of precision than supported by the `BINARY_FLOAT`.

**See Also:** `TO_CHAR (number)` on page 7-362 and "Floating-Point Numbers" on page 2-15

**Examples**

Using table `float_point_demo` created for `TO_BINARY_DOUBLE` on page 7-354, the following example converts a value of data type `NUMBER` to a value of data type `BINARY_FLOAT`:

```sql
SELECT dec_num, TO_BINARY_FLOAT(dec_num)
FROM float_point_demo;
```

<table>
<thead>
<tr>
<th>DEC_NUM</th>
<th>TO_BINARY_FLOAT(DEC_NUM)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234.56</td>
<td>1.235E+003</td>
</tr>
</tbody>
</table>
**TO_BLOB**

**Syntax**

\[ \text{to_blob} ::= \]

\[ \text{TO_BLOB}(\text{raw_value}) \]

**Purpose**

TO_BLOB converts LONG RAW and RAW values to BLOB values.

From within a PL/SQL package, you can use TO_BLOB to convert RAW and BLOB values to BLOB.

**Examples**

The following hypothetical example returns the BLOB of a RAW column value:

```
SELECT TO_BLOB(raw_column) blob FROM raw_table;
```

BLOB

-----------------------

00AADD343CDBBD

00AADD341CDBBD
TO_CHAR (character)

Syntax

to_char_char::=

Purpose

TO_CHAR (character) converts NCHAR, NVARCHAR2, CLOB, or NCLOB data to the database character set. The value returned is always VARCHAR2.

When you use this function to convert a character LOB into the database character set, if the LOB value to be converted is larger than the target type, then the database returns an error.

Examples

The following example interprets a simple string as character data:

```sql
SELECT TO_CHAR('01110') FROM DUAL;
```

```
TO_CH
-----
01110
```

Compare this example with the first example for TO_CHAR (number) on page 7-362.

The following example converts some CLOB data from the pm.print_media table to the database character set:

```sql
SELECT TO_CHAR(ad_sourcetext) FROM print_media
WHERE product_id = 2268;
```

```
TO_CHAR(AD_SOURCETEXT)
*****************************************************************************
TIGER2 2268...Standard Hayes Compatible Modem
Product ID: 2268
The #1 selling modem in the universe! Tiger2’s modem includes call management and Internet voicing. Make real-time full duplex phone calls at the same time you’re online.
*****************************************************************************
```
TO_CHAR (datetime)

Syntax

to_char_date::=

```
TO_CHAR (datetime) [ interval ] , , fmt , , nlsparam
```

Purpose

TO_CHAR (datetime) converts a datetime or interval value of DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, TIMESTAMP WITH LOCAL TIME ZONE, INTERVAL DAY TO SECOND, or INTERVAL YEAR TO MONTH data type to a value of VARCHAR2 data type in the format specified by the date format fmt. If you omit fmt, then date is converted to a VARCHAR2 value as follows:

- DATE values are converted to values in the default date format.
- TIMESTAMP and TIMESTAMP WITH LOCAL TIME ZONE values are converted to values in the default timestamp format.
- TIMESTAMP WITH TIME ZONE values are converted to values in the default timestamp with time zone format.
- Interval values are converted to the numeric representation of the interval literal.

Refer to "Format Models" on page 2-59 for information on datetime formats.

The 'nlsparam' argument specifies the language in which month and day names and abbreviations are returned. This argument can have this form:

```
‘NLS_DATE_LANGUAGE = language’
```

If you omit ‘nlsparam’, then this function uses the default date language for your session.

See Also: "Security Considerations for Data Conversion" on page 2-47

You can use this function in conjunction with any of the XML functions to generate a date in the database format rather than the XML Schema standard format.

See Also:
- Oracle XML DB Developer’s Guide for information about formatting of XML dates and timestamps, including examples
- "XML Functions" on page 7-8 for a listing of the XML functions

Examples

The following example uses this table:

```
CREATE TABLE date_tab (  
   ts_col TIMESTAMP,  
   tsltz_col TIMESTAMP WITH LOCAL TIME ZONE,  
   tstz_col TIMESTAMP WITH TIME ZONE);  
```
The example shows the results of applying `TO_CHAR` to different `TIMESTAMP` data types. The result for a `TIMESTAMP` WITH LOCAL TIME ZONE column is sensitive to session time zone, whereas the results for the `TIMESTAMP` and `TIMESTAMP` WITH TIME ZONE columns are not sensitive to session time zone:

```sql
ALTER SESSION SET TIME_ZONE = '-8:00';
INSERT INTO date_tab VALUES (
  TIMESTAMP'1999-12-01 10:00:00',
  TIMESTAMP'1999-12-01 10:00:00',
  TIMESTAMP'1999-12-01 10:00:00');
INSERT INTO date_tab VALUES (
  TIMESTAMP'1999-12-02 10:00:00 -8:00',
  TIMESTAMP'1999-12-02 10:00:00 -8:00',
  TIMESTAMP'1999-12-02 10:00:00 -8:00');

SELECT TO_CHAR(ts_col, 'DD-MON-YYYY HH24:MI:SSxFF') AS ts_date,
       TO_CHAR(tstz_col, 'DD-MON-YYYY HH24:MI:SS.hxx TZH:TZM') AS tstz_date
FROM date_tab
ORDER BY ts_date, tstz_date;

<table>
<thead>
<tr>
<th>TS_DATE</th>
<th>TSTZ_DATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>01-DEC-1999 10:00:00.000000</td>
<td>01-DEC-1999 10:00:00.000000 -08:00</td>
</tr>
<tr>
<td>02-DEC-1999 10:00:00.000000</td>
<td>02-DEC-1999 10:00:00.000000 -08:00</td>
</tr>
</tbody>
</table>

SELECT SESSIONTIMEZONE,
       TO_CHAR(tsltz_col, 'DD-MON-YYYY HH24:MI:SS.hxx') AS tsltz
FROM date_tab
ORDER BY sessiontimezone, tsltz;

<table>
<thead>
<tr>
<th>SESSIONTIME</th>
<th>TSLTZ</th>
</tr>
</thead>
<tbody>
<tr>
<td>-08:00</td>
<td>01-DEC-1999 10:00:00.000000</td>
</tr>
<tr>
<td>-08:00</td>
<td>02-DEC-1999 10:00:00.000000</td>
</tr>
</tbody>
</table>

ALTER SESSION SET TIME_ZONE = '-5:00';
SELECT TO_CHAR(ts_col, 'DD-MON-YYYY HH24:MI:SS.hxx') AS ts_col,
       TO_CHAR(tstz_col, 'DD-MON-YYYY HH24:MI:SS.hxx TZH:TZM') AS tstz_col
FROM date_tab
ORDER BY ts_col, tstz_col;

<table>

<td>01-DEC-1999 10:00:00.000000 -08:00</td>
</tr>
<tr>
<td>02-DEC-1999 10:00:00.000000</td>
<td>02-DEC-1999 10:00:00.000000 -08:00</td>
</tr>
</tbody>
</table>

SELECT SESSIONTIMEZONE,
       TO_CHAR(tsltz_col, 'DD-MON-YYYY HH24:MI:SS.hxx') AS tsltz_col
FROM date_tab
ORDER BY sessiontimezone, tsltz_col;

<table>
<thead>
<tr>
<th>SESSIONTIME</th>
<th>TSLTZ_COL</th>
</tr>
</thead>
<tbody>
<tr>
<td>-05:00</td>
<td>01-DEC-1999 13:00:00.000000</td>
</tr>
<tr>
<td>-05:00</td>
<td>02-DEC-1999 13:00:00.000000</td>
</tr>
</tbody>
</table>

The following example converts an interval literal into a text literal:

```sql
SELECT TO_CHAR(INTERVAL '123-2' YEAR(3) TO MONTH) FROM DUAL;
```
TO_CHAR
---------
+123-02
TO_CHAR (number)

Syntax

\texttt{to\_char\_number ::=}

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{syntax_diagram}
\caption{Syntax diagram for \texttt{to\_char\_number}.}
\end{figure}

Purpose

\texttt{TO\_CHAR (number)} converts \textit{n} to a value of \texttt{VARCHAR2} data type, using the optional number format \textit{fmt}. The value \textit{n} can be of type \texttt{NUMBER}, \texttt{BINARY\_FLOAT}, or \texttt{BINARY\_DOUBLE}. If you omit \textit{fmt}, then \textit{n} is converted to a \texttt{VARCHAR2} value exactly long enough to hold its significant digits.

If \textit{n} is negative, then the sign is applied after the format is applied. Thus \texttt{TO\_CHAR(-1, '9')} returns -$1, rather than $-1.

Refer to "Format Models" on page 2-59 for information on number formats.

The 'nlsparam' argument specifies these characters that are returned by number format elements:

- Decimal character
- Group separator
- Local currency symbol
- International currency symbol

This argument can have this form:

\begin{verbatim}
'NLS_NUMERIC_CHARACTERS = ''dg''
    NLS_CURRENCY = ''text''
    NLS_ISO_CURRENCY = territory '
\end{verbatim}

The characters \textit{d} and \textit{g} represent the decimal character and group separator, respectively. They must be different single-byte characters. Within the quoted string, you must use two single quotation marks around the parameter values. Ten characters are available for the currency symbol.

If you omit 'nlsparam' or any one of the parameters, then this function uses the default parameter values for your session.

\textbf{See Also:} "Security Considerations for Data Conversion" on page 2-47

Examples

The following statement uses implicit conversion to combine a string and a number into a number:

\begin{verbatim}
SELECT TO\_CHAR(''01110'' + 1) FROM DUAL;
\end{verbatim}

\begin{verbatim}
TO\_C
----
1111
\end{verbatim}
Compare this example with the first example for **TO_CHAR (character)** on page 7-358.

In the next example, the output is blank padded to the left of the currency symbol. In the optional number format *fmt*, `L` designates local currency symbol and `MI` designates a trailing minus sign. See Table 2–13, "Number Format Elements" on page 2-71 for a complete listing of number format elements. The example shows the output in a session in which the session parameter `NLS_TERRITORY` is set to **AMERICA**.

```
SELECT TO_CHAR(-10000,'L99G999D99MI') "Amount"
   FROM DUAL;
```

```
Amount
-------------
$10,000.00-
```

In the next example, `NLS_CURRENCY` specifies the string to use as the local currency symbol for the `L` number format element. `NLS_NUMERIC_CHARACTERS` specifies comma as the character to use as the decimal separator for the `D` number format element and period as the character to use as the group separator for the `G` number format element. These characters are expected in many countries, for example in Germany.

```
SELECT TO_CHAR(-10000,'L99G999D99MI',
   'NLS_NUMERIC_CHARACTERS = '',.''
   NLS_CURRENCY = ''AusDollars''') "Amount"
   FROM DUAL;
```

```
Amount
-------------------
AusDollars10.000,00-
```

In the next example, `NLS_ISO_CURRENCY` instructs the database to use the international currency symbol for the territory of **POLAND** for the `C` number format element:

```
SELECT TO_CHAR(-10000,'99G999D99C',
   'NLS_NUMERIC_CHARACTERS = '',.''
   NLS_ISO_CURRENCY=POLAND') "Amount"
   FROM DUAL;
```

```
Amount
-----------------
-10.000,00PLN
```
TO_CLOB

Syntax

```sql
TO_CLOB (lob_column char)
```

Purpose

TO_CLOB converts NCLOB values in a LOB column or other character strings to CLOB values. `char` can be any of the data types CHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB. Oracle Database executes this function by converting the underlying LOB data from the national character set to the database character set.

From within a PL/SQL package, you can use the TO_CLOB function to convert RAW, CHAR, VARCHAR, VARCHAR2, NCHAR, NVARCHAR2, CLOB, or NCLOB values to CLOB or NCLOB values.

Examples

The following statement converts NCLOB data from the sample `pm_print_media` table to CLOB and inserts it into a CLOB column, replacing existing data in that column.

```sql
UPDATE PRINT_MEDIA
  SET AD_FINALTEXT = TO_CLOB (AD_FLTEXTN);
```
TO_DATE

Syntax

\[
\text{TO_DATE}(\text{char}, \text{fmt}, \text{nlsparam})
\]

Purpose

TO_DATE converts char of CHAR, VARCHAR2, NCHAR, or NVARCHAR2 data type to a value of DATE data type.

**Note:** This function does not convert data to any of the other datetime data types. For information on other datetime conversions, refer to TO_TIMESTAMP on page 7-377, TO_TIMESTAMP_TZ on page 7-378, TO_DSINTERVAL on page 7-367, and TO_YMINTERVAL on page 7-380.

The fmt is a datetime model format specifying the format of char. If you omit fmt, then char must be in the default date format. The default date format is determined implicitly by the NLS_TERRITORY initialization parameter or can be set explicitly by the NLS_DATE_FORMAT parameter. If fmt is J, for Julian, then char must be an integer.

**Caution:** It is good practice always to specify a format mask (fmt) with TO_DATE, as shown in the examples in the section that follows. When it is used without a format mask, the function is valid only if char uses the same format as is determined by the NLS_TERRITORY or NLS_DATE_FORMAT parameters. Furthermore, the function may not be stable across databases unless the explicit format mask is specified to avoid dependencies.

The 'nlsparam' argument specifies the language of the text string that is being converted to a date. This argument can have this form:

'NLS_DATE_LANGUAGE = language'

Do not use the TO_DATE function with a DATE value for the char argument. The first two digits of the returned DATE value can differ from the original char, depending on fmt or the default date format.

This function does not support CLOB data directly. However, CLOBs can be passed in as arguments through implicit data conversion.

**See Also:** "Datetime Format Models" on page 2-63 and "Data Type Comparison Rules" on page 2-39 for more information

Examples

The following example converts a character string into a date:

```sql
SELECT TO_DATE(
    'January 15, 1989, 11:00 A.M.',
    'Month dd, YYYY, HH:MI A.M.',
)
```
TO_DATE('January 15, 1989, 11:00 A.M.',
'Month dd, YYYY, HH:MI A.M.',
'NLS_DATE_LANGUAGE = American')
FROM DUAL;

TO_DATE('15-JAN-89
---------
15-JAN-89

The value returned reflects the default date format if the NLS_TERRITORY parameter is set to 'AMERICA'. Different NLS_TERRITORY values result in different default date formats:

ALTER SESSION SET NLS_TERRITORY = 'KOREAN';

SELECT TO_DATE(
'January 15, 1989, 11:00 A.M.',
'Month dd, YYYY, HH:MI A.M.',
'NLS_DATE_LANGUAGE = American')
FROM DUAL;

TO_DATE('89/01/15
---------
89/01/15
**TO_DSINTERVAL**

**Syntax**

```
TO_DSINTERVAL (sql_format
    ds_iso_format)
```

**sql_format**:=

```
<days><hours><minutes><seconds><frac_secs>
```

**ds_iso_format**:=

```
P<days>D<T<hours>H<minutes>M<seconds>S<frac_secs>
```

**Note:** In earlier releases, the TO_DSINTERVAL function accepted an optional nlsparam clause. This clause is still accepted for backward compatibility, but has no effect.

**Purpose**

TO_DSINTERVAL converts a character string of CHAR, VARCHAR2, NCHAR, or NVARCHAR2 data type to an INTERVAL DAY TO SECOND type.

TO_DSINTERVAL accepts argument in one of the two formats:

- SQL interval format compatible with the SQL standard (ISO/IEC 9075:2003)
- ISO duration format compatible with the ISO 8601:2004 standard

In the SQL format, *days* is an integer between 0 and 999999999, *hours* is an integer between 0 and 23, and *minutes* and *seconds* are integers between 0 and 59. *frac_secs* is the fractional part of seconds between .0 and .999999999. One or more blanks separate days from hours. Additional blanks are allowed between format elements.

In the ISO format, *days*, *hours*, *minutes* and *seconds* are integers between 0 and 999999999. *frac_secs* is the fractional part of seconds between .0 and .999999999. No blanks are allowed in the value. If you specify *T*, then you must specify at least one of the *hours*, *minutes*, or *seconds* values.

**Examples**

The following example uses the SQL format to select from the hr.employees table the employees who had worked for the company for at least 100 days on November 1, 2002:
SELECT employee_id, last_name FROM employees
    WHERE hire_date + TO_DSINTERVAL('100 00:00:00')
    <= DATE '2002-11-01'
ORDER BY employee_id;

EMPLOYEE_ID LAST_NAME
------------- ---------------
  102 De Haan  
  203 Mavris  
  204 Baer  
  205 Higgins  
  206 Giet

The following example uses the ISO format to display the timestamp 100 days and 5 hours after the beginning of the year 2009:

SELECT TO_CHAR(TIMESTAMP '2009-01-01 00:00:00' + TO_DSINTERVAL('P100D', 'HOURS', 05), 'YYYY-MM-DD HH24:MI:SS') "Time Stamp"
FROM DUAL;

Time Stamp
-----------
2009-04-11 05:00:00
**TO_LOB**

**Syntax**

```
TO_LOB(long_column)
```

**Purpose**

TO_LOB converts LONG or LONG RAW values in the column `long_column` to LOB values. You can apply this function only to a LONG or LONG RAW column, and only in the select list of a subquery in an INSERT statement.

Before using this function, you must create a LOB column to receive the converted LONG values. To convert LONG values, create a CLOB column. To convert LONG RAW values, create a BLOB column.

You cannot use the TO_LOB function to convert a LONG column to a LOB column in the subquery of a CREATE TABLE ... AS SELECT statement if you are creating an index-organized table. Instead, create the index-organized table without the LONG column, and then use the TO_LOB function in an INSERT ... AS SELECT statement.

You cannot use this function within a PL/SQL package. Instead use the TO_CLOB or TO_BLOB functions.

**See Also:**

- the modify_col_properties clause of ALTER TABLE on page 12-2 for an alternative method of converting LONG columns to LOB
- INSERT on page 18-62 for information on the subquery of an INSERT statement

**Examples**

The following syntax shows how to use the TO_LOB function on your LONG data in a hypothetical table `old_table`:

```sql
CREATE TABLE new_table (col1, col2, ... lob_col CLOB);
INSERT INTO new_table (select o.col1, o.col2, ... TO_LOB(o.old_long_col)
FROM old_table o;
```

TO_MULTI_BYTE

Syntax

```
TO_MULTI_BYTE(char)
```

Purpose

`TO_MULTI_BYTE` returns `char` with all of its single-byte characters converted to their corresponding multibyte characters. `char` can be of data type `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2`. The value returned is in the same data type as `char`.

Any single-byte characters in `char` that have no multibyte equivalents appear in the output string as single-byte characters. This function is useful only if your database character set contains both single-byte and multibyte characters.

This function does not support `CLOB` data directly. However, `CLOBs` can be passed in as arguments through implicit data conversion.

See Also: "Data Type Comparison Rules" on page 2-39 for more information.

Examples

The following example illustrates converting from a single byte `A` to a multibyte `A` in UTF8:

```
SELECT dump(TO_MULTI_BYTE('A')) FROM DUAL;
```

```
DUMP(TO_MULTI_BYTE('A'))
------------------------
Typ=1 Len=3: 239,188,161
```
TO_NCHAR (character)

Syntax

to_nchar_char::=

Purpose

TO_NCHAR (character) converts a character string, CHAR, VARCHAR2, CLOB, or NCLOB value to the national character set. The value returned is always NVARCHAR2. This function is equivalent to the TRANSLATE ... USING function with a USING clause in the national character set.

See Also:  "Data Conversion" on page 2-43 and TRANSLATE ... USING on page 7-383

Examples

The following example converts VARCHAR2 data from the oe.customers table to the national character set:

    SELECT TO_NCHAR(cust_last_name) FROM customers
        WHERE customer_id=103;

    TO_NCHAR(CUST_LAST_NAME)
    -------------------------------
    Taylor
TO_NCHAR (datetime)

Syntax

\[ \text{to\_nchar\_date::=} \]

Purpose

TO_NCHAR (datetime) converts a datetime or interval value of DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, TIMESTAMP WITH LOCAL TIME ZONE, INTERVAL MONTH TO YEAR, or INTERVAL DAY TO SECOND data type from the database character set to the national character set.

See Also: "Security Considerations for Data Conversion" on page 2-47

Examples

The following example converts the order_date of all orders whose status is 9 to the national character set:

```sql
SELECT TO_NCHAR(ORDER_DATE) AS order_date
FROM ORDERS
WHERE ORDER_STATUS > 9
ORDER BY order_date;
```

<table>
<thead>
<tr>
<th>ORDER_DATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>06-DEC-99 02.22.34.225609 PM</td>
</tr>
<tr>
<td>13-SEP-99 10.19.00.654279 AM</td>
</tr>
<tr>
<td>14-SEP-99 09.53.40.223345 AM</td>
</tr>
<tr>
<td>26-JUN-00 10.19.43.190089 PM</td>
</tr>
<tr>
<td>27-JUN-00 09.53.32.335522 PM</td>
</tr>
</tbody>
</table>
TO_NCHAR (number)

Syntax

to_nchar_number::= 

Purpose

TO_NCHAR (number) converts \( n \) to a string in the national character set. The value \( n \) can be of type NUMBER, BINARY_FLOAT, or BINARY_DOUBLE. The function returns a value of the same type as the argument. The optional \( fmt \) and \( 'nlsparam' \) corresponding to \( n \) can be of DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, TIMESTAMP WITH LOCAL TIME ZONE, INTERVAL MONTH TO YEAR, or INTERVAL DAY TO SECOND data type.

See Also:  "Security Considerations for Data Conversion" on page 2-47

Examples

The following example converts the customer_id values from the sample table oe.orders to the national character set:

```
SELECT TO_NCHAR(customer_id) "NCHAR_Customer_ID"  FROM orders WHERE order_status > 9 ORDER BY "NCHAR_Customer_ID";
```

<table>
<thead>
<tr>
<th>NCHAR_Customer_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>102</td>
</tr>
<tr>
<td>103</td>
</tr>
<tr>
<td>148</td>
</tr>
<tr>
<td>148</td>
</tr>
<tr>
<td>149</td>
</tr>
</tbody>
</table>
Syntax

```
TO_NCLOB (lob_column char)
```

Purpose

`TO_NCLOB` converts CLOB values in a LOB column or other character strings to NCLOB values. `char` can be any of the data types `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, `CLOB`, or `NCLOB`. Oracle Database implements this function by converting the character set of `char` from the database character set to the national character set.

Examples

The following example inserts some character data into an `NCLOB` column of the `pm.print_media` table by first converting the data with the `TO_NCLOB` function:

```
INSERT INTO print_media (product_id, ad_id, ad_fltextn)
VALUES (3502, 31001,
        TO_NCLOB('Placeholder for new product description'));
```
TO_NUMBER

Syntax

```
TO_NUMBER(expr, fmt, 'nlsparam')
```

Purpose

TO_NUMBER converts `expr` to a value of `NUMBER` data type. The `expr` can be a number value of `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, `BINARY_FLOAT`, or `BINARY_DOUBLE` data type.

- If you specify an `expr` of `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type, then you can optionally specify the format model `fmt`.
- If you specify an `expr` of `BINARY_FLOAT` or `BINARY_DOUBLE` data type, then you cannot specify a format model because a `BINARY_FLOAT` or `BINARY_DOUBLE` can be interpreted only by its internal representation.

Refer to "Format Models" on page 2-59 for information on format models.

The `'nlsparam'` argument in this function has the same purpose as it does in the `TO_CHAR` function for number conversions. Refer to `TO_CHAR (number)` on page 7-362 for more information.

This function does not support `CLOB` data directly. However, `CLOBs` can be passed in as arguments through implicit data conversion.

See Also: "Data Type Comparison Rules" on page 2-39 for more information.

Examples

The following examples convert character string data into a number:

```
UPDATE employees SET salary = salary +
    TO_NUMBER('100.00', '9G999D99')
WHERE last_name = 'Perkins';

SELECT TO_NUMBER('AusDollars100', 'L9G999D99',
    'NLS_NUMERIC_CHARACTERS = ', 'NLS_CURRENCY            = 'AusDollars')
'Amount'
FROM DUAL;

Amount
--------
  -100
```
TO_SINGLE_BYTE

Syntax

```
TO_SINGLE_BYTE(char)
```

Purpose

TO_SINGLE_BYTE returns `char` with all of its multibyte characters converted to their corresponding single-byte characters. `char` can be of data type `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2`. The value returned is in the same data type as `char`.

Any multibyte characters in `char` that have no single-byte equivalents appear in the output as multibyte characters. This function is useful only if your database character set contains both single-byte and multibyte characters.

This function does not support `CLOB` data directly. However, `CLOBs` can be passed in as arguments through implicit data conversion.

See Also: "Data Type Comparison Rules" on page 2-39 for more information.

Examples

The following example illustrates going from a multibyte A in UTF8 to a single byte ASCII A:

```
SELECT TO_SINGLE_BYTE(CHR(15711393)) FROM DUAL;
```

```
T
A
```
TO_TIMESTAMP

Syntax

```
TO_TIMESTAMP(char, fmt, 'nlsparam')
```

Purpose

TO_TIMESTAMP converts char of CHAR, VARCHAR2, NCHAR, or NVARCHAR2 data type to a value of TIMESTAMP data type.

The optional fmt specifies the format of char. If you omit fmt, then char must be in the default format of the TIMESTAMP data type, which is determined by the NLS_TIMESTAMP_FORMAT initialization parameter. The optional 'nlsparam' argument has the same purpose in this function as in the TO_CHAR function for date conversion.

This function does not support CLOB data directly. However, CLOBs can be passed in as arguments through implicit data conversion.

See Also: "Data Type Comparison Rules" on page 2-39 for more information.

Examples

The following example converts a character string to a timestamp. The character string is not in the default TIMESTAMP format, so the format mask must be specified:

```
SELECT TO_TIMESTAMP ('10-Sep-02 14:10:10.123000', 'DD-Mon-RR HH24:MI:SS.FF')
FROM DUAL;
```

```
TO_TIMESTAMP('10-SEP-0214:10:10.123000','DD-MON-RRHH24:MI:SS.FF')
```

```
---------------------------------------------------------------------------
10-SEP-02 02.10.10.123000000 PM
```

See Also: NLS_TIMESTAMP_FORMAT parameter for information on the default TIMESTAMP format and "Datetime Format Models" on page 2-63 for information on specifying the format mask.
TO_TIMESTAMP_TZ

Syntax

```
TO_TIMESTAMP_TZ(char, fmt, 'nlsparam')
```

Purpose

TO_TIMESTAMP_TZ converts char of CHAR, VARCHAR2, NCHAR, or NVARCHAR2 data type to a value of TIMESTAMP WITH TIME ZONE data type.

Note: This function does not convert character strings to TIMESTAMP WITH LOCAL TIME ZONE. To do this, use a CAST function, as shown in CAST on page 7-37.

The optional fmt specifies the format of char. If you omit fmt, then char must be in the default format of the TIMESTAMP WITH TIME ZONE data type. The optional 'nlsparam' has the same purpose in this function as in the TO_CHAR function for date conversion.

Examples

The following example converts a character string to a value of TIMESTAMP WITH TIME ZONE:

```
SELECT TO_TIMESTAMP_TZ('1999-12-01 11:00:00 -8:00', 'YYYY-MM-DD HH:MI:SS TZH:TZM') FROM DUAL;
```

```
01-DEC-99 11.00.00.000000000 AM -08:00
```

The following example casts a null column in a UNION operation as TIMESTAMP WITH LOCAL TIME ZONE using the sample tables oe.order_items and oe.orders:

```
SELECT order_id, line_item_id,
    CAST(NULL AS TIMESTAMP WITH LOCAL TIME ZONE) order_date
FROM order_items
UNION
SELECT order_id, to_number(null), order_date
FROM orders;
```

```
ORDER_ID LINE_ITEM_ID ORDER_DATE
---------- ---------- -------------------
    2354           1
    2354           2
    2354           3
    2354           4
    2354           5
    2354           6
    2354           7
    2354           8
    2354           9
    2354          10
    2354          11
    2354          12
```
<table>
<thead>
<tr>
<th>2354</th>
<th>13</th>
</tr>
</thead>
<tbody>
<tr>
<td>2354</td>
<td>14-JUL-00 05.18.23.34567 PM</td>
</tr>
<tr>
<td>2355</td>
<td>1</td>
</tr>
<tr>
<td>2355</td>
<td>2</td>
</tr>
</tbody>
</table>

...
TO_YMINTERVAL

Syntax

ym_iso_format::=

Purpose

TO_YMINTERVAL converts a character string of CHAR, VARCHAR2, NCHAR, or NVARCHAR2 data type to an INTERVAL YEAR TO MONTH type.

TO_YMINTERVAL accepts argument in one of the two formats:

- SQL interval format compatible with the SQL standard (ISO/IEC 9075:2003)
- ISO duration format compatible with the ISO 8601:2004 standard

In the SQL format, years is an integer between 0 and 999999999, and months is an integer between 0 and 11. Additional blanks are allowed between format elements.

In the ISO format, years and months are integers between 0 and 999999999. Days, hours, minutes, seconds, and frac_secs are non-negative integers, and are ignored, if specified. No blanks are allowed in the value. If you specify T, then you must specify at least one of the hours, minutes, or seconds values.

Examples

The following example calculates for each employee in the sample hr.employees table a date one year two months after the hire date:

```sql
SELECT hire_date, hire_date + TO_YMINTERVAL('01-02') "14 months"
FROM employees;
```

<table>
<thead>
<tr>
<th>HIRE_DATE</th>
<th>14 months</th>
</tr>
</thead>
<tbody>
<tr>
<td>17-JUN-03</td>
<td>17-AUG-04</td>
</tr>
<tr>
<td>21-SEP-05</td>
<td>21-NOV-06</td>
</tr>
<tr>
<td>13-JAN-01</td>
<td>13-MAR-02</td>
</tr>
<tr>
<td>20-MAY-08</td>
<td>20-JUL-09</td>
</tr>
<tr>
<td>21-MAY-07</td>
<td>21-JUL-08</td>
</tr>
</tbody>
</table>

The following example makes the same calculation using the ISO format:
SELECT hire_date, hire_date + TO_YMINTERVAL('P1Y2M') FROM employees;
**Syntax**

```
TRANSLATE(expr, from_string, to_string)
```

**Purpose**

`TRANSLATE` returns `expr` with all occurrences of each character in `from_string` replaced by its corresponding character in `to_string`. Characters in `expr` that are not in `from_string` are not replaced. The argument `from_string` can contain more characters than `to_string`. In this case, the extra characters at the end of `from_string` have no corresponding characters in `to_string`. If these extra characters appear in `expr`, then they are removed from the return value.

If a character appears multiple times in `from_string`, then the `to_string` mapping corresponding to the first occurrence is used.

You cannot use an empty string for `to_string` to remove all characters in `from_string` from the return value. Oracle Database interprets the empty string as null, and if this function has a null argument, then it returns null. To remove all characters in `from_string`, concatenate another character to the beginning of `from_string` and specify this character as the `to_string`. For example, `TRANSLATE(expr,'x0123456789','x')` removes all digits from `expr`.

`TRANSLATE` provides functionality related to that provided by the `REPLACE` function. `REPLACE` lets you substitute a single string for another single string, as well as remove character strings. `TRANSLATE` lets you make several single-character, one-to-one substitutions in one operation.

This function does not support `CLOB` data directly. However, `CLOB`s can be passed in as arguments through implicit data conversion.

**See Also:** "Data Type Comparison Rules" on page 2-39 for more information and `REPLACE` on page 7-285

**Examples**

The following statement translates a book title into a string that could be used (for example) as a filename. The `from_string` contains four characters: a space, asterisk, slash, and apostrophe (with an extra apostrophe as the escape character). The `to_string` contains only three underscores. This leaves the fourth character in the `from_string` without a corresponding replacement, so apostrophes are dropped from the returned value.

```
SELECT TRANSLATE('SQL*Plus User''s Guide', ' */''', '___') FROM DUAL;
```

```
TRANSLATE('SQL*PLUSU
-------------------
SQL_Plus_Users_Guide
```
TRANSLATE ... USING

Syntax

```
TRANSLATE (char) USING (CHAR_CS | NCHAR_CS)
```

Purpose

TRANSLATE ... USING converts char into the character set specified for conversions between the database character set and the national character set.

**Note:** The `TRANSLATE ... USING` function is supported primarily for ANSI compatibility. Oracle recommends that you use the `TO_CHAR` and `TO_NCHAR` functions, as appropriate, for converting data to the database or national character set. `TO_CHAR` and `TO_NCHAR` can take as arguments a greater variety of data types than `TRANSLATE ... USING`, which accepts only character data.

The char argument is the expression to be converted.

- Specifying the `USING CHAR_CS` argument converts char into the database character set. The output data type is VARCHAR2.
- Specifying the `USING NCHAR_CS` argument converts char into the national character set. The output data type is NVARCHAR2.

This function is similar to the Oracle `CONVERT` function, but must be used instead of `CONVERT` if either the input or the output data type is being used as NCHAR or NVARCHAR2. If the input contains UCS2 code points or backslash characters (\), then use the `UNISTR` function.

**See Also:** `CONVERT` on page 7-67 and `UNISTR` on page 7-391

Examples

The following statements use data from the sample table oe.product_descriptions to show the use of the `TRANSLATE ... USING` function:

```sql
CREATE TABLE translate_tab (char_col  VARCHAR2(100),
                          nchar_col NVARCHAR2(50));

INSERT INTO translate_tab
SELECT NULL, translated_name
FROM product_descriptions
WHERE product_id = 3501;

SELECT * FROM translate_tab;
```

<table>

TREAT

Syntax

TREAT(expr) AS REF schema.type

Purpose

TREAT changes the declared type of an expression.

You must have the EXECUTE object privilege on type to use this function.

- expr and type must be user-defined object types, excluding top-level collections.
- type must be some supertype or subtype of the declared type of expr. If the most specific type of expr is type (or some subtype of type), then TREAT returns expr. If the most specific type of expr is not type (or some subtype of type), then TREAT returns NULL.
- You can specify REF only if the declared type of expr is a REF type.
- If the declared type of expr is a REF to a source type of expr, then type must be some subtype or supertype of the source type of expr. If the most specific type of DEREF(expr) is type (or a subtype of type), then TREAT returns expr. If the most specific type of DEREF(expr) is not type (or a subtype of type), then TREAT returns NULL.

See Also: "Data Type Comparison Rules" on page 2-39 for more information

Examples

The following statement uses the table oe.persons, which is created in "Substitutable Table and Column Examples" on page 16-91. The example retrieves the salary attribute of all people in the persons table, the value being null for instances of people that are not employees.

```
SELECT name, TREAT(VALUE(p) AS employee_t).salary salary
FROM persons p;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bob</td>
<td></td>
</tr>
<tr>
<td>Joe</td>
<td>100000</td>
</tr>
<tr>
<td>Tim</td>
<td>1000</td>
</tr>
</tbody>
</table>

You can use the TREAT function to create an index on the subtype attributes of a substitutable column. For an example, see "Indexing on Substitutable Columns: Examples" on page 14-102.
TRIM

Syntax

```plaintext
TRIM(trim_character FROM trim_source) 
```

Purpose

TRIM enables you to trim leading or trailing characters (or both) from a character string. If `trim_character` or `trim_source` is a character literal, then you must enclose it in single quotation marks.

- If you specify `LEADING`, then Oracle Database removes any leading characters equal to `trim_character`.
- If you specify `TRAILING`, then Oracle removes any trailing characters equal to `trim_character`.
- If you specify `BOTH` or none of the three, then Oracle removes leading and trailing characters equal to `trim_character`.
- If you do not specify `trim_character`, then the default value is a blank space.
- If you specify only `trim_source`, then Oracle removes leading and trailing blank spaces.
- The function returns a value with data type `VARCHAR2`. The maximum length of the value is the length of `trim_source`.
- If either `trim_source` or `trim_character` is null, then the TRIM function returns null.

Both `trim_character` and `trim_source` can be VARCHAR2 or any data type that can be implicitly converted to VARCHAR2. The string returned is a VARCHAR2 (NVARCHAR2) data type if `trim_source` is a CHAR or VARCHAR2 (NCHAR or NVARCHAR2) data type, and a CLOB if `trim_source` is a CLOB data type. The return string is in the same character set as `trim_source`.

Examples

This example trims leading zeros from the hire date of the employees in the hr schema:

```sql
SELECT employee_id, 
       TO_CHAR(TRIM(LEADING 0 FROM hire_date)) 
FROM employees 
WHERE department_id = 60 
ORDER BY employee_id;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>TO_CHAR(T</th>
</tr>
</thead>
<tbody>
<tr>
<td>103</td>
<td>20-MAY-08</td>
</tr>
<tr>
<td>104</td>
<td>21-MAY-07</td>
</tr>
<tr>
<td>105</td>
<td>25-JUN-05</td>
</tr>
<tr>
<td>106</td>
<td>5-FEB-06</td>
</tr>
<tr>
<td>107</td>
<td>7-FEB-07</td>
</tr>
</tbody>
</table>
TRUNC (date)

Syntax

\[ \text{trunc
data} := \]

\[ \text{TRUNC} \text{date} \rightarrow \text{fmt} \rightarrow \]

Purpose

The TRUNC (date) function returns date with the time portion of the day truncated to the unit specified by the format model fmt. This function is not sensitive to the NLSCALENDAR session parameter. It operates according to the rules of the Gregorian calendar. The value returned is always of data type DATE, even if you specify a different datetime data type for date. If you omit fmt, then the default format model 'DD' is used and the value returned is date truncated to the day with a time of midnight. Refer to "ROUND and TRUNC Date Functions" on page 7-437 for the permitted format models to use in fmt.

Examples

The following example truncates a date:

```
SELECT TRUNC(TO_DATE('27-OCT-92', 'DD-MON-YY'), 'YEAR')
   'New Year' FROM DUAL;
```

New Year
---------
01-JAN-92
TRUNC (number)

Syntax

\[
\text{trunc\_number ::= TRUNC(n1, n2)}
\]

Purpose

The TRUNC (number) function returns \( n1 \) truncated to \( n2 \) decimal places. If \( n2 \) is omitted, then \( n1 \) is truncated to 0 places. \( n2 \) can be negative to truncate (make zero) \( n2 \) digits left of the decimal point.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. If you omit \( n2 \), then the function returns the same data type as the numeric data type of the argument. If you include \( n2 \), then the function returns NUMBER.

See Also: Table 2-10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

Examples

The following examples truncate numbers:

```sql
SELECT TRUNC(15.79, 1) 'Truncate' FROM DUAL;
```

```
Truncate
---------
 15.7
```

```sql
SELECT TRUNC(15.79, -1) 'Truncate' FROM DUAL;
```

```
Truncate
---------
 10
```
TZ_OFFSET

Syntax

```
TZ_OFFSET(time_zone_name) + hh:mm
```

Purpose

TZ_OFFSET returns the time zone offset corresponding to the argument based on the date the statement is executed. You can enter a valid time zone region name, a time zone offset from UTC (which simply returns itself), or the keyword SESSIONTIMEZONE or DBTIMEZONE. For a listing of valid values for time_zone_name, query the TZNAME column of the V$TIMEZONE_NAMES dynamic performance view.

**Note:** Time zone region names are needed by the daylight saving feature. These names are stored in two types of time zone files: one large and one small. One of these files is the default file, depending on your environment and the release of Oracle Database you are using. For more information regarding time zone files and names, see Oracle Database Globalization Support Guide.

Examples

The following example returns the time zone offset of the US/Eastern time zone from UTC:

```
SELECT TZ_OFFSET('US/Eastern') FROM DUAL;
```

```
TZ_OFFSET
-------
-04:00
```
Syntax

```
UID
```

Purpose

`UID` returns an integer that uniquely identifies the session user (the user who logged on).

**See Also:** [USER on page 7-395](#) to learn how Oracle Database determines the session user

Examples

The following example returns the UID of the session user:

```
SELECT UID FROM DUAL;
```
UNISTR

Syntax

```
UNISTR ( string )
```

Purpose

UNISTR takes as its argument a text literal or an expression that resolves to character data and returns it in the national character set. The national character set of the database can be either AL16UTF16 or UTF8. UNISTR provides support for Unicode string literals by letting you specify the Unicode encoding value of characters in the string. This is useful, for example, for inserting data into NCHAR columns.

The Unicode encoding value has the form '
xxxx' where 'xxxx' is the hexadecimal value of a character in UCS-2 encoding format. Supplementary characters are encoded as two code units, the first from the high-surrogates range (U+D800 to U+DBFF), and the second from the low-surrogates range (U+DC00 to U+DFFF). To include the backslash in the string itself, precede it with another backslash (\\).

For portability and data preservation, Oracle recommends that in the UNISTR string argument you specify only ASCII characters and the Unicode encoding values.

See Also: Oracle Database Globalization Support Guide for information on Unicode and national character sets

Examples

The following example passes both ASCII characters and Unicode encoding values to the UNISTR function, which returns the string in the national character set:

```
SELECT UNISTR('abc\00e5\00f1\00f6') FROM DUAL;
```

UNISTR

------

abcåñö
UPDATEXML

**Note:** The `UPDATEXML` function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use XQuery Update instead. See *Oracle XML DB Developer’s Guide* for more information.

**Syntax**

```sql
UPDATEXML (XMLType_instance, XPath_string, value_expr, namespace_string)
```

**Purpose**

`UPDATEXML` takes as arguments an `XMLType` instance and an XPath-value pair and returns an `XMLType` instance with the updated value. If `XPath_string` is an XML element, then the corresponding `value_expr` must be an `XMLType` instance. If `XPath_string` is an attribute or text node, then the `value_expr` can be any scalar data type. You can specify an absolute `XPath_string` with an initial slash or a relative `XPath_string` by omitting the initial slash. If you omit the initial slash, then the context of the relative path defaults to the root node.

The data types of the target of each `XPath_string` and its corresponding `value_expr` must match. The optional `namespace_string` must resolve to a `VARCHAR2` value that specifies a default mapping or namespace mapping for prefixes, which Oracle Database uses when evaluating the XPath expression(s).

If you update an XML element to null, then Oracle removes the attributes and children of the element, and the element becomes empty. If you update the text node of an element to null, Oracle removes the text value of the element, and the element itself remains but is empty.

In most cases, this function materializes an XML document in memory and updates the value. However, `UPDATEXML` is optimized for `UPDATE` statements on object-relational columns so that the function updates the value directly in the column. This optimization requires the following conditions:

- The `XMLType_instance` must be the same as the column in the `UPDATE ... SET` clause.
- The `XPath_string` must resolve to scalar content.

**Examples**

The following example updates to 4 the number of docks in the San Francisco warehouse in the sample schema `OE`, which has a `warehouse_spec` column of type `XMLType`:

```sql
SELECT warehouse_name,
       EXTRACT(warehouse_spec, '/Warehouse/Docks')
       'Number of Docks'
FROM warehouses
WHERE warehouse_name = 'San Francisco';

WAREHOUSE_NAME       Number of Docks
```

Note: The `UPDATEXML` function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use XQuery Update instead. See *Oracle XML DB Developer’s Guide* for more information.
UPDATE warehouses SET warehouse_spec =
  UPDATEXML(warehouse_spec,
       '/Warehouse/Docks/text()',4)
  WHERE warehouse_name = 'San Francisco';

1 row updated.

SELECT warehouse_name,
       EXTRACT(warehouse_spec, '/Warehouse/Docks')
  'Number of Docks'
FROM warehouses
WHERE warehouse_name = 'San Francisco';

<table>
<thead>
<tr>
<th>WAREHOUSE_NAME</th>
<th>Number of Docks</th>
</tr>
</thead>
<tbody>
<tr>
<td>San Francisco</td>
<td>&lt;Docks&gt;4&lt;/Docks&gt;</td>
</tr>
</tbody>
</table>
Syntax

\[
\text{UPPER}(\text{char})
\]

Purpose

UPPER returns char, with all letters uppercase. char can be any of the data types \text{CHAR}, \text{VARCHAR2}, \text{NCHAR}, \text{NVARCHAR2}, \text{CLOB}, or \text{NCLOB}. The return value is the same data type as char. The database sets the case of the characters based on the binary mapping defined for the underlying character set. For linguistic-sensitive uppercase, refer to \text{NLS\_UPPER} on page 7-207.

Examples

The following example returns each employee's last name in uppercase:

\[
\text{SELECT UPPER(last\_name) 'Uppercase'
FROM employees;}
\]
USER

Syntax

USER

Purpose

USER returns the name of the session user (the user who logged on). This may change during the duration of a database session as Real Application Security sessions are attached or detached. For enterprise users, this function returns the schema. For other users, it returns the database user name. If a Real Application Security session is currently attached to the database session, then it returns user XS$NULL.

This function returns a VARCHAR2 value.

Oracle Database compares values of this function with blank-padded comparison semantics.

In a distributed SQL statement, the UID and USER functions together identify the user on your local database. You cannot use these functions in the condition of a CHECK constraint.

See Also: Oracle Database 2 Day + Security Guide for more information on user XS$NULL

Examples

The following example returns the session user and the user’s UID:

SELECT USER, UID FROM DUAL;
USERENV

Syntax

```
USERENV( parameter )
```

Purpose

**Note:** USERENV is a legacy function that is retained for backward compatibility. Oracle recommends that you use the SYS_CONTEXT function with the built-in USERENV namespace for current functionality. See SYS_CONTEXT on page 7-334 for more information.

USERENV returns information about the current session. This information can be useful for writing an application-specific audit trail table or for determining the language-specific characters currently used by your session. You cannot use USERENV in the condition of a `CHECK` constraint. Table 7–12 describes the values for the parameter argument.

All calls to USERENV return VARCHAR2 data except for calls with the SESSIONID, SID, and ENTRYID parameters, which return NUMBER.

**Table 7–12 Parameters of the USERENV Function**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT_INFO</td>
<td>CLIENT_INFO returns up to 64 bytes of user session information that can be stored by an application using the DBMS_APPLICATION_INFO package.</td>
</tr>
<tr>
<td>ISDBA</td>
<td>ISDBA returns 'TRUE' if the user has been authenticated as having DBA privileges either through the operating system or through a password file.</td>
</tr>
<tr>
<td>LANG</td>
<td>LANG returns the ISO abbreviation for the language name, a shorter form than the existing 'LANGUAGE' parameter.</td>
</tr>
<tr>
<td>LANGUAGE</td>
<td>LANGUAGE returns the language and territory used by the current session along with the database character set in this form: language_territory.characterset</td>
</tr>
<tr>
<td>SESSIONID</td>
<td>SESSIONID returns the auditing session identifier. You cannot specify this parameter in distributed SQL statements.</td>
</tr>
<tr>
<td>SID</td>
<td>SID returns the session ID.</td>
</tr>
</tbody>
</table>
The following example returns the `LANGUAGE` parameter of the current session:

```
SELECT USERENV('LANGUAGE') "Language" FROM DUAL;
```

Language
----------
AMERICAN_AMERICA.WE8ISO8859P1

**Examples**

The following example returns the `LANGUAGE` parameter of the current session:

```
SELECT USERENV('LANGUAGE') "Language" FROM DUAL;
```

Language
----------
AMERICAN_AMERICA.WE8ISO8859P1
VALUE

Syntax

```
VALUE (correlation_variable)
```

Purpose

VALUE takes as its argument a correlation variable (table alias) associated with a row of an object table and returns object instances stored in the object table. The type of the object instances is the same type as the object table.

Examples

The following example uses the sample table `oe.persons`, which is created in "Substitutable Table and Column Examples" on page 16-91:

```
SELECT VALUE(p) FROM persons p;
```

```
VALUE(P)(NAME, SSN)
-------------------------------------------------------------
PERSON_T('Bob', 1234)
EMPLOYEE_T('Joe', 32456, 12, 100000)
PART_TIME_EMP_T('Tim', 5678, 13, 1000, 20)
```

See Also: "IS OF type Condition" on page 6-34 for information on using IS OF type conditions with the VALUE function
VAR_POP

Syntax

VAR_POP(expr) OVER (analytic_clause)

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

VAR_POP returns the population variance of a set of numbers after discarding the nulls in this set. You can use it as both an aggregate and analytic function.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

See Also: Table 2–10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion

If the function is applied to an empty set, then it returns null. The function makes the following calculation:

\[
\text{SUM((expr - (\text{SUM}(expr) / \text{COUNT}(expr)))^2)} / \text{COUNT}(expr)
\]

See Also: "About SQL Expressions" on page 5-1 for information on valid forms of expr and "Aggregate Functions" on page 7-10

Aggregate Example

The following example returns the population variance of the salaries in the employees table:

```
SELECT VAR_POP(salary) FROM employees;
```

VAR_POP(SALARY)
---------------
15141964.9

Analytic Example

The following example calculates the cumulative population and sample variances in the sh.sales table of the monthly sales in 1998:

```
SELECT t.calendar_month_desc,
       VAR_POP(SUM(s.amount_sold)) AS Var_Pop,
       VAR_SAMP(SUM(s.amount_sold)) AS Var_Samp
FROM sales s, times t
WHERE s.time_id = t.time_id AND t.calendar_year = 1998
GROUP BY t.calendar_month_desc
ORDER BY t.calendar_month_desc, "Var_Pop", "Var_Samp";
```

CALENDAR Var_Pop Var_Samp

</tr>
</tbody>
</table>
VAR_SAMP

Syntax

```
VAR_SAMP(expr) [OVER (analytic_clause)]
```

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

VAR_SAMP returns the sample variance of a set of numbers after discarding the nulls in this set. You can use it as both an aggregate and analytic function.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

See Also: Table 2-10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion.

If the function is applied to an empty set, then it returns null. The function makes the following calculation:

\[
\frac{(\text{SUM} \{ \text{expr} - (\text{SUM} \{ \text{expr} \} / \text{COUNT} \{ \text{expr} \}) \}^2)}{\text{COUNT} \{ \text{expr} \} - 1}
\]

This function is similar to VARIANCE, except that given an input set of one element, VARIANCE returns 0 and VAR_SAMP returns null.

See Also: "About SQL Expressions" on page 5-1 for information on valid forms of expr and "Aggregate Functions" on page 7-10

Aggregate Example

The following example returns the sample variance of the salaries in the sample employees table.

```sql
SELECT VAR_SAMP(salary) FROM employees;
```

```
VAR_SAMP(SALARY)
---------------
15284813.7
```

Analytic Example

Refer to the analytic example for VAR_POP on page 7-399.
VARIANCE

Syntax

\[
\text{VARIANCE} \left( \begin{array}{c}
\text{DISTINCT} \\
\text{ALL}
\end{array} \right) \text{ expr} \left( \begin{array}{c}
\text{OVER (analytic_clause)}
\end{array} \right)
\]

See Also: "Analytic Functions" on page 7-12 for information on syntax, semantics, and restrictions

Purpose

VARIANCE returns the variance of expr. You can use it as an aggregate or analytic function.

Oracle Database calculates the variance of expr as follows:

- 0 if the number of rows in expr = 1
- VAR_SAMP if the number of rows in expr > 1

If you specify DISTINCT, then you can specify only the query_partition_clause of the analytic_clause. The order_by_clause and windowing_clause are not allowed.

This function takes as an argument any numeric data type or any nonnumeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

See Also: Table 2-10, "Implicit Type Conversion Matrix" on page 2-43 for more information on implicit conversion, "About SQL Expressions" on page 5-1 for information on valid forms of expr and "Aggregate Functions" on page 7-10

Aggregate Example

The following example calculates the variance of all salaries in the sample employees table:

```sql
SELECT VARIANCE(salary) "Variance"
FROM employees;
```

```
Variance
----------
15283140.5
```

Analytic Example

The following example returns the cumulative variance of salary values in Department 30 ordered by hire date.

```sql
SELECT last_name, salary, VARIANCE(salary)
OVER (ORDER BY hire_date) "Variance"
FROM employees
WHERE department_id = 30
ORDER BY last_name, salary, "Variance";
```

```
LAST_NAME  SALARY  Variance
--------------------------  --------
Baida       2900    16283333.3
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
<th>Variance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Colmenares</td>
<td>2500</td>
<td>11307000</td>
</tr>
<tr>
<td>Himuro</td>
<td>2600</td>

</tr>
<tr>
<td>Khoo</td>
<td>3100</td>
<td>31205000</td>
</tr>
<tr>
<td>Raphaely</td>
<td>11000</td>
<td>0</td>
</tr>
<tr>
<td>Tobias</td>
<td>2800</td>
<td>21621333.3</td>
</tr>
</tbody>
</table>
VSIZE

Syntax

\[ \text{VSIZE(expr)} \]

Purpose

VSIZE returns the number of bytes in the internal representation of expr. If expr is null, then this function returns null.

This function does not support CLOB data directly. However, CLOBs can be passed in as arguments through implicit data conversion.

See Also: "Data Type Comparison Rules" on page 2-39 for more information

Examples

The following example returns the number of bytes in the last_name column of the employees in department 10:

```sql
SELECT last_name, VSIZE (last_name) "BYTES"
FROM employees
WHERE department_id = 10
ORDER BY employee_id;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>BYTES</th>
</tr>
</thead>
<tbody>
<tr>
<td>Whalen</td>
<td>6</td>
</tr>
</tbody>
</table>
WIDTH_BUCKET

Syntax

WIDTH_BUCKET(expr, min_value, max_value, num_buckets)

Purpose

WIDTH_BUCKET lets you construct equiwidth histograms, in which the histogram range is divided into intervals that have identical size. (Compare this function with NTILE, which creates equiheight histograms.) Ideally each bucket is a closed-open interval of the real number line. For example, a bucket can be assigned to scores between 10.00 and 19.999... to indicate that 10 is included in the interval and 20 is excluded. This is sometimes denoted [10, 20).

For a given expression, WIDTH_BUCKET returns the bucket number into which the value of this expression would fall after being evaluated.

- `expr` is the expression for which the histogram is being created. This expression must evaluate to a numeric or datetime value or to a value that can be implicitly converted to a numeric or datetime value. If `expr` evaluates to null, then the expression returns null.
- `min_value` and `max_value` are expressions that resolve to the end points of the acceptable range for `expr`. Both of these expressions must also evaluate to numeric or datetime values, and neither can evaluate to null.
- `num_buckets` is an expression that resolves to a constant indicating the number of buckets. This expression must evaluate to a positive integer.

Examples

The following example creates a ten-bucket histogram on the `credit_limit` column for customers in Switzerland in the sample table `oe.customers` and returns the bucket number ("Credit Group") for each customer. Customers with credit limits greater than or equal to the maximum value are assigned to the overflow bucket, 11:

```sql
SELECT customer_id, cust_last_name, credit_limit,
       WIDTH_BUCKET(credit_limit, 100, 5000, 10) "Credit Group"
FROM customers WHERE nls_territory = 'SWITZERLAND'
ORDER BY "Credit Group", customer_id, cust_last_name, credit_limit;
```

</tbody>
</table>
XMLAGG

Syntax

XMLAGG( XMLType_instance order_by_clause )

Purpose

XMLAgg is an aggregate function. It takes a collection of XML fragments and returns an aggregated XML document. Any arguments that return null are dropped from the result.

XMLAgg is similar to SYS_XMLAgg except that XMLAgg returns a collection of nodes but it does not accept formatting using the XMLFormat object. Also, XMLAgg does not enclose the output in an element tag as does SYS_XMLAgg.

Within the order_by_clause, Oracle Database does not interpret number literals as column positions, as it does in other uses of this clause, but simply as number literals.

See Also: XMLELEMENT on page 7-416 and SYS_XMLAGG on page 7-347

Examples

The following example produces a Department element containing Employee elements with employee job ID and last name as the contents of the elements:

SELECT XMLELEMENT('Department',
    XMLAGG(XMLELEMENT('Employee',
        e.job_id||' '||e.last_name)
    ORDER BY last_name))
AS 'Dept_list'
FROM employees e
WHERE e.department_id = 30;

Dept_list
-------------------------------------------------------------
<Department>
  <Employee>PU_CLERK Baida</Employee>
  <Employee>PU_CLERK Colmenares</Employee>
  <Employee>PU_CLERK Himuro</Employee>
  <Employee>PU_CLERK Khoo</Employee>
  <Employee>PU_MAN Raphaely</Employee>
  <Employee>PU_CLERK Tobias</Employee>
</Department>

The result is a single row, because XMLAgg aggregates the rows. You can use the GROUP BY clause to group the returned set of rows into multiple groups:

SELECT XMLELEMENT('Department',
    XMLAGG(XMLELEMENT('Employee', e.job_id||' '||e.last_name)))
AS 'Dept_list'
FROM employees e
GROUP BY e.department_id;

Dept_list
---------------------------------------------------------
<Department>
<Employee>AD_ASST Whalen</Employee>
</Department>

<Department>
  <Employee>MK_MAN Hartstein</Employee>
  <Employee>MK_REP Fay</Employee>
</Department>

<Department>
  <Employee>PU_MAN Raphaely</Employee>
  <Employee>PU_CLERK Khoo</Employee>
  <Employee>PU_CLERK Tobias</Employee>
  <Employee>PU_CLERK Baida</Employee>
  <Employee>PU_CLERK Colmenares</Employee>
  <Employee>PU_CLERK Himuro</Employee>
</Department>
XMLCAST

Syntax

```sql
XMLCAST (value_expression) AS datatype
```

Purpose

XMLCast casts `value_expression` to the scalar SQL data type specified by `datatype`. The `value_expression` argument is a SQL expression that is evaluated. The `datatype` argument can be of data type `NUMBER`, `VARCHAR2`, `CHAR`, `CLOB`, `BLOB`, `REF XMLTYPE`, and any of the datetime data types.

See Also: Oracle XML DB Developer's Guide for more information on uses for this function and examples
XMLCDATA

Syntax

```
XMLCDATA (value_expr)
```

Purpose

XMLCDATA generates a CDATA section by evaluating `value_expr`. The `value_expr` must resolve to a string. The value returned by the function takes the following form:

```
<![[CDATA[string]]>]
```

If the resulting value is not a valid XML CDATA section, then the function returns an error.

The following conditions apply to `XMLCDATA`:

- The `value_expr` cannot contain the substring `]]>`.  
- If `value_expr` evaluates to null, then the function returns null.

See Also:  *Oracle XML DB Developer’s Guide* for more information on this function

Examples

The following statement uses the `DUAL` table to illustrate the syntax of `XMLCDATA`:

```sql
SELECT XMLELEMENT("PurchaseOrder",
   XMLAttributes(dummy as 'pono'),
   XMLCDATA('<!DOCTYPE po_dom_group [
      <!ELEMENT po_dom_group(student_name)*)
      <!ELEMENT po_purch_name (#PCDATA)>
      <!ATTLIST po_name po_no ID #REQUIRED>
      <!ATTLIST po_name trust_1 IDREF #IMPLIED>
      <!ATTLIST po_name trust_2 IDREF #IMPLIED>
    ]>')) "XMLCDATA" FROM DUAL;
```

```
<PurchaseOrder pono="X"><![CDATA[
<!DOCTYPE po_dom_group [ 
   <!ELEMENT po_dom_group(student_name)*)
   <!ELEMENT po_purch_name (#PCDATA)>
   <!ATTLIST po_name po_no ID #REQUIRED>
   <!ATTLIST po_name trust_1 IDREF #IMPLIED>
   <!ATTLIST po_name trust_2 IDREF #IMPLIED>
 ]>'] "XMLCDATA" FROM DUAL;
```

```xml
< PurchaseOrder pono=",X"> <![[CDATA[
<!DOCTYPE po_dom_group [ 
   <!ELEMENT po_dom_group(student_name)*)
   <!ELEMENT po_purch_name (#PCDATA)>
   <!ATTLIST po_name po_no ID #REQUIRED>
   <!ATTLIST po_name trust_1 IDREF #IMPLIED>
   <!ATTLIST po_name trust_2 IDREF #IMPLIED>
 ]>']
```

```
</PurchaseOrder>
```
XMLCOLATTVAL

Syntax

XMLCOLATTVAL (value_expr AS c_alias EVALNAME value_expr)

Purpose

XMLColAttVal creates an XML fragment and then expands the resulting XML so that each XML fragment has the name column with the attribute name.

You can use the AS clause to change the value of the name attribute to something other than the column name. You can do this by specifying c_alias, which is a string literal, or by specifying EVALNAME value_expr. In the latter case, the value expression is evaluated and the result, which must be a string literal, is used as the alias. The alias can be up to 4000 characters if the initialization parameter MAX_STRING_SIZE = STANDARD, and 32767 characters if MAX_STRING_SIZE = EXTENDED. See "Extended Data Types" on page 2-29 for more information.

You must specify a value for value_expr. If value_expr is null, then no element is returned.

Restriction on XMLColAttVal  You cannot specify an object type column for value_expr.

Examples

The following example creates an Emp element for a subset of employees, with nested employee_id, last_name, and salary elements as the contents of Emp. Each nested element is named column and has a name attribute with the column name as the attribute value:

```sql
SELECT XMLELEMENT("Emp",
    XMLCOLATTVAL(e.employee_id, e.last_name, e.salary) "Emp Element"
FROM employees e
WHERE employee_id = 204;
```

Emp Element

```
<Emp>
  <column name='EMPLOYEE_ID'>204</column>
  <column name='LAST_NAME'>Baer</column>
  <column name='SALARY'>10000</column>
</Emp>
```

Refer to the example for XMLFOREST on page 7-420 to compare the output of these two functions.
**XMLComment**

**Syntax**

XMLComment (value_expr)

**Purpose**

XMLComment generates an XML comment using an evaluated result of `value_expr`. The `value_expr` must resolve to a string. It cannot contain two consecutive dashes (hyphens). The value returned by the function takes the following form:

`<!--string-->`

If `value_expr` resolves to null, then the function returns null.

**See Also:** Oracle XML DB Developer’s Guide for more information on this function

**Examples**

The following example uses the DUAL table to illustrate the XMLComment syntax:

```
SELECT XMLComment('OrderAnalysisComp imported, reconfigured, disassembled')
    AS "XMLCOMMENT" FROM DUAL;
```

```
<!--OrderAnalysisComp imported, reconfigured, disassembled-->  
```
XMLCONCAT

Syntax

```
XMLCONCAT(1, XMLType_instance, 1)
```

Purpose

XMLConcat takes as input a series of XMLType instances, concatenates the series of elements for each row, and returns the concatenated series. XMLConcat is the inverse of XMLSequence.

Null expressions are dropped from the result. If all the value expressions are null, then the function returns null.

See Also:  XMLSEQUENCE on page 7-428

Examples

The following example creates XML elements for the first and last names of a subset of employees, and then concatenates and returns those elements:

```sql
SELECT XMLCONCAT(XMLELEMENT("First", e.first_name),
                   XMLELEMENT("Last", e.last_name)) AS "Result"
FROM employees e
WHERE e.employee_id > 202;
```

Result

```
<First>Susan</First>
<Last>Mavris</Last>

<First>Hermann</First>
<Last>Baer</Last>

<First>Shelley</First>
<Last>Higgins</Last>

<First>William</First>
<Last>Gietz</Last>
```

4 rows selected.
XMLDIFF

Syntax

XMLDIFF

Purpose

The XMLDiff function is the SQL interface for the XmlDiff C API. This function compares two XML documents and captures the differences in XML conforming to an X diff schema. The diff document is returned as an XMLType document.

- For the first two arguments, specify the names of two XMLType documents.
- For the integer, specify a number representing the hashLevel for a C function XmlDiff. If you do not want hashing, set this argument to 0 or omit it entirely. If you do not want hashing, but you want to specify flags, then you must set this argument to 0.
- For string, specify the flags that control the behavior of the function. These flags are specified by one or more names separated by semicolon. The names are the same as the names of constants for XmlDiff function.

See Also: Oracle XML Developer’s Kit Programmer’s Guide for more information on using this function, including examples, and Oracle Database XML C API Reference for information on the XML APIs for C

Examples

The following example compares two XML documents and returns the difference as an XMLType document:

```sql
SELECT XMLDIFF(
    XMLTYPE '<?xml version="1.0"?'
    <bk:book xmlns:bk="http://example.com">
    <bk:tr>
      <bk:td>
        <bk:chapter>
          Chapter 1.
        </bk:chapter>
      </bk:td>
      <bk:td>
        <bk:chapter>
          Chapter 2.
        </bk:chapter>
      </bk:td>
    </bk:tr>
</bk:book>'),
    XMLTYPE '<?xml version="1.0"?'
    <bk:book xmlns:bk="http://example.com">
    <bk:tr>
      <bk:td>
        <bk:chapter>
          Chapter 1.
        </bk:chapter>
      </bk:td>
      <bk:td>
        <bk:chapter>
          Chapter 2.
        </bk:chapter>
      </bk:td>
    </bk:tr>
</bk:book>')
```
FROM DUAL;
**Syntax**

```sql
XML_ELEMENT(ENTITYESCAPING, NOENTITYESCAPING, NAME, identifier, EVALNAME, value_expr, XML_attributes_clause, value_expr, AS, c_alias)
```

**XML_attributes_clause::=**

```sql
XML_ATTRIBUTES(ENTITYESCAPING, NOENTITYESCAPING, SCHEMACHECK, NOSCHEMACHECK, value_expr, AS, c_alias, EVALNAME, value_expr, AS)
```

**Purpose**

`XML_ELEMENT` takes an element name for `identifier` or evaluates an element name for `EVALNAME value_expr`, an optional collection of attributes for the element, and arguments that make up the content of the element. It returns an instance of type `XMLType`. `XML_ELEMENT` is similar to `SYS_XMLGen` except that `XML_ELEMENT` can include attributes in the XML returned, but it does not accept formatting using the `XMLFormat` object.

The `XML_ELEMENT` function is typically nested to produce an XML document with a nested structure, as in the example in the following section.

For an explanation of the `ENTITYESCAPING` and `NONENTITYESCAPING` keywords, refer to Oracle XML DB Developer's Guide.

You must specify a value for Oracle Database to use an the enclosing tag. You can do this by specifying `identifier`, which is a string literal, or by specifying `EVALNAME value_expr`. In the latter case, the value expression is evaluated and the result, which must be a string literal, is used as the identifier. The identifier does not have to be a column name or column reference. It cannot be an expression or null. It can be up to 4000 characters if the initialization parameter `MAX_STRING_SIZE = STANDARD`, and 32767 characters if `MAX_STRING_SIZE = EXTENDED`. 

You can include attributes in the XML returned, but you cannot use formatting using the `XML_FORMAT` object.
The objects that make up the element content follow the XML_ATTRIBUTES keyword. In the XML_attributes_clause, if the value_expr is null, then no attribute is created for that value expression. The type of value_expr cannot be an object type or collection. If you specify an alias for value_expr using the AS clause, then the c_alias or the evaluated value expression (EVALNAME value_expr) can be up to 4000 characters if the initialization parameter MAX_STRING_SIZE = STANDARD, and 32767 characters if MAX_STRING_SIZE = EXTENDED.

See Also: "Extended Data Types" on page 2-29 for more information on MAX_STRING_SIZE

For the optional value_expr that follows the XML_attributes_clause in the diagram:

- If value_expr is a scalar expression, then you can omit the AS clause, and Oracle uses the column name as the element name.
- If value_expr is an object type or collection, then the AS clause is mandatory, and Oracle uses the specified c_alias as the enclosing tag.
- If value_expr is null, then no element is created for that value expression.

See Also: SYS_XMLGEN on page 7-348

**Examples**

The following example produces an Emp element for a series of employees, with nested elements that provide the employee’s name and hire date:

```
SELECT XMLELEMENT('Emp', XMLELEMENT("Name", e.job_id||' '||e.last_name),
                   XMLELEMENT("Hiredate", e.hire_date)) as "Result"
FROM employees e WHERE employee_id > 200;
```

```
Result
----------------------------------------------
<Emp>
  <Name>MK_MAN Hartstein</Name>
  <Hiredate>2004-02-17</Hiredate>
</Emp>

<Emp>
  <Name>MK_REP Fay</Name>
  <Hiredate>2005-08-17</Hiredate>
</Emp>

<Emp>
  <Name>HR_REP Mavris</Name>
  <Hiredate>2002-06-07</Hiredate>
</Emp>

<Emp>
  <Name>PR_REP Baer</Name>
  <Hiredate>2002-06-07</Hiredate>
</Emp>

<Emp>
  <Name>AC_MGR Higgins</Name>
  <Hiredate>2002-06-07</Hiredate>
</Emp>

<Emp>
```

See Also:
The following similar example uses the XMLELEMENT function with the XML attributes_clause to create nested XML elements with attribute values for the top-level element:

```sql
SELECT XMLELEMENT("Emp",
    XMLATTRIBUTES(e.employee_id AS 'ID', e.last_name),
    XMLELEMENT("Dept", e.department_id),
    XMLELEMENT("Salary", e.salary)) AS "Emp Element"
FROM employees e
WHERE e.employee_id = 206;
```

```
Emp Element

<Emp ID="206" LAST_NAME="Gietz">
    <Dept>110</Dept>
    <Salary>8300</Salary>
</Emp>
```

Notice that the AS identifier clause was not specified for the last_name column. As a result, the XML returned uses the column name last_name as the default.

Finally, the next example uses a subquery within the XML attributes_clause to retrieve information from another table into the attributes of an element:

```sql
SELECT XMLELEMENT("Emp",
    XMLATTRIBUTES(e.employee_id, e.last_name),
    XMLELEMENT("Dept", XMLATTRIBUTES(e.department_id,
        (SELECT d.department_name FROM departments d
         WHERE d.department_id = e.department_id) as "Dept_name"),
    XMLELEMENT("Salary", e.salary),
    XMLELEMENT("Hiredate", e.hire_date)) AS "Emp Element"
FROM employees e
WHERE employee_id = 205;
```

```
Emp Element

<Emp EMPLOYEE_ID="205" LAST_NAME="Higgins">
    <Dept DEPARTMENT_ID="110" Dept_name="Accounting"/>
    <salary>12008</salary>
    <Hiredate>2002-06-07</Hiredate>
</Emp>
```
XMLEXISTS

Syntax

```
XMLEXISTS (XQuery_string XML_passing_clause)
```

**XML_passing_clause::=**

```
PASSING BY VALUE expr AS identifier
```

**Purpose**

The function `XMLEXISTS` checks whether a given XQuery expression returns a nonempty XQuery sequence. If so, the function returns `TRUE`; otherwise, it returns `FALSE`. The argument `XQuery_string` is a literal string, but it can contain XQuery variables that you bind using the `XML_passing_clause`.

The `expr` in the `XML_passing_clause` is an expression returning an `XMLType` or an instance of a SQL scalar data type that is used as the context for evaluating the XQuery expression. You can specify only one `expr` in the `PASSING` clause without an identifier. The result of evaluating each `expr` is bound to the corresponding identifier in the `XQuery_string`. If any `expr` that is not followed by an `AS` clause, then the result of evaluating that expression is used as the context item for evaluating the `XQuery_string`.

**See Also:** Oracle XML DB Developer’s Guide for more information on uses for this function and examples
XMLFOREST

Syntax

```
XMLFOREST value_expr
```

Purpose

XMLForest converts each of its argument parameters to XML, and then returns an XML fragment that is the concatenation of these converted arguments.

- If `value_expr` is a scalar expression, then you can omit the `AS` clause, and Oracle Database uses the column name as the element name.

- If `value_expr` is an object type or collection, then the `AS` clause is mandatory, and Oracle uses the specified expression as the enclosing tag.

You can do this by specifying `c_alias`, which is a string literal, or by specifying `EVALNAME value_expr`. In the latter case, the value expression is evaluated and the result, which must be a string literal, is used as the identifier. The identifier does not have to be a column name or column reference. It cannot be an expression or null. It can be up to 4000 characters if the initialization parameter `MAX_STRING_SIZE = STANDARD`, and 32767 characters if `MAX_STRING_SIZE = EXTENDED`. See "Extended Data Types" on page 2-29 for more information.

- If `value_expr` is null, then no element is created for that `value_expr`.

Examples

The following example creates an `Emp` element for a subset of employees, with nested `employee_id`, `last_name`, and `salary` elements as the contents of `Emp`:

```
SELECT XMLELEMENT("Emp",
    XMLFOREST(e.employee_id, e.last_name, e.salary))
  "Emp Element"
FROM employees e WHERE employee_id = 204;
```

```
Emp Element
----------------------------------------------------------------
<Emp>
  <EMPLOYEE_ID>204</EMPLOYEE_ID>
  <LAST_NAME>Baer</LAST_NAME>
  <SALARY>10000</SALARY>
</Emp>
```

Refer to the example for `XMLCOLATTVAL` on page 7-411 to compare the output of these two functions.
XMLISVALID

Syntax

```
XMLISVALID (XMLType_instance, XMLSchema_URL, element)
```

Purpose

XMLISVALID checks whether the input XMLType_instance conforms to the relevant XML schema. It does not change the validation status recorded for XMLType_instance. If the input XML document is determined to be valid, then XMLISVALID returns 1; otherwise, it returns 0. If you provide XMLSchema_URL as an argument, then that is used to check conformance. Otherwise, the XML schema specified by the XML document is used to check conformance.

- XMLType_instance is the XMLType instance to be validated.
- XMLSchema_URL is the URL of the XML schema against which to check conformance.
- element is the element of the specified schema against which to check conformance. Use this if you have an XML schema that defines more than one top level element, and you want to check conformance against a specific one of those elements.

See Also: Oracle XML DB Developer’s Guide for information on the use of this function, including examples
XMLPARSE

Syntax

```
XMLPARSE (DOCUMENT value_expr) WELLFORMED
```

Purpose

XMLParse parses and generates an XML instance from the evaluated result of `value_expr`. The `value_expr` must resolve to a string. If `value_expr` resolves to null, then the function returns null.

- If you specify `DOCUMENT`, then `value_expr` must resolve to a singly rooted XML document.
- If you specify `CONTENT`, then `value_expr` must resolve to a valid XML value.
- When you specify `WELLFORMED`, you are guaranteeing that `value_expr` resolves to a well-formed XML document, so the database does not perform validity checks to ensure that the input is well formed.

See Also: Oracle XML DB Developer’s Guide for more information on this function

Examples

The following example uses the DUAL table to illustrate the syntax of XMLParse:

```
SELECT XMLPARSE(CONTENT '124 <purchaseOrder poNo="12435">
  <customerName> Acme Enterprises</customerName>
  <itemNo>32987457</itemNo>
</purchaseOrder>' WELLFORMED) AS PO FROM DUAL;
```

```
PO
-----------------------------
124 <purchaseOrder poNo="12435">
  <customerName> Acme Enterprises</customerName>
  <itemNo>32987457</itemNo>
</purchaseOrder>
```
XMLPATCH

Syntax

```sql
XMLPatch(.XMLType_document, XMLType_document)
```

Purpose

The `XMLPATCH` function is the SQL interface for the XmlPatch C API. This function patches an XML document with the changes specified. A patched `XMLType` document is returned.

- For the first argument, specify the name of the input `XMLType` document.
- For the second argument, specify the `XMLType` document containing the changes to be applied to the first document. The changes should conform to the Xdiff XML schema. You can supply the XML output from the Oracle XML Developer's Kit Java method `diff()`.

See Also: Oracle XML Developer's Kit Programmer's Guide for more information on using this function, including examples, and Oracle Database XML C API Reference for information on the XML APIs for C

Examples

The following example patches an `XMLType` document with the changes specified in another `XMLType` and returns a patched `XMLType` document:

```sql
SELECT XMLPATCH(
XMLTYPE('<?xml version="1.0"?><bk:book xmlns:bk="http://example.com">
  <bk:tr>
    <bk:td>
      <bk:chapter>
        Chapter 1.
      </bk:chapter>
    </bk:td>
    <bk:td>
      <bk:chapter>
        Chapter 2.
      </bk:chapter>
    </bk:td>
  </bk:tr>
</bk:book>'),
XMLTYPE('<?xml version="1.0"?>
xmlns:xd="http://xmlns.oracle.com/xdb/xdiff.xsd"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:bk="http://example.com">
  <xd:delete-node xd:node-type="element"
</xd:xdiff>')
) FROM DUAL;
```
XMLPI generates an XML processing instruction using identifier and optionally the evaluated result of value_expr. A processing instruction is commonly used to provide to an application information that is associated with all or part of an XML document. The application uses the processing instruction to determine how best to process the XML document.

You must specify a value for Oracle Database to use in the enclosing tag. You can do this by specifying identifier, which is a string literal, or by specifying EVALNAME value_expr. In the latter case, the value expression is evaluated and the result, which must be a string literal, is used as the identifier. The identifier does not have to be a column name or column reference. It cannot be an expression or null. It can be up to 4000 characters if the initialization parameter MAX_STRING_SIZE = STANDARD, and 32767 characters if MAX_STRING_SIZE = EXTENDED. See "Extended Data Types" on page 2-29 for more information.

The optional value_expr must resolve to a string. If you omit the optional value_expr, then a zero-length string is the default. The value returned by the function takes this form:

```xml
<?identifier string?>
```

XMLPI is subject to the following restrictions:

- The identifier must be a valid target for a processing instruction.
- You cannot specify xml in any case combination for identifier.
- The identifier cannot contain the consecutive characters `?>`.

See Also: Oracle XML DB Developer’s Guide for more information on this function

### Examples

The following statement uses the DUAL table to illustrate the use of the XMLPI syntax:

```sql
SELECT XMLPI(NAME "Order analysisComp", 'imported, reconfigured, disassembled') AS "XMLPI" FROM DUAL;
```

```xml
<?Order analysisComp imported, reconfigured, disassembled?>
```
XMLQUERY

Syntax

```plaintext
XMLQUERY(XQuery_string, XML_passing_clause, RETURNING CONTENT, NULL ON EMPTY)
```

**XML_passing_clause::=**

```plaintext
PASSING BY VALUE expr AS identifier,
```

**Purpose**

XMLQUERY lets you query XML data in SQL statements. It takes an XQuery expression as a string literal, an optional context item, and other bind variables and returns the result of evaluating the XQuery expression using these input values.

- **XQuery_string** is a complete XQuery expression, including prolog.
- The `expr` in the `XML_passing_clause` is an expression returning an `XMLType` or an instance of a SQL scalar data type that is used as the context for evaluating the XQuery expression. You can specify only one `expr` in the PASSING clause without an identifier. The result of evaluating each `expr` is bound to the corresponding identifier in the `XQuery_string`. If any `expr` that is not followed by an `AS` clause, then the result of evaluating that expression is used as the context item for evaluating the `XQuery_string`.
- **RETURNING CONTENT** indicates that the result from the XQuery evaluation is either an XML 1.0 document or a document fragment conforming to the XML 1.0 semantics.
- If the result set is empty, then the function returns the SQL NULL value. The `NULL ON EMPTY` keywords are implemented by default and are shown for semantic clarity.

**See Also:** Oracle XML DB Developer’s Guide for more information on this function

**Examples**

The following statement specifies the `warehouse_spec` column of the `oe.warehouses` table in the `XML_passing_clause` as a context item. The statement returns specific information about the warehouses with area greater than 50K.

```sql
SELECT warehouse_name,
EXTRACTVALUE(warehouse_spec, '/Warehouse/Area'),
XMLQuery('for $i in /Warehouse
where $i/Area > 50000
return <Details>
<Docks num="{$i/Docks}"/>
<Rail>
{
if ($i/RailAccess = "Y") then "true" else "false"
')
```

Functions 7-425
```sql
FROM warehouses;

<table>

</tbody>
</table>
```
XMLROOT

Syntax

XMLROOT (value_expr, VERSION value_expr, STANDALONE {YES | NO})

Purpose

XMLROOT lets you create a new XML value by providing version and standalone properties in the XML root information (prolog) of an existing XML value. If the value_expr already has a prolog, then the database returns an error. If the input is null, then the function returns null.

The value returned takes the following form:

```xml
<?xml version = "version" [ STANDALONE = "(yes | no)" ]?>
```

- The first value_expr specifies the XML value for which you are providing prolog information.
- In the VERSION clause, value_expr must resolve to a string representing a valid XML version. If you specify NO VALUE for VERSION, then the version defaults to 1.0.
- If you omit the optional STANDALONE clause, or if you specify it with NO VALUE, then the standalone property is absent from the value returned by the function.

Examples

The following statement uses the DUAL table to illustrate the syntax of XMLROOT:

```sql
SELECT XMLROOT (XMLType('<poid>143598</poid>'), VERSION '1.0', STANDALONE YES) AS 'XMLROOT' FROM DUAL;
```

```
<?xml version="1.0" standalone="yes"?><poid>143598</poid>
```
XMLSEQUENCE

Note: The XMLSEQUENCE function is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you use the XMLTABLE function instead. See XMLTABLE on page 7-432 for more information.

Syntax

```
XMLSEQUENCE (XMLType_instance, sys_refcursor_instance, fmt)
```

Purpose

XMLSequence has two forms:

- The first form takes as input an XMLType instance and returns a varray of the top-level nodes in the XMLType. This form is effectively superseded by the SQL/XML standard function XMLTable, which provides for more readable SQL code. Prior to Oracle Database 10g Release 2, XMLSequence was used with SQL function TABLE to do some of what can now be done better with the XMLTable function.

- The second form takes as input a REFCURSOR instance, with an optional instance of the XMLFormat object, and returns as an XMLSequence type an XML document for each row of the cursor.

Because XMLSequence returns a collection of XMLType, you can use this function in a TABLE clause to unnest the collection values into multiple rows, which can in turn be further processed in the SQL query.

See Also: Oracle XML DB Developer’s Guide for more information on this function, and XMLTABLE on page 7-432

Examples

The following example shows how XMLSequence divides up an XML document with multiple elements into VARRAY single-element documents. In this example, the TABLE keyword instructs Oracle Database to consider the collection a table value that can be used in the FROM clause of the subquery:

```
SELECT EXTRACT(warehouse_spec, '/Warehouse') as "Warehouse"
FROM warehouses WHERE warehouse_name = 'San Francisco';
```

```
Warehouse
----------------------------------------
<Building>Rented</Building>
<Area>50000</Area>
<Docks>1</Docks>
<DockType>Side load</DockType>
<WaterAccess>Y</WaterAccess>
<RailAccess>N</RailAccess>
<Parking>Lot</Parking>
<VClearance>12 ft</VClearance>
```
SELECT VALUE(p)
FROM warehouses w,
    TABLE(XMLSEQUENCE(EXTRACT(warehouse_spec, '/Warehouse/*'))) p
WHERE w.warehouse_name = 'San Francisco';

VALUE(P)
----------------------------------------------------------------
<Building>Rented</Building>
<Area>50000</Area>
<Docks>1</Docks>
<DockType>Side load</DockType>
<WaterAccess>Y</WaterAccess>
<RailAccess>N</RailAccess>
<Parking>Lot</Parking>
<VClearance>12 ft</VClearance>

8 rows selected.
XMLSERIALIZE

Syntax

```
XMLSERIALIZE
  DOCUMENT  value_expr  AS  datatype
  CONTENT

ENCODING  xml_encoding_spec

VERSION  string_literal

NO  INDENT

INDENT  SIZE =  number

HIDE  SHOW  DEFAULTS
```

Purpose

XMLSerialize creates a string or LOB containing the contents of value_expr.

- If you specify DOCUMENT, then the value_expr must be a valid XML document.
- If you specify CONTENT, then the value_expr need not be a singly rooted XML document. However it must be valid XML content.
- The datatype specified can be a string type (VARCHAR2 or VARCHAR, but not NVARCHAR2), BLOB, or CLOB. The default is CLOB.
- If datatype is BLOB, then you can specify the ENCODING clause to use the specified encoding in the prolog. The xml_encoding_spec is an XML encoding declaration (encoding="...").
- Specify the VERSION clause to use the version you provide as string_literal in the XML declaration (<?xml version="..." ...?>).
- Specify NO INDENT to strip all insignificant whitespace from the output. Specify INDENT SIZE = N, where N is a whole number, for output that is pretty-printed using a relative indentation of N spaces. If N is 0, then pretty-printing inserts a newline character after each element, placing each element on a line by itself, but omitting all other insignificant whitespace in the output. If INDENT is present without a SIZE specification, then 2-space indenting is used. If you omit this clause, then the behavior (pretty-printing or not) is indeterminate.
- HIDE DEFAULTS and SHOW DEFAULTS apply only to XML schema-based data. If you specify SHOW DEFAULTS and the input data is missing any optional elements or attributes for which the XML schema defines default values, then those elements or attributes are included in the output with their default values. If you specify HIDE DEFAULTS, then no such elements or attributes are included in the output. HIDE DEFAULTS is the default behavior.

See Also: Oracle XML DB Developer’s Guide for more information on this function

Examples

The following statement uses the DUAL table to illustrate the syntax of XMLSerialize:

```
SELECT XMLSERIALIZE(CONTENT XMLTYPE('<Owner>Grandco</Owner>')) AS xmlserialize_doc
```
FROM DUAL;

XMLSERIALIZE_DOC

<Owner>Grandco</Owner>
XMLTABLE

Syntax

XMLTABLE (XMLnamespaces_clause, XQuery_string, XMLTABLE_options)

XMLnamespaces_clause ::= XMLNAMESPACES (string AS identifier DEFAULT string, )

Note: You can specify at most one DEFAULT string clause.

XMLTABLE_options ::= XML_passing_clause RETURNING SEQUENCE BY REF COLUMNS XML_table_column

XML_passing_clause ::= PASSING BY VALUE expr AS identifier

XML_table_column ::= column

FOR ORDINALITY datatype

Purpose

XMLTable maps the result of an XQuery evaluation into relational rows and columns. You can query the result returned by the function as a virtual relational table using SQL.

- The XMLNAMESPACES clause contains a set of XML namespace declarations. These declarations are referenced by the XQuery expression (the evaluated XQuery_string), which computes the row, and by the XPath expression in the PATH clause of XML_table_column, which computes the columns for the entire XMLTable function. If you want to use qualified names in the PATH expressions of the COLUMNS clause, then you need to specify the XMLNAMESPACES clause.
- **XQuery_string** is a literal string. It is a complete XQuery expression and can include prolog declarations. The value of XQuery_string serves as input to the XMLTable function; it is this XQuery result that is decomposed and stored as relational data.

- The **expr** in the **XML_passing_clause** is an expression returning an **XMLType** or an instance of a SQL scalar data type that is used as the context for evaluating the XQuery expression. You can specify only one **expr** in the PASSING clause without an identifier. The result of evaluating each **expr** is bound to the corresponding identifier in the **XQuery_string**. If any **expr** that is not followed by an **AS** clause, then the result of evaluating that expression is used as the context item for evaluating the **XQuery_string**. This clause supports only passing by value, not passing by reference. Therefore, the **BY VALUE** keywords are optional and are provided for semantic clarity.

- The optional **RETURNING SEQUENCE BY REF** clause causes the result of the XQuery evaluation to be returned by reference. This allows you to refer to any part of the source data in the **XML_table_column** clause.

  If you omit this clause, then the result of the XQuery evaluation is returned by value. That is, a copy of the targeted nodes is returned instead of a reference to the actual nodes. In this case, you cannot refer to any data that is not in the returned copy in the **XML_table_column** clause. In particular, you cannot refer to data that precedes the targeted nodes in the source data.

- The optional **COLUMNS** clause defines the columns of the virtual table to be created by XMLTable.
  - If you omit the **COLUMNS** clause, then XMLTable returns a row with a single XMLType pseudocolumn named **COLUMN_VALUE**.
  - **FOR ORDINALITY** specifies that **column** is to be a column of generated row numbers. There must be at most one **FOR ORDINALITY** clause. It is created as a **NUMBER** column.
  - For each resulting column except the **FOR ORDINALITY** column, you must specify the column data type, which can be **XMLType** or any other data type.

    If the column data type is **XMLType**, then specify the **XMLTYPE** clause. If you specify the optional (**SEQUENCE**) **BY REF** clause, then a reference to the source data targeted by the **PATH** expression is returned as the column content. Otherwise, **column** contains a copy of that targeted data.

    Returning the **XMLType** data by reference lets you specify other columns whose paths target nodes in the source data that are outside those targeted by the **PATH** expression for column.

    If the column data type is any other data type, then specify **datatype**.

    - The optional **PATH** clause specifies that the portion of the XQuery result that is addressed by XQuery expression string is to be used as the column content.

      If you omit **PATH**, then the XQuery expression **column** is assumed. For example:

      ```
      XMLTable(... COLUMNS xyz)
      ```

      is equivalent to

      ```
      XMLTable(... COLUMNS xyz PATH 'XYZ')
      ```

      You can use different **PATH** clauses to split the XQuery result into different virtual-table columns.
The optional `DEFAULT` clause specifies the value to use when the `PATH` expression results in an empty sequence. Its `expr` is an XQuery expression that is evaluated to produce the default value.

**Examples**

The following example converts the result of applying the XQuery `/Warehouse` to each value in the `warehouse_spec` column of the `warehouses` table into a virtual relational table with columns `Water` and `Rail`:

```sql
SELECT warehouse_name warehouse, warehouse2."Water", warehouse2."Rail"
FROM warehouses,
XMLTABLE('/Warehouse'
PASSING warehouses.warehouse_spec
COLUMNS
 "Water" varchar2(6) PATH 'WaterAccess',
 "Rail" varchar2(6) PATH 'RailAccess')
warehouse2;
```

<table>
<thead>
<tr>
<th>WAREHOUSE</th>
<th>Water</th>
<th>Rail</th>
</tr>
</thead>
<tbody>
<tr>
<td>Southlake, Texas</td>
<td>Y</td>
<td>N</td>
</tr>
<tr>
<td>San Francisco</td>
<td>Y</td>
<td>N</td>
</tr>
<tr>
<td>New Jersey</td>
<td>N</td>
<td>N</td>
</tr>
<tr>
<td>Seattle, Washington</td>
<td>N</td>
<td>Y</td>
</tr>
</tbody>
</table>

See Also: Oracle XML DB Developer’s Guide for more information on the `XMLTable` function, including additional examples, and on XQuery in general.
**XMLTRANSFORM**

**Syntax**

```
XMLTRANSFORM(XMLType_instance, string) XMLType_instance
```

**Purpose**

XMLTransform takes as arguments an XMLType instance and an XSL style sheet, which is itself a form of XMLType instance. It applies the style sheet to the instance and returns an XMLType.

This function is useful for organizing data according to a style sheet as you are retrieving it from the database.

**See Also:** Oracle XMLDB Developer's Guide for more information on this function

**Examples**

The XMLTransform function requires the existence of an XSL style sheet. Here is an example of a very simple style sheet that alphabetizes elements within a node:

```xml
CREATE TABLE xsl_tab (col1 XMLTYPE);

INSERT INTO xsl_tab VALUES (
   /XMLTYPE.createxml('"
    <xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
      <xsl:output encoding="utf-8"/>
      <!-- alphabetizes an xml tree -->
      <xsl:template match="*">
        <xsl:copy>
          <xsl:apply-templates select="*|text()">
            <xsl:sort select="name(.)" data-type="text" order="ascending"/>
          </xsl:apply-templates>
        </xsl:copy>
      </xsl:template>
      <xsl:template match="text()">
        <xsl:value-of select="normalize-space(.)"/>
      </xsl:template>
    </xsl:stylesheet>"
);
```

1 row created.

The next example uses the `xsl_tab` XSL style sheet to alphabetize the elements in one `warehouse_spec` of the sample table `oe.warehouses`:

```sql
SELECT XMLTRANSFORM(w.warehouse_spec, x.col1).GetClobVal()
FROM warehouses w, xsl_tab x
WHERE w.warehouse_name = 'San Francisco';
```

```
Warehouse
<Area>50000</Area>
<Building>Rented</Building>
```
<DockType>Side load</DockType>
<Docks>1</Docks>
<Parking>Lot</Parking>
<RailAccess>N</RailAccess>
<VClearance>12 ft</VClearance>
<WaterAccess>Y</WaterAccess>
</Warehouse>
ROUND and TRUNC Date Functions

Table 7–13 lists the format models you can use with the ROUND and TRUNC date functions and the units to which they round and truncate dates. The default model, 'DD', returns the date rounded or truncated to the day with a time of midnight.

<table>
<thead>
<tr>
<th>Format Model</th>
<th>Rounding or Truncating Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>CC</td>
<td>One greater than the first two digits of a four-digit year</td>
</tr>
<tr>
<td>SCC</td>
<td></td>
</tr>
<tr>
<td>YYYY</td>
<td>Year (rounds up on July 1)</td>
</tr>
<tr>
<td>YEAR</td>
<td></td>
</tr>
<tr>
<td>SYEAR</td>
<td></td>
</tr>
<tr>
<td>YYY</td>
<td></td>
</tr>
<tr>
<td>YY</td>
<td></td>
</tr>
<tr>
<td>Y</td>
<td></td>
</tr>
<tr>
<td>IYYYY</td>
<td>Year containing the calendar week, as defined by the ISO 8601 standard</td>
</tr>
<tr>
<td>IYY</td>
<td></td>
</tr>
<tr>
<td>IY</td>
<td></td>
</tr>
<tr>
<td>I</td>
<td></td>
</tr>
<tr>
<td>Q</td>
<td>Quarter (rounds up on the sixteenth day of the second month of the quarter)</td>
</tr>
<tr>
<td>MONTH</td>
<td>Month (rounds up on the sixteenth day)</td>
</tr>
<tr>
<td>MON</td>
<td></td>
</tr>
<tr>
<td>MM</td>
<td></td>
</tr>
<tr>
<td>RM</td>
<td></td>
</tr>
<tr>
<td>WW</td>
<td>Same day of the week as the first day of the year</td>
</tr>
<tr>
<td>IW</td>
<td>Same day of the week as the first day of the calendar week as defined by the ISO 8601 standard, which is Monday</td>
</tr>
<tr>
<td>W</td>
<td>Same day of the week as the first day of the month</td>
</tr>
<tr>
<td>DDD</td>
<td>Day</td>
</tr>
<tr>
<td>DD</td>
<td></td>
</tr>
<tr>
<td>J</td>
<td></td>
</tr>
<tr>
<td>DAY</td>
<td>Starting day of the week</td>
</tr>
<tr>
<td>DY</td>
<td></td>
</tr>
<tr>
<td>D</td>
<td></td>
</tr>
<tr>
<td>HH</td>
<td>Hour</td>
</tr>
<tr>
<td>HH12</td>
<td></td>
</tr>
<tr>
<td>HH24</td>
<td></td>
</tr>
<tr>
<td>MI</td>
<td>Minute</td>
</tr>
</tbody>
</table>

The starting day of the week used by the format models DAY, DY, and D is specified implicitly by the initialization parameter NLS_TERRITORY.

See Also: Oracle Database Reference and Oracle Database Globalization Support Guide for information on this parameter.
About User-Defined Functions

You can write user-defined functions in PL/SQL, Java, or C to provide functionality that is not available in SQL or SQL built-in functions. User-defined functions can appear in a SQL statement wherever an expression can occur.

For example, user-defined functions can be used in the following:

- The select list of a SELECT statement
- The condition of a WHERE clause
- CONNECT BY, START WITH, ORDER BY, and GROUP BY clauses
- The VALUES clause of an INSERT statement
- The SET clause of an UPDATE statement

**Note:** Oracle SQL does not support calling of functions with Boolean parameters or returns. Therefore, if your user-defined functions will be called from SQL statements, you must design them to return numbers (0 or 1) or character strings ('TRUE' or 'FALSE').

```
user_defined_function::= 
```

The optional expression list must match attributes of the function, package, or operator.

**Restriction on User-defined Functions**  The DISTINCT and ALL keywords are valid only with a user-defined aggregate function.

**See Also:**

- **CREATE FUNCTION** on page 14-71 for information on creating functions, including restrictions on user-defined functions
- **Oracle Database Development Guide** for a complete discussion of the creation and use of user functions
Prerequisites

User-defined functions must be created as top-level functions or declared with a package specification before they can be named within a SQL statement.

To use a user function in a SQL expression, you must own or have `EXECUTE` privilege on the user function. To query a view defined with a user function, you must have the `READ` or `SELECT` privilege on the view. No separate `EXECUTE` privileges are needed to select from the view.

**See Also:** [CREATE FUNCTION](#) on page 14-71 for information on creating top-level functions and [CREATE PACKAGE](#) on page 15-55 for information on specifying packaged functions
Name Precedence

Within a SQL statement, the names of database columns take precedence over the names of functions with no parameters. For example, if the Human Resources manager creates the following two objects in the hr schema:

```
CREATE TABLE new_emps (new_sal NUMBER, ...);
CREATE FUNCTION new_sal RETURN NUMBER IS BEGIN ... END;
```

then in the following two statements, the reference to new_sal refers to the column new_emps.new_sal:

```
SELECT new_sal FROM new_emps;
SELECT new_emps.new_sal FROM new_emps;
```

To access the function new_sal, you would enter:

```
SELECT hr.new_sal FROM new_emps;
```

Here are some sample calls to user functions that are allowed in SQL expressions:

```
circle_area (radius)
payroll.tax_rate (empno)
hr.employees.tax_rate (dependent, empno)@remote
```

**Example**  
To call the tax_rate user function from schema hr, execute it against the ss_no and sal columns in tax_table, specify the following:

```
SELECT hr.tax_rate (ss_no, sal)
    INTO income_tax
    FROM tax_table WHERE ss_no = tax_id;
```

The INTO clause is PL/SQL that lets you place the results into the variable income_tax.

Naming Conventions

If only one of the optional schema or package names is given, then the first identifier can be either a schema name or a package name. For example, to determine whether PAYROLL in the reference PAYROLL.TAX_RATE is a schema or package name, Oracle Database proceeds as follows:

1. Check for the PAYROLL package in the current schema.
2. If a PAYROLL package is not found, then look for a schema name PAYROLL that contains a top-level TAX_RATE function. If no such function is found, then return an error.
3. If the PAYROLL package is found in the current schema, then look for a TAX_RATE function in the PAYROLL package. If no such function is found, then return an error.

You can also refer to a stored top-level function using any synonym that you have defined for it.
This chapter describes some SQL data definition clauses that appear in multiple SQL statements.

This chapter contains these sections:
- allocate_extent_clause
- constraint
- deallocate_unused_clause
- file_specification
- logging_clause
- parallel_clause
- physical_attributes_clause
- size_clause
- storage_clause
allocate_extent_clause

Purpose

Use the *allocate_extent_clause* clause to explicitly allocate a new extent for a database object.

Explicitly allocating an extent with this clause does not change the values of the *NEXT* and *PCTINCREASE* storage parameters, so does not affect the size of the next extent to be allocated implicitly by Oracle Database. Refer to *storage_clause* on page 8-48 for information about the *NEXT* and *PCTINCREASE* storage parameters.

You can allocate an extent in the following SQL statements:

- **ALTER CLUSTER** (see *ALTER CLUSTER* on page 10-28)
- **ALTER INDEX**: to allocate an extent to the index, an index partition, or an index subpartition (see *ALTER INDEX* on page 10-107)
- **ALTER MATERIALIZED VIEW**: to allocate an extent to the materialized view, one of its partitions or subpartitions, or the overflow segment of an index-organized materialized view (see *ALTER MATERIALIZED VIEW* on page 11-3)
- **ALTER MATERIALIZED VIEW LOG** (see *ALTER MATERIALIZED VIEW LOG* on page 11-20)
- **ALTER TABLE**: to allocate an extent to the table, a table partition, a table subpartition, the mapping table of an index-organized table, the overflow segment of an index-organized table, or a LOB storage segment (see *ALTER TABLE* on page 12-2)

Syntax

```
allocate_extent_clause::=  
ALLOCATE EXTENT (SIZE size_clause DATAFILE 'filename' INSTANCE integer)
```

(size_clause::= on page 8-47)

Semantics

This section describes the parameters of the *allocate_extent_clause*. For additional information, refer to the SQL statement in which you set or reset these parameters for a particular database object.

You cannot specify the *allocate_extent_clause* and the *deallocate_unused_clause* in the same statement.

**SIZE**

Specify the size of the extent in bytes. The value of *integer* can be 0 through 2147483647. To specify a larger extent size, use an integer within this range with *K*, *M*, *G*, or *T* to specify the extent size in kilobytes, megabytes, gigabytes, or terabytes.
For a table, index, materialized view, or materialized view log, if you omit SIZE, then Oracle Database determines the size based on the values of the storage parameters of the object. However, for a cluster, Oracle does not evaluate the cluster’s storage parameters, so you must specify SIZE if you do not want Oracle to use a default value.

**DATAFILE ‘filename’**
Specify one of the data files in the tablespace of the table, cluster, index, materialized view, or materialized view log to contain the new extent. If you omit DATAFILE, then Oracle chooses the data file.

**INSTANCE integer**
Use this parameter only if you are using Oracle Real Application Clusters. Specifying INSTANCE integer makes the new extent available to the freelist group associated with the specified instance. If the instance number exceeds the maximum number of freelist groups, then Oracle divides the specified number by the maximum number and uses the remainder to identify the freelist group to be used. An instance is identified by the value of its initialization parameter INSTANCE_NUMBER.

If you omit this parameter, then the space is allocated to the table, cluster, index, materialized view, or materialized view log but is not drawn from any particular freelist group. Instead, Oracle uses the master freelist and allocates space as needed.

**Note:** If you are using automatic segment-space management, then the INSTANCE parameter of the allocate_extent_clause may not reserve the newly allocated space for the specified instance, because automatic segment-space management does not maintain rigid affinity between extents and instances.
Use a constraint to define an integrity constraint—a rule that restricts the values in a database. Oracle Database lets you create six types of constraints and lets you declare them in two ways.

The six types of integrity constraint are described briefly here and more fully in "Semantics" on page 8-8:

- A **NOT NULL constraint** prohibits a database value from being null.
- A **unique constraint** prohibits multiple rows from having the same value in the same column or combination of columns but allows some values to be null.
- A **primary key constraint** combines a **NOT NULL constraint** and a unique constraint in a single declaration. It prohibits multiple rows from having the same value in the same column or combination of columns and prohibits values from being null.
- A **foreign key constraint** requires values in one table to match values in another table.
- A **check constraint** requires a value in the database to comply with a specified condition.
- A **REF column** by definition references an object in another object type or in a relational table. A **REF constraint** lets you further describe the relationship between the REF column and the object it references.

You can define constraints syntactically in two ways:

- As part of the definition of an individual column or attribute. This is called **inline** specification.
- As part of the table definition. This is called **out-of-line** specification.

NOT NULL constraints must be declared inline. All other constraints can be declared either inline or out of line.

Constraint clauses can appear in the following statements:

- **CREATE TABLE** (see CREATE TABLE on page 16-6)
- **ALTER TABLE** (see ALTER TABLE on page 12-2)
- **CREATE VIEW** (see CREATE VIEW on page 17-15)
- **ALTER VIEW** (see ALTER VIEW on page 13-16)

**View Constraints**  
Oracle Database does not enforce view constraints. However, you can enforce constraints on views through constraints on base tables.

You can specify only unique, primary key, and foreign key constraints on views, and they are supported only in **DISABLE NOVALIDATE** mode. You cannot define view constraints on attributes of an object column.

**See Also:**  "View Constraints" on page 8-19 for additional information on view constraints and "DISABLE Clause" on page 8-16 for information on **DISABLE NOVALIDATE** mode
Prerequisites

You must have the privileges necessary to issue the statement in which you are defining the constraint.

To create a foreign key constraint, in addition, the parent table or view must be in your own schema or you must have the `REFERENCES` privilege on the columns of the referenced key in the parent table or view.

Syntax

```
constraint ::= 

inline_constraint ::= 

out_of_line_constraint ::= 

inline_ref_constraint ::= 

out_of_line_ref_constraint ::= 
```

```
inline_constraint ::= ( inline_constraint::= on page 8-5, out_of_line_constraint::= on page 8-5, inline_ref_constraint::= on page 8-6, out_of_line_ref_constraint::= on page 8-6 )

out_of_line_constraint ::= ( references_clause::= on page 8-6, constraint_state::= on page 8-6 )
```

```
inline_constraint ::= ( CONSTRAINT constraint_name [ NOT NULL ] UNIQUE PRIMARY KEY references_clause CHECK ( condition ) constraint_state )

out_of_line_constraint ::= ( CONSTRAINT constraint_name [ NOT NULL ] UNIQUE PRIMARY KEY references_clause CHECK ( condition ) constraint_state )
```

```
references_clause ::= ( references_clause::= on page 8-6 )
```

```
constraint_state ::= ( references_clause::= on page 8-6, constraint_state::= on page 8-6 )
```
**inline_ref_constraint**:=

![Diagram of index_properties]

*(global_partitioned_index::= on page 14-78, local_partitioned_index::= on page 14-79--part of CREATE INDEX, index_attributes::= on page 8-7. The INDEXTYPE IS ... clause is not valid when defining a constraint.)*

**index_attributes ::=**

![Diagram of index_attributes]

*(physical_attributes_clause::= on page 14-12, logging_clause::= on page 8-38, index_compression::= on page 14-76, partial_index_clause::= on page 14-77--all part of CREATE INDEX, parallel_clause: not supported in using_index_clause)*
exceptions_clause::=

Semantics

This section describes the semantics of constraint. For additional information, refer to
the SQL statement in which you define or redefine a constraint for a table or view.

Oracle Database does not support constraints on columns or attributes whose type is a
user-defined object, nested table, VARRAY, REF, or LOB, with two exceptions:

- NOT NULL constraints are supported for a column or attribute whose type is
  user-defined object, VARRAY, REF, or LOB.
- NOT NULL, foreign key, and REF constraints are supported on a column of type REF.

CONSTRAINT constraint_name Specify a name for the constraint. If you omit this
identifier, then Oracle Database generates a name with the form SYS_Cn. Oracle stores
the name and the definition of the integrity constraint in the USER_, ALL_, and DBA_
CONSTRAINTS data dictionary views (in the CONSTRAINT_NAME and SEARCH_CONDITION
columns, respectively).

See Also: Oracle Database Reference for information on the data
dictionary views

NOT NULL Constraints

A NOT NULL constraint prohibits a column from containing nulls. The NULL keyword by
itself does not actually define an integrity constraint, but you can specify it to explicitly
permit a column to contain nulls. You must define NOT NULL and NULL using inline
specification. If you specify neither NOT NULL nor NULL, then the default is NULL.

NOT NULL constraints are the only constraints you can specify inline on XMLType and
VARRAY columns.

To satisfy a NOT NULL constraint, every row in the table must contain a value for the
column.

Note: Oracle Database does not index table rows in which all key
columns are null except in the case of bitmap indexes. Therefore, if
you want an index on all rows of a table, then you must either specify
NOT NULL constraints for at least one of the index key columns or create
a bitmap index.

Restrictions on NOT NULL Constraints NOT NULL constraints are subject to the
following restrictions:

- You cannot specify NULL or NOT NULL in a view constraint.
- You cannot specify NULL or NOT NULL for an attribute of an object. Instead, use a
  CHECK constraint with the IS [NOT] NULL condition.

See Also: "Attribute-Level Constraints Example" on page 8-25 and
"NOT NULL Example" on page 8-21
Unique Constraints

A unique constraint designates a column as a unique key. A composite unique key designates a combination of columns as the unique key. When you define a unique constraint inline, you need only the UNIQUE keyword. When you define a unique constraint out of line, you must also specify one or more columns. You must define a composite unique key out of line.

To satisfy a unique constraint, no two rows in the table can have the same value for the unique key. However, the unique key made up of a single column can contain nulls. To satisfy a composite unique key, no two rows in the table or view can have the same combination of values in the key columns. Any row that contains nulls in all key columns automatically satisfies the constraint. However, two rows that contain nulls for one or more key columns and the same combination of values for the other key columns violate the constraint.

When you specify a unique constraint on one or more columns, Oracle implicitly creates an index on the unique key. If you are defining uniqueness for purposes of query performance, then Oracle recommends that you instead create the unique index explicitly using a CREATE UNIQUE INDEX statement. You can also use the CREATE UNIQUE INDEX statement to create a unique function-based index that defines a conditional unique constraint. See "Using a Function-based Index to Define Conditional Uniqueness: Example" on page 14-99 for more information.

When you specify an enabled unique constraint on an extended data type column, you may receive a "maximum key length exceeded" error when Oracle tries to create the index to enforce uniqueness for the enabled constraint. See "Creating an Index on an Extended Data Type Column" on page 14-83 for information on how to work around this issue.

Restrictions on Unique Constraints

Unique constraints are subject to the following restrictions:

- None of the columns in the unique key can be of LOB, LONG, RAW, VARRAY, NESTED TABLE, OBJECT, REF, TIMESTAMP WITH TIME ZONE, or user-defined type. However, the unique key can contain a column of TIMESTAMP WITH LOCAL TIME ZONE.

- A composite unique key cannot have more than 32 columns.

- You cannot designate the same column or combination of columns as both a primary key and a unique key.

- You cannot specify a unique key when creating a subview in an inheritance hierarchy. The unique key can be specified only for the top-level (root) view.

See Also: "Unique Key Example" on page 8-19 and Composite Unique Key Example on page 8-20

Primary Key Constraints

A primary key constraint designates a column as the primary key of a table or view. A composite primary key designates a combination of columns as the primary key. When you define a primary key constraint inline, you need only the PRIMARY KEY keywords. When you define a primary key constraint out of line, you must also specify one or more columns. You must define a composite primary key out of line.

To satisfy a primary key constraint:

- No primary key value can appear in more than one row in the table.

- No column that is part of the primary key can contain a null.
When you create a primary key constraint:

- Oracle Database uses an existing index if it contains a unique set of values before enforcing the primary key constraint. The existing index can be defined as unique or nonunique. When a DML operation is performed, the primary key constraint is enforced using this existing index.

- If no existing index can be used, then Oracle Database generates a unique index.

When you drop a primary key constraint:

- If the primary key was created using an existing index, then the index is not dropped.

- If the primary key was created using a system-generated index, then the index is dropped.

When you designate an extended data type column as an enabled primary key, you may receive a "maximum key length exceeded" error when Oracle tries to create the index to enforce uniqueness for the enabled constraint. See "Creating an Index on an Extended Data Type Column" on page 14-83 for information on how to work around this issue.

**Restrictions on Primary Key Constraints**  Primary constraints are subject to the following restrictions:

- A table or view can have only one primary key.

- None of the columns in the primary key can be LOB, `LONG`, `LONG RAW`, `VARRAY`, `NESTED TABLE`, `BFILE`, `REF`, `TIMESTAMP WITH TIME ZONE`, or user-defined type. However, the primary key can contain a column of `TIMESTAMP WITH LOCAL TIME ZONE`.

- The size of the primary key cannot exceed approximately one database block.

- A composite primary key cannot have more than 32 columns.

- You cannot designate the same column or combination of columns as both a primary key and a unique key.

- You cannot specify a primary key when creating a subview in an inheritance hierarchy. The primary key can be specified only for the top-level (root) view.

  **See Also:**  "Primary Key Example" on page 8-20 and "Composite Primary Key Example" on page 8-21

**Foreign Key Constraints**

A **foreign key constraint** (also called a **referential integrity constraint**) designates a column as the foreign key and establishes a relationship between that foreign key and a specified primary or unique key, called the **referenced key**. A **composite foreign key** designates a combination of columns as the foreign key.

The table or view containing the foreign key is called the **child object**, and the table or view containing the referenced key is called the **parent object**. The foreign key and the referenced key can be in the same table or view. In this case, the parent and child tables are the same. If you identify only the parent table or view and omit the column name, then the foreign key automatically references the primary key of the parent table or view. The corresponding column or columns of the foreign key and the referenced key must match in order and data type.
You can define a foreign key constraint on a single key column either inline or out of line. You must specify a composite foreign key and a foreign key on an attribute out of line.

To satisfy a composite foreign key constraint, the composite foreign key must refer to a composite unique key or a composite primary key in the parent table or view, or the value of at least one of the columns of the foreign key must be null.

You can designate the same column or combination of columns as both a foreign key and a primary or unique key. You can also designate the same column or combination of columns as both a foreign key and a cluster key.

You can define multiple foreign keys in a table or view. Also, a single column can be part of more than one foreign key.

**Restrictions on Foreign Key Constraints** Foreign key constraints are subject to the following restrictions:

- None of the columns in the foreign key can be of LOB, LONG, LONG RAW, VARRAY, NESTED TABLE, BFILE, REF, TIMESTAMP WITH TIME ZONE, or user-defined type. However, the primary key can contain a column of TIMESTAMP WITH LOCAL TIME ZONE.
- The referenced unique or primary key constraint on the parent table or view must already be defined.
- A composite foreign key cannot have more than 32 columns.
- The child and parent tables must be on the same database. To enable referential integrity constraints across nodes of a distributed database, you must use database triggers. See `CREATE TRIGGER` on page 16-118.
- If either the child or parent object is a view, then the constraint is subject to all restrictions on view constraints. See “View Constraints” on page 8-19.
- You cannot define a foreign key constraint in a `CREATE TABLE` statement that contains an `AS subquery` clause. Instead, you must create the table without the constraint and then add it later with an `ALTER TABLE` statement.
- When a table has a foreign key, and the parent of the foreign key is an index-organized table, a session that updates a row that contains the foreign key can hang when another session is updating a non-key column in the parent table.

**See Also:**

- *Oracle Database Development Guide* for more information on using constraints
- "Foreign Key Constraint Example" on page 8-21 and "Composite Foreign Key Constraint Example" on page 8-23

**references_clause** Foreign key constraints use the `references_clause` syntax. When you specify a foreign key constraint inline, you need only the `references_clause`. When you specify a foreign key constraint out of line, you must also specify the `FOREIGN KEY` keywords and one or more columns.

**ON DELETE Clause** The `ON DELETE` clause lets you determine how Oracle Database automatically maintains referential integrity if you remove a referenced primary or unique key value. If you omit this clause, then Oracle does not allow you to delete referenced key values in the parent table that have dependent rows in the child table.

- Specify `CASCADE` if you want Oracle to remove dependent foreign key values.
- Specify `SET NULL` if you want Oracle to convert dependent foreign key values to `NULL`. You cannot specify this clause for a virtual column, because the values in a virtual column cannot be updated directly. Rather, the values from which the virtual column are derived must be updated.

**Restriction on ON DELETE**  You cannot specify this clause for a view constraint.

**See Also:**  "ON DELETE Example" on page 8-22

**Check Constraints**

A check constraint lets you specify a condition that each row in the table must satisfy. To satisfy the constraint, each row in the table must make the condition either `TRUE` or unknown (due to a null). When Oracle evaluates a check constraint condition for a particular row, any column names in the condition refer to the column values in that row.

The syntax for inline and out-of-line specification of check constraints is the same. However, inline specification can refer only to the column (or the attributes of the column if it is an object column) currently being defined, whereas out-of-line specification can refer to multiple columns or attributes.

Oracle does not verify that conditions of check constraints are not mutually exclusive. Therefore, if you create multiple check constraints for a column, design them carefully so their purposes do not conflict. Do not assume any particular order of evaluation of the conditions.

**See Also:**

- Chapter 6, "Conditions" for additional information and syntax
- "Check Constraint Examples" on page 8-23 and "Attribute-Level Constraints Example" on page 8-25

**Restrictions on Check Constraints**  Check constraints are subject to the following restrictions:

- You cannot specify a check constraint for a view. However, you can define the view using the `WITH CHECK OPTION` clause, which is equivalent to specifying a check constraint for the view.

- The condition of a check constraint can refer to any column in the table, but it cannot refer to columns of other tables.

- Conditions of check constraints cannot contain the following constructs:
  - Subqueries and scalar subquery expressions
  - Calls to the functions that are not deterministic (`CURRENT_DATE`, `CURRENT_TIMESTAMP`, `DBTIMEZONE`, `LOCALTIMESTAMP`, `SESSIONTIMEZONE`, `SYSDATE`, `SYSTIMESTAMP`, `UID`, `USER`, and `USERENV`)  
  - Calls to user-defined functions
  - Dereferencing of `REF` columns (for example, using the `DEREF` function)
  - Nested table columns or attributes
  - The pseudocolumns `CURRVAL`, `NEXTVAL`, `LEVEL`, or `ROWNUM`
  - Date constants that are not fully specified
**REF Constraints**

**COMMON SQL DDL CLAUSES**

**8-13**

**Ref Constraints**

**Ref constraints** let you describe the relationship between a column of type **Ref** and the object it references.

**Ref_constraint**  **Ref constraints** use the **ref_constraint** syntax. You define a **Ref** constraint either inline or out of line. Out-of-line specification requires you to specify the **Ref** column or attribute you are further describing.

- For **ref_column**, specify the name of a **Ref** column of an object or relational table.
- For **ref_attribute**, specify an embedded **Ref** attribute within an object column of a relational table.

Both inline and out-of-line specification let you define a scope constraint, a rowid constraint, or a referential integrity constraint on a **Ref** column.

If the scope table or referenced table of the **Ref** column has a primary-key-based object identifier, then the **Ref** column is a **user-defined Ref column**.

**See Also:**

- *Oracle Database Object-Relational Developer’s Guide* for more information on **Ref** data types
- “Foreign Key Constraints” on page 8-10, and "Ref Constraint Examples” on page 8-25

**Scope Ref Constraints**

In a table with a **Ref** column, each **Ref** value in the column can conceivably reference a row in a different object table. The **Scope** clause restricts the scope of references to a single table, **scope_table**. The values in the **Ref** column or attribute point to objects in **scope_table**, in which object instances of the same type as the **Ref** column are stored.

Specify the **Scope** clause to restrict the scope of references in the **Ref** column to a single table. For you to specify this clause, **scope_table** must be in your own schema, or you must have the **Read** or **Select** privilege on **scope_table**, or you must have the **Read Any Table** or **Select Any Table** system privilege. You can specify only one scope table for each **Ref** column.

**Restrictions on Scope Constraints**  Scope constraints are subject to the following restrictions:

- You cannot add a scope constraint to an existing column unless the table is empty.
- You cannot specify a scope constraint for the **Ref** elements of a **VARRAY** column.
- You must specify this clause if you specify **As subquery** and the subquery returns user-defined **Ref** data types.
- You cannot subsequently drop a scope constraint from a **Ref** column.

**Rowid Ref Constraints**

Specify **With Rowid** to store the rowid along with the **Ref** value in **ref_column** or **ref_attribute**. Storing the rowid with the **Ref** value can improve the performance of dereferencing operations, but will also use more space. Default storage of **Ref** values is without rowids.

**See Also:**  The function **Deref** on page 7-100 for an example of dereferencing
Restrictions on Rowid Constraints  Rowid constraints are subject to the following restrictions:

- You cannot define a rowid constraint for the `REF` elements of a `VARRAY` column.
- You cannot subsequently drop a rowid constraint from a `REF` column.
- If the `REF` column or attribute is scoped, then this clause is ignored and the rowid is not stored with the `REF` value.

Referential Integrity Constraints on REF Columns
The `references_clause` of the `ref_constraint` syntax lets you define a foreign key constraint on the `REF` column. This clause also implicitly restricts the scope of the `REF` column or attribute to the referenced table. However, whereas a foreign key constraint on a non-`REF` column references an actual column in the parent table, a foreign key constraint on a `REF` column references the implicit object identifier column of the parent table.

If you do not specify a constraint name, then Oracle generates a system name for the constraint of the form `SYS_Cn`.

If you add a referential integrity constraint to an existing `REF` column that is already scoped, then the referenced table must be the same as the scope table of the `REF` column. If you later drop the referential integrity constraint, then the `REF` column will remain scoped to the referenced table.

As is the case for foreign key constraints on other types of columns, you can use the `references_clause` alone for inline declaration. For out-of-line declaration you must also specify the `FOREIGN KEY` keywords plus one or more `REF` columns or attributes.

See Also: Oracle Database Object-Relational Developer’s Guide for more information on object identifiers

Restrictions on Foreign Key Constraints on REF Columns  Foreign key constraints on `REF` columns have the following additional restrictions:

- Oracle implicitly adds a scope constraint when you add a referential integrity constraint to an existing unscoped `REF` column. Therefore, all the restrictions that apply for scope constraints also apply in this case.
- You cannot specify a column after the object name in the `references_clause`.

Specifying Constraint State
As part of constraint definition, you can specify how and when Oracle should enforce the constraint.

`constraint_state`  You can use the `constraint_state` with both inline and out-of-line specification. Specify the clauses of `constraint_state` in the order shown, from top to bottom, and do not specify any clause more than once.

DEFERRABLE Clause  The `DEFERRABLE` and `NOT DEFERRABLE` parameters indicate whether or not, in subsequent transactions, constraint checking can be deferred until the end of the transaction using the `SET CONSTRAINT(S)` statement. If you omit this clause, then the default is `NOT DEFERRABLE`.

- Specify `NOT DEFERRABLE` to indicate that in subsequent transactions you cannot use the `SET CONSTRAINT[S]` clause to defer checking of this constraint until the transaction is committed. The checking of a `NOT DEFERRABLE` constraint can never be deferred to the end of the transaction.
If you declare a new constraint **NOT DEFERRABLE**, then it must be valid at the time the `CREATE TABLE` or `ALTER TABLE` statement is committed or the statement will fail.

- **Specify DEFERRABLE** to indicate that in subsequent transactions you can use the `SET CONSTRAINT[S]` clause to defer checking of this constraint until a `COMMIT` statement is submitted. If the constraint check fails, then the database returns an error and the transaction is not committed. This setting in effect lets you disable the constraint temporarily while making changes to the database that might violate the constraint until all the changes are complete.

---

**Note:** The optimizer does not consider indexes on deferrable constraints as usable.

---

You cannot alter the deferrability of a constraint. Whether you specify either of these parameters, or make the constraint **NOT DEFERRABLE** implicitly by specifying neither of them, you cannot specify this clause in an `ALTER TABLE` statement. You must drop the constraint and re-create it.

**See Also:**
- `SET CONSTRAINT[S]` on page 19-79 for information on setting constraint checking for a transaction
- *Oracle Database Administrator’s Guide* and *Oracle Database Concepts* for more information about deferred constraints
- “DEFERRABLE Constraint Examples” on page 8-26

**Restriction on [NOT] DEFERRABLE** You cannot specify either of these parameters for a view constraint.

**INITIALLY Clause** The **INITIALLY** clause establishes the default checking behavior for constraints that are **DEFERRABLE**. The **INITIALLY** setting can be overridden by a `SET CONSTRAINT[S]` statement in a subsequent transaction.

- **Specify INITIALLY IMMEDIATE** to indicate that Oracle should check this constraint at the end of each subsequent SQL statement. If you do not specify **INITIALLY** at all, then the default is **INITIALLY IMMEDIATE**.

  If you declare a new constraint **INITIALLY IMMEDIATE**, then it must be valid at the time the `CREATE TABLE` or `ALTER TABLE` statement is committed or the statement will fail.

- **Specify INITIALLY DEFERRED** to indicate that Oracle should check this constraint at the end of subsequent transactions.

  This clause is not valid if you have declared the constraint to be **NOT DEFERRABLE**, because a **NOT DEFERRABLE** constraint is automatically **INITIALLY IMMEDIATE** and cannot ever be **INITIALLY DEFERRED**.

**VALIDATE | NOVALIDATE** The behavior of **VALIDATE** and **NOVALIDATE** depends on whether the constraint is enabled or disabled, either explicitly or by default. Therefore, the **VALIDATE** and **NOVALIDATE** keywords are described in the context of “**ENABLE Clause**” on page 8-16 and “**DISABLE Clause**” on page 8-16.

**Note on Foreign Key Constraints in NOVALIDATE Mode** When a foreign key constraint is in **NOVALIDATE** mode, if existing data in the table does not comply with the
constraint and the `QUERY_REWRITE_INTEGRITY` parameter is not set to `ENFORCED`, then the optimizer may use join elimination during queries on the table. In this case, a query may return table rows with noncompliant foreign key values even if the query contains a join condition that should filter out those rows.

**ENABLE Clause** Specify `ENABLE` if you want the constraint to be applied to the data in the table.

If you enable a unique or primary key constraint, and if no index exists on the key, then Oracle Database creates a unique index. Unless you specify `KEEP_INDEX` when subsequently disabling the constraint, this index is dropped and the database rebuilds the index every time the constraint is reenabled.

You can also avoid rebuilding the index and eliminate redundant indexes by creating new primary key and unique constraints initially disabled. Then create (or use existing) nonunique indexes to enforce the constraint. Oracle does not drop a nonunique index when the constraint is disabled, so subsequent `ENABLE` operations are facilitated.

- **ENABLE VALIDATE** specifies that all old and new data also complies with the constraint. An enabled validated constraint guarantees that all data is and will continue to be valid.

  If any row in the table violates the integrity constraint, then the constraint remains disabled and Oracle returns an error. If all rows comply with the constraint, then Oracle enables the constraint. Subsequently, if new data violates the constraint, then Oracle does not execute the statement and returns an error indicating the integrity constraint violation.

  If you place a primary key constraint in `ENABLE VALIDATE` mode, then the validation process will verify that the primary key columns contain no nulls. To avoid this overhead, mark each column in the primary key `NOT NULL` before entering data into the column and before enabling the primary key constraint of the table.

- **ENABLE NOVALIDATE** ensures that all new DML operations on the constrained data comply with the constraint. This clause does not ensure that existing data in the table complies with the constraint.

If you specify neither `VALIDATE` nor `NOVALIDATE`, then the default is `VALIDATE`.

If you change the state of any single constraint from `ENABLE NOVALIDATE` to `ENABLE VALIDATE`, then the operation can be performed in parallel, and does not block reads, writes, or other DDL operations.

**Restriction on the ENABLE Clause** You cannot enable a foreign key that references a disabled unique or primary key.

**DISABLE Clause** Specify `DISABLE` to disable the integrity constraint. Disabled integrity constraints appear in the data dictionary along with enabled constraints. If you do not specify this clause when creating a constraint, then Oracle automatically enables the constraint.

- **DISABLE VALIDATE** disables the constraint and drops the index on the constraint, but keeps the constraint valid. This feature is most useful in data warehousing situations, because it lets you load large amounts of data while also saving space by not having an index. This setting lets you load data from a nonpartitioned table into a partitioned table using the `exchange_partition_subpart` clause of the `ALTER TABLE` statement or using SQL*Loader. All other modifications to the table (inserts, updates, and deletes) by other SQL statements are disallowed.
**See Also:** *Oracle Database Data Warehousing Guide* for more information on using this setting

- **DISABLE NOVALIDATE** signifies that Oracle makes no effort to maintain the constraint (because it is disabled) and cannot guarantee that the constraint is true (because it is not being validated).

You cannot drop a table whose primary key is being referenced by a foreign key even if the foreign key constraint is in **DISABLE NOVALIDATE** state. Further, the optimizer can use constraints in **DISABLE NOVALIDATE** state.

**See Also:** *Oracle Database SQL Tuning Guide* for information on when to use this setting

If you specify neither **VALIDATE** nor **NOVALIDATE**, then the default is **NOVALIDATE**.

If you disable a unique or primary key constraint that is using a unique index, then Oracle drops the unique index. Refer to the `CREATE TABLE enable_disable_clause` on page 16-82 for additional notes and restrictions.

**RELY Clause**  The **RELY** and **NORELY** parameters specify whether a constraint in **NOVALIDATE** mode is to be taken into account for query rewrite. Specify **RELY** to activate a constraint in **NOVALIDATE** mode for query rewrite in an unenforced query rewrite integrity mode. The constraint is in **NOVALIDATE** mode, so Oracle does not enforce it. The default is **NORELY**.

Unenforced constraints are generally useful only with materialized views and query rewrite. Depending on the **QUERY_REWRITE_INTEGRITY** mode, query rewrite can use only constraints that are in **VALIDATE** mode, or that are in **NOVALIDATE** mode with the **RELY** parameter set, to determine join information.

**Restriction on the RELY Clause**  You cannot set a nondeferrable **NOT NULL** constraint to **RELY**.

**See Also:** *Oracle Database Data Warehousing Guide* for more information on materialized views and query rewrite

**Using Indexes to Enforce Constraints**  When defining the state of a unique or primary key constraint, you can specify an index for Oracle to use to enforce the constraint, or you can instruct Oracle to create the index used to enforce the constraint.

**using_index_clause**  You can specify the **using_index_clause** only when enabling unique or primary key constraints. You can specify the clauses of the **using_index_clause** in any order, but you can specify each clause only once.

- If you specify `schema.index`, then Oracle attempts to enforce the constraint using the specified index. If Oracle cannot find the index or cannot use the index to enforce the constraint, then Oracle returns an error.
- If you specify the `create_index_statement`, then Oracle attempts to create the index and use it to enforce the constraint. If Oracle cannot create the index or cannot use the index to enforce the constraint, then Oracle returns an error.
- If you neither specify an existing index nor create a new index, then Oracle creates the index. In this case:
  - The index receives the same name as the constraint.
– If table is partitioned, then you can specify a locally or globally partitioned
index for the unique or primary key constraint.

Restrictions on the using_index_clause  The following restrictions apply to the
using_index_clause:

■ You cannot specify this clause for a view constraint.
■ You cannot specify this clause for a NOT NULL, foreign key, or check constraint.
■ You cannot specify an index (schema.index) or create an index (create_index_
statement) when enabling the primary key of an index-organized table.
■ You cannot specify the parallel_clause of index_attributes.
■ The INDEXTYPE IS ... clause of index_properties is not valid in the definition of a
constraint.

and storage_clause on page 8-48
■ "Explicit Index Control Example" on page 8-26

Handling Constraint Exceptions
When defining the state of a constraint, you can specify a table into which Oracle
places the rowids of all rows violating the constraint.

exceptions_clause  Use the exceptions_clause syntax to define exception handling.
If you omit schema, then Oracle assumes the exceptions table is in your own schema. If
you omit this clause altogether, then Oracle assumes that the table is named
EXCEPTIONS. The EXCEPTIONS table or the table you specify must exist on your local
database.

You can create the EXCEPTIONS table using one of these scripts:
■ UTEXCEPT.SQL uses physical rowids. Therefore it can accommodate rows from
conventional tables but not from index-organized tables. (See the Note that
follows.)
■ UTEXPT1.SQL uses universal rowids, so it can accommodate rows from both
conventional and index-organized tables.

If you create your own exceptions table, then it must follow the format prescribed by
one of these two scripts.

If you are collecting exceptions from index-organized tables based on primary keys
(rather than universal rowids), then you must create a separate exceptions table for
each index-organized table to accommodate its primary-key storage. You create
multiple exceptions tables with different names by modifying and resubmitting the
script.

Restrictions on the exceptions_clause  The following restrictions apply to the
exceptions_clause:
■ You cannot specify this clause for a view constraint.
You cannot specify this clause in a CREATE TABLE statement, because no rowids exist until after the successful completion of the statement.

View Constraints
Data warehousing applications recognize multidimensional data in the Oracle Database by identifying referential integrity constraints in the relational schema. These constraints represent primary and foreign key relationships among tables. By querying the Oracle Database data dictionary, applications can recognize such constraints and therefore recognize the multidimensional data in the database. For schema complexity or security reasons, you might want to define views on fact and dimension tables. Oracle Database provides the ability to constrain these views. By allowing constraint definitions between views, you can propagate base table constraints to the views, thereby allowing applications to recognize multidimensional data even in the restricted environment provided by the view.

Oracle does not enforce view constraints. However, operations on views are subject to the integrity constraints defined on the underlying base tables. This means that you can enforce constraints on views through constraints on base tables.

Notes on View Constraints
View constraints are a subset of table constraints and are subject to the following restrictions:
- You can specify only unique, primary key, and foreign key constraints on views. However, you can define the view using the WITH CHECK OPTION clause, which is equivalent to specifying a check constraint for the view.
- View constraints are supported only in DISABLE NOVALIDATE mode. You cannot specify any other mode. You must specify the keyword DISABLE when you declare the view constraint. You need not specify NOVALIDATE explicitly, as it is the default.
- The RELY and NORELY parameters are optional. View constraints, because they are unenforced, are usually specified with the RELY parameter to make them more useful. The RELY or NORELY keyword must precede the DISABLE keyword. Refer to "RELY Clause" on page 8-17 for more information.
- Because view constraints are not enforced directly, you cannot specify INITIALLY DEFERRED or DEFERRABLE.
- You cannot specify the using_index_clause, the exceptions_clause clause, or the ON DELETE clause of the references_clause.
- You cannot define view constraints on attributes of an object column.

Examples

Unique Key Example
The following statement is a variation of the statement that created the sample table sh.promotions. It defines inline and implicitly enables a unique key on the promo_id column (other constraints are not shown):

```
CREATE TABLE promotions_var1
   ( promo_id NUMBER(6)
     CONSTRAINT promo_id_u UNIQUE
```

The constraint `promo_id_u` identifies the `promo_id` column as a unique key. This constraint ensures that no two promotions in the table have the same ID. However, the constraint does allow promotions without identifiers.

Alternatively, you can define and enable this constraint out of line:

```sql
CREATE TABLE promotions_var2
    ( promo_id         NUMBER(6)
    , promo_name       VARCHAR2(20)
    , promo_category   VARCHAR2(15)
    , promo_cost       NUMBER(10,2)
    , promo_begin_date DATE
    , promo_end_date   DATE
    , CONSTRAINT promo_id_u UNIQUE (promo_id)
    USING INDEX PCTFREE 20
    TABLESPACE stocks
    STORAGE (INITIAL 8M) );
```

The preceding statement also contains the `using_index_clause`, which specifies storage characteristics for the index that Oracle creates to enable the constraint.

**Composite Unique Key Example**  The following statement defines and enables a composite unique key on the combination of the `warehouse_id` and `warehouse_name` columns of the `oe.warehouses` table:

```sql
ALTER TABLE warehouses
    ADD CONSTRAINT wh_unq UNIQUE (warehouse_id, warehouse_name)
    USING INDEX PCTFREE 5
    EXCEPTIONS INTO wrong_id;
```

The `wh_unq` constraint ensures that the same combination of `warehouse_id` and `warehouse_name` values does not appear in the table more than once.

The `ADD CONSTRAINT` clause also specifies other properties of the constraint:

- The `USING INDEX` clause specifies storage characteristics for the index Oracle creates to enable the constraint.
- The `EXCEPTIONS INTO` clause causes Oracle to write to the `wrong_id` table information about any rows currently in the `warehouses` table that violate the constraint. If the `wrong_id` exceptions table does not already exist, then this statement will fail.

**Primary Key Example**  The following statement is a variation of the statement that created the sample table `hr.locations`. It creates the `locations_demo` table and defines and enables a primary key on the `location_id` column (other constraints from the `hr.locations` table are omitted):

```sql
CREATE TABLE locations_demo
    ( location_id    NUMBER(4) CONSTRAINT loc_id_pk PRIMARY KEY
    , street_address VARCHAR2(40)
    , postal_code    VARCHAR2(12)
    , city           VARCHAR2(30)
    , state_province VARCHAR2(25)
    );
```
The `loc_id_pk` constraint, specified inline, identifies the `location_id` column as the primary key of the `locations_demo` table. This constraint ensures that no two locations in the table have the same location number and that no location identifier is NULL.

Alternatively, you can define and enable this constraint out of line:

```sql
CREATE TABLE locations_demo
    ( location_id    NUMBER(4)
    , street_address VARCHAR2(40)
    , postal_code    VARCHAR2(12)
    , city           VARCHAR2(30)
    , state_province VARCHAR2(25)
    , country_id     CHAR(2)
    , CONSTRAINT loc_id_pk PRIMARY KEY (location_id));
```

**NOT NULL Example**  The following statement alters the `locations_demo` table (created in “Primary Key Example” on page 8-20) to define and enable a **NOT NULL** constraint on the `country_id` column:

```sql
ALTER TABLE locations_demo
    MODIFY (country_id CONSTRAINT country_nn NOT NULL);
```

The constraint `country_nn` ensures that no location in the table has a null `country_id`.

**Composite Primary Key Example**  The following statement defines a composite primary key on the combination of the `prod_id` and `cust_id` columns of the sample table `sh.sales`:

```sql
ALTER TABLE sales
    ADD CONSTRAINT sales_pk PRIMARY KEY (prod_id, cust_id) DISABLE;
```

This constraint identifies the combination of the `prod_id` and `cust_id` columns as the primary key of the `sales` table. The constraint ensures that no two rows in the table have the same combination of values for the `prod_id` column and `cust_id` columns.

The constraint clause (**PRIMARY KEY**) also specifies the following properties of the constraint:

- The constraint definition does not include a constraint name, so Oracle generates a name for the constraint.
- The **DISABLE** clause causes Oracle to define the constraint but not enable it.

**Foreign Key Constraint Example**  The following statement creates the `dept_20` table and defines and enables a foreign key on the `department_id` column that references the primary key on the `department_id` column of the `departments` table:

```sql
CREATE TABLE dept_20
    (employee_id     NUMBER(4),
    last_name       VARCHAR2(10),
    job_id          VARCHAR2(9),
    manager_id      NUMBER(4),
    hire_date       DATE,
    salary          NUMBER(7,2),
    commission_pct  NUMBER(7,2),
    department_id   CONSTRAINT fk_deptno
                    REFERENCES departments(department_id) );
```
The constraint `fk_deptno` ensures that all departments given for employees in the `dept_20` table are present in the `departments` table. However, employees can have null department numbers, meaning they are not assigned to any department. To ensure that all employees are assigned to a department, you could create a `NOT NULL` constraint on the `department_id` column in the `dept_20` table in addition to the `REFERENCES` constraint.

Before you define and enable this constraint, you must define and enable a constraint that designates the `department_id` column of the `departments` table as a primary or unique key.

The foreign key constraint definition does not use the `FOREIGN KEY` clause, because the constraint is defined inline. The data type of the `department_id` column is not needed, because Oracle automatically assigns to this column the data type of the referenced key.

The constraint definition identifies both the parent table and the columns of the referenced key. Because the referenced key is the primary key of the parent table, the referenced key column names are optional.

Alternatively, you can define this foreign key constraint out of line:

```sql
CREATE TABLE dept_20
  (employee_id     NUMBER(4),
   last_name       VARCHAR2(10),
   job_id          VARCHAR2(9),
   manager_id      NUMBER(4),
   hire_date       DATE,
   salary          NUMBER(7,2),
   commission_pct  NUMBER(7,2),
   department_id,  
CONSTRAINT fk_deptno
     FOREIGN KEY (department_id) 
     REFERENCES departments(department_id) );
```

The foreign key definitions in both variations of this statement omit the `ON DELETE` clause, causing Oracle to prevent the deletion of a department if any employee works in that department.

**ON DELETE Example** This statement creates the `dept_20` table, defines and enables two referential integrity constraints, and uses the `ON DELETE` clause:

```sql
CREATE TABLE dept_20
  (employee_id     NUMBER(4) PRIMARY KEY,
   last_name       VARCHAR2(10),
   job_id          VARCHAR2(9),
   manager_id      NUMBER(4) CONSTRAINT fk_mgr
     REFERENCES employees ON DELETE SET NULL,
   hire_date       DATE,
   salary          NUMBER(7,2),
   commission_pct  NUMBER(7,2),
   department_id   NUMBER(2)   CONSTRAINT fk_deptno
     REFERENCES departments(department_id) ON DELETE CASCADE );
```

Because of the first `ON DELETE` clause, if manager number 2332 is deleted from the `employees` table, then Oracle sets to null the value of `manager_id` for all employees in the `dept_20` table who previously had manager 2332.

Because of the second `ON DELETE` clause, Oracle cascades any deletion of a `department_id` value in the `departments` table to the `department_id` values of its dependent rows.
of the dept_20 table. For example, if Department 20 is deleted from the departments table, then Oracle deletes all of the employees in Department 20 from the dept_20 table.

**Composite Foreign Key Constraint Example** The following statement defines and enables a foreign key on the combination of the employee_id and hire_date columns of the dept_20 table:

```
ALTER TABLE dept_20
ADD CONSTRAINT fk_empid_hiredate
FOREIGN KEY (employee_id, hire_date)
REFERENCES hr.job_history(employee_id, start_date)
EXCEPTIONS INTO wrong_emp;
```

The constraint `fk_empid_hiredate` ensures that all the employees in the dept_20 table have employee_id and hire_date combinations that exist in the employees table. Before you define and enable this constraint, you must define and enable a constraint that designates the combination of the employee_id and hire_date columns of the employees table as a primary or unique key.

The `EXCEPTIONS INTO` clause causes Oracle to write information to the `wrong_emp` table about any rows in the dept_20 table that violate the constraint. If the `wrong_emp` exceptions table does not already exist, then this statement will fail.

**Check Constraint Examples** The following statement creates a divisions table and defines a check constraint in each column of the table:

```
CREATE TABLE divisions
(div_no NUMBER CONSTRAINT check_divno
  CHECK (div_no BETWEEN 10 AND 99)
DISABLE,
  div_name VARCHAR2(9) CONSTRAINT check_divname
  CHECK (div_name = UPPER(div_name))
DISABLE,
  office VARCHAR2(10) CONSTRAINT check_office
  CHECK (office IN ('DALLAS','BOSTON', 'PARIS','TOKYO'))
DISABLE);
```

Each constraint restricts the values of the column in which it is defined:

- `check_divno` ensures that no division numbers are less than 10 or greater than 99.
- `check_divname` ensures that all division names are in uppercase.
- `check_office` restricts office locations to Dallas, Boston, Paris, or Tokyo.

Because each `CONSTRAINT` clause contains the `DISABLE` clause, Oracle only defines the constraints and does not enable them.

The following statement creates the dept_20 table, defining out of line and implicitly enabling a check constraint:

```
CREATE TABLE dept_20
(employee_id NUMBER(4) PRIMARY KEY,
  last_name VARCHAR2(10),
  job_id VARCHAR2(9),
  manager_id NUMBER(4),
  salary NUMBER(7,2),
  commission_pct NUMBER(7,2),
  department_id NUMBER(2),
CONSTRAINT check_sal CHECK (salary * commission_pct <= 5000));
```
This constraint uses an inequality condition to limit an employee’s total commission, the product of salary and commission_pct, to $5000:

- If an employee has non-null values for both salary and commission, then the product of these values must not exceed $5000 to satisfy the constraint.
- If an employee has a null salary or commission, then the result of the condition is unknown and the employee automatically satisfies the constraint.

Because the constraint clause in this example does not supply a constraint name, Oracle generates a name for the constraint.

The following statement defines and enables a primary key constraint, two foreign key constraints, a NOT NULL constraint, and two check constraints:

```sql
CREATE TABLE order_detail
  (CONSTRAINT pk_od PRIMARY KEY (order_id, part_no),
   order_id    NUMBER
     CONSTRAINT fk_oid
      REFERENCES oe.orders(order_id),
   part_no     NUMBER
     CONSTRAINT fk_pno
      REFERENCES oe.product_information(product_id),
   quantity    NUMBER
     CONSTRAINT nn_qty NOT NULL
     CONSTRAINT check_qty CHECK (quantity > 0),
   cost        NUMBER
     CONSTRAINT check_cost CHECK (cost > 0) );
```

The constraints enable the following rules on table data:

- **pk_od** identifies the combination of the order_id and part_no columns as the primary key of the table. To satisfy this constraint, no two rows in the table can contain the same combination of values in the order_id and the part_no columns, and no row in the table can have a null in either the order_id or the part_no column.

- **fk_oid** identifies the order_id column as a foreign key that references the order_id column in the orders table in the sample schema oe. All new values added to the column order_detail.order_id must already appear in the column oe.orders.order_id.

- **fk_pno** identifies the product_id column as a foreign key that references the product_id column in the product_information table owned by oe. All new values added to the column order_detail.product_id must already appear in the column oe.product_information.product_id.

- **nn_qty** forbids nulls in the quantity column.

- **check_qty** ensures that values in the quantity column are always greater than zero.

- **check_cost** ensures the values in the cost column are always greater than zero.

This example also illustrates the following points about constraint clauses and column definitions:

- Out-of-line constraint definition can appear before or after the column definitions. In this example, the out-of-line definition of the pk_od constraint precedes the column definitions.
A column definition can contain multiple inline constraint definitions. In this example, the definition of the quantity column contains the definitions of both the nn_qty and check_qty constraints.

A table can have multiple CHECK constraints. Multiple CHECK constraints, each with a simple condition enforcing a single business rule, are preferable to a single CHECK constraint with a complicated condition enforcing multiple business rules. When a constraint is violated, Oracle returns an error identifying the constraint. Such an error more precisely identifies the violated business rule if the identified constraint enables a single business rule.

Attribute-Level Constraints Example The following example guarantees that a value exists for both the first_name and last_name attributes of the name column in the students table:

```sql
CREATE TYPE person_name AS OBJECT
    (first_name VARCHAR2(30), last_name VARCHAR2(30));
/
CREATE TABLE students (name person_name, age INTEGER,
    CHECK (name.first_name IS NOT NULL AND
            name.last_name IS NOT NULL));
```

REF Constraint Examples The following example creates a duplicate of the sample schema object type cust_address_typ, and then creates a table containing a REF column with a SCOPE constraint:

```sql
CREATE TYPE cust_address_typ_new AS OBJECT
    ( street_address VARCHAR2(40), postal_code VARCHAR2(10),
      city VARCHAR2(30), state_province VARCHAR2(10),
      country_id CHAR(2) );
/
CREATE TABLE address_table OF cust_address_typ_new;
CREATE TABLE customer_addresses (
    add_id NUMBER,
    address REF cust_address_typ_new SCOPE IS address_table);
```

The following example creates the same table but with a referential integrity constraint on the REF column that references the object identifier column of the parent table:

```sql
CREATE TABLE customer_addresses (
    add_id NUMBER,
    address REF cust_address_typ REFERENCES address_table);
```

The following example uses the type department_typ and the table departments_obj_t, created in "Creating Object Tables: Examples" on page 16-100. A table with a scoped REF is then created.

```sql
CREATE TABLE employees_obj
    ( e_name VARCHAR2(100),
      e_number NUMBER,
      e_dept REF department Typ SCOPE IS departments_obj_t );
```

The following statement creates a table with a REF column which has a referential integrity constraint defined on it:
CREATE TABLE employees_obj
  ( e_name   VARCHAR2(100),
    e_number NUMBER,
    e_dept   REF department_typ REFERENCES departments_obj_t);

**Explicit Index Control Example**  The following statement shows another way to create a unique (or primary key) constraint that gives you explicit control over the index (or indexes) Oracle uses to enforce the constraint:

CREATE TABLE promotions_var3
  ( promo_id         NUMBER(6)
  , promo_name       VARCHAR2(20)
  , promo_category   VARCHAR2(15)
  , promo_cost       NUMBER(10,2)
  , promo_begin_date DATE
  , promo_end_date   DATE
  , CONSTRAINT promo_id_u UNIQUE (promo_id, promo_cost)
    USING INDEX (CREATE UNIQUE INDEX promo_ix1
      ON promotions_var3 (promo_id, promo_cost))
  , CONSTRAINT promo_id_u2 UNIQUE (promo_cost, promo_id)
    USING INDEX promo_ix1);

This example also shows that you can create an index for one constraint and use that index to create and enable another constraint in the same statement.

**DEFERRABLE Constraint Examples**  The following statement creates table games with a NOT DEFERRABLE INITIALLY IMMEDIATE constraint check (by default) on the scores column:

CREATE TABLE games (scores NUMBER CHECK (scores >= 0));

To define a unique constraint on a column as INITIALLY DEFERRED DEFERRABLE, issue the following statement:

CREATE TABLE games
  (scores NUMBER,
   CONSTRAINT unq_num UNIQUE (scores)
   INITIALLY DEFERRED DEFERRABLE);
**deallocate_unused_clause**

**Purpose**

Use the `deallocate_unused_clause` to explicitly deallocate unused space at the end of a database object segment and make the space available for other segments in the tablespace.

You can deallocate unused space using the following statements:

- `ALTER CLUSTER` (see ALTER CLUSTER on page 10-28)
- `ALTER INDEX`: to deallocate unused space from the index, an index partition, or an index subpartition (see ALTER INDEX on page 10-107)
- `ALTER MATERIALIZED VIEW`: to deallocate unused space from the overflow segment of an index-organized materialized view (see ALTER MATERIALIZED VIEW on page 11-3)
- `ALTER TABLE`: to deallocate unused space from the table, a table partition, a table subpartition, the mapping table of an index-organized table, the overflow segment of an index-organized table, or a LOB storage segment (see ALTER TABLE on page 12-2)

**Syntax**

```
deallocate_unused_clause ::= deallocate UNUSED size_clause
```

(size_clause ::= on page 8-47)

**Semantics**

This section describes the semantics of the `deallocate_unused_clause`. For additional information, refer to the SQL statement in which you set or reset this clause for a particular database object.

You cannot specify both the `deallocate_unused_clause` and the `allocate_extent_clause` in the same statement.

Oracle Database frees only unused space above the high water mark (the point beyond which database blocks have not yet been formatted to receive data). Oracle deallocates unused space beginning from the end of the object and moving toward the beginning of the object to the high water mark.

If an extent is completely contained in the deallocation, then the whole extent is freed for reuse. If an extent is partially contained in the deallocation, then the used part up to the high water mark becomes the extent, and the remaining unused space is freed for reuse.

Oracle credits the amount of the released space to the user quota for the tablespace in which the deallocation occurs.

The exact amount of space freed depends on the values of the `INITIAL`, `MINEXTENTS`, and `NEXT` storage parameters. Refer to the `storage_clause` on page 8-48 for a description of these parameters.
**KEEP integer**

Specify the number of bytes above the high water mark that the segment of the database object is to have after deallocation.

- If you omit `KEEP` and the high water mark is above the size of `INITIAL` and `MINEXTENTS`, then all unused space above the high water mark is freed. When the high water mark is less than the size of `INITIAL` or `MINEXTENTS`, then all unused space above `MINEXTENTS` is freed.

- If you specify `KEEP`, then the specified amount of space is kept and the remaining space is freed. When the remaining number of extents is less than `MINEXTENTS`, then Oracle adjusts `MINEXTENTS` to the new number of extents. If the initial extent becomes smaller than `INITIAL`, then Oracle adjusts `INITIAL` to the new size.

- In either case, Oracle sets the value of the `NEXT` storage parameter to the size of the last extent that was deallocated.
**file_specification**

**Purpose**

Use one of the `file_specification` forms to specify a file as a data file or temp file, or to specify a group of one or more files as a redo log file group. If you are storing your files in Oracle Automatic Storage Management (Oracle ASM) disk groups, then you can further specify the file as a disk group file.

A `file_specification` can appear in the following statements:

- CREATE CONTROLFILE (see CREATE CONTROLFILE on page 14-22)
- CREATE DATABASE (see CREATE DATABASE on page 14-29)
- ALTER DATABASE (see ALTER DATABASE on page 10-32)
- CREATE TABLESPACE (see CREATE TABLESPACE on page 16-102)
- ALTER TABLESPACE (see ALTER TABLESPACE on page 12-114)
- ALTER DISKGROUP (see ALTER DISKGROUP on page 10-78)

**Prerequisites**

You must have the privileges necessary to issue the statement in which the file specification appears.

**Syntax**

```
file_specification::=
  datafile_tempfile_spec
  redo_log_file_spec

datafile_tempfile_spec::=
  filename
  ASM_filename
  SIZE size_clause
  REUSE
  autoextend_clause
  (size_clause::= on page 8-47)

redo_log_file_spec::=
  filename
  ASM_filename
  SIZE size_clause
  BLOCKSIZE size_clause
  REUSE
```

Common SQL DDL Clauses  8-29
file_specification

(size_clause::= on page 8-47)

ASM_filename::=

fullyQualified_file_name
numeric_file_name
incomplete_file_name
alias_file_name

fullyQualified_file_name::=

diskgroup_name | db_name | file_type | file_type_tag | filenumber | incarnation_number

numeric_file_name::=

diskgroup_name | filenumber | incarnation_number

autoextend_clause::=

AUTOEXTEND
OFF
ON NEXT size_clause maxsize_clause

(maxsize_clause::= on page 8-47)

maxsize_clause::=

MAXSIZE UNLIMITED
size_clause

(maxsize_clause::= on page 8-47)

Semantics

This section describes the semantics of file_specification. For additional information, refer to the SQL statement in which you specify a data file, temp file, redo log file, or Oracle ASM disk group or disk group file.
**datafile tempfile spec**

Use this clause to specify the attributes of data files and temp files if your database storage is in a file system or in Oracle ASM disk groups.

**redo log file spec**

Use this clause to specify the attributes of redo log files if your database storage is in a file system or in Oracle ASM disk groups.

**filename**

Use `filename` for files stored in a file system. The `filename` can specify either a new file or an existing file. For a new file:

- If you are not using Oracle Managed Files, then you must specify both `filename` and the `SIZE` clause or the statement fails. When you specify a `filename` without a size, Oracle attempts to reuse an existing file and returns an error if the file does not exist.
- If you are using Oracle Managed Files, then `filename` is optional, as are the remaining clauses of the specification. In this case, Oracle Database creates a unique name for the file and saves it in the directory specified by one of the following initialization parameters:
  - The `DB_RECOVERY_FILE_DEST` (for logfiles and control files)
  - The `DB_CREATE_FILE_DEST` initialization parameter (for any type of file)
  - The `DB_CREATE_ONLINE_LOG_DEST_n` initialization parameter, which takes precedence over `DB_CREATE_FILE_DEST` and `DB_RECOVERY_FILE_DEST` for log files.

For an existing file, specify the name of either a data file, temp file, or a redo log file member. The `filename` can contain only single-byte characters from 7-bit ASCII or EBCDIC character sets. Multibyte characters are not valid.

The `filename` can include a path prefix. If you do not specify such a path prefix, then the database adds the path prefix for the default storage location, which is platform dependent.

A redo log file group can have one or more members (copies). Each `filename` must be fully specified according to the conventions for your operating system.

The way the database interprets `filename` also depends on whether you specify it with the `SIZE` and `REUSE` clauses.

- If you specify `filename` only, or with the `REUSE` clause but without the `SIZE` clause, then the file must already exist.
- If you specify `filename` with `SIZE` but without `REUSE`, then the file must be a new file.
- If you specify `filename` with both `SIZE` and `REUSE`, then the file can be either new or existing. If the file exists, then it is reused with the new size. If it does not exist, then the database ignores the `REUSE` keyword and creates a new file of the specified size.

**See Also:** Oracle Automatic Storage Management Administrator’s Guide for more information on Oracle Managed Files, “Specifying a Data File: Example” on page 8-36, and “Specifying a Log File: Example” on page 8-35
**ASM_filename**

Use a form of `ASM_filename` for files stored in Oracle ASM disk groups. You can create or refer to data files, temp files, and redo log files with this syntax.

All forms of `ASM_filename` begin with the plus sign (+) followed by the name of the disk group. You can determine the names of all Oracle ASM disk groups by querying the `V$ASM_DISKGROUP` view.

**See Also:** *Oracle Automatic Storage Management Administrator’s Guide*  
for information on using Oracle ASM

**fully_qualified_file_name**

When you create a file in an Oracle ASM disk group, the file receives a system-generated fully qualified Oracle ASM filename. You can use this form only when referring to an existing Oracle ASM file. Therefore, if you are using this form during file creation, you must also specify `REUSE`.

- `db_name` is the value of the `DB_UNIQUE_NAME` initialization parameter. This name is equivalent to the name of the database on which the file resides, but the parameter distinguishes between primary and standby databases, if both exist.
- `file_type` and `file_type_tag` indicate the type of database file. Table 8–1 on page 8-32 lists all of the file types and their corresponding Oracle ASM tags.
- `filenumber` and `incarnation_number` are system-generated identifiers to guarantee uniqueness.

You can determine the fully qualified names of Oracle ASM files by querying the dynamic performance view appropriate for the file type (for example `V$DATAFILE` for data files, `V$CONTROLFILE` for control files, and so on). You can also obtain the `filenumber` and `incarnation_number` portions of the fully qualified names by querying the `V$ASM_FILE` view.

**Table 8–1 Oracle File Types and Oracle ASM File Type Tags**

</table>
**numeric_file_name**

A numeric Oracle ASM filename is similar to a fully qualified filename except that it uses only the unique `filenumber.incarnation_number` string. You can use this form only to refer to an existing file. Therefore, if you are using this form during file creation, you must also specify REUSE.

**incomplete_file_name**

Incomplete Oracle ASM filenames are used during file creation only. If you specify the disk group name alone, then Oracle ASM uses the appropriate default template for the file type. For example, if you are creating a data file in a `CREATE TABLESPACE` statement, Oracle ASM uses the default `DATAFILE` template to create an Oracle ASM data file. If you specify the disk group name with a template, then Oracle ASM uses the specified template to create the file. In both cases, Oracle ASM also creates a fully qualified filename.

**template_name**

A template is a named collection of attributes. You can create templates and apply them to files in a disk group. You can determine the names of all Oracle ASM template names by querying the `V$ASM_TEMPLATE` data dictionary view. Refer to `diskgroup_template_clauses` on page 10-91 for instructions on creating Oracle ASM templates.

You can specify `template` only during file creation. It appears in the incomplete and alias name forms of the `ASM_filename` diagram:

- If you specify `template` immediately after the disk group name, then Oracle ASM uses the specified template to create the file, and gives the file a fully qualified filename.
- If you specify `template` after specifying an alias, then Oracle ASM uses the specified template to create the file, gives the file a fully qualified filename, and also creates the alias so that you can subsequently use it to refer to the file. If the alias you specify refers to an existing file, then Oracle ASM ignores the template specification unless you also specify REUSE.

**See Also:** `diskgroup_template_clauses` on page 10-91 for information about the default templates
**alias_file_name**

An alias is a user-friendly name for an Oracle ASM file. You can use alias filenames during file creation or reference. You can specify a template with an alias, but only during file creation. To determine the alias names for Oracle ASM files, query the V$ASM_ALIAS data dictionary view.

If you are specifying an alias during file creation, then refer to `diskgroup_directory_clauses` on page 10-94 and `diskgroup_alias_clauses` on page 10-94 for instructions on specifying the full alias name.

**SIZE Clause**

Specify the size of the file in bytes. Use K, M, G, or T to specify the size in kilobytes, megabytes, gigabytes, or terabytes.

- For undo tablespaces, you must specify the SIZE clause for each data file. For other tablespaces, you can omit this parameter if the file already exists, or if you are creating an Oracle Managed File.
- If you omit this clause when creating an Oracle Managed File, then Oracle creates a 100M file.
- The size of a tablespace must be one block greater than the sum of the sizes of the objects contained in it.

**See Also:** *Oracle Database Administrator’s Guide* for information on automatic undo management and undo tablespaces and "Adding a Log File: Example" on page 8-36

**BLOCKSIZE Clause**

Specify BLOCKSIZE to override the operating system-dependent sector size. If you omit this clause, then the database uses the operating system-dependent sector size as the block size.

When you add a redo log file to a 512-byte sector disk or to a 4KB sector disk with 512-byte emulation, the blocksize of the new file must be the original platform base block size or 4KB.

- If the redo log file is being added to a 512-byte sector disk, then you must specify 512 or 1024 (or 1K) as the block size, depending on your platform.
- If the redo log file is being added to a 4KB sector disk (native), then you must specify either 4096 or 4K as the block size.
- If the redo log file is being added to a 4KB sector disk with 512-byte emulation, then you can specify either 512, 1024 (or 1K), or 4096 (or 4K) as the block size, depending on your platform.

All logs within a log group must have the same block size. Two log groups created on separate disks can have different block sizes. However, the mixed configuration introduces overhead at every log switch. Oracle recommends that you create all log files with the same block size.

This clause is useful when the 4K sector size is in use, but you want to optimize disk space use rather than performance. In such a case you can override the operating system sector size by specifying BLOCKSIZE 512 or, for HP-UX, BLOCKSIZE 1024.

**See Also:** "Adding a Log File: Example" on page 8-36
REUSE
Specify REUSE to allow Oracle to reuse an existing file.

- If the file already exists, then Oracle reuses the filename and applies the new size (if you specify SIZE) or retains the original size.
- If the file does not exist, then Oracle ignores this clause and creates the file.

Restriction on the REUSE Clause  You cannot specify REUSE unless you have specified filename.
Whenever Oracle uses an existing file, the previous contents of the file are lost.

See Also: "Adding a Data File: Example" on page 8-36 and "Adding a Log File: Example" on page 8-36

autoextend_clause
The autoextend_clause is valid for data files and temp files but not for redo log files. Use this clause to enable or disable the automatic extension of a new or existing data file or temp file. If you omit this clause, then:

- For Oracle Managed Files:
  - If you specify SIZE, then Oracle Database creates a file of the specified size with AUTOEXTEND disabled.
  - If you do not specify SIZE, then the database creates a 100M file with AUTOEXTEND enabled. When autoextension is required, the database extends the file by its original size or 100MB, whichever is smaller. You can override this default behavior by specifying the NEXT clause.
- For user-managed files, with or without SIZE specified, Oracle creates a file with AUTOEXTEND disabled.

ON  Specify ON to enable autoextend.

OFF Specify OFF to turn off autoextend if is turned on. When you turn off autoextend, the values of NEXT and MAXSIZE are set to zero. If you turn autoextend back on in a subsequent statement, then you must reset these values.

NEXT Use the NEXT clause to specify the size in bytes of the next increment of disk space to be allocated automatically when more extents are required. The default is the size of one data block.

MAXSIZE Use the MAXSIZE clause to specify the maximum disk space allowed for automatic extension of the data file.

UNLIMITED Use the UNLIMITED clause if you do not want to limit the disk space that Oracle can allocate to the data file or temp file.

Restriction on the autoextend_clause  You cannot specify this clause as part of the datafile_tempfile_spec in a CREATE CONTROLFILE statement or in an ALTER DATABASE CREATE DATAFILE clause.

Examples

Specifying a Log File: Example  The following statement creates a database named payable that has two redo log file groups, each with two members, and one data file:
CREATE DATABASE payable
   LOGFILE GROUP 1 ('diska:log1.log', 'diskb:log1.log') SIZE 50K,
   GROUP 2 ('diska:log2.log', 'diskb:log2.log') SIZE 50K
   DATAFILE 'diskc:dbone.dbf' SIZE 30M;

The first file specification in the LOGFILE clause specifies a redo log file group with the GROUP value 1. This group has members named 'diska:log1.log' and 'diskb:log1.log', each 50 kilobytes in size.

The second file specification in the LOGFILE clause specifies a redo log file group with the GROUP value 2. This group has members named 'diska:log2.log' and 'diskb:log2.log', also 50 kilobytes in size.

The file specification in the DATAFILE clause specifies a data file named 'diskc:dbone.dbf', 30 megabytes in size.

Each file specification specifies a value for the SIZE parameter and omits the REUSE clause, so none of these files can already exist. Oracle must create them.

**Adding a Log File: Example** The following statement adds another redo log file group with two members to the payable database:

```sql
ALTER DATABASE payable
   ADD LOGFILE GROUP 3 ('diska:log3.log', 'diskb:log3.log')
   SIZE 50K REUSE;
```

The file specification in the ADD LOGFILE clause specifies a new redo log file group with the GROUP value 3. This new group has members named 'diska:log3.log' and 'diskb:log3.log', each 50 kilobytes in size. Because the file specification specifies the REUSE clause, each member can (but need not) already exist.

The following statement adds a logfile group 5 with member log files on migration target disks 4k_disk_a and 4k_disk_b. After executing this statement, you can switch existing log files on disks with 512-byte block size to logs with 4K block size using the switch_logfile_clause on page 10-57.

```sql
ALTER DATABASE ADD LOGFILE GROUP 5
   ('4k_disk_a:log5.log', '4k_disk_b:log5.log')
   SIZE 100M BLOCKSIZE 4096 REUSE;
```

**Specifying a Data File: Example** The following statement creates a tablespace named stocks that has three data files:

```sql
CREATE TABLESPACE stocks
   DATAFILE 'stock1.dbf' SIZE 10M,
           'stock2.dbf' SIZE 10M,
           'stock3.dbf' SIZE 10M;
```

The file specifications for the data files specify files named 'diskc:stock1.dbf', 'diskc:stock2.dbf', and 'diskc:stock3.dbf'.

**Adding a Data File: Example** The following statement alters the stocks tablespace and adds a new data file:

```sql
ALTER TABLESPACE stocks
   ADD DATAFILE 'stock4.dbf' SIZE 10M REUSE;
```

The file specification specifies a data file named 'stock4.dbf'. If the filename does not exist, then Oracle simply ignores the REUSE keyword.
Using a Fully Qualified Oracle ASM Data File Name: Example  When using Oracle ASM, the following syntax shows how to use the `fullyQualifiedFileName` clause to bring online a data file in a hypothetical database, `testdb`:

```sql
ALTER DATABASE testdb
  DATAFILE '+dgroup_01/testdb/datafile/system.261.1' ONLINE;
```
The `logging_clause` lets you specify whether certain DML operations will be logged in the redo log file (`LOGGING`) or not (`NOLOGGING`).

You can specify the `logging_clause` in the following statements:

- `CREATE TABLE` and `ALTER TABLE`: for logging of the table, a table partition, a LOB segment, or the overflow segment of an index-organized table (see `CREATE TABLE` on page 16-6 and `ALTER TABLE` on page 12-2).

**Note:** Logging specified for a LOB column can differ from logging set at the table level. If you specify `LOGGING` at the table level and `NOLOGGING` for a LOB column, then DML changes to the base table row are logged, but DML changes to the LOB data are not logged.

- `CREATE INDEX` and `ALTER INDEX`: for logging of the index or an index partition (see `CREATE INDEX` on page 14-73 and `ALTER INDEX` on page 10-107).

- `CREATE MATERIALIZED VIEW` and `ALTER MATERIALIZED VIEW`: for logging of the materialized view, one of its partitions, or a LOB segment (see `CREATE MATERIALIZED VIEW` on page 15-4 and `ALTER MATERIALIZED VIEW` on page 11-3).

- `CREATE MATERIALIZED VIEW LOG` and `ALTER MATERIALIZED VIEW LOG`: for logging of the materialized view log or one of its partitions (see `CREATE MATERIALIZED VIEW LOG` on page 15-31 and `ALTER MATERIALIZED VIEW LOG` on page 11-20).

- `CREATE TABLESPACE` and `ALTER TABLESPACE`: to set or modify the default logging characteristics for all objects created in the tablespace (see `CREATE TABLESPACE` on page 16-102 and `ALTER TABLESPACE` on page 12-114).

- `CREATE PLUGGABLE DATABASE` and `ALTER PLUGGABLE DATABASE`: to set or modify the default logging characteristics for all tablespaces created in the pluggable database (PDB) (see `CREATE PLUGGABLE DATABASE` on page 15-61 and `ALTER PLUGGABLE DATABASE` on page 11-38).

You can also specify `LOGGING` or `NOLOGGING` for the following operations:

- Rebuilding an index (using `CREATE INDEX ... REBUILD`)
- Moving a table (using `ALTER TABLE ... MOVE`)

**Syntax**

```
logging_clause ::=  
  LOGGING | NOLOGGING | FILESYSTEM_LIKE_LOGGING 
```
Semantics

This section describes the semantics of the `logging_clause`. For additional information, refer to the SQL statement in which you set or reset logging characteristics for a particular database object.

- If you specify `LOGGING`, then the creation of a database object, as well as subsequent inserts into the object, will be logged in the redo log file.
- If you specify `NOLOGGING`, then the creation of a database object, as well as subsequent conventional inserts, will be logged in the redo log file. Direct-path inserts will not be logged.
  - For a nonpartitioned object, the value specified for this clause is the actual physical attribute of the segment associated with the object.
  - For partitioned objects, the value specified for this clause is the default physical attribute of the segments associated with all partitions specified in the `CREATE` statement (and in subsequent `ALTER ... ADD PARTITION` statements), unless you specify the logging attribute in the `PARTITION` description.
  - For SecureFiles LOBs, the `NOLOGGING` setting is converted internally to `FILESYSTEM_LIKE_LOGGING`.
  - `CACHE NOLOGGING` is not allowed for BasicFiles LOBs.
- The `FILESYSTEM_LIKE_LOGGING` clause is valid only for logging of SecureFiles LOB segments. You cannot specify this setting for BasicFiles LOBs. Specify this setting if you want to log only metadata changes. This setting is similar to the metadata journaling of file systems, which reduces mean time to recovery from failures. The `LOGGING` setting, for SecureFiles LOBs, is similar to the data journaling of file systems. Both the `LOGGING` and `FILESYSTEM_LIKE_LOGGING` settings provide a complete transactional file system by way of SecureFiles.

**Note:** For LOB segments, with the `NOLOGGING` and `FILESYSTEM_LIKE_LOGGING` settings it is possible for data to be changed on disk during a backup operation, resulting in an inconsistent backup. To avoid this situation, ensure that changes to LOB segments are saved in the redo log file by setting `LOGGING` for LOB storage. Alternatively, change the database to `FORCE LOGGING` mode so that changes to all LOB segments are saved in the redo.

If the object for which you are specifying the logging attributes resides in a database or tablespace in force logging mode, then Oracle Database ignores any `NOLOGGING` setting until the database or tablespace is taken out of force logging mode.

If the database is running in `ARCHIVELOG` mode, then media recovery from a backup made before the `LOGGING` operation re-creates the object. However, media recovery from a backup made before the `NOLOGGING` operation does not re-create the object.

The size of a redo log generated for an operation in `NOLOGGING` mode is significantly smaller than the log generated in `LOGGING` mode.

In `NOLOGGING` mode, data is modified with minimal logging (to mark new extents `INVALID` and to record dictionary changes). When applied during media recovery, the extent invalidation records mark a range of blocks as logically corrupt, because the redo data is not fully logged. Therefore, if you cannot afford to lose the database object, then you should take a backup after the `NOLOGGING` operation.
NOLOGGING is supported in only a subset of the locations that support LOGGING. Only the following operations support the NOLOGGING mode:

**DML:**
- Direct-path INSERT (serial or parallel) resulting either from an INSERT or a MERGE statement. NOLOGGING is not applicable to any UPDATE operations resulting from the MERGE statement.
- Direct Loader (SQL*Loader)

**DDL:**
- CREATE TABLE ... AS SELECT (In NOLOGGING mode, the creation of the table will be logged, but direct-path inserts will not be logged.)
- CREATE TABLE ... LOB_storage_clause ... LOB_parameters ... CACHE | NOCACHE | CACHE READS
- ALTER TABLE ... LOB_storage_clause ... LOB_parameters ... CACHE | NOCACHE | CACHE READS (to specify logging of newly created LOB columns)
- ALTER TABLE ... modify_LOB_storage_clause ... modify_LOB_parameters ... CACHE | NOCACHE | CACHE READS (to change logging of existing LOB columns)
- ALTER TABLE ... MOVE
- ALTER TABLE ... (all partition operations that involve data movement)
  - ALTER TABLE ... ADD PARTITION (hash partition only)
  - ALTER TABLE ... MERGE PARTITIONS
  - ALTER TABLE ... SPLIT PARTITION
  - ALTER TABLE ... MOVE PARTITION
  - ALTER TABLE ... MODIFY PARTITION ... ADD SUBPARTITION
  - ALTER TABLE ... MODIFY PARTITION ... COALESCE SUBPARTITION
- CREATE INDEX
- ALTER INDEX ... REBUILD
- ALTER INDEX ... REBUILD [SUB] PARTITION
- ALTER INDEX ... SPLIT PARTITION

For **objects other than LOBs**, if you omit this clause, then the logging attribute of the object defaults to the logging attribute of the tablespace in which it resides.

For **LOBs**, if you omit this clause, then:
- If you specify CACHE, then LOGGING is used (because you cannot have CACHE NOLOGGING).
- If you specify NOCACHE or CACHE READS, then the logging attribute defaults to the logging attribute of the tablespace in which it resides.

NOLOGGING does not apply to LOBs that are stored internally (in the table with row data). If you specify NOLOGGING for LOBs with values less than 4000 bytes and you have not disabled STORAGE IN ROW, then Oracle ignores the NOLOGGING specification and treats the LOB data the same as other table data.
parallel_clause

Purpose

The parallel_clause lets you parallelize the creation of a database object and set the default degree of parallelism for subsequent queries of and DML operations on the object.

You can specify the parallel_clause in the following statements:

- **CREATE TABLE**: to set parallelism for the table (see CREATE TABLE on page 16-6).
- **ALTER TABLE** (see ALTER TABLE on page 12-2):
  - To change parallelism for the table
  - To parallelize the operations of adding, coalescing, exchanging, merging, splitting, truncating, dropping, or moving a table partition
- **CREATE CLUSTER** and **ALTER CLUSTER**: to set or alter parallelism for a cluster (see CREATE CLUSTER on page 14-11 and ALTER CLUSTER on page 10-28).
- **CREATE INDEX**: to set parallelism for the index (see CREATE INDEX on page 14-73).
- **ALTER INDEX** (see ALTER INDEX on page 10-107):
  - To change parallelism for the index
  - To parallelize the rebuilding of the index or the splitting of an index partition
- **CREATE MATERIALIZED VIEW**: to set parallelism for the materialized view (see CREATE MATERIALIZED VIEW on page 15-4).
- **ALTER MATERIALIZED VIEW** (see ALTER MATERIALIZED VIEW on page 11-3):
  - To change parallelism for the materialized view
  - To parallelize the operations of adding, coalescing, exchanging, merging, splitting, truncating, dropping, or moving a materialized view partition
  - To parallelize the operations of adding or moving materialized view subpartitions
- **CREATE MATERIALIZED VIEW LOG**: to set parallelism for the materialized view log (see CREATE MATERIALIZED VIEW LOG on page 15-31).
- **ALTER MATERIALIZED VIEW LOG** (see ALTER MATERIALIZED VIEW LOG on page 11-20):
  - To change parallelism for the materialized view log
  - To parallelize the operations of adding, coalescing, exchanging, merging, splitting, truncating, dropping, or moving a materialized view log partition
- **ALTER DATABASE ... RECOVER**: to recover the database (see ALTER DATABASE on page 10-32).
- **ALTER DATABASE ... standby_database_clauses**: to parallelize operations on the standby database (see ALTER DATABASE on page 10-32).

See Also: Oracle Database PL/SQL Packages and Types Reference for information on the DBMS_PARALLEL_EXECUTE package, which provides methods to apply table changes in chunks of rows. Changes to each chunk are independently committed when there are no errors.
Syntax

\texttt{parallel\_clause::=}

\begin{itemize}
\item \texttt{NOPARALLEL}
\item \texttt{PARALLEL} \hspace{1cm} \texttt{integer}
\end{itemize}

Semantics

This section describes the semantics of the \texttt{parallel\_clause}. For additional information, refer to the SQL statement in which you set or reset parallelism for a particular database object or operation.

\begin{itemize}
\item \textbf{Note:} The syntax of the \texttt{parallel\_clause} supersedes syntax appearing in earlier releases of Oracle. Superseded syntax is still supported for backward compatibility but may result in slightly different behavior from that documented.
\end{itemize}

The database interprets the \texttt{parallel\_clause} based on the setting of the \texttt{PARALLEL\_DEGREE\_POLICY} initialization parameter. When that parameter is set to \texttt{AUTO}, the \texttt{parallel\_clause} is ignored entirely, and the optimizer determines the best degree of parallelism for all statements. When \texttt{PARALLEL\_DEGREE\_POLICY} is set to either \texttt{MANUAL} or \texttt{LIMITED}, the \texttt{parallel\_clause} is interpreted as follows:

\begin{itemize}
\item \textbf{NOPARALLEL} \hspace{1cm} Specify \texttt{NOPARALLEL} for serial execution. This is the default.
\item \textbf{PARALLEL} \hspace{1cm} Specify \texttt{PARALLEL} for parallel execution.
\begin{itemize}
\item If \texttt{PARALLEL\_DEGREE\_POLICY} is set to \texttt{MANUAL}, then the optimizer calculates a degree of parallelism equal to the number of CPUs available on all participating instances times the value of the \texttt{PARALLEL\_THREADS\_PER\_CPU} initialization parameter.
\item If \texttt{PARALLEL\_DEGREE\_POLICY} is set to \texttt{LIMITED}, then the optimizer determines the best degree of parallelism.
\end{itemize}
\end{itemize}

\begin{itemize}
\item \textbf{PARALLEL} \hspace{1cm} \texttt{integer} \hspace{1cm} Specification of \texttt{integer} indicates the degree of parallelism, which is the number of parallel threads used in the parallel operation. Each parallel thread may use one or two parallel execution servers.
\end{itemize}

\begin{itemize}
\item \textbf{Notes on the parallel\_clause} \hspace{1cm} The following notes apply to the \texttt{parallel\_clause}:
\begin{itemize}
\item Parallelism is disabled for DML operations on tables on which you have defined a trigger or referential integrity constraint.
\item Parallelism is not supported for \texttt{UPDATE} or \texttt{DELETE} operations on index-organized tables.
\item When you specify the \texttt{parallel\_clause} during creation of a table, if the table contains any columns of LOB or user-defined object type, then subsequent \texttt{INSERT, UPDATE, DELETE} or \texttt{MERGE} operations that modify the LOB or object type column are executed serially without notification. Subsequent queries, however, will be executed in parallel.
\item A parallel hint overrides the effect of the \texttt{parallel\_clause}.
\end{itemize}
\end{itemize}
- DML statements and `CREATE TABLE ... AS SELECT` statements that reference remote objects can run in parallel. However, the remote object must really be on a remote database. The reference cannot loop back to an object on the local database, for example, by way of a synonym on the remote database pointing back to an object on the local database.

- DML operations on tables with LOB columns can be parallelized. However, intrapartition parallelism is not supported.

**See Also:** *Oracle Database VLDB and Partitioning Guide* for more information on parallelized operations, and "Creating a Table: Parallelism Examples" on page 16-91
物理属性子句

目的

物理属性子句允许您指定 PCTFREE、PCTUSED 和 INITRANS 参数的值，以及表、簇、索引或物化视图的存储特性。

您可以使用物理属性子句在以下语句中:

- 创建簇 (CREATE CLUSTER) 和更改变簇 (ALTER CLUSTER): 设置或更改簇及其所有表的物理属性（见 CREATE CLUSTER 页 14-11 和 ALTER CLUSTER 页 10-28）。
- 创建表 (CREATE TABLE): 设置表、表分区、对象表的 OIDINDEX，或索引组织表的溢出段（见 CREATE TABLE 页 16-6）。
- 更改变表 (ALTER TABLE): 更改变表的物理属性、未来表分区的默认物理属性，或现有表分区的物理属性（见 ALTER TABLE 页 12-2）。以下是限制条件:
  - 您不能为临时表指定物理属性。
  - 您不能为簇表指定物理属性。簇中的表继承簇的物理属性。
- 创建索引 (CREATE INDEX): 设置索引或索引分区的物理属性（见 CREATE INDEX 页 14-73）。
- 更改索引 (ALTER INDEX): 更改索引的物理属性、未来索引分区的默认物理属性，或现有索引分区的物理属性（见 ALTER INDEX 页 10-107）。
- 创建物化视图 (CREATE MATERIALIZED VIEW): 设置物化视图、物化视图分区或 Oracle 生成的维护物化视图的索引（见 CREATE MATERIALIZED VIEW 页 15-4）。
- 更改物化视图 (ALTER MATERIALIZED VIEW): 更改变物化视图的物理属性、未来分区的默认物理属性，或现有分区的物理属性，或 Oracle 创建的维护物化视图的索引（见 ALTER MATERIALIZED VIEW 页 11-3）。
- 创建物化视图日志 (CREATE MATERIALIZED VIEW LOG) 和更改物化视图日志 (ALTER MATERIALIZED VIEW LOG): 设置或更改物化视图日志的物理属性（见 CREATE MATERIALIZED VIEW LOG 页 15-31 和 ALTER MATERIALIZED VIEW LOG 页 11-20）。

语法

physical_attributes_clause::= PCTFREE integer PCTUSED integer INITRANS integer storage_clause
Semantics

This section describes the parameters of the `physical_attributes_clause`. For additional information, refer to the SQL statement in which you set or reset these parameters for a particular database object.

**PCTFREE** integer

Specify a whole number representing the percentage of space in each data block of the database object reserved for future updates to rows of the object. The value of `PCTFREE` must be a value from 0 to 99. A value of 0 means that the entire block can be filled by inserts of new rows. The default value is 10. This value reserves 10% of each block for updates to existing rows and allows inserts of new rows to fill a maximum of 90% of each block.

`PCTFREE` has the same function in the statements that create and alter tables, partitions, clusters, indexes, materialized views, materialized view logs, and zone maps. The combination of `PCTFREE` and `PCTUSED` determines whether new rows will be inserted into existing data blocks or into new blocks. See "How PCTFREE and PCTUSED Work Together" on page 8-45.

**Restriction on the PCTFREE Clause**

When altering an index, you can specify this parameter only in the `modify_index_default_attrs` clause and the `split_index_partition` clause.

**PCTUSED** integer

Specify a whole number representing the minimum percentage of used space that Oracle maintains for each data block of the database object. `PCTUSED` is specified as a positive integer from 0 to 99 and defaults to 40.

`PCTUSED` has the same function in the statements that create and alter tables, partitions, clusters, materialized views, materialized view logs, and zone maps.

`PCTUSED` is not a valid table storage characteristic for an index-organized table.

The sum of `PCTFREE` and `PCTUSED` must be equal to or less than 100. You can use `PCTFREE` and `PCTUSED` together to utilize space within a database object more efficiently. See "How PCTFREE and PCTUSED Work Together" on page 8-45.

**Restrictions on the PCTUSED Clause**

The `PCTUSED` parameter is subject to the following restrictions:

- You cannot specify this parameter for an index or for the index segment of an index-organized table.
- This parameter is not useful and is ignored for objects with automatic segment-space management.

**See Also:** Oracle Database Performance Tuning Guide for information on the performance effects of different values of `PCTUSED` and `PCTFREE` and `CREATE TABLESPACE segment_management_clause` on page 16-111 for information on automatic segment-space management.

**How PCTFREE and PCTUSED Work Together**

In a newly allocated data block, the space available for inserts is the block size minus the sum of the block overhead and free space (`PCTFREE`). Updates to existing data can
use any available space in the block. Therefore, updates can reduce the available space of a block to less than PCTFREE.

After a data block is filled to the limit determined by PCTFREE, Oracle Database considers the block unavailable for the insertion of new rows until the percentage of that block falls beneath the parameter PCTUSED. Until this value is achieved, Oracle Database uses the free space of the data block only for updates to rows already contained in the data block. A block becomes a candidate for row insertion when its used space falls below PCTUSED.

See Also: FREELISTS on page 8-53 for information on how PCTUSED and PCTFREE work with freelist segment space management

INITRANS integer
Specify the initial number of concurrent transaction entries allocated within each data block allocated to the database object. This value can range from 1 to 255 and defaults to 1, with the following exceptions:

- The default INITRANS value for a cluster is 2 or the default INITRANS value of the tablespace in which the cluster resides, whichever is greater.
- The default value for an index is 2.

In general, you should not change the INITRANS value from its default.

Each transaction that updates a block requires a transaction entry in the block. This parameter ensures that a minimum number of concurrent transactions can update the block and helps avoid the overhead of dynamically allocating a transaction entry.

The INITRANS parameter serves the same purpose in the statements that create and alter tables, partitions, clusters, indexes, materialized views, and materialized view logs.

MAXTRANS Parameter
In earlier releases, the MAXTRANS parameter determined the maximum number of concurrent update transactions allowed for each data block in the segment. This parameter has been deprecated. Oracle now automatically allows up to 255 concurrent update transactions for any data block, depending on the available space in the block.

Existing objects for which a value of MAXTRANS has already been set retain that setting. However, if you attempt to change the value for MAXTRANS, Oracle ignores the new specification and substitutes the value 255 without returning an error.

storage_clause
The storage_clause lets you specify storage characteristics for the table, object table OIDINDEX, partition, LOB data segment, or index-organized table overflow data segment. This clause has performance ramifications for large tables. Storage should be allocated to minimize dynamic allocation of additional space. Refer to the storage_clause on page 8-48 for more information.
size_clause

Purpose

The size_clause lets you specify a number of bytes, kilobytes (K), megabytes (M), gigabytes (G), terabytes (T), petabytes (P), or exabytes (E) in any statement that lets you establish amounts of disk or memory space.

Syntax

size_clause ::= 

Semantics

Use the size_clause to specify a number or multiple of bytes. If you do not specify any of the multiple abbreviations, then the integer is interpreted as bytes.

Note: Not all multiples of bytes are appropriate in all cases, and context-sensitive limitations may apply. In the latter case, Oracle issues an error message.
**storage_clause**

**Purpose**

The *storage_clause* lets you specify how Oracle Database should store a permanent database object. Storage parameters for temporary segments always use the default storage parameters for the associated tablespace. Storage parameters affect both how long it takes to access data stored in the database and how efficiently space in the database is used.

**See Also:** *Oracle Automatic Storage Management Administrator’s Guide* for a discussion of the effects of the storage parameters

When you create a cluster, index, materialized view, materialized view log, rollback segment, table, LOB, varray, nested table, or partition, you can specify values for the storage parameters for the segments allocated to these objects. If you omit any storage parameter, then Oracle uses the value of that parameter specified for the tablespace in which the object resides. If no value was specified for the tablespace, then the database uses default values.

**Note:** The specification of storage parameters for objects in locally managed tablespaces is supported for backward compatibility. If you are using locally managed tablespaces, then you can omit these storage parameter when creating objects in those tablespaces.

When you alter a cluster, index, materialized view, materialized view log, rollback segment, table, varray, nested table, or partition, you can change the values of storage parameters. The new values affect only future extent allocations.

The *storage_clause* is part of the *physical_attributes_clause*, so you can specify this clause in any of the statements where you can specify the physical attributes clause (see *physical_attributes_clause* on page 8-44). In addition, you can specify the *storage_clause* in the following statements:

- **CREATE CLUSTER** and **ALTER CLUSTER**: to set or change the storage characteristics of the *cluster and all tables in the cluster* (see CREATE CLUSTER on page 14-11 and ALTER CLUSTER on page 10-28).

- **CREATE INDEX** and **ALTER INDEX**: to set or change the storage characteristics of an index segment created for a *table index or index partition* or an *index segment created for an index used to enforce a primary key or unique constraint* (see CREATE INDEX on page 14-73 and ALTER INDEX on page 10-107).

- The **ENABLE ... USING INDEX** clause of **CREATE TABLE** or **ALTER TABLE**: to set or change the storage characteristics of an *index created by the system to enforce a primary key or unique constraint*.

- **CREATE MATERIALIZED VIEW** and **ALTER MATERIALIZED VIEW**: to set or change the storage characteristics of a *materialized view, one of its partitions, or the index Oracle generates to maintain the materialized view* (see CREATE MATERIALIZED VIEW on page 15-4 and ALTER MATERIALIZED VIEW on page 11-3).

- **CREATE MATERIALIZED VIEW LOG** and **ALTER MATERIALIZED VIEW LOG**: to set or change the storage characteristics of the *materialized view log* (see CREATE MATERIALIZED VIEW LOG on page 15-31 and ALTER MATERIALIZED VIEW LOG).
LOG on page 11-20).

- **CREATE ROLLBACK SEGMENT** and **ALTER ROLLBACK SEGMENT**: to set or change the storage characteristics of a rollback segment (see **CREATE ROLLBACK SEGMENT** on page 15-91 and **ALTER ROLLBACK SEGMENT** on page 11-60).

- **CREATE TABLE** and **ALTER TABLE**: to set the storage characteristics of a LOB or varray data segment of the nonclustered table or one of its partitions or subpartitions, or the storage table of a nested table (see **CREATE TABLE** on page 16-6 and **ALTER TABLE** on page 12-2).

- **CREATE TABLESPACE** and **ALTER TABLESPACE**: to set or change the default storage characteristics for objects created in the tablespace (see **CREATE TABLESPACE** on page 16-102 and **ALTER TABLESPACE** on page 12-114). Changes to tablespace storage parameters affect only new objects created in the tablespace or new extents allocated for a segment.

- **constraint**: to specify storage for the index (and its partitions, if it is a partitioned index) used to enforce the constraint (see **constraint** on page 8-4).

**Prerequisites**

To change the value of a **STORAGE** parameter, you must have the privileges necessary to use the appropriate **CREATE** or **ALTER** statement.
Syntax

storage_clause ::= (size_clause ∥ on page 8-47)

maxsize_clause ::= (size_clause := on page 8-47)

Semantics

This section describes the parameters of the storage_clause. For additional information, refer to the SQL statement in which you set or reset these storage parameters for a particular database object.
INITIAL

Specify the size of the first extent of the object. Oracle allocates space for this extent when you create the schema object. Refer to size_clause on page 8-47 for information on that clause.

In locally managed tablespaces, Oracle uses the value of INITIAL, in conjunction with the type of local management—AUTOALLOCATE or UNIFORM—and the values of MINEXTENTS, NEXT and PCTINCREASE, to determine the initial size of the segment.

- With AUTOALLOCATE extent management, Oracle uses the INITIAL setting to optimize the number of extents allocated. Extents of 64K, 1M, 8M, and 64M can be allocated. During segment creation, the system chooses the greatest of these four sizes that is equal to or smaller than INITIAL, and allocates as many extents of that size as are needed to reach the INITIAL setting. For example, if you set INITIAL to 4M, then the database creates four 1M extents.

- For UNIFORM extent management, the number of extents is determined from initial segment size and the uniform extent size specified at tablespace creation time. For example, in a uniform locally managed tablespace with 1M extents, if you specify an INITIAL value of 5M, then Oracle creates five 1M extents.

Consider this comparison: With AUTOALLOCATE, if you set INITIAL to 72K, then the initial segment size will be 128K (greater than INITIAL). The database cannot allocate an extent smaller than 64K, so it must allocate two 64K extents. If you set INITIAL to 72K with a UNIFORM extent size of 24K, then the database will allocate three 24K extents to equal 72K.

In dictionary-managed tablespaces, the default initial extent size is 5 blocks, and all subsequent extents are rounded to 5 blocks. If MINIMUM EXTENT was specified at tablespace creation time, then the extent sizes are rounded to the value of MINIMUM EXTENT.

Restriction on INITIAL  You cannot specify INITIAL in an ALTER statement.

NEXT

Specify in bytes the size of the next extent to be allocated to the object. Refer to size_clause on page 8-47 for information on that clause.

In locally managed tablespaces, any user-supplied value for NEXT is ignored and the size of NEXT is determined by Oracle if the tablespace is set for autoallocate extent management. In UNIFORM tablespaces, the size of NEXT is the uniform extent size specified at tablespace creation time.

In dictionary-managed tablespaces, the default value is the size of 5 data blocks. The minimum value is the size of 1 data block. The maximum value depends on your operating system. Oracle rounds values up to the next multiple of the data block size.
for values less than 5 data blocks. For values greater than 5 data blocks, Oracle rounds up to a value that minimizes fragmentation.

See Also: Oracle Database Concepts for information on how Oracle minimizes fragmentation

PCTINCREASE
In locally managed tablespaces, Oracle Database uses the value of PCTINCREASE during segment creation to determine the initial segment size and ignores this parameter during subsequent space allocation.

In dictionary-managed tablespaces, specify the percent by which the third and subsequent extents grow over the preceding extent. The default value is 50, meaning that each subsequent extent is 50% larger than the preceding extent. The minimum value is 0, meaning all extents after the first are the same size. The maximum value depends on your operating system. Oracle rounds the calculated size of each new extent to the nearest multiple of the data block size. If you change the value of the PCTINCREASE parameter by specifying it in an ALTER statement, then Oracle calculates the size of the next extent using this new value and the size of the most recently allocated extent.

Restriction on PCTINCREASE You cannot specify PCTINCREASE for rollback segments. Rollback segments always have a PCTINCREASE value of 0.

MINEXTENTS
In locally managed tablespaces, Oracle Database uses the value of MINEXTENTS in conjunction with PCTINCREASE, INITIAL and NEXT to determine the initial segment size.

In dictionary-managed tablespaces, specify the total number of extents to allocate when the object is created. The default and minimum value is 1, meaning that Oracle allocates only the initial extent, except for rollback segments, for which the default and minimum value is 2. The maximum value depends on your operating system.

■ In a locally managed tablespace, MINEXTENTS is used to compute the initial amount of space allocated, which is equal to INITIAL * MINEXTENTS. Thereafter this value is set to 1, which is reflected in the DBA_SEGMENTS view.

■ In a dictionary-managed tablespace, MINEXTENTS is simply the minimum number of extents that must be allocated to the segment.

If the MINEXTENTS value is greater than 1, then Oracle calculates the size of subsequent extents based on the values of the INITIAL, NEXT, and PCTINCREASE storage parameters.

When changing the value of MINEXTENTS by specifying it in an ALTER statement, you can reduce the value from its current value, but you cannot increase it. Resetting MINEXTENTS to a smaller value might be useful, for example, before a TRUNCATE ... DROP STORAGE statement, if you want to ensure that the segment will maintain a minimum number of extents after the TRUNCATE operation.

Restrictions on MINEXTENTS The MINEXTENTS storage parameter is subject to the following restrictions:

■ MINEXTENTS is not applicable at the tablespace level.

■ You cannot change the value of MINEXTENTS in an ALTER statement or for an object that resides in a locally managed tablespace.
MAXEXTENTS
This storage parameter is valid only for objects in dictionary-managed tablespaces. Specify the total number of extents, including the first, that Oracle can allocate for the object. The minimum value is 1 except for rollback segments, which always have a minimum of 2. The default value depends on your data block size.

Restriction on MAXEXTENTS  MAXEXTENTS is ignored for objects residing in a locally managed tablespace, unless the value of ALLOCATION_TYPE is USER for the tablespace in the DBA_TABLESPACES data dictionary view.

See Also:  Oracle Database Reference for more information on the DBA_TABLESPACES data dictionary view

UNLIMITED Specify UNLIMITED if you want extents to be allocated automatically as needed. Oracle recommends this setting as a way to minimize fragmentation.

Do not use this clause for rollback segments. Doing so allows the possibility that long-running rogue DML transactions will continue to create new extents until a disk is full.

Caution:  A rollback segment that you create without specifying the storage_clause has the same storage parameters as the tablespace in which the rollback segment is created. Thus, if you create a tablespace with MAXEXTENTS UNLIMITED, then the rollback segment will have this same default.

MAXSIZE
The MAXSIZE clause lets you specify the maximum size of the storage element. For LOB storage, MAXSIZE has the following effects

- If you specify RETENTION MAX in LOB_parameters, then the LOB segment increases to the specified size before any space can be reclaimed from undo space.
- If you specify RETENTION AUTO, MIN, or NONE in LOB_parameters, then the specified size is a hard limit on the LOB segment size and has no bearing on undo retention.

UNLIMITED Use the UNLIMITED clause if you do not want to limit the disk space of the storage element. This clause is not compatible with a specification of RETENTION MAX in LOB_parameters. If you specify both, then the database uses RETENTION AUTO and MAXSIZE UNLIMITED.

FREELISTS
In tablespaces with manual segment-space management, Oracle Database uses the FREELISTS storage parameter to improve performance of space management in OLTP systems by increasing the number of insert points in the segment. In tablespaces with automatic segment-space management, this parameter is ignored, because the database adapts to varying workload.

In tablespaces with manual segment-space management, for objects other than tablespaces and rollback segments, specify the number of free lists for each of the free list groups for the table, partition, cluster, or index. The default and minimum value for this parameter is 1, meaning that each free list group contains one free list. The maximum value of this parameter depends on the data block size. If you specify a
**FREELISTS** value that is too large, then Oracle returns an error indicating the maximum value.

This clause is not valid or useful if you have specified the **SECUREFILE** parameter of **LOB_parameters** on page 16-58. If you specify both the **SECUREFILE** parameter and **FREELISTS**, then the database silently ignores the **FREELISTS** specification.

**Restriction on FREELISTS** You can specify **FREELISTS** in the *storage_clause* of any statement except when creating or altering a tablespace or rollback segment.

**FREELIST GROUPS**

In tablespaces with manual segment-space management, Oracle Database uses the value of this storage parameter to statically partition the segment free space in an Oracle Real Application Clusters environment. This partitioning improves the performance of space allocation and deallocation by avoiding inter instance transfer of segment metadata. In tablespaces with automatic segment-space management, this parameter is ignored, because Oracle dynamically adapts to inter instance workload.

In tablespaces with manual segment-space management, specify the number of groups of free lists for the database object you are creating. The default and minimum value for this parameter is 1. Oracle uses the instance number of Oracle Real Application Clusters (Oracle RAC) instances to map each instance to one free list group.

Each free list group uses one database block. Therefore:

- If you do not specify a large enough value for **INITIAL** to cover the minimum value plus one data block for each free list group, then Oracle increases the value of **INITIAL** the necessary amount.
- If you are creating an object in a uniform locally managed tablespace, and the extent size is not large enough to accommodate the number of freelist groups, then the create operation will fail.

This clause is not valid or useful if you have specified the **SECUREFILE** parameter of **LOB_parameters** on page 16-58. If you specify both the **SECUREFILE** parameter and **FREELIST GROUPS**, then the database silently ignores the **FREELIST GROUPS** specification.

**Restriction on FREELIST GROUPS** You can specify the **FREELIST GROUPS** parameter only in **CREATE TABLE**, **CREATE CLUSTER**, **CREATE MATERIALIZED VIEW**, **CREATE MATERIALIZED VIEW LOG**, and **CREATE INDEX** statements.

**OPTIMAL**

The **OPTIMAL** keyword is relevant only to rollback segments. It specifies an optimal size in bytes for a rollback segment. Refer to *size_clause* on page 8-47 for information on that clause.

Oracle tries to maintain this size for the rollback segment by dynamically deallocating extents when their data is no longer needed for active transactions. Oracle deallocates as many extents as possible without reducing the total size of the rollback segment below the **OPTIMAL** value.

The value of **OPTIMAL** cannot be less than the space initially allocated by the **MINEXTENTS**, **INITIAL**, **NEXT**, and **PCTINCREASE** parameters. The maximum value depends on your operating system. Oracle rounds values up to the next multiple of the data block size.

**NULL** Specify **NULL** for no optimal size for the rollback segment, meaning that Oracle never deallocates the extents of the rollback segment. This is the default behavior.
The `BUFFER_POOL` clause lets you specify a default buffer pool or cache for a schema object. All blocks for the object are stored in the specified cache.

- If you define a buffer pool for a partitioned table or index, then the partitions inherit the buffer pool from the table or index definition unless overridden by a partition-level definition.
- For an index-organized table, you can specify a buffer pool separately for the index segment and the overflow segment.

**Restrictions on the `BUFFER_POOL` Parameter** `BUFFER_POOL` is subject to the following restrictions:

- You cannot specify this clause for a cluster table. However, you can specify it for a cluster.
- You cannot specify this clause for a tablespace or a rollback segment.

**KEEP** Specify `KEEP` to put blocks from the segment into the `KEEP` buffer pool. Maintaining an appropriately sized `KEEP` buffer pool lets Oracle retain the schema object in memory to avoid I/O operations. `KEEP` takes precedence over any `NOCACHE` clause you specify for a table, cluster, materialized view, or materialized view log.

**RECYCLE** Specify `RECYCLE` to put blocks from the segment into the `RECYCLE` pool. An appropriately sized `RECYCLE` pool reduces the number of objects whose default pool is the `RECYCLE` pool from taking up unnecessary cache space.

**DEFAULT** Specify `DEFAULT` to indicate the default buffer pool. This is the default for objects not assigned to `KEEP` or `RECYCLE`.

**FLASH_CACHE** The `FLASH_CACHE` clause lets you override the automatic buffer cache policy and specify how specific schema objects are cached in flash memory. To use this clause, Database Smart Flash Cache (flash cache) must be configured on your system. The flash cache is an extension of the database buffer cache that is stored on a flash disk, a storage device that uses flash memory. Because flash memory is faster than magnetic disks, the database can improve performance by caching buffers in the flash cache instead of reading from magnetic disk.

**KEEP** Specify `KEEP` if you want the schema object buffers to remain cached in the flash cache as long as the flash cache is large enough.

**NONE** Specify `NONE` to ensure that the schema object buffers are never cached in the flash cache. This allows you to reserve the flash cache space for more frequently accessed objects.

**DEFAULT** Specify `DEFAULT` if you want the schema object buffers to be written to the flash cache when they are aged out of main memory, and then be aged out of the flash cache with the standard buffer cache replacement algorithm. This is the default if flash cache is configured and you do not specify `KEEP` or `NONE`.

See Also: Oracle Database Performance Tuning Guide for more information about using multiple buffer pools.
ENCRYPT
This clause is valid only when you are creating a tablespace. Specify ENCRYPT to encrypt the entire tablespace. You must also specify the ENCRYPTION clause in the CREATE TABLESPACE statement.

See Also: The CREATE TABLESPACE "ENCRYPTION Clause" on page 16-109

Example

Specifying Table Storage Attributes: Example  The following statement creates a table and provides storage parameter values:

```
CREATE TABLE divisions
  (div_no NUMBER(2),
   div_name VARCHAR2(14),
   location VARCHAR2(13) )
   STORAGE  ( INITIAL 8M MAXSIZE 1G );
```

Oracle allocates space for the table based on the STORAGE parameter values as follows:

- The INITIAL value is 8M, so the size of the first extent is 8 megabytes.
- The MAXSIZE value is 1G, so the maximum size of the storage element is 1 gigabyte.
This chapter describes SQL queries and subqueries.

This chapter contains these sections:

- About Queries and Subqueries
- Creating Simple Queries
- Hierarchical Queries
- The UNION [ALL], INTERSECT, MINUS Operators
- Sorting Query Results
- Joins
- Using Subqueries
- Unnesting of Nested Subqueries
- Selecting from the DUAL Table
- Distributed Queries

About Queries and Subqueries

A query is an operation that retrieves data from one or more tables or views. In this reference, a top-level SELECT statement is called a query, and a query nested within another SQL statement is called a subquery.

This section describes some types of queries and subqueries and how to use them. The top level of the syntax is shown in this chapter. Refer to SELECT on page 19-4 for the full syntax of all the clauses and the semantics of this statement.

\[
\text{select} ::= \text{subquery} \quad \text{for_update_clause}
\]
Creating Simple Queries

The list of expressions that appears after the `SELECT` keyword and before the `FROM` clause is called the **select list**. Within the select list, you specify one or more columns in the set of rows you want Oracle Database to return from one or more tables, views, or materialized views. The number of columns, as well as their data type and length, are determined by the elements of the select list.

If two or more tables have some column names in common, then you must qualify column names with names of tables. Otherwise, fully qualified column names are optional. However, it is always a good idea to qualify table and column references explicitly. Oracle often does less work with fully qualified table and column names.

You can use a column alias, `c_alias`, to label the immediately preceding expression in the select list so that the column is displayed with a new heading. The alias effectively renames the select list item for the duration of the query. The alias can be used in the `ORDER BY` clause, but not other clauses in the query.

You can use comments in a `SELECT` statement to pass instructions, or **hints**, to the Oracle Database optimizer. The optimizer uses hints to choose an execution plan for the statement. Refer to "Hints" on page 2-77 for more information on hints.
Hierarchical Queries

If a table contains hierarchical data, then you can select rows in a hierarchical order using the hierarchical query clause:

$hierarchical\_query\_clause::=\$

$condition$

$START\ WITH$ specifies the root row(s) of the hierarchy.

$CONNECT\ BY$ specifies the relationship between parent rows and child rows of the hierarchy.

- The NOCYCLE parameter instructs Oracle Database to return rows from a query even if a $CONNECT\ BY$ loop exists in the data. Use this parameter along with the $CONNECT\_BY\_ISCYCLE$ pseudocolumn to see which rows contain the loop. Refer to $CONNECT\_BY\_ISCYCLE$ Pseudocolumn on page 3-1 for more information.

- In a hierarchical query, one expression in $condition$ must be qualified with the PRIOR operator to refer to the parent row. For example,
  
  ...
  PRIOR $expr = expr$
  or
  ...
  $expr = PRIOR expr$

If the $CONNECT\ BY$ $condition$ is compound, then only one condition requires the PRIOR operator, although you can have multiple PRIOR conditions. For example:

CONNECT BY last_name != 'King' AND PRIOR employee_id = manager_id 
CONNECT BY PRIOR employee_id = manager_id and
PRIOR account_mgr_id = customer_id ...

PRIOR is a unary operator and has the same precedence as the unary + and - arithmetic operators. It evaluates the immediately following expression for the parent row of the current row in a hierarchical query.

PRIOR is most commonly used when comparing column values with the equality operator. (The PRIOR keyword can be on either side of the operator.) PRIOR causes Oracle to use the value of the parent row in the column. Operators other than the equal sign (=) are theoretically possible in $CONNECT\ BY$ clauses. However, the conditions created by these other operators can result in an infinite loop through the possible combinations. In this case Oracle detects the loop at run time and returns an error.

Both the $CONNECT\ BY$ $condition$ and the PRIOR expression can take the form of an uncorrelated subquery. However, CURRVAL and NEXTVAL are not valid PRIOR expressions, so the PRIOR expression cannot refer to a sequence.

You can further refine a hierarchical query by using the $CONNECT\ BY\_ROOT$ operator to qualify a column in the select list. This operator extends the functionality of the $CONNECT\ BY\ [PRIOR]$ condition of hierarchical queries by returning not only the immediate parent row but all ancestor rows in the hierarchy.
Oracle processes hierarchical queries as follows:

- A join, if present, is evaluated first, whether the join is specified in the `FROM` clause or with `WHERE` clause predicates.
- The `CONNECT BY` condition is evaluated.
- Any remaining `WHERE` clause predicates are evaluated.

Oracle then uses the information from these evaluations to form the hierarchy using the following steps:

1. Oracle selects the root row(s) of the hierarchy—those rows that satisfy the `START WITH` condition.
2. Oracle selects the child rows of each root row. Each child row must satisfy the condition of the `CONNECT BY` condition with respect to one of the root rows.
3. Oracle selects successive generations of child rows. Oracle first selects the children of the rows returned in step 2, and then the children of those children, and so on. Oracle always selects children by evaluating the `CONNECT BY` condition with respect to a current parent row.
4. If the query contains a `WHERE` clause without a join, then Oracle eliminates all rows from the hierarchy that do not satisfy the condition of the `WHERE` clause. Oracle evaluates this condition for each row individually, rather than removing all the children of a row that does not satisfy the condition.
5. Oracle returns the rows in the order shown in Figure 9–1. In the diagram, children appear below their parents. For an explanation of hierarchical trees, see Figure 3–1, "Hierarchical Tree" on page 3-3.

Figure 9–1 Hierarchical Queries

![Hierarchical Queries Diagram](image-url)

To find the children of a parent row, Oracle evaluates the `PRIOR` expression of the `CONNECT BY` condition for the parent row and the other expression for each row in the table. Rows for which the condition is true are the children of the parent. The `CONNECT BY` condition can contain other conditions to further filter the rows selected by the query.

If the `CONNECT BY` condition results in a loop in the hierarchy, then Oracle returns an error. A loop occurs if one row is both the parent (or grandparent or direct ancestor) and a child (or a grandchild or a direct descendent) of another row.
Hierarchical Queries

**CONNECT BY Example**  The following hierarchical query uses the CONNECT BY clause to define the relationship between employees and managers:

```sql
SELECT employee_id, last_name, manager_id
FROM employees
CONNECT BY PRIOR employee_id = manager_id;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>MANAGER_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>Kochhar</td>
<td>100</td>
</tr>
<tr>
<td>108</td>
<td>Greenberg</td>
<td>101</td>
</tr>
<tr>
<td>109</td>
<td>Faviet</td>
<td>108</td>
</tr>
<tr>
<td>110</td>
<td>Chen</td>
<td>108</td>
</tr>
<tr>
<td>111</td>
<td>Sciarra</td>
<td>108</td>
</tr>
<tr>
<td>112</td>
<td>Urman</td>
<td>108</td>
</tr>
<tr>
<td>113</td>
<td>Popp</td>
<td>108</td>
</tr>
<tr>
<td>200</td>
<td>Whalen</td>
<td>101</td>
</tr>
<tr>
<td>203</td>
<td>Mavris</td>
<td>101</td>
</tr>
<tr>
<td>204</td>
<td>Baer</td>
<td>101</td>
</tr>
</tbody>
</table>

```

**LEVEL Example**  The next example is similar to the preceding example, but uses the LEVEL pseudocolumn to show parent and child rows:

```sql
SELECT employee_id, last_name, manager_id, LEVEL
FROM employees
CONNECT BY PRIOR employee_id = manager_id;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>MANAGER_ID</th>
<th>LEVEL</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>Kochhar</td>
<td>100</td>
<td>1</td>
</tr>
<tr>
<td>108</td>
<td>Greenberg</td>
<td>101</td>
<td>2</td>
</tr>
<tr>
<td>109</td>
<td>Faviet</td>
<td>108</td>
<td>3</td>
</tr>
<tr>
<td>110</td>
<td>Chen</td>
<td>108</td>
<td>3</td>
</tr>
<tr>
<td>111</td>
<td>Sciarra</td>
<td>108</td>
<td>3</td>
</tr>
<tr>
<td>112</td>
<td>Urman</td>
<td>108</td>
<td>3</td>
</tr>
<tr>
<td>113</td>
<td>Popp</td>
<td>108</td>
<td>3</td>
</tr>
<tr>
<td>200</td>
<td>Whalen</td>
<td>101</td>
<td>2</td>
</tr>
<tr>
<td>203</td>
<td>Mavris</td>
<td>101</td>
<td>2</td>
</tr>
<tr>
<td>204</td>
<td>Baer</td>
<td>101</td>
<td>2</td>
</tr>
<tr>
<td>205</td>
<td>Higgins</td>
<td>101</td>
<td>2</td>
</tr>
<tr>
<td>206</td>
<td>Gietz</td>
<td>205</td>
<td>3</td>
</tr>
<tr>
<td>102</td>
<td>De Haan</td>
<td>100</td>
<td>1</td>
</tr>
</tbody>
</table>

```

**START WITH Examples**  The next example adds a START WITH clause to specify a root row for the hierarchy and an ORDER BY clause using the SIBLINGS keyword to preserve ordering within the hierarchy:

```sql
SELECT last_name, employee_id, manager_id, LEVEL
FROM employees
CONNECT BY PRIOR employee_id = manager_id;
```

```sql
SELECT last_name, employee_id, manager_id, LEVEL
FROM employees
CONNECT BY PRIOR employee_id = manager_id;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>EMPLOYEE_ID</th>
<th>MANAGER_ID</th>
<th>LEVEL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kochhar</td>
<td>101</td>
<td>100</td>
<td>1</td>
</tr>
<tr>
<td>Greenberg</td>
<td>108</td>
<td>101</td>
<td>2</td>
</tr>
<tr>
<td>Faviet</td>
<td>109</td>
<td>108</td>
<td>3</td>
</tr>
<tr>
<td>Chen</td>
<td>110</td>
<td>108</td>
<td>3</td>
</tr>
<tr>
<td>Sciarra</td>
<td>111</td>
<td>108</td>
<td>3</td>
</tr>
<tr>
<td>Urman</td>
<td>112</td>
<td>108</td>
<td>3</td>
</tr>
<tr>
<td>Popp</td>
<td>113</td>
<td>108</td>
<td>3</td>
</tr>
<tr>
<td>Whalen</td>
<td>200</td>
<td>101</td>
<td>2</td>
</tr>
<tr>
<td>Mavris</td>
<td>203</td>
<td>101</td>
<td>2</td>
</tr>
<tr>
<td>Baer</td>
<td>204</td>
<td>101</td>
<td>2</td>
</tr>
<tr>
<td>Higgins</td>
<td>205</td>
<td>101</td>
<td>2</td>
</tr>
<tr>
<td>Gietz</td>
<td>206</td>
<td>205</td>
<td>3</td>
</tr>
<tr>
<td>De Haan</td>
<td>102</td>
<td>100</td>
<td>1</td>
</tr>
</tbody>
</table>

```

---

**Note:** In a hierarchical query, do not specify either ORDER BY or GROUP BY, as they will override the hierarchical order of the CONNECT BY results. If you want to order rows of siblings of the same parent, then use the ORDER SIBLINGS BY clause. See order_by_clause on page 19-40.
START WITH employee_id = 100
CONNECT BY PRIOR employee_id = manager_id
ORDER SIBLINGS BY last_name;

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>EMPLOYEE_ID</th>
<th>MANAGER_ID</th>
<th>LEVEL</th>
</tr>
</thead>
<tbody>
<tr>
<td>King</td>
<td>100</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>Cambrault</td>
<td>148</td>
<td>100</td>
<td>2</td>
</tr>
<tr>
<td>Bates</td>
<td>172</td>

</tbody>
</table>

In the hr.employees table, the employee Steven King is the head of the company and has no manager. Among his employees is John Russell, who is the manager of department 80. If you update the employees table to set Russell as King's manager, you create a loop in the data:

UPDATE employees SET manager_id = 145
WHERE employee_id = 100;

SELECT last_name 'Employee',
   LEVEL, SYS_CONNECT_BY_PATH(last_name, '/') "Path"
FROM employees
WHERE level <= 3 AND department_id = 80
START WITH last_name = 'King'
CONNECT BY PRIOR employee_id = manager_id AND LEVEL <= 4;

ERROR:
ORA-01436: CONNECT BY loop in user data

The NOCYCLE parameter in the CONNECT BY condition causes Oracle to return the rows in spite of the loop. The CONNECT_BY_ISCYCLE pseudocolumn shows you which rows contain the cycle:

SELECT last_name 'Employee', CONNECT_BY_ISCYCLE 'Cycle',
   LEVEL, SYS_CONNECT_BY_PATH(last_name, '/') "Path"
FROM employees
WHERE level <= 3 AND department_id = 80
START WITH last_name = 'King'
CONNECT BY NOCYCLE PRIOR employee_id = manager_id AND LEVEL <= 4
ORDER BY "Employee", "Cycle", LEVEL, "Path";

<table>
<thead>
<tr>
<th>Employee</th>
<th>Cycle</th>
<th>LEVEL</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abel</td>
<td>0</td>
<td>3</td>
<td>/King/Zlotkey/Abel</td>
</tr>
<tr>
<td>Ande</td>
<td>0</td>
<td>3</td>
<td>/King/Errazuriz/Ande</td>
</tr>
<tr>
<td>Banda</td>
<td>0</td>
<td>3</td>
<td>/King/Errazuriz/Banda</td>
</tr>
<tr>
<td>Bates</td>
<td>0</td>
<td>3</td>
<td>/King/Cambrault/Bates</td>
</tr>
</tbody>
</table>
CONNECT_BY_ISLEAF Example The following statement shows how you can use a hierarchical query to turn the values in a column into a comma-delimited list:

```sql
SELECT LTRIM(SYS_CONNECT_BY_PATH (warehouse_id,','),',') FROM
(SELECT ROWNUM r, warehouse_id FROM warehouses)
WHERE CONNECT_BY_ISLEAF = 1
START WITH r = 1
CONNECT BY r = PRIOR r + 1
ORDER BY warehouse_id;
```

```
1,2,3,4,5,6,7,8,9
```

CONNECT_BY_ROOT Examples The following example returns the last name of each employee in department 110, each manager at the highest level above that employee in the hierarchy, the number of levels between manager and employee, and the path between the two:

```sql
SELECT last_name "Employee", CONNECT_BY_ROOT last_name "Manager",
LEVEL-1 "Pathlen", SYS_CONNECT_BY_PATH(last_name, '/') "Path"
FROM employees
WHERE LEVEL > 1 and department_id = 110
CONNECT BY PRIOR employee_id = manager_id
ORDER BY "Employee", "Manager", "Pathlen", "Path";
```

```
Employee        Manager            Pathlen Path
--------------- --------------- ---------- ------------------------------
Gietz           Higgins                  1 /Higgins/Gietz
Gietz           King                     3 /King/Kochhar/Higgins/Gietz
Gietz           Kochhar                  2 /Kochhar/Higgins/Gietz
Higgins         King                     2 /King/Kochhar/Higgins
Higgins         Kochhar                  1 /Kochhar/Higgins
```

The following example uses a GROUP BY clause to return the total salary of each employee in department 110 and all employees above that employee in the hierarchy:

```sql
SELECT name, SUM(salary) "Total_Salary" FROM (SELECT CONNECT_BY_ROOT last_name as name, Salary FROM employees
WHERE department_id = 110
CONNECT BY PRIOR employee_id = manager_id)
GROUP BY name
ORDER BY name, "Total_Salary";
```

```
NAME                      Total_Salary
------------------------- ------------
Gietz                             8300
Higgins                          20300
King                             20300
Kochhar                          20300
```
The UNION [ALL], INTERSECT, MINUS Operators

You can combine multiple queries using the set operators `UNION`, `UNION ALL`, `INTERSECT`, and `MINUS`. All set operators have equal precedence. If a SQL statement contains multiple set operators, then Oracle Database evaluates them from the left to right unless parentheses explicitly specify another order.

The corresponding expressions in the select lists of the component queries of a compound query must match in number and must be in the same data type group (such as numeric or character).

If component queries select character data, then the data type of the return values are determined as follows:

- If both queries select values of data type `CHAR` of equal length, then the returned values have data type `CHAR` of that length. If the queries select values of `CHAR` with different lengths, then the returned value is `VARCHAR2` with the length of the larger `CHAR` value.
- If either or both of the queries select values of data type `VARCHAR2`, then the returned values have data type `VARCHAR2`.

If component queries select numeric data, then the data type of the return values is determined by numeric precedence:

- If any query selects values of type `BINARY_DOUBLE`, then the returned values have data type `BINARY_DOUBLE`.
- If no query selects values of type `BINARY_DOUBLE` but any query selects values of type `BINARY_FLOAT`, then the returned values have data type `BINARY_FLOAT`.
- If all queries select values of type `NUMBER`, then the returned values have data type `NUMBER`.

In queries using set operators, Oracle does not perform implicit conversion across data type groups. Therefore, if the corresponding expressions of component queries resolve to both character data and numeric data, Oracle returns an error.

See Also: Table 2–10, “Implicit Type Conversion Matrix” on page 2-43 for more information on implicit conversion and “Numeric Precedence” on page 2-16 for information on numeric precedence

Examples The following query is valid:

See Also: LEVEL Pseudocolumn on page 3-2 and CONNECT_BY_ISCYCLE Pseudocolumn on page 3-1 for a discussion of how these pseudocolumns operate in a hierarchical query

SYS_CONNECT_BY_PATH on page 7-333 for information on retrieving the path of column values from root to node

`order_by_clause` on page 19-40 for more information on the `SIBLINGS` keyword of `ORDER BY` clauses

`subquery_factoring_clause` on page 19-18, which supports recursive subquery factoring (recursive WITH) and lets you query hierarchical data. This feature is more powerful than `CONNECT BY` in that it provides depth-first search and breadth-first search, and supports multiple recursive branches.
SELECT 3 FROM DUAL
   INTERSECT
SELECT 3f FROM DUAL;

This is implicitly converted to the following compound query:

SELECT TO_BINARY_FLOAT(3) FROM DUAL
   INTERSECT
SELECT 3f FROM DUAL;

The following query returns an error:

SELECT '3' FROM DUAL
   INTERSECT
SELECT 3f FROM DUAL;

Restrictions on the Set Operators  The set operators are subject to the following restrictions:

- The set operators are not valid on columns of type BLOB, CLOB, BFILE, VARRAY, or nested table.
- The UNI仪表, INTERSECT, and MINUS operators are not valid on LONG columns.
- If the select list preceding the set operator contains an expression, then you must provide a column alias for the expression in order to refer to it in the order_by_clause.
- You cannot also specify the for update clause with the set operators.
- You cannot specify the order_by_clause in the subquery of these operators.
- You cannot use these operators in SELECT statements containing TABLE collection expressions.

Note:  To comply with emerging SQL standards, a future release of Oracle will give the INTERSECT operator greater precedence than the other set operators. Therefore, you should use parentheses to specify order of evaluation in queries that use the INTERSECT operator with other set operators.

UNION Example  The following statement combines the results of two queries with the UNION operator, which eliminates duplicate selected rows. This statement shows that you must match data type (using the TO_CHAR function) when columns do not exist in one or the other table:

SELECT location_id, department_name "Department",
       TO_CHAR(NULL) "Warehouse" FROM departments
UNION
SELECT location_id, TO_CHAR(NULL) "Department", warehouse_name
     FROM warehouses;

<table>
<thead>
<tr>
<th>LOCATION_ID</th>
<th>Department</th>
<th>Warehouse</th>
</tr>
</thead>
<tbody>
<tr>
<td>1400</td>
<td>IT</td>
<td>Southlake, Texas</td>
</tr>
<tr>
<td>1400</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1500</td>
<td>Shipping</td>
<td>San Francisco</td>
</tr>
<tr>
<td>1500</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1600</td>
<td></td>
<td>New Jersey</td>
</tr>
<tr>
<td>1700</td>
<td>Accounting</td>
<td></td>
</tr>
<tr>
<td>1700</td>
<td>Administration</td>
<td></td>
</tr>
</tbody>
</table>
UNION ALL Example The UNION operator returns only distinct rows that appear in either result, while the UNION ALL operator returns all rows. The UNION ALL operator does not eliminate duplicate selected rows:

```
SELECT product_id FROM order_items
UNION
SELECT product_id FROM inventories
ORDER BY product_id;

SELECT location_id FROM locations
UNION ALL
SELECT location_id FROM departments
ORDER BY location_id;
```

A location_id value that appears multiple times in either or both queries (such as '1700') is returned only once by the UNION operator, but multiple times by the UNION ALL operator.

INTERSECT Example The following statement combines the results with the INTERSECT operator, which returns only those unique rows returned by both queries:

```
SELECT product_id FROM inventories
INTERSECT
SELECT product_id FROM order_items
ORDER BY product_id;
```

MINUS Example The following statement combines results with the MINUS operator, which returns only unique rows returned by the first query but not by the second:

```
SELECT product_id FROM inventories
MINUS
SELECT product_id FROM order_items
ORDER BY product_id;
```

Sorting Query Results

Use the ORDER BY clause to order the rows selected by a query. Sorting by position is useful in the following cases:

- To order by a lengthy select list expression, you can specify its position in the ORDER BY clause rather than duplicate the entire expression.
- For compound queries containing set operators UNION, INTERSECT, MINUS, or UNION ALL, the ORDER BY clause must specify positions or aliases rather than explicit expressions. Also, the ORDER BY clause can appear only in the last component query. The ORDER BY clause orders all rows returned by the entire compound query.

The mechanism by which Oracle Database sorts character values for the ORDER BY clause, also known as the collation, is specified by the NLS_SORT session parameter. If this parameter is not set, then its default is derived from the NLS_LANGUAGE session parameter. You can change the collation dynamically using the ALTER SESSION SET NLS_SORT statement. You can also apply a specific collation by including the character expressions to be sorted as arguments to the NLSSORT function, with the collation specified in the second parameter.
When character values are compared linguistically for the ORDER BY clause, they are first transformed to collation keys and then compared like RAW values. The collation keys are generated either explicitly as specified in NLSSORT or implicitly using the same method that NLSSORT uses. Both explicitly and implicitly generated collation keys are subject to the same restrictions that are described in "NLSSORT" on page 7-208. As a result of these restrictions, two values may compare as linguistically equal if they do not differ in the prefix that was used to produce the collation key, even if they differ in the rest of the value.

See Also: NLSSORT on page 7-208 and Oracle Database Globalization Support Guide for information on the NLS parameters

Joins

A join is a query that combines rows from two or more tables, views, or materialized views. Oracle Database performs a join whenever multiple tables appear in the FROM clause of the query. The select list of the query can select any columns from any of these tables. If any two of these tables have a column name in common, then you must qualify all references to these columns throughout the query with table names to avoid ambiguity.

Join Conditions

Most join queries contain at least one join condition, either in the FROM clause or in the WHERE clause. The join condition compares two columns, each from a different table. To execute a join, Oracle Database combines pairs of rows, each containing one row from each table, for which the join condition evaluates to TRUE. The columns in the join conditions need not also appear in the select list.

To execute a join of three or more tables, Oracle first joins two of the tables based on the join conditions comparing their columns and then joins the result to another table based on join conditions containing columns of the joined tables and the new table. Oracle continues this process until all tables are joined into the result. The optimizer determines the order in which Oracle joins tables based on the join conditions, indexes on the tables, and, any available statistics for the tables.

A WHERE clause that contains a join condition can also contain other conditions that refer to columns of only one table. These conditions can further restrict the rows returned by the join query.

Note: You cannot specify LOB columns in the WHERE clause if the WHERE clause contains the join condition. The use of LOBs in WHERE clauses is also subject to other restrictions. See Oracle Database SecureFiles and Large Objects Developer’s Guide for more information.

Equijoins

An equijoin is a join with a join condition containing an equality operator. An equijoin combines rows that have equivalent values for the specified columns. Depending on the internal algorithm the optimizer chooses to execute the join, the total size of the columns in the equijoin condition in a single table may be limited to the size of a data block minus some overhead. The size of a data block is specified by the initialization parameter DB_BLOCK_SIZE.

See Also: "Using Join Queries: Examples" on page 19-68
Self Joins

A self join is a join of a table to itself. This table appears twice in the FROM clause and is followed by table aliases that qualify column names in the join condition. To perform a self join, Oracle Database combines and returns rows of the table that satisfy the join condition.

See Also: "Using Self Joins: Example" on page 19-69

Cartesian Products

If two tables in a join query have no join condition, then Oracle Database returns their Cartesian product. Oracle combines each row of one table with each row of the other. A Cartesian product always generates many rows and is rarely useful. For example, the Cartesian product of two tables, each with 100 rows, has 10,000 rows. Always include a join condition unless you specifically need a Cartesian product. If a query joins three or more tables and you do not specify a join condition for a specific pair, then the optimizer may choose a join order that avoids producing an intermediate Cartesian product.

Inner Joins

An inner join (sometimes called a simple join) is a join of two or more tables that returns only those rows that satisfy the join condition.

Outer Joins

An outer join extends the result of a simple join. An outer join returns all rows that satisfy the join condition and also returns some or all of those rows from one table for which no rows from the other satisfy the join condition.

- To write a query that performs an outer join of tables A and B and returns all rows from A (a left outer join), use the LEFT [OUTER] JOIN syntax in the FROM clause, or apply the outer join operator (+) to all columns of B in the join condition in the WHERE clause. For all rows in A that have no matching rows in B, Oracle Database returns null for any select list expressions containing columns of B.

- To write a query that performs an outer join of tables A and B and returns all rows from B (a right outer join), use the RIGHT [OUTER] JOIN syntax in the FROM clause, or apply the outer join operator (+) to all columns of A in the join condition in the WHERE clause. For all rows in B that have no matching rows in A, Oracle returns null for any select list expressions containing columns of A.

- To write a query that performs an outer join and returns all rows from A and B, extended with nulls if they do not satisfy the join condition (a full outer join), use the FULL [OUTER] JOIN syntax in the FROM clause.

You cannot compare a column with a subquery in the WHERE clause of any outer join, regardless which form you specify.

You can use outer joins to fill gaps in sparse data. Such a join is called a partitioned outer join and is formed using the query_partition_clause of the join_clause syntax. Sparse data is data that does not have rows for all possible values of a dimension such as time or department. For example, tables of sales data typically do not have rows for products that had no sales on a given date. Filling data gaps is useful in situations where data sparsity complicates analytic computation or where some data might be missed if the sparse data is queried directly.
Oracle recommends that you use the `FROM clause OUTER JOIN syntax rather than the Oracle join operator. Outer join queries that use the Oracle join operator (+) are subject to the following rules and restrictions, which do not apply to the `FROM clause OUTER JOIN syntax:

- You cannot specify the (+) operator in a query block that also contains `FROM clause join syntax.
- The (+) operator can appear only in the `WHERE clause or, in the context of left-correlation (when specifying the `TABLE clause) in the `FROM clause, and can be applied only to a column of a table or view.
- If A and B are joined by multiple join conditions, then you must use the (+) operator in all of these conditions. If you do not, then Oracle Database will return only the rows resulting from a simple join, but without a warning or error to advise you that you do not have the results of an outer join.
- The (+) operator does not produce an outer join if you specify one table in the outer query and the other table in an inner query.
- You cannot use the (+) operator to outer-join a table to itself, although self joins are valid. For example, the following statement is not valid:

```sql
-- The following statement is not valid:
SELECT employee_id, manager_id
FROM employees
WHERE employees.manager_id(+) = employees.employee_id;
```

However, the following self join is valid:

```sql
SELECT e1.employee_id, e1.manager_id, e2.employee_id
FROM employees e1, employees e2
WHERE e1.manager_id(+) = e2.employee_id
ORDER BY e1.employee_id, e1.manager_id, e2.employee_id;
```

- The (+) operator can be applied only to a column, not to an arbitrary expression. However, an arbitrary expression can contain one or more columns marked with the (+) operator.
- A `WHERE` condition containing the (+) operator cannot be combined with another condition using the `OR` logical operator.
- A `WHERE` condition cannot use the `IN` comparison condition to compare a column marked with the (+) operator with an expression.

If the `WHERE` clause contains a condition that compares a column from table B with a constant, then the (+) operator must be applied to the column so that Oracle returns the rows from table A for which it has generated nulls for this column. Otherwise Oracle returns only the results of a simple join.

In previous releases of Oracle Database, in a query that performed outer joins of more than two pairs of tables, a single table could be the null-generated table for only one other table. Beginning with Oracle Database 12c, a single table can be the
null-generated table for multiple tables. For example, the following statement is allowed in Oracle Database 12c:

```sql
SELECT * FROM A, B, D
WHERE A.c1 = B.c2(+) and D.c3 = B.c4(+);
```

In this example, `B`, the null-generated table, is outer-joined to two tables, `A` and `D`. Refer to `SELECT` on page 19-4 for the syntax for an outer join.

### Antijoins

An antijoin returns rows from the left side of the predicate for which there are no corresponding rows on the right side of the predicate. It returns rows that fail to match (NOT IN) the subquery on the right side.

**See Also:** "Using Antijoins: Example" on page 19-72

### Semijoins

A semijoin returns rows that match an EXISTS subquery without duplicating rows from the left side of the predicate when multiple rows on the right side satisfy the criteria of the subquery.

Semijoin and antijoin transformation cannot be done if the subquery is on an OR branch of the WHERE clause.

**See Also:** "Using Semijoins: Example" on page 19-72

### Using Subqueries

A subquery answers multiple-part questions. For example, to determine who works in Taylor’s department, you can first use a subquery to determine the department in which Taylor works. You can then answer the original question with the parent `SELECT` statement. A subquery in the FROM clause of a `SELECT` statement is also called an inline view. You can nest any number of subqueries in an inline view. A subquery in the WHERE clause of a `SELECT` statement is also called a nested subquery. You can nest up to 255 levels of subqueries in the a nested subquery.

A subquery can contain another subquery. Oracle Database imposes no limit on the number of subquery levels in the FROM clause of the top-level query. You can nest up to 255 levels of subqueries in the WHERE clause.

If columns in a subquery have the same name as columns in the containing statement, then you must prefix any reference to the column of the table from the containing statement with the table name or alias. To make your statements easier to read, always qualify the columns in a subquery with the name or alias of the table, view, or materialized view.

Oracle performs a correlated subquery when a nested subquery references a column from a table referred to a parent statement one level above the subquery. The parent statement can be a `SELECT`, `UPDATE`, or `DELETE` statement in which the subquery is nested. A correlated subquery conceptually is evaluated once for each row processed by the parent statement. However, the optimizer may choose to rewrite the query as a join or use some other technique to formulate a query that is semantically equivalent. Oracle resolves unqualified columns in the subquery by looking in the tables named in the subquery and then in the tables named in the parent statement.

A correlated subquery answers a multiple-part question whose answer depends on the value in each row processed by the parent statement. For example, you can use a
correlated subquery to determine which employees earn more than the average salaries for their departments. In this case, the correlated subquery specifically computes the average salary for each department.

See Also: "Using Correlated Subqueries: Examples" on page 19-76

Use subqueries for the following purposes:

■ To define the set of rows to be inserted into the target table of an INSERT or CREATE TABLE statement

■ To define the set of rows to be included in a view or materialized view in a CREATE VIEW or CREATE MATERIALIZED VIEW statement

■ To define one or more values to be assigned to existing rows in an UPDATE statement

■ To provide values for conditions in a WHERE clause, HAVING clause, or START WITH clause of SELECT, UPDATE, and DELETE statements

■ To define a table to be operated on by a containing query

You do this by placing the subquery in the FROM clause of the containing query as you would a table name. You may use subqueries in place of tables in this way as well in INSERT, UPDATE, and DELETE statements.

Subqueries so used can employ correlation variables, both defined within the subquery itself and those defined in query blocks containing the subquery. Refer to table_collection_expression on page 19-26 for more information.

Scalar subqueries, which return a single column value from a single row, are a valid form of expression. You can use scalar subquery expressions in most of the places where expr is called for in syntax. Refer to "Scalar Subquery Expressions" on page 5-16 for more information.

Unnesting of Nested Subqueries

Subqueries are nested when they appear in the WHERE clause of the parent statement. When Oracle Database evaluates a statement with a nested subquery, it must evaluate the subquery portion multiple times and may overlook some efficient access paths or joins.

Subquery unnesting unnests and merges the body of the subquery into the body of the statement that contains it, allowing the optimizer to consider them together when evaluating access paths and joins. The optimizer can unnest most subqueries, with some exceptions. Those exceptions include hierarchical subqueries and subqueries that contain a ROWNUM pseudocolumn, one of the set operators, a nested aggregate function, or a correlated reference to a query block that is not the immediate outer query block of the subquery.

Assuming no restrictions exist, the optimizer automatically unnests some (but not all) of the following nested subqueries:

■ Uncorrelated IN subqueries

■ IN and EXISTS correlated subqueries, as long as they do not contain aggregate functions or a GROUP BY clause

You can enable extended subquery unnesting by instructing the optimizer to unnest additional types of subqueries:
You can unnest an uncorrelated **NOT IN** subquery by specifying the **HASH_AJ** or **MERGE_AJ** hint in the subquery.

You can unnest other subqueries by specifying the **UNNEST** hint in the subquery.

**See Also:** "Hints" on page 2-77 for information on hints

### Selecting from the DUAL Table

**DUAL** is a table automatically created by Oracle Database along with the data dictionary. **DUAL** is in the schema of the user **SYS** but is accessible by the name **DUAL** to all users. It has one column, **DUMMY**, defined to be **VARCHAR2(1)**, and contains one row with a value **X**. Selecting from the **DUAL** table is useful for computing a constant expression with the **SELECT** statement. Because **DUAL** has only one row, the constant is returned only once. Alternatively, you can select a constant, pseudocolumn, or expression from any table, but the value will be returned as many times as there are rows in the table. Refer to "About SQL Functions" on page 7-2 for many examples of selecting a constant value from **DUAL**.

**Note:** Beginning with Oracle Database 10g Release 1, logical I/O is not performed on the **DUAL** table when computing an expression that does not include the **DUMMY** column. This optimization is listed as **FAST DUAL** in the execution plan. If you **SELECT** the **DUMMY** column from **DUAL**, then this optimization does not take place and logical I/O occurs.

### Distributed Queries

The Oracle distributed database management system architecture lets you access data in remote databases using Oracle Net and an Oracle Database server. You can identify a remote table, view, or materialized view by appending **@dblink** to the end of its name. The **dblink** must be a complete or partial name for a database link to the database containing the remote table, view, or materialized view.

**See Also:**
- "References to Objects in Remote Databases" on page 2-126 for more information on referring to database links
- *Oracle Database Net Services Administrator’s Guide* for information on accessing remote databases

**Restrictions on Distributed Queries** Distributed queries are currently subject to the restriction that all tables locked by a **FOR UPDATE** clause and all tables with **LONG** columns selected by the query must be located on the same database. In addition, Oracle Database currently does not support distributed queries that select user-defined types or object **REF** data types on remote tables.
This chapter lists the various types of SQL statements and then describes the first set (in alphabetical order) of SQL statements. The remaining SQL statements appear in alphabetical order in Chapter 11 through Chapter 19.

This chapter contains the following sections:

- Types of SQL Statements
- How the SQL Statement Chapters are Organized
- ADMINISTER KEY MANAGEMENT
- ALTER AUDIT POLICY (Unified Auditing)
- ALTER CLUSTER
- ALTER DATABASE
- ALTER DATABASE LINK
- ALTER DIMENSION
- ALTER DISKGROUP
- ALTER FLASHBACK ARCHIVE
- ALTER FUNCTION
- ALTER INDEX
- ALTER INDEXTYPE
- ALTER JAVA

Types of SQL Statements

The lists in the following sections provide a functional summary of SQL statements and are divided into these categories:

- Data Definition Language (DDL) Statements
- Data Manipulation Language (DML) Statements
- Transaction Control Statements
- Session Control Statements
- System Control Statement
- Embedded SQL Statements
Data Definition Language (DDL) Statements

Data definition language (DDL) statements let you to perform these tasks:

- Create, alter, and drop schema objects
- Grant and revoke privileges and roles
- Analyze information on a table, index, or cluster
- Establish auditing options
- Add comments to the data dictionary

The `CREATE`, `ALTER`, and `DROP` commands require exclusive access to the specified object. For example, an `ALTER TABLE` statement fails if another user has an open transaction on the specified table.

The `GRANT`, `REVOKE`, `ANALYZE`, `AUDIT`, and `COMMENT` commands do not require exclusive access to the specified object. For example, you can analyze a table while other users are updating the table.

Oracle Database implicitly commits the current transaction before and after every DDL statement.

A DDL statement is either blocking or nonblocking, and both types of DDL statements require exclusive locks on internal structures.

**See Also:** Oracle Database Development Guide to learn about the difference between blocking and nonblocking DDL

Many DDL statements may cause Oracle Database to recompile or reauthorize schema objects. For information on how Oracle Database compiles and reauthorizes schema objects and the circumstances under which a DDL statement would cause this, see Oracle Database Concepts.

DDL statements are supported by PL/SQL with the use of the `DBMS_SQL` package.

**See Also:** Oracle Database PL/SQL Packages and Types Reference for more information about this package

The DDL statements are:

- `ALTER` ... (All statements beginning with `ALTER`, except `ALTER SESSION` and `ALTER SYSTEM`—see “Session Control Statements” on page 10-3 and “System Control Statement” on page 10-3)
- `ANALYZE`
- `ASSOCIATE STATISTICS`
- `AUDIT`
- `COMMENT`
- `CREATE` ... (All statements beginning with `CREATE`)
- `DISASSOCIATE STATISTICS`
- `DROP` ... (All statements beginning with `DROP`)
- `FLASHBACK` ... (All statements beginning with `FLASHBACK`)
- `GRANT`
- `NOAUDIT`
- `PURGE`
- `RENAME`
- `REVOKE`
- `TRUNCATE`
Data Manipulation Language (DML) Statements

Data manipulation language (DML) statements access and manipulate data in existing schema objects. These statements do not implicitly commit the current transaction. The data manipulation language statements are:

- CALL
- DELETE
- EXPLAIN PLAN
- INSERT
- LOCK TABLE
- MERGE
- SELECT
- UPDATE

The `SELECT` statement is a limited form of DML statement in that it can only access data in the database. It cannot manipulate data stored in the database, although it can manipulate the accessed data before returning the results of the query.

The `SELECT` statement is supported in PL/SQL only when executed dynamically. However, you can use the similar PL/SQL statement `SELECT INTO` in PL/SQL code, and you do not have to execute it dynamically. The `CALL` and `EXPLAIN PLAN` statements are supported in PL/SQL only when executed dynamically. All other DML statements are fully supported in PL/SQL.

Transaction Control Statements

Transaction control statements manage changes made by DML statements. The transaction control statements are:

- COMMIT
- ROLLBACK
- SAVEPOINT
- SET TRANSACTION
- SET CONSTRAINT

All transaction control statements, except certain forms of the `COMMIT` and `ROLLBACK` commands, are supported in PL/SQL. For information on the restrictions, see `COMMIT` on page 13-57 and `ROLLBACK` on page 18-110.

Session Control Statements

Session control statements dynamically manage the properties of a user session. These statements do not implicitly commit the current transaction.

PL/SQL does not support session control statements. The session control statements are:

- ALTER SESSION
- SET ROLE

System Control Statement

The single system control statement, `ALTER SYSTEM`, dynamically manages the properties of an Oracle Database instance. This statement does not implicitly commit the current transaction and is not supported in PL/SQL.
Embedded SQL Statements

Embedded SQL statements place DDL, DML, and transaction control statements within a procedural language program. Embedded SQL is supported by the Oracle precompilers and is documented in the following books:

- Pro*COBOL Programmer’s Guide
- Pro*C/C++ Programmer’s Guide
- Oracle SQL*Module for Ada Programmer’s Guide

How the SQL Statement Chapters are Organized

All SQL statements in this chapter, as well as in Chapter 11 through Chapter 19, are organized into the following sections:

Syntax  The syntax diagrams show the keywords and parameters that make up the statement.

Caution:  Not all keywords and parameters are valid in all circumstances. Be sure to refer to the “Semantics” section of each statement and clause to learn about any restrictions on the syntax.

Purpose  The “Purpose” section describes the basic uses of the statement.

Prerequisites  The “Prerequisites” section lists privileges you must have and steps that you must take before using the statement. In addition to the prerequisites listed, most statements also require that the database be opened by your instance, unless otherwise noted.

Semantics  The “Semantics” section describes the purpose of the keywords, parameters, and clauses that make up the syntax, as well as restrictions and other usage notes that may apply to them. (The conventions for keywords and parameters used in this chapter are explained in the "Preface" of this reference.)

Examples  The "Examples" section shows how to use the various clauses and parameters of the statement.
ADMINISTER KEY MANAGEMENT

Purpose

The `ADMINISTER KEY MANAGEMENT` statement provides a unified key management interface for Transparent Data Encryption. Use this statement to:

- Manage software and hardware keystores
- Manage encryption keys
- Manage secrets

Prerequisites

You must have the `ADMINISTER KEY MANAGEMENT` or `SYSKM` system privilege.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root and you must have the commonly granted `ADMINISTER KEY MANAGEMENT` or `SYSKM` privilege.

```

delete_secret ::= 
```
DELETE SECRET FOR CLIENT client_identifier
```
```
IDENTIFIED BY keystore_password WITH BACKUP USING backup_identifier
```

Semantics

**keystore_management_clauses**

Use these clauses to perform the following keystore management operations:

- Create a software keystore
- Open and close a software keystore or a hardware keystore
- Back up a password-based software keystore
- Change the password of a password-based software keystore
- Merge two existing software keystores into a new password-based software keystore
- Merge one existing software keystore into an existing password-based software keystore
create_keystore
This clause lets you create the following types of software keystores: password-based software keystores and auto-login software keystores. To issue this clause in a multitenant environment, you must be connected to the root.

CREATE KEYSTORE Specify this clause to create a password-based software keystore.

- For `keystore_location`, specify the full path name of the software keystore directory. The keystore will be created in this directory in a file named `ewallet.p12`. Refer to Oracle Database Advanced Security Guide to learn how to determine the software keystore directory for your system.
- Use `keystore_password` to set the password for the keystore. Refer to "Notes on Specifying Keystore Passwords" on page 10-18 for more information.

CREATE [ LOCAL ] AUTO_LOGIN KEYSTORE Specify this clause to create an auto-login software keystore. An auto-login software keystore is created from an existing password-based software keystore. The auto-login keystore has a system-generated password. It is stored in a PKCS#12-based file named `cwallet.sso` in the same directory as the password-based software keystore.

- By default, Oracle creates an auto-login keystore, which can be opened from computers other than the computer on which the keystore resides. If you specify the `LOCAL` keyword, then Oracle Database creates a local auto-login keystore, which can be opened only from the computer on which the keystore resides.
- For `keystore_location`, specify the full path name of the directory in which the existing password-based software keystore resides. The password-based software keystore can be open or closed.
- For `keystore_password`, specify the password for the existing password-based software keystore.

Restriction on Creating Keystores You can create at most one password-based software keystore and one auto-login software keystore, either local or not, in any single directory.

See Also: Oracle Database Advanced Security Guide for more information on creating software keystores

open_keystore
This clause lets you open a password-based software keystore or a hardware keystore.

Note: You do not need to use this clause to open auto-login and local auto-login software keystores because they are opened automatically when they are required—that is, when the master encryption key is accessed.

- For `keystore_password`, specify the password for the keystore.
- The CONTAINER clause applies when you are connected to a CDB.

If the current container is a pluggable database (PDB), then specify `CONTAINER = CURRENT` to open the keystore in the PDB. The keystore must be open in the root before you open it in the PDB.
If the current container is the root, then specify `CONTAINER = CURRENT` to open the keystore in the root, or specify `CONTAINER = ALL` to open the keystore in the root and in all PDBs.

If you omit this clause, then `CONTAINER = CURRENT` is the default.

**See Also:** Oracle Database Advanced Security Guide for more information on opening password-based software keystores and hardware keystores

### close_keystore

This clause lets you close a password-based software keystore, an auto-login software keystore, or a hardware keystore. Closing a keystore disables all encryption and decryption operations. Any attempt to encrypt or decrypt data or access encrypted data results in an error.

- To close a password-based software keystore or a hardware keystore, specify the `keystore_password`.
- To close an auto-login keystore, do not specify `keystore_password`. Before you close an auto-login keystore, check the `WALLET_TYPE` column of the `V$ENCRYPTION_WALLET` view. If it returns `AUTOLOGIN`, then you can close the keystore. Otherwise, if you attempt to close the keystore, then an error occurs.
- The `CONTAINER` clause applies when you are connected to a CDB.
  - If the current container is a PDB, then specify `CONTAINER = CURRENT` to close the keystore in the PDB.
  - If the current container is the root, then the `CONTAINER = CURRENT` and `CONTAINER = ALL` clauses have the same effect; both clauses close the keystore in the root and in all PDBs.
  - If you omit this clause, then `CONTAINER = CURRENT` is the default.

**See Also:** Oracle Database Advanced Security Guide for more information on closing keystores

### backup_keystore

This clause lets you back up a password-based software keystore. The keystore must be open.

- By default, Oracle Database creates a backup file with a name of the form `ewallet_timestamp.p12`, where `timestamp` is the file creation timestamp in UTC format. The optional `USING 'backup_identifier'` clause lets you specify a backup identifier which is added to the backup file name. For example, if you specify a backup identifier of 'Backup1', then Oracle Database creates a backup file with a name of the form `ewallet_timestamp_Backup1.p12`.
- For `keystore_password`, specify the password for the keystore.
- The optional `TO 'keystore_location'` clause lets you specify the directory in which the backup file is created. If you omit this clause, then the backup is created in the same directory as the keystore that you are backing up.

**See Also:** Oracle Database Advanced Security Guide for more information on backing up password-based software keystores
**alter_keystore_password**
This clause lets you change the password for a password-based software keystore. The keystore must be open.

- For `old_keystore_password`, specify the old password for the keystore.
- For `new_keystore_password`, specify the new password for the keystore.
- The optional `WITH BACKUP` clause instructs the database to create a backup of the keystore before changing the password. Refer to "Notes on the WITH BACKUP Clause" on page 10-18 for more information.

**See Also:** Oracle Database Advanced Security Guide for more information on changing a password-based software keystore password

**merge_into_new_keystore**
This clause lets you merge two software keystores into a new keystore. The keys and attributes in the two constituent keystores are added to the new keystore. The constituent keystores can be password-based or auto-login (including local auto-login) software keystores; they can be open or closed. The new keystore is a password-based software keystore. It is in a closed state when the merge completes. Any or none of the keystores specified in this clause can be the keystore configured for use by the database.

- For `keystore1_location`, specify the full path name of the directory in which the first keystore resides.
- Specify `IDENTIFIED BY keystore1_password` only if the first keystore is a password-based software keystore.
- For `keystore2_location`, specify the full path name of the directory in which the second keystore resides.
- Specify `IDENTIFIED BY keystore2_password` only if the second keystore is a password-based software keystore.
- For `keystore1_location`, specify the full path name of the directory in which the new keystore is created.
- For `keystore1_password`, specify the password for the new keystore. Refer to "Notes on Specifying Keystore Passwords" on page 10-18 for more information.

**See Also:** Oracle Database Advanced Security Guide for more information on merging software keystores

**merge_into_exist_keystore**
This clause lets you merge a software keystore into another existing software keystore. The keys and attributes in the keystore from which you merge are added to the keystore into which you merge. The keystore from which you merge can be a password-based or auto-login (including local auto-login) software keystore; it can be open or closed. The keystore into which you merge must be a password-based software keystore. It can be open or closed when the merge begins. However, it will be in a closed state when the merge completes. Either or neither of the keystores specified in this clause can be the keystore configured for use by the database.

- For `keystore1_location`, specify the full path name of the directory in which the keystore from which you merge resides.
Specify IDENTIFIED BY keystore1_password only if the keystore from which you merge is a password-based software keystore.

For keystore2_location, specify the full path name of the directory in which the keystore into which you merge resides.

For keystore2_password, specify the password for the keystore into which you merge.

The optional WITH BACKUP clause instructs the database to create a backup of the keystore into which you merge before performing the merge. Refer to "Notes on the WITH BACKUP Clause" on page 10-18 for more information.

See Also: Oracle Database Advanced Security Guide for more information on merging software keystores

key_management_clauses
Use these clauses to perform the following key management operations:

- Create and activate a master encryption key
- Set the tag for an encryption key
- Export encryption keys from a keystore into a file
- Import encryption keys from a file into a keystore
- Migrate from a password-based software keystore to a hardware keystore
- Migrate from a hardware keystore to a password-based software keystore

set_key
This clause creates a new master encryption key and activates it. You can use this clause to create the first master encryption key in a keystore or to rotate (change) the master encryption key. If a master encryption key is active when you use this clause, then it is deactivated before the new master encryption key is activated. The keystore that contains the key can be a password-based software keystore or a hardware keystore. The keystore must be open.

- The ENCRYPTION keyword is optional and is provided for semantic clarity.
- Specify the optional USING TAG clause to associate a tag to the new master encryption key. Refer to "Notes on the USING TAG Clause" on page 10-18 for more information.
- For keystore_password, specify the password for the keystore.
- Specify the WITH BACKUP clause, and optionally the USING 'backup_identifier' clause, to create a backup of the keystore before the new master encryption key is created. Refer to "Notes on the WITH BACKUP Clause" on page 10-18 for more information.
- The CONTAINER clause applies when you are connected to a CDB.
  - If the current container is a PDB, then specify CONTAINER = CURRENT to create and activate a new master encryption key in the PDB. A master encryption key must exist in the root before you create a master encryption key in the PDB.
  - If the current container is the root, then specify CONTAINER = CURRENT to create and activate a new master encryption key in the root, or specify CONTAINER = ALL to create and activate new master encryption keys in the root and in all PDBs.
  - If you omit this clause, then CONTAINER = CURRENT is the default.
create_key
This clause lets you create a master encryption key for later use. You can subsequently activate the key by using the use_key clause on page 10-14. The keystore that contains the key can be a password-based software keystore or a hardware keystore. The keystore must be open.

- The ENCRYPTION keyword is optional and is provided for semantic clarity.
- Specify the optional USING TAG clause to associate a tag to the encryption key. Refer to "Notes on the USING TAG Clause" on page 10-18 for more information.
- For keystore_password, specify the password for the keystore in which the key will be created.
- Specify the WITH BACKUP clause, and optionally the USING 'backup_identifier' clause, to create a backup of the keystore before the key is created. Refer to "Notes on the WITH BACKUP Clause" on page 10-18 for more information.
- The CONTAINER clause applies when you are connected to a CDB.
  - If the current container is a PDB, then specify CONTAINER = CURRENT to create a master encryption key in the PDB. A master encryption key must exist in the root before you create a master encryption key in the PDB.
  - If the current container is the root, then specify CONTAINER = CURRENT to create a master encryption key in the root, or specify CONTAINER = ALL to create master encryption keys in the root and in all PDBs.
  - If you omit this clause, then CONTAINER = CURRENT is the default.

use_key
This clause lets you activate a master encryption key that has already been created. If a master encryption key is active when you use this clause, then it is deactivated before the new master encryption key is activated. The keystore that contains the key can be a password-based software keystore or a hardware keystore. The keystore must be open.

- The ENCRYPTION keyword is optional and is provided for semantic clarity.
- For key_id, specify the identifier of the key that you want to activate. You can find the key identifier by querying the KEY_ID column of the V$ENCRYPTION KEYS view.
- Specify the optional USING TAG clause to associate a tag to the encryption key. Refer to "Notes on the USING TAG Clause" on page 10-18 for more information.
- For keystore_password, specify the password for the keystore that contains the key.
- Specify the WITH BACKUP clause, and optionally the USING 'backup_identifier' clause, to create a backup of the keystore before the key is activated. Refer to "Notes on the WITH BACKUP Clause" on page 10-18 for more information.

See Also: Oracle Database Advanced Security Guide for more information on creating a master encryption key for later use
**set_key_tag**
This clause lets you set the tag for the specified encryption key. The tag is an optional, user-defined descriptor for the key. If the key has no tag, then use this clause to create a tag. If the key already has a tag, then use this clause to replace the tag. You can view encryption key tags by querying the `TAG` column of the `V$ENCRYPTION_KEYS` view.

- For **tag**, specify an alphanumeric string. Enclose **tag** in single quotation marks.
- For **key_id**, specify the identifier of the encryption key. You can find the key identifier by querying the `KEY_ID` column of the `V$ENCRYPTION_KEYS` view.
- For **keystore_password**, specify the password for the keystore that contains the key.
- Specify the **WITH BACKUP** clause, and optionally the **USING 'backup_identifier'** clause, to create a backup of the keystore before you set the key tag. Refer to "Notes on the WITH BACKUP Clause" on page 10-18 for more information.

**See Also:** Oracle Database Advanced Security Guide for more information on setting a key tag

**export_keys**
Use this clause to export one or more encryption keys from a password-based software keystore into a file. The keystore must be open. Each encryption key is exported together with its key identifier and key attributes. The exported keys are protected in the file with a password (secret). You can subsequently import one or more of the keys into a password-based software keystore by using the **import_keys** clause on page 10-16.

- The **ENCRYPTION** keyword is optional and is provided for semantic clarity.
- Specify **secret** to set the password (secret) that protects the keys in the file. The secret is an alphanumeric string. You can optionally enclose the secret in double quotation marks. Quoted and nonquoted secrets are case sensitive.
- For **filename**, specify the full path name of the file to which the keys are to be exported. Enclose **filename** in single quotation marks.
- For **keystore_password**, specify the password for the keystore that contains the keys you want to export.
- Use the **WITH IDENTIFIER IN** clause to specify one or more encryption keys that you would like to export using one of the following methods:
  - Use **key_id** to specify the identifier of the encryption key you would like to export. You can specify more than one **key_id** in a comma-separated list. You can find key identifiers by querying the `KEY_ID` column of the `V$ENCRYPTION_KEYS` view.
  - Use **subquery** to specify a query that returns a list of key identifiers for the encryption keys you would like to export. For example, the following **subquery** returns the key identifiers for all encryption keys in the database whose tags begin with the string `mytag`:

```
SELECT KEY_ID FROM V$ENCRYPTION_KEYS WHERE TAG LIKE 'mytag%'
```

Be aware that Oracle Database executes **subquery** within the current user’s rights and not with definer’s rights.
- If you omit the **WITH IDENTIFIER IN** clause, then all encryption keys in the database are exported.
Restriction on the WITH IDENTIFIER IN Clause  In a multitenant environment, you cannot specify WITH IDENTIFIER IN when exporting keys from a PDB. This ensures that all of the keys in the PDB are exported, along with metadata about the active encryption key. If you subsequently clone the PDB, or unplug and plug in the PDB, then you can use the export file to import the keys into the cloned or newly plugged-in PDB and preserve information about the active encryption key.

See Also: Oracle Database Advanced Security Guide for more information on exporting encryption keys

import_keys
Use this clause to import one or more encryption keys from a file into a password-based software keystore. The keystore must be open. Each encryption key is imported together with its key identifier and key attributes. The keys must have been previously exported to the file by using the export_keys clause on page 10-15. You cannot re-import keys that have already been imported into the keystore.

- The ENCRYPTION keyword is optional and is provided for semantic clarity.
- For secret, specify the password (secret) that protects the keys in the file. The secret is an alphanumeric string. You can optionally enclose the secret in double quotation marks. Quoted and nonquoted secrets are case sensitive.
- For filename, specify the full path name of the file from which the keys are to be imported. Enclose filename in single quotation marks.
- For keystore_password, specify the password for the keystore into which you want to import the keys.
- Specify the WITH BACKUP clause, and optionally the USING 'backup_identifier' clause, to create a backup of the keystore before the keys are imported. Refer to "Notes on the WITH BACKUP Clause" on page 10-18 for more information.

See Also: Oracle Database Advanced Security Guide for more information on importing encryption keys

migrate_key
Use this clause to migrate from a password-based software keystore to a hardware keystore. This clause decrypts existing table encryption keys and tablespace encryption keys with the master encryption key in the software keystore and then re-encrypts them with the newly created master encryption key in the hardware keystore.

- The ENCRYPTION keyword is optional and is provided for semantic clarity.
- For HSM_auth_string, specify the hardware keystore password. Refer to "Notes on Specifying Keystore Passwords" on page 10-18 for more information.
- For software_keystore_password, specify the password-based software keystore password. Refer to "Notes on Specifying Keystore Passwords" on page 10-18 for more information.

Note: The use of this clause is only one step in a series of steps for migrating from a password-based software keystore to a hardware keystore. Refer to Oracle Database Advanced Security Guide for the complete set of steps before you use this clause.
- Specify the WITH BACKUP clause, and optionally the USING 'backup_identifier' clause, to create a backup of the keystore before the migration occurs. Refer to "Notes on the WITH BACKUP Clause" on page 10-18 for more information.

**reverse_migrate_key**

Use this clause to migrate from a hardware keystore to a password-based software keystore. This clause decrypts existing table encryption keys and tablespace encryption keys with the master encryption key in the hardware keystore and then re-encrypts them with the newly created master encryption key in the password-based software keystore.

**Note:** The use of this clause is only one step in a series of steps for migrating from a hardware keystore to a password-based software keystore. Refer to Oracle Database Advanced Security Guide for the complete set of steps before you use this clause.

- The ENCRYPTION keyword is optional and is provided for semantic clarity.
- For software_keystore_password, specify the password-based software keystore password. Refer to "Notes on Specifying Keystore Passwords" on page 10-18 for more information.
- For HSM_auth_string, specify the hardware keystore password. Refer to "Notes on Specifying Keystore Passwords" on page 10-18 for more information.

**secret_management_clauses**

Use these clauses to add, update, and delete secrets in a password-based software keystores or a hardware keystore.

**See Also:** Oracle Database Advanced Security Guide for more information on adding, updating, and deleting secrets

**add_update_secret**

This clause lets you add or update a secret.

- Specify ADD to add a secret to a keystore.
- Specify UPDATE to update an existing secret in a keystore.
- For secret, specify the secret to be added or updated. The secret is an alphanumeric string. Enclose the secret in single quotation marks.
- For client_identifier, specify an alphanumeric string used to identify the secret. Enclose client_identifier in single quotation marks.
- Specify the optional USING TAG clause to associate a tag to secret. The tag is an optional, user-defined descriptor for the secret. Enclose the tag in single quotation marks. You can view secret tags by querying the SECRET_TAG column of the V$CLIENT_SECRETS view.
- For keystore_password, specify the password for the keystore.
- Specify the WITH BACKUP clause, and optionally the USING 'backup_identifier' clause, to create a backup of the keystore before adding or updating the secret in a password-based software keystore. Refer to "Notes on the WITH BACKUP Clause" on page 10-18 for more information.
delete_secret
This clause lets you delete a secret.

- For `client_identifier`, specify an alphanumeric string used to identify the secret. Enclose `client_identifier` in single quotation marks. You can view client identifiers by querying the `CLIENT` column of the `V$CLIENT_SECRETS` view.

- For `keystore_password`, specify the password for the keystore.

- Specify the `WITH BACKUP` clause, and optionally the `USING 'backup_identifier'` clause, to create a backup of the keystore before deleting the secret from a password-based software keystore. Refer to "Notes on the WITH BACKUP Clause" on page 10-18 for more information.

Notes on Specifying Keystore Passwords Specify keystore passwords as follows:

- For a password-based software keystore, specify the password as a character string. You can optionally enclose the password in double quotation marks. Quoted and nonquoted passwords are case sensitive. Keystore passwords adhere to the same rules as database user passwords. Refer to the `BY password` clause of `CREATE USER` on page 17-9 for the complete details.

- For a hardware keystore, specify the password as a string of the form "user_id:password" where:
  - `user_id` is the user ID created for the database using the HSM management interface
  - `password` is the password created for the user ID using the HSM management interface

  Enclose the `user_id:password` string in double quotation marks (" ") and separate `user_id` and `password` with a colon (:).

Notes on the WITH BACKUP Clause Many ADMINISTER KEY MANAGEMENT operations include the WITH BACKUP clause. This clause applies only to password-based software keystores. It indicates that the keystore must be backed up before the operation is performed. Therefore, you must either specify the WITH BACKUP clause when performing the operation, or issue the ADMINISTER KEY MANAGEMENT `backup_clause` statement immediately before performing the operation.

When you specify the WITH BACKUP clause, Oracle Database creates a backup file with a name of the form `ewallet_timestamp.p12`, where `timestamp` is the file creation timestamp in UTC format. The backup file is created in the same directory as the keystore you are backing up.

The optional `USING 'backup_identifier'` clause lets you specify a backup identifier, which is added to the backup file name. For example, if you specify a backup identifier of 'Backup1', then Oracle Database creates a backup file with a name of the form `ewallet_timestamp_Backup1.p12`.

Notes on the USING TAG Clause Many ADMINISTER KEY MANAGEMENT operations include the USING TAG clause, which lets you associate a tag to an encryption key. The `tag` is an optional, user-defined descriptor for the key. It is a character string enclosed in single quotation marks.

You can view encryption key tags by querying the `TAG` column of the `V$ENCRYPTION_KEYS` view.
Examples

**Creating a Keystore: Examples**  The following statement creates a password-based software keystore in directory `/etc/ORACLE/WALLETS/orcl`:

```
ADMINISTER KEY MANAGEMENT
  CREATE KEYSTORE '/etc/ORACLE/WALLETS/orcl'
  IDENTIFIED BY password;
```

The following statement creates an auto-login software keystore from the keystore created in the previous statement:

```
ADMINISTER KEY MANAGEMENT
  CREATE AUTO_LOGIN KEYSTORE FROM KEYSTORE '/etc/ORACLE/WALLETS/orcl'
  IDENTIFIED BY password;
```

**Opening a Keystore: Examples**  The following statement opens a password-based software keystore:

```
ADMINISTER KEY MANAGEMENT
  SET KEYSTORE OPEN
  IDENTIFIED BY password;
```

If you are connected to a CDB, then the following statement opens a password-based software keystore in the current container:

```
ADMINISTER KEY MANAGEMENT
  SET KEYSTORE OPEN
  IDENTIFIED BY password
  CONTAINER = CURRENT;
```

The following statement opens a hardware keystore:

```
ADMINISTER KEY MANAGEMENT
  SET KEYSTORE OPEN
  IDENTIFIED BY "user_id:password";
```

**Closing a Keystore: Examples**  The following statement closes a password-based software keystore:

```
ADMINISTER KEY MANAGEMENT
  SET KEYSTORE CLOSE
  IDENTIFIED BY password;
```

The following statement closes an auto-login software keystore:

```
ADMINISTER KEY MANAGEMENT
  SET KEYSTORE CLOSE;
```

The following statement closes a hardware keystore:

```
ADMINISTER KEY MANAGEMENT
  SET KEYSTORE CLOSE
  IDENTIFIED BY "user_id:password";
```

**Backing Up a Keystore: Example**  The following statement creates a backup of a password-based software keystore. The backup is stored in directory `/etc/ORACLE/KEYSTORE/DB1` and the backup file name contains the tag `hr.emp_keystore`.

```
ADMINISTER KEY MANAGEMENT
  BACKUP KEYSTORE USING 'hr.emp_keystore'
```
IDENTIFIED BY password
TO '/etc/ORACLE/KEYSTORE/DB1/
;

Changing a Keystore Password: Example  The following statement changes the
password for a password-based software keystore. It also creates a backup of the
keystore, with the tag pwd_change, before changing the password.

ADMINISTER KEY MANAGEMENT
ALTER KEystore PASSWORD IDENTIFIED BY old_password
SET new_password WITH BACKUP USING 'pwd_change';

Merging Two Keystores Into a New Keystore: Example  The following statement
merges an auto-login software keystore with a password-based software keystore to
create a new password-based software keystore at a new location:

ADMINISTER KEY MANAGEMENT
MERGE KEystore '/etc/ORACLE/KEYSTORE/DB1'
AND KEystore '/etc/ORACLE/KEYSTORE/DB2'
IDENTIFIED BY existing_keystore_password
INTO New keystore '/etc/ORACLE/KEYSTORE/DB3'
IDENTIFIED BY new_keystore_password;

Merging a Keystore Into an Existing Keystore: Example  The following statement
merges an auto-login software keystore into a password-based software keystore. It
also creates a backup of the password-based software keystore before performing the
merge.

ADMINISTER KEY MANAGEMENT
MERGE KEystore '/etc/ORACLE/KEYSTORE/DB1'
INTO EXISTING KEystore '/etc/ORACLE/KEYSTORE/DB2'
IDENTIFIED BY existing_keystore_password
WITH BACKUP;

Creating and Activating a Master Encryption Key: Examples  The following
statement creates and activates a master encryption key in a password-based software
keystore. It also creates a backup of the keystore before creating the new master
encryption key.

ADMINISTER KEY MANAGEMENT
SET KEY IDENTIFIED BY password
WITH BACKUP;

The following statement creates a master encryption key in a password-based software
keystore, but does not activate the key. It also creates a backup of the keystore before
creating the new master encryption key.

ADMINISTER KEY MANAGEMENT
CREATE KEY USING TAG 'mykey1'
IDENTIFIED BY password
WITH BACKUP;

The following query displays the key identifier for the master encryption key that was
created in the previous statement:

SELECT TAG, KEY_ID
FROM V$ENCRYPTION KEYS
WHERE TAG = 'mykey1';

TAG       KEY_ID
---------- -------------------------------
mykey1    ARgEtzPxpE/Nv8WdPu8LJUU______________________________________
The following statement activates the master encryption key that was queried in the previous statement. It also creates a backup of the keystore before activating the new master encryption key.

```
ADMINISTER KEY MANAGEMENT
  USE KEY 'ARgEtzPxpE/Nv8WdPu8LJJUAAAAAAAAAAAAAAAAAAAAAAAAAAAAA'
  IDENTIFIED BY password
  WITH BACKUP;
```

**Setting a Key Tag: Example**  The following statement changes the tag to mykey2 for the master encryption key that was activated in the previous example. It also creates a backup of the keystore before changing the tag.

```
ADMINISTER KEY MANAGEMENT
  SET TAG 'mykey2' FOR 'ARgEtzPxpE/Nv8WdPu8LJJUAAAAAAAAAAAAAAAAAAAAAAAAAAAAA'
  IDENTIFIED BY password
  WITH BACKUP;
```

**Exporting Keys: Examples**  The following statement exports two master encryption keys from a password-based software keystore to file /etc/TDE/export.exp. The statement encrypts the master encryption keys in the file using the secret my_secret. The identifiers of the master encryption keys to be exported are provided as a comma-separated list.

```
ADMINISTER KEY MANAGEMENT
  EXPORT KEYS WITH SECRET "my_secret"
  TO '/etc/TDE/export.exp'
  IDENTIFIED BY password
  WITH IDENTIFIER IN 'AdoxnJ0uH08cv7xkz83ovwsAAAAAAAAAAAAAAAAAAAAAAAAAAAAA',
  'AW5z3CoyKE/yv3cNT5CWXUAAAAAAAAAAAAAAAAAAAAAAAAA';
```

The following statement exports master encryption keys from a password-based software keystore to file /etc/TDE/export.exp. Only the keys whose tags are mytag1 or mytag2 are exported. The master encryption keys in the file are encrypted using the secret my_secret. The key identifiers are found by querying the V$ENCRYPTION_KEYS view.

```
ADMINISTER KEY MANAGEMENT
  EXPORT KEYS WITH SECRET "my_secret"
  TO '/etc/TDE/export.exp'
  IDENTIFIED BY password
  WITH IDENTIFIER IN (SELECT KEY_ID FROM V$ENCRYPTION_KEYS WHERE TAG IN ('mytag1', 'mytag2'));
```

The following statement exports all master encryption keys of the database to file /etc/TDE/export.exp. The master encryption keys in the file are encrypted using the secret my_secret.

```
ADMINISTER KEY MANAGEMENT
  EXPORT KEYS WITH SECRET "my_secret"
  TO '/etc/TDE/export.exp'
  IDENTIFIED BY password;
```

In a multitenant environment, the following statements exports all master encryption keys of the PDB salespdb, along with metadata, to file /etc/TDE/salespdb.exp. The master encryption keys in the file are encrypted using the secret my_secret. If the PDB is subsequently cloned, or unplugged and plugged back in, then the export file created by this statement can be used to import the keys into the cloned or newly plugged-in PDB.
ALTER SESSION SET CONTAINER = salespdb;
ADMINISTER KEY MANAGEMENT
   EXPORT KEYS WITH SECRET 'my_secret'
   TO '/etc/TDE/salespdb.exp'
   IDENTIFIED BY password;

**Importing Keys: Example** The following statement imports the master encryption keys, encrypted with secret my_secret, from file /etc/TDE/export.exp to a password-based software keystore. It also creates a backup of the password-based software keystore before importing the keys.

ADMINISTER KEY MANAGEMENT
   IMPORT KEYS WITH SECRET 'my_secret'
   FROM '/etc/TDE/export.exp'
   IDENTIFIED BY password
   WITH BACKUP;

**Migrating a Keystore: Example** The following statement migrates from a password-based software keystore to a hardware keystore. It also creates a backup of the password-based software keystore before performing the migration.

ADMINISTER KEY MANAGEMENT
   SET ENCRYPTION KEY IDENTIFIED BY 'user_id:password'
   MIGRATE USING software_keystore_password
   WITH BACKUP;

**Reverse Migrating a Keystore: Example** The following statement reverse migrates from a hardware keystore to a password-based software keystore:

ADMINISTER KEY MANAGEMENT
   SET ENCRYPTION KEY IDENTIFIED BY software_keystore_password
   REVERSE MIGRATE USING 'user_id:password';

**Adding a Secret to a Keystore: Examples** The following statement adds secret secret1, with the tag My first secret, for client client1 to a password-based software keystore. It also creates a backup of the password-based software keystore before adding the secret.

ADMINISTER KEY MANAGEMENT
   ADD SECRET 'secret1' FOR CLIENT 'client1'
   USING TAG 'My first secret'
   IDENTIFIED BY password
   WITH BACKUP;

The following statement adds a similar secret to a hardware keystore:

ADMINISTER KEY MANAGEMENT
   ADD SECRET 'secret2' FOR CLIENT 'client2'
   USING TAG 'My second secret'
   IDENTIFIED BY 'user_id:password';

**Updating a Secret in a Keystore: Examples** The following statement updates the secret that was created in the previous example in a password-based software keystore. It also creates a backup of the password-based software keystore before updating the secret.

ADMINISTER KEY MANAGEMENT
   UPDATE SECRET 'secret1' FOR CLIENT 'client1'
   USING TAG 'New Tag 1'
   IDENTIFIED BY password
   WITH BACKUP;
The following statement updates the secret that was created in the previous example in a hardware keystore:

```
ADMINISTER KEY MANAGEMENT
 UPDATE SECRET 'secret2' FOR CLIENT 'client2'
 USING TAG 'New Tag 2'
 IDENTIFIED BY 'user_id:password';
```

**Deleting a Secret from a Keystore: Examples**  The following statement deletes the secret that was updated in the previous example from a password-based software keystore. It also creates a backup of the password-based software keystore before deleting the secret.

```
ADMINISTER KEY MANAGEMENT
 DELETE SECRET FOR CLIENT 'client1'
 IDENTIFIED BY password
 WITH BACKUP;
```

The following statement deletes the secret that was updated in the previous example from a hardware keystore:

```
ADMINISTER KEY MANAGEMENT
 DELETE SECRET FOR CLIENT 'client2'
 IDENTIFIED BY 'user_id:password';
```
ALTER AUDIT POLICY (Unified Auditing)

This section describes the `ALTER AUDIT POLICY` statement for **unified auditing**. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to *Oracle Database Security Guide* for more information on unified auditing.

**Purpose**

Use the `ALTER AUDIT POLICY` statement to modify a unified audit policy.

See Also:

- CREATE AUDIT POLICY (Unified Auditing) on page 14-2
- DROP AUDIT POLICY (Unified Auditing) on page 17-38
- AUDIT (Unified Auditing) on page 13-45
- NOAUDIT (Unified Auditing) on page 18-92

**Prerequisites**

You must have the `AUDIT SYSTEM` system privilege or the `AUDIT_ADMIN` role.

If you are connected to a multitenant container database (CDB), then to modify a common unified audit policy, the current container must be the root and you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role. To modify a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role, or you must have the locally granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` local role in the container.

**Syntax**

```
alter_audit_policy::=

ALTER AUDIT POLICY policy

ADD privilege_audit_clause action_audit_clause role_audit_clause

DROP privilege_audit_clause action_audit_clause role_audit_clause

CONDITION DROP audit_condition EVALUATE PER STATEMENT SESSION INSTANCE
```
**Note:** If you specify the `ADD` or `DROP` clause, then you must specify at least one of the clauses `privilege_audit_clause`, `action_audit_clause`, or `role_audit_clause`.

(privilege_audit_clause::= on page 10-25, action_audit_clause::= on page 10-25, role_audit_clause::= on page 10-25)

### privilege_audit_clause::=

- PRIVILEGES
  - system_privilege

### action_audit_clause::=

- standard_actions
  - component_actions

### standard_actions::=

- object_action
  - ACTION ON DIRECTORY directory_name
  - ACTION ON MINING MODEL schema object_name
  - ACTION ON system_action ALL

### component_actions::=

- ACTIONS COMPONENT
  - ACTION DATAPUMP component_action
  - ACTION DIRECT_LOAD component_action
  - ACTION OLS component_action
  - ACTION XS component_action
  - ACTION DV component_action

### role_audit_clause::=

- ROLES
  - role
Semantics

**policy**
Specify the name of the unified audit policy to be modified. The policy must have been created using the `CREATE AUDIT POLICY` statement. You can find descriptions of all unified audit policies by querying the `AUDIT_UNIFIED_POLICIES` view.

**ADD | DROP**
Use the `ADD` clause to add privileges to be audited to `policy`.
Use the `DROP` clause to remove privileges to be audited from `policy`.
Refer to `privilege_audit_clause`, `action_audit_clause`, and `role_audit_clause` of `CREATE AUDIT POLICY` for the full semantics of these clauses.

**CONDITION**
Use this clause to drop, add, or replace the audit condition for `policy`.
Specify `DROP` to drop the audit condition from `policy`.
Specify `'audit_condition' ...` to add or replace the audit condition for `policy`.
Refer to `audit_condition`, `EVALUATE PER STATEMENT`, `EVALUATE PER SESSION`, and `EVALUATE PER INSTANCE` of `CREATE AUDIT POLICY` for the full semantics of these clauses.

Examples

The following examples modify unified audit policies that were created in the `CREATE AUDIT POLICY "Examples"` on page 14-8.

**Adding Privileges, Actions, and Roles to a Unified Audit Policy: Examples**
The following statement adds the system privileges `CREATE ANY TABLE` and `DROP ANY TABLE` to unified audit policy `dml_pol`:
```
ALTER AUDIT POLICY dml_pol
  ADD PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE;
```

The following statement adds the system actions `CREATE JAVA`, `ALTER JAVA`, and `DROP JAVA` to unified audit policy `java_pol`:
```
ALTER AUDIT POLICY java_pol
  ADD ACTIONS CREATE JAVA, ALTER JAVA, DROP JAVA;
```

The following statement adds the role `dba` to unified audit policy `table_pol`:
```
ALTER AUDIT POLICY table_pol
  ADD ROLES dba;
```

The following statement adds multiple system privileges, actions, and roles to unified audit policy `security_pol`:
```
ALTER AUDIT POLICY security_pol
  ADD PRIVILEGES CREATE ANY LIBRARY, DROP ANY LIBRARY
```
ALTER AUDIT POLICY (Unified Auditing)

```sql
ALTER AUDIT POLICY table_pol
   DROP PRIVILEGES CREATE ANY TABLE;

The following statement drops the INSERT and UPDATE actions on hr.employees from 
unified audit policy dml_pol:

ALTER AUDIT POLICY dml_pol
   DROP ACTIONS INSERT on hr.employees,
       UPDATE on hr.employees;

The following statement drops the role java_deploy from unified audit policy java_ 
pol:

ALTER AUDIT POLICY java_pol
   DROP ROLES java_deploy;

The following statement drops a system privilege, an action, and a role from unified 
audit policy hr_admin_pol:

ALTER AUDIT POLICY hr_admin_pol
   DROP PRIVILEGES CREATE ANY TABLE
       ACTIONS LOCK TABLE
   ROLES audit_viewer;

Adding and Dropping Actions for a Unified Audit Policy: Example  The following 
statement adds EXPORT actions for Oracle Data Pump to unified audit policy dp_ 
actions_pol and drops IMPORT actions for Oracle Data Pump:

ALTER AUDIT POLICY dp_actions_pol
   ADD ACTIONS COMPONENT = datapump EXPORT
   DROP ACTIONS COMPONENT = datapump IMPORT;

Dropping the Audit Condition from a Unified Audit Policy: Example  The following 
statement drops the audit condition from unified audit policy order_updates_pol:

ALTER AUDIT POLICY order_updates_pol
   CONDITION DROP;

Modifying the Audit Condition for a Unified Audit Policy: Example  The following 
statement modifies the audit condition for unified audit policy emp_updates_pol so 
that the policy is enforced only when the auditable statement is issued by a user whose 
UID is 102:

ALTER AUDIT POLICY emp_updates_pol
   CONDITION 'UID = 102'
   EVALUATE PER STATEMENT;
```
ALTER CLUSTER

Purpose

Use the ALTER CLUSTER statement to redefine storage and parallelism characteristics of a cluster.

Note: You cannot use this statement to change the number or the name of columns in the cluster key, and you cannot change the tablespace in which the cluster is stored.

See Also: CREATE CLUSTER on page 14-11 for information on creating a cluster, DROP CLUSTER on page 17-40 and DROP TABLE on page 18-5 for information on removing tables from a cluster, and CREATE TABLE ... physical_properties on page 16-43 for information on adding a table to a cluster

Prerequisites

The cluster must be in your own schema or you must have the ALTER ANY CLUSTER system privilege.

Syntax

alter_cluster::=

ALTER CLUSTER schema.cluster

physical_attributes_clause

SIZE size_clause

MODIFY PARTITION partition

allocate_extent_clause

deallocate_unused_clause

ALTERTABLESPACE

CACHE

NOCACHE

parallel_clause

PCTFREE integer

PCTUSED integer

INITRANS integer

storage_clause

(physical_attributes_clause::= on page 10-28, size_clause::= on page 8-47, MODIFY PARTITION on page 10-30, allocate_extent_clause::= on page 10-29, deallocate_unused_clause::= on page 10-29, parallel_clause::= on page 10-29)

physical_attributes_clause::=

(storage_clause::= on page 8-50)
**allocate_extent_clause::=**

```
ALLOCATE EXTENT
```

(size_clause::= on page 8-47)

**deallocate_unused_clause::=**

```
DEALLOCATE UNUSED KEEP size_clause
```

(size_clause::= on page 8-47)

**parallel_clause::=**

```
PARALLEL integer
```

**Semantics**

**schema**
Specify the schema containing the cluster. If you omit schema, then Oracle Database assumes the cluster is in your own schema.

**cluster**
Specify the name of the cluster to be altered.

**physical_attributes_clause**
Use this clause to change the values of the PCTUSED, PCTFREE, and INITRANS parameters of the cluster.

Use the STORAGE clause to change the storage characteristics of the cluster.

See Also:
- physical_attributes_clause on page 8-44 for information on the parameters
- storage_clause on page 8-46 for a full description of that clause

**Restriction on Physical Attributes** You cannot change the values of the storage parameters INITIAL and MINEXTENTS for a cluster.

**SIZE integer**
Use the SIZE clause to specify the number of cluster keys that will be stored in data blocks allocated to the cluster.
**Restriction on SIZE**  You can change the SIZE parameter only for an indexed cluster, not for a hash cluster.

**See Also:**  CREATE CLUSTER on page 14-11 for a description of the SIZE parameter and "Modifying a Cluster: Example" on page 10-30

**MODIFY PARTITION**
Specify MODIFY PARTITION partition allocate_extent_clause to explicitly allocate a new extent for a cluster partition. This operation is valid only for range-partitioned hash clusters and is available starting with Oracle Database 12c Release 1 (12.1.0.2). For partition, specify the cluster partition name.

**allocate_extent_clause**
Specify allocate_extent_clause to explicitly allocate a new extent for a cluster. This operation is valid only for indexed clusters and nonpartitioned hash clusters.

When you explicitly allocate an extent with the allocate_extent_clause, Oracle Database does not evaluate the storage parameters of the cluster and determine a new size for the next extent to be allocated (as it does when you create a table). Therefore, specify SIZE if you do not want Oracle Database to use a default value.

**See Also:**  allocate_extent_clause on page 8-2 for a full description of this clause

**deallocate_unused_clause**
Use the deallocate_unused_clause to explicitly deallocate unused space at the end of the cluster and make the freed space available for other segments.

**See Also:**  deallocate_unused_clause on page 8-27 for a full description of this clause and "Deallocating Unused Space: Example" on page 10-31

**CACHE | NOCACHE**
This clause has the same behavior in CREATE CLUSTER and ALTER CLUSTER statements.

**See Also:**  "CACHE | NOCACHE" on page 14-16 for information on this clause.

**parallel_clause**
Specify the parallel_clause to change the default degree of parallelism for queries on the cluster.

**See Also:**  parallel_clause on page 16-81 in the documentation on CREATE TABLE for complete information on this clause

**Examples**
The following examples modify the clusters that were created in the CREATE CLUSTER "Examples" on page 14-17.

**Modifying a Cluster: Example**  The next statement alters the personnel cluster:

```sql
ALTER CLUSTER personnel
  SIZE 1024 CACHE;
```
Oracle Database allocates 1024 bytes for each cluster key value and enables the cache attribute. Assuming a data block size of 2 kilobytes, future data blocks within this cluster contain 2 cluster keys in each data block, or 2 kilobytes divided by 1024 bytes.

**Deallocating Unused Space: Example**  The following statement deallocates unused space from the language cluster, keeping 30 kilobytes of unused space for future use:

```
ALTER CLUSTER language
   DEALLOCATE UNUSED KEEP 30 K;
```
ALTER DATABASE

Purpose

Use the `ALTER DATABASE` statement to modify, maintain, or recover an existing database.

See Also:

- *Oracle Database Backup and Recovery User’s Guide* for examples of performing media recovery
- *Oracle Data Guard Concepts and Administration* for additional information on using the `ALTER DATABASE` statement to maintain standby databases
- `CREATE DATABASE` on page 14-29 for information on creating a database

Prerequisites

You must have the `ALTER DATABASE` system privilege.

To specify the `startup_clauses`, you must also be connected as `AS SYSDBA`, `AS SYSOPER`, `AS SYSBACKUP`, or `AS SYSDG`.

To specify the `general_recovery` clause, you must also have the `SYSDBA` or `SYSBACKUP` system privilege.

To specify the `DEFAULT_EDITION` clause, you must also have the `USE` object privilege with `GRANT OPTION` on the specified edition.

If you are connected to a multitenant container database (CDB):

- To modify the entire CDB, the current container must be the root and you must have the commonly granted `ALTER DATABASE` privilege.
- To modify a container, it must be the current container and you must have the `ALTER DATABASE` privilege, either granted commonly or granted locally in the container.

See Also: "Notes on Using ALTER DATABASE in a CDB" on page 10-42 to determine which clauses of `ALTER DATABASE` modify the entire CDB and which clauses modify only a container
Syntax

```
alter_database ::= 
```

Semantics

Notes on Using ALTER DATABASE in a CDB  When you issue the ALTER DATABASE statement while connected to a CDB, the behavior of the statement depends on the current container and the clause(s) you specify.

If the current container is the root, then ALTER DATABASE statements with the following clauses modify the entire CDB. In order to specify these clauses, you must have the commonly granted ALTER DATABASE privilege:

- startup_clauses
- recovery_clauses

Note: A subset of the recovery_clauses are supported to back up and recover an individual pluggable database (PDB). In order to specify these clauses, you must have the ALTER DATABASE privilege, either granted commonly or granted locally in the PDB. Refer to "Notes on Using the recovery_clauses in a CDB" on page 10-44 for more information.

- logfile_clauses
- controlfile_clauses
- standby_database_clauses
- instance_clauses
- security_clause
- RENAME GLOBAL_NAME TO
- ENABLE BLOCK CHANGE TRACKING
- DISABLE BLOCK CHANGE TRACKING

If the current container is the root, then ALTER DATABASE statements with the following clauses modify only the root. In order to specify these clauses, you must have the ALTER DATABASE privilege, either granted commonly or granted locally in the root:

- database_file_clauses
- DEFAULT EDITION
- DEFAULT TABLESPACE

If the current container is the root, then ALTER DATABASE statements with the following clauses modify the root and set default values for the PDBs. In order to specify these clauses, you must have the commonly granted ALTER DATABASE privilege:

- DEFAULT TEMPORARY TABLESPACE
- flashback_mode_clause
- SET DEFAULT { BIGFILE | SMALLFILE } TABLESPACE
- set_time_zone_clause

If the current container is a PDB, then ALTER DATABASE statements modify that PDB. In this case, you can issue only ALTER DATABASE clauses that are also supported by the ALTER PLUGGABLE DATABASE statement. This functionality is provided to maintain backward compatibility for applications that have been migrated to a CDB environment. The exception is modifying PDB storage limits, for which you must use the pdb_storage_clause of ALTER PLUGGABLE DATABASE. Refer to the documentation on ALTER PLUGGABLE DATABASE on page 11-38 for complete information on these clauses.
database
Specify the name of the database to be altered. If you omit database, then Oracle Database alters the database identified by the value of the initialization parameter DB_NAME. You can alter only the database whose control files are specified by the initialization parameter CONTROL_FILES. The database identifier is not related to the Oracle Net database specification.

startup clauses
The startup clauses let you mount and open the database so that it is accessible to users.

MOUNT Clause
Use the MOUNT clause to mount the database. Do not use this clause when the database is already mounted.

MOUNT STANDBY DATABASE You can specify MOUNT STANDBY DATABASE to mount a physical standby database. The keywords STANDBY DATABASE are optional, because Oracle Database determines automatically whether the database to be mounted is a primary or standby database. As soon as this statement executes, the standby instance can receive redo data from the primary instance.

See Also: Oracle Data Guard Concepts and Administration for more information on standby databases

MOUNT CLONE DATABASE Specify MOUNT CLONE DATABASE to mount the clone database.

OPEN Clause
Use the OPEN clause to make the database available for normal use. You must mount the database before you can open it.

If you specify only OPEN without any other keywords, then the default is OPEN READ WRITE NORESETLOGS on a primary database, logical standby database, or snapshot standby database and OPEN READ ONLY on a physical standby database.

OPEN READ WRITE Specify OPEN READ WRITE to open the database in read/write mode, allowing users to generate redo logs. This is the default if you are opening a primary database. You cannot specify this clause for a physical standby database.

See Also: "READ ONLY / READ WRITE: Example" on page 10-69

RESETLOGS | NORESETLOGS This clause determines whether Oracle Database resets the current log sequence number to 1, archives any unarchived logs (including the current log), and discards any redo information that was not applied during recovery, ensuring that it will never be applied. Oracle Database uses NORESETLOGS automatically except in the following specific situations, which require a setting for this clause:

- You must specify RESETLOGS:
  - After performing incomplete media recovery or media recovery using a backup control file
  - After a previous OPEN RESETLOGS operation that did not complete
  - After a FLASHBACK DATABASE operation

See Also: Oracle Data Guard Concepts and Administration for more information on standby databases

SQL Statements: ADMINISTER KEY MANAGEMENT to ALTER JAVA   10-43
If a created control file is mounted, then you must specify **RESETLOGS** if the online logs are lost, or you must specify **NORESETLOGS** if they are not lost.

**UPGRADE | DOWNGRADE** Use these **OPEN** clause parameters only if you are upgrading or downgrading a database. This clause instructs Oracle Database to modify system parameters dynamically as required for upgrade and downgrade, respectively. You can achieve the same result using the SQL*Plus **STARTUP UPGRADE** or **STARTUP DOWNGRADE** command.

When you use the **UPGRADE** or **DOWNGRADE** parameters for a CDB, the root container is opened in the specified mode, but all other containers are opened in **READ WRITE** mode.

**See Also:**
- *Oracle Database Upgrade Guide* for information on the steps required to upgrade or downgrade a database from one release to another
- *SQL*Plus User’s Guide and Reference* for information on the SQL*Plus **STARTUP** command

**OPEN READ ONLY** Specify **OPEN READ ONLY** to restrict users to read-only transactions, preventing them from generating redo logs. This setting is the default when you are opening a physical standby database, so that the physical standby database is available for queries even while archive logs are being copied from the primary database site.

**Restrictions on Opening a Database** The following restrictions apply to opening a database:

- You cannot open a database in **READ ONLY** mode if it is currently opened in **READ WRITE** mode by another instance.
- You cannot open a database in **READ ONLY** mode if it requires recovery.
- You cannot take table spaces offline while the database is open in **READ ONLY** mode. However, you can take data files offline and online, and you can recover offline data files and table spaces while the database is open in **READ ONLY** mode.

**See Also:** *Oracle Data Guard Concepts and Administration* for additional information about opening a physical standby database

**recovery_clauses**

The **recovery_clauses** include post-backup operations. For all of these clauses, Oracle Database recovers the database using any incarnations of data files and log files that are known to the current control file.

**See Also:** *Oracle Database Backup and Recovery User’s Guide* for information on backing up the database and "Database Recovery: Examples" on page 10-72

**Notes on Using the recovery_clauses in a CDB** When the current container is the root, you can specify all of the **recovery_clauses** to back up and recover the entire CDB.

When the current container is a PDB, you can specify the following subclauses of the **recovery_clauses** to back up and recover the PDB:
ALTER DATABASE

SQL Statements: ADMINISTER KEY MANAGEMENT to ALTER JAVA

BEGIN
BACKUP

full_database_recovery: You can specify only the DATABASE keyword

partial_database_recovery

The LOGFILE and CONTINUE clauses of general_recovery

You can also specify the preceding subclauses using the pdb_recovery_clauses of ALTER PLUGGABLE DATABASE. Refer to the syntax diagram pdb_recovery_clauses::= of ALTER PLUGGABLE DATABASE on page 11-40.

general_recovery

The general_recovery clause lets you control media recovery for the database or standby database or for specified tablespaces or files. You can use this clause when your instance has the database mounted, open or closed, and the files involved are not in use.

Note: Parallelism is enabled by default during full or partial database recovery and logfile recovery. The database computes the degree of parallelism. You can disable parallelism of these operations by specifying NOPARALLEL, or specify a degree of parallelism with PARALLEL integer, as shown in the respective syntax diagrams.

Restrictions on General Database Recovery

General recovery is subject to the following restrictions:

- You can recover the entire database only when the database is closed.
- Your instance must have the database mounted in exclusive mode.
- You can recover tablespaces or data files when the database is open or closed, if the tablespaces or data files to be recovered are offline.
- You cannot perform media recovery if you are connected to Oracle Database through the shared server architecture.

See Also:

- Oracle Database Backup and Recovery User's Guide for more information on RMAN media recovery and user-defined media recovery
- SQL*Plus User's Guide and Reference for information on the SQL*Plus RECOVER command

AUTOMATIC

Specify AUTOMATIC if you want Oracle Database to automatically generate the name of the next archived redo log file needed to continue the recovery operation. If the LOG_ARCHIVE_DEST_n parameters are defined, then Oracle Database scans those that are valid and enabled for the first local destination. It uses that destination in conjunction with LOG_ARCHIVE_FORMAT to generate the target redo log filename. If the LOG_ARCHIVE_DEST_n parameters are not defined, then Oracle Database uses the value of the LOG_ARCHIVE_DEST parameter instead.
If the resulting file is found, then Oracle Database applies the redo contained in that file. If the file is not found, then Oracle Database prompts you for a filename, displaying the generated filename as a suggestion.

If you specify neither `AUTOMATIC` nor `LOGFILE`, then Oracle Database prompts you for a filename, displaying the generated filename as a suggestion. You can then accept the generated filename or replace it with a fully qualified filename. If you know that the archived filename differs from what Oracle Database would generate, then you can save time by using the `LOGFILE` clause.

**FROM 'location'**
Specify `FROM 'location'` to indicate the location from which the archived redo log file group is read. The value of `location` must be a fully specified file location following the conventions of your operating system. If you omit this parameter, then Oracle Database assumes that the archived redo log file group is in the location specified by the initialization parameter `LOG_ARCHIVE_DEST` or `LOG_ARCHIVE_DEST_1`.

**full_database_recovery**
The `full_database_recovery` clause lets you recover an entire database.

**DATABASE** Specify the `DATABASE` clause to recover the entire database. This is the default. You can use this clause only when the database is closed.

**STANDBY DATABASE** Specify the `STANDBY DATABASE` clause to manually recover a physical standby database using the control file and archived redo log files copied from the primary database. The standby database must be mounted but not open.
This clause recovers only online data files.

- Use the `UNTIL` clause to specify the duration of the recovery operation.
  - `CANCEL` indicates cancel-based recovery. This clause recovers the database until you issue the `ALTER DATABASE` statement with the `RECOVER CANCEL` clause.
  - `TIME` indicates time-based recovery. This parameter recovers the database to the time specified by the date. The date must be a character literal in the format `'YYYY-MM-DD:HH24:MI:SS'`.
  - `CHANGE` indicates change-based recovery. This parameter recovers the database to a transaction-consistent state immediately before the system change number specified by `integer`.
  - `CONSISTENT` recovers the database until all online files are brought to a consistent SCN point so that the database can be open in read only mode. This clauses requires the controlfile to be a backup controlfile.

- Specify `USING BACKUP CONTROLFILE` if you want to use a backup control file instead of the current control file.

- Specify the `SNAPSHOT TIME` clause to recover the database with a storage snapshot using Storage Snapshot Optimization. This clause can be used in cases where the database was not placed in backup mode when the storage snapshot was created.
  - `date` must be a character literal in the format `'YYYY-MM-DD:HH24:MI:SS'`. It must represent a time that is immediately after the snapshot was completed. If you specify the `UNTIL TIME` clause, then `SNAPSHOT TIME` `date` must be earlier than `UNTIL TIME` `date`.

**See Also:** *Oracle Database Backup and Recovery User’s Guide* for more information on recovery using Storage Snapshot Optimization.
**partial_database_recovery**
The `partial_database_recovery` clause lets you recover individual tablespaces and data files.

**TABLESPACE** Specify the `TABLESPACE` clause to recover only the specified tablespaces. You can use this clause if the database is open or closed, provided the tablespaces to be recovered are offline.

**See Also:**  "Using Parallel Recovery Processes: Example" on page 10-69

**DATAFILE** Specify the `DATAFILE` clause to recover the specified data files. You can use this clause when the database is open or closed, provided the data files to be recovered are offline.

You can identify the data file by name or by number. If you identify it by number, then `filenumber` is an integer representing the number found in the `FILE#` column of the `V$DATAFILE` dynamic performance view or in the `FILE_ID` column of the `DBA_DATA_FILES` data dictionary view.

**STANDBY (TABLESPACE | DATAFILE)** In earlier releases, you could specify `STANDBY TABLESPACE` or `STANDBY DATAFILE` to recover older backups of a specific tablespace or a specific data file on the standby to be consistent with the rest of the standby database. These two clauses are now desupported. Instead, to recover the standby database to a consistent point, but no further, use the statement `ALTER DATABASE RECOVER MANAGED STANDBY DATABASE UNTIL CONSISTENT`.

**LOGFILE**
Specify the `LOGFILE 'filename'` to continue media recovery by applying the specified redo log file.

**TEST**
Use the `TEST` clause to conduct a trial recovery. A trial recovery is useful if a normal recovery procedure has encountered some problem. It lets you look ahead into the redo stream to detect possible additional problems. The trial recovery applies redo in a way similar to normal recovery, but it does not write changes to disk, and it rolls back its changes at the end of the trial recovery.

You can use this clause only if you have restored a backup taken since the last `RESETLOGS` operation. Otherwise, Oracle Database returns an error.

**ALLOW ... CORRUPTION**
The `ALLOW integer CORRUPTION` clause lets you specify, in the event of logfile corruption, the number of corrupt blocks that can be tolerated while allowing recovery to proceed.

**See Also:**
- Oracle Database Backup and Recovery User’s Guide for information on database recovery in general
- Oracle Data Guard Concepts and Administration for information on managed recovery of standby databases
**CONTINUE**

Specify `CONTINUE` to continue multi-instance recovery after it has been interrupted to disable a thread.

Specify `CONTINUE DEFAULT` to continue recovery using the redo log file that Oracle Database would automatically generate if no other logfile were specified. This clause is equivalent to specifying `AUTOMATIC`, except that Oracle Database does not prompt for a filename.

**CANCEL**

Specify `CANCEL` to terminate cancel-based recovery.

**managed_standby_recovery**

Use the `managed_standby_recovery` clause to start and stop Redo Apply on a physical standby database. Redo Apply keeps the standby database transactionally consistent with the primary database by continuously applying redo received from the primary database.

A primary database transmits its redo data to standby sites. As the redo data is written to redo log files at the physical standby site, the log files become available for use by Redo Apply. You can use the `managed_standby_recovery` clause when your standby instance has the database mounted or is opened read-only.

---

**Note:** Beginning with Oracle Database 12c, *real-time apply* is enabled by default during Redo Apply. Real-time apply recovers redo from the standby redo log files as soon as they are written, without requiring them to be archived first at the physical standby database. You can disable real-time apply with the `USING ARCHIVED LOGFILE` clause. Refer to:

- *Oracle Data Guard Concepts and Administration* for more information on real-time apply
- *USING ARCHIVED LOGFILE Clause* on page 10-48

---

**Note:** Parallelism is enabled by default during Redo Apply. The database computes the degree of parallelism. You can disable parallelism of these operations by specifying `NOPARALLEL`, or specify a degree of parallelism with `PARALLEL integer`, as shown in the respective syntax diagrams.

**Restrictions on Managed Standby Recovery** The same restrictions listed under `general_recovery` on page 10-45 apply to this clause.

**See Also:** *Oracle Data Guard Concepts and Administration* for more information on the use of this clause

**USING ARCHIVED LOGFILE Clause** Specify `USING ARCHIVED LOGFILE` to start Redo Apply without enabling real-time apply.

**DISCONNECT** Specify `DISCONNECT` to indicate that Redo Apply should be performed in the background, leaving the current session available for other tasks. The `FROM SESSION` keywords are optional and are provided for semantic clarity.
**NODELAY**  The NODELAY clause overrides the DELAY attribute on the LOG_ARCHIVE_DEST_n parameter on the primary database. If you do not specify the NODELAY clause, then application of the archived redo log file is delayed according to the DELAY attribute of the LOG_ARCHIVE_DEST_n setting (if any). If the DELAY attribute was not specified on that parameter, then the archived redo log file is applied immediately to the standby database.

If you specify real-time apply with the USING CURRENT LOGFILE clause, then any DELAY value specified for the LOG_ARCHIVE_DEST_n parameter at the primary for this standby is ignored, and NODELAY is the default.

**UNTIL CHANGE Clause**  Use this clause to instruct Redo Apply to recover redo data up to, but not including, the specified system change number.

**UNTIL CONSISTENT**  Use this clause to recover the standby database to a consistent SCN point so that the standby database can be opened in read only mode.

**FINISH**  Specify FINISH to complete applying all available redo data in preparation for a failover.

Use the FINISH clause only in the event of the failure of the primary database. This clause overrides any specified delay intervals and applies all available redo immediately. After the FINISH command completes, this database can no longer run in the standby database role, and it must be converted to a primary database by issuing the ALTER DATABASE COMMIT TO SWITCHOVER TO PRIMARY statement.

**CANCEL**  Specify CANCEL to stop Redo Apply immediately. Control is returned as soon as Redo Apply stops.

**TO LOGICAL STANDBY Clause**  Use this clause to convert a physical standby database into a logical standby database.

**db_name**  Specify a database name to identify the new logical standby database. If you are using a server parameter file (spfile) at the time you issue this statement, then the database will update the file with appropriate information about the new logical standby database. If you are not using an spfile, then the database issues a message reminding you to set the name of the DB_NAME parameter after shutting down the database. In addition, you must invoke the DBMS_LOGSTDBY.BUILD PL/SQL procedure on the primary database before using this clause on the standby database.

See Also:  *Oracle Database PL/SQL Packages and Types Reference* for information about the DBMS_LOGSTDBY.BUILD procedure

**KEEP IDENTITY**  Use this clause if you want to use the rolling upgrade feature provided by a logical standby and also revert to the original configuration of a primary database and a physical standby. A logical standby database created using this clause provides only limited support for switchover and failover. Therefore, do not use this clause create a general-purpose logical standby database.

See Also:  *Oracle Data Guard Concepts and Administration* for more information on rolling upgrade

**Deprecated Managed Standby Recovery Clauses**  The following clauses appeared in the syntax of earlier releases. They have been deprecated and are no longer needed. Oracle recommends that you do not use these clauses.
**FINISH FORCE, FINISH WAIT, FINISH NOWAIT** These optional forms of the `FINISH` clause are deprecated. Their semantics are presented here for backward compatibility:

- `FORCE` terminates inactive redo transport sessions that would otherwise prevent `FINISH` processing from beginning.
- `NOWAIT` returns control to the foreground process before the recovery completes
- `WAIT` (the default) returns control to the foreground process after recovery completes

When specified, these clauses are ignored. Terminal recovery now runs in the foreground and always terminates all redo transport sessions. Therefore control is not returned to the user until recovery completes.

**CANCEL IMMEDIATE, CANCEL WAIT, CANCEL NOWAIT** These optional forms of the `CANCEL` clause are deprecated. Their semantics are presented here for backward compatibility:

- Include the `IMMEDIATE` keyword to stop Redo Apply before completely applying the current redo log file. Session control returns when Redo Apply actually stops.
- Include the `NOWAIT` keyword to return session control without waiting for the `CANCEL` operation to complete.

When specified, these clauses are ignored. Redo Apply is now always cancelled immediately and control returns to the session only after the operation completes.

**USING CURRENT LOGFILE Clause** The `USING CURRENT LOGFILE` clause is deprecated. It invokes real-time apply during Redo Apply. However, this is now the default behavior and this clause is no longer useful.

**BACKUP Clauses**

Use these clauses to move all the data files in the database into or out of online backup mode (also called hot backup mode).

**See Also:** `ALTER TABLESPACE` on page 12-114 for information on moving all data files in an individual tablespace into and out of online backup mode

**BEGIN BACKUP Clause**

Specify `BEGIN BACKUP` to move all data files in the database into online backup mode. The database must be mounted and open, and media recovery must be enabled (the database must be in `ARCHIVELOG` mode).

While the database is in online backup mode, you cannot shut down the instance normally, begin backup of an individual tablespace, or take any tablespace offline or make it read only.

This clause has no effect on data files that are in offline or on read-only tablespaces.

**END BACKUP Clause**

Specify `END BACKUP` to take out of online backup mode any data files in the database currently in online backup mode. The database must be mounted (either open or closed) when you perform this operation.

After a system failure, instance failure, or `SHUTDOWN ABORT` operation, Oracle Database does not know whether the files in online backup mode match the files at the time the system crashed. If you know the files are consistent, then you can take either
individual data files or all data files out of online backup mode. Doing so avoids media recovery of the files upon startup.

- To take an individual data file out of online backup mode, use the `ALTER DATABASE DATAFILE ... END BACKUP` statement. See `database_file_clauses` on page 10-51.
- To take all data files in a tablespace out of online backup mode, use an `ALTER TABLESPACE ... END BACKUP` statement.

### database_file_clauses

The `database_file_clauses` let you modify data files and temp files. You can use any of the following clauses when your instance has the database mounted, open or closed, and the files involved are not in use. The exception is the `move_datafile_clause`, which allows you to move a data file that is in use.

### RENAME FILE Clause

Use the `RENAME FILE` clause to rename data files, temp files, or redo log file members. You must create each filename using the conventions for filenames on your operating system before specifying this clause.

- To use this clause for a data file or temp file, the database must be mounted. The database can also be open, but the data file or temp file being renamed must be offline. In addition, you must first rename the file on the file system to the new name.
- To use this clause for logfiles, the database must be mounted but not open.
- If you have enabled block change tracking, then you can use this clause to rename the block change tracking file. The database must be mounted but not open when you rename the block change tracking file.

This clause renames only files in the control file. It does not actually rename them on your operating system. The operating system files continue to exist, but Oracle Database no longer uses them.

### See Also:

- `Oracle Database Backup and Recovery User’s Guide` for information on recovery of data files and temp files
- "Renaming a Log File Member: Example" on page 10-70 and "Manipulating Temp Files: Example" on page 10-71

### create_datafile_clause

Use the `CREATE DATAFILE` clause to create a new empty data file in place of an old one. You can use this clause to re-create a data file that was lost with no backup. The `filename` or `filenumber` must identify a file that is or was once part of the database. If you identify the file by number, then `filenumber` is an integer representing the number found in the `FILE#` column of the `V$DATAFILE` dynamic performance view or in the `FILE_ID` column of the `DBA_DATA_FILES` data dictionary view.

- Specify `AS NEW` to create an Oracle-managed data file with a system-generated filename, the same size as the file being replaced, in the default file system location for data files.
- Specify `AS file_specification` to assign a file name (and optional size) to the new data file. Use the `datafile_tempfile_spec` form of `file_specification` (see `file_specification` on page 8-29) to list regular data files and temp files in an
ALTER DATABASE

operating system file system or to list Oracle Automatic Storage Management (Oracle ASM) disk group files.

If the original file (filename or filenumber) is an existing Oracle-managed data file, then Oracle Database attempts to delete the original file after creating the new file. If the original file is an existing user-managed data file, then Oracle Database does not attempt to delete the original file.

If you omit the AS clause entirely, then Oracle Database creates the new file with the same name and size as the file specified by filename or filenumber.

During recovery, all archived redo logs written to since the original data file was created must be applied to the new, empty version of the lost data file.

Oracle Database creates the new file in the same state as the old file when it was created. You must perform media recovery on the new file to return it to the state of the old file at the time it was lost.

Restrictions on Creating New Data Files The creation of new data files is subject to the following restrictions:

- You cannot create a new file based on the first data file of the SYSTEM tablespace.
- You cannot specify the autoextend clause of datafile_tempfile_spec in this CREATE DATAFILE clause.

See Also:
- "DATAFILE Clause" on page 14-25 of CREATE DATABASE for information on the result of this clause if you do not specify a name for the new data file.
- file_specification on page 8-29 for a full description of the file specification (datafile_tempfile_spec) and "Creating a New Data File: Example" on page 10-71

alter_datafile_clause

The DATAFILE clause lets you manipulate a file that you identify by name or by number. If you identify it by number, then filenumber is an integer representing the number found in the FILE# column of the V$DATAFILE dynamic performance view or in the FILE_ID column of the DBA_DATA_FILES data dictionary view. The DATAFILE clauses affect your database files as follows:

ONLINE Specify ONLINE to bring the data file online.

OFFLINE Specify OFFLINE to take the data file offline. If the database is open, then you must perform media recovery on the data file before bringing it back online, because a checkpoint is not performed on the data file before it is taken offline.

FOR DROP If the database is in NOARCHIVELOG mode, then you must specify FOR DROP clause to take a data file offline. However, this clause does not remove the data file from the database. To do that, you must use an operating system command or drop the tablespace in which the data file resides. Until you do so, the data file remains in the data dictionary with the status RECOVER or OFFLINE.

If the database is in ARCHIVELOG mode, then Oracle Database ignores the FOR DROP clause.
ALTER DATABASE

RESIZE Specify RESIZE if you want Oracle Database to attempt to increase or decrease the size of the data file to the specified absolute size in bytes. There is no default, so you must specify a size.

If sufficient disk space is not available for the increased size, or if the file contains data beyond the specified decreased size, then Oracle Database returns an error.

See Also: "Resizing a Data File: Example" on page 10-71

END BACKUP Specify END BACKUP to take the data file out of online backup mode. The END BACKUP clause is described more fully at the top level of the syntax of ALTER DATABASE. See "END BACKUP Clause" on page 10-50.

alter tempfile clause
Use the TEMPFILE clause to resize your temporary data file or specify the autoextend_clause, with the same effect as for a permanent data file. The database must be open. You can identify the temp file by name or by number. If you identify it by number, then filenumber is an integer representing the number found in the FILE# column of the V$TEMPFILE dynamic performance view.

Note: On some operating systems, Oracle does not allocate space for a temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. To avoid potential problems, before you create or resize a temp file, ensure that the available disk space exceeds the size of the new temp file or the increased size of a resized temp file. The excess space should allow for anticipated increases in disk space use by unrelated operations as well. Then proceed with the creation or resizing operation.

DROP Specify DROP to drop tempfile from the database. The tablespace remains.
If you specify INCLUDING DATAFILES, then Oracle Database also deletes the associated operating system files and writes a message to the alert log for each such deleted file. You can achieve the same result using an ALTER TABLESPACE ... DROP TEMPFILE statement. Refer to the ALTER TABLESPACE DROP Clause on page 12-120 for more information.

move datafile clause
Use the MOVE DATAFILE clause to move an online data file to a new location. The database can be open and accessing the data file when you perform this operation. The database creates a copy of the data file when it is performing this operation. Ensure that there is adequate disk space for the original data file and the copy before using this clause.

You can specify the original data file using the file_name, ASM_filename, or file_number. Refer to ASM_filename on page 8-32 for information on ASM file names. If you identify the file by number, then file_number is an integer representing the number found in the FILE# column of the V$DATAFILE dynamic performance view or in the FILE_ID column of the DBA_DATA_FILES data dictionary view.

Use the TO clause to specify the new file_name or ASM_filename. If you are using Oracle Managed Files, then you can omit the TO clause. In this case, Oracle Database
creates a unique name for the data file and saves it in the directory specified by the **DB_CREATE_FILE_DEST** initialization parameter.

If you specify **REUSE**, then the new data file is created even if it already exists.

If you specify **KEEP**, then the original data file will be kept after the **MOVE DATAFILE** operation. You cannot specify **KEEP** if the original data file is an Oracle Managed File. You can specify **KEEP** if the new data file is an Oracle Managed File.

**autoextend_clause**

Use the **autoextend_clause** to enable or disable the automatic extension of a new or existing data file or temp file. Refer to **file_specification** on page 8-29 for information about this clause.

**logfile_clauses**

The logfile clauses let you add, drop, or modify log files.

**ARCHIVELOG**

Specify **ARCHIVELOG** if you want the contents of a redo log file group to be archived before the group can be reused. This mode prepares for the possibility of media recovery. Use this clause only after shutting down your instance normally, or immediately with no errors, and then restarting it and mounting the database.

**MANUAL**  Specify **MANUAL** to indicate that Oracle Database should create redo log files, but the archiving of the redo log files is controlled entirely by the user. This clause is provided for backward compatibility, for example for users who archive directly to tape. If you specify **MANUAL**, then:

- Oracle Database does not archive redo log files when a log switch occurs. You must handle this manually.
- You cannot have specified a standby database as an archivelog destinations. As a result, the database cannot be in **MAXIMUM PROTECTION** or **MAXIMUM AVAILABILITY** standby protection mode.

If you omit this clause, then Oracle Database automatically archives the redo log files to the destination specified in the **LOG_ARCHIVE_DEST_n** initialization parameters.

**NOARCHIVELOG**

Specify **NOARCHIVELOG** if you do not want the contents of a redo log file group to be archived so that the group can be reused. This mode does not prepare for recovery after media failure. Use this clause only if your instance has the database mounted but not open.

**[NO] FORCE LOGGING**

Use this clause to put the database into or take the database out of **FORCE LOGGING** mode. The database must be mounted or open.

In **FORCE LOGGING** mode, Oracle Database logs all changes in the database except changes in temporary tablespaces and temporary segments. This setting takes precedence over and is independent of any **NOLOGGING** or **FORCE LOGGING** settings you specify for individual tablespaces and any **NOLOGGING** settings you specify for individual database objects.

If you specify **FORCE LOGGING**, then Oracle Database waits for all ongoing unlogged operations to finish.
**See Also:** *Oracle Database Administrator’s Guide* for information on when to use **FORCE LOGGING** mode

### RENAME FILE Clause

This clause has the same function for logfiles that it has for data files and temp files. See “RENAME FILE Clause” on page 10-51.

### CLEAR LOGFILE Clause

Use the `CLEAR LOGFILE` clause to reinitialize an online redo log, optionally without archiving the redo log. `CLEAR LOGFILE` is similar to adding and dropping a redo log, except that the statement may be issued even if there are only two logs for the thread and may be issued for the current redo log of a closed thread.

For a standby database, if the `STANDBY_FILE_MANAGEMENT` initialization parameter is set to `AUTO`, and if any of the log files are Oracle Managed Files, Oracle Database will create as many Oracle-managed log files as are in the control file. The log file members will reside in the current default log file destination.

- You must specify **UNARCHIVED** if you want to reuse a redo log that was not archived.

  **Caution:** Specifying **UNARCHIVED** makes backups unusable if the redo log is needed for recovery.

- You must specify **UNRECOVERABLE DATAFILE** if you have taken the data file offline with the database in **ARCHIVELOG** mode (that is, you specified `ALTER DATABASE ... DATAFILE OFFLINE` without the **DROP** keyword), and if the unarchived log to be cleared is needed to recover the data file before bringing it back online. In this case, you must drop the data file and the entire tablespace once the `CLEAR LOGFILE` statement completes.

  Do not use `CLEAR LOGFILE` to clear a log needed for media recovery. If it is necessary to clear a log containing redo after the database checkpoint, then you must first perform incomplete media recovery. The current redo log of an open thread can be cleared. The current log of a closed thread can be cleared by switching logs in the closed thread.

  If the `CLEAR LOGFILE` statement is interrupted by a system or instance failure, then the database may hang. In this case, reissue the statement after the database is restarted. If the failure occurred because of I/O errors accessing one member of a log group, then that member can be dropped and other members added.

  **See Also:** “Clearing a Log File: Example” on page 10-71

### ADD LOGFILE Clauses

Use these clauses to add redo log file groups to the database and to add new members to existing redo log file groups.

**ADD LOGFILE Clause**

Use the `ADD LOGFILE` clause to add one or more redo log file groups to the online redo log or standby log.
See Also:

- "LOGFILE Clause" on page 14-34 of CREATE DATABASE for information on the result of this clause for Oracle Managed Files if you do not specify a name for the new log file group
- "Adding Redo Log File Groups: Examples" on page 10-70
- Oracle Data Guard Concepts and Administration for more information on standby redo logs

STANDBY Use the STANDBY clause to add a redo log file group to the standby redo log. If you do not specify this clause, then a log file group is added to the online redo log.

INSTANCE The INSTANCE clause is applicable only for Oracle Real Application Clusters (Oracle RAC) or Oracle RAC One Node databases. Specify the name of the instance for which you want to add a redo log file group. The instance name is a string of up to 80 characters. Oracle Database automatically uses the thread that is mapped to the specified instance. If no thread is mapped to the specified instance, then Oracle Database automatically acquires an available unmapped thread and assigns it to that instance. If you do not specify this clause, then Oracle Database executes the command as if you had specified the current instance. If the specified instance has no current thread mapping and there are no available unmapped threads, then Oracle Database returns an error.

THREAD When adding a redo log file group to the standby redo log, use the THREAD clause to assign the log file group to a specific primary database redo thread. Query the V$INSTANCE view on the primary database to determine which redo threads have been opened, and specify one of these thread numbers.

You can also use the THREAD clause to assign a log file group to a specific redo thread when adding the log file group to the online redo log. This usage has been deprecated. The INSTANCE clause achieves the same purpose and is easier to use.

GROUP The GROUP clause uniquely identifies the redo log file group among all groups in all threads and can range from 1 to the value specified for MAXLOGFILES in the CREATE DATABASE statement. You cannot add multiple redo log file groups having the same GROUP value. If you omit this parameter, then Oracle Database generates its value automatically. You can examine the GROUP value for a redo log file group through the dynamic performance view V$LOG.

redo_log_file_spec Each redo_log_file_spec specifies a redo log file group containing one or more members (copies). If you do not specify a filename for the new log file, then Oracle Database creates Oracle Managed Files according to the rules described in the "LOGFILE Clause" on page 14-34 of CREATE DATABASE.

See Also:

- file_specification on page 8-29
- Oracle Database Reference for information on dynamic performance views

ADD LOGFILE MEMBER Clause Use the ADD LOGFILE MEMBER clause to add new members to existing redo log file groups. Each new member is specified by 'filename'. If the file already exists, then it must be the same size as the other group members and you must specify REUSE. If the file does not exist, then Oracle Database
creates a file of the correct size. You cannot add a member to a group if all of the members of the group have been lost through media failure.

**STANDBY** You must specify `STANDBY` when adding a member to a standby redo log file group. Otherwise, Oracle Database returns an error.

You can use the `logfile_descriptor` clause to specify an existing redo log file group in one of two ways:

* **GROUP integer** Specify the value of the `GROUP` parameter that identifies the redo log file group.

* **filename(s)** List all members of the redo log file group. You must fully specify each filename according to the conventions of your operating system.

**See Also:**

- "LOGFILE Clause" on page 14-34 of `CREATE DATABASE` for information on the result of this clause for Oracle Managed Files if you do not specify a name for the new log file group

- "Adding Redo Log File Group Members: Example" on page 10-70

**drop_logfile_clauses**

Use these clauses to drop redo log file groups or redo log file members.

**DROP LOGFILE Clause** Use the `DROP LOGFILE` clause to drop all members of a redo log file group. If you use this clause to drop Oracle Managed Files, then Oracle Database also removes all log file members from disk. Specify a redo log file group as indicated for the `ADD LOGFILE MEMBER` clause.

- To drop the current log file group, you must first issue an `ALTER SYSTEM SWITCH LOGFILE` statement.

- You cannot drop a redo log file group if it needs archiving.

- You cannot drop a redo log file group if doing so would cause the redo thread to contain less than two redo log file groups.

**See Also:** `ALTER SYSTEM` on page 11-81 and "Dropping Log File Members: Example" on page 10-70

**DROP LOGFILE MEMBER Clause** Use the `DROP LOGFILE MEMBER` clause to drop one or more redo log file members. Each `filename` must fully specify a member using the conventions for filenames on your operating system.

- To drop a log file in the current log, you must first issue an `ALTER SYSTEM SWITCH LOGFILE` statement. Refer to `ALTER SYSTEM` on page 11-81 for more information.

- You cannot use this clause to drop all members of a redo log file group that contains valid data. To perform that operation, use the `DROP LOGFILE` clause.

**See Also:** "Dropping Log File Members: Example" on page 10-70

**switch_logfile_clause**

This clause is useful when you are migrating the database to disks with a different block size that the block size of the current database. Use this clause to switch logfiles to a different block size for all externally enabled threads, including both open and closed threads. If you are migrating the database to use 4KB sector disks, then you
must specify 4096 for integer. If you are unmigrating the database back to using 512B sector disks, then you must specify 512 for integer.

This clause is an extension of the existing ALTER SYSTEM SWITCH LOGFILE statement. That statement switches logs for a single thread. This clause switches logfiles for all externally enabled threads, including both open and closed threads.

Before using this clause, you must already have created at least two redo log groups with the same target block size on the migration target disk.

See Also:  Oracle Database Administrator’s Guide for more information on migrating the database to disks with a different block size, and “Adding a Log File: Example” on page 8-36

**supplemental_db_logging**

Use these clauses to instruct Oracle Database to add or stop adding supplemental data into the log stream.

**ADD SUPPLEMENTAL LOG Clause**  Specify ADD SUPPLEMENTAL LOG DATA to enable minimal supplemental logging. Specify ADD SUPPLEMENTAL LOG supplemental_id_key_clause to enable column data logging in addition to minimal supplemental logging. Specify ADD SUPPLEMENTAL LOG supplemental_plsql_clause to enable supplemental logging of PL/SQL calls. Oracle Database does not enable either minimal supplemental logging or supplemental logging by default.

Minimal supplemental logging ensures that LogMiner (and any products building on LogMiner technology) will have sufficient information to support chained rows and various storage arrangements such as cluster tables.

If the redo generated on one database is to be the source of changes (to be mined and applied) at another database, as is the case with logical standby, then the affected rows need to be identified using column data (as opposed to rowids). In this case, you should specify the supplemental_id_key_clause.

You can query the appropriate columns in the V$DATABASE view to determine whether any supplemental logging has already been enabled.

You can use this clause when the database is open. However, Oracle Database will invalidate all DML cursors in the cursor cache, which will have an effect on performance until the cache is repopulated.

If you use this clause in a CDB, then the current container must be the root and the operation will be performed on the entire CDB.

For a full discussion of the supplemental_id_clause, refer to supplemental_id_key_clause on page 16-42 in the documentation on CREATE TABLE.

See Also:

-  Oracle Data Guard Concepts and Administration for information on supplemental logging on the primary database to support a logical standby database
-  Oracle Database Utilities for examples using the supplemental_db_logging clause syntax

**DROP SUPPLEMENTAL LOG Clause**

Use this clause to stop supplemental logging.
ALTER DATABASE

- Specify `DROP SUPPLEMENTAL LOG DATA` to instruct Oracle Database to stop placing minimal additional log information into the redo log stream whenever an update operation occurs. If Oracle Database is doing column data supplemental logging specified with the `supplemental_id_key_clause`, then you must first stop the column data supplemental logging with the `DROP SUPPLEMENTAL LOG supplemental_id_key_clause` and then specify this clause.

- Specify `DROP SUPPLEMENTAL LOG supplemental_id_key_clause` to drop some or all of the system-generated supplemental log groups. You must specify the `supplemental_id_key_clause` if the supplemental log groups you want to drop were added using that clause.

- Specify `DROP SUPPLEMENTAL LOG supplemental_plsql_clause disable supplementary logging of PL/SQL calls.`

If you use this clause in a CDB, then the current container must be the root and the operation will be performed on the entire CDB.

**See Also:** *Oracle Data Guard Concepts and Administration* for information on supplemental logging

### controlfile_clauses

The `controlfile_clauses` let you create or back up a control file.

#### CREATE CONTROLFILE Clause

The `CREATE CONTROLFILE` clause lets you create a control file.

- Specify `PHYSICAL STANDBY` to create a control file to be used to maintain a physical database. This is the default if you specify `STANDBY` and do not specify `PHYSICAL` or `LOGICAL`.

- Specify `LOGICAL STANDBY` to create a control file to be used to maintain a logical database.

- Specify `FAR SYNC INSTANCE` to create a control file to be used to maintain a Data Guard far sync instance.

If the file already exists, then you must specify `REUSE`. In an Oracle RAC environment, the control file must be on shared storage.

**See Also:** *Oracle Data Guard Concepts and Administration* for more information on creating control files

#### BACKUP CONTROLFILE Clause

Use the `BACKUP CONTROLFILE` clause to back up the current control file. The database must be open or mounted when you specify this clause.

**TO ‘filename’** Use this clause to specify a binary backup of the control file. You must fully specify the `filename` using the conventions for your operating system. If the specified file already exists, then you must specify `REUSE`. In an Oracle RAC environment, `filename` must be on shared storage.

A binary backup contains information that is not captured if you specify `TO TRACE`, such as the archived log history, offline range for read-only and offline tablespaces, and backup sets and copies (if you use RMAN). If the `COMPATIBLE` initialization parameter is 10.2 or higher, binary control file backups include temp file entries.
ALTER DATABASE

TO TRACE  Specify TO TRACE if you want Oracle Database to write SQL statements to a trace file rather than making a physical backup of the control file. You can use SQL statements written to the trace file to start up the database, re-create the control file, and recover and open the database appropriately, based on the created control file. If you issue an ALTER DATABASE BACKUP CONTROLFILE TO TRACE statement while block change tracking is enabled, then the resulting trace file will contain a command to reenable block change tracking.

This statement issues an implicit ALTER DATABASE REGISTER LOGFILE statement, which creates incarnation records if the archived log files reside in the current archivelog destinations.

The trace file will also include ALTER DATABASE REGISTER LOGFILE statements for existing logfiles that reside in the current archivelog destinations. This will implicitly create database incarnation records for the branches of redo to which the logfiles apply.

You can copy the statements from the trace file into a script file, edit the statements as necessary, and use the script if all copies of the control file are lost (or to change the size of the control file).

- Specify AS filename if you want Oracle Database to place the trace output into a file called filename rather than into the standard trace file.
- Specify REUSE to allow Oracle Database to overwrite any existing file called filename.
- RESETLOGS indicates that the SQL statement written to the trace file for starting the database is ALTER DATABASE OPEN RESETLOGS. This setting is valid only if the online logs are unavailable.
- NORESETLOGS indicates that the SQL statement written to the trace file for starting the database is ALTER DATABASE OPEN NORESETLOGS. This setting is valid only if all the online logs are available.

If you cannot predict the future state of the online logs, then specify neither RESETLOGS nor NORESETLOGS. In this case, Oracle Database puts both versions of the script into the trace file, and you can choose which version is appropriate when the script becomes necessary.

The trace files are stored in a subdirectory determined by the DIAGNOSTIC_DEST initialization parameter. You can find the name and location of the trace file to which the CREATE CONTROLFILE statements were written by looking in the alert log. You can also find the directory for trace files by querying the NAME and VALUE columns of the V$DIAG_INFO dynamic performance view.

See Also: Oracle Database Administrator’s Guide for information on viewing the alert log

standby_database_clauses

Use these clauses to activate the standby database or to specify whether it is in protected or unprotected mode.

See Also: Oracle Data Guard Concepts and Administration for descriptions of the physical and logical standby database and for information on maintaining and using standby databases
**activate_standby_db_clause**

Use the `ALTER DATABASE` clause to convert a standby database into a primary database.

---

**Caution:** Before using this command, refer to Oracle Data Guard Concepts and Administration for important usage information.

---

**PHYSICAL** Specify PHYSICAL to activate a physical standby database. This is the default.

**LOGICAL** Specify LOGICAL to activate a logical standby database. If you have more than one logical standby database, then you should first ensure that the same log data is available on all the standby systems.

**FINISH APPLY** This clause applies only to logical standby databases. Use it to initiate terminal apply, which is the application of any remaining redo to bring the logical standby database to the same state as the primary database. When terminal apply is complete, the database completes the switchover from logical standby to primary database.

If you require immediate restoration of the database in spite of data loss, then omit this clause. The database will execute the switchover from logical standby to primary database immediately without terminal apply.

**maximize_standby_db_clause**

Use this clause to specify the level of protection for the data in your database environment. You specify this clause from the primary database.

---

**Note:** The PROTECTED and UNPROTECTED keywords have been replaced for clarity but are still supported. PROTECTED is equivalent to TO MAXIMIZE PROTECTION. UNPROTECTED is equivalent to TO MAXIMIZE PERFORMANCE.

---

**TO MAXIMIZE PROTECTION** This setting establishes maximum protection mode and offers the highest level of data protection. A transaction does not commit until all data needed to recover that transaction has been written to at least one physical standby database that is configured to use the SYNC log transport mode. If the primary database is unable to write the redo records to at least one such standby database, then the primary database is shut down. This mode guarantees zero data loss, but it has the greatest potential impact on the performance and availability of the primary database.

**Restriction on Establishing Maximum Protection Mode** You can specify TO MAXIMIZE PROTECTION on an open database only if the current data protection mode is MAXIMUM AVAILABILITY and there is at least one synchronized standby database.

**TO MAXIMIZE AVAILABILITY** This setting establishes maximum availability mode and offers the next highest level of data protection. A transaction does not commit until all data needed to recover that transaction has been written to at least one physical or logical standby database that is configured to use the SYNC log transport mode. Unlike maximum protection mode, the primary database does not shut down if it is unable to write the redo records to at least one such standby database. Instead, the protection is lowered to maximum performance mode until the fault has been corrected and the standby database has caught up with the primary database. This
mode guarantees zero data loss unless the primary database fails while in maximum performance mode. Maximum availability mode provides the highest level of data protection that is possible without affecting the availability of the primary database.

**TO MAXIMIZE PERFORMANCE** This setting establishes maximum performance mode and is the default setting. A transaction commits before the data needed to recover that transaction has been written to a standby database. Therefore, some transactions may be lost if the primary database fails and you are unable to recover the redo records from the primary database. This mode provides the highest level of data protection that is possible without affecting the performance of the primary database.

To determine the current mode of the database, query the `PROTECTION_MODE` column of the `V$DATABASE` dynamic performance view.

**See Also:** Oracle Data Guard Concepts and Administration for full information on using these standby database settings

### register_logfile_clause
Specify the `REGISTER LOGFILE` clause from the standby database to manually register log files from the failed primary. Use the `redo_log_file_spec` form of `file_specification` (see `file_specification` on page 8-29) to list regular redo log files in an operating system file system or to list Oracle ASM disk group redo log files.

When a log file is from an unknown incarnation, the `REGISTER LOGFILE` clause causes an incarnation record to be added to the `V$DATABASE_INCARNATION` view. If the newly registered log file belongs to an incarnation having a higher `RECOVERY_TARGET_INCARNATION#` than the current `RECOVERY_TARGET_INCARNATION#`, then the `REGISTER LOGFILE` clause also causes `RECOVERY_TARGET_INCARNATION#` to be changed to correspond to the newly added incarnation record.

**OR REPLACE** Specify `OR REPLACE` to allow an existing archivelog entry in the standby database to be updated, for example, when its location or file specification changes. The system change numbers of the entries must match exactly, and the original entry must have been created by the managed standby log transmittal mechanism.

**FOR logminer_session_name** This clause is useful in a Streams environment. It lets you register the log file with one specified LogMiner session.

### switchover_clause

**Caution:** Before using this command, refer to Oracle Data Guard Concepts and Administration for complete usage information.

Use this clause to perform a switchover to a physical standby database. Specify this clause from the primary database. For `target_db_name`, specify the `DB_UNIQUE_NAME` of the standby database.

**VERIFY** Use this clause to verify that a physical standby database is ready for a switchover. Specify this clause from the primary database. For `target_db_name`, specify the `DB_UNIQUE_NAME` of the standby database. If the standby database is ready for a switchover, then the "Database Altered" message is returned. Otherwise, an error message that will assist you in preparing the standby database for a switchover is returned.
**FORCE**  Use this clause if a previous switchover command failed and created a configuration with no primary database. Specify this clause from the physical standby database that you want to convert to the primary database. For `target_db_name`, specify the `DB_UNIQUE_NAME` of the database that you want to convert to the primary database.

**failover_clause**

---

**Caution:** Before using this command, refer to Oracle Data Guard Concepts and Administration for complete usage information.

---

Use this clause to perform a failover to a physical standby database. Specify this clause from the standby database. For `target_db_name`, specify the `DB_UNIQUE_NAME` of the standby database.

**FORCE**  This clause has meaning only when the failover target is serviced by a Data Guard far sync instance. Use this clause when a previous failover command failed and the reason for the failure cannot be resolved. It instructs the failover to ignore any failures encountered when interacting with the Data Guard far sync instance and proceed with the failover, if at all possible.

**commit_switchover_clause**

Use this clause to perform database role transitions in a Data Guard configuration.

---

**Caution:** Before using this command, refer to Oracle Data Guard Concepts and Administration for complete usage information.

---

**PREPARE TO SWITCHOVER**  This clause prepares a primary database to become a logical standby database or a logical standby database to become a primary database.

- Specify `PREPARE TO SWITCHOVER TO LOGICAL STANDBY` on a primary database.
- Specify `PREPARE TO SWITCHOVER TO PRIMARY DATABASE` on a logical standby database.

**COMMIT TO SWITCHOVER**  This clause switches a primary database to a standby database role or switches a standby database to the primary database role.

- Specify `COMMIT TO SWITCHOVER TO PHYSICAL STANDBY` or `COMMIT TO SWITCHOVER TO LOGICAL STANDBY` on a primary database.
- Specify `COMMIT TO SWITCHOVER TO PRIMARY DATABASE` on a standby database.

**PHYSICAL**  This clause is always optional. Use of this clause with the `COMMIT TO SWITCHOVER TO PRIMARY` clause has been deprecated.

**LOGICAL**  This clause is specified with the `PREPARE TO SWITCHOVER` or `COMMIT TO SWITCHOVER` clauses when switching a primary database to the logical standby database role. Use of this clause with the `COMMIT TO SWITCHOVER TO PRIMARY` clause has been deprecated.

**WITH SESSION SHUTDOWN**  This clause causes all database sessions to be closed and uncommitted transactions to be rolled back before performing a database role transition.
ALTER DATABASE

WITHOUT SESSION SHUTDOWN  This clause prevents a requested role transition from occurring if there are any database sessions. This is the default.

WAIT  Specify this clause to wait for a role transition to complete before returning control to the user.

NOWAIT  Specify this clause to return control to the user without waiting for a role transition to complete. This is the default.

CANCEL  Specify this clause to reverse the effect of a previously specified PREPARE TO SWITCHOVER statement.

See Also:  Oracle Data Guard Concepts and Administration for full information on switchover between primary and standby databases

start_standby_clause
Specify the START LOGICAL STANDBY APPLY clause to begin applying redo logs to a logical standby database. This clause enables primary key, unique index, and unique constraint supplemental logging as well as PL/SQL call logging.

- Specify IMMEDIATE to apply redo data from the current standby redo log file.
- Specify NODELAY if you want Oracle Database to ignore a delay for this apply. This is useful if the primary database is no longer present, which would otherwise require a PL/SQL call to be made.
- Specify INITIAL the first time you apply the logs to the standby database.
- The NEW PRIMARY clause is needed in two situations:
  - On a failover to a logical standby, specify this clause on a logical standby not participating in the failover operation, and on the old primary database after it has been reinstated as a logical standby database.
  - During a rolling upgrade using a logical standby database (which uses an unprepared switchover operation), specify this clause after the original primary database has been upgraded to the new database software.
- Specify SKIP FAILED [TRANSACTION] to skip the last transaction in the events table and restart the apply.
- Specify FINISH to force the standby redo logfile information into archived logs. If the primary database becomes disabled, then you can then apply the data in the redo log files.

stop_standby_clause
Use this clause to stop the log apply services. This clause applies only to logical standby databases, not to physical standby databases. Use the STOP clause to stop the apply in an orderly fashion.

convert_database_clause
Use this clause to convert a database from one form to another.

- Specify CONVERT TO PHYSICAL STANDBY to convert a primary database, a logical standby database, or a snapshot standby database into a physical standby database.
  Perform these steps before specifying this clause:
- On an Oracle Real Application Clusters (Oracle RAC) database, shut down all but one instance.
- Ensure that the database is mounted, but not open.

The database is dismounted after conversion and must be restarted.

Specify **CONVERT TO SNAPSHOT STANDBY** to convert a physical standby database into a snapshot standby database.

Ensure that redo apply is stopped before specifying this clause.

---

**Note:** A snapshot standby database must be opened at least once in read/write mode before it can be converted into a physical standby database.

---

**See Also:** *Oracle Data Guard Concepts and Administration* for more information about standby databases

---

**default_settings_clauses**

Use these clauses to modify the default settings of the database.

**DEFAULT EDITION Clause**

Use this clause to designate the specified edition as the default edition for the database. The specified edition must already have been created and must be **USABLE**. The change takes place immediately and is visible to all nodes in an Oracle RAC environment. New database sessions automatically start out in the specified edition. The new setting persists across database shutdown and startup.

When you designate an edition as the database default edition, all users can use the edition, as though the **USE** object privilege were granted on the specified edition to the role **PUBLIC**.

You can determine the current default edition of the database with the following query:

```
SELECT PROPERTY_VALUE FROM DATABASE_PROPERTIES
WHERE PROPERTY_NAME = 'DEFAULT_EDITION';
```

**See Also:** *CREATE EDITION* on page 14-64 for more information on editions and *Oracle Database PL/SQL Language Reference* for information on how editions are designated as **USABLE**

---

**CHARACTER SET, NATIONAL CHARACTER SET**

You can no longer change the database character set or the national character set using the `ALTER DATABASE` statement. Refer to *Oracle Database Globalization Support Guide* for information on database character set migration.

**SET DEFAULT TABLESPACE Clause**

Use this clause to specify or change the default type of subsequently created tablespaces. Specify **BIGFILE** or **SMALLFILE** to indicate whether the tablespaces should be bigfile or smallfile tablespaces.

- A **bigfile tablespace** contains only one data file or temp file, which can contain up to approximately 4 billion \((2^{32})\) blocks. The maximum size of the single data file or temp file is 128 terabytes (TB) for a tablespace with 32K blocks and 32TB for a tablespace with 8K blocks.
A **smallfile tablespace** is a traditional Oracle tablespace, which can contain 1022 data files or temp files, each of which can contain up to approximately 4 million \(2^{22}\) blocks.

**See Also:**
- *Oracle Database Administrator’s Guide* for more information about bigfile tablespaces
- "Setting the Default Type of Tablespaces: Example" on page 10-70

**DEFAULT TABLESPACE Clause**
Specify this clause to establish or change the default permanent tablespace of the database. The tablespace you specify must already have been created. After this operation completes, Oracle Database automatically reassigns to the new default tablespace all non-`SYSTEM` users. All objects subsequently created by those users will by default be stored in the new default tablespace. If you are replacing a previously specified default tablespace, then you can move the previously created objects from the old to the new default tablespace, and then drop the old default tablespace if you want to.

**DEFAULT TEMPORARY TABLESPACE Clause**
Specify this clause to change the default temporary tablespace of the database to a new tablespace or tablespace group.

- Specify `tablespace` to indicate the new default temporary tablespace of the database. After this operation completes, Oracle Database automatically reassigns to the new default temporary tablespace all users who had been assigned to the old default temporary tablespace. You can then drop the old default temporary tablespace if you want to.

- Specify `tablespace_group_name` to indicate that all tablespaces in the tablespace group specified by `tablespace_group_name` are now default temporary tablespace for the database. After this operation completes, users who have not been explicitly assigned a default temporary tablespace can create temporary segments in any of the tablespaces that are part of `tablespace_group_name`. You cannot drop the old default temporary tablespace if it is part of the default temporary tablespace group.

To learn the name of the current default temporary tablespace or default temporary tablespace group, query the `TEMPORARY_TABLESPACE` column of the `ALL_`, `DBA_`, or `USER_ USERS` data dictionary views.

**Restrictions on Default Temporary Tablespaces**
Default temporary tablespaces are subject to the following restrictions:

- The tablespace you assign or reassign as the default temporary tablespace must have a standard block size.

- If the `SYSTEM` tablespace is locally managed, then the tablespace you specify as the default temporary tablespace must also be locally managed.

**See Also:**
- *Oracle Database Administrator’s Guide* for information on tablespace groups
- "Changing the Default Temporary Tablespace: Examples" on page 10-70
instance_clauses
In an Oracle Real Application Clusters environment, specify ENABLE INSTANCE to enable the thread that is mapped to the specified database instance. The thread must have at least two redo log file groups, and the database must be open.

Specify DISABLE INSTANCE to disable the thread that is mapped to the specified database instance. The name of the instance is a string of up to 80 characters. If no thread is currently mapped to the specified instance, then Oracle Database returns an error. The database must be open, but you cannot disable a thread if an instance using it has the database mounted.

See Also: Oracle Real Application Clusters Administration and Deployment Guide for more information on enabling and disabling instances

RENAME GLOBAL_NAME Clause
Specify RENAME GLOBAL_NAME to change the global name of the database. The database must be open. The database is the new database name and can be as long as eight bytes. The optional domain specifies where the database is effectively located in the network hierarchy. If you specify a domain name, then the components of the domain name must be legal identifiers. See "Database Object Naming Rules" on page 2-119 for information on valid identifiers.

Note: Renaming your database does not change global references to your database from existing database links, synonyms, and stored procedures and functions on remote databases. Changing such references is the responsibility of the administrator of the remote databases.

See Also: "Changing the Global Database Name: Example" on page 10-71

BLOCK CHANGE TRACKING Clauses
The block change tracking feature causes Oracle Database to keep track of the physical locations of all database updates on both the primary database and any physical standby database. You must enable block change tracking on each database for which you want tracking to be performed. The tracking information is maintained in a separate file called the block change tracking file. If you are using Oracle Managed Files, then Oracle Database automatically creates the block change tracking file in the location specified by DB_CREATE_FILE_DEST. If you are not using Oracle Managed Files, then you must specify the change tracking filename. Oracle Database uses change tracking data for some internal tasks, such as increasing the performance of incremental backups. You can enable or disable block change tracking with the database either open or mounted, in either archivelog or NOARCHIVELOG mode.

ENABLE BLOCK CHANGE TRACKING This clause enables block change tracking and causes Oracle Database to create a block change tracking file.

- Specify USING FILE 'filename' if you want to name the block change tracking file instead of letting Oracle Database generate a name for it. You must specify this clause if you are not using Oracle Managed Files.
- Specify REUSE to allow Oracle Database to overwrite an existing block change tracking file of the same name.
DISABLE BLOCK CHANGE TRACKING Specify this clause if you want Oracle Database to stop tracking changes and delete the existing block change tracking file.

See Also: Oracle Database Backup and Recovery User’s Guide for information on setting up block change tracking and "Enabling and Disabling Block Change Tracking: Examples" on page 10-71

[NO] FORCE FULL DATABASE CACHING
Use this clause to enable or disable the force full database caching mode. In contrast to the default mode, which is automatic, the force full database caching mode considers the entire database, including NOCACHE LOBs, as eligible for caching in the buffer cache. This mode is available starting with Oracle Database 12c Release 1 (12.1.0.2).

The database must be mounted but not open. In an Oracle RAC environment, the database must be mounted but not open in the current instance and unmounted in all other instances.

- Specify FORCE FULL DATABASE CACHING to enable the force full database caching mode.
- Specify NO FORCE FULL DATABASE CACHING to disable the force full database caching mode. This is the default mode.

You can determine whether the force full database caching mode is enabled by querying the FORCE_FULL_DB_CACHING column of the V$DATABASE dynamic performance view.

See Also:
- Oracle Database Concepts for more information on the force full database caching mode
- Oracle Database Administrator’s Guide to learn how to enable the force full database caching mode
- Oracle Database Reference for more information on the V$DATABASE dynamic performance view

flashback_mode_clause
Use this clause to put the database in or take the database out of FLASHBACK mode. You can specify this clause only if the database is in ARCHIVELOG mode and you have already prepared a fast recovery area for the database. You can specify this clause when the database is mounted or open. This clause cannot be specified on a physical standby database if redo apply is active.

See Also: Oracle Database Backup and Recovery User’s Guide for information on preparing the fast recovery area for Flashback operations

FLASHBACK ON Use this clause to put the database in FLASHBACK mode. When the database is in FLASHBACK mode, Oracle Database automatically creates and manages Flashback Database logs in the fast recovery area. Users with SYSDBA system privilege can then issue a FLASHBACK DATABASE statement.

FLASHBACK OFF Use this clause to take the database out of FLASHBACK mode. Oracle Database stops logging Flashback data and deletes all existing Flashback Database logs. Any attempt to issue a FLASHBACK DATABASE will fail with an error.
**set_time_zone_clause**

This clause has the same semantics in **CREATE DATABASE** and **ALTER DATABASE** statements. When used in with **ALTER DATABASE**, this clause resets the time zone of the database. To determine the time zone of the database, query the built-in function **DBTIMEZONE** on page 7-91. After setting or changing the time zone with this clause, you must restart the database for the new time zone to take effect.

Oracle Database normalizes all new **TIMESTAMP WITH LOCAL TIME ZONE** data to the time zone of the database when the data is stored on disk. Oracle Database does not automatically update existing data in the database to the new time zone. Therefore, you cannot reset the database time zone if there is any **TIMESTAMP WITH LOCAL TIME ZONE** data in the database. You must first delete or export the **TIMESTAMP WITH LOCAL TIME ZONE** data and then reset the database time zone. For this reason, Oracle does not encourage you to change the time zone of a database that contains data.

For a full description of this clause, refer to **set_time_zone_clause** on page 14-40 in the documentation on **CREATE DATABASE**.

**security_clause**

Use the **security_clause** (**GUARD**) to protect data in the database from being changed. You can override this setting for a current session using the **ALTER SESSION DISABLE GUARD** statement. Refer to **ALTER SESSION** on page 11-65 for more information.

**ALL**  Specify **ALL** to prevent all users other than **SYS** from making any changes to the database.

**STANDBY**  Specify **STANDBY** to prevent all users other than **SYS** from making changes to any database object being maintained by logical standby. This setting is useful if you want report operations to be able to modify data as long as it is not being replicated by logical standby.

**NONE**  Specify **NONE** if you want normal security for all data in the database.

---

**Caution:** Oracle strongly recommends that you not use this setting on a logical standby database.

---

**Examples**

**READ ONLY / READ WRITE: Example**  The following statement opens the database in read-only mode:

```
ALTER DATABASE OPEN READ ONLY;
```

The following statement opens the database in read/write mode and clears the online redo logs:

```
ALTER DATABASE OPEN READ WRITE RESETLOGS;
```

**Using Parallel Recovery Processes: Example**  The following statement performs tablespace recovery using parallel recovery processes:

```
ALTER DATABASE
  RECOVER TABLESPACE tbs_03
```
PARALLEL;

Adding Redo Log File Groups: Examples The following statement adds a redo log file group with two members and identifies it with a GROUP parameter value of 3:

```
ALTER DATABASE
  ADD LOGFILE GROUP 3
  ('diska:log3.log',
   'diskb:log3.log') SIZE 50K;
```

The following statement adds a redo log file group containing two members to thread 5 (in a Real Application Clusters environment) and assigns it a GROUP parameter value of 4:

```
ALTER DATABASE
  ADD LOGFILE THREAD 5 GROUP 4
  ('diska:log4.log',
   'diskb:log4:log');
```

Adding Redo Log File Group Members: Example The following statement adds a member to the redo log file group added in the previous example:

```
ALTER DATABASE
  ADD LOGFILE MEMBER 'diskc:log3.log'
  TO GROUP 3;
```

Dropping Log File Members: Example The following statement drops one redo log file member added in the previous example:

```
ALTER DATABASE
  DROP LOGFILE MEMBER 'diskb:log3.log';
```

The following statement drops all members of the redo log file group 3:

```
ALTER DATABASE DROP LOGFILE GROUP 3;
```

Renaming a Log File Member: Example The following statement renames a redo log file member:

```
ALTER DATABASE
  RENAME FILE 'diskc:log3.log' TO 'diskb:log3.log';
```

The preceding statement only changes the member of the redo log group from one file to another. The statement does not actually change the name of the file diskc:log3.log to diskb:log3.log. Before issuing this statement, you must change the name of the file through your operating system.

Setting the Default Type of Tablespaces: Example The following statement specifies that subsequently created tablespaces be created as bigfile tablespaces by default:

```
ALTER DATABASE
  SET DEFAULT BIGFILE TABLESPACE;
```

Changing the Default Temporary Tablespace: Examples The following statement makes the tbs_05 tablespace (created in "Creating a Temporary Tablespace: Example" on page 16-115) the default temporary tablespace of the database. This statement either establishes a default temporary tablespace if none was specified at create time, or replaces an existing default temporary tablespace with tbs_05:

```
ALTER DATABASE
  DEFAULT TEMPORARY TABLESPACE tbs_05;
```
Alternatively, a group of tablespaces can be defined as the default temporary tablespace by using a tablespace group. The following statement makes the tablespaces in the tablespace group `tbs_group_01` (created in "Adding a Temporary Tablespace to a Tablespace Group: Example" on page 16-116) the default temporary tablespaces of the database:

```sql
ALTER DATABASE
  DEFAULT TEMPORARY TABLESPACE tbs_grp_01;
```

**Creating a New Data File: Example**  The following statement creates a new data file `tbs_f04.dbf` based on the file `tbs_f03.dbf`. Before creating the new data file, you must take the existing data file (or the tablespace in which it resides) offline.

```sql
ALTER DATABASE
  CREATE DATAFILE 'tbs_f03.dbf'
    AS 'tbs_f04.dbf';
```

**Manipulating Temp Files: Example**  The following takes offline the temp file `temp02.dbf` created in `Adding and Dropping Data Files and Temp Files: Examples` on page 12-125 and then renames the temp file:

```sql
ALTER DATABASE TEMPFILE 'temp02.dbf' OFFLINE;
ALTER DATABASE RENAME FILE 'temp02.dbf' TO 'temp03.dbf';
```

The statement renaming the temp file requires that you first create the file `temp03.dbf` on the operating system.

**Changing the Global Database Name: Example**  The following statement changes the global name of the database and includes both the database name and domain:

```sql
ALTER DATABASE
  RENAME GLOBAL_NAME TO demo.world.example.com;
```

**Enabling and Disabling Block Change Tracking: Examples**  The following statement enables block change tracking and causes Oracle Database to create a block change tracking file named `tracking_file` and overwrite the file if it already exists:

```sql
ALTER DATABASE
  ENABLE BLOCK CHANGE TRACKING
    USING FILE 'tracking_file' REUSE;
```

The following statement disables block change tracking and deletes the existing block change tracking file:

```sql
ALTER DATABASE
  DISABLE BLOCK CHANGE TRACKING;
```

**Resizing a Data File: Example**  The following statement attempts to change the size of data file `diskb:tbs_f5.dbf`:

```sql
ALTER DATABASE
  DATAFILE 'diskb:tbs_f5.dbf' RESIZE 10 M;
```

**Clearing a Log File: Example**  The following statement clears a log file:

```sql
ALTER DATABASE
  CLEAR LOGFILE 'diskc:log3.log';
```
**Database Recovery: Examples**  The following statement performs complete recovery of the entire database, letting Oracle Database generate the name of the next archived redo log file needed:

```sql
ALTER DATABASE
  RECOVER AUTOMATIC DATABASE;
```

The following statement explicitly names a redo log file for Oracle Database to apply:

```sql
ALTER DATABASE
  RECOVER LOGFILE 'diskc:log3.log';
```

The following statement performs time-based recovery of the database:

```sql
ALTER DATABASE
  RECOVER AUTOMATIC UNTIL TIME '2001-10-27:14:00:00';
```

Oracle Database recovers the database until 2:00 p.m. on October 27, 2001.

For an example of recovering a tablespace, see "Using Parallel Recovery Processes: Example" on page 10-69.
ALTER DATABASE LINK

Purpose

Use the ALTER DATABASE LINK statement to modify a fixed-user database link when the
password of the connection or authentication user changes.

Notes:

- You cannot use this statement to change the connection or
  authentication user associated with the database link. To change
  user, you must re-create the database link.
- You cannot use this statement to change the password of a
  connection or authentication user. You must use the ALTER USER
  on page 13-6 statement for this purpose, and then alter the
database link with the ALTER DATABASE LINK statement.
- This statement is valid only for fixed-user database links, not for
  connected-user or current user database links. See CREATE
  DATABASE LINK on page 14-44 for more information on these
two types of database links.

Prerequisites

To alter a private database link, you must have the ALTER DATABASE LINK system
privilege. To alter a public database link, you must have the ALTER PUBLIC DATABASE
LINK system privilege.

Syntax

```sql
alter_database_link::=

ALTER [SHARED | PUBLIC] DATABASE LINK dblink_name

CONNECT TO user IDENTIFIED BY password|dblink_authentication

dblink_authentication::=

AUTHENTICATED BY user IDENTIFIED BY password
```

Semantics

The ALTER DATABASE LINK statement is intended only to update fixed-user database
links with the current passwords of connection and authentication users. Therefore,
any clauses valid in a CREATE DATABASE LINK statement that do not appear in the syntax
diagram above are not valid in an ALTER DATABASE LINK statement. The semantics of all
of the clauses permitted in this statement are the same as the semantics for those
clauses in CREATE DATABASE LINK. Refer to CREATE DATABASE LINK on page 14-44
for this information.
Examples

The following statements show the valid variations of the `ALTER DATABASE LINK` statement:

```
ALTER DATABASE LINK private_link
    CONNECT TO hr IDENTIFIED BY hr_new_password;

ALTER PUBLIC DATABASE LINK public_link
    CONNECT TO scott IDENTIFIED BY scott_new_password;

ALTER SHARED PUBLIC DATABASE LINK shared_pub_link
    CONNECT TO scott IDENTIFIED BY scott_new_password
    AUTHENTICATED BY hr IDENTIFIED BY hr_new_password;

ALTER SHARED DATABASE LINK shared_pub_link
    CONNECT TO scott IDENTIFIED BY scott_new_password;
```
**ALTER DIMENSION**

**Purpose**
Use the ALTER DIMENSION statement to change the hierarchical relationships or dimension attributes of a dimension.

**See Also:** CREATE DIMENSION on page 14-49 and DROP DIMENSION on page 17-45

**Prerequisites**
The dimension must be in your schema or you must have the ALTER ANY DIMENSION system privilege to use this statement.
A dimension is always altered under the rights of the owner.

**Syntax**

```sql
alter_dimension ::= ...
```

```sql
ALTER DIMENSION (level_clause::= on page 10-75, hierarchy_clause::= on page 10-76, attribute_clause::= on page 10-76, extended_attribute_clause::= on page 10-76)
```

**level_clause::=**

```sql
LEVEL level IS level_table.level_column (level_table.level_column) SKIP WHEN NULL
```
### Semantics

The following keywords, parameters, and clauses have meaning unique to `ALTER DIMENSION`. Keywords, parameters, and clauses that do not appear here have the same functionality that they have in the `CREATE DIMENSION` statement. Refer to `CREATE DIMENSION` on page 14-49 for more information.

#### schema

Specify the schema of the dimension you want to modify. If you do not specify `schema`, then Oracle Database assumes the dimension is in your own schema.

#### dimension

Specify the name of the dimension. This dimension must already exist.

#### ADD

The `ADD` clauses let you add a level, hierarchy, or attribute to the dimension. Adding one of these elements does not invalidate any existing materialized view. Oracle Database processes `ADD LEVEL` clauses prior to any other `ADD` clauses.

#### DROP

The `DROP` clauses let you drop a level, hierarchy, or attribute from the dimension. Any level, hierarchy, or attribute you specify must already exist.
Within one attribute, you can drop one or more level-to-column relationships associated with one level.

**Restriction on DROP** If any attributes or hierarchies reference a level, then you cannot drop the level until you either drop all the referencing attributes and hierarchies or specify `CASCADE`.

**CASCADE** Specify `CASCADE` if you want Oracle Database to drop any attributes or hierarchies that reference the level, along with the level itself.

**RESTRICT** Specify `RESTRICT` if you want to prevent Oracle Database from dropping a level that is referenced by any attributes or hierarchies. This is the default.

**COMPILE**
Specify `COMPILE` to explicitly recompile an invalidated dimension. Oracle Database automatically compiles a dimension when you issue an `ADD` clause or `DROP` clause. However, if you alter an object referenced by the dimension (for example, if you drop and then re-create a table referenced in the dimension), Oracle Database invalidates, and you must recompile it explicitly.

**Examples**

**Modifying a Dimension: Examples** The following examples modify the `customers_dim` dimension in the sample schema `sh`:

```sql
ALTER DIMENSION customers_dim
  DROP ATTRIBUTE country;

ALTER DIMENSION customers_dim
  ADD LEVEL zone IS customers.cust_postal_code
  ADD ATTRIBUTE zone DETERMINES (cust_city);
```
**ALTER DISKGROUP**

**Purpose**

The `ALTER DISKGROUP` statement lets you perform a number of operations on a disk group or on the disks in a disk group.

**See Also:**
- `CREATE DISKGROUP` on page 14-56 for information on creating disk groups
- *Oracle Automatic Storage Management Administrator’s Guide* for information on Oracle ASM and using disk groups to simplify database administration

**Prerequisites**

You must have an Oracle ASM instance started from which you issue this statement. The disk group to be modified must be mounted.

You can issue all `ALTER DISKGROUP` clauses if you have the `SYSASM` system privilege. You can issue specific clauses as follows:

- The `SYSOPER` privilege permits the following subset of the `ALTER DISKGROUP` operations: `diskgroup_availability`, `rebalance_diskgroup_clause`, `check_diskgroup_clause` (without the `REPAIR` option).

- If you are connected as `SYSDBA`, you have limited privileges to use this statement. The following operations are always granted to users connected as `SYSDBA`:
  - `ALTER DISKGROUP ... ADD DIRECTORY`
  - `ALTER DISKGROUP ... ADD/ALTER/DROP TEMPLATE` (nonsystem templates only)
  - `ALTER DISKGROUP ... ADD USERGROUP`
  - `SELECT`
  - `SHOW PARAMETER`

Table 10–1 shows additional privileges granted to users connected as `SYSDBA` under the conditions shown:

<table>
<thead>
<tr>
<th><code>ALTER DISKGROUP</code> Operation</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>DROP FILE</td>
<td>User must have read-write permission on the file.</td>
</tr>
<tr>
<td>ADD ALIAS</td>
<td>User must have read-write permission on the related file.</td>
</tr>
<tr>
<td>RENAME ALIAS</td>
<td>User must have read-write permission on the related file.</td>
</tr>
</tbody>
</table>

**Note:** This SQL statement is valid only if you are using Oracle ASM and you have started an Oracle ASM instance. You must issue this statement from within the Oracle ASM instance, not from a normal database instance. For information on starting an Oracle ASM instance, refer to *Oracle Automatic Storage Management Administrator’s Guide*.

---

ALTER DISKGROUP

Semantics

**diskgroup_name**
Specify the name of the disk group you want to modify. To determine the names of existing disk groups, query the V$ASM_DISKGROUP dynamic performance view.

**add_disk_clause**
Use this clause to add one or more disks to the disk group and specify attributes for the newly added disk. Oracle ASM automatically rebalances the disk group as part of this operation.

You cannot use this clause to change the failure group of a disk. Instead you must drop the disk from the disk group and then add the disk back into the disk group as part of the new failure group.

To determine the names of the disks already in this disk group, query the V$ASM_DISK dynamic performance view.

**QUORUM | REGULAR** The semantics of these keyword are the same as the semantics in a CREATE DISKGROUP statement. See QUORUM | REGULAR on page 14-58 for more information on these keywords.

You cannot change this qualifier for an existing disk or disk group. Therefore, you cannot specify in this clause a keyword different from the keyword that was specified when the disk group was created.

See Also: Oracle Automatic Storage Management Administrator’s Guide for more information about the use of these keywords

**FAILGROUP Clause** Use this clause to assign the newly added disk to a failure group. If you omit this clause and you are adding the disk to a normal or high redundancy disk group, then Oracle Database automatically adds the newly added disk to its own failure group. The implicit name of the failure group is the same as the operating system independent disk name (see "NAME Clause" on page 14-59).

You cannot specify this clause if you are creating an external redundancy disk group.

**qualified_disk_clause**
This clause has the same semantics in CREATE DISKGROUP and ALTER DISKGROUP statements. For complete information on this clause, refer to qualified_disk_clause on page 14-58 in the documentation on CREATE DISKGROUP.

**drop_disk_clause**
Use this clause to drop one or more disks from the disk group.

**DROP DISK** The DROP DISK clause lets you drop one or more disks from the disk group and automatically rebalance the disk group. When you drop a disk, Oracle ASM relocates all the data from the disk and clears the disk header so that it no longer is part of the disk group. The disk header is not cleared if you specify the FORCE keyword.

Specify disk_name as shown in the NAME column of the V$ASM_DISK dynamic performance view.

If a disk to be dropped is a quorum disk or belongs to a quorum failure group, then you must specify QUORUM in order to drop the disk. See QUORUM | REGULAR on page 10-87.
**DROP DISKS IN FAILGROUP**  The `DROP DISKS IN FAILGROUP` clause lets you drop all the disks in the specified failure group. The behavior is otherwise the same as that for the `DROP DISK` clause.

If the specified failure group is a quorum failure group, then you must specify the `QUORUM` keyword in order to drop the disks. See `QUORUM | REGULAR` on page 10-87.

**FORCE | NOFORCE**  These keywords let you specify when the disk is considered to be no longer part of the disk group. The default and recommended setting is `NOFORCE`.

- When you specify `NOFORCE`, Oracle ASM reallocates all of the extents of the disk to other disks and then expels the disk from the disk group and rebalances the disk group.

  **Caution:**  `DROP DISK ... NOFORCE` returns control to the user before the disk can be safely reused or removed from the system. To ensure that the drop disk operation has completed, query the `V$ASM_DISK` view to verify that `HEADER_STATUS` has the value `FORMER`. Do not attempt to remove or reuse a disk if `STATE` has the value `DROPPING`. Query the `V$ASM_OPERATION` view for approximate information on how long it will take to complete the rebalance resulting from dropping the disk.

  If you also specify `REBALANCE ... WAIT` (see `rebalance_diskgroup_clause` on page 10-90), then the statement will not return until the rebalance operation is complete and the disk has been cleared. However, you should always verify that the `HEADER_STATUS` column of `V$ASM_DISK` is `FORMER`, because of the unlikely event the rebalance operations fails.

- When you specify `FORCE`, Oracle Database expels the disk from the disk group immediately. It then reconstructs the data from the redundant copies on other disks, reallocates the data to other disks, and rebalances the disk group.

  The `FORCE` clause can be useful, for example, if Oracle ASM can no longer read the disk to be dropped. However, it is more time consuming than a `NOFORCE` drop, and it can leave portions of a file with reduced protection. You cannot specify `FORCE` for an external redundancy disk group at all, because in the absence of redundant data on the disk, Oracle ASM must read the data from the disk before it can be dropped.

The rebalance operation invoked when a disk is dropped is time consuming, whether or not you specify `FORCE` or `NOFORCE`. You can monitor the progress by querying the `V$ASM_OPERATION` dynamic performance view. Refer to `rebalance_diskgroup_clause` on page 10-90 for more information on rebalance operations.

**resize_disk_clause**

Use this clause to specify a new size for every disk in the disk group. This clause lets you override the size being returned by the operating system or the size you specified previously for the disks.

**SIZE**  Specify the new size in kilobytes, megabytes, gigabytes, or terabytes. You cannot specify a size greater than the capacity of the disk. If you specify a size smaller than the disk capacity, then you limit the amount of disk space Oracle ASM will use. If you omit this clause, then Oracle ASM attempts programmatically to determine the size of the disks.
**replace_disk_clause**

Use this clause to replace one or more disks in the disk group. This clause allows you to replace disks with a single operation, which is more efficient than dropping and adding each disk.

For `disk_name`, specify the name of the disk you want to replace. This name is assigned to the replacement disk. You can view disk names by querying the `NAME` column of the `V$ASM_DISK` dynamic performance view.

For `path_name`, specify the full path name for the replacement disk.

**FORCE** Specify `FORCE` if you want Oracle ASM to add the replacement disk to the disk group even if the replacement disk is already a member of a disk group.

**Caution:** Using `FORCE` in this way may destroy existing disk groups.

**NOFORCE** Specify `NOFORCE` if you want Oracle ASM to return an error if the replacement disk is already a member of a disk group. `NOFORCE` is the default.

**POWER** The `POWER` clause has the same semantics here as for a manual rebalancing of a disk group, except that the power value cannot be set to 0. See `POWER` on page 10-90.

**WAIT | NOWAIT** The `WAIT` and `NOWAIT` keywords have the same semantics here as for a manual rebalancing of a disk group. See `WAIT | NOWAIT` on page 10-90.

**rename_disk_clause**

Use this clause to rename one or more disks in the disk group. The disk group must be in the `MOUNT RESTRICTED` state and all disks in the disk group must be online.

**RENAME DISK** Specify this clause to rename one or more disks. For each disk, specify the `old_disk_name` and `new_disk_name`. If `new_disk_name` already exists, then this operation fails.

**RENAME DISKS ALL** Specify this clause to rename all disks in the disk group to a name of the form `diskgroupname_####`, where `####` is the disk number. Disk names that are already in the `diskgroupname_####` format are not changed.

**disk_online_clause**

Use the `disk_online_clause` to bring one or more disks online and rebalance the disk group. Specify `disk_name` as shown in the `NAME` column of the `V$ASM_DISK` dynamic performance view. The `QUORUM` and `REGULAR` keywords have the same semantics here as they have when adding a disk to a disk group. See `QUORUM | REGULAR` on page 10-87. The `POWER` clause has the same semantics here as for a manual rebalancing of a disk group. See `POWER` on page 10-90. The `WAIT` and `NOWAIT` keywords have the same semantics here as for a manual rebalancing of a disk group. See `WAIT | NOWAIT` on page 10-90.

**disk_offline_clause**

Use the `disk_offline_clause` to take one or more disks offline. This clause fails if the redundancy level of the disk group would be violated by taking the specified disks offline.
Specify `disk_name` as shown in the `NAME` column of the V$ASM_DISK dynamic performance view.

The QUORUM and REGULAR keywords have the same semantics here as they have when adding a disk to a disk group. See QUORUM | REGULAR on page 10-87.

By default, Oracle ASM drops a disk shortly after it is taken offline. You can delay this operation by specifying the `timeout_clause`, which gives you the opportunity to repair the disk and bring it back online. You can specify the timeout value in units of minute or hour. If you omit the unit, then the default is hour.

You can change the timeout period by specifying this clause multiple times. Each time you specify it, Oracle ASM measures the time from the most recent previous `disk_offline_clause` while the disk group is mounted. To learn how much time remains before Oracle ASM will drop an offline disk, query the `repair_timer` column of V$ASM_DISK.

This clause overrides any previous setting of the `disk_repair_time` attribute. Refer to Table 14–2, " Disk Group Attributes" for more information about disk group attributes.

See Also: Oracle Automatic Storage Management Administrator’s Guide
for more information about taking Oracle ASM disks online and offline

**rebalance_diskgroup_clause**

Use this clause to manually rebalance the disk group. Oracle ASM redistributes data files evenly across all drives. This clause is rarely necessary, because Oracle ASM allocates files evenly and automatically rebalances disk groups when the storage configuration changes. However, it is useful if you want to use the POWER clause to control the speed of what would otherwise be an automatic rebalance operation.

**POWER** In the `POWER` clause, specify a value from 0 to 11, where 0 stops the rebalance operation and 11 permits Oracle ASM to execute the rebalance as fast as possible. The value you specify in the `POWER` clause defaults to the value of the `ASM_POWER_LIMIT` initialization parameter.

If you omit the `POWER` clause, then Oracle ASM executes both automatic and specified rebalance operations at the power determined by the value of the `ASM_POWER_LIMIT` initialization parameter.

---

**Note:** Beginning with Oracle Database 11g Release 2 (11.2.0.2), if the COMPATIBLE_ASM disk group attribute is set to 11.2.0.2 or higher, then you can specify a value from 0 to 1024 in the `POWER` clause.

---

**WAIT | NOWAIT** Use this clause to specify when in the course of the rebalance operation control should be returned to the user.

- Specify `WAIT` to allow a script that adds or removes disks to wait for the disk group to be rebalanced before returning control to the user. You can explicitly terminate a rebalance operation running in `WAIT` mode, although doing so does not undo any completed disk add or drop operation in the same statement.

- Specify `NOWAIT` if you want control returned to the user immediately after the statement is issued. This is the default.

You can monitor the progress of the rebalance operation by querying the V$ASM_OPERATION dynamic performance view.
check_diskgroup_clause

The check_diskgroup_clause lets you verify the internal consistency of Oracle ASM disk group metadata. The disk group must be mounted. Oracle ASM displays summary errors and writes the details of the detected errors in the alert log.

The CHECK keyword performs the following operations:

- Checks the consistency of the disk.
- Cross checks all the file extent maps and allocation tables for consistency.
- Checks that the alias metadata directory and file directory are linked correctly.
- Checks that the alias directory tree is linked correctly.
- Checks that Oracle ASM metadata directories do not have unreachable allocated blocks.

REPAIR | NOREPAIR This clause lets you instruct Oracle ASM whether or not to attempt to repair any errors found during the consistency check. The default is NOREPAIR. The NOREPAIR setting is useful if you want to be alerted to any inconsistencies but do not want Oracle ASM to take any automatic action to resolve them.

Deprecated Clauses In earlier releases, you could specify CHECK for ALL, DISK, DISKS IN FAILGROUP, or FILE. Those clauses have been deprecated as they are no longer needed. If you specify them, then their behavior is the same as in earlier releases and a message is added to the alert log. However, Oracle recommends that you do not introduce these clauses into your new code, as they are scheduled for desupport. The deprecated clauses are these:

- ALL checks all disks and files in the disk group.
- DISK checks one or more specified disks in the disk group.
- DISKS IN FAILGROUP checks all disks in a specified failure group.
- FILE checks one or more specified files in the disk group. You must use one of the reference forms of the filename. Refer to ASM_filename on page 8-32 for information on the reference forms of Oracle ASM filenames.

diskgroup_template_clauses

A template is a named collection of attributes. When you create a disk group, Oracle ASM associates a set of initial system default templates with that disk group. The attributes defined by the template are applied to all files in the disk group. Table 10–2 lists the system default templates and the attributes they apply to the various file types. The diskgroup_template_clauses described following the table let you change the template attributes and create new templates.

You cannot use this clause to change the attributes of a disk group file after it has been created. Instead, you must use Recovery Manager (RMAN) to copy the file into a new file with the new attributes.
## ALTER DISKGROUP

Use this clause to add one or more named templates to a disk group. To determine the names of existing templates, query the `V$ASM_TEMPLATE` dynamic performance view.

**ADD TEMPLATE**

Use this clause to add one or more named templates to a disk group. To determine the names of existing templates, query the `V$ASM_TEMPLATE` dynamic performance view.

**MODIFY TEMPLATE**

Use this clause to modify the attributes of a system default or user-defined disk group template. Only the specified attributes are altered. Unspecified properties retain their current values.

---

</table>

---

**Note:** In earlier releases, the keywords `ALTER TEMPLATE` were used instead of `MODIFY TEMPLATE`. The `ALTER` keyword is still supported for backward compatibility, but is replaced with `MODIFY` for consistency with other Oracle SQL.
template_name Specify the name of the template to be added or modified. Template names are subject to the same naming conventions and restrictions as database schema objects. Refer to "Database Object Naming Rules" on page 2-119 for information on database object names.

redundancy_clause Specify the redundancy level of the newly added or modified template:

- MIRROR: Files to which this template are applied are protected by mirroring their data blocks. In normal redundancy disk groups, each primary extent has one mirror extent (2-way mirroring). For high redundancy disk groups, each primary extent has two mirror extents (3-way mirroring). You cannot specify MIRROR for templates in external redundancy disk groups.
- HIGH: Files to which this template are applied are protected by mirroring their data blocks. Each primary extent has two mirror extents (3-way mirroring) for both normal redundancy and high redundancy disk groups. You cannot specify HIGH for templates in external redundancy disk groups.
- UNPROTECTED: Files to which this template are applied are not protected by Automated Storage Management from media failures. Disks taken offline, either through system action or by user command, can cause loss of unprotected files. UNPROTECTED is the only valid setting for external redundancy disk groups. UNPROTECTED may not be specified for templates in high redundancy disk groups. Oracle discourages the use of unprotected files in high and normal redundancy disk groups.

If you omit this clause, then the value defaults to MIRROR for a normal redundancy disk group, HIGH for a high redundancy disk group, and UNPROTECTED for an external redundancy disk group.

striping_clause Specify how the files to which this template are applied will be striped:

- FINE: Files to which this template are applied are striped every 128KB. This striping mode is not valid for an Oracle ASM spfile.
- COARSE: Files to which this template are applied are striped every 1MB. This is the default value.

disk_region_clause This clause lets you determine the Intelligent Data Placement attribute of the disk group file. Specify the region of the disk in which you want Oracle ASM to allocate extents for the file:

- HOT: Extents are allocated in the region of the disk furthest away from the spindle. These outer tracks on the disk are longer than inner tracks, and so have more sectors and increased throughput.
- COLD: Extents are allocated in the region of the disk closest to the spindle.
- MIRRORHOT and MIRRORCOLD: Specify the region desired for the mirrored datablocks of the file.

If no space is available in the desired disk region, then Oracle ASM allocates extents in the other region but initiates a rebalance to adjust the size of the region.

See Also: Oracle Automatic Storage Management Administrator’s Guide for more information on Intelligent Data Placement
**DROP TEMPLATE**  Use this clause to drop one or more templates from the disk group. You can use this clause to drop only user-defined templates, not system default templates.

**diskgroup_directory_clauses**

Before you can create alias names for Oracle ASM filenames (see diskgroup_alias_clauses on page 10-94), you must specify the full directory structure in which the alias name will reside. The diskgroup_directory_clauses let you create and manipulate such a directory structure.

**ADD DIRECTORY**  Use this clause to create a new directory path for hierarchically named aliases. Use a slash (/) to separate components of the directory. Each directory component can be up to 48 bytes in length and must not contain the slash character. You cannot use a space for the first or last character of any component. The total length of the directory path cannot exceed 256 bytes minus the length of any alias name you intend to create in this directory (see diskgroup_alias_clauses on page 10-94).

**DROP DIRECTORY**  Use this clause to drop a directory for hierarchically named aliases. Oracle ASM will not drop the directory if it contains any alias definitions unless you also specify FORCE. This clause is not valid for dropping directories created as part of a system alias. Such directories are labeled with the value Y in the SYSTEM_CREAT column of the V$ASM_ALIAS dynamic performance view.

**RENAME DIRECTORY**  Use this clause to change the name of a directory for hierarchically named aliases. This clause is not valid for renaming directories created as part of a system alias. Such directories are labeled with the value Y in the SYSTEM_CREAT column of the V$ASM_ALIAS dynamic performance view.

**diskgroup_alias_clauses**

When an Oracle ASM file is created, either implicitly or by user specification, Oracle ASM assigns to the file a fully qualified name ending in a dotted pair of numbers (see file_specification on page 8-29). The diskgroup_alias_clauses let you create more user-friendly alias names for the Oracle ASM filenames. You cannot specify an alias name that ends in a dotted pair of numbers, as this format is indistinguishable from an Oracle ASM filename.

Before specifying this clause, you must first create the directory structure appropriate for your naming conventions (see diskgroup_directory_clauses on page 10-94). The total length of the alias name, including the directory prefix, is limited to 256 bytes. Alias names are case insensitive but case retentive.

**ADD ALIAS**  Use this clause to create an alias name for an Oracle ASM filename. The alias_name consists of the full directory path and the alias itself. To determine the names of existing Oracle ASM aliases, query the V$ASM_ALIAS dynamic performance view. Refer to ASM_filename on page 8-32 for information on Oracle ASM filenames.

**DROP ALIAS**  Use this clause to remove an alias name from the disk group directory. Each alias name consists of the full directory path and the alias itself. The underlying file to which the alias refers remains unchanged.

**RENAME ALIAS**  Use this clause to change the name of an existing alias. The alias_name consists of the full directory path and the alias itself.
**Restriction on Dropping and Renaming Aliases** You cannot drop or rename a system-generated alias. To determine whether an alias was system generated, query the `SYSTEM_CREATED` column of the `V$ASM_ALIAS` dynamic performance view.

**diskgroup_volume_clauses**
Use these clauses to manipulate logical Oracle ASM Dynamic Volume Manager (Oracle ADVM) volumes corresponding to physical volume devices. To use these clauses, Oracle ASM must be started and the disk group being modified must be mounted.

**See Also:** *Oracle Automatic Storage Management Administrator’s Guide* for more information about disk group volumes, including examples

**add_volume_clause** Use this clause to add a volume to the disk group.

For `asm_volume`, specify the name of the volume. The name can contain only alphanumeric characters and the first character must be alphabetic. The maximum length of the name is platform dependent. Refer to *Oracle Automatic Storage Management Administrator’s Guide* for more information.

For `size_clause`, specify the size of the Oracle ADVM volume. The Oracle ASM instance determines whether sufficient space exists to create the volume. If sufficient space does not exist, then the Oracle ASM instance returns an error. If sufficient space does exist, then all nodes in the cluster with an Oracle ASM instance running and the disk group mounted are notified of the addition. Oracle ASM creates and enables on those nodes a volume device that can be used to create and mount file systems.

The following optional settings are also available:

- In the `redundancy_clause`, specify the redundancy level of the Oracle ADVM volume. You can specify this clause only when creating a volume in a normal redundancy disk group. You can specify the following volume redundancy levels:
  - MIRROR: 2-way mirroring of the volume. This is the default.
  - HIGH: 3-way mirroring of the volume.
  - UNPROTECTED: No mirroring of the volume.

You cannot specify the `redundancy_clause` when creating a volume in a high redundancy disk group or an external redundancy disk group. If you do so, then an error will result. In high redundancy disk groups, Oracle Database automatically sets the volume redundancy to `HIGH` (3-way mirroring). In external redundancy disk groups, Oracle Database automatically sets the volume redundancy to `UNPROTECTED` (no mirroring).

- In the `STRIPE_WIDTH` clause, specify a stripe width for the Oracle ADVM volume. The valid range is from 4KB to 1MB, at intervals of the power of 2. The default value is 128K.

- In the `STRIPE_COLUMNS` clause, specify the number of stripes in a stripe set of the Oracle ADVM volume. The valid range is 1 to 8. The default is 4. If `STRIPE_COLUMNS` is set to 1, then striping becomes disabled. In this case, the stripe width is the extent size of the volume. This volume extent size is 64 times the allocation unit (AU) size of the disk group.

- In the `disk_region_clause` clause, specify the Intelligent Data Placement attribute of both the primary and nonprimary mirror of the disk group volume. The default for both is `COLD`. See `disk_region_clause` on page 10-93 for details on this clause.
**modify_volume_clause**  Use this clause to modify the characteristics of an existing Oracle ADVM volume. You must specify at least one of the following clauses:

- In the `disk_region_clause` clause, specify the Intelligent Data Placement attribute of both the primary and nonprimary mirror of the disk group volume. The default for the primary mirror is `COLD`. The default for mirror and high redundancy is `HOT`. See `disk_region_clause` on page 10-93 for details on this clause.

- In the `MOUNTPATH` clause, specify the mountpath name associated with the volume. The `mountpath_name` can be up to 1024 characters.

- In the `USAGE` clause, specify the usage name associated with the volume. The `usage_name` can be up to 30 characters.

**RESIZE VOLUME Clause**  Use this clause to change the size of an existing Oracle ADVM volume. In an Oracle ASM cluster, the new size is propagated to all nodes. If an Oracle Automatic Storage Management File System (ACFS) exists on the volume, then you must use the `acfsutil size` command instead of the `ALTER DISKGROUP` statement.

See Also: *Oracle Automatic Storage Management Administrator’s Guide* for more information about the `acfsutil size` command

**DROP VOLUME Clause**  Use this clause to remove the Oracle ASM file that is the storage container for an existing Oracle ADVM volume. In an Oracle ASM cluster, all nodes with an Oracle ASM instance running and with this disk group open are notified of the drop operation, which results in removal of the volume device. If the volume file is open, then this clause returns an error.

**diskgroup_attributes**  Use this clause to specify attributes for the disk group. *Table 14–2, "Disk Group Attributes"* on page 14-60 lists the attributes you can set with this clause. Refer to the `CREATE DISKGROUP "ATTRIBUTE Clause"` on page 14-59 for information on the behavior of this clause.

**modify_diskgroup_file**  Use this clause to modify the Intelligent Data Placement attributes of an existing disk group file. When you modify the Intelligent Data Placement for a file, this action will apply to new extensions of the file, but existing file contents are not affected until a rebalance operation. To apply the new Intelligent Data Placement policy for existing file contents, you can manually initiate a rebalance. A rebalance operation uses the last specified policy for the file extents.

See Also:
- `disk_region_clause` on page 10-93 for more information on this clause
- *Oracle Automatic Storage Management Administrator’s Guide* for more information on manually rebalancing disk groups

**drop_diskgroup_file_clause**  Use this clause to drop a file from the disk group. Oracle ASM also drops all aliases associated with the file being dropped. You must use one of the reference forms of the filename. Most Oracle ASM files do not need to be manually deleted because, as Oracle Managed Files, they are removed automatically when they are no longer
ALTER DISKGROUP

SQL Statements: ADMINISTER KEY MANAGEMENT to ALTER JAVA

needed. Refer to ASM_filename on page 8-32 for information on the reference forms of Oracle ASM filenames.

You cannot drop a disk group file if it is the spfile that was used to start up the current instance or any instance in the Oracle ASM cluster.

usergroup_clauses

Use these clauses to add a user group to the disk group, remove a user group from the disk group, or to add a member to or drop a member from an existing user group.

See Also: Oracle Automatic Storage Management Administrator’s Guide
for detailed information about user groups and members, including examples

ADD USERGROUP  Use this clause to add a user group to the disk group. You must have SYSA SM or SYSDBA privilege to create a user group. The user group name can be up to 30 characters long. If you specify the user name, then it must be in the OS password file.

MODIFY USERGROUP  Use these clauses to add a member to or drop a member from an existing user group. You must be an Oracle ASM administrator (with SYSA SM privilege) or the creator (with SYSA SM privilege) of the user group to use these clauses. The user name must be an existing user in the OS password file.

DROP USERGROUP  Use this clause to drop an existing user group from the disk group. You must be an Oracle ASM administrator (with SYSA SM privilege) or the creator (with SYSA SM privilege) of the user group to use this clause. Dropping a user group may leave a disk group file without a valid user group. In this case, you can update the disk group file manually to add a new, valid group using the file_permissions_clause on page 10-98.

user_clauses

Use these clauses to add a user to, drop a user from, or replace a user in a disk group.

ADD USER  Use this clause to add one or more operating system (OS) users to an Oracle ASM disk group and give those users access privileges on the disk group. If a specified user already exists in the disk group, as shown by V$ASM_USER, then the command records an error and continues to add other users, if any have been specified. This command is seldom needed, because the OS user running the database instance is added to a disk group automatically when the instance accesses the disk group. However, this clause is useful when adding users that are not associated with a particular database instance.

DROP USER  Use this clause to drop one or more users from the disk group. If a specified user is not in the disk group, then this clause records an error and continues to drop other users, if any are specified. If the user owns any files, then you must specify the CASCADE keyword, which drops the user and all the user's files. If any files owned by the user are open, then DROP USER CASCADE fails with an error.

Note: When administering users with SQL*Plus, the users must be existing operating system users and their user names must have corresponding operating system user IDs. However, only users in the same cluster as the Oracle ASM instance can be validated.
To delete a user without deleting the files owned by that user, change the owner of each of these files to another user and then issue an `ALTER DISKGROUP ... DROP USER` statement on the user. Alternatively, you can issue an `ALTER DISKGROUP ... REPLACE USER` statement to replace the user you want to drop with a user that currently does not exist in the disk group. This operation has the side effect of making the new user the owner of files that were previously owned by the dropped user.

**REPLACE USER**  Use this clause to replace `old_user` with `new_user` in the disk group. All files that are currently owned by `old_user` will become owned by `new_user`, and `old_user` will be dropped from the disk group. `old_user` must exist in the disk group and `new_user` must not exist in the disk group.

**file_permissions_clause**

Use this clause to change the permission settings of a disk group file. The three classes of permissions are owner, user group, and other. You must be the file owner or the Oracle ASM administrator to use this clause.

If you change the permission settings of an open file, then the operation currently running on the file will complete using the old permission settings. The new permission settings will take effect when re-authentication is required.

**file_owner_clause**

Use this clause to set the owner or user group for a specified file. You must be the Oracle ASM administrator to change the owner of the file. You must be the owner of the file or the Oracle ASM administrator to change the user group of a file. In addition, to change the associated user group of a file, the specified user group must already exist in the disk group, and the owner of the file must be a member of that user group.

If you use this clause on an open file, then the following conditions apply:

- If you change the owner or user group of an open file, then the operation currently running on the file will complete using the old owner or user group. The new owner or user group will take effect when re-authentication is required.
- If you change the owner of an open file, then the new owner of the file cannot be dropped from the disk group until the instance has been restarted. In an Oracle ASM cluster, the new owner of the file cannot be dropped until all instances in the cluster have been restarted.
- If you change the owner of an open file, then the old owner cannot be dropped while the file is still open, even after the ownership of the file has changed.

**scrub_clause**

Use this clause to scrub a disk group. The scrub operation checks for logical data corruptions and repairs the corruptions automatically in normal and high redundancy disks groups.

- Use the `FILE` clause to scrub the specified Oracle ASM file in the disk group. You must use one of the reference forms of the `ASM_filename`. Refer to `ASM_filename` on page 8-32 for information on the reference forms of Oracle ASM filenames.
- Use the `DISK` clause to scrub the specified disk in the disk group.
- If you do not specify `FILE` or `DISK`, then all files and disks in the disk group are scrubbed.
REPAIR | NOREPAIR Specify REPAIR to attempt to repair any errors found during the logical data corruption check. Specify NOREPAIR to be alerted of any corruptions; Oracle ASM will not take any action to resolve them. The default is NOREPAIR.

POWER Use the POWER clause to specify the power level of the scrub operation. Valid values are AUTO, LOW, HIGH, and MAX. If you omit this clause, then the power level defaults to AUTO and the power adjusts to the optimum level for the system.

WAIT | NOWAIT Specify WAIT to allow the scrub operation to complete before returning control to the user. Specify NOWAIT to add the operation to the scrubbing queue and return control to the user immediately. The default is NOWAIT.

FORCE | NOFORCE Specify FORCE to process the command even if the system I/O load is high or scrubbing has been disabled at the system level. Specify NOFORCE to process the command normally. The default is NOFORCE.

You can monitor the progress of the scrub operation by querying the V$ASM_OPERATION dynamic performance view.

See Also: Oracle Automatic Storage Management Administrator’s Guide for more information on scrubbing disk groups and "Scrubbing a Disk Group: Example" on page 10-102

undrop_disk_clause
Use this clause to cancel the drop of disks from the disk group. You can cancel the pending drop of all the disks in one or more disk groups (by specifying diskgroup_name) or of all the disks in all disk groups (by specifying ALL).

This clause is not relevant for disks that have already been completely dropped from the disk group or for disk groups that have been completely dropped. This clause results in a long-running operation. You can see the status of the operation by querying the V$ASM_OPERATION dynamic performance view.

See Also: V$ASM_OPERATION for more information on the details of long-running Oracle ASM operations

diskgroup_availability
Use this clause to make one or more disk groups available or unavailable to the database instances running on the same node as the Oracle ASM instance. This clause does not affect the status of the disk group on other nodes in a cluster.

MOUNT Specify MOUNT to mount the disk groups in the local Oracle ASM instance. Specify ALL MOUNT to mount all disk groups specified in the ASM_DISKGROUPS initialization parameter. File operations can only be performed when a disk group is mounted. If Oracle ASM is running in a cluster or a standalone server managed by Oracle Restart, then the MOUNT clause automatically brings the corresponding resource online.

RESTRICTED | NORMAL Use these clauses to determine the manner in which the disk groups are mounted.

- In the RESTRICTED mode, the disk group is mounted in single-instance exclusive mode. No other Oracle ASM instance in the same cluster can mount that disk group. In this mode the disk group is not usable by any Oracle ASM client.
- In the NORMAL mode, the disk group is mounted in shared mode, so that other Oracle ASM instances and clients can access the disk group. This is the default.
FORCEx NOFORCE  Use these clauses to determine the circumstances under which the disk groups are mounted.

- In the FORCEx mode, Oracle ASM attempts to mount the disk group even if it cannot discover all of the devices that belong to the disk group. This setting is useful if some of the disks in a normal or high redundancy disk group became unavailable while the disk group was dismounted. When MOUNT FORCEx succeeds, Oracle ASM takes the missing disks offline.

If Oracle ASM discovers all of the disks in the disk group, then MOUNT FORCEx fails. Therefore, use the MOUNT FORCEx setting only if some disks are unavailable. Otherwise, use NOFORCE.

In normal- and high-redundancy disk groups, disks from one failure group can be unavailable and MOUNT FORCEx will succeed. Also in high-redundancy disk groups, two disks in two different failure groups can be unavailable and MOUNT FORCEx will succeed. Any other combination of unavailable disks causes the operation to fail, because Oracle ASM cannot guarantee that a valid copy of all user data or metadata exists on the available disks.

- In the NOFORCE mode, Oracle ASM does not attempt to mount the disk group unless it can discover all the member disks. This is the default.

See Also: ASM_DISKGROUPS for more information about adding disk group names to the initialization parameter file

DISMOUNT  Specify DISMOUNT to dismount the specified disk groups. Oracle ASM returns an error if any file in the disk group is open unless you also specify FORCEx. Specify ALL DISMOUNT to dismount all currently mounted disk groups. File operations can only be performed when a disk group is mounted. If Oracle ASM is running in a cluster or a standalone server managed by Oracle Restart, then the DISMOUNT clause automatically takes the corresponding resource offline.

FORCEx  Specify FORCEx if you want Oracle ASM to dismount the disk groups even if some files in the disk group are open.

enable_disable_volume  Use this clause to enable or disable one or more volumes in the disk group.

- For each volume you enable, Oracle ASM creates a volume device file on the local node that can be used to create or mount the file system.

- For each volume you disable, Oracle ASM deletes the device file on the local node. If the volume file is open on the local node, then the DISABLE clause returns an error.

Use the ALL keyword to enable or disable all volumes in the disk group. If you specify ALTER DISKGROUP ALL . . ., then you must use the ALL keyword in this clause as well.

See Also: Oracle Automatic Storage Management Administrator’s Guide for more information about disk group volumes

Examples  The following examples require a disk group called dgroup_01. They assume that ASM_DISKSTRING is set to /devices/disks/*. In addition, they assume the Oracle user has read/write permission to /devices/disks/d100. Refer to “Creating a Diskgroup: Example” on page 14-63 to create dgroup_01.
Adding a Disk to a Disk Group: Example  To add a disk, d100, to a disk group, dgroup_01, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  ADD DISK '/devices/disks/d100';
```

Dropping a Disk from a Disk Group: Example  To drop a disk, dgroup_01_0000, from a disk group, dgroup_01, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  DROP DISK dgroup_01_0000;
```

Undropping a Disk from a Disk Group: Example  To cancel the drop of disks from a disk group, dgroup_01, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  UNDROP DISKS;
```

Resizing a Disk Group: Example  To resize every disk in a disk group, dgroup_01, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  RESIZE ALL
  SIZE 36G;
```

Rebalancing a Disk Group: Example  To manually rebalance a disk group, dgroup_01, and permit Oracle ASM to execute the rebalance as fast as possible, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  REBALANCE POWER 11 WAIT;
```

The WAIT keyword causes the database to wait for the disk group to be rebalanced before returning control to the user.

Verifying the Internal Consistency of Disk Group Metadata: Example  To verify the internal consistency of Oracle ASM disk group metadata and instruct Oracle ASM to repair any errors found, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  CHECK ALL
  REPAIR;
```

Adding a Named Template to a Disk Group: Example  To add a named template, template_01 to a disk group, dgroup_01, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  ADD TEMPLATE template_01
    ATTRIBUTES (UNPROTECTED COARSE);
```

Changing the Attributes of a Disk Group Template: Example  To modify the attributes of a system default or user-defined disk group template, template_01, issue the following statement:

```
ALTER DISKGROUP dgroup_01
  MODIFY TEMPLATE template_01
    ATTRIBUTES (FINE);
```

Dropping a User-Defined Template from a Disk Group: Example  To drop a user-defined template, template_01, from a disk group, dgroup_01, issue the following statement:
ALTER DISKGROUP dgroup_01
   DROP TEMPLATE template_01;

**Creating a Directory Path for Hierarchically Named Aliases: Example** To specify the directory structure in which alias names will reside, issue the following statement:

ALTER DISKGROUP dgroup_01
   ADD DIRECTORY '+dgroup_01/alias_dir';

**Creating an Alias Name for an Oracle ASM Filename: Example** To create a user alias by specifying the numeric Oracle ASM filename, issue the following statement:

ALTER DISKGROUP dgroup_01
   ADD ALIAS '+dgroup_01/alias_dir/datafile.dbf'
      FOR '+dgroup_01.261.1';

**Scrubbing a Disk Group: Example** To scrub a disk group, `dgroup_01`, issue the following statement. This statement attempts to repair any errors found during the logical data corruption check and allows the scrub operation to complete before returning control to the user:

ALTER DISKGROUP dgroup_01
   SCRB REPAIR WAIT;

**Dismounting a Disk Group: Example** To dismount a disk group, `dgroup_01`, issue the following statement. This statement dismounts the disk group even if one or more files are active:

ALTER DISKGROUP dgroup_01
   DISMOUNT FORCE;

**Mounting a Disk Group: Example** To mount a disk group, `dgroup_01`, issue the following statement:

ALTER DISKGROUP dgroup_01
   MOUNT;
ALTER FLASHBACK ARCHIVE

Purpose

Use the ALTER FLASHBACK ARCHIVE statement for these operations:

- Designate a flashback data archive as the default flashback data archive for the system
- Add a tablespace for use by the flashback data archive
- Change the quota of a tablespace used by the flashback data archive
- Remove a tablespace from use by the flashback data archive
- Change the retention period of the flashback data archive
- Purge the flashback data archive of old data that is no longer needed

See Also: Oracle Database Development Guide and CREATE FLASHBACK ARCHIVE on page 14-68 for more information on using flashback data archives

Prerequisites

You must have the FLASHBACK ARCHIVE ADMINISTER system privilege to alter a flashback data archive in any way. You must also have appropriate privileges on the affected tablespaces to add, modify, or remove a flashback data archive tablespace.

Syntax

```
alter_flashback_archive ::= 
  ALTER FLASHBACK ARCHIVE flashback_archive 
  SET DEFAULT 
  ADD TABLESPACE tablespace 
  MODIFY TABLESPACE tablespace 
  REMOVE TABLESPACE tablespace_name 
  MODIFY RETENTION flashback_archive_retention 
  PURGE ALL BEFORE SCN expr 
  PURGE ALL BEFORE TIMESTAMP expr 
  NO OPTIMIZE DATA 
```
**ALTER FLASHBACK ARCHIVE**

### flashback_archive_quota::=

```
QUOTA [integer [M | G | T | P | E]]
```

### flashback_archive_retention::=

```
RETENTION [integer [YEAR | MONTH | DAY]]
```

#### Semantics

**flashback_archive**

Specify the name of an existing flashback data archive.

**SET DEFAULT**

You must be logged in as SYSDBA to specify this clause. Use this clause to designate this flashback data archive as the default flashback data archive for the system. When a CREATE TABLE or ALTER TABLE statement specifies the `flashback_archive_clause` without specifying a flashback data archive name, the database uses the default flashback data archive to store data from that table.

This statement overrides any previous designation of a different flashback data archive as the default.

*See Also:* The CREATE TABLE `flashback_archive_clause` on page 16-84 for more information

**ADD TABLESPACE**

Use this clause to add a tablespace to the flashback data archive. You can use the `flashback_archive_quota` clause to specify the amount of space that can be used by the flashback data archive in the new tablespace. If you omit that clause, then the flashback data archive has unlimited space in the newly added tablespace.

**MODIFY TABLESPACE**

Use this clause to change the tablespace quota of a tablespace already used by the flashback data archive.

**REMOVE TABLESPACE**

Use this clause to remove a tablespace from use by the flashback data archive. You cannot remove the last remaining tablespace used by the flashback data archive.

If the tablespace to be removed contains any data within the retention period of the flashback archive, then that data will be dropped as well. Therefore, you should move your data to another tablespace before removing the tablespace with this clause.
MODIFY RETENTION
Use this clause to change the retention period of the flashback data archive.

PURGE
Use this clause to purge data from the flashback data archive.

- Specify PURGE ALL to remove all data from the flashback data archive. This historical information can be retrieved using a flashback query only if the SCN or timestamp specified in the flashback query is within the undo retention duration.
- Specify PURGE BEFORE SCN to remove all data from the flashback data archive before the specified system change number.
- Specify PURGE BEFORE TIMESTAMP to remove all data from the flashback data archive before the specified timestamp.

[NO] OPTIMIZE DATA
This clause has the same semantics as the [NO] OPTIMIZE DATA clause of CREATE FLASHBACK ARCHIVE on page 14-70.

See Also: CREATE FLASHBACK ARCHIVE on page 14-68 for information on creating flashback data archives and for some simple examples of using flashback data archives
ALTER FUNCTION

Purpose

Functions are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the ALTER FUNCTION statement to recompile an invalid standalone stored function. Explicit recompilation eliminates the need for implicit run-time recompilation and prevents associated run-time compilation errors and performance overhead.

This statement does not change the declaration or definition of an existing function. To redefine a function, use the CREATE FUNCTION statement with the OR REPLACE clause. See CREATE FUNCTION on page 14-71.

Prerequisites

The function must be in your own schema or you must have ALTER ANY PROCEDURE system privilege.

Syntax

\[ \text{alter\_function::=} \]

\[ \text{ALTER\_FUNCTION\textunderscore\_schema\_function\_name\_function\_compile\_clause} \]

\[ \text{EDITIONABLE | NONEDITIONABLE} \]

(function_compile_clause: See Oracle Database PL/SQL Language Reference for the syntax of this clause.)

Semantics

\textit{schema}

Specify the schema containing the function. If you omit \textit{schema}, then Oracle Database assumes the function is in your own schema.

\textit{function\_name}

Specify the name of the function to be recompiled.

\textit{function\_compile\_clause}

See Oracle Database PL/SQL Language Reference for the syntax and semantics of this clause and for complete information on creating and compiling functions.

\textbf{EDITIONABLE | NONEDITIONABLE}

Use these clauses to specify whether the function becomes an editioned or noneditioned object if editioning is later enabled for the schema object type FUNCTION in \textit{schema}. The default is EDITIONABLE. For information about altering editioned and noneditioned objects, see Oracle Database Development Guide.
ALTER INDEX

Purpose

Use the ALTER INDEX statement to change or rebuild an existing index.

See Also: CREATE INDEX on page 14-73 for information on creating an index

Prerequisites

The index must be in your own schema or you must have the ALTER ANY INDEX system privilege.

To execute the MONITORING USAGE clause, the index must be in your own schema.

To modify a domain index, you must have EXECUTE object privilege on the indextype of the index.

Object privileges are granted on the parent index, not on individual index partitions or subpartitions.

You must have tablespace quota to modify, rebuild, or split an index partition or to modify or rebuild an index subpartition.
ALTER INDEX

Syntax

\textit{alter\_index::=}

\begin{itemize}
\item \texttt{deallocate\_unused\_clause}
\item \texttt{allocate\_extent\_clause}
\item \texttt{shrink\_clause}
\item \texttt{parallel\_clause}
\item \texttt{physical\_attributes\_clause}
\item \texttt{logging\_clause}
\item \texttt{partial\_index\_clause}
\item \texttt{rebuild\_clause}
\item \texttt{PARAMETERS}\hspace{1em}\texttt{ODCI\_parameters}
\item \texttt{COMPILE}
\item \texttt{ENABLE}
\item \texttt{DISABLE}
\item \texttt{UNUSABLE}
\item \texttt{ONLINE}
\item \texttt{VISIBLE}
\item \texttt{INVISIBLE}
\item \texttt{RENAME}\hspace{1em}\texttt{TO}\hspace{1em}\texttt{new\_name}
\item \texttt{COALESCE}
\item \texttt{CLEANUP}\hspace{1em}\texttt{parallel\_clause}
\item \texttt{MONITORING}
\item \texttt{NOMONITORING}
\item \texttt{USAGE}
\item \texttt{UPDATE}\hspace{1em}\texttt{BLOCK}\hspace{1em}\texttt{REFERENCES}
\item \texttt{alter\_index\_partitioning}
\end{itemize}

(\texttt{deallocate\_unused\_clause::=} on page 10-108, \texttt{allocate\_extent\_clause::=} on page 10-109, \texttt{shrink\_clause::=} on page 10-109, \texttt{parallel\_clause::=} on page 10-109, \texttt{physical\_attributes\_clause::=} on page 10-109, \texttt{logging\_clause::=} on page 8-38, \texttt{partial\_index\_clause::=} on page 10-109, \texttt{rebuild\_clause::=} on page 10-110, \texttt{alter\_index\_partitioning::=} on page 10-111)

(The \texttt{ODCI\_parameters} are documented in Oracle Database Data Cartridge Developer’s Guide.)

\textit{deallocate\_unused\_clause::=}

\begin{itemize}
\item \texttt{DEALLOCATE}
\item \texttt{UNUSED}
\item \texttt{KEEP}\hspace{1em}\texttt{size\_clause}
\end{itemize}

(\texttt{size\_clause::=} on page 8-47)
ALTER INDEX

allocate_extent_clause ::= 

\[\text{ALLOCATE EXTENT} \] 

\[\text{SIZE size\_clause}\] 

\[\text{DATAFILE filename}\] 

\[\text{INSTANCE integer}\] 

\[(\text{size\_clause ::= on page 8-47)}\] 

shrink_clause ::= 

\[\text{SHRINK SPACE COMPACT CASCADE}\] 

parallel_clause ::= 

\[\text{NOPARALLEL}\] 

\[\text{PARALLEL integer}\] 

physical_attributes_clause ::= 

\[\text{PCTFREE integer}\] 

\[\text{PCTUSED integer}\] 

\[\text{INTRANS integer}\] 

\[\text{storage\_clause ::= on page 8-50}\] 

logging_clause ::= 

\[\text{LOGGING}\] 

\[\text{NOLOGGING}\] 

\[\text{FILESYSTEM\_LIKE\_LOGGING}\] 

partial_index_clause ::= 

\[\text{INDEXING PARTIAL}\] 

\[\text{FULL}\]
**ALTER INDEX**

**rebuild_clause ::=**

- **PARTITION**
- **SUBPARTITION**
- **REVERSE**
- **NOREVERSE**

- **parallel_clause**
  - **TABLESPACE**
  - **PARAMETERS**
  - **ODCI_parameters**
  - **XMLIndex_parameters_clause**
  - **ONLINE**
  - **physical_attributes_clause**
  - **index_compression**
  - **logging_clause**
  - **partial_index_clause**

**index_compression ::=**

- **prefix_compression**
  - **advanced_index_compression**

**prefix_compression ::=**

- **COMPRESS**
- **NOCOMPRESS**

**advanced_index_compression ::=**

- **COMPRESS ADVANCED LOW**
- **NOCOMPRESS**

(\(parallel\_clause::= on page 10-109, physical\_attributes\_clause::= on page 10-109, index\_compression::= on page 10-110, logging\_clause::= on page 8-38, partial\_index\_clause::= on page 10-109\))

(The **ODCI_parameters** are documented in Oracle Database Data Cartridge Developer's Guide. The **XMLIndex_parameters_clause** is documented in Oracle XML DB Developer's Guide.)
**ALTER INDEX**

\[ \textit{alter\_index\_partitioning} ::= \]

\[ \textit{modify\_index\_default\_attrs} \]
\[ \textit{add\_hash\_index\_partition} \]
\[ \textit{modify\_index\_partition} \]
\[ \textit{rename\_index\_partition} \]
\[ \textit{drop\_index\_partition} \]
\[ \textit{split\_index\_partition} \]
\[ \textit{coalesce\_index\_partition} \]
\[ \textit{modify\_index\_subpartition} \]

\[(\textit{modify\_index\_default\_attrs} ::= \) on page 10-111, \textit{add\_hash\_index\_partition} ::= \) on page 10-111, \textit{modify\_index\_partition} ::= \) on page 10-112, \textit{rename\_index\_partition} ::= \) on page 10-112, \textit{drop\_index\_partition} ::= \) on page 10-112, \textit{split\_index\_partition} ::= \) on page 10-112, \textit{coalesce\_index\_partition} ::= \) on page 10-111, \textit{modify\_index\_subpartition} ::= \) on page 10-113\]

\[ \textit{modify\_index\_default\_attrs} ::= \]

\[ \textit{MODIFY DEFAULT ATTRIBUTES FOR PARTITION partition \(\text{physical\_attributes\_clause} \rightarrow \text{TABLESPACE tablespace \(\text{logging\_clause} \rightarrow \text{DEFAULT})}\) \]

\[(\textit{physical\_attributes\_clause} ::= \) on page 10-109, \textit{logging\_clause} ::= \) on page 8-38\]

\[ \textit{add\_hash\_index\_partition} ::= \]

\[ \textit{ADD PARTITION partition \(\text{TABLESPACE tablespace \(\text{index\_compression} \rightarrow \text{parallel\_clause})})\) \]

\[(\textit{index\_compression} ::= \) on page 10-110, \textit{parallel\_clause} ::= \) on page 10-109\]

\[ \textit{coalesce\_index\_partition} ::= \]

\[ \textit{COALESCE PARTITION parallel\_clause} \]

\[(\textit{parallel\_clause} ::= \) on page 10-109\]
**modify_index_partition::=**

- MODIFY PARTITION partition
- PARAMETERS (OCCI_parameters)
- COALESCE
- CLEANUP
- UPDATE BLOCK REFERENCES
- UNUSABLE

*(deallocate_unused_clause::= on page 10-108, allocateExtentClause::= on page 10-109, physical_attributes_clause::= on page 10-109, logging_clause::= on page 8-38, index_compression::= on page 10-110)*

**rename_index_partition::=**

- RENAME PARTITION partition SUBPARTITION subpartition TO new_name

**drop_index_partition::=**

- DROP PARTITION partition_name

**split_index_partition::=**

- SPLIT PARTITION partition_name_old AT (literal)
- INTO (index_partition_description, index_partition_description) parallel_clause

*(parallel_clause::= on page 10-109)*

**index_partition_description::=**

- PARTITION partition
- PARAMETERS (OCCI_parameters)
- USABLE
- UNUSABLE

*(segment_attributes_clause::= on page 10-113, index_compression::= on page 10-110)*
ALTER INDEX

**Note:** The `USABLE` and `UNUSABLE` keywords are not supported when `index_partition_description` is specified for the `split_index_partition` clause.

```
segment_attributes_clause ::= 
```

```
physical_attributes_clause ::= on page 10-109, 
logging_clause ::= on page 8-38
```

```
modify_index_subpartition ::= 
```

```
allocate_extent_clause ::= on page 10-109, 
deallocate_unused_clause ::= on page 10-108
```

**Semantics**

**schema**
Specify the schema containing the index. If you omit `schema`, then Oracle Database assumes the index is in your own schema.

**index**
Specify the name of the index to be altered.

**Restrictions on Modifying Indexes**
The modification of indexes is subject to the following restrictions:

- If `index` is a domain index, then you can specify only the `PARAMETERS` clause, the `RENAME` clause, the `rebuild_clause` (with or without the `PARAMETERS` clause), the `parallel_clause`, or the `UNUSABLE` clause. No other clauses are valid.

- You cannot alter or rename a domain index that is marked `LOADING` or `FAILED`. If an index is marked `FAILED`, then the only clause you can specify is `REBUILD`.

**See Also:** Oracle Database Data Cartridge Developer’s Guide for information on the `LOADING` and `FAILED` states of domain indexes

**deallocate_unused_clause**
Use the `deallocate_unused_clause` to explicitly deallocate unused space at the end of the index and make the freed space available for other segments in the tablespace.

If `index` is range-partitioned or hash-partitioned, then Oracle Database deallocates unused space from each index partition. If `index` is a local index on a composite-partitioned table, then Oracle Database deallocates unused space from each index subpartition.
Restrictions on Deallocation of Space  Deallocation of space is subject to the following restrictions:

- You cannot specify this clause for an index on a temporary table.
- You cannot specify this clause and also specify the `rebuild_clause`.

Refer to `deallocate_unused_clause` on page 8-27 for a full description of this clause.

**KEEP integer**  The `KEEP` clause lets you specify the number of bytes above the high water mark that the index will have after deallocation. If the number of remaining extents is less than `MINEXTENTS`, then `MINEXTENTS` is set to the current number of extents. If the initial extent becomes smaller than `INITIAL`, then `INITIAL` is set to the value of the current initial extent. If you omit `KEEP`, then all unused space is freed.

Refer to `ALTER TABLE` on page 12-2 for a complete description of this clause.

**allocate_extent_clause**  The `allocate_extent_clause` lets you explicitly allocate a new extent for the index. For a local index on a hash-partitioned table, Oracle Database allocates a new extent for each partition of the index.

**Restriction on Allocating Extents**  You cannot specify this clause for an index on a temporary table or for a range-partitioned or composite-partitioned index.

Refer to `allocate_extent_clause` on page 8-2 for a full description of this clause.

**shrink_clause**  Use this clause to compact the index segments. Specifying `ALTER INDEX ... SHRINK SPACE COMPACT` is equivalent to specifying `ALTER INDEX ... COALESCE`.

For complete information on this clause, refer to `shrink_clause` on page 12-51 in the documentation on `CREATE TABLE`.

**Restriction on Shrinking Index Segments**  You cannot specify this clause for a bitmap join index or for a function-based index.

**parallel_clause**  Use the `PARALLEL` clause to change the default degree of parallelism for queries and DML on the index.

**Restriction on Parallelizing Indexes**  You cannot specify this clause for an index on a temporary table.

For complete information on this clause, refer to `parallel_clause` on page 16-81 in the documentation on `CREATE TABLE`.

See Also: "Enabling Parallel Queries: Example" on page 10-125

**physical_attributes_clause**  Use the `physical_attributes_clause` to change the values of parameters for a nonpartitioned index, all partitions and subpartitions of a partitioned index, a specified partition, or all subpartitions of a specified partition.
See Also:
- the physical attributes parameters in CREATE TABLE on page 16-6
- "Modifying Real Index Attributes: Example" on page 10-125 and "Changing MAXEXTENTS: Example" on page 10-125

Restrictions on Index Physical Attributes Index physical attributes are subject to the following restrictions:
- You cannot specify this clause for an index on a temporary table.
- You cannot specify the PCTUSED parameter at all when altering an index.
- You can specify the PCTFREE parameter only as part of the rebuild_clause, the modify_index_default_attrs clause, or the split_index_partition clause.

storage_clause
Use the storage_clause to change the storage parameters for a nonpartitioned index, index partition, or all partitions of a partitioned index, or default values of these parameters for a partitioned index. Refer to storage_clause on page 8-46 for complete information on this clause.

logging_clause
Use the logging_clause to change the logging attribute of the index. If you also specify the REBUILD clause, then this new setting affects the rebuild operation. If you specify a different value for logging in the REBUILD clause, then Oracle Database uses the last logging value specified as the logging attribute of the index and of the rebuild operation.

An index segment can have logging attributes different from those of the base table and different from those of other index segments for the same base table.

Restriction on Index Logging You cannot specify this clause for an index on a temporary table.

See Also:
- logging_clause on page 8-38 for a full description of this clause
- Oracle Database VLDB and Partitioning Guide for more information about parallel DML

partial_index_clause
Use the partial_index_clause to change the index to a full index or a partial index. Specify INDEXING FULL to change the index to a full index. Specify INDEXING PARTIAL to change the index to a partial index. This clause is valid only for indexes on partitioned tables. Refer to the partial_index_clause of CREATE INDEX on page 14-88 for the full semantics of this clause.

RECOVERABLE | UNRECOVERABLE
These keywords are deprecated and have been replaced with LOGGING and NOLOGGING, respectively. Although RECOVERABLE and UNRECOVERABLE are supported for backward compatibility, Oracle strongly recommends that you use the LOGGING and NOLOGGING keywords.
RECOVERABLE is not a valid keyword for creating partitioned tables or LOB storage characteristics. UNRECOVERABLE is not a valid keyword for creating partitioned or index-organized tables. Also, it can be specified only with the AS subquery clause of CREATE INDEX.

**rebuild_clause**

Use the rebuild_clause to re-create an existing index or one of its partitions or subpartitions. If index is marked UNUSABLE, then a successful rebuild will mark it USABLE. For a function-based index, this clause also enables the index. If the function on which the index is based does not exist, then the rebuild statement will fail.

---

**Restrictions on Rebuilding Indexes**

The rebuilding of indexes is subject to the following restrictions:

- You cannot rebuild an index on a temporary table.
- You cannot rebuild a bitmap index that is marked INVALID. Instead, you must drop and then re-create it.
- You cannot rebuild an entire partitioned index. You must rebuild each partition or subpartition, as described for the PARTITION clause.
- You cannot specify the deallocate_unused_clause in the same statement as the rebuild_clause.
- You cannot change the value of the PCTFREE parameter for the index as a whole (ALTER INDEX) or for a partition (ALTER INDEX ... MODIFY PARTITION). You can specify PCTFREE in all other forms of the ALTER INDEX statement.
- For a domain index:
  - You can specify only the PARAMETERS clause (either for the index or for a partition of the index) or the parallel_clause. No other rebuild clauses are valid.
  - You can rebuild an index only if the index is not marked IN_PROGRESS.
  - You can rebuild an index partition only if the index is not marked IN_PROGRESS or FAILED and the partition is not marked IN_PROGRESS.
- You cannot rebuild a local index, but you can rebuild a partition of a local index (ALTER INDEX ... REBUILD PARTITION).
- For a local index on a hash partition or subpartition, the only parameter you can specify is TABLESPACE.
- You cannot rebuild an online index that is used to enforce a deferrable unique constraint.

---

Note: When you rebuild the secondary index of an index-organized table, Oracle Database preserves the primary key columns contained in the logical rowid when the index was created. Therefore, if the index was created with the COMPATIBLE initialization parameter set to less than 10.0.0, the rebuilt index will contain the index key and any of the primary key columns of the table that are not also in the index key. If the index was created with the COMPATIBLE initialization parameter set to 10.0.0 or greater, then the rebuilt index will contain the index key and all the primary key columns of the table, including those also in the index key.
PARTITION Clause
Use the PARTITION clause to rebuild one partition of an index. You can also use this clause to move an index partition to another tablespace or to change a create-time physical attribute.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to Oracle Database VLDB and Partitioning Guide for a discussion of these restrictions.

Restriction on Rebuilding Partitions You cannot specify this clause for a local index on a composite-partitioned table. Instead, use the REBUILD SUBPARTITION clause.

See Also: Oracle Database VLDB and Partitioning Guide for more information about partition maintenance operations and "Rebuilding Unusable Index Partitions: Example" on page 10-125

SUBPARTITION Clause
Use the SUBPARTITION clause to rebuild one subpartition of an index. You can also use this clause to move an index subpartition to another tablespace. If you do not specify TABLESPACE, then the subpartition is rebuilt in the same tablespace.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to Oracle Database VLDB and Partitioning Guide for a discussion of these restrictions.

Restriction on Modifying Index Subpartitions The only parameters you can specify for a subpartition are TABLESPACE, ONLINE, and the parallel_clause.

REVERSE | NOREVERSE
Indicate whether the bytes of the index block are stored in reverse order:

- REVERSE stores the bytes of the index block in reverse order and excludes the rowid when the index is rebuilt.
- NOREVERSE stores the bytes of the index block without reversing the order when the index is rebuilt. Rebuilding a REVERSE index without the NOREVERSE keyword produces a rebuilt, reverse-keyed index.

Restrictions on Reverse Indexes Reverse indexes are subject to the following restrictions:

- You cannot reverse a bitmap index or an index-organized table.
- You cannot specify REVERSE or NOREVERSE for a partition or subpartition.

See Also: "Storing Index Blocks in Reverse Order: Example" on page 10-125

parallel_clause
Use the parallel_clause to parallelize the rebuilding of the index and to change the degree of parallelism for the index itself. All subsequent operations on the index will be executed with the degree of parallelism specified by this clause, unless overridden by a subsequent data definition language (DDL) statement with the parallel_clause. The following exceptions apply:

- If ALTER SESSION DISABLE PARALLEL DDL was specified before rebuilding the index, then the index will be rebuilt serially and the degree of parallelism for the index will be changed to 1.
If `ALTER SESSION FORCE PARALLEL DDL` was specified before rebuilding the index, then the index will be rebuilt in parallel and the degree of parallelism for the index will be changed to the value that was specified in the `ALTER SESSION` statement, or `DEFAULT` if no value was specified.

See Also: "Rebuilding an Index in Parallel: Example" on page 10-125

**TABLESPACE Clause**
Specify the tablespace where the rebuilt index, index partition, or index subpartition will be stored. The default is the default tablespace where the index or partition resided before you rebuilt it.

**index_compression**
Use the `index_compression` clauses to enable or disable index compression for the index. Specify the `prefix_compression` clause to enable or disable prefix compression for the index. Specify the `advanced_index_compression` clause to enable or disable advanced index compression for the index.

The `index_compression` clauses have the same semantics for `CREATE INDEX` and `ALTER INDEX`. For full information on these clauses, refer to `index_compression` on page 14-87 in the documentation on `CREATE INDEX`.

**ONLINE Clause**
Specify `ONLINE` to allow DML operations on the table or partition during rebuilding of the index.

**Restrictions on Online Indexes**
Online indexes are subject to the following restrictions:

- Parallel DML is not supported during online index building. If you specify `ONLINE` and subsequently issue parallel DML statements, then Oracle Database returns an error.
- You cannot specify `ONLINE` for a bitmap join index or a cluster index.
- For a nonunique secondary index on an index-organized table, the number of index key columns plus the number of primary key columns that are included in the logical rowid in the index-organized table cannot exceed 32. The logical rowid excludes columns that are part of the index key.

**logging_clause**
Specify whether the `ALTER INDEX ... REBUILD` operation will be logged.

Refer to the `logging_clause` on page 8-38 for a full description of this clause.

**PARAMETERS Clause**
This clause is valid only for domain indexes in a top-level `ALTER INDEX` statement and in the `rebuild_clause`. This clause specifies the parameter string that is passed uninterpreted to the appropriate ODCI indextype routine.

The maximum length of the parameter string is 1000 characters.

If you are altering or rebuilding an entire index, then the string must refer to index-level parameters. If you are rebuilding a partition of the index, then the string must refer to partition-level parameters.

If `index` is marked `UNUSABLE`, then modifying the parameters alone does not make it `USABLE`. You must also rebuild the `UNUSABLE` index to make it usable.
If you have installed Oracle Text, then you can rebuild your Oracle Text domain indexes using parameters specific to that product. For more information on those parameters, refer to Oracle Text Reference.

Restriction on the PARAMETERS Clause  You can modify index partitions only if `index` is not marked `IN_PROGRESS` or `FAILED`, no index partitions are marked `IN_PROGRESS`, and the partition being modified is not marked `FAILED`.

See Also:
- Oracle Database Data Cartridge Developer’s Guide for more information on indextype routines for domain indexes
- CREATE INDEX on page 14-73 for more information on domain indexes

**XMLIndex_parameters_clause**
This clause is valid only for XMLIndex indexes. This clause specifies the parameter string that defines the XMLIndex implementation.

The maximum length of the parameter string is 1000 characters.

If you are altering or rebuilding an entire index, then the string must refer to index-level parameters. If you are rebuilding a partition of the index, then the string must refer to partition-level parameters.

If `index` is marked `UNUSABLE`, then modifying the parameters alone does not make it `USABLE`. You must also rebuild the `UNUSABLE` index to make it usable.

See Also:  Oracle XML DB Developer’s Guide for more information on XMLIndex, including the syntax and semantics of the `XMLIndex_parameters_clause`

Restriction on the `XMLIndex_parameters_clause`  You can modify index partitions only if `index` is not marked `IN_PROGRESS` or `FAILED`, no index partitions are marked `IN_PROGRESS`, and the partition being modified is not marked `FAILED`.

**COMPILE Clause**
Use this clause to recompile an invalid index explicitly. For domain indexes, this clause is useful when the underlying indextype has been altered to support system-managed domain indexes, so that the existing domain index has been marked `INVALID`. In this situation, this `ALTER INDEX` statement migrates the domain index from a user-managed domain index to a system-managed domain index. For all types of indexes, this clause is useful when an index has been marked `INVALID` by an `ALTER TABLE` statement. In this situation, this `ALTER INDEX` statement revalidates the index without rebuilding it.

See Also:  The `CREATE INDEXTYPE` `storage_table_clause` on page 14-105 and Oracle Database Data Cartridge Developer’s Guide for information on creating system-managed domain indexes

**ENABLE Clause**
`ENABLE` applies only to a function-based index that has been disabled, either by an `ALTER INDEX` ... `DISABLE` statement, or because a user-defined function used by the index was dropped or replaced. This clause enables such an index if these conditions are true:
- The function is currently valid.
The signature of the current function matches the signature of the function when
the index was created.

The function is currently marked as **DETERMINISTIC**.

**Restrictions on Enabling Function-based Indexes**  The **ENABLE** clause is subject to the
following restrictions:

- You cannot specify any other clauses of **ALTER INDEX** in the same statement with
  **ENABLE**.
- You cannot specify this clause for an index on a temporary table. Instead, you
  must drop and recreate the index. You can retrieve the creation DDL for the index
  using the **DBMS_METADATA** package.

**DISABLE Clause**

**DISABLE** applies only to a function-based index. This clause lets you disable the use of
a function-based index. You might want to do so, for example, while working on the
body of the function. Afterward you can either rebuild the index or specify another
**ALTER INDEX** statement with the **ENABLE** keyword.

**USABLE | UNUSABLE**

Specify **UNUSABLE** to mark the index or index partition(s) or index subpartition(s)
**UNUSABLE**. The space allocated for an index or index partition or subpartition is freed
immediately when the object is marked **UNUSABLE**. An unusable index must be rebuilt,
dropped and re-created, before it can be used. While one partition is marked
**UNUSABLE**, the other partitions of the index are still valid. You can execute statements
that require the index if the statements do not access the unusable partition. You can
also split or rename the unusable partition before rebuilding it. Refer to **CREATE INDEX**
... **USABLE | UNUSABLE** on page 14-95 for more information.

**ONLINE** Specify **ONLINE** to indicate that DML operations on the table or partition will
be allowed while marking the index **UNUSABLE**. If you specify this clause, then the
database will not drop the index segments.

**Restrictions on Marking Indexes Unusable**  The following restrictions apply to
marking indexes unusable:

- You cannot specify **UNUSABLE** for an index on a temporary table.
- When a global index is marked **UNUSABLE** during a partition maintenance
  operation, the database does not drop the unusable index segments.

**VISIBLE | INVISIBLE**

Use this clause to specify whether the index is visible or invisible to the optimizer.
Refer to **"VISIBLE | INVISIBLE"** in **CREATE INDEX** on page 14-89 for a full description
of this clause.

**RENAME Clause**

Use this clause to rename an index. The **new_index_name** is a single identifier and does
not include the schema name.

**Restriction on Renaming Indexes**  For a domain index, neither **index** nor any
partitions of **index** can be marked **IN_PROGRESS** or **FAILED**.

See Also: **"Renaming an Index: Example"** on page 10-125
COALESCE Clause
Specify COALESCE to instruct Oracle Database to merge the contents of index blocks where possible to free blocks for reuse.

CLEANUP  Specify CLEANUP to remove orphaned index entries for records that were previously dropped or truncated by a table partition maintenance operation.

To determine whether an index contains orphaned index entries, you can query the ORPHANED_ENTRIES column of the USER_, DBA_, ALL_INDEXES data dictionary views. Refer to Oracle Database Reference for more information.

parallel_clause  Use the parallel_clause to specify whether to parallelize the coalesce operation.

For complete information on this clause, refer to parallel_clause on page 16-81 in the documentation on CREATE TABLE.

Restrictions on Coalescing Index Blocks  Coalescing of index blocks is subject to the following restrictions:

■ You cannot specify this clause for an index on a temporary table.

■ Do not specify this clause for the primary key index of an index-organized table. Instead use the COALESCE clause of ALTER TABLE.

MONITORING USAGE | NOMONITORING USAGE
Use this clause to determine whether Oracle Database should monitor index use.

■ Specify MONITORING USAGE to begin monitoring the index. Oracle Database first clears existing information on index use, and then monitors the index for use until a subsequent ALTER INDEX ... NOMONITORING USAGE statement is executed.

■ To terminate monitoring of the index, specify NOMONITORING USAGE.

To see whether the index has been used since this ALTER INDEX ... NOMONITORING USAGE statement was issued, query the USED column of the USER_OBJECT_USAGE data dictionary view.

See Also: Oracle Database Reference for information on the USER_OBJECT_USAGE data dictionary view

UPDATE BLOCK REFERENCES Clause
The UPDATE BLOCK REFERENCES clause is valid only for normal and domain indexes on index-organized tables. Specify this clause to update all the stale guess data block addresses stored as part of the index row with the correct database address for the corresponding block identified by the primary key.
For a domain index, Oracle Database executes the ODCIIndexAlter routine with the alter_option parameter set to AlterIndexUpdBlockRefs. This routine enables the cartridge code to update the stale guess data block addresses in the index.

**Restriction on UPDATE BLOCK REFERENCES**  You cannot combine this clause with any other clause of ALTER INDEX.

**alter_index_partitioning**

The partitioning clauses of the ALTER INDEX statement are valid only for partitioned indexes.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to Oracle Database VLDB and Partitioning Guide for a discussion of these restrictions.

**Restrictions on Modifying Index Partitions**  Modifying index partitions is subject to the following restrictions:

- You cannot specify any of these clauses for an index on a temporary table.
- You can combine several operations on the base index into one ALTER INDEX statement (except RENAME and REBUILD), but you cannot combine partition operations with other partition operations or with operations on the base index.

**modify_index_default_attrs**

Specify new values for the default attributes of a partitioned index.

**Restriction on Modifying Partition Default Attributes**  The only attribute you can specify for a hash-partitioned global index or for an index on a hash-partitioned table is TABLESPACE.

**TABLESPACE**  Specify the default tablespace for new partitions of an index or subpartitions of an index partition.

**logging_clause**  Specify the default logging attribute of a partitioned index or an index partition.

Refer to logging_clause on page 8-38 for a full description of this clause.

**FOR PARTITION**  Use the FOR PARTITION clause to specify the default attributes for the subpartitions of a partition of a local index on a composite-partitioned table.

**Restriction on FOR PARTITION**  You cannot specify FOR PARTITION for a list partition.

See Also:  "Modifying Default Attributes: Example" on page 10-126

**add_hash_index_partition**

Use this clause to add a partition to a global hash-partitioned index. Oracle Database adds hash partitions and populates them with index entries rehashed from an existing hash partition of the index, as determined by the hash function. If you omit the partition name, then Oracle Database assigns a name of the form SYS_Pn. If you omit the TABLESPACE clause, then Oracle Database places the partition in the tablespace specified for the index. If no tablespace is specified for the index, then Oracle Database places the partition in the default tablescape of the user, if one has been specified, or in the system default tablespace.
**modify_index_partition**

Use the `modify_index_partition` clause to modify the real physical attributes, logging attribute, or storage characteristics of index partition `partition` or its subpartitions. For a hash-partitioned global index, the only subclause of this clause you can specify is `UNUSABLE`.

**COALESCE** Specify this clause to merge the contents of index partition blocks where possible to free blocks for reuse.

**CLEANUP** Specify `CLEANUP` to remove orphaned index entries for records that were previously dropped or truncated by a table partition maintenance operation.

To determine whether an index partition contains orphaned index entries, you can query the `ORPHANED_ENTRIES` column of the `USER_INDEXES`, `DBA_INDEXES`, `ALL_INDEXES` dictionary views. Refer to Oracle Database Reference for more information.

**UPDATE BLOCK REFERENCES** The `UPDATE BLOCK REFERENCES` clause is valid only for normal indexes on index-organized tables. Use this clause to update all stale guess data block addresses stored in the secondary index partition.

**Restrictions on UPDATE BLOCK REFERENCES** This clause is subject to the following restrictions:

- You cannot specify the `physical_attributes_clause` for an index on a hash-partitioned table.
- You cannot specify `UPDATE BLOCK REFERENCES` with any other clause in `ALTER INDEX`.

**Note:** If the index is a local index on a composite-partitioned table, then the changes you specify here will override any attributes specified earlier for the subpartitions of index, as well as establish default values of attributes for future subpartitions of that partition. To change the default attributes of the partition without overriding the attributes of subpartitions, use `ALTER TABLE ... MODIFY DEFAULT ATTRIBUTES FOR PARTITION`.

**UNUSABLE Clause** This clause has the same function for index partitions that it has for the index as a whole. Refer to "USABLE | UNUSABLE" on page 10-120.

**index_compression** This clause is relevant for composite-partitioned indexes. Use this clause to change the compression attribute for the partition and every subpartition in that partition. Oracle Database marks each index subpartition in the partition `UNUSABLE` and you must then rebuild these subpartitions. Prefix compression must already have been specified for the index before you can specify the `prefix_compression` clause for a partition, or advanced index compression must have already been specified for the index before you can specify the `advanced_index_compression` clause for a partition. You can specify this clause only at the partition level. You cannot change the compression attribute for an individual subpartition.

You can use this clause for noncomposite index partitions. However, it is more efficient to use the `rebuild_clause` for noncomposite partitions, which lets you rebuild and set the compression attribute in one step.
rename_index_partition
Use the rename_index_partition clauses to rename index partition or subpartition to new_name.

Restrictions on Renaming Index Partitions  Renaming index partitions is subject to the following restrictions:

- You cannot rename the subpartition of a list partition.
- For a partition of a domain index, index cannot be marked IN_PROGRESS or FAILED, none of the partitions can be marked IN_PROGRESS, and the partition you are renaming cannot be marked FAILED.

See Also:  "Renaming an Index Partition: Example" on page 10-126

drop_index_partition
Use the drop_index_partition clause to remove a partition and the data in it from a partitioned global index. When you drop a partition of a global index, Oracle Database marks the next index partition UNUSABLE. You cannot drop the highest partition of a global index.

See Also:  "Dropping an Index Partition: Example" on page 10-126

split_index_partition
Use the split_index_partition clause to split a partition of a global range-partitioned index into two partitions, adding a new partition to the index. This clause is not valid for hash-partitioned global indexes. Instead, use the add_hash_index_partition clause.

Splitting a partition marked UNUSABLE results in two partitions, both marked UNUSABLE. You must rebuild the partitions before you can use them.

Splitting a partition marked USABLE results in two partitions populated with index data. Both new partitions are marked USABLE.

AT Clause  Specify the new noninclusive upper bound for split_partition_1. The value_list must evaluate to less than the presplit partition bound for partition_name_old and greater than the partition bound for the next lowest partition (if there is one).

INTO Clause  Specify (optionally) the name and physical attributes of each of the two partitions resulting from the split.

See Also:  "Splitting a Partition: Example" on page 10-126

coalesce_index_partition
This clause is valid only for hash-partitioned global indexes. Oracle Database reduces by one the number of index partitions. Oracle Database selects the partition to coalesce based on the requirements of the hash function. Use this clause if you want to distribute index entries of a selected partition into one of the remaining partitions and then remove the selected partition.

modify_index_subpartition
Use the modify_index_subpartition clause to mark UNUSABLE or allocate or deallocate storage for a subpartition of a local index on a composite-partitioned table. All other attributes of such a subpartition are inherited from partition-level default attributes.
Examples

**Storing Index Blocks in Reverse Order: Example**  The following statement rebuilds
index `ord_customer_ix` (created in “Creating an Index: Example” on page 14-96) so
that the bytes of the index block are stored in reverse order:

```
ALTER INDEX ord_customer_ix REBUILD REVERSE;
```

**Rebuilding an Index in Parallel: Example**  The following statement causes the index
to be rebuilt from the existing index by using parallel execution processes to scan the
old and to build the new index:

```
ALTER INDEX ord_customer_ix REBUILD PARALLEL;
```

**Modifying Real Index Attributes: Example**  The following statement alters the
`oe.cust_lname_ix` index so that future data blocks within this index use 5 initial
transaction entries:

```
ALTER INDEX oe.cust_lname_ix
  INITRANS 5;
```

If the `oe.cust_lname_ix` index were partitioned, then this statement would also alter
the default attributes of future partitions of the index. Partitions added in the future
would then use 5 initial transaction entries and an incremental extent of 100K.

**Enabling Parallel Queries: Example**  The following statement sets the parallel
attributes for index `upper_ix` (created in "Creating a Function-Based Index: Example"
on page 14-97) so that scans on the index will be parallelized:

```
ALTER INDEX upper_ix PARALLEL;
```

**Renaming an Index: Example**  The following statement renames an index:

```
ALTER INDEX upper_ix RENAME TO upper_name_ix;
```

**Marking an Index Unusable: Examples**  The following statements use the `cost_ix`
index, which was created in "Creating a Range-Partitioned Global Index: Example" on
page 14-99. Partition `p1` of that index was dropped in "Dropping an Index Partition:
Example" on page 10-126. The first statement marks index partition `p2` as UNUSABLE:

```
ALTER INDEX cost_ix
  MODIFY PARTITION p2 UNUSABLE;
```

The next statement marks the entire index `cost_ix` as UNUSABLE:

```
ALTER INDEX cost_ix UNUSABLE;
```

**Rebuilding Unusable Index Partitions: Example**  The following statements rebuild
partitions `p2` and `p3` of the `cost_ix` index, making the index once more usable: The
rebuilding of partition `p3` will not be logged:

```
ALTER INDEX cost_ix
  REBUILD PARTITION p2;
ALTER INDEX cost_ix
  REBUILD PARTITION p3 NOLOGGING;
```

**Changing MAXEXTENTS: Example**  The following statement changes the maximum
number of extents for partition `p3` and changes the logging attribute:

```
/* This example will fail if the tablespace in which partition p3
resides is locally managed.
```
Renaming an Index Partition: Example  The following statement renames an index partition of the `cost_ix` index (created in "Creating a Range-Partitioned Global Index: Example" on page 14-99):

```sql
ALTER INDEX cost_ix
  RENAME PARTITION p3 TO p3_Q3;
```

Splitting a Partition: Example  The following statement splits partition `p2` of index `cost_ix` (created in "Creating a Range-Partitioned Global Index: Example" on page 14-99) into `p2a` and `p2b`:

```sql
ALTER INDEX cost_ix
  SPLIT PARTITION p2 AT (1500)
  INTO ( PARTITION p2a TABLESPACE tbs_01 LOGGING,
          PARTITION p2b TABLESPACE tbs_02);
```

Dropping an Index Partition: Example  The following statement drops index partition `p1` from the `cost_ix` index:

```sql
ALTER INDEX cost_ix
  DROP PARTITION p1;
```

Modifying Default Attributes: Example  The following statement alters the default attributes of local partitioned index `prod_idx`, which was created in "Creating an Index on a Hash-Partitioned Table: Example" on page 14-99 on page 14-96. Partitions added in the future will use 5 initial transaction entries:

```sql
ALTER INDEX prod_idx
  MODIFY DEFAULT ATTRIBUTES INITRANS 5;
```
ALTER INDEXTYPE

Purpose

Use the ALTER INDEXTYPE statement to add or drop an operator of the indextype or to modify the implementation type or change the properties of the indextype.

Prerequisites

The indextype must be in your own schema or you must have the ALTER ANY INDEXTYPE system privilege.

To add a new operator, you must have the EXECUTE object privilege on the operator.

To change the implementation type, you must have the EXECUTE object privilege on the new implementation type.

Syntax

\[
alter\_indextype::=\]
\[
\text{ALTER INDEXTYPE}\ (\text{ADD} / \text{DROP}) \text{ schema}\ . \text{indextype} \ (\text{ADD} / \text{DROP}) \text{ schema}\ . \text{operator} (\text{parameter_types}) \ (\text{ADD} / \text{DROP}) \text{ schema}\ . \text{implementation_type} \text{ storage_table_clause};
\]

\[
\text{using_type_clause::= on page 10-127, storage_table_clause on page 10-129)
\]

\[
\text{using_type_clause::=}
\]
\[
\text{USING}\ \text{schema}\ . \text{implementation_type} \ (\text{ADD} / \text{DROP}) \text{ schema}\ . \text{implementation_type} \text{ storage_table_clause};
\]

\[
\text{array_DML_clause::= on page 10-128)
\]
ALTER INDEXTYPE

array_DML_clause ::= 

WITH 
WITHOUT 

ARRAY DML

storage_table_clause ::= 

WITH 
SYSTEM 
USER 

MANAGED 
STORAGE 
TABLES

Semantics

**schema**
Specify the name of the schema in which the indextype resides. If you omit *schema*, then Oracle Database assumes the indextype is in your own schema.

**indextype**
Specify the name of the indextype to be modified.

**ADD | DROP**
Use the *ADD* or *DROP* clause to add or drop an operator.

No special privilege needed to drop.

- For *schema*, specify the schema containing the operator. If you omit *schema*, then Oracle assumes the operator is in your own schema.

- For *operator*, specify the name of the operator supported by the indextype.
  All the operators listed in this clause must be valid operators.

- For *parameter_type*, list the types of parameters to the operator.

**using_type_clause**
The *USING* clause lets you specify a new type to provide the implementation for the indextype.

**array_DML_clause**
Use this clause to modify the indextype to support the array interface for the ODCIIndexInsert method.

**type and varray_type** If the data type of the column to be indexed is a user-defined object type, then you must specify this clause to identify the varray *varray_type* that Oracle should use to hold column values of *type*. If the indextype supports a list of types, then you can specify a corresponding list of varray types. If you omit *schema* for either *type* or *varray_type*, then Oracle assumes the type is in your own schema.
If the data type of the column to be indexed is a built-in system type, then any varray type specified for the indextype takes precedence over the ODCI types defined by the system.

**COMPILE**
Use this clause to recompile the indextype explicitly. This clause is required only after some upgrade operations, because Oracle Database normally recompiles the indextype automatically.

**storage_table_clause**
This clause has the same behavior when altering an indextype that it has when you are creating an indextype. Refer to the CREATE INDEXTYPE *storage_table_clause* on page 14-105 for more information.

**WITH LOCAL PARTITION**
This clause has the same behavior when altering an indextype that it has when you create an indextype. Refer to the CREATE INDEXTYPE clause *WITH LOCAL PARTITION* on page 14-105 for more information.

### Examples

**Altering an Indextype: Example**  The following example compiles the *position_indextype* indextype created in "Creating an Indextype: Example" on page 14-106.

```
ALTER INDEXTYPE position_indextype COMPILE;
```
**ALTER JAVA**

**Purpose**

Use the `ALTER JAVA` statement to force the resolution of a Java class schema object or compilation of a Java source schema object. (You cannot call the methods of a Java class before all its external references to Java names are associated with other classes.)

*See Also: Oracle Database Java Developer’s Guide* for more information on resolving Java classes and compiling Java sources.

**Prerequisites**

The Java source or class must be in your own schema, or you must have the `ALTER ANY PROCEDURE` system privilege. You must also have the `EXECUTE` object privilege on Java classes.

**Syntax**

```
alter_java ::= 
```

```
ALTER JAVA SOURCE schema object_name 
```

```
ALTER JAVA CLASS schema object_name 
```

```
RESOLVER (match_string, schema_name) 
```

```
invoker_rights_clause::= 
```

```
AUTHID (CURRENT_USER, DEFINER) 
```

*(invoker_rights_clause::= on page 10-130)*

```
invoker_rights_clause::= 
```

```
AUTHID (CURRENT_USER, DEFINER) 
```

**Semantics**

**JAVA SOURCE**

Use `ALTER JAVA SOURCE` to compile a Java source schema object.

**JAVA CLASS**

Use `ALTER JAVA CLASS` to resolve a Java class schema object.
object_name
Specify a previously created Java class or source schema object. Use double quotation marks to preserve lower- or mixed-case names.

RESOLVER
The RESOLVER clause lets you specify how schemas are searched for referenced fully specified Java names, using the mapping pairs specified when the Java class or source was created.

See Also: CREATE JAVA on page 14-107 and “Resolving a Java Class: Example” on page 10-131

RESOLVE | COMPILE
RESOLVE and COMPILE are synonymous keywords. They let you specify that Oracle Database should attempt to resolve the primary Java class schema object.

- When applied to a class, resolution of referenced names to other class schema objects occurs.
- When applied to a source, source compilation occurs.

invoker_rights_clause
The invoker_rights_clause lets you specify whether the methods of the class execute with the privileges and in the schema of the user who defined it or with the privileges and in the schema of CURRENT_USER.

This clause also determines how Oracle Database resolves external names in queries, DML operations, and dynamic SQL statements in the member functions and procedures of the type.

AUTHID CURRENT_USER Specify CURRENT_USER if you want the methods of the class to execute with the privileges of CURRENT_USER. This clause is the default and creates an invoker-rights class.

This clause also specifies that external names in queries, DML operations, and dynamic SQL statements resolve in the schema of CURRENT_USER. External names in all other statements resolve in the schema in which the methods reside.

AUTHID DEFINER Specify DEFINER if you want the methods of the class to execute with the privileges of the user who defined the class.

This clause also specifies that external names resolve in the schema where the methods reside.

See Also: Oracle Database PL/SQL Language Reference for information on how CURRENT_USER is determined

Examples

Resolving a Java Class: Example The following statement forces the resolution of a Java class:

```
ALTER JAVA CLASS "Agent"
  RESOLVER ("/usr/bin/bfile_dir/*" pm)(* public)
  RESOLVE;
```
This chapter contains the following SQL statements:

- ALTER LIBRARY
- ALTER MATERIALIZED VIEW
- ALTER MATERIALIZED VIEW LOG
- ALTER MATERIALIZED ZONEMAP
- ALTER OPERATOR
- ALTER OUTLINE
- ALTER PACKAGE
- ALTER PLUGGABLE DATABASE
- ALTER PROCEDURE
- ALTER PROFILE
- ALTER RESOURCE COST
- ALTER ROLE
- ALTER ROLLBACK SEGMENT
- ALTER SEQUENCE
- ALTER SESSION
- ALTER SYNONYM
- ALTER SYSTEM
ALTER LIBRARY

Purpose

The **ALTER LIBRARY** statement explicitly recompiles a library. Explicit recompilation eliminates the need for implicit run-time recompilation and prevents associated run-time compilation errors and performance overhead.

**Note:** This statement does not change the declaration or definition of an existing library. To redefine or redefine a library, use the "CREATE LIBRARY" on page 15-2 with the **OR REPLACE** clause.

Prerequisites

If the library is in the **SYS** schema, you must be connected as **SYSDBA**. Otherwise, the library must be in your own schema or you must have the **ALTER ANY LIBRARY** system privilege.

Syntax

```
alter_library ::= 
```

```
ALTER LIBRARY schema . library_name library_compile_clause 
```

(library_compile_clause: See *Oracle Database PL/SQL Language Reference* for the syntax of this clause.)

Semantics

**schema**

Specify the schema containing the library. If you omit **schema**, then Oracle Database assumes the procedure is in your own schema.

**library_name**

Specify the name of the library to be recompiled.

**library_compile_clause**

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling libraries.

**EDITIONABLE | NONEDITIONABLE**

Use these clauses to specify whether the library becomes an editioned or noneditioned object if editioning is later enabled for the schema object type **LIBRARY** in **schema**. The default is **EDITIONABLE**. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*. 
ALTER MATERIALIZED VIEW

Purpose
A materialized view is a database object that contains the results of a query. The FROM clause of the query can name tables, views, and other materialized views. Collectively these source objects are called master tables (a replication term) or detail tables (a data warehousing term). This reference uses the term master tables for consistency. The databases containing the master tables are called the master databases.

Use the ALTER MATERIALIZED VIEW statement to modify an existing materialized view in one or more of the following ways:
- To change its storage characteristics
- To change its refresh method, mode, or time
- To alter its structure so that it is a different type of materialized view
- To enable or disable query rewrite

Note: The keyword SNAPSHOT is supported in place of MATERIALIZED VIEW for backward compatibility.

See Also:
- CREATE MATERIALIZED VIEW on page 15-4 for more information on creating materialized views
- Oracle Database Advanced Replication for information on materialized views in a replication environment
- Oracle Database Data Warehousing Guide for information on materialized views in a data warehousing environment

Prerequisites
The materialized view must be in your own schema, or you must have the ALTER ANY MATERIALIZED VIEW system privilege.

To enable a materialized view for query rewrite:
- If all of the master tables in the materialized view are in your schema, then you must have the QUERY REWRITE privilege.
- If any of the master tables are in another schema, then you must have the GLOBAL QUERY REWRITE privilege.
- If the materialized view is in another user’s schema, then both you and the owner of that schema must have the appropriate QUERY REWRITE privilege, as described in the preceding two items. In addition, the owner of the materialized view must have SELECT access to any master tables that the materialized view owner does not own.

To specify an edition in the evaluation_edition_clause or the unusable_editions_clause, you must have the USE privilege on the edition.
Syntax

                                   |
                                   |
                                   |
                                   |
                                   |
                                   |
                                   |
                                   |
                                   |
                                   |
                                   |
                                   |
                                   |
                                   |
                                   |
                                   |
**table_compression**

Use the `table_compression` clause to instruct Oracle Database whether to compress data segments to reduce disk and memory use. Refer to the `table_compression` clause of `CREATE TABLE` on page 16-45 for the full semantics of this clause.

**inmemory_alter_table_clause**

Use the `inmemory_alter_table_clause` to enable or disable the In-Memory Column Store for the materialized view. This clause has the same semantics in `ALTER MATERIALIZED VIEW` and `ALTER TABLE`. Refer to the `inmemory_alter_table_clause` of `ALTER TABLE` on page 12-45.

**LOB_storage_clause**

The `LOB_storage_clause` lets you specify the storage characteristics of a new LOB. LOB storage behaves for materialized views exactly as it does for tables. Refer to the `LOB_storage_clause` on page 16-57 (in `CREATE TABLE`) for information on the LOB storage parameters.

**modify_LOB_storage_clause**

The `modify_LOB_storage_clause` lets you modify the physical attributes of the LOB attribute `LOB_item` or the LOB object attribute. Modification of LOB storage behaves for materialized views exactly as it does for tables.

See Also: The `modify_LOB_storage_clause` of `ALTER TABLE` on page 12-69 for information on the LOB storage parameters that can be modified.

**alter_table_partitioning**

The syntax and general functioning of the partitioning clauses for materialized views is the same as for partitioned tables. Refer to `alter_table_partitioning` on page 12-73 in the documentation on `ALTER TABLE`.

Restriction on Altering Materialized View Partitions  You cannot specify the `LOB_storage_clause` or `modify_LOB_storage_clause` within any of the `partitioning_clauses`.

---

**Note:** If you want to keep the contents of the materialized view synchronized with those of the master table, then Oracle recommends that you manually perform a complete refresh of all materialized views dependent on the table after dropping or truncating a table partition.

**MODIFY PARTITION UNUSABLE LOCAL INDEXES**  Use this clause to mark `UNUSABLE` all the local index partitions associated with `partition`.

**MODIFY PARTITION REBUILD UNUSABLE LOCAL INDEXES**  Use this clause to rebuild the unusable local index partitions associated with `partition`.

**parallel_clause**

The `parallel_clause` lets you change the default degree of parallelism for the materialized view.
For complete information on this clause, refer to `parallel_clause` on page 16-81 in the documentation on `CREATE TABLE`.

**logging_clause**

Specify or change the logging characteristics of the materialized view. Refer to the `logging_clause` on page 8-38 for a full description of this clause.

**allocate_extent_clause**

The `allocate_extent_clause` lets you explicitly allocate a new extent for the materialized view. Refer to the `allocate_extent_clause` on page 8-2 for a full description of this clause.

**deallocate_unused_clause**

Use the `deallocate_unused_clause` to explicitly deallocate unused space at the end of the materialized view and make the freed space available for other segments. Refer to the `deallocate_unused_clause` on page 8-27 for a full description of this clause.

**shrink_clause**

Use this clause to compact the materialized view segments. For complete information on this clause, refer to `shrink_clause` on page 12-51 in the documentation on `CREATE TABLE`.

**CACHE | NOCACHE**

For data that will be accessed frequently, `CACHE` specifies that the blocks retrieved for this table are placed at the most recently used end of the LRU list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables. `NOCACHE` specifies that the blocks are placed at the least recently used end of the LRU list. Refer to "CACHE | NOCACHE | CACHE READS" on page 16-80 in the documentation on `CREATE TABLE` for more information about this clause.

**alter_iot_clauses**

Use the `alter_iot_clauses` to change the characteristics of an index-organized materialized view. The keywords and parameters of the components of the `alter_iot_clauses` have the same semantics as in `ALTER TABLE`, with the restrictions that follow.

**Restrictions on Altering Index-Organized Materialized Views**

You cannot specify the `mapping_table_clause` or the `prefix_compression` clause of the `index_org_table_clause`.

See Also: `index_org_table_clause` on page 15-17 of `CREATE MATERIALIZED VIEW` for information on creating an index-organized materialized view

**USING INDEX Clause**

Use this clause to change the value of `INITRANS` and `STORAGE` parameters for the index Oracle Database uses to maintain the materialized view data.

**Restriction on the USING INDEX clause**

You cannot specify the `PCTUSED` or `PCTFREE` parameters in this clause.
**MODIFY scoped_table_ref_constraint**

Use the `MODIFY scoped_table_ref_constraint` clause to rescope a `REF` column or attribute to a new table or to an alias for a new column.

**Restrictions on Rescoping REF Columns** You can rescope only one `REF` column or attribute in each `ALTER MATERIALIZED VIEW` statement, and this must be the only clause in this statement.

**alter_mv_refresh**

Use the `alter_mv_refresh` clause to change the default method and mode and the default times for automatic refreshes. If the contents of the master tables of a materialized view are modified, then the data in the materialized view must be updated to make the materialized view accurately reflect the data currently in its master table(s). This clause lets you schedule the times and specify the method and mode for Oracle Database to refresh the materialized view.

---

**Note:** This clause only sets the default refresh options. For instructions on actually implementing the refresh, refer to `Oracle Database Advanced Replication` and `Oracle Database Data Warehousing Guide`.

---

**FAST Clause**

Specify `FAST` for the fast refresh method, which performs the refresh according to the changes that have occurred to the master tables. The changes are stored either in the materialized view log associated with the master table (for conventional DML changes) or in the direct loader log (for direct-path `INSERT` operations).

For both conventional DML changes and for direct-path `INSERT` operations, other conditions may restrict the eligibility of a materialized view for fast refresh. When you change the refresh method to `FAST` in an `ALTER MATERIALIZED VIEW` statement, Oracle Database does not perform this verification. If the materialized view is not eligible for fast refresh, then Oracle Database returns an error when you attempt to refresh this view.

**See Also:**

- `Oracle Database Advanced Replication` for restrictions on fast refresh in replication environments
- `Oracle Database Data Warehousing Guide` for restrictions on fast refresh in data warehouse environments
- "Automatic Refresh: Examples" on page 11-18

**COMPLETE Clause**

Specify `COMPLETE` for the complete refresh method, which is implemented by executing the defining query of the materialized view. If you specify a complete refresh, then Oracle Database performs a complete refresh even if a fast refresh is possible.

**See Also:** "Complete Refresh: Example" on page 11-19

**FORCE Clause**

Specify `FORCE` if, when a refresh occurs, you want Oracle Database to perform a fast refresh if one is possible or a complete refresh otherwise.
ON COMMIT Clause
Specify ON COMMIT if you want a refresh to occur whenever Oracle Database commits a transaction that operates on a master table of the materialized view.

You cannot specify both ON COMMIT and ON DEMAND. If you specify ON COMMIT, then you cannot also specify START WITH or NEXT.

Restriction on ON COMMIT  This clause is supported only for materialized join views and single-table materialized aggregate views.

See Also:  Oracle Database Advanced Replication and Oracle Database Data Warehousing Guide

ON DEMAND Clause
Specify ON DEMAND if you want the materialized view to be refreshed on demand by calling one of the three DBMS_MVIEW refresh procedures. If you omit both ON COMMIT and ON DEMAND, then ON DEMAND is the default.

You cannot specify both ON COMMIT and ON DEMAND. START WITH and NEXT take precedence over ON DEMAND. Therefore, in most circumstances it is not meaningful to specify ON DEMAND when you have specified START WITH or NEXT.

See Also:
- Oracle Database PL/SQL Packages and Types Reference for information on these procedures
- Oracle Database Data Warehousing Guide on the types of materialized views you can create by specifying REFRESH ON DEMAND

START WITH Clause
Specify START WITH date to indicate a date for the first automatic refresh time.

NEXT Clause
Specify NEXT to indicate a date expression for calculating the interval between automatic refreshes.

Both the START WITH and NEXT values must evaluate to a time in the future. If you omit the START WITH value, then Oracle Database determines the first automatic refresh time by evaluating the NEXT expression with respect to the creation time of the materialized view. If you specify a START WITH value but omit the NEXT value, then Oracle Database refreshes the materialized view only once. If you omit both the START WITH and NEXT values, or if you omit the alter_mv_refresh entirely, then Oracle Database does not automatically refresh the materialized view.

WITH PRIMARY KEY Clause
Specify WITH PRIMARY KEY to change a rowid materialized view to a primary key materialized view. Primary key materialized views allow materialized view master tables to be reorganized without affecting the ability of the materialized view to continue to fast refresh.

For you to specify this clause, the master table must contain an enabled primary key constraint and must have defined on it a materialized view log that logs primary key information.
See Also:

- *Oracle Database Advanced Replication* for detailed information about primary key materialized views
- "Primary Key Materialized View: Example" on page 11-19

**USING ROLLBACK SEGMENT Clause**

This clause is not valid if your database is in automatic undo mode, because in that mode Oracle Database uses undo tablespaces instead of rollback segments. Oracle strongly recommends that you use automatic undo mode. This clause is supported for backward compatibility with replication environments containing older versions of Oracle Database that still use rollback segments.

For complete information on this clause, refer to `CREATE MATERIALIZED VIEW ... "USING ROLLBACK SEGMENT Clause"` on page 15-22.

**USING ... CONSTRAINTS Clause**

This clause has the same semantics in `CREATE MATERIALIZED VIEW` and `ALTER MATERIALIZED VIEW` statements. For complete information, refer to "USING ... CONSTRAINTS Clause" on page 15-23 in the documentation on `CREATE MATERIALIZED VIEW`.

**evaluation_edition_clause**

Use this clause to change the evaluation edition for the materialized view. This clause has the same semantics in `CREATE MATERIALIZED VIEW` and `ALTER MATERIALIZED VIEW` statements. For complete information on this clause, refer to `evaluation_edition_clause` on page 15-23 in the documentation on `CREATE MATERIALIZED VIEW`.

**Notes on Changing the Evaluation Edition of a Materialized View**

The following notes apply when changing the evaluation edition of a materialized view:

- If you change the evaluation edition of a refresh-on-commit materialized view, then Oracle Database performs a complete refresh of the materialized view unless you specify `CONSIDER FRESH`.

- If you change the evaluation edition of a refresh-on-demand materialized view, then Oracle Database sets the staleness state of the materialized view to `STALE` unless you specify `CONSIDER FRESH`.

- For both refresh-on-commit and refresh-on-demand materialized views: If you change the evaluation edition and specify `CONSIDER FRESH`, then Oracle Database does not update the staleness state of the materialized view and does not rebuild the materialized view. Therefore, you can specify `CONSIDER FRESH` to indicate that, although the evaluation edition has changed, there is no difference in the results that `subquery` will produce. If the materialized view is stale and in need of either a fast refresh or a complete refresh before this statement is issued, then the state will not be changed and the materialized view may contain bad data.

**alter_query_rewrite_clause**

Use this clause to specify whether the materialized view is eligible to be used for query rewrite.

**ENABLE Clause**

Specify `ENABLE` to enable the materialized view for query rewrite. If you currently specify, or previously specified, the `unusable_editions_clause` for the materialized view, then it is not enabled for query rewrite in the unusable editions.
Restrictions on Enabling Materialized Views

Enabling materialized views is subject to the following restrictions:

- If the materialized view is in an invalid or unusable state, then it is not eligible for query rewrite in spite of the `ENABLE` mode.
- You cannot enable query rewrite if the materialized view was created totally or in part from a view.
- You can enable query rewrite only if all user-defined functions in the materialized view are `DETERMINISTIC`.
- You can enable query rewrite only if expressions in the statement are repeatable. For example, you cannot include `CURRENT_TIME` or `USER`.

DISABLE Clause

Specify `DISABLE` if you do not want the materialized view to be eligible for use by query rewrite. If a materialized view is in the invalid state, then it is not eligible for use by query rewrite, whether or not it is disabled. However, a disabled materialized view can be refreshed.

`unusable_editions_clause`

Use this clause to specify the editions in which the materialized view is not eligible for query rewrite. This clause has the same semantics in `CREATE MATERIALIZED VIEW` and `ALTER MATERIALIZED VIEW` statements. For complete information on this clause, refer to `unusable_editions_clause` on page 15-25 in the documentation on `CREATE MATERIALIZED VIEW`.

Cursors that use the materialized view for query rewrite and were compiled in an edition that is made unusable will be invalidated.

**COMPILE**

Specify `COMPILE` to explicitly revalidate a materialized view. If an object upon which the materialized view depends is dropped or altered, then the materialized view remains accessible, but it is invalid for query rewrite. You can use this clause to explicitly revalidate the materialized view to make it eligible for query rewrite.

If the materialized view fails to revalidate, then it cannot be refreshed or used for query rewrite.

**CONSIDER FRESH**

This clause lets you manage the staleness state of a materialized view after changes have been made to its master tables. `CONSIDER FRESH` directs Oracle Database to consider the materialized view fresh and therefore eligible for query rewrite in the `TRUSTED` or `STALE_TOLERATED` modes.
Because Oracle Database cannot guarantee the freshness of the materialized view, query rewrite in ENFORCED mode is not supported. This clause also sets the staleness state of the materialized view to UNKNOWN. The staleness state is displayed in the STALENESS column of the ALL_MVIEWS, DBA_MVIEWS, and USER_MVIEWS data dictionary views.

A materialized view is stale if changes have been made to the contents of any of its master tables. This clause directs Oracle Database to assume that the materialized view is fresh and that no such changes have been made. Therefore, actual updates to those tables pending refresh are purged with respect to the materialized view.

**Examples**

**Automatic Refresh: Examples** The following statement changes the default refresh method for the sales_by_month_by_state materialized view (created in "Creating Materialized Aggregate Views: Example" on page 15-27) to FAST:

```sql
ALTER MATERIALIZED VIEW sales_by_month_by_state
    REFRESH FAST;
```

The next automatic refresh of the materialized view will be a fast refresh provided it is a simple materialized view and its master table has a materialized view log that was created before the materialized view was created or last refreshed.

Because the REFRESH clause does not specify START WITH or NEXT values, Oracle Database will use the refresh intervals established by the REFRESH clause when the sales_by_month_by_state materialized view was created or last altered.

The following statement establishes a new interval between automatic refreshes for the sales_by_month_by_state materialized view:

```sql
ALTER MATERIALIZED VIEW sales_by_month_by_state
    REFRESH NEXT SYSDATE+7;
```

Because the REFRESH clause does not specify a START WITH value, the next automatic refresh occurs at the time established by the START WITH and NEXT values specified when the sales_by_month_by_state materialized view was created or last altered.

At the time of the next automatic refresh, Oracle Database refreshes the materialized view, evaluates the NEXT expression SYSDATE+7 to determine the next automatic refresh time, and continues to refresh the materialized view automatically once a week.

**Caution:** The CONSIDER FRESH clause also directs Oracle Database to no longer apply any rows in a materialized view log or Partition Change Tracking changes to the materialized view prior to the issuance of the CONSIDER FRESH clause. In other words, the pending changes will be ignored and deleted, not applied to the materialized view. This may result in the materialized view containing more or less data than the base table.
Because the REFRESH clause does not explicitly specify a refresh method, Oracle Database continues to use the refresh method specified by the REFRESH clause of the CREATE MATERIALIZED VIEW or most recent ALTER MATERIALIZED VIEW statement.

**CONSIDER FRESH: Example** The following statement instructs Oracle Database that materialized view sales_by_month_by_state should be considered fresh. This statement allows sales_by_month_by_state to be eligible for query rewrite in TRUSTED mode even after you have performed partition maintenance operations on the master tables of sales_by_month_by_state:

```
ALTER MATERIALIZED VIEW sales_by_month_by_state CONSIDER FRESH;
```

As a result of the preceding statement, any partition maintenance operations that were done to the base table since the last refresh of the materialized view will not be applied to the materialized view. For example, the add, drop, or change of data in a partition in the base table will not be reflected in the materialized view if CONSIDER FRESH is used before the next refresh of the materialized view. Refer to CONSIDER FRESH on page 11-17 for more information.

**See Also:** "Splitting Table Partitions: Examples" on page 12-104 for a partitioning maintenance example that would require this ALTER MATERIALIZED VIEW example

**Complete Refresh: Example** The following statement specifies a new refresh method, a new NEXT refresh time, and a new interval between automatic refreshes of the emp_data materialized view (created in "Periodic Refresh of Materialized Views: Example" on page 15-28):

```
ALTER MATERIALIZED VIEW emp_data
    REFRESH COMPLETE
    START WITH TRUNC(SYSDATE+1) + 9/24
    NEXT SYSDATE+7;
```

The START WITH value establishes the next automatic refresh for the materialized view to be 9:00 a.m. tomorrow. At that point, Oracle Database performs a complete refresh of the materialized view, evaluates the NEXT expression, and subsequently refreshes the materialized view every week.

**Enabling Query Rewrite: Example** The following statement enables query rewrite on the materialized view emp_data and implicitly revalidates it:

```
ALTER MATERIALIZED VIEW emp_data
    ENABLE QUERY REWRITE;
```

**Primary Key Materialized View: Example** The following statement changes the rowid materialized view order_data (created in "Creating Rowid Materialized Views: Example" on page 15-28) to a primary key materialized view. This example requires that you have already defined a materialized view log with a primary key on order_data.

```
ALTER MATERIALIZED VIEW order_data
    REFRESH WITH PRIMARY KEY;
```

**Compiling a Materialized View: Example** The following statement revalidates the materialized view store_mv:

```
ALTER MATERIALIZED VIEW order_data COMPILE;
```
ALTER MATERIALIZED VIEW LOG

Purpose

A materialized view log is a table associated with the master table of a materialized view. Use the `ALTER MATERIALIZED VIEW LOG` statement to alter the storage characteristics or type of an existing materialized view log.

**Note:** The keyword `SNAPSHOT` is supported in place of `MATERIALIZED VIEW` for backward compatibility.

See Also:

- `CREATE MATERIALIZED VIEW LOG` on page 15-31 for information on creating a materialized view log
- `ALTER MATERIALIZED VIEW` on page 11-3 for more information on materialized views, including refreshing them
- `CREATE MATERIALIZED VIEW` on page 15-4 for a description of the various types of materialized views

Prerequisites

You must be the owner of the master table, or you must have the `READ` or `SELECT` privilege on the master table and the `ALTER` privilege on the materialized view log.

See Also: *Oracle Database Advanced Replication* for detailed information about the prerequisites for `ALTER MATERIALIZED VIEW LOG`

Syntax

```
alter_materialized_view_log ::=

Semantics

FORCE
If you specify FORCE and any items specified with the ADD clause have already been specified for the materialized view log, then Oracle Database does not return an error, but silently ignores the existing elements and adds to the materialized view log any items that do not already exist in the log. Likewise, if you specify INCLUDING NEW VALUES and that attribute has already been specified for the materialized view log, Oracle Database ignores the redundancy and does not return an error.
**schema**
Specify the schema containing the master table. If you omit `schema`, then Oracle Database assumes the materialized view log is in your own schema.

**table**
Specify the name of the master table associated with the materialized view log to be altered.

**physical_attributes_clause**
The `physical_attributes_clause` lets you change the value of the `PCTFREE`, `PCTUSED`, and `INITRANS` parameters and the storage characteristics for the materialized view log, the partition, the overflow data segment, or the default characteristics of a partitioned materialized view log.

**Restriction on Materialized View Log Physical Attributes**
You cannot use the `storage_clause` to modify extent parameters if the materialized view log resides in a locally managed tablespace. Refer to `CREATE TABLE` on page 16-6 for a description of these parameters.

**add_mv_log_column_clause**
When you add a column to the master table of the materialized view log, the database does not automatically add a column to the materialized view log. Therefore, use this clause to add a column to the materialized view log, Oracle Database will encrypt the newly added column if the corresponding column of the master table is encrypted.

**alter_table_partitioning**
The syntax and general functioning of the partitioning clauses is the same as described for the `ALTER TABLE` statement. Refer to `alter_table_partitioning` on page 12-73 in the documentation on `ALTER TABLE`.

**Restrictions on Altering Materialized View Log Partitions**
Altering materialized view log partitions is subject to the following restrictions:
- You cannot use the `LOB_storage_clause` or `modify_LOB_storage_clause` when modifying partitions of a materialized view log.
- If you attempt to drop, truncate, or exchange a materialized view log partition, then Oracle Database raises an error.

**parallel_clause**
The `parallel_clause` lets you specify whether parallel operations will be supported for the materialized view log.

For complete information on this clause, refer to `parallel_clause` on page 16-81 in the documentation on `CREATE TABLE`.

**logging_clause**
Specify the logging attribute of the materialized view log. Refer to the `logging_clause` on page 8-38 for a full description of this clause.

**allocate_extent_clause**
Use the `allocate_extent_clause` to explicitly allocate a new extent for the materialized view log. Refer to `allocate_extent_clause` on page 8-2 for a full description of this clause.
shrink_clause
Use this clause to compact the materialized view log segments. For complete information on this clause, refer to `shrink_clause` on page 12-51 in the documentation on `CREATE TABLE`.

move_mv_log_clause
Use the `MOVE` clause to move the materialized view log table to a different tablespace, to change other segment or storage attributes of the materialized view log, or to change the parallelism of the materialized view log.

Restriction on Moving Materialized View Logs  The `ENCRYPT` clause of the `storage_clause` of `segment_attributes` is not valid for materialized view logs.

CACHE | NOCACHE Clause
For data that will be accessed frequently, `CACHE` specifies that the blocks retrieved for this log are placed at the most recently used end of the LRU list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables. `NOCACHE` specifies that the blocks are placed at the least recently used end of the LRU list. Refer to “CACHE | NOCACHE | CACHE READS” on page 16-80 in the documentation on `CREATE TABLE` for more information about this clause.

mv_log_augmentation
Use the `ADD` clause to augment the materialized view log so that it records the primary key values, rowid values, object ID values, or a sequence when rows in the materialized view master table are changed. This clause can also be used to record additional columns.

To stop recording any of this information, you must first drop the materialized view log and then re-create it. Dropping the materialized view log and then re-creating it forces a complete refresh for each of the existing materialized views that depend on the master table on its next refresh.

Restriction on Augmenting Materialized View Logs  You can specify only one `PRIMARY KEY`, one `ROWID`, one `OBJECT ID`, one `SEQUENCE`, and each column in the column list once for each materialized view log. You can specify only a single occurrence of `PRIMARY KEY`, `ROWID`, `OBJECT ID`, `SEQUENCE`, and column list within this `ALTER` statement. Also, if any of these values was specified at create time (either implicitly or explicitly), you cannot specify that value in this `ALTER` statement unless you use the `FORCE` option.

OBJECT ID  Specify `OBJECT ID` if you want the appropriate object identifier of all rows that are changed to be recorded in the materialized view log.

Restriction on the `OBJECT ID` clause  You can specify `OBJECT ID` only for logs on object tables, and you cannot specify it for storage tables.

PRIMARY KEY  Specify `PRIMARY KEY` if you want the primary key values of all rows that are changed to be recorded in the materialized view log.

ROWID  Specify `ROWID` if you want the rowid values of all rows that are changed to be recorded in the materialized view log.

SEQUENCE  Specify `SEQUENCE` to indicate that a sequence value providing additional ordering information should be recorded in the materialized view log.
**column**  Specify the additional columns whose values you want to be recorded in the materialized view log for all rows that are changed. Typically these columns are filter columns (non-primary-key columns referenced by subquery materialized views) and join columns (non-primary-key columns that define a join in the `WHERE` clause of the subquery).

**See Also:**
- CREATE MATERIALIZED VIEW on page 15-4 for details on explicit and implicit inclusion of materialized view log values
- Oracle Database Advanced Replication for more information about filter columns and join columns
- "Rowid Materialized View Log: Example" on page 11-26

**NEW VALUES Clause**

The `NEW VALUES` clause lets you specify whether Oracle Database saves both old and new values for update DML operations in the materialized view log. The value you set in this clause applies to all columns in the log, not only to columns you may have added in this `ALTER MATERIALIZED VIEW LOG` statement.

**INCLUDING**  Specify `INCLUDING` to save both new and old values in the log. If this log is for a table on which you have a single-table materialized aggregate view, and if you want the materialized view to be eligible for fast refresh, then you must specify `INCLUDING`.

**EXCLUDING**  Specify `EXCLUDING` to disable the recording of new values in the log. You can use this clause to avoid the overhead of recording new values.

If you have a fast-refreshable single-table materialized aggregate view defined on this table, then do not specify `EXCLUDING NEW VALUES` unless you first change the refresh mode of the materialized view to something other than `FAST`.

**See Also:**  "Materialized View Log EXCLUDING NEW VALUES: Example" on page 11-26

**mv_log_purge_clause**

Use this clause alter the purge attributes of the materialized view log in the following ways:

- Change the purge from `IMMEDIATE SYNCHRONOUS` to `IMMEDIATE ASYNCHRONOUS` or from `IMMEDIATE ASYNCHRONOUS` to `IMMEDIATE SYNCHRONOUS`
- Change the purge from `IMMEDIATE` to scheduled or from scheduled to `IMMEDIATE`
- Specify a new start time and a new `next time` and `interval`

If you are altering purge from scheduled to `IMMEDIATE`, then the scheduled purged job associated with that materialized view log is dropped. If you are altering purge from `IMMEDIATE` to scheduled, then a purge job is created with the attributes provided. If you are altering scheduled purge attributes, then only those attributes specified will be changed in the scheduler purge job.

You must specify `FORCE` if you are altering log purge to its current state (that is, you are not making any change), unless you are changing scheduled purge attributes.

To learn whether the purge time or interval has already been set for this materialized view log, query the `*_MVIEW_LOGS` data dictionary views. See the CREATE MATERIALIZED VIEW LOG clause `mv_log_purge_clause` on page 15-38 for the full semantics of this clause.
for_refresh_clause
Use this clause to change the refresh method for which the materialized view log will be used.

FOR SYNCHRONOUS REFRESH Specify this clause to change from fast refresh to synchronous refresh, or complete refresh to synchronous refresh. A staging log will be created.

If you are changing from fast refresh, then ensure that the following conditions are satisfied before using this clause:

- All changes in the materialized view log have been consumed.
- Any refresh-on-demand materialized views associated with the master table have been refreshed.
- Any refresh-on-commit materialized views associated with the master table have been converted to refresh-on-demand materialized views.

After you use this clause, you cannot perform DML operations directly on the master table. You must use the procedures in the DBMS_SYNC_REFRESH package to prepare and execute change data operations.

FOR FAST REFRESH Specify this clause to change from synchronous refresh to fast refresh, or complete refresh to fast refresh. A materialized view log will be created.

If you are changing from synchronous refresh to fast refresh, then ensure that all changes in the staging log have been consumed before using this clause.

After you use this clause, you can perform DML operations directly on the master table.

See the CREATE MATERIALIZED VIEW LOG clause for_refresh_clause on page 15-38 for the full semantics of this clause.

Examples

Rowid Materialized View Log: Example The following statement alters an existing primary key materialized view log to also record rowid information:

```
ALTER MATERIALIZED VIEW LOG ON order_items ADD ROWID;
```

Materialized View Log EXCLUDING NEW VALUES: Example The following statement alters the materialized view log on hr.employees by adding a filter column and excluding new values. Any materialized aggregate views that use this log will no longer be fast refreshable. However, if fast refresh is no longer needed, this action avoids the overhead of recording new values:

```
ALTER MATERIALIZED VIEW LOG ON employees
  ADD (commission_pct)
  EXCLUDING NEW VALUES;
```
ALTER MATERIALIZED ZONEMAP

Purpose

Use the ALTER MATERIALIZED ZONEMAP statement to modify an existing zone map in one of the following ways:

- To change its attributes
- To change its default refresh method and mode
- To enable or disable its use for pruning
- To compile it, rebuild it, or make it unusable

See Also:

- CREATE MATERIALIZED ZONEMAP on page 15-41 for information on creating zone maps
- Oracle Database Data Warehousing Guide for more information on zone maps

Prerequisites

The zone map must be in your own schema or you must have the ALTER ANY MATERIALIZED VIEW system privilege.

The user who owns the schema containing the zone map must have access to any base tables of the zone map that reside outside of that schema, either through a READ or SELECT object privilege on each of the tables, or through the READ ANY TABLE or SELECT ANY TABLE system privilege.

Syntax

```
alter_materialized_zonemap ::= 
ALTER MATERIALIZED ZONEMAP schema zonemap_name alter_zonemap_attributes zonemap_refresh_clause
```

Note: The ALTER MATERIALIZED ZONEMAP statement is available starting with Oracle Database 12c Release 1 (12.1.0.2).
**ALTER MATERIALIZED ZONEMAP**

**alter_zonemap_attributes::=**

```
PCTFREE integer
PCTUSED integer
CACHE
NOCACHE
```

**zonemap_refresh Clause::=**

```
REFRESH

demand
commit
load data
load data movement
force
complete
fast
on
```

---

**Note:** When specifying the `zonemap_refresh_clause`, you must specify at least one clause after the `REFRESH` keyword.

---

**Semantics**

**schema**

Specify the schema containing the zone map. If you omit `schema`, then Oracle Database assumes the zone map is in your own schema.

**zonemap_name**

Specify the name of the zone map to be altered.

**alter_zonemap_attributes**

Use this clause to modify the following attributes for the zone map: PCTFREE, PCTUSED, and CACHE or NOCACHE. These attributes have the same semantics for ALTER MATERIALIZED ZONEMAP and CREATE MATERIALIZED ZONEMAP. For complete information on these attributes, refer to PCTFREE on page 15-45, PCTUSED on page 15-45, and CACHE | NOCACHE on page 15-45 in the documentation on CREATE MATERIALIZED ZONEMAP.

**zonemap_refresh_clause**

Use this clause to modify the default refresh method and mode for the zone map. This clause has the same semantics for ALTER MATERIALIZED ZONEMAP and CREATE MATERIALIZED ZONEMAP. For complete information on this clause, refer to `zonemap_refresh_clause` on page 15-45 in the documentation on CREATE MATERIALIZED ZONEMAP.

**ENABLE | DISABLE PRUNING**

Use this clause to enable or disable use of the zone map for pruning. This clause has the same semantics for ALTER MATERIALIZED ZONEMAP and CREATE MATERIALIZED ZONEMAP. For complete information on this clause, refer to ENABLE | DISABLE PRUNING on page 15-46 in the documentation on CREATE MATERIALIZED ZONEMAP.
COMPILE
This clause lets you explicitly compile the zone map. This operation validates the zone map after a DDL operation changes the structure of one or more of its base tables. It is usually not necessary to issue this clause because Oracle database automatically compiles a zone map that requires compilation before using it. However, if you would like to explicitly compile a zone map, then you can use this clause to do so.

The result of compiling a zone map depends on whether a base table is changed in a way that affects the zone map. For example, if a column is added to a base table, then the zone map will be valid after compilation because the change does not affect the zone map. However, if a column that is included in the defining subquery of the zone map is dropped from a base table, then the zone map will be invalid after compilation.

You can determine if a zone map requires compilation by querying the COMPILE_STATE column of the ALL_, DBA_, and USER_ZONEMAPS data dictionary views. If the value of the column is NEEDS_COMPILE, then the zone map requires compilation.

REBUILD
This clause lets you explicitly rebuild the zone map. This operation refreshes the data in the zone map. This clause is useful in the following situations:

- You can use this clause to refresh the data for a refresh-on-demand zone map. Refer to the ON DEMAND clause on page 15-46 in the documentation on CREATE MATERIALIZED ZONEMAP for more information.
- You must issue this clause after an EXCHANGE PARTITION operation on one of the base tables of a zone map, regardless of the default refresh mode of the zone map.
- If a zone map is marked unusable, then you must issue this clause to mark it usable. You can determine if a zone map is marked unusable by querying the UNUSABLE column of the ALL_, DBA_, and USER_ZONEMAPS data dictionary views.

UNUSABLE
Specify this clause to make the zone map unusable. Subsequent queries will not use the zone map and the database will no longer maintain the zone map. You can make the zone map usable again by issuing an ALTER MATERIALIZED ZONEMAP ... REBUILD statement.

Examples

Modifying Zone Map Attributes: Example The following statement modifies the PCTFREE and PCTUSED attributes of zone map sales_zmap, and modifies the zone map so that it does not use caching:

ALTER MATERIALIZED ZONEMAP sales_zmap
   PCTFREE 20 PCTUSED 50 NOCACHE;

Modifying the Default Refresh Method and Mode for a Zone Map: Example The following statement changes the default refresh method to FAST and the default refresh mode to ON COMMIT for zone map sales_zmap:

ALTER MATERIALIZED ZONEMAP sales_zmap
   REFRESH FAST ON COMMIT;

Disabling Use of a Zone Map for Pruning: Example The following statement disables use of zone map sales_zmap for pruning:

ALTER MATERIALIZED ZONEMAP sales_zmap
DISABLE PRUNING;

**Compiling a Zone Map: Example**  The following statement compiles zone map sales_zmap:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
  COMPILE;
```

**Rebuilding a Zone Map: Example**  The following statement rebuilds zone map sales_zmap:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
  REBUILD;
```

**Making a Zone Map Unusable: Example**  The following statement makes zone map sales_zmap unusable:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
  UNUSABLE;
```
ALTER OPERATOR

Purpose

Use the ALTER OPERATOR statement to add bindings to, drop bindings from, or compile an existing operator.

See Also: CREATE OPERATOR on page 15-49

Prerequisites

The operator must already have been created by a previous CREATE OPERATOR statement. The operator must be in your own schema or you must have the ALTER ANY OPERATOR system privilege. You must have the EXECUTE object privilege on the operators and functions referenced in the ALTER OPERATOR statement.

Syntax

\[
\text{alter_operator}::= \\
\text{add_binding_clause}::= \\
\text{implementation_clause}::= \\
\text{using_function_clause}::= \\
\text{context_clause}::= 
\]

(add_binding_clause::= on page 11-31, drop_binding_clause::= on page 11-32)

(add_binding_clause::= on page 11-31, drop_binding_clause::= on page 11-32)

implementation_clause::=

(implementation_clause::= on page 11-31, using_function_clause::= on page 11-32)

context_clause::=

(context_clause::= on page 11-32)
context_clause ::=  

\[
\text{schema} \quad \text{operator} \quad \text{add_binding_clause} \quad \text{implementation_clause} 
\]

using_function_clause ::=  

\[
\text{usage} \quad \text{function} \quad \text{context_clause} 
\]

drop_binding_clause ::=  

\[
\text{drop} \quad \text{binding} \quad \text{force} 
\]

**Semantics**

**schema**  
Specify the schema containing the operator. If you omit this clause, then Oracle Database assumes the operator is in your own schema.

**operator**  
Specify the name of the operator to be altered.

**add_binding_clause**  
Use this clause to add an operator binding and specify its parameter data types and return type. The signature must be different from the signature of any existing binding for this operator.

If a binding of an operator is associated with an indextype and you add another binding to the operator, then Oracle Database does not automatically associate the new binding with the indextype. If you want to make such an association, then you must issue an explicit `ALTER INDEXTYPE ... ADD OPERATOR` statement.

**implementation_clause**  
This clause has the same semantics in `CREATE OPERATOR` and `ALTER OPERATOR` statements. For full information, refer to `implementation_clause` on page 15-50 in the documentation on `CREATE OPERATOR`.

**context_clause**  
This clause has the same semantics in `CREATE OPERATOR` and `ALTER OPERATOR` statements. For full information, refer to `context_clause` on page 15-51 in the documentation on `CREATE OPERATOR`.
**using_function_clause**

This clause has the same semantics in `CREATE OPERATOR` and `ALTER OPERATOR` statements. For full information, refer to `using_function_clause` on page 15-51 in the documentation on `CREATE OPERATOR`.

**drop_binding_clause**

Use this clause to specify the list of parameter data types of the binding you want to drop from the operator. You must specify `FORCE` if the binding has any dependent objects, such as an indextype or an ancillary operator binding. If you specify `FORCE`, then Oracle Database marks `INVALID` all objects that are dependent on the binding. The dependent objects are revalidated the next time they are referenced in a DDL or DML statement or a query.

You cannot use this clause to drop the only binding associated with this operator. Instead you must use the `DROP OPERATOR` statement. Refer to `DROP OPERATOR` on page 17-64 for more information.

**COMPILE**

Specify `COMPILE` to cause Oracle Database to recompile the operator.

**Examples**

**Compiling a User-defined Operator: Example**

The following example compiles the operator `eq_op` (which was created in "Creating User-Defined Operators: Example" on page 15-51):

```
ALTER OPERATOR eq_op COMPILE;
```
ALTER OUTLINE

Purpose

Note: Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. SQL plan management creates SQL plan baselines, which offer superior SQL performance stability compared with stored outlines.

You can migrate existing stored outlines to SQL plan baselines by using the MIGRATE_STORED_OUTLINE function of the DBMS_SPM package or Enterprise Manager Cloud Control. When the migration is complete, the stored outlines are marked as migrated and can be removed. You can drop all migrated stored outlines on your system by using the DROP_MIGRATED_STORED_OUTLINE function of the DBMS_SPM package.

See Also: Oracle Database SQL Tuning Guide for more information about SQL plan management and Oracle Database PL/SQL Packages and Types Reference for information about the DBMS_SPM package.

Use the ALTER OUTLINE statement to rename a stored outline, reassign it to a different category, or regenerate it by compiling the outline’s SQL statement and replacing the old outline data with the outline created under current conditions.

See Also: CREATE OUTLINE on page 15-52 for information on creating an outline.

Prerequisites

To modify an outline, you must have the ALTER ANY OUTLINE system privilege.

Syntax

alter_outline::=

Semantics

PUBLIC | PRIVATE

Specify PUBLIC if you want to modify the public version of this outline. This is the default.
Specify `PRIVATE` if you want to modify an outline that is private to the current session and whose data is stored in the current parsing schema.

`outline`
Specify the name of the outline to be modified.

**REBUILD**
Specify `REBUILD` to regenerate the execution plan for `outline` using current conditions.

*See Also:* "Rebuilding an Outline: Example" on page 11-35

**RENAME TO Clause**
Use the `RENAME TO` clause to specify an outline name to replace `outline`.

**CHANGE CATEGORY TO Clause**
Use the `CHANGE CATEGORY TO` clause to specify the name of the category into which the `outline` will be moved.

**ENABLE | DISABLE**
Use this clause to selectively enable or disable this outline. Outlines are enabled by default. The `DISABLE` keyword lets you disable one outline without affecting the use of other outlines.

**Examples**

**Rebuilding an Outline: Example**  The following statement regenerates a stored outline called `salaries` by compiling the text of the outline and replacing the old outline data with the outline created under current conditions.

```sql
ALTER OUTLINE salaries REBUILD;
```
ALTER PACKAGE

Purpose

Packages are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the ALTER PACKAGE statement to explicitly recompile a package specification, body, or both. Explicit recompilation eliminates the need for implicit run-time recompilation and prevents associated run-time compilation errors and performance overhead.

Because all objects in a package are stored as a unit, the ALTER PACKAGE statement recompiles all package objects together. You cannot use the ALTER PROCEDURE statement or ALTER FUNCTION statement to recompile individually a procedure or function that is part of a package.

Note: This statement does not change the declaration or definition of an existing package. To redeclare or redefine a package, use the CREATE PACKAGE or the CREATE PACKAGE BODY on page 15-55 statement with the OR REPLACE clause.

Prerequisites

For you to modify a package, the package must be in your own schema or you must have ALTER ANY PROCEDURE system privilege.

Syntax

\[
\text{alter\_package ::= \{\text{ALTER\ PACKAGE} \text{schema} \text{package\_name} \text{package\_compile\_clause}\ \text{EDITIONABLE}\ | \text{NONEDITIONABLE}\}}
\]

(packages_compile_clause: See Oracle Database PL/SQL Language Reference for the syntax of this clause.)

Semantics

\text{schema}

Specify the schema containing the package. If you omit \text{schema}, then Oracle Database assumes the package is in your own schema.

\text{package\_name}

Specify the name of the package to be recompiled.

\text{package\_compile\_clause}

See Oracle Database PL/SQL Language Reference for the syntax and semantics of this clause and for complete information on creating and compiling packages.
EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the package becomes an editioned or noneditioned object if editioning is later enabled for the schema object type PACKAGE in schema. The default is EDITIONABLE. For information about altering editioned and noneditioned objects, see Oracle Database Development Guide.
ALTER PLUGGABLE DATABASE

Purpose

Use the ALTER PLUGGABLE DATABASE statement to modify a pluggable database (PDB). This statement enables you to perform the following tasks:

- Unplug a PDB from a multitenant container database (CDB) (using the `pdb_unplug_clause`)
- Modify the settings of a PDB (using the `pdb_settings_clauses`)
- Bring PDB data files online or take them offline (using the `pdb_datafile_clause`)
- Back up and recover a PDB (using the `pdb_recovery_clauses`)
- Modify the state of a PDB (using the `pdb_change_state clause`)
- Modify the state of multiple PDBs within a CDB (using the `pdb_change_state_from_root clause`)

**Note:** You can perform all ALTER PLUGGABLE DATABASE tasks by connecting to a PDB and running the corresponding ALTER DATABASE statement. This functionality is provided to maintain backward compatibility for applications that have been migrated to a CDB environment. The exception is modifying PDB storage limits, for which you must use the `pdb_storage_clause` of ALTER PLUGGABLE DATABASE.

**See Also:** CREATE PLUGGABLE DATABASE on page 15-61 for information on creating PDBs

Prerequisites

You must be connected to a CDB.

To specify the `pdb_unplug_clause`, the current container must be the root, you must be authenticated as SYSDBA or AS SYSOPER, and the SYSDBA or SYSOPER privilege must be either granted to you commonly, or granted to you locally in the root and locally in the PDB you want to unplug.

To specify the `pdb_settings_clauses`, the current container must be the PDB whose settings you want to modify and you must have the ALTER DATABASE privilege, either granted commonly or granted locally in the PDB. To specify the `pdb_logging_clauses` or the `RENAME GLOBAL_NAME` clause, you must also have the RESTRICTED SESSION privilege, either granted commonly or granted locally in the PDB being renamed, and the PDB must be in READ WRITE RESTRICTED mode.

To specify the `pdb_datafile_clause`, the current container must be the PDB whose datafiles you want to bring online or take offline and you must have the ALTER DATABASE privilege, either granted commonly or granted locally in the PDB.

To specify the `pdb_recovery_clauses`, the current container must be the PDB you want to back up or recover and you must have the ALTER DATABASE privilege, either granted commonly or granted locally in the PDB.
To specify the `pdb_change_state` clause, the current container must be the PDB whose state you want to change and you must be authenticated as `SYSBACKUP`, `SYSDBA`, `SYSDG`, or `SYSOPER`.

To specify the `pdb_change_state_from_root` clause, the current container must be the root, you must be authenticated as `SYSBACKUP`, `SYSDBA`, `SYSDG`, or `SYSOPER`, and the `SYSBACKUP`, `SYSDBA`, `SYSDG`, or `SYSOPER` privilege must be either granted to you commonly, or granted to you locally in the root and locally in the PDB(s) whose state(s) you want to change.

**Syntax**

```

*(pdb_open::= on page 11-41, pdb_close::= on page 11-42, pdb_save_or_discard_state::= on page 11-42)*

**Semantics**

**pdb_unplug_clause**

This clause lets you unplug a PDB from a CDB. When you unplug a PDB, Oracle stores metadata for the PDB in an XML file. You can use this XML file to subsequently plug the PDB into a CDB.

- For **pdb_name**, specify the name of the PDB you want to unplug. The PDB must be closed—that is, the open mode must be MOUNTED. In an Oracle Real Application Clusters (Oracle RAC) environment, the PDB must be closed in all Oracle RAC instances.
- For **filename**, specify the full path name of the XML file in which to store the metadata for the unplugged PDB.

After a PDB is unplugged, it remains in the CDB with an open mode of MOUNTED and a status of UNPLUGGED. The only operation you can perform on an unplugged PDB is DROP PLUGGABLE DATABASE, which will remove it from the CDB. You must drop the PDB before you can plug it into the same CDB or another CDB.
See Also:

- Oracle Database Administrator’s Guide for more information on unplugging a PDB
- The create_pdb_from_xml clause of CREATE PLUGGABLE DATABASE on page 15-71 for information on plugging in a PDB

**pdb_settings_clauses**

These clauses let you modify various settings for a PDB.

**pdb_name**

You can optionally use pdb_name to specify the name of the PDB whose settings you want to modify.

**DEFAULT EDITION Clause**

Use this clause to designate the specified edition as the default edition for the PDB. For the full semantics of this clause, refer to "DEFAULT EDITION Clause" on page 10-65 in the ALTER DATABASE documentation.

**SET DEFAULT TABLESPACE Clause**

Use this clause to specify or change the default type of tablespaces subsequently created in the PDB. For the full semantics of this clause, refer to "SET DEFAULT TABLESPACE Clause" on page 10-65 in the ALTER DATABASE documentation.

**DEFAULT TABLESPACE Clause**

Use this clause to establish or change the default permanent tablespace of the PDB. For the full semantics of this clause, refer to "DEFAULT TABLESPACE Clause" on page 10-66 in the ALTER DATABASE documentation.

**DEFAULT TEMPORARY TABLESPACE Clause**

Use this clause to change the default temporary tablespace of the PDB to a new tablespace or tablespace group. For the full semantics of this clause, refer to "DEFAULT TEMPORARY TABLESPACE Clause" on page 10-66 in the ALTER DATABASE documentation.

**RENAME GLOBAL_NAME TO Clause**

Use this clause to change the global name of the PDB. The new global name must be unique within the CDB. For an Oracle Real Application Clusters (Oracle RAC) database, the PDB must be open in READ WRITE RESTRICTED mode on the current instance only. The PDB must be closed on all other instances. For the full semantics of this clause, refer to "RENAME GLOBAL_NAME Clause" on page 10-67 in the ALTER DATABASE documentation.

---

**Note:** When you change the global name of a PDB, be sure to change the PLUGGABLE DATABASE property for database services that are used to connect to the PDB.

---

**set_time_zone_clauses**

Use this clause to modify the time zone setting for the PDB. For the full semantics of this clause, refer to set_time_zone_clause on page 10-69 in the ALTER DATABASE documentation.
**database_file_clauses**
Use this clause to modify data files and temp files for the PDB. For the full semantics of this clause, refer to `database_file_clauses` on page 10-51 in the ALTER DATABASE documentation.

**supplemental_db_logging**
Use these clauses to instruct Oracle Database to add or stop adding supplemental data into the log stream for the PDB. The `ADD SUPPLEMENTAL LOG` clause has the side effect of instructing the database to add minimal supplemental data into the log stream for the entire CDB. For the full semantics of this clause, refer to `supplemental_db_logging` on page 10-58 in the ALTER DATABASE documentation.

**pdb_storage_clause**
Use this clause to modify the storage limits for a PDB.

This clause has the same semantics as the `pdb_storage_clause` on page 15-66 in the CREATE PLUGGABLE DATABASE documentation, with the following additions:

- If you specify `MAXSIZE size_clause`, then the value you specify for `size_clause` must be greater than or equal to the combined size of the existing tablespaces belonging to the PDB. Otherwise, an error occurs.
- If you specify `MAX_SHARED_TEMP_SIZE size_clause`, and the value you specify for `size_clause` is less than that used by sessions that are connected to the PDB, then no additional storage in the shared temporary tablespace will be available for sessions connected to the PDB until the amount of storage used by them becomes smaller than the value you specify for `size_clause`.

**pdb_logging_clauses**
Use these clauses to set or change the logging characteristics of the PDB.

**logging_clause**
Use this clause to change the default logging attribute for tablespaces subsequently created within the PDB. This clause has the same semantics as the `logging_clause` on page 15-68 in the CREATE PLUGGABLE DATABASE documentation.

**pdb_force_logging_clause**
Use this clause to place a PDB into force logging or force nologging mode or take a PDB out of force logging or force nologging mode.

Force logging mode instructs the database to log all changes in the PDB, except changes in temporary tablespaces and temporary segments. Force nologging mode instructs the database to not log any changes in the PDB.

CDB-wide force logging mode takes precedence over PDB-level force nologging mode. PDB-level force logging mode and force nologging mode take precedence over and are independent of any LOGGING, NOLOGGING, or FORCE LOGGING settings you specify for individual tablespaces in the PDB and any LOGGING or NOLOGGING settings you specify for individual database objects in the PDB.

- Specify `ENABLE FORCE LOGGING` to place the PDB in force logging mode. If the PDB is currently in force nologging mode, then specifying this clause results in an error. You must first specify `DISABLE FORCE NOLOGGING`.
- Specify `DISABLE FORCE LOGGING` to take the PDB out of force logging mode. If the PDB is not currently in force logging mode, then specifying this clause results in an error.
■ Specify `ENABLE FORCE NOLOGGING` to place the PDB in force nologging mode. If the PDB is currently in force logging mode, then specifying this clause results in an error. You must first specify `DISABLE FORCE LOGGING`.

■ Specify `DISABLE FORCE NOLOGGING` to take the PDB out of force nologging mode. If the PDB is not currently in force nologging mode, then specifying this clause results in an error.

This clause does not change the default `LOGGING` or `NOLOGGING` mode of the PDB specified by the `logging_clause` on page 11-44.

`pdb_datafile_clause`

This clause lets you bring data files associated with a PDB online or take them offline. The PDB must be closed when you issue this clause.

■ For `pdb_name`, specify the name of the PDB. If the current container is the PDB, then you can omit `pdb_name`.

■ The `DATAFILE` clauses let you specify the data files you want to bring online or take offline. Use `filename` or `filenumber` to identify specific data files by name or by number. You can view data file names and numbers by querying the `NAME` and `FILE#` columns of the `V$DATAFILE` dynamic performance view. Use `ALL` to specify all data files associated with the PDB.

■ Specify `ONLINE` to bring the data files online or `OFFLINE` to take the data files offline.

`pdb_recovery_clauses`

Use the `pdb_recovery_clauses` to back up and recover a PDB.

`pdb_name`

You can optionally use `pdb_name` to specify the name of the PDB you want to back up or recover.

`pdb_general_recovery`

This clause lets you control media recovery for the PDB or standby database or for specified tablespaces or files. The `pdb_general_recovery` clause has the same semantics as the `general_recovery` clause of `ALTER DATABASE`. Refer to the `general_recovery` clause of `ALTER DATABASE` on page 10-45 for more information.

BACKUP Clauses

Use these clauses to move all of the data files in the PDB into or out of online backup mode (also called hot backup mode). These clauses have the same semantics in `ALTER PLUGGABLE DATABASE` and `ALTER DATABASE`. Refer to the "BACKUP Clauses" of `ALTER DATABASE` on page 10-50 for more information.

RECOVERY Clauses

Use these clauses to enable or disable a PDB for recovery. The PDB must be closed—that is, the open mode must be `MOUNTED`. The `RECOVERY` clauses are available starting with Oracle Database 12c Release 1 (12.1.0.2).

■ Specify `ENABLE RECOVERY` to bring all data files that belong to a PDB online and enable the PDB for recovery.

■ Specify `DISABLE RECOVERY` to take all data files that belong to a PDB offline and disable the PDB for recovery.
See Also: Oracle Data Guard Concepts and Administration for more information on the RECOVERY clauses

**pdb_change_state**
This clause enables you to change the state, or open mode, of a PDB. Table 11–1 lists the open modes of a PDB.

- Specify the `pdb_open` clause to change the open mode to READ WRITE, READ ONLY, or MIGRATE.
- Specify the `pdb_close` clause to change the open mode to MOUNTED.

### Table 11–1  PDB Open Modes

<table>
<thead>
<tr>
<th>Open Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>READ WRITE</td>
<td>A PDB in open read/write mode allows queries and user transactions to proceed and allows users to generate redo logs.</td>
</tr>
<tr>
<td>READ ONLY</td>
<td>A PDB in open read-only mode allows queries but does not allow user changes.</td>
</tr>
<tr>
<td>MIGRATE</td>
<td>When a PDB is in open migrate mode, you can run database upgrade scripts on the PDB.</td>
</tr>
<tr>
<td>MOUNTED</td>
<td>When a PDB is in mounted mode, it behaves like a non-CDB in mounted mode. It does not allow changes to any objects, and it is accessible only to database administrators. It cannot read from or write to data files. Information about the PDB is removed from memory caches. Cold backups of the PDB are possible.</td>
</tr>
</tbody>
</table>

You can view the open mode of a PDB by querying the `OPEN_MODE` column of the `V$PDBS` view.

See Also: Oracle Database Administrator’s Guide for a complete description of PDB open modes

**pdb_name**
You can optionally use `pdb_name` to specify the name of the PDB whose open mode you want to change.

**pdb_open**
This clause lets you change the open mode of a PDB to READ WRITE, READ ONLY, or MIGRATE. When you specify this clause, the PDB must be in MOUNTED mode unless you specify the FORCE keyword.

If you do not specify READ WRITE or READ ONLY, then the default is READ WRITE. The exception is when the PDB belongs to a CDB that is used as a physical standby database, in which case the default is READ ONLY.

**READ WRITE** Specify this clause to change the open mode to READ WRITE.

**READ ONLY** Specify this clause to change the open mode to READ ONLY.

**[READ WRITE] UPGRADE** Specify this clause to change the open mode to MIGRATE. The READ WRITE keywords are optional and are provided for semantic clarity.

**RESTRICTED** If you specify the optional RESTRICTED keyword, then the PDB is accessible only to users with the RESTRICTED SESSION privilege in the PDB.
If the PDB is in READ WRITE or READ ONLY mode, and you specify the RESTRICTED and FORCE keywords while changing the open mode, then all sessions connected to the PDB that do not have the RESTRICTED SESSION privilege in the PDB are terminated, and their transactions are rolled back.

**FORCE** Specify this keyword to change the open mode of a PDB from READ WRITE to READ ONLY, or from READ ONLY to READ WRITE. The FORCE keyword allows users to remain connected to the PDB while the open mode is changed.

When you specify FORCE to change the open mode of a PDB from READ WRITE to READ ONLY, any READ WRITE transaction that is open when you change the open mode will not be allowed to perform any more DML operations or to COMMIT.

**Restriction on FORCE** You cannot specify the FORCE keyword if the PDB is currently in MIGRATE mode, and you cannot specify the FORCE keyword to change a currently open PDB to MIGRATE mode.

**RESETLOGS** Specify this clause to create a new PDB incarnation and open the PDB in READ WRITE mode after point-in-time recovery of the PDB.

**instances_clause** In an Oracle Real Application Clusters environment, use this clause to modify the state of the PDB in the specified Oracle RAC instances. If you omit this clause, then the state of the PDB is modified only in the current instance.

- Use instance_name to specify one or more instance names, in a comma-separated list enclosed in parenthesis. This modifies the state of the PDB only in those instances.
- Specify ALL to modify the state of the PDB in all instances.
- Specify ALL EXCEPT to modify the state of the PDB in all instances except the specified instances.

If the PDB is already open in one or more instances, then you can open it in additional instances, but it must be opened in the same mode as in the instances in which it is already open.

**pdb_close** This clause lets you change the open mode of a PDB to MOUNTED. When you specify this clause, the PDB must be in READ WRITE, READ ONLY, or MIGRATE mode. This clause is the PDB equivalent of the SQL*Plus SHUTDOWN command.

**IMMEDIATE** If you specify the optional IMMEDIATE keyword, then this clause is the PDB equivalent of the SQL*Plus SHUTDOWN command with the immediate mode. Otherwise, the PDB is shut down with the normal mode.

**instances_clause** In an Oracle Real Application Clusters environment, use this clause to modify the state of the PDB in the specified Oracle RAC instances. You can close a PDB in some instances and leave it open in others. Refer to the instances_clause on page 11-47 for the full semantics of this clause.

See Also: Oracle Database Backup and Recovery User’s Guide for more information on performing point-in-time recovery of CDBs and PDBs

See Also: SQL*Plus User’s Guide and Reference for more information on the SQL*Plus SHUTDOWN command

See Also: SQL*Plus User’s Guide and Reference for more information on the SQL*Plus SHUTDOWN command
**alter_pluggable_database**

In an Oracle Real Application Clusters environment, use this clause to instruct the database to reopen the PDB on a different Oracle RAC instance.

- Specify `RELOCATE` to reopen the PDB on a different instance that is selected by Oracle Database.
- Specify `RELOCATE TO 'instance_name'` to reopen the PDB in the specified instance.
- Specify `NORELOCATE` to close the PDB in the current instance. This is the default.

**pdb_save_or_discard_state**

Use this clause to instruct the database to save or discard the open mode of the PDB when the CDB restarts.

- If you specify `SAVE`, then the PDB’s open mode after the CDB restarts will be identical to its open mode just before the CDB restarted.
- If you specify `DISCARD`, then the PDB’s open mode after the CDB restarts will be MOUNTED. This is the default.

**instances_clause**

In an Oracle Real Application Clusters environment, use this clause to instruct the database to save or discard the open mode of the PDB in the specified Oracle RAC instances. If you omit this clause, then the database applies the `SAVE` or `DISCARD` setting only to the PDB in the current instance.

- Use `instance_name` to specify one or more instance names, in a comma-separated list enclosed in parenthesis. This applies the `SAVE` or `DISCARD` setting to the PDB only in those instances.
- Specify `ALL` to apply the `SAVE` or `DISCARD` setting to the PDB in all instances.
- Specify `ALL EXCEPT` to apply the `SAVE` or `DISCARD` setting to the PDB in all instances except the specified instances.

**pdb_change_state_from_root**

This clause enables you to modify the state of one or more PDBs.

- Specify the `pdb_name` for one or more PDBs whose state you want to modify.
- Specify `ALL` to modify the state of all PDBs in the CDB.
- Specify `ALL EXCEPT` to modify the state of all PDBs in the CDB except those specified by using `pdb_name`.

If a PDB is already in the specified state, then the PDB’s state is unchanged and no error is returned. If the state of a PDB cannot be changed, then an error occurs only for that PDB.

Refer to `pdb_open` on page 11-46 and `pdb_close` on page 11-47 for the full semantics of these clauses.

**Examples**

**Unplugging a PDB from a CDB: Example**  The following statement unplugs PDB pdb1 and stores metadata for the PDB into XML file `/oracle/data/pdb1.xml`:

```
ALTER PLUGGABLE DATABASE pdb1
  UNPLUG INTO '/oracle/data/pdb1.xml';
```

**Modifying the Settings of a PDB: Example**  The following statement changes the limit for the amount of storage used by all tablespaces in PDB pdb2 to 500M:
ALTER PLUGGABLE DATABASE pdb2
   STORAGE (MAXSIZE 500M);

**Taking the Data Files of a PDB Offline: Example**  The following statement takes the data files associated with PDB pdb3 offline:

```
ALTER PLUGGABLE DATABASE pdb3
   DATAFILE ALL OFFLINE;
```

**Changing the State of a PDB: Examples**  Assume that PDB pdb4 is closed—that is, its open mode is MOUNTED. The following statement opens pdb4 with open mode READ ONLY:

```
ALTER PLUGGABLE DATABASE pdb4
   OPEN READ ONLY;
```

The following statement uses the FORCE keyword to change the open mode of pdb4 from READ ONLY to READ WRITE:

```
ALTER PLUGGABLE DATABASE pdb4
   OPEN READ WRITE FORCE;
```

The following statement closes PDB pdb4:

```
ALTER PLUGGABLE DATABASE pdb4
   CLOSE;
```

The following statement opens PDB pdb4 with open mode READ ONLY. Because the RESTRICTED keyword is specified, the PDB is accessible only to users with the RESTRICTED SESSION privilege in the PDB:

```
ALTER PLUGGABLE DATABASE pdb4
   OPEN READ ONLY RESTRICTED;
```

Assume that PDB pdb5 is closed—that is, its open mode is MOUNTED. In an Oracle Real Application Clusters environment, the following statement opens PDB pdb5 with open mode READ WRITE in instances ORCLDB_1 and ORCLDB_2:

```
ALTER PLUGGABLE DATABASE pdb5
   OPEN READ WRITE INSTANCES = ('ORCLDB_1', 'ORCLDB_2');
```

In an Oracle Real Application Clusters environment, the following statement closes PDB pdb6 in the current instance and instructs the database to reopen pdb6 in instance ORCLDB_3:

```
ALTER PLUGGABLE DATABASE pdb6
   CLOSE RELOCATE TO 'ORCLDB_3';
```

**Changing the State of All PDBs in a CDB: Example**  Assume that the current container is the root. The following statement opens all PDBs in the CDB with open mode READ ONLY:

```
ALTER PLUGGABLE DATABASE ALL
   OPEN READ ONLY;
```
ALTER PROCEDURE

Purpose

Packages are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the ALTER PROCEDURE statement to explicitly recompile a standalone stored procedure. Explicit recompilation eliminates the need for implicit run-time recompilation and prevents associated run-time compilation errors and performance overhead.

To recompile a procedure that is part of a package, recompile the entire package using the ALTER PACKAGE statement (see ALTER PACKAGE on page 11-36).

**Note:** This statement does not change the declaration or definition of an existing procedure. To redeclare or redefine a procedure, use the CREATE PROCEDURE statement with the OR REPLACE clause (see CREATE PROCEDURE on page 15-75).

The ALTER PROCEDURE statement is quite similar to the ALTER FUNCTION statement. Refer to ALTER FUNCTION on page 10-106 for more information.

Prerequisites

The procedure must be in your own schema or you must have ALTER ANY PROCEDURE system privilege.

Syntax

```
alter_procedure::=
```

```
ALTER PROCEDURE schema procedure_name procedure_compile_clause
```

```
procedure_compile_clause: See Oracle Database PL/SQL Language Reference for the syntax of this clause.
```

Semantics

**schema**

Specify the schema containing the procedure. If you omit schema, then Oracle Database assumes the procedure is in your own schema.

**procedure_name**

Specify the name of the procedure to be recompiled.
**procedure_compile_clause**

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling procedures.

**EDITIONABLE | NONEDITIONABLE**

Use these clauses to specify whether the procedure becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `PROCEDURE` in `schema`. The default is `EDITIONABLE`. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.
**ALTER PROFILE**

**Purpose**

Use the `ALTER PROFILE` statement to add, modify, or remove a resource limit or password management parameter in a profile.

Changes made to a profile with an `ALTER PROFILE` statement affect users only in their subsequent sessions, not in their current sessions.

*See Also:* `CREATE PROFILE` on page 15-77 for information on creating a profile

**Prerequisites**

You must have the `ALTER PROFILE` system privilege.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root. To specify `CONTAINER = CURRENT`, the current container must be a pluggable database (PDB).

**Syntax**

```sql
ALTER PROFILE profile LIMIT resource_parameters [password_parameters] [CONTAINER = CURRENT | ALL];
```

(resource_parameters::= on page 11-52, password_parameters::= on page 11-53)

(resource_parameters::= on page 11-52, password_parameters::= on page 11-53)

(size_clause::= on page 8-47)
password_parameters::=

Semantics

The keywords, parameters, and clauses in the ALTER PROFILE statement all have the same meaning as in the CREATE PROFILE statement.

You cannot remove a limit from the DEFAULT profile.

Refer to CREATE PROFILE on page 15-77 and to the examples in the next section for more information.

Examples

Making a Password Unavailable: Example  The following statement makes the password of the new_profile profile (created in "Creating a Profile: Example" on page 15-82) unavailable for reuse for 90 days:

```sql
ALTER PROFILE new_profile
  LIMIT PASSWORD_REUSE_TIME 90
  PASSWORD_REUSE_MAX UNLIMITED;
```

Setting Default Password Values: Example  The following statement defaults the PASSWORD_REUSE_TIME value of the app_user profile (created in "Setting Profile Resource Limits: Example" on page 15-82) to its defined value in the DEFAULT profile:

```sql
ALTER PROFILE app_user
  LIMIT PASSWORD_REUSE_TIME DEFAULT
  PASSWORD_REUSE_MAX UNLIMITED;
```

Limiting Login Attempts and Password Lock Time: Example  The following statement alters profile app_user with FAILED_LOGIN_ATTEMPTS set to 5 and PASSWORD_LOCK_TIME set to 1:

```sql
ALTER PROFILE app_user LIMIT
  FAILED_LOGIN_ATTEMPTS 5
  PASSWORD_LOCK_TIME 1;
```

This statement causes any user account to which the app_user profile is assigned to become locked for one day after five consecutive unsuccessful login attempts.

Changing Password Lifetime and Grace Period: Example  The following statement modifies the profile app_user2 PASSWORD_LIFE_TIME to 90 days and PASSWORD_GRACE_TIME to 5 days:
ALTER PROFILE app_user2 LIMIT
  PASSWORD_LIFE_TIME 90
  PASSWORD_GRACE_TIME 5;

Limiting Concurrent Sessions: Example  This statement defines a new limit of 5 concurrent sessions for the app_user profile:
ALTER PROFILE app_user LIMIT SESSIONS_PER_USER 5;

If the app_user profile does not currently define a limit for SESSIONS_PER_USER, then the preceding statement adds the limit of 5 to the profile. If the profile already defines a limit, then the preceding statement redefines it to 5. Any user assigned the app_user profile is subsequently limited to 5 concurrent sessions.

Removing Profile Limits: Example  This statement removes the IDLE_TIME limit from the app_user profile:
ALTER PROFILE app_user LIMIT IDLE_TIME DEFAULT;

Any user assigned the app_user profile is subject in their subsequent sessions to the IDLE_TIME limit defined in the DEFAULT profile.

Limiting Profile Idle Time: Example  This statement defines a limit of 2 minutes of idle time for the DEFAULT profile:
ALTER PROFILE default LIMIT IDLE_TIME 2;

This IDLE_TIME limit applies to these users:
- Users who are not explicitly assigned any profile
- Users who are explicitly assigned a profile that does not define an IDLE_TIME limit

This statement defines unlimited idle time for the app_user2 profile:
ALTER PROFILE app_user2 LIMIT IDLE_TIME UNLIMITED;

Any user assigned the app_user2 profile is subsequently permitted unlimited idle time.
ALTER RESOURCE COST

Purpose
Use the ALTER RESOURCE COST statement to specify or change the formula by which Oracle Database calculates the total resource cost used in a session.

Although Oracle Database monitors the use of other resources, only the four resources shown in the syntax can contribute to the total resource cost for a session.

This statement lets you apply weights to the four resources. Oracle Database then applies the weights to the value of these resources that were specified for a profile to establish a formula for calculating total resource cost. You can limit this cost for a session with the COMPOSITE_LIMIT parameter of the CREATE PROFILE statement. If the resource cost of a session exceeds the limit, then Oracle Database aborts the session and returns an error. If you use the ALTER RESOURCE COST statement to change the weight assigned to each resource, then Oracle Database uses these new weights to calculate the total resource cost for all current and subsequent sessions.

See Also: CREATE PROFILE on page 15-77 for information on all resources and on establishing resource limits

Prerequisites
You must have the ALTER RESOURCE COST system privilege.

Syntax

alter_resource_cost ::= alter RESOURCE COST CPU_PER_SESSION CONNECT_TIME LOGICAL_READS_PER_SESSION PRIVATE_SGA integer

Semantics
Oracle Database calculates the total resource cost by first multiplying the amount of each resource used in the session by the weight of the resource, and then summing the products for all four resources. For any session, this cost is limited by the value of the COMPOSITE_LIMIT parameter in the user's profile. Both the products and the total cost are expressed in units called service units.

CPU_PER_SESSION
Use this keyword to apply a weight to the CPU_PER_SESSION resource.

CONNECT_TIME
Use this keyword to apply a weight to the CONNECT_TIME resource.

LOGICAL_READS_PER_SESSION
Use this clause to apply a weight to the LOGICAL_READS_PER_SESSION resource. Logical reads include blocks read from both memory and disk.
PRIVATE_SGA

Use this clause to apply a weight to the PRIVATE_SGA resource. This limit applies only if you are using shared server architecture and allocating private space in the SGA for your session.

integer

Specify the weight of each resource. The weight that you assign to each resource determines how much the use of that resource contributes to the total resource cost. If you do not assign a weight to a resource, then the weight defaults to 0, and use of the resource subsequently does not contribute to the cost. The weights you assign apply to all subsequent sessions in the database.

Examples

Altering Resource Costs: Examples  The following statement assigns weights to the resources CPU_PER_SESSION and CONNECT_TIME:

```sql
ALTER RESOURCE COST
  CPU_PER_SESSION 100
  CONNECT_TIME 1;
```

The weights establish this cost formula for a session:

\[
\text{cost} = (100 \times \text{CPU_PER_SESSION}) + (1 \times \text{CONNECT_TIME})
\]

In this example, the values of CPU_PER_SESSION and CONNECT_TIME are either values in the DEFAULT profile or in the profile of the user of the session.

Because the preceding statement assigns no weight to the resources LOGICAL_READS_PER_SESSION and PRIVATE_SGA, these resources do not appear in the formula.

If a user is assigned a profile with a COMPOSITE_LIMIT value of 500, then a session exceeds this limit whenever cost exceeds 500. For example, a session using 0.04 seconds of CPU time and 101 minutes of elapsed time exceeds the limit. A session using 0.0301 seconds of CPU time and 200 minutes of elapsed time also exceeds the limit.

You can subsequently change the weights with another ALTER RESOURCE statement:

```sql
ALTER RESOURCE COST
  LOGICAL_READS_PER_SESSION 2
  CONNECT_TIME 0;
```

These new weights establish a new cost formula:

\[
\text{cost} = (100 \times \text{CPU_PER_SESSION}) + (2 \times \text{LOGICAL_READ_PER_SECOND})
\]

where the values of CPU_PER_SESSION and LOGICAL_READS_PER_SECOND are either the values in the DEFAULT profile or in the profile of the user of this session.

This ALTER RESOURCE COST statement changes the formula in these ways:

- The statement omits a weight for the CPU_PER_SESSION resource. That resource was already assigned a weight, so the resource remains in the formula with its original weight.
- The statement assigns a weight to the LOGICAL_READS_PER_SESSION resource, so this resource now appears in the formula.
- The statement assigns a weight of 0 to the CONNECT_TIME resource, so this resource no longer appears in the formula.

- The statement omits a weight for the PRIVATE_SGA resource. That resource was not already assigned a weight, so the resource still does not appear in the formula.
ALTER ROLE

Purpose

Use the ALTER ROLE statement to change the authorization needed to enable a role.

See Also:
- CREATE ROLE on page 15-87 for information on creating a role
- SET ROLE on page 19-81 for information on enabling or disabling a role for your session

Prerequisites

You must either have been granted the role with the ADMIN OPTION or have ALTER ANY ROLE system privilege.

Before you alter a role to IDENTIFIED GLOBALLY, you must:
- Revoke all grants of roles identified externally to the role and
- Revoke the grant of the role from all users, roles, and PUBLIC.

The one exception to this rule is that you should not revoke the role from the user who is currently altering the role.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root. To specify CONTAINER = CURRENT, the current container must be a pluggable database (PDB).

Syntax

```
alter_role ::= 
```

Semantics

The keywords, parameters, and clauses in the ALTER ROLE statement all have the same meaning as in the CREATE ROLE statement.

Restriction on Altering a Role  You cannot alter a NOT IDENTIFIED role to any of the IDENTIFIED types if it is granted to another role.

Notes on Altering a Role  The following notes apply when altering a role:
- User sessions in which the role is already enabled are not affected.
- If you change a role identified by password to an application role (with the USING package clause), then password information associated with the role is lost. Oracle
Database will use the new authentication mechanism the next time the role is to be enabled.

- If you have the ALTER ANY ROLE system privilege and you change a role that is IDENTIFIED GLOBALLY to IDENTIFIED BY password, IDENTIFIED EXTERNALLY, or NOT IDENTIFIED, then Oracle Database grants you the altered role with the ADMIN OPTION, as it would have if you had created the role identified nonglobally.

For more information, refer to CREATE ROLE on page 15-87 and to the examples that follow.

Examples

**Changing Role Identification: Example**  The following statement changes the role warehouse_user (created in "Creating a Role: Example" on page 15-89) to NOT IDENTIFIED:

```
ALTER ROLE warehouse_user NOT IDENTIFIED;
```

**Changing a Role Password: Example**  This statement changes the password on the dw_manager role (created in "Creating a Role: Example" on page 15-89) to data:

```
ALTER ROLE dw_manager
  IDENTIFIED BY data;
```

Users granted the dw_manager role must subsequently use the new password data to enable the role.

**Application Roles: Example**  The following example changes the dw_manager role to an application role using the hr.admin package:

```
ALTER ROLE dw_manager IDENTIFIED USING hr.admin;
```
ALTER ROLLBACK SEGMENT

Purpose

Use the ALTER ROLLBACK SEGMENT statement to bring a rollback segment online or offline, change its storage characteristics, or shrink it to an optimal or specified size.

This section assumes that your database is running in rollback undo mode (the UNDO_MANAGEMENT initialization parameter is set to MANUAL or not set at all). If your database is running in automatic undo mode (the UNDO_MANAGEMENT initialization parameter is set to AUTO, which is the default), then user-created rollback segments are irrelevant.

See Also:

- CREATE ROLLBACK SEGMENT on page 15-91 for information on creating a rollback segment
- Oracle Database Reference for information on the UNDO_MANAGEMENT parameter

Prerequisites

You must have the ALTER ROLLBACK SEGMENT system privilege.

Syntax

```
alter.rollback.segment ::= 

ALTER ROLLBACK SEGMENT rollback_segment storage_clause ONLINE OFFLINE 

SHRINK TO size_clause
```

(storage_clause on page 8-48, size_clause::= on page 8-47)

Semantics

rollback_segment

Specify the name of an existing rollback segment.

ONLINE

Specify ONLINE to bring the rollback segment online. When you create a rollback segment, it is initially offline and not available for transactions. This clause brings the
rollback segment online, making it available for transactions by your instance. You can also bring a rollback segment online when you start your instance with the initialization parameter ROLLBACK_SEGMENTS.

**See Also:** "Bringing a Rollback Segment Online: Example" on page 11-62

**OFFLINE**
Specify OFFLINE to take the rollback segment offline.

- If the rollback segment does not contain any information needed to roll back an active transaction, then Oracle Database takes it offline immediately.

- If the rollback segment does contain information for active transactions, then the database makes the rollback segment unavailable for future transactions and takes it offline after all the active transactions are committed or rolled back.

When the rollback segment is offline, it can be brought online by any instance.

To see whether a rollback segment is online or offline, query STATUS column of the data dictionary view DBA_ROLLBACK_SEGS. Online rollback segments have a value of IN_USE. Offline rollback segments have a value of AVAILABLE.

**Restriction on Taking Rollback Segments Offline**
You cannot take the SYSTEM rollback segment offline.

**storage_clause**
Use the storage_clause to change the storage characteristics of the rollback segment.

**Restrictions on Rollback Segment Storage**
You cannot change the value of INITIAL parameter. If the rollback segment is in a locally managed tablespace, then the only storage parameter you can change is OPTIMAL. If the rollback segment is in a dictionary-managed tablespace, then the only storage parameters you can change are NEXT, MINEXTENTS, MAXEXTENTS and OPTIMAL.

**See Also:** storage_clause on page 8-48 for syntax and additional information

**SHRINK Clause**
Specify SHRINK if you want Oracle Database to attempt to shrink the rollback segment to an optimal or specified size. The success and amount of shrinkage depend on the available free space in the rollback segment and how active transactions are holding space in the rollback segment.

If you do not specify TO size_clause, then the size defaults to the OPTIMAL value of the storage_clause of the CREATE ROLLBACK SEGMENT statement that created the rollback segment. If OPTIMAL was not specified, then the size defaults to the MINEXTENTS value of the storage_clause of the CREATE ROLLBACK SEGMENT statement.

Regardless of whether you specify TO size_clause:

- The value to which Oracle Database shrinks the rollback segment is valid for the execution of the statement. Thereafter, the size reverts to the OPTIMAL value of the CREATE ROLLBACK SEGMENT statement.

- The rollback segment cannot shrink to less than two extents.

To determine the actual size of a rollback segment after attempting to shrink it, query the BYTES, BLOCKS, and EXTENTS columns of the DBA_SEGMENTS view.
Restriction on Shrinking Rollback Segments  In an Oracle Real Application Clusters environment, you can shrink only rollback segments that are online to your instance.

See Also:  size_clause on page 8-47 for information on that clause, and "Resizing a Rollback Segment: Example" on page 11-62

Examples

The following examples use the rbs_one rollback segment, which was created in "Creating a Rollback Segment: Example" on page 15-93.

Bringing a Rollback Segment Online: Example  This statement brings the rollback segment rbs_one online:

```
ALTER ROLLBACK SEGMENT rbs_one ONLINE;
```

Resizing a Rollback Segment: Example  This statement shrinks the rollback segment rbs_one:

```
ALTER ROLLBACK SEGMENT rbs_one
      SHRINK TO 100M;
```
ALTER SEQUENCE

Purpose

Use the \texttt{ALTER SEQUENCE} statement to change the increment, minimum and maximum values, cached numbers, and behavior of an existing sequence. This statement affects only future sequence numbers.

\textbf{See Also:} \texttt{CREATE SEQUENCE} on page 15-96 for additional information on sequences

Prerequisites

The sequence must be in your own schema, or you must have the \texttt{ALTER} object privilege on the sequence, or you must have the \texttt{ALTER ANY SEQUENCE} system privilege.

Syntax

\begin{verbatim}
alter_sequence::=
\end{verbatim}

Semantics

The keywords and parameters in this statement serve the same purposes they serve when you create a sequence.

- To restart the sequence at a different number, you must drop and re-create it.
- If you change the \texttt{INCREMENT BY} value before the first invocation of \texttt{NEXTVAL}, then some sequence numbers will be skipped. Therefore, if you want to retain the original \texttt{START WITH} value, you must drop the sequence and re-create it with the original \texttt{START WITH} value and the new \texttt{INCREMENT BY} value.
If you alter the sequence by specifying the KEEP or NOKEEP clause between runtime and failover of a request, then the original value of NEXTVAL is not retained during replay for Application Continuity for that request.

Oracle Database performs some validations. For example, a new MAXVALUE cannot be imposed that is less than the current sequence number.

See Also: CREATE SEQUENCE on page 15-96 for information on creating a sequence and DROP SEQUENCE on page 18-2 for information on dropping and re-creating a sequence

Examples

Modifying a Sequence: Examples

This statement sets a new maximum value for the customers_seq sequence, which was created in "Creating a Sequence: Example" on page 15-100:

```
ALTER SEQUENCE customers_seq
  MAXVALUE 1500;
```

This statement turns on CYCLE and CACHE for the customers_seq sequence:

```
ALTER SEQUENCE customers_seq
  CYCLE
  CACHE 5;
```
ALTERT SESSION

Purpose

Use the ALTER SESSION statement to set or modify any of the conditions or parameters that affect your connection to the database. The statement stays in effect until you disconnect from the database.

Prerequisites

To enable and disable the SQL trace facility, you must have ALTER SESSION system privilege.

To enable or disable resumable space allocation, you must have the RESUMABLE system privilege.

You do not need any privileges to perform the other operations of this statement unless otherwise indicated.

Syntax

```
alter_session ::= 
```

![Diagram of ALTER SESSION syntax]
**ALTER SESSION**

### alter_session_set_clause::=  

```
  SET
  | parameter_name = parameter_value
  | EDITION = edition_name
  | CONTAINER = container_name
  | ROW ARCHIVAL VISIBILITY = ACTIVE
  | ALL
```

#### Semantics

**ADVISE Clause**

The `ADVISE` clause sends advice to a remote database to force a distributed transaction. The advice appears in the `ADVICE` column of the `DBA_2PC_PENDING` view on the remote database (the values are 'C' for COMMIT, 'R' for ROLLBACK, and ' ' for NOTHING). If the transaction becomes in doubt, then the administrator of that database can use this advice to decide whether to commit or roll back the transaction.

You can send different advice to different remote databases by issuing multiple `ALTER SESSION` statements with the `ADVISE` clause in a single transaction. Each such statement sends advice to the databases referenced in the following statements in the transaction until another such statement is issued.

**See Also:** "Forcing a Distributed Transaction: Example" on page 11-76

**CLOSE DATABASE LINK Clause**

Specify `CLOSE DATABASE LINK` to close the database link `dblink`. When you issue a statement that uses a database link, Oracle Database creates a session for you on the remote database using that link. The connection remains open until you end your local session or until the number of database links for your session exceeds the value of the initialization parameter `OPEN_LINKS`. If you want to reduce the network overhead associated with keeping the link open, then use this clause to close the link explicitly if you do not plan to use it again in your session.

**See Also:** Closing a Database Link: Example on page 11-77

**ENABLE | DISABLE COMMIT IN PROCEDURE**

Procedures and stored functions written in PL/SQL can issue `COMMIT` and `ROLLBACK` statements. If your application would be disrupted by a `COMMIT` or `ROLLBACK` statement not issued directly by the application itself, then specify `DISABLE COMMIT IN PROCEDURE` clause to prevent procedures and stored functions called during your session from issuing these statements.

You can subsequently allow procedures and stored functions to issue `COMMIT` and `ROLLBACK` statements in your session by issuing the `ENABLE COMMIT IN PROCEDURE`. Some applications automatically prohibit `COMMIT` and `ROLLBACK` statements in procedures and stored functions. Refer to your application documentation for more information.
ENABLE | DISABLE GUARD
The security_clause of ALTER DATABASE lets you prevent anyone other than the SYS user from making any changes to data or database objects on the primary or standby database. This clause lets you override that setting for the current session.

See Also: security_clause on page 10-69 for more information on the GUARD setting

PARALLEL DML | DDL | QUERY
The PARALLEL parameter determines whether all subsequent DML, DDL, or query statements in the session will be considered for parallel execution. This clause enables you to override the degree of parallelism of tables during the current session without changing the tables themselves. Uncommitted transactions must either be committed or rolled back prior to executing this clause for DML.

See Also: "Enabling Parallel DML: Example" on page 11-76

ENABLE Clause
Specify ENABLE to execute subsequent statements in the session in parallel. This is the default for DDL and query statements.

- DML: DML statements are executed in parallel mode if a parallel hint or a parallel clause is specified.
- DDL: DDL statements are executed in parallel mode if a parallel clause is specified.
- QUERY: Queries are executed in parallel mode if a parallel hint or a parallel clause is specified.

Restriction on the ENABLE clause  You cannot specify the optional PARALLEL integer with ENABLE.

DISABLE Clause
Specify DISABLE to execute subsequent statements in the session serially. This is the default for DML statements.

- DML: DML statements are executed serially.
- DDL: DDL statements are executed serially.
- QUERY: Queries are executed serially.

Restriction on the DISABLE clause  You cannot specify the optional PARALLEL integer with DISABLE.

FORCE Clause
FORCE forces parallel execution of subsequent statements in the session. If no parallel clause or hint is specified, then a default degree of parallelism is used. This clause overrides any parallel_clause specified in subsequent statements in the session but is overridden by a parallel hint.

- DML: Provided no parallel DML restrictions are violated, subsequent DML statements in the session are executed with the default degree of parallelism, unless a degree is specified in this clause.
- DDL: Subsequent DDL statements in the session are executed with the default degree of parallelism, unless a degree is specified in this clause. Resulting database objects will have associated with them the prevailing degree of parallelism.
Specifying `FORCE DDL` automatically causes all tables created in this session to be created with a default level of parallelism. The effect is the same as if you had specified the `parallel_clause` (with the default degree) in the `CREATE TABLE` statement.

- **QUERY**: Subsequent queries are executed with the default degree of parallelism, unless a degree is specified in this clause.

**PARALLEL `integer`** Specify an integer to explicitly specify a degree of parallelism:

- For `FORCE DDL`, the degree overrides any parallel clause in subsequent DDL statements.
- For `FORCE DML` and `QUERY`, the degree overrides the degree currently stored for the table in the data dictionary.
- A degree specified in a statement through a hint will override the degree being forced.

The following types of DML operations are not parallelized regardless of this clause:

- Operations on cluster tables
- Operations with embedded functions that either write or read database or package states
- Operations on tables with triggers that could fire
- Operations on tables or schema objects containing object types, or `LONG` or `LOB` data types

**RESUMABLE Clauses**
These clauses let you enable and disable resumable space allocation. This feature allows an operation to be suspended in the event of an out-of-space error condition and to resume automatically from the point of interruption when the error condition is fixed.

---

**Note**: Resumable space allocation is fully supported for operations on locally managed tablespaces. Some restrictions apply if you are using dictionary-managed tablespaces. For information on these restrictions, refer to *Oracle Database Administrator’s Guide*.

---

**ENABLE RESUMABLE**
This clause enables resumable space allocation for the session.

**TIMEOUT** `TIMEOUT` lets you specify (in seconds) the time during which an operation can remain suspended while waiting for the error condition to be fixed. If the error condition is not fixed within the `TIMEOUT` period, then Oracle Database aborts the suspended operation.

**NAME** `NAME` lets you specify a user-defined text string to help users identify the statements issued during the session while the session is in resumable mode. Oracle Database inserts the text string into the `USER_RESUMABLE` and `DBA_RESUMABLE` data dictionary views. If you do not specify `NAME`, then Oracle Database inserts the default string ‘User username(userid), Session sessionid, Instance instanceid’.

**See Also**: *Oracle Database Reference* for information on the data dictionary views
DISABLE RESUMABLE
This clause disables resumable space allocation for the session.

SYNC WITH PRIMARY
Use this clause to synchronize redo apply on a physical standby database with the primary database. An ALTER SESSION statement with this clause blocks until redo apply has applied all redo data received by the standby at the time the statement is issued. This clause returns an error, and synchronization does not occur, if the redo transport state for the standby database is not SYNCHRONIZED or if redo apply is not active.

See Also: Oracle Data Guard Concepts and Administration for more information on this session parameter

alter_session_set_clause
Use the alter_session_set_clause to set initialization parameter values or to set an edition for the current session.

Initialization Parameters
You can set two types of parameters using this clause:

- Initialization parameters that are dynamic in the scope of the ALTER SESSION statement (listed in "Initialization Parameters and ALTER SESSION" on page 11-71)
- Session parameters (listed in "Session Parameters and ALTER SESSION" on page 11-72)

You can set values for multiple parameters in the same alter_session_set_clause.

EDITION
Specify EDITION = edition to set the specified edition as the edition in the database session. You must have the USE object privilege on edition, edition must already have been created, and it must be USABLE.

When this statement is successful, the database discards PL/SQL package state corresponding to editionable packages but retains package state corresponding to packages that are not editionable.

You can also set the edition for the current session at startup with the EDITION parameter of the SQL*Plus CONNECT command. However, you cannot specify an ALTER SESSION SET EDITION statement in a recursive SQL or PL/SQL block.

You can determine the edition in use by the current session with the following query:

SELECT SYS_CONTEXT('USERENV', 'CURRENT_EDITION_NAME') FROM DUAL;

See Also: CREATE EDITION on page 14-64 for more information on editions and Oracle Database PL/SQL Language Reference for information on how editions are designated as USABLE

CONTAINER
Use this clause in a multitenant container database (CDB) to switch to the container specified by container_name.

To use this clause, you must be a common user with the SET CONTAINER privilege, either granted commonly or granted locally in container_name.

For container_name, specify one of the following:

- CDB$ROOT to switch to the root
- PDB$SEED to switch to the seed
A pluggable database (PDB) name to switch to that PDB. You can view the names of the PDBs in a CDB by querying the `DBA_PDBS` view.

You can determine the container to which the current session is connected by using the SQL*Plus `SHOW CON_NAME` command or with the following SQL query:

```
SELECT SYS_CONTEXT('USERENV', 'CON_NAME') FROM DUAL;
```

See Also: *Oracle Database Administrator’s Guide* for more information on switching to a container

**ROW ARCHIVAL VISIBILITY**  Use this clause to configure row archival visibility for the session. This clause lets you implement In-Database Archiving, which allows you to designate table rows as active or archived. You can then perform queries on only the active rows within the table.

- If you specify `ACTIVE`, then the database will consider only active rows when performing queries on tables that are enabled for row archival. This is the default.
- If you specify `ALL`, then the database will consider all rows when performing queries on tables that are enabled for row archival.

This clause has no effect on queries on tables that are not enabled for row archival.

See Also:
- The `CREATE TABLE ROW ARCHIVAL` clause on page 16-85 to learn how to enable a new table for row archival
- The `ALTER TABLE [NO] ROW ARCHIVAL` clause on page 12-52 to learn how to enable or disable an existing table for row archival
- *Oracle Database VLDB and Partitioning Guide* for more information on In-Database Archiving
Initialization Parameters and ALTER SESSION

Some initialization parameter are dynamic in the scope of ALTER SESSION. When you set these parameters using ALTER SESSION, the value you set persists only for the duration of the current session. To determine whether a parameter can be altered using an ALTER SESSION statement, query the `ISSES_MODIFIABLE` column of the `V$PARAMETER` dynamic performance view.

---

**Caution:** Before changing the values of initialization parameters, refer to their full description in *Oracle Database Reference*.

---

A number of parameters that can be set using ALTER SESSION are not initialization parameters. You can set them only with ALTER SESSION, not in an initialization parameter file. Those session parameters are described in “Session Parameters and ALTER SESSION” on page 11-72.
Session Parameters and ALTER SESSION

The following parameters are session parameters only, not initialization parameters:

**CONSTRAINT[S]**

Syntax:

\[
\text{CONSTR}A\text{IN[T][S]} = \{ \text{IMMEDIATE} \mid \text{DEFERRED} \mid \text{DEFAULT} \}
\]

The `CONSTRAINT[S]` parameter determines when conditions specified by a deferrable constraint are enforced.

- **IMMEDIATE** indicates that the conditions specified by the deferrable constraint are checked immediately after each DML statement. This setting is equivalent to issuing the `SET CONSTRAINTS ALL IMMEDIATE` statement at the beginning of each transaction in your session.
- **DEFERRED** indicates that the conditions specified by the deferrable constraint are checked when the transaction is committed. This setting is equivalent to issuing the `SET CONSTRAINTS ALL DEFERRED` statement at the beginning of each transaction in your session.
- **DEFAULT** restores all constraints at the beginning of each transaction to their initial state of DEFERRED or IMMEDIATE.

**CURRENT_SCHEMA**

Syntax:

\[
\text{CURRENT_SCHEMA} = \text{schema}
\]

The `CURRENT_SCHEMA` parameter changes the current schema of the session to the specified schema. Subsequent unqualified references to schema objects during the session will resolve to objects in the specified schema. The setting persists for the duration of the session or until you issue another `ALTER SESSION SET CURRENT_SCHEMA` statement.

This setting offers a convenient way to perform operations on objects in a schema other than that of the current user without having to qualify the objects with the schema name. This setting changes the current schema, but it does not change the session user or the current user, nor does it give the session user any additional system or object privileges for the session.

**ERROR_ON_OVERLAP_TIME**

Syntax:

\[
\text{ERROR_ON_OVERLAP_TIME} = (\text{TRUE} \mid \text{FALSE})
\]

The `ERROR_ON_OVERLAP_TIME` parameter determines how Oracle Database should handle an ambiguous boundary datetime value—a case in which it is not clear whether the datetime is in standard or daylight saving time.

- Specify **TRUE** to return an error for the ambiguous overlap timestamp.
- Specify **FALSE** to default the ambiguous overlap timestamp to the standard time. This is the default.
Refer to "Support for Daylight Saving Times" on page 2-24 for more information on boundary datetime values.

**FLAGGER**

**Syntax:**

```
FLAGGER = { ENTRY | OFF }
```

The `FLAGGER` parameter specifies FIPS flagging (as specified in Federal Information Processing Standard 127-2), which causes an error message to be generated when a SQL statement issued is an extension of the Entry Level of SQL-92 (officially, ANSI X3.135-1992, a standard that is now superseded by SQL:2008). `FLAGGER` is a session parameter only, not an initialization parameter.

After flagging is set in a session, a subsequent `ALTER SESSION SET FLAGGER` statement will work, but generates the message, ORA-00097. This allows FIPS flagging to be altered without disconnecting the session. `OFF` turns off flagging.

**See Also:** Appendix C, "Oracle and Standard SQL", for more information about Oracle compliance with current ANSI SQL standards

**INSTANCE**

**Syntax:**

```
INSTANCE = integer
```

Setting the `INSTANCE` parameter lets you access another instance as if you were connected to your own instance. `INSTANCE` is a session parameter only, not an initialization parameter. In an Oracle Real Application Clusters (Oracle RAC) environment, each Oracle RAC instance retains static or dynamic ownership of disk space for optimal DML performance based on the setting of this parameter.

**ISOLATION_LEVEL**

**Syntax:**

```
ISOLATION_LEVEL = {SERIALIZABLE | READ COMMITTED}
```

The `ISOLATION_LEVEL` parameter specifies how transactions containing database modifications are handled. `ISOLATION_LEVEL` is a session parameter only, not an initialization parameter.

- `SERIALIZABLE` indicates that transactions in the session use the serializable transaction isolation mode as specified in the SQL standard. If a serializable transaction attempts to execute a DML statement that updates rows currently being updated by another uncommitted transaction at the start of the serializable transaction, then the DML statement fails. A serializable transaction can see its own updates.
- `READ COMMITTED` indicates that transactions in the session will use the default Oracle Database transaction behavior. If the transaction contains DML that requires row locks held by another transaction, then the DML statement will wait until the row locks are released.
**Note:** Serializable transactions do not work with deferred segment creation or interval partitioning. Trying to insert data into an empty table with no segment created, or into a partition of an interval partitioned table that does not yet have a segment, causes an error.

---

### STANDBY_MAX_DATA_DELAY

**Syntax:**

\[
\text{STANDBY\_MAX\_DATA\_DELAY} = \begin{cases} 
\text{integer} & | \text{NONE} 
\end{cases}
\]

In an Active Data Guard environment, this session parameter can be used to specify a session-specific apply lag tolerance, measured in seconds, for queries issued by non-administrative users to a physical standby database that is in real-time query mode. This capability allows queries to be safely offloaded from the primary database to a physical standby database, because it is possible to detect if the standby database has become unacceptably stale.

If `STANDBY_MAX_DATA_DELAY` is set to the default value of `NONE`, queries issued to a physical standby database will be executed regardless of the apply lag on that database.

If `STANDBY_MAX_DATA_DELAY` is set to a non-zero value, a query issued to a physical standby database will be executed only if the apply lag is less than or equal to `STANDBY_MAX_DATA_DELAY`. Otherwise, an ORA-3172 error is returned to alert the client that the apply lag is too large.

If `STANDBY_MAX_DATA_DELAY` is set to 0, a query issued to a physical standby database is guaranteed to return the exact same result as if the query were issued on the primary database, unless the standby database is lagging behind the primary database, in which case an ORA-3172 error is returned.

**See Also:** Oracle Data Guard Concepts and Administration for more information on Active Data Guard and using this session parameter

---

### TIME_ZONE

**Syntax:**

\[
\text{TIME\_ZONE} = \begin{cases} 
[+ | -] \text{hh:mi} & | \text{LOCAL} & | \text{DBTIMEZONE} & | \text{time\_zone\_region}
\end{cases}
\]

The `TIME_ZONE` parameter specifies the default local time zone offset or region name for the current SQL session. `TIME_ZONE` is a session parameter only, not an initialization parameter. To determine the time zone of the current session, query the built-in function `SESSIONTIMEZONE` (see `SESSIONTIMEZONE` on page 7-297).

- Specify a format mask (`'[+ | -]hh:mi'`) indicating the hours and minutes before or after UTC (Coordinated Universal Time—formerly Greenwich Mean Time). The valid range for `hh:mi` is -12:00 to +14:00.
- Specify `LOCAL` to set the default local time zone offset of the current SQL session to the original default local time zone offset that was established when the current SQL session was started.
- Specify `DBTIMEZONE` to set the current session time zone to match the value set for the database time zone. If you specify this setting, then the `DBTIMEZONE` function will return the database time zone as a UTC offset or a time zone region, depending on how the database time zone has been set.

- Specify a valid `time_zone_region`. To see a listing of valid time zone region names, query the `TZNAME` column of the `V$TIMEZONE_NAMES` dynamic performance view. If you specify this setting, then the `SESSIONTIMEZONE` function will return the region name.

---

**Note:** Time zone region names are needed by the daylight saving feature. These names are stored in two types of time zone files: one large and one small. One of these files is the default file, depending on your environment and the release of Oracle Database you are using. For more information regarding time zone files and names, see *Oracle Database Globalization Support Guide*.

**See Also:** *Oracle Database Globalization Support Guide* for a complete listing of the time zone region names in both files

---

**USE_PRIVATE_OUTLINES**

**Syntax:**

```
USE_PRIVATE_OUTLINES = { TRUE | FALSE | category_name }
```

The `USE_PRIVATE_OUTLINES` parameter lets you control the use of private outlines. When this parameter is enabled and an outlined SQL statement is issued, the optimizer retrieves the outline from the session private area rather than the public area used when `USE_STORED_OUTLINES` is enabled. If no outline exists in the session private area, then the optimizer will not use an outline to compile the statement. `USE_PRIVATE_OUTLINES` is not an initialization parameter.

- **TRUE** causes the optimizer to use private outlines stored in the `DEFAULT` category when compiling requests.

- **FALSE** specifies that the optimizer should not use stored private outlines. This is the default. If `USE_STORED_OUTLINES` is enabled, then the optimizer will use stored public outlines.

- **category_name** causes the optimizer to use outlines stored in the `category_name` category when compiling requests.

**Restriction on USE_PRIVATE_OUTLINES** You cannot enable this parameter if `USE_STORED_OUTLINES` is enabled.

---

**Note:** You can also set the default client session time zone using the `ORA_SDTZ` environment variable. Refer to *Oracle Database Globalization Support Guide* for more information on this variable.
USE_STORED_OUTLINES

Syntax:

USE_STORED_OUTLINES = { TRUE | FALSE | category_name }

The USE_STORED_OUTLINES parameter determines whether the optimizer will use stored public outlines to generate execution plans. USE_STORED_OUTLINES is not an initialization parameter.

- **TRUE** causes the optimizer to use outlines stored in the DEFAULT category when compiling requests.
- **FALSE** specifies that the optimizer should not use stored outlines. This is the default.
- **category_name** causes the optimizer to use outlines stored in the category_name category when compiling requests.

Restriction on USE_STORED_OUTLINES

You cannot enable this parameter if USE_PRIVATE_OUTLINES is enabled.

Examples

**Enabling Parallel DML: Example**  
Issue the following statement to enable parallel DML mode for the current session:

```
ALTER SESSION ENABLE PARALLEL DML;
```

**Forcing a Distributed Transaction: Example**  
The following transaction inserts an employee record into the employees table on the database identified by the database link remote and deletes an employee record from the employees table on the database identified by local:

```
ALTER SESSION
    ADVISE COMMIT;

INSERT INTO employees@remote
    VALUES (8002, 'Juan', 'Fernandez', 'juanf@example.com', NULL,
            TO_DATE('04-OCT-1992', 'DD-MON-YYYY'), 'SA_CLERK', 3000,
            NULL, 121, 20);

ALTER SESSION
    ADVISE ROLLBACK;

DELETE FROM employees@local
    WHERE employee_id = 8002;

COMMIT;
```

This transaction has two ALTER SESSION statements with the ADVISE clause. If the transaction becomes in doubt, then remote is sent the advice 'COMMIT' by virtue of the

---

**Note:** Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. Refer to Oracle Database SQL Tuning Guide for more information about SQL plan management.
first ALTER SESSION statement and local is sent the advice 'ROLLBACK' by virtue of the second statement.

**Closing a Database Link: Example**  
This statement updates the jobs table on the local database using a database link, commits the transaction, and explicitly closes the database link:

```
UPDATE jobs@local SET min_salary = 3000
    WHERE job_id = 'SH_CLERK';

COMMIT;

ALTER SESSION
    CLOSE DATABASE LINK local;
```

**Changing the Date Format Dynamically: Example**  
The following statement dynamically changes the default date format for your session to 'YYYY MM DD-HH24:MI:SS':

```
ALTER SESSION
    SET NLS_DATE_FORMAT = 'YYYY MM DD HH24:MI:SS';
```

Oracle Database uses the new default date format:

```
SELECT TO_CHAR(SYSDATE) FROM DUAL;
```

```
TODAY
-------------------
2001 04 12 12:30:38
```

**Changing the Date Language Dynamically: Example**  
The following statement changes the language for date format elements to French:

```
ALTER SESSION
    SET NLS_DATE_LANGUAGE = French;

SELECT TO_CHAR(SYSDATE, 'Day DD Month YYYY') FROM DUAL;
```

```
TODAY
---------------------------
Jeudi    12 Avril     2001
```

**Changing the ISO Currency: Example**  
The following statement dynamically changes the ISO currency symbol to the ISO currency symbol for the territory America:

```
ALTER SESSION
    SET NLS_ISO_CURRENCY = America;

SELECT TO_CHAR( SUM(salary), 'C999G999D99') FROM employees;
```

```
TOTAL
------------------
USD694,900.00
```

**Changing the Decimal Character and Group Separator: Example**  
The following statement dynamically changes the decimal character to comma (,) and the group separator to period (.):
ALTER SESSION SET NLS_NUMERIC_CHARACTERS = ','; 

Oracle Database returns these new characters when you use their number format elements:

ALTER SESSION SET NLS_CURRENCY = 'FF';

SELECT TO_CHAR(SUM(salary), 'L999G999D99') Total FROM employees;

TOTAL
---------------------
FF694.900,00

Changing the NLS Currency: Example  The following statement dynamically changes the local currency symbol to 'DM':

ALTER SESSION
  SET NLS_CURRENCY = 'DM';

SELECT TO_CHAR(SUM(salary), 'L999G999D99') Total
  FROM employees;

TOTAL
---------------------
DM694.900,00

Changing the NLS Language: Example  The following statement dynamically changes to French the language in which error messages are displayed:

ALTER SESSION
  SET NLS_LANGUAGE = FRENCH;

Session modifiée.

SELECT * FROM DMP;

ORA-00942: Table ou vue inexistante

Changing the Linguistic Sort Sequence: Example  The following statement dynamically changes the linguistic sort sequence to Spanish:

ALTER SESSION
  SET NLS_SORT = XSpanish;

Oracle Database sorts character values based on their position in the Spanish linguistic sort sequence.

Enabling Query Rewrite: Example  This statement enables query rewrite in the current session for all materialized views that have not been explicitly disabled:

ALTER SESSION
  SET QUERY_REWRITE_ENABLED = TRUE;
ALTER SYNONYM

Purpose
Use the ALTER SYNONYM statement to modify an existing synonym.

Prerequisites
To modify a private synonym in another user’s schema, you must have the CREATE ANY SYNONYM and DROP ANY SYNONYM system privileges.

To modify a PUBLIC synonym, you must have the CREATE PUBLIC SYNONYM and DROP PUBLIC SYNONYM system privileges.

Syntax

\[alter\_synonym::=\]

```
ALTER PUBLIC SYNONYM [schema] synonym [EDITIONABLE | NONEDITIONABLE] [COMPILE]
```

Semantics

PUBLIC
Specify PUBLIC if synonym is a public synonym. You cannot use this clause to change a public synonym to a private synonym, or vice versa.

schema
Specify the schema containing the synonym. If you omit schema, then Oracle Database assumes the synonym is in your own schema.

synonym
Specify the name of the synonym to be altered.

EDITIONABLE | NONEDITIONABLE
Use these clauses to specify whether the synonym becomes an editioned or noneditioned object if editioning is later enabled for the schema object type SYNONYM in schema. The default is EDITIONABLE. For information about altering editioned and noneditioned objects, see Oracle Database Development Guide.

Restriction on EDITIONABLE | NONEDITIONABLE You cannot specify these clauses for a public synonym because editioning is always enabled for the object type SYNONYM in the PUBLIC schema.

COMPILE
Use this clause to compile synonym. A synonym places a dependency on its target object and becomes invalid if the target object is changed or dropped. When you compile an invalid synonym, it becomes valid again.
Notes: You can determine if a synonym is valid or invalid by querying the STATUS column of the ALL_, DBA_, and USER_OBJECTS data dictionary views.

Examples

The following examples modify synonyms that were created in the CREATE SYNONYM "Examples" on page 16-4.

The following statement compiles synonym offices:

ALTER SYNONYM offices COMPILE;

The following statement compiles public synonym emp_table:

ALTER PUBLIC SYNONYM emp_table COMPILE;

The following statement causes synonym offices to remain a noneditioned object if editioning is later enabled for schema object type SYNONYM in the schema that contains the synonym offices:

ALTER SYNONYM offices NONEDITIONABLE;
ALTER SYSTEM

Purpose

Use the ALTER SYSTEM statement to dynamically alter your Oracle Database instance. The settings stay in effect as long as the database is mounted.

When you use the ALTER SYSTEM statement in a multitenant container database (CDB), you can specify some clauses to alter the CDB as a whole and other clauses to alter a specific pluggable database (PDB).

See Also: Oracle Database Administrator’s Guide for complete information on using the ALTER SYSTEM statement in a CDB

Prerequisites

To specify the RELOCATE CLIENT clause, you must be authenticated AS SYSASM.

To specify all other clauses, you must have the ALTER SYSTEM system privilege.

If you are connected to a CDB:

- To alter the CDB as a whole, the current container must be the root and you must have the commonly granted ALTER SYSTEM privilege.
- To alter a PDB, the current container must be the PDB and you must have the ALTER SYSTEM privilege, either granted commonly or granted locally in the PDB.

**Semantics**

**archive\_log\_clause**

The *archive\_log\_clause* manually archives redo log files or enables or disables automatic archiving. To use this clause, your instance must have the database mounted. The database can be either open or closed unless otherwise noted.

**INSTANCE Clause**

This clause is relevant only if you are using Oracle Real Application Clusters (Oracle RAC). Specify the name of the instance for which you want the redo log file group to be archived. The instance name is a string of up to 80 characters. Oracle Database automatically determines the thread that is mapped to the specified instance and archives the corresponding redo log file group. If no thread is mapped to the specified instance, then Oracle Database returns an error.

**SEQUENCE Clause**

Specify *SEQUENCE* to manually archive the online redo log file group identified by the log sequence number *integer* in the specified thread. If you omit the *THREAD* parameter, then Oracle Database archives the specified group from the thread assigned to your instance.

**CHANGE Clause**

Specify *CHANGE* to manually archive the online redo log file group containing the redo log entry with the system change number (SCN) specified by *integer* in the specified thread. If the SCN is in the current redo log file group, then Oracle Database performs a log switch. If you omit the *THREAD* parameter, then Oracle Database archives the groups containing this SCN from all enabled threads.

You can use this clause only when your instance has the database open.
CURRENT Clause
Specify CURRENT to manually archive the current redo log file group of the specified thread, forcing a log switch. If you omit the THREAD parameter, then Oracle Database archives all redo log file groups from all enabled threads, including logs previous to current logs. You can specify CURRENT only when the database is open.

NOSWITCH Specify NOSWITCH if you want to manually archive the current redo log file group without forcing a log switch. This setting is used primarily with standby databases to prevent data divergence when the primary database shuts down. Divergence implies the possibility of data loss in case of primary database failure.

You can use the NOSWITCH clause only when your instance has the database mounted but not open. If the database is open, then this operation closes the database automatically. You must then manually shut down the database before you can reopen it.

GROUP Clause
Specify GROUP to manually archive the online redo log file group with the GROUP value specified by integer. You can determine the GROUP value for a redo log file group by querying the dynamic performance view V$LOG. If you specify both the THREAD and GROUP parameters, then the specified redo log file group must be in the specified thread.

LOGFILE Clause
Specify LOGFILE to manually archive the online redo log file group containing the redo log file member identified by 'filename'. If you specify both the THREAD and LOGFILE parameters, then the specified redo log file group must be in the specified thread.

If the database was mounted with a backup control file, then specify USING BACKUP CONTROLFILE to permit archiving of all online logfiles, including the current logfile.

Restriction on the LOGFILE clause You must archive redo log file groups in the order in which they are filled. If you specify a redo log file group for archiving with the LOGFILE parameter, and earlier redo log file groups are not yet archived, then Oracle Database returns an error.

NEXT Clause
Specify NEXT to manually archive the next online redo log file group from the specified thread that is full but has not yet been archived. If you omit the THREAD parameter, then Oracle Database archives the earliest unarchived redo log file group from any enabled thread.

ALL Clause
Specify ALL to manually archive all online redo log file groups from the specified thread that are full but have not been archived. If you omit the THREAD parameter, then Oracle Database archives all full unarchived redo log file groups from all enabled threads.

TO location Clause
Specify TO 'location' to indicate the primary location to which the redo log file groups are archived. The value of this parameter must be a fully specified file location following the conventions of your operating system. If you omit this parameter, then Oracle Database archives the redo log file group to the location specified by the initialization parameters LOG_ARCHIVE_DEST or LOG_ARCHIVE_DEST_n.
checkpoint_clause
Specify CHECKPOINT to explicitly force Oracle Database to perform a checkpoint, ensuring that all changes made by committed transactions are written to data files on disk. You can specify this clause only when your instance has the database open. Oracle Database does not return control to you until the checkpoint is complete.

GLOBAL In an Oracle Real Application Clusters (Oracle RAC) environment, this setting causes Oracle Database to perform a checkpoint for all instances that have opened the database. This is the default.

LOCAL In an Oracle RAC environment, this setting causes Oracle Database to perform a checkpoint only for the thread of redo log file groups for the instance from which you issue the statement.

See Also: "Forcing a Checkpoint: Example" on page 11-101

check_datafiles_clause
In a distributed database system, such as an Oracle RAC environment, this clause updates an instance’s SGA from the database control file to reflect information on all online data files.

- Specify GLOBAL to perform this synchronization for all instances that have opened the database. This is the default.
- Specify LOCAL to perform this synchronization only for the local instance.

Your instance should have the database open.

end_session_clauses
The end_session_clauses give you several ways to end the current session.

DISCONNECT SESSION Clause
Use the DISCONNECT SESSION clause to disconnect the current session by destroying the dedicated server process (or virtual circuit if the connection was made by way of a Shared Server). To use this clause, your instance must have the database open. You must identify the session with both of the following values from the V$SESSION view:

- For integer1, specify the value of the SID column.
- For integer2, specify the value of the SERIAL# column.

If system parameters are appropriately configured, then application failover will take effect.

- The POST_TRANSACTION setting allows ongoing transactions to complete before the session is disconnected. If the session has no ongoing transactions, then this clause has the same effect described for as KILL SESSION.
- The IMMEDIATE setting disconnects the session and recovers the entire session state immediately, without waiting for ongoing transactions to complete.
  - If you also specify POST_TRANSACTION and the session has ongoing transactions, then the IMMEDIATE keyword is ignored.
  - If you do not specify POST_TRANSACTION, or you specify POST_TRANSACTION but the session has no ongoing transactions, then this clause has the same effect as described for KILL SESSION IMMEDIATE.

See Also: "Disconnecting a Session: Example" on page 11-103
**KILL SESSION Clause**

The **KILL SESSION** clause lets you mark a session as terminated, roll back ongoing transactions, release all session locks, and partially recover session resources. To use this clause, your instance must have the database open. Your session and the session to be terminated must be on the same instance unless you specify `integer3`. You must identify the session with the following values from the `V$SESSION` view:

- For `integer1`, specify the value of the `SID` column.
- For `integer2`, specify the value of the `SERIAL#` column.
- For the optional `integer3`, specify the ID of the instance where the target session to be killed exists. You can find the instance ID by querying the GV$ tables.

If the session is performing some activity that must be completed, such as waiting for a reply from a remote database or rolling back a transaction, then Oracle Database waits for this activity to complete, marks the session as terminated, and then returns control to you. If the waiting lasts a minute, then Oracle Database marks the session to be terminated and returns control to you with a message that the session is marked to be terminated. The PMON background process then marks the session as terminated when the activity is complete.

Whether or not the session has an ongoing transaction, Oracle Database does not recover the entire session state until the session user issues a request to the session and receives a message that the session has been terminated.

**See Also:** "Terminating a Session: Example" on page 11-103

**IMMEDIATE** Specify IMMEDIATE to instruct Oracle Database to roll back ongoing transactions, release all session locks, recover the entire session state, and return control to you immediately.

**NOREPLAY** This clause is valid if you are using Application Continuity. When connected to a service with Application Continuity enabled (that is, `FAILOVER_TYPE = TRANSACTION`), the session is recovered after the session fails or is killed. If you do not want to recover a session after it is terminated, then specify NOREPLAY.

**distributed_recov_clauses**

The **DISTRIBUTED RECOVERY** clause lets you enable or disable distributed recovery. To use this clause, your instance must have the database open.

**ENABLE** Specify ENABLE to enable distributed recovery. In a single-process environment, you must use this clause to initiate distributed recovery.

You may need to issue the `ENABLE DISTRIBUTED RECOVERY` statement more than once to recover an in-doubt transaction if the remote node involved in the transaction is not accessible. In-doubt transactions appear in the data dictionary view `DBA_2PC_PENDING`.

**See Also:** "Enabling Distributed Recovery: Example" on page 11-103

**DISABLE** Specify DISABLE to disable distributed recovery.

**FLUSH SHARED_POOL Clause**

The **FLUSH SHARED_POOL** clause lets you clear data from the shared pool in the system global area (SGA). The shared pool stores:

- Cached data dictionary information and
• Shared SQL and PL/SQL areas for SQL statements, stored procedures, function, packages, and triggers.

This statement does not clear global application context information, nor does it clear shared SQL and PL/SQL areas for items that are currently being executed. You can use this clause regardless of whether your instance has the database dismounted or mounted, open or closed.

See Also: "Clearing the Shared Pool: Example" on page 11-101

FLUSH GLOBAL CONTEXT Clause
The FLUSH GLOBAL CONTEXT clause lets you flush all global application context information from the shared pool in the system global area (SGA). You can use this clause regardless of whether your instance has the database dismounted or mounted, open or closed.

FLUSH BUFFER_CACHE Clause
The FLUSH BUFFER_CACHE clause lets you clear all data from the buffer cache in the system global area (SGA), including the KEEP, RECYCLE, and DEFAULT buffer pools.

Caution: This clause is intended for use only on a test database. Do not use this clause on a production database, because as a result of this statement, subsequent queries will have no hits, only misses.

This clause is useful if you need to measure the performance of rewritten queries or a suite of queries from identical starting points.

FLUSH REDO Clause
Use the FLUSH REDO clause to flush redo data from a primary database to a standby database and to optionally wait for the flushed redo data to be applied to a physical or logical standby database.

This clause can allow a failover to be performed on the target standby database without data loss, even if the primary database is not in a zero data loss data protection mode, provided that all redo data that has been generated by the primary database can be flushed to the standby database.

The FLUSH REDO clause must be issued on a mounted, but not open, primary database.

target_db_name
For target_db_name, specify the DB_UNIQUE_NAME of the standby database that is to receive the redo data flushed from the primary database.

The value of the LOG_ARCHIVE_DEST_n database initialization parameter that corresponds to the target standby database must contain the DB_UNIQUE_NAME attribute, and the value of that attribute must match the DB_UNIQUE_NAME of the target standby database.

NO CONFIRM APPLY
If you specify this clause, then the ALTER SYSTEM statement will not complete until the standby database has received all of the flushed redo data. You must specify this clause if the target standby database is a snapshot standby database.
CONFIRM APPLY
If you specify this clause, then the ALTER SYSTEM statement will not complete until the target standby database has received and applied all flushed redo data. This is the default behavior unless you specify NO CONFIRM APPLY. You cannot specify this clause if the target standby database is a snapshot standby database.

See Also: Oracle Data Guard Concepts and Administration for more information about the FLUSH REDO clause and failovers

SWITCH LOGFILE Clause
The SWITCH LOGFILE clause lets you explicitly force Oracle Database to begin writing to a new redo log file group, regardless of whether the files in the current redo log file group are full. When you force a log switch, Oracle Database begins to perform a checkpoint but returns control to you immediately rather than when the checkpoint is complete. To use this clause, your instance must have the database open.

See Also: "Forcing a Log Switch: Example" on page 11-103

SUSPEND | RESUME
The SUSPEND clause lets you suspend all I/O (data file, control file, and file header) as well as queries, in all instances, enabling you to make copies of the database without having to handle ongoing transactions.

Restrictions on SUSPEND and RESUME  SUSPEND and RESUME are subject to the following restrictions:

- Do not use this clause unless you have put the database tablespaces in hot backup mode.
- Do not terminate the session that issued the ALTER SYSTEM SUSPEND statement. An attempt to reconnect while the system is suspended may fail because of recursive SQL that is running during the SYS login.
- If you start a new instance while the system is suspended, then that new instance will not be suspended.

The RESUME clause lets you make the database available once again for queries and I/O.

QUIESCE clauses
Use the QUIESCE RESTRICTED and UNQUIESCE clauses to put the database in and take it out of the quiesced state. This state enables database administrators to perform administrative operations that cannot be safely performed in the presence of concurrent transactions, queries, or PL/SQL operations.

Note: The QUIESCE RESTRICTED clause is valid only if the Database Resource Manager is installed and only if the Resource Manager has been on continuously since database startup in any instances that have opened the database.

If multiple QUIESCE RESTRICTED or UNQUIESCE statements issue at the same time from different sessions or instances, then all but one will receive an error.
**QUIESCE RESTRICTED**

Specify **QUIESCE RESTRICTED** to put the database in the quiesced state. For all instances with the database open, this clause has the following effect:

- Oracle Database instructs the Database Resource Manager in all instances to prevent all inactive sessions (other than **SYS** and **SYSTEM**) from becoming active. No user other than **SYS** and **SYSTEM** can start a new transaction, a new query, a new fetch, or a new PL/SQL operation.

- Oracle Database waits for all existing transactions in all instances that were initiated by a user other than **SYS** or **SYSTEM** to finish (either commit or abort). Oracle Database also waits for all running queries, fetches, and PL/SQL procedures in all instances that were initiated by users other than **SYS** or **SYSTEM** and that are not inside transactions to finish. If a query is carried out by multiple successive OCI fetches, then Oracle Database does not wait for all fetches to finish. It waits for the current fetch to finish and then blocks the next fetch. Oracle Database also waits for all sessions (other than those of **SYS** or **SYSTEM**) that hold any shared resources (such as enqueues) to release those resources. After all these operations finish, Oracle Database places the database into quiesced state and finishes executing the **QUIESCE RESTRICTED** statement.

- If an instance is running in shared server mode, then Oracle Database instructs the Database Resource Manager to block logins (other than **SYS** or **SYSTEM**) on that instance. If an instance is running in non-shared-server mode, then Oracle Database does not impose any restrictions on user logins in that instance.

During the quiesced state, you cannot change the Resource Manager plan in any instance.

**UNQUIESCE**

Specify **UNQUIESCE** to take the database out of quiesced state. Doing so permits transactions, queries, fetches, and PL/SQL procedures that were initiated by users other than **SYS** or **SYSTEM** to be undertaken once again. The **UNQUIESCE** statement does not have to originate in the same session that issued the **QUIESCE RESTRICTED** statement.

**rolling_migration_clauses**

Use these clauses in a clustered Oracle Automatic Storage Management (Oracle ASM) environment to migrate one node at a time to a different Oracle ASM version without affecting the overall availability of the Oracle ASM cluster or the database clusters using Oracle ASM for storage.

**START ROLLING MIGRATION**

When starting rolling upgrade, for **ASM_version**, you must specify the following string:

'\<version_num>, <release_num>, <update_num>,<port_release_num>,<port_update_num>'

**ASM_version** must be equal to or greater than 11.1.0.0.0. The surrounding single quotation marks are required. Oracle ASM first verifies that the current release is compatible for migration to the specified release, and then goes into limited functionality mode. Oracle ASM then determines whether any rebalance operations are under way anywhere in the cluster. If there are any such operations, then the statement fails and must be reissued after the rebalance operations are complete.

Rolling upgrade mode is a cluster-wide in-memory persistent state. The cluster continues to be in this state until there is at least one Oracle ASM instance running in the cluster. Any new instance joining the cluster switches to migration mode.
immediately upon startup. If all the instances in the cluster terminate, then subsequent startup of any Oracle ASM instance will not be in rolling upgrade mode until you reissue this statement to restart rolling upgrade of the Oracle ASM instances.

**STOP ROLLING MIGRATION** Use this clause to stop rolling upgrade and bring the cluster back into normal operation. Specify this clause only after all instances in the cluster have migrated to the same software version. The statement will fail if the cluster is not in rolling upgrade mode.

When you specify this clause, the Oracle ASM instance validates that all the members of the cluster are at the same software version, takes the instance out of rolling upgrade mode, and returns to full functionality of the Oracle ASM cluster. If any rebalance operations are pending because disks have gone offline, then those operations are restarted if the `ASM_POWER_LIMIT` parameter would not be violated by such a restart.

**See Also:** *Oracle Automatic Storage Management Administrator’s Guide* for more information about rolling upgrade

**rolling_patch_clauses**

Use these clauses in a clustered Oracle Automatic Storage Management (Oracle ASM) environment to update one node at a time to the latest patch level without affecting the overall availability of the Oracle ASM cluster or the database clusters using Oracle ASM for storage.

**START ROLLING PATCH** Use this clause to start the rolling patch operation. Oracle ASM first verifies that all live nodes in the cluster are at the same version, and then goes into rolling patch mode, which is a cluster-wide in-memory persistent state. The cluster continues to be in this state until all live nodes have been patched to the latest patch level.

Any nodes that are down during this operation are not patched. This does not affect the success of the rolling patch operation. However, you must patch these nodes before they are started. Otherwise, they will not be allowed to join the cluster.

**STOP ROLLING PATCH** use this clause to stop the rolling patch operation and bring the cluster back into normal operation. Specify this clause only after all live nodes in the cluster have been patched to the latest patch level. The statement will fail if the cluster is not in rolling patch mode.

When you specify this clause, the Oracle ASM instance validates that all members of the cluster are at the same patch level, takes the instance out of rolling patch mode, and returns full functionality of the Oracle ASM cluster. If any members of the cluster are not at the latest patch level, then this operation fails and the cluster goes into limited functionality mode.

The following queries display information about rolling patches. In order to run these queries, you must be connected to the Oracle ASM instance in the Grid home, and the Grid Infrastructure home must be configured with the Oracle Clusterware option for an Oracle RAC environment.

- You can determine whether a cluster is in rolling patch mode with the following query:
  
  ```sql
  SELECT SYS_CONTEXT('SYS_CLUSTER_PROPERTIES', 'CLUSTER_STATE') FROM DUAL;
  ```

- You can determine the patch level of a cluster with the following query:
  
  ```sql
  SELECT SYS_CONTEXT('SYS_CLUSTER_PROPERTIES', 'CURRENT_PATCHLVL') FROM DUAL;
  ```
You can display a list of patches applied on the Oracle ASM instance, by querying the V$PATCHES dynamic performance view. Refer to Oracle Database Reference for more information.

**See Also:** Oracle Automatic Storage Management Administrator’s Guide for more information about rolling patches

**security_clauses**
The security_clauses let you control access to the instance. They also allow you to enable or disable access to the encrypted data in the instance.

**RESTRICTED SESSION**
The RESTRICTED SESSION clause lets you restrict logon to Oracle Database. You can use this clause regardless of whether your instance has the database dismounted or mounted, open or closed.

- Specify **ENABLE** to allow only users with RESTRICTED SESSION system privilege to log on to Oracle Database. Existing sessions are not terminated.
  
  This clause applies only to the current instance. Therefore, in an Oracle RAC environment, authorized users without the RESTRICTED SESSION system privilege can still access the database by way of other instances.

- Specify **DISABLE** to reverse the effect of the **ENABLE RESTRICTED SESSION** clause, allowing all users with CREATE SESSION system privilege to log on to Oracle Database. This is the default.

  **See Also:** "Restricting Sessions: Example" on page 11-101

**SET ENCRYPTION WALLET Clause**
Use this clause to manage database access to the Transparent Data Encryption (TDE) master encryption key. The TDE master encryption key is stored in an external security module, which can be an encryption wallet or Hardware Security Module (HSM).

Although this statement begins with the keyword ALTER, an ALTER SYSTEM SET ENCRYPTION WALLET statement is not a DDL clause. However, you cannot roll back such a statement.

Although this clause begins with the SET keyword, do not confuse it with the alter_system_set_clause on page 11-96, which allows you to use the SET keyword to set the value of initialization parameters. ENCRYPTION WALLET is not an initialization parameter.

**OPEN** When you specify this clause, the database uses the specified password to open the wallet and load the TDE master key into database memory for the duration of the instance, or establish a connection to the HSM in order to send the encrypted table and tablespace keys to the HSM and receive them back decrypted.

- Specify **wallet_password** to retrieve the master encryption key from the encryption wallet. If the wallet is not available or is already open, then the database returns an error. The double quotation marks around **wallet_password** are required.

- Specify **HSM_auth_string** to make the HSM accessible. **HSM_auth_string** is of the form "user_id:password" where:
  
  - **user_id** is the user ID created for the database using the HSM management interface
password is the password created for the user ID using the HSM management interface

The double quotation marks around HSM_auth_string are required

CLOSE  Use this clause to disable encryption and decryption in your database. The wallet_password is required to close an encryption wallet. HSM_auth_string is required to disable access to the HSM. Refer to OPEN on page 11-93 for details on specifying HSM_auth_string.

A password is not required to close an auto-open wallet when only an auto-open wallet is present. The password is required to close an auto-open wallet when both an auto-open wallet and an encryption wallet are open. In this case, using CLOSE with a password will close the auto-open wallet and the encryption wallet.

See Also: Oracle Real Application Clusters Administration and Deployment Guide for information on setting encryption wallets in an Oracle Real Application Clusters (Oracle RAC) environment

set_encryption_key

Use this clause to generate a new TDE master encryption key, if none exists. If there are existing master keys in the HSM or keystore, then this clause rekeys the existing table and tablespace keys, that is, it decrypts all table and tablespace keys with the old master key and reencrypts them with the new master key.

An ALTER SYSTEM SET ENCRYPTION KEY statement is a DDL statement and will automatically commit any pending transactions in the schema.

Although this clause begins with the SET keyword, do not confuse it with the alter_system_set_clause on page 11-96, which allows you to use the SET keyword to set the value of initialization parameters. ENCRYPTION KEY is not an initialization parameter.

IDENTIFIED BY wallet_password  This clause loads the TDE master encryption key from the encryption wallet into memory for access to encrypted data.

The certificate_id is required if you are using PKI asymmetric key pairs as master encryption keys. Specify the integer that identifies the certificate. You can find this value by querying the CERT_ID column of the V$WALLET dynamic performance view. Do not specify certificate_id if you are using symmetric keys, which are the default.

For wallet_password, specify the password used to connect to the security module.

If you specify an invalid certificate_id or wallet_password, then the database returns an error. The double quotation marks around certificate_id and wallet_password are required.

Restriction on IDENTIFIED BY wallet_password  PKI-based master keys, including unified master encryption keys, can only be used with TDE column encryption and an Oracle Wallet, not with HSM.

Note: The use of PKI encryption with Transparent Data Encryption is deprecated. To configure Transparent Data Encryption, use the ADMINISTER KEY MANAGEMENT statement on page 10-5. See Oracle Database Advanced Security Guide for more information.
**IDENTIFIED BY HSM_auth_string**  This clause creates a master encryption key that will be stored inside the HSM. The master encryption key is used to encrypt or decrypt table keys inside the HSM.

*HSM_auth_string* is of the form "user_id:password" where:

- **user_id** is the user ID created for the database using the HSM management interface
- **password** is the password created for the user ID using the HSM management interface

The double quotation marks around *HSM_auth_string* are required.

If you are already using Transparent Data Encryption with an Oracle Wallet and you would like to migrate to an HSM, then specify the `MIGRATE USING wallet_password` clause. This decrypts the existing table and tablespace keys, and then reencrypts them with the newly created, HSM-based, master encryption key. Note that the wallet is still in use after you migrate to an HSM, because it may contain master encryption keys that were used for export files, RMAN backups, or encrypted data in temporary or undo tablespaces or redo log files. After migrating, perform one of the following steps:

- Change the wallet password to the *HSM_auth_string* using Oracle Wallet Manager or the `orapki` command-line tool.
- Create a local auto-open wallet from the encryption wallet and either rename the encryption wallet, or move it out of the directory specified in `ENCRYPTION_WALLET_LOCATION` in `sqlnet.ora`. Do not delete the encryption wallet and do not forget the wallet password.

**See Also:**

- Oracle Database Advanced Security Guide for more information on using Transparent Data Encryption
- The description of the CREATE TABLE "encryption_spec" on page 16-35 for information on using that feature to encrypt table columns
- "Establishing a Wallet and Encryption Key: Examples" on page 11-101

**shutdown_dispatcher_clause**

The `SHUTDOWN` clause is relevant only if your system is using the shared server architecture of Oracle Database. It shuts down a dispatcher identified by *dispatcher_name*.

---

**Note:** Do not confuse this clause with the SQL*Plus command `SHUTDOWN`, which is used to shut down the entire database.

---

The *dispatcher_name* must be a string of the form 'Dxxx', where *xxx* indicates the number of the dispatcher. For a listing of dispatcher names, query the `NAME` column of the `V$DISPATCHER` dynamic performance view.

- If you specify `IMMEDIATE`, then the dispatcher stops accepting new connections immediately and Oracle Database terminates all existing connections through that dispatcher. After all sessions are cleaned up, the dispatcher process shuts down.
If you do not specify `IMMEDIATE`, then the dispatcher stops accepting new connections immediately but waits for all its users to disconnect and for all its database links to terminate. Then it shuts down.

REGISTER Clause
Specify `REGISTER` to instruct the `PMON` background process to register the instance with the listeners immediately. If you do not specify this clause, then registration of the instance does not occur until the next time `PMON` executes the discovery routine. As a result, clients may not be able to access the services for as long as 60 seconds after the listener is started.

See Also: `Oracle Database Concepts` and `Oracle Database Net Services Administrator’s Guide` for information on the `PMON` background process and listeners.

`alter_system_set_clause`
You can change the value of many initialization parameters for the current instance, whether you have started the database with a traditional plain-text parameter file (pfile) or with a server parameter file (spfile). `Oracle Database Reference` indicates these parameters in the “Modifiable” category of each parameter description. If you are using a pfile, then the change will persist only for the duration of the instance. However, if you have started the database with an spfile, then you can change the value of the parameter in the spfile itself, so that the new value will occur in subsequent instances.

Oracle Database Reference documents all initialization parameters in full. The parameters fall into three categories:

- **Basic parameters**: Database administrators should be familiar with and consider the setting for all of the basic parameters.
- **Functional categories**: `Oracle Database Reference` also lists the initialization parameters by their functional category.
- **Alphabetical listing**: The Table of Contents of `Oracle Database Reference` contains all initialization parameters in alphabetical order.

The ability to change initialization parameter values depends on whether you have started up the database with a traditional plain-text initialization parameter file (pfile) or with a server parameter file (spfile). To determine whether you can change the value of a particular parameter, query the `ISSYS_MODIFIABLE` column of the `V$PARAMETER` dynamic performance view.

`set_parameter_clause`
When setting a parameter value, you can specify additional settings as follows:

**COMMENT** The `COMMENT` clause lets you associate a comment string with this change in the value of the parameter. The comment string cannot contain control characters or a line break. If you also specify `SPFILE`, then this comment will appear in the parameter file to indicate the most recent change made to this parameter.

**DEFERRED** The `DEFERRED` keyword sets or modifies the value of the parameter for future sessions that connect to the database. Current sessions retain the old value.

You must specify `DEFERRED` if the value of the `ISSYS_MODIFIABLE` column of `V$PARAMETER` for this parameter is `DEFERRED`. If the value of that column is `IMMEDIATE`,
then the **DEFERRED** keyword in this clause is optional. If the value of that column is **FALSE**, then you cannot specify **DEFERRED** in this **ALTER SYSTEM** statement.

**See Also:** *Oracle Database Reference* for information on the **V$PARAMETER** dynamic performance view

**CONTAINER** You can specify the **CONTAINER** clause when you set a parameter value in a CDB. A CDB uses an inheritance model for initialization parameters in which PDBs inherit initialization parameter values from the root. In this case, inheritance means that the value of a particular parameter in the root applies to a particular PDB.

A PDB can override the root’s setting for some parameters, which means that a PDB has an inheritance property for each initialization parameter that is either true or false. The inheritance property is true for a parameter when the PDB inherits the root’s value for the parameter. The inheritance property is false for a parameter when the PDB does not inherit the root’s value for the parameter.

The inheritance property for some parameters must be true. For other parameters, you can change the inheritance property by running the **ALTER SYSTEM** **SET** statement to set the parameter when the current container is the PDB. If **ISPDB_MODIFIABLE** is **TRUE** for an initialization parameter in the **V$SYSTEM_PARAMETER** view, then the inheritance property can be false for the parameter.

- If you specify **CONTAINER = ALL**, then the parameter setting applies to all containers in the CDB, including the root and all of the PDBs. The current container must be the root.

  Specifying **ALL** sets the inheritance property to true for the parameter in all PDBs.

- If you specify **CONTAINER = CURRENT**, then the parameter setting applies only to the current container. When the current container is the root, the parameter setting applies to the root and to any PDB with an inheritance property of true for the parameter.

If you omit this clause, then **CONTAINER = CURRENT** is the default.

**See Also:** *Oracle Database Administrator’s Guide* for more information on modifying parameters in a CDB

**SCOPE** The **SCOPE** clause lets you specify when the change takes effect. The behavior of this clause depends on whether you are connected to a non-CDB, a CDB root, or a PDB.

When you issue the **ALTER SYSTEM** statement while connected to a non-CDB or a CDB root, the scope depends on whether you started up the database using a traditional plain-text parameter file (pfile) or server parameter file (spfile).

- **MEMORY** indicates that the change is made in memory, takes effect immediately, and persists until the database is shut down. If you started up the database using a parameter file (pfile), then this is the only scope you can specify.

- **SPFILE** indicates that the change is made in the server parameter file. The new setting takes effect when the database is next shut down and started up again. You must specify **SPFILE** when changing the value of a static parameter that is described as not modifiable in *Oracle Database Reference*.

- **BOTH** indicates that the change is made in memory and in the server parameter file. The new setting takes effect immediately and persists after the database is shut down and started up again.
If a server parameter file was used to start up the database, then BOTH is the default. If a parameter file was used to start up the database, then MEMORY is the default, as well as the only scope you can specify.

When you issue the ALTER SYSTEM statement while connected to a PDB, you can modify only initialization parameters for which the ISPDB_MODIFIABLE column is TRUE in the V$SYSTEM_PARAMETER view. The initialization parameter value takes effect only for the PDB. For any initialization parameter that is not set explicitly for a PDB, the PDB inherits the CDB root's parameter value.

- MEMORY indicates that the change is made in memory and takes effect immediately in the PDB. The setting reverts to the value set in the CDB root in the any of the following cases:
  - An ALTER SYSTEM SET statement sets the value of the parameter in the root with SCOPE equal to BOTH or MEMORY, and the PDB is closed and reopened. The parameter value in the PDB is not changed if SCOPE is equal to SPFILE, and the PDB is closed and reopened.
  - The PDB is closed and reopened.
  - The CDB is shut down and reopened.

- SPFILE indicates that the change is made for the PDB and stored persistently. The new setting affects only the PDB and takes effect in either of the following cases:
  - The PDB is closed and reopened.
  - The CDB is shut down and reopened.

- BOTH indicates that the change is made in memory, made for the PDB, and stored persistently. The new setting takes effect immediately in the PDB and persists after the PDB is closed and reopened or the CDB is shut down and reopened. The new setting affects only the PDB.

When a PDB is unplugged from a CDB, the values of the initialization parameters that were specified for the PDB with SCOPE=BOTH or SCOPE=SPFILE are added to the PDB's XML metadata file. These values are restored for the PDB when it is plugged in to a CDB.

SID The SID clause lets you specify the SID of the instance where the value will take effect.

- Specify SID = '*' if you want Oracle Database to change the value of the parameter for all instances that do not already have an explicit setting for this parameter.

- Specify SID = 'sid' if you want Oracle Database to change the value of the parameter only for the instance sid. This setting takes precedence over previous and subsequent ALTER_SYSTEM_SET statements that specify SID = '*'.

If you do not specify this clause, then:

- If the instance was started up with a pfile (traditional plain-text initialization parameter file), then Oracle Database assumes the SID of the current instance.

- If the instance was started up with an spfile (server parameter file), then Oracle Database assumes SID = '*'.

If you specify an instance other than the current instance, then Oracle Database sends a message to that instance to change the parameter value in the memory of that instance.
USE_STORED_OUTLINES Clause

---

**Note:** Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. Refer to Oracle Database SQL Tuning Guide for more information about SQL plan management.

USE_STORED_OUTLINES is a system parameter, not an initialization parameter. You cannot set it in a pfile or spfile, but you can set it with an ALTER SYSTEM statement. This parameter determines whether the optimizer will use stored public outlines to generate execution plans.

- **TRUE** causes the optimizer to use outlines stored in the DEFAULT category when compiling requests.
- **FALSE** specifies that the optimizer should not use stored outlines. This is the default.
- **category_name** causes the optimizer to use outlines stored in the category_name category when compiling requests.

GLOBAL_TOPIC_ENABLED

GLOBAL_TOPIC_ENABLED is a system parameter, not an initialization parameter. You cannot set it in a pfile or spfile, but you can set it with an ALTER SYSTEM statement. This parameter determines whether all queues and topics created in Oracle Streams AQ are automatically registered with the LDAP server. If GLOBAL_TOPIC_ENABLED = TRUE when a queue table is created, altered, or dropped, then the corresponding Lightweight Directory Access Protocol (LDAP) entry is also created, altered or dropped.

The parameter works the same way for the Java Message Service (JMS). If a database has been configured to use LDAP and the GLOBAL_TOPIC_ENABLED parameter has been set to TRUE, then all JMS queues and topics are automatically registered with the LDAP server when they are created. The administrator can also create aliases to the queues and topics registered in LDAP. Queues and topics that are registered in LDAP can be looked up through JNDI using the name or alias of the queue or topic.

Shared Server Parameters

When you start your instance, Oracle Database creates shared server processes and dispatcher processes for the shared server architecture based on the values of the SHARED_SERVERS and DISPATCHERS initialization parameters. You can also set the SHARED_SERVERS and DISPATCHERS parameters with ALTER SYSTEM to perform one of the following operations while the instance is running:

- Create additional shared server processes by increasing the minimum number of shared server processes.
- Terminate existing shared server processes after their current calls finish processing.
- Create more dispatcher processes for a specific protocol, up to a maximum across all protocols specified by the initialization parameter MAX_DISPATCHERS.
- Terminate existing dispatcher processes for a specific protocol after their current user processes disconnect from the instance.
**alter_system_reset_clause**

This clause lets you remove the setting, for any instance, of any initialization parameter in the spfile that was used to start the instance. Neither `SCOPE=MEMORY` nor `SCOPE=BOTH` are allowed. The `SCOPE = SPFILE` clause is not required, but is included for semantic clarity. You can use this clause in a single-instance environment, but only if the instance was started using an spfile rather than a pfile.

Use the `SID` clause to remove the spfile parameter setting for a specified instance. In a non-Oracle RAC environment, you can omit this clause, because there is only one instance. In an Oracle RAC environment, if you omit this clause, then the default of `SID = '*'` is used, which means that the all settings of the parameter of the form `*.parameter = value` are removed.

**See Also:**

- Oracle Real Application Clusters Administration and Deployment Guide for information on setting parameter values for an individual instance in an Oracle Real Application Clusters environment

**RELOCATE CLIENT**

This clause is valid only if you are using Oracle Flex ASM. You must issue this clause from within an Oracle ASM instance, not from a normal database instance.

Use this clause to relocate the specified client to the least loaded Oracle ASM instance. When you issue this clause, the connection to the client is terminated and the client fails over to the least loaded instance. If the client is currently connected to the least loaded instance, then the connection to the client is terminated and the client fails over to that same instance.

For `client_id`, specify a string of the following form enclosed in single quotation marks:

```
instance_name:db_name
```

where `instance_name` is the identifier for the client and `db_name` is the database name for the client. You can find these values by querying the `INSTANCE_NAME` and `DB_NAME` columns of the `V$ASM_CLIENT` dynamic performance view.

**See Also:**

- Oracle Automatic Storage Management Administrator’s Guide for more information on managing Oracle Flex ASM
- Oracle Database Reference for more information on the `V$ASM_CLIENT` dynamic performance view

**Examples**

**Archiving Redo Logs Manually: Examples**  The following statement manually archives the redo log file group containing the redo log entry with the SCN 9356083:
ALTER SYSTEM ARCHIVE LOG CHANGE 9356083;

The following statement manually archives the redo log file group containing a member named 'disk1:log6.log' to an archived redo log file in the location 'diska:[arch$]':

```
ALTER SYSTEM ARCHIVE LOG
  LOGFILE 'disk1:log6.log'
  TO 'diska:[arch$]';
```

Enabling Query Rewrite: Example  This statement enables query rewrite in all sessions for all materialized views for which query rewrite has not been explicitly disabled:

```
ALTER SYSTEM SET QUERY_REWRITE_ENABLED = TRUE;
```

Restricting Sessions: Example  You might want to restrict sessions if you are performing application maintenance and you want only application developers with RESTRICTED SESSION system privilege to log on. To restrict sessions, issue the following statement:

```
ALTER SYSTEM ENABLE RESTRICTED SESSION;
```

You can then terminate any existing sessions using the KILL SESSION clause of the ALTER SYSTEM statement.

After performing maintenance on your application, issue the following statement to allow any user with CREATE SESSION system privilege to log on:

```
ALTER SYSTEM DISABLE RESTRICTED SESSION;
```

Establishing a Wallet and Encryption Key: Examples  The following statements load information from the server wallet into memory and set the Transparent Data Encryption master key:

```
ALTER SYSTEM SET ENCRYPTION WALLET OPEN IDENTIFIED BY "password";
ALTER SYSTEM SET ENCRYPTION KEY IDENTIFIED BY "password";
```

These statements assume that you have initialized the security module and created a wallet with password.

Closing a Wallet: Examples  The following statement removes password-based wallet information from memory:

```
ALTER SYSTEM SET ENCRYPTION WALLET CLOSE IDENTIFIED BY "password";
```

The following statement removes password-based wallet information and auto-login information, if present, from memory:

```
ALTER SYSTEM SET ENCRYPTION WALLET CLOSE;
```

Clearing the Shared Pool: Example  You might want to clear the shared pool before beginning performance analysis. To clear the shared pool, issue the following statement:

```
ALTER SYSTEM FLUSH SHARED_POOL;
```

Forcing a Checkpoint: Example  The following statement forces a checkpoint:

```
ALTER SYSTEM CHECKPOINT;
```
Enabling Resource Limits: Example

This ALTER SYSTEM statement dynamically enables resource limits:

```
ALTER SYSTEM SET RESOURCE_LIMIT = TRUE;
```

Changing Shared Server Settings: Examples

The following statement changes the minimum number of shared server processes to 25:

```
ALTER SYSTEM SET SHARED_SERVERS = 25;
```

If there are currently fewer than 25 shared server processes, then Oracle Database creates more. If there are currently more than 25, then Oracle Database terminates some of them when they are finished processing their current calls if the load could be managed by the remaining 25.

The following statement dynamically changes the number of dispatcher processes for the TCP/IP protocol to 5 and the number of dispatcher processes for the ipc protocol to 10:

```
ALTER SYSTEM
  SET DISPATCHERS =
    '(INDEX=0) (PROTOCOL=TCP) (DISPATCHERS=5)',
    '(INDEX=1) (PROTOCOL=ipc) (DISPATCHERS=10)';
```

If there are currently fewer than 5 dispatcher processes for TCP, then Oracle Database creates new ones. If there are currently more than 5, then Oracle Database terminates some of them after the connected users disconnect.

If there are currently fewer than 10 dispatcher processes for ipc, then Oracle Database creates new ones. If there are currently more than 10, then Oracle Database terminates some of them after the connected users disconnect.

If there are currently existing dispatchers for another protocol, then the preceding statement does not affect the number of dispatchers for that protocol.

Changing Licensing Parameters: Examples

The following statement dynamically changes the limit on sessions for your instance to 64 and the warning threshold for sessions on your instance to 54:

```
ALTER SYSTEM
  SET LICENSE_MAX_SESSIONS = 64
  LICENSE_SESSIONS_WARNING = 54;
```

If the number of sessions reaches 54, then Oracle Database writes a warning message to the ALERT file for each subsequent session. Also, users with RESTRICTED SESSION system privilege receive warning messages when they begin subsequent sessions.

If the number of sessions reaches 64, then only users with RESTRICTED SESSION system privilege can begin new sessions until the number of sessions falls below 64 again.

The following statement dynamically disables the limit for sessions on your instance. After you issue this statement, Oracle Database no longer limits the number of sessions on your instance.

```
ALTER SYSTEM SET LICENSE_MAX_SESSIONS = 0;
```

The following statement dynamically changes the limit on the number of users in the database to 200. After you issue the preceding statement, Oracle Database prevents the number of users in the database from exceeding 200.

```
ALTER SYSTEM SET LICENSE_MAX_USERS = 200;
```
Forcing a Log Switch: Example  You might want to force a log switch to drop or rename the current redo log file group or one of its members, because you cannot drop or rename a file while Oracle Database is writing to it. The forced log switch affects only the redo log thread of your instance. The following statement forces a log switch:

```
ALTER SYSTEM SWITCH LOGFILE;
```

Enabling Distributed Recovery: Example  The following statement enables distributed recovery:

```
ALTER SYSTEM ENABLE DISTRIBUTED RECOVERY;
```

You might want to disable distributed recovery for demonstration or testing purposes. You can disable distributed recovery in both single-process and multiprocess mode with the following statement:

```
ALTER SYSTEM DISABLE DISTRIBUTED RECOVERY;
```

When your demonstration or testing is complete, you can then enable distributed recovery again by issuing an `ALTER SYSTEM` statement with the `ENABLE DISTRIBUTED RECOVERY` clause.

Terminating a Session: Example  You might want to terminate the session of a user that is holding resources needed by other users. The user receives an error message indicating that the session has been terminated. That user can no longer make calls to the database without beginning a new session. Consider this data from the `V$SESSION` dynamic performance table, when the users `SYS` and `oe` both have open sessions:

```
SELECT sid, serial#, username
FROM V$SESSION;
```

<table>
<thead>
<tr>
<th>SID</th>
<th>SERIAL#</th>
<th>USERNAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>29</td>
<td>85</td>
<td>SYS</td>
</tr>
<tr>
<td>33</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>35</td>
<td>8</td>
<td></td>
</tr>
<tr>
<td>39</td>
<td>23</td>
<td>OE</td>
</tr>
<tr>
<td>40</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

The following statement terminates the session of the user `scott` using the `SID` and `SERIAL#` values from `V$SESSION`:

```
ALTER SYSTEM KILL SESSION '39, 23';
```

Disconnecting a Session: Example  The following statement disconnects user `scott`'s session, using the `SID` and `SERIAL#` values from `V$SESSION`:

```
ALTER SYSTEM DISCONNECT SESSION '13, 8' POST_TRANSACTION;
```
This chapter contains the following SQL statements:

- ALTER TABLE
- ALTER TABLESPACE
ALTER TABLE

Purpose

Use the ALTER TABLE statement to alter the definition of a nonpartitioned table, a partitioned table, a table partition, or a table subpartition. For object tables or relational tables with object columns, use ALTER TABLE to convert the table to the latest definition of its referenced type after the type has been altered.

Note: Oracle recommends that you use the ALTER MATERIALIZED VIEW LOG statement, rather than ALTER TABLE, whenever possible for operations on materialized view log tables.

See Also:
- CREATE TABLE on page 16-6 for information on creating tables
- Oracle Text Reference for information on ALTER TABLE statements in conjunction with Oracle Text

Prerequisites

The table must be in your own schema, or you must have ALTER object privilege on the table, or you must have ALTER ANY TABLE system privilege.

Additional Prerequisites for Partitioning Operations

If you are not the owner of the table, then you need the DROP ANY TABLE privilege in order to use the drop_table_partition or truncate_table_partition clause.

You must also have space quota in the tablespace in which space is to be acquired in order to use the add_table_partition, modify_table_partition, move_table_partition, and split_table_partition clauses.

When a partitioning operation cascades to reference-partitioned child tables, privileges are not required on the reference-partitioned child tables.

When using the exchange_partition_subpart clause, if the table data being exchanged contains an identity column and you are not the owner of both tables involved in the exchange, then you must have the ALTER ANY SEQUENCE system privilege.

Additional Prerequisites for Constraints and Triggers

To enable a unique or primary key constraint, you must have the privileges necessary to create an index on the table. You need these privileges because Oracle Database creates an index on the columns of the unique or primary key in the schema containing the table.

To enable or disable triggers, the triggers must be in your schema or you must have the ALTER ANY TRIGGER system privilege.

See Also: CREATE INDEX on page 14-73 for information on the privileges needed to create indexes

Additional Prerequisites When Using Object Types

To use an object type in a column definition when modifying a table, either that object must belong to the same schema as the table being altered, or you must have either the EXECUTE ANY TYPE system privilege or the EXECUTE object privilege for the object type.
**Additional Prerequisites for Flashback Data Archive Operations** To use the `flashback_archive_clause` to enable historical tracking for the table, you must have the `FLASHBACK ARCHIVE` object privilege on the flashback data archive that will contain the historical data. To use the `flashback_archive_clause` to disable historical tracking for the table, you must have the `FLASHBACK ARCHIVE ADMINSTER` system privilege or you must be logged in as `SYSDBA`.

**Additional Prerequisite for Referring to Editioned Objects** To specify an edition in the `evaluation_edition_clause` or the `unusable_editions_clause`, you must have the `USE` privilege on the edition.

**Syntax**

```
alter_table ::= 
```

**Note:** You must specify some clause after `table`. None of the clauses after `table` are required, but you must specify at least one of them.

**Groups of ALTER TABLE syntax:**

- `alter_table_properties ::=` on page 12-4
- `column_clauses ::=` on page 12-12
- `constraint_clauses ::=` on page 12-17
- `alter_table_partitioning ::=` on page 12-25
- `alter_external_table ::=` on page 12-24
- `move_table_clause ::=` on page 12-41
- `modify_opaque_type ::=` on page 12-41
- `enable_disable_clause ::=` on page 12-41

After each clause you will find links to its component subclauses.
alter_table_properties ::=

**Semantics**

Many clauses of the `ALTER TABLE` statement have the same functionality they have in a `CREATE TABLE` statement. For more information on such clauses, see `CREATE TABLE` on page 16-6.

**Note:** Operations performed by the `ALTER TABLE` statement can cause Oracle Database to invalidate procedures and stored functions that access the table. For information on how and when the database invalidates such objects, see `Oracle Database Development Guide`. 
**schema**
Specify the schema containing the table. If you omit `schema`, then Oracle Database assumes the table is in your own schema.

**table**
Specify the name of the table to be altered.

---

**Note:** If you alter a table that is a master table for one or more materialized views, then Oracle Database marks the materialized views **INVALID**. Invalid materialized views cannot be used by query rewrite and cannot be refreshed. For information on revalidating a materialized view, see `ALTER MATERIALIZED VIEW` on page 11-3.

---

**See Also:** *Oracle Database Data Warehousing Guide* for more information on materialized views in general

**Restrictions on Altering Temporary Tables** You can modify, drop columns from, or rename a temporary table. However, for a temporary table you cannot:

- Add columns of nested table type. You can add columns of other types.
- Specify referential integrity (foreign key) constraints for an added or modified column.
- Specify the following clauses of the `LOB_storage_clause` for an added or modified LOB column: `TABLESPACE`, `storage_clause`, `logging_clause`, `allocate_extent_clause`, or `deallocate_unused_clause`.
- Specify the `physical_attributes_clause`, `nested_table_col_properties`, `parallel_clause`, `allocate_extent_clause`, `deallocate_unused_clause`, or any of the index-organized table clauses.
- Exchange partitions between a partition and a temporary table.
- Specify the `logging_clause`.
- Specify `MOVE`.
- Add an `INVISIBLE` column or modify an existing column to be `INVISIBLE`.

**Restrictions on Altering External Tables** You can add, drop, or modify the columns of an external table. However, for an external table you cannot:

- Add a `LONG`, `LOB`, or object type column or change the data type of an external table column to any of these data types.
- Add a constraint to an external table.
- Modify the storage parameters of an external table.
- Specify the `logging_clause`.
- Specify `MOVE`.
- Add an `INVISIBLE` column or modify an existing column to be `INVISIBLE`.

**alter_table_properties**
Use the `alter_table_clauses` to modify a database table.
**physical_attributes_clause**

The `physical_attributes_clause` lets you change the value of the PCTFREE, PCTUSED, and INITRANS parameters and storage characteristics. Refer to `physical_attributes_clause` on page 8-44 and `storage_clause` on page 8-46 for a full description of these parameters and characteristics.

**Restrictions on Altering Table Physical Attributes** Altering physical attributes is subject to the following restrictions:

- You cannot specify the PCTUSED parameter for the index segment of an index-organized table.

- If you attempt to alter the storage attributes of tables in locally managed tablespaces, then Oracle Database raises an error. However, if some segments of a partitioned table reside in a locally managed tablespace and other segments reside in a dictionary-managed tablespace, then the database alters the storage attributes of the segments in the dictionary-managed tablespace but does not alter the attributes of the segments in the locally managed tablespace, and does not raise an error.

- For segments with automatic segment-space management, the database ignores attempts to change the PCTUSED setting. If you alter the PCTFREE setting, then you must subsequently run the `DBMS_REPAIR.SEGMENT_FIX_STATUS` procedure to implement the new setting on blocks already allocated to the segment.

**Cautions on Altering Tables Physical Attributes** The values you specify in this clause affect the table as follows:

- For a nonpartitioned table, the values you specify override any values specified for the table at create time.

- For a range-, list-, or hash-partitioned table, the values you specify are the default values for the table and the actual values for every existing partition, overriding any values already set for the partitions. To change default table attributes without overriding existing partition values, use the `modify_table_default_attrs` clause.

- For a composite-partitioned table, the values you specify are the default values for the table and all partitions of the table and the actual values for all subpartitions of the table, overriding any values already set for the subpartitions. To change default partition attributes without overriding existing subpartition values, use the `modify_table_default_attrs` clause with the FOR PARTITION clause.

**logging_clause**

Use the `logging_clause` to change the logging attribute of the table. The `logging_clause` specifies whether subsequent `ALTER TABLE ... MOVE` and `ALTER TABLE ... SPLIT` operations will be logged or not logged.

When used with the `modify_table_default_attrs` clause, this clause affects the logging attribute of a partitioned table.

**See Also:**

- `logging_clause` on page 8-38 for a full description of this clause
- `Oracle Database VLDB and Partitioning Guide` for more information about the `logging_clause` and parallel DML
**table_compression**
The `table_compression` clause is valid only for heap-organized tables. Use this clause to instruct Oracle Database whether to compress data segments to reduce disk and memory use. Refer to the `CREATE TABLE table_compression` on page 16-45 for the full semantics of this clause and for information on creating objects with table compression.

---

**Note:** The first time a table is altered in such a way that compressed data will be added, all bitmap indexes and bitmap index partitions on that table must be marked `UNUSABLE`.

---

**inmemory_alter_table_clause**
Use this clause to enable or disable a table or table column for the In-Memory Column Store (IM column store), or to change the in-memory parameters for a table or table column.

- Specify `INMEMORY` to enable a table for the IM column store, or to change the `inmemory_parameters` for a table that is already enabled for the IM column store.
- Specify the `inmemory_column_clause` to enable or disable a table column for the IM column store, or to change the `inmemory_memcompress` setting for a table column.
- Specify `NO INMEMORY` to disable a table for the IM column store.

This `inmemory_alter_table_clause` has the same semantics as the `inmemory_table_clause` of `CREATE TABLE` on page 16-48 with the following additions:

- When you change the data compression method for a table that is already enabled for the IM column store, any columns that were previously assigned a specific data compression method will retain their data compression method.
- When you disable a table for the IM column store, any column-level data compression method settings are lost. If you subsequently enable the table for the IM column store, all columns will use the table’s data compression method unless you specify otherwise when enabling the table.

The clauses `inmemory_parameters` and `inmemory_column_clause` have the same semantics in `CREATE TABLE` and `ALTER TABLE`. Refer to `inmemory_parameters` on page 16-49 and `inmemory_column_clause` on page 16-50 in the documentation on `CREATE TABLE` for the full semantics of these clauses.

**inmemory_clause**
Use this clause to enable or disable a table partition for the IM column store, or to change the in-memory parameters for a table partition. This clause has the same semantics in `CREATE TABLE` and `ALTER TABLE`. Refer to the `inmemory_clause` on page 16-51 in the documentation on `CREATE TABLE` for the full semantics of this clause.

**ilm_clause**
Use this clause to add, delete, enable, or disable Automatic Data Optimization policies for the table.

**ADD POLICY** Specify this clause to add a policy for the table.

Use the `ilm_policy_clause` to specify the policy. Refer to the `ilm_policy_clause` on page 12-46 for the full semantics of this clause.
Oracle Database assigns a name to the policy of the form \( P_n \), where \( n \) is an integer value.

\{ DELETE | ENABLE | DISABLE \} POLICY Specify these clauses to delete a policy for the table, enable a policy for the table, or disable a policy for the table, respectively.

For \( iIm\_policy\_name \), specify the name of the policy. You can view policy names by querying the POLICY_NAME column of the DBA_ILMPOLICIES view.

\{ DELETE\_ALL, ENABLE\_ALL, DISABLE\_ALL \} Specify these clauses to delete all policies for the table, enable all policies for the table, or disable all policies for the table, respectively.

See Also: Oracle Database VLDB and Partitioning Guide for more information on managing policies for Automatic Data Optimization

**ilm\_policy\_clause**

This clause lets you specify an Automatic Data Optimization policy. You can use the ilm\_compression\_policy clause to specify a compression policy or the ilm\_tiering\_policy clause to specify a storage tiering policy.

**ilm\_compression\_policy**

Use this clause to specify a compression policy. This type of policy instructs the database to compress data when a specified condition is met. Use the SEGMENT, GROUP, or ROW clause to specify a segment-level, group-level, or row-level compression policy.

**table\_compression** Use the table\_compression clause to specify the compression type. This clause applies to segment-level and group-level compression policies.

You must specify a compression type that is higher than the current compression type. The order of compression types from lowest to highest is:

NOCOMPRESS
ROW STORE COMPRESS BASIC
ROW STORE COMPRESS ADVANCED
COLUMN STORE COMPRESS FOR QUERY LOW
COLUMN STORE COMPRESS FOR QUERY HIGH
COLUMN STORE COMPRESS FOR ARCHIVE LOW
COLUMN STORE COMPRESS FOR ARCHIVE HIGH

Refer to table\_compression on page 16-45 for the full semantics of this clause.

**SEGMENT** Specify SEGMENT to create a segment-level compression policy. This type of policy instructs the database to compress table segments when the condition specified in the AFTER clause is met or when the PL/SQL function specified in the ON clause returns TRUE.

**GROUP** Specify GROUP to create a group-level compression policy. This type of policy instructs the database to compress the table and its dependent objects, such as indexes and SecureFiles LOBs, when the condition specified in the AFTER clause is met or when the PL/SQL function specified in the ON clause returns TRUE.

**ROW** Specify ROW to create a row-level compression policy. This type of policy instructs the database to compress database blocks in which all the rows have not been modified for a specified period of time. When creating a row-level policy, you must specify ROW STORE COMPRESS ADVANCED compression and you must specify AFTER ilm_
time_period OF NO MODIFICATION. Refer to table_compression on page 16-45 for the full semantics of the ROW STORE COMPRESS ADVANCED clause.

**AFTER** Use this clause to describe the condition that must be met in order for the policy to take effect. The condition consists of a length of time, specified with the ilm_time_period clause, and one of the following condition types:

- **OF NO ACCESS**: The policy will take effect after table has not been accessed for the specified length of time.
- **OF NO MODIFICATION**: The policy will take effect after table has not been modified for the specified length of time.
- **OF CREATION**: The policy will take effect when the specified length of time has passed since table was created.

**ilm_time_period** Specify a length of time in days, months, or years after which the condition must be met. For integer, specify a positive integer. The DAY and DAYS keywords can be used interchangeably and are provided for semantic clarity. This is also the case for the MONTH and MONTHS keywords, and the YEAR and YEARS keywords.

**ON** Use this clause to specify a PL/SQL function that returns a boolean value. For function_name, specify the name of the function. The policy will take effect when the function returns TRUE.

**ilm_tiering_policy** Use this clause to specify a storage tiering policy. This type of policy instructs the database to migrate data to a specified tablespace, either when a specified condition is met or when data usage reaches a specified limit. Use the SEGMENT or GROUP clause to specify a segment-level or group-level policy. You can migrate data to a read/write tablespace or a read-only tablespace.

**TIER TO tablespace** Use this clause to migrate data to a read/write tablespace.

- If you specify the ON function clause, then data will be migrated when function returns TRUE. Refer to the ON clause on page 12-47 for the full semantics of this clause.
- If you omit the ON function clause, then data will be migrated when data usage of the tablespace quota reaches the percentage defined by TBS_PERCENT_USED. The database will make a best effort to migrate enough data so that the amount of free space within the tablespace quota reaches the percentage defined by TBS_PERCENT_FREE. Refer to Oracle Database PL/SQL Packages and Types Reference for more information on TBS_PERCENT_USED and TBS_PERCENT_FREE, which are constants in the DBMS_ILM_ADMIN package.

**TIER TO tablespace READ ONLY** Use this clause to migrate data to a read-only tablespace. When migrating data to the tablespace, the database temporarily places the tablespace in read/write mode, migrates the data, and then places the tablespace back in read-only mode.

- If you specify the AFTER clause, then data will be migrated when the specified condition is met. Refer to the AFTER clause on page 12-47 for the full semantics of this clause.
- If you specify the ON function clause, then data will be migrated when function returns TRUE. Refer to the ON clause on page 12-47 for the full semantics of this clause.
SEGMENT | GROUP
Specify SEGMENT to create a segment-level storage tiering policy. This type of policy instructs the database to migrate table segments to tablespace. Specify GROUP to create a group-level storage tiering policy. This type of policy instructs the database to migrate the table and its dependent objects, such as indexes and SecureFiles LOBs, to tablespace. The default is SEGMENT.

supplemental_table_logging
Use the supplemental_table_logging clause to add or drop a redo log group or one or more supplementally logged columns in a redo log group.

- In the ADD clause, use supplemental_log_grp_clause to create named supplemental log group. Use the supplemental_id_key_clause to create a system-generated log group.
- On the DROP clause, use GROUP log_group syntax to drop a named supplemental log group and use the supplemental_id_key_clause to drop a system-generated log group.

The supplemental_log_grp_clause and the supplemental_id_key_clause have the same semantics in CREATE TABLE and ALTER TABLE statements. For full information on these clauses, refer to supplemental_log_grp_clause on page 16-42 and supplemental_id_key_clause on page 16-42 in the documentation on CREATE TABLE.

See Also: Oracle Data Guard Concepts and Administration for information on supplemental redo log groups

allocate_extent_clause
Use the allocate_extent_clause to explicitly allocate a new extent for the table, the partition or subpartition, the overflow data segment, the LOB data segment, or the LOB index.

Restriction on Allocating Table Extents You cannot allocate an extent for a temporary table or for a range- or composite-partitioned table.

See Also: allocate_extent_clause on page 8-2 for a full description of this clause and "Allocating Extents: Example" on page 12-108

deallocate_unused_clause
Use the deallocate_unused_clause to explicitly deallocate unused space at the end of the table, partition or subpartition, overflow data segment, LOB data segment, or LOB index and make the space available for other segments in the tablespace.

See Also: deallocate_unused_clause on page 8-27 for a full description of this clause and "Deallocating Unused Space: Example" on page 12-103

CACHE | NOCACHE
The CACHE and NOCACHE clauses have the same semantics in CREATE TABLE and ALTER TABLE statements. For complete information on these clauses, refer to "CACHE | NOCACHE | CACHE READS" on page 16-80 in the documentation on CREATE TABLE. If you omit both of these clauses in an ALTER TABLE statement, then the existing value is unchanged.
RESULT_CACHE

The RESULT_CACHE clause has the same semantics in CREATE TABLE and ALTER TABLE statements. For complete information on this clause, refer to “RESULT_CACHE Clause” on page 16-81 in the documentation on CREATE TABLE. If you omit this clause in an ALTER TABLE statement, then the existing setting is unchanged.

upgrade_table_clause

The upgrade_table_clause is relevant for object tables and for relational tables with object columns. It lets you instruct Oracle Database to convert the metadata of the target table to conform with the latest version of each referenced type. If table is already valid, then the table metadata remains unchanged.

Restriction on Upgrading Object Tables and Columns Within this clause, you cannot specify object_type_col_properties as a clause of column_properties.

INCLUDING DATA Specify INCLUDING DATA if you want Oracle Database to convert the data in the table to the latest type version format. You can define the storage for any new column while upgrading the table by using the column_properties and the LOB_partition_storage. This is the default.

You can convert data in the table at the time you upgrade the type by specifying CASCADE INCLUDING TABLE DATA in the dependent_handling_clause of the ALTER TYPE statement. See Oracle Database PL/SQL Language Reference for information on this clause. For information on whether a table contains data based on an older type version, refer to the DATA_UPGRADED column of the USER_TAB_COLUMNS data dictionary view.

NOT INCLUDING DATA Specify NOT INCLUDING DATA if you want Oracle Database to leave column data unchanged.

Restriction on NOT INCLUDING DATA You cannot specify NOT INCLUDING DATA if the table contains columns in Oracle8 release 8.0.x image format. To determine whether the table contains such columns, refer to the V80_FMT_IMAGE column of the USER_TAB_COLUMNS data dictionary view.

See Also:

■ Oracle Database Reference for information on the data dictionary views
■ ALTER TYPE on page 13-4 for information on converting dependent table data when modifying a type upon which the table depends

records_per_block_clause

The records_per_block_clause lets you specify whether Oracle Database restricts the number of records that can be stored in a block. This clause ensures that any bitmap indexes subsequently created on the table will be as compressed as possible.

Restrictions on Records in a Block The record_per_block_clause is subject to the following restrictions:

■ You cannot specify either MINIMIZE or NOMINIMIZE if a bitmap index has already been defined on table. You must first drop the bitmap index.
■ You cannot specify this clause for an index-organized table or a nested table.
MINIMIZE  Specify MINIMIZE to instruct Oracle Database to calculate the largest number of records in any block in the table and to limit future inserts so that no block can contain more than that number of records.

Oracle recommends that a representative set of data already exist in the table before you specify MINIMIZE. If you are using table compression (see table_compression on page 12-45), then a representative set of compressed data should already exist in the table.

Restriction on MINIMIZE  You cannot specify MINIMIZE for an empty table.

NOMINIMIZE  Specify NOMINIMIZE to disable the MINIMIZE feature. This is the default.

row_movement_clause
You cannot disable row movement in a reference-partitioned table unless row movement is also disabled in the parent table. Otherwise, this clause has the same semantics in CREATE TABLE and ALTER TABLE statements. For complete information on these clauses, refer to row_movement_clause on page 16-83 in the documentation on CREATE TABLE.

flashback_archive_clause
You must have the FLASHBACK ARCHIVE object privilege on the specified flashback data archive to specify this clause. Use this clause to enable or disable historical tracking for the table.

- Specify FLASHBACK ARCHIVE to enable tracking for the table. You can specify flashback_archive to designate a particular flashback data archive for this table. The flashback data archive you specify much already exist.
  If you omit the archive name, then the database uses the default flashback data archive designated for the system. If no default flashback data archive has been designated for the system, then you must specify flashback_archive.
  You cannot specify FLASHBACK ARCHIVE to change the flashback data archive for this table. Instead you must first issue an ALTER TABLE statement with the NO FLASHBACK ARCHIVE clause and then issue an ALTER TABLE statement with the FLASHBACK ARCHIVE clause.

- Specify NO FLASHBACK ARCHIVE to disable tracking for the table.

See Also:  The CREATE TABLE flashback_archive_clause on page 16-84 for information on creating a table with tracking enabled and CREATE FLASHBACK ARCHIVE on page 14-68 for information on creating default flashback data archives

RENAME TO
Use the RENAME clause to rename table to new_table_name.

Using this clause invalidates any dependent materialized views. For more information on materialized views, see CREATE MATERIALIZED VIEW on page 15-4 and Oracle Database Data Warehousing Guide.

If a domain index is defined on the table, then the database invokes the ODCIIndexAlter() method with the RENAME option. This operation establishes correspondence between the indextype metadata and the base table.
shrink_clause

The shrink clause lets you manually shrink space in a table, index-organized table or its overflow segment, index, partition, subpartition, LOB segment, materialized view, or materialized view log. This clause is valid only for segments in tablespaces with automatic segment management. By default, Oracle Database compacts the segment, adjusts the high water mark, and releases the recuperated space immediately.

Compacting the segment requires row movement. Therefore, you must enable row movement for the object you want to shrink before specifying this clause. Further, if your application has any rowid-based triggers, you should disable them before issuing this clause.

---

Note: Do not attempt to enable row movement for an index-organized table before specifying the shrink_clause. The ROWID of an index-organized table is its primary key, which never changes. Therefore, row movement is neither relevant nor valid for such tables.

---

COMPACT  If you specify COMPACT, then Oracle Database only defragments the segment space and compacts the table rows for subsequent release. The database does not readjust the high water mark and does not release the space immediately. You must issue another ALTER TABLE ... SHRINK SPACE statement later to complete the operation. This clause is useful if you want to accomplish the shrink operation in two shorter steps rather than one longer step.

For an index or index-organized table, specifying ALTER [INDEX | TABLE] ... SHRINK SPACE COMPACT is equivalent to specifying ALTER [INDEX | TABLE] ... COALESCE. The shrink_clause can be cascaded (refer to the CASCADE clause, which follows) and compacts the segment more densely than does a coalesce operation, which can improve performance. However, if you do not want to release the unused space, then you can use the appropriate COALESCE clause.

CASCADE  If you specify CASCADE, then Oracle Database performs the same operations on all dependent objects of table, including secondary indexes on index-organized tables.

Restrictions on the shrink_clause  The shrink_clause is subject to the following restrictions:

- You cannot combine this clause with any other clauses in the same ALTER TABLE statement.
- You cannot specify this clause for a cluster, a clustered table, or any object with a LONG column.
- Segment shrink is not supported for tables with function-based indexes, domain indexes, or bitmap join indexes.
- This clause does not shrink mapping tables of index-organized tables, even if you specify CASCADE.
- You can specify this clause for a table with Advanced Row Compression enabled (ROW STORE COMPRESS ADVANCED). You cannot specify this clause for a table with any other type of table compression enabled.
- You cannot shrink a table that is the master table of an ON COMMIT materialized view. Rowid materialized views must be rebuilt after the shrink operation.
READ ONLY | READ WRITE
Specify READ ONLY to put the table in read-only mode. When the table is in READ ONLY mode, you cannot issue any DML statements that affect the table or any SELECT ... FOR UPDATE statements. You can issue DDL statements as long as they do not modify any table data. Operations on indexes associated with the table are allowed when the table is in READ ONLY mode.

Specify READ WRITE to return a read-only table to read/write mode.

REKEY encryption_spec
Use the REKEY clause to generate a new encryption key or to switch between different algorithms. This operation returns only after all encrypted columns in the table, including LOB columns, have been reencrypted.

[NO] ROW ARCHIVAL
Specify this clause to enable or disable table for row archival.

- Specify ROW ARCHIVAL to enable table for row archival. A hidden column ORA_ARCHIVE_STATE is created in the table. If the table is already populated with data, then the value of ORA_ARCHIVE_STATE is set to 0 for each existing row in the table. You can subsequently use the UPDATE statement to set the value of ORA_ARCHIVE_STATE to 1 for rows you want to archive.

- Specify NO ROW ARCHIVAL to disable table for row archival. The hidden column ORA_ARCHIVE_STATE is dropped from the table.

Restrictions on [NO] ROW ARCHIVAL
The following restrictions apply to this clause:

- You cannot specify the ROW ARCHIVAL clause for a table that already contains a column named ORA_ARCHIVE_STATE.

- You cannot specify the NO ROW ARCHIVAL clause for tables owned by SYS.

See Also:
- The CREATE TABLE ROW ARCHIVAL clause on page 16-85 for the full semantics of this clause
- Oracle Database VLDB and Partitioning Guide for more information on In-Database Archiving

attribute_clustering_clause
Use the ADD attribute_clustering_clause to enable the table for attribute clustering. The attribute_clustering_clause has the same semantics for ALTER TABLE and CREATE TABLE. Refer to the attribute_clustering_clause on page 16-78 in the documentation on CREATE TABLE.

MODIFY CLUSTERING
Use this clause to allow or disallow attribute clustering for the table during direct-path insert operations or data movement operations. The table must be enabled for attribute clustering. The clustering_when clause and the zonemap_clause have the same semantics for ALTER TABLE and CREATE TABLE. Refer to the clustering_when clause on page 16-79 and the zonemap_clause on page 16-79 in the documentation on CREATE TABLE.

DROP CLUSTERING
Use this clause to disable the table for attribute clustering.
If a zone map on the table was created using the `WITH MATERIALIZED ZONEMAP` clause of `CREATE TABLE` or `ALTER TABLE`, then the zone map will be dropped. If a zone map on the table was created using the `CREATE MATERIALIZED ZONEMAP` statement, then the zone map will not be dropped.

**alter_iot_clauses**

**index_org_table_clause**
This clause lets you alter some of the characteristics of an existing index-organized table. Index-organized tables keep data sorted on the primary key and are therefore best suited for primary-key-based access and manipulation. See `index_org_table_clause` on page 16-52 in the context of `CREATE TABLE`.

*See Also:* "Modifying Index-Organized Tables: Examples" on page 12-103

**prefix_compression**
Use the `prefix_compression` clause to enable prefix compression for the table. Specify `COMPRESS` to instruct Oracle Database to combine the primary key index blocks of the index-organized table where possible to free blocks for reuse. You can specify this clause with the `parallel_clause`. Specify `NOCOMPRESS` to disable prefix compression for the table.

**PCTTHRESHOLD integer** Refer to "PCTTHRESHOLD integer" on page 16-53 in the documentation on `CREATE TABLE`.

**INCLUDING column_name** Refer to "INCLUDING column_name" on page 16-54 in the documentation on `CREATE TABLE`.

**overflow_attributes**
The `overflow_attributes` let you specify the overflow data segment physical storage and logging attributes to be modified for the index-organized table. Parameter values specified in this clause apply only to the overflow data segment.

*See Also:* `CREATE TABLE` on page 16-6

**add_overflow_clause**
The `add_overflow_clause` lets you add an overflow data segment to the specified index-organized table. You can also use this clause to explicitly allocate an extent to or deallocate unused space from an existing overflow segment.

Use the `STORE IN tablespace` clause to specify tablespace storage for the entire overflow segment. Use the `PARTITION` clause to specify tablespace storage for the segment by partition.

For a partitioned index-organized table:

- If you do not specify `PARTITION`, then Oracle Database automatically allocates an overflow segment for each partition. The physical attributes of these segments are inherited from the table level.
- If you want to specify separate physical attributes for one or more partitions, then you must specify such attributes for each partition in the table. You need not specify the name of the partitions, but you must specify their attributes in the order in which they were created.
You can find the order of the partitions by querying the `PARTITION_NAME` and `PARTITION_POSITION` columns of the `USER_IND_PARTITIONS` view.

If you do not specify `TABLESPACE` for a particular partition, then the database uses the tablespace specified for the table. If you do not specify `TABLESPACE` at the table level, then the database uses the tablespace of the partition primary key index segment.

**Restrictions on Overflow Attributes**

Within the `segment_attributes_clause`:

- You cannot specify the `OPTIMAL` parameter of the `physical_attributes_clause`.
- You cannot specify tablespace storage for the overflow segment using this clause. For a nonpartitioned table, you can use `ALTER TABLE ... MOVE ... OVERFLOW` to move the segment to a different tablespace. For a partitioned table, use `ALTER TABLE ... MODIFY DEFAULT ATTRIBUTES ... OVERFLOW` to change the default tablespace of the overflow segment.

Additional restrictions apply if `table` is in a locally managed tablespace, because in such tablespaces several segment attributes are managed automatically by the database.

**See Also:** `allocate_extent_clause` on page 8-2 and `deallocate_unused_clause` on page 8-27 for full descriptions of these clauses of the `add_overflow_clause`

**alter_overflow_clause**

The `alter_overflow_clause` lets you change the definition of the overflow segment of an existing index-organized table.

The restrictions that apply to the `add_overflow_clause` also apply to the `alter_overflow_clause`.

---

**Note:** When you add a column to an index-organized table, Oracle Database evaluates the maximum size of each column to estimate the largest possible row. If an overflow segment is needed but you have not specified `OVERFLOW`, then the database raises an error and does not execute the `ALTER TABLE` statement. This checking function guarantees that subsequent DML operations on the index-organized table will not fail because an overflow segment is lacking.

---

**alter_mapping_table_clauses**

The `alter_mapping_table_clauses` is valid only if `table` is index organized and has a mapping table.

**allocate_extent_clause**

Use the `allocate_extent_clause` to allocate a new extent at the end of the mapping table for the index-organized table. Refer to `allocate_extent_clause` on page 8-2 for a full description of this clause.

**deallocate_unused_clause**

Specify the `deallocate_unused_clause` to deallocate unused space at the end of the mapping table of the index-organized table. Refer to `deallocate_unused_clause` on page 8-27 for a full description of this clause.

Oracle Database automatically maintains all other attributes of the mapping table or its partitions.
COALESCE Clause
Specify COALESCE to instruct Oracle Database to merge the contents of index blocks of the index the database uses to maintain the index-organized table where possible to free blocks for reuse. Refer to the shrink Clause on page 12-51 for information on the relationship between these two clauses.

alter_XMLSchema_clause
This clause is valid as part of alter_table_properties only if you are modifying an XMLType table with BINARY XML storage. Refer to XMLSchema_spec on page 16-88 in the documentation on CREATE TABLE for more information on the ALLOW and DISALLOW clauses.

column_clauses
Use these clauses to add, drop, or otherwise modify a column.

add_column_clause
The add_column_clause lets you add a column to a table.

See Also:  CREATE TABLE on page 16-6 for a description of the keywords and parameters of this clause and “Adding a Table Column: Example” on page 12-107

column_definition
Unless otherwise noted in this section, the elements of column_definition have the same behavior when adding a column to an existing table as they do when creating a new table. Refer to column_definition on page 16-32 for information.

Restriction on column_definition  The SORT parameter is valid only when creating a new table. You cannot specify SORT in the column_definition of an ALTER TABLE ... ADD statement.

When you add a column, the initial value of each row for the new column is null, unless you specify the DEFAULT clause.

You can add an overflow data segment to each partition of a partitioned index-organized table.

You can add LOB columns to nonpartitioned and partitioned tables. You can specify LOB storage at the table and at the partition or subpartition level.

If you previously created a view with a query that used the SELECT * syntax to select all columns from table, and you now add a column to table, then the database does not automatically add the new column to the view. To add the new column to the view, re-create the view using the CREATE VIEW statement with the OR REPLACE clause. Refer to CREATE VIEW on page 17-15 for more information.

Restrictions on Adding Columns  The addition of columns is subject to the following restrictions:

- You cannot add a LOB column or an INVISIBLE column to a cluster table.
- If you add a LOB column to a hash-partitioned table, then the only attribute you can specify for the new partition is TABLESPACE.
- You cannot add a column with a NOT NULL constraint if table has any rows unless you also specify the DEFAULT clause.
If you specify this clause for an index-organized table, then you cannot specify any other clauses in the same statement.

**DEFAULT**

Use the `DEFAULT` clause to specify a default for a new column or a new default for an existing column. Oracle Database assigns this value to the column if a subsequent `INSERT` statement omits a value for the column.

The data type of the expression must match the data type specified for the column. The column must also be large enough to hold this expression.

The `DEFAULT` expression can include any SQL function as long as the function does not return a literal argument, a column reference, or a nested function invocation.

The `DEFAULT` expression can include the sequence pseudocolumns `CURRVAL` and `NEXTVAL`, as long as the sequence exists and you have the privileges necessary to access it. Users who perform subsequent inserts that use the `DEFAULT` expression must have the `INSERT` privilege on the table and the `SELECT` privilege on the sequence. If the sequence is later dropped, then subsequent insert statements where the `DEFAULT` expression is used will result in an error. If you are adding a new column to a table, then the order in which `NEXTVAL` is assigned to each existing row is nondeterministic. If you do not fully qualify the sequence by specifying the sequence owner, for example, `SCOTT.SEQ1`, then Oracle Database will default the sequence owner to be the user who issues the `ALTER TABLE` statement. For example, if user `MARY` adds a column to `SCOTT.TABLE` and refers to a sequence that is not fully qualified, such as `SEQ2`, then the column will use sequence `MARY.SEQ2`. Synonyms on sequences undergo a full name resolution and are stored as the fully qualified sequence in the data dictionary; this is true for public and private synonyms. For example, if user `BETH` adds a column referring to public or private synonym `SYN1` and the synonym refers to `PETER.SEQ7`, then the column will store `PETER.SEQ7` as the default.

If you specify the `DEFAULT` clause for a column, then the default value is stored as metadata but the column itself is not populated with data. However, subsequent queries that specify the new column are rewritten so that the default value is returned in the result set. This optimized behavior is subject to the following restrictions:

- The table cannot have any LOB columns. It cannot be index-organized, temporary, or part of a cluster. It also cannot be a queue table, an object table, or the container table of a materialized view.
- If the table has a Virtual Private Database (VPD) policy on it, then the optimized behavior will not take place unless the user who issues the `ALTER TABLE ... ADD` statement has the `EXEMPT ACCESS POLICY` system privilege.
- The column being added cannot be encrypted, and cannot be an object column, nested table column, or a LOB column.
- The `DEFAULT` expression cannot include the sequence pseudocolumns `CURRVAL` or `NEXTVAL`.

If the optimized behavior cannot take place due to the preceding restrictions, then Oracle Database updates each row in the newly created column with the default value. In this case, the database does not fire any `UPDATE` triggers that are defined on the table.

**Restrictions on Default Column Values**

Default column values are subject to the following restrictions:
- A `DEFAULT` expression cannot contain references to PL/SQL functions or to other columns, the pseudocolumns `LEVEL`, `PRIOR`, and `ROWNUM`, or date constants that are not fully specified.

- The expression can be of any form except a scalar subquery expression.

**ON NULL** If you specify the `ON NULL` clause, then Oracle Database assigns the `DEFAULT` column value when a subsequent `INSERT` statement attempts to assign a value that evaluates to NULL.

When you specify `ON NULL`, the `NOT NULL` constraint and `NOT DEFERRABLE` constraint state are implicitly specified. If you specify an inline constraint that conflicts with `NOT NULL` and `NOT DEFERRABLE`, then an error is raised.

**See Also:** "Specifying a Default Column Value: Examples" on page 12-108

**identity_clause**

The `identity_clause` has the same semantics when you add an identity column that it has when you create an identity column. Refer to `CREATE TABLE identity_clause` on page 16-35 for more information.

When you add a new identity column to a table, all existing rows are updated using the sequence generator. The order in which a value is assigned to each existing row is nondeterministic.

**identity_options**

Use the `identity_options` clause to configure the sequence generator. The `identity_options` clause has the same parameters as the `CREATE SEQUENCE` statement. Refer to `CREATE SEQUENCE` on page 15-96 for a full description of these parameters and characteristics. The exception is `START WITH LIMIT VALUE`, which is specific to `identity_options` and can only be used with `ALTER TABLE MODIFY`. Refer to `identity_options` on page 12-62 for more information.

**inline_constraint**

Use `inline_constraint` to add a constraint to the new column.

**inline_ref_constraint**

This clause lets you describe a new column of type `REF`. Refer to `constraint` on page 8-4 for syntax and description of this type of constraint, including restrictions.

**virtual_column_definition**

The `virtual_column_definition` has the same semantics when you add a column that it has when you create a column.

**See Also:** The `CREATE TABLE virtual_column_definition` on page 16-37 and "Adding a Virtual Table Column: Example" on page 12-107 for more information

**Restriction on Adding a Virtual Column** You cannot add a virtual column when the SQL expression for the virtual column involves a column on which an Oracle Data Redaction policy is defined.
column_properties
The clauses of column_properties determine the storage characteristics of an object type, nested table, varray, or LOB column.

object_type_col_properties  This clause is valid only when you are adding a new object type column or attribute. To modify the properties of an existing object type column, use the modify_column_clauses. The semantics of this clause are the same as for CREATE TABLE unless otherwise noted.

Use the object_type_col_properties clause to specify storage characteristics for a new object column or attribute or an element of a collection column or attribute.

For complete information on this clause, refer to object_type_col_properties on page 16-56 in the documentation on CREATE TABLE.

nested_table_col_properties  The nested_table_col_properties clause lets you specify separate storage characteristics for a nested table, which in turn lets you to define the nested table as an index-organized table. You must include this clause when creating a table with columns or column attributes whose type is a nested table. (Clauses within this clause that function the same way they function for parent object tables are not repeated here. See the CREATE TABLE clause nested_table_col_properties on page 16-63 for more information about these clauses.)

- For nested_item, specify the name of a column (or a top-level attribute of the nested table object type) whose type is a nested table.

  If the nested table is a multilevel collection, and the inner nested table does not have a name, then specify COLUMN_VALUE in place of the nested_item name.

- For storage_table, specify the name of the table where the rows of nested_item reside. The storage table is created in the same schema and the same tablespace as the parent table.

Restrictions on Nested Table Column Properties  Nested table column properties are subject to the following restrictions:

- You cannot specify the parallel_clause.
- You cannot specify CLUSTER as part of the physical_properties clause.

See Also:  "Nested Tables: Examples" on page 12-111

varray_col_properties  The varyarray_col_properties clause lets you specify separate storage characteristics for the LOB in which a varray will be stored. If you specify this clause, then Oracle Database will always store the varray in a LOB, even if it is small enough to be stored inline. If varray_item is a multilevel collection, then the database stores all collection items nested within varray_item in the same LOB in which varray_item is stored.

Restriction on Varray Column Properties  You cannot specify TABLESPACE as part of LOB_parameters for a varray column. The LOB tablespace for a varray defaults to the tablespace of the containing table.

out_of_line_part_storage
This clause lets you specify storage attributes the newly added column for each partition or subpartition in a partitioned table. For any partition or subpartition you do not name in this clause, the storage attributes for the new column are the same as those specified in the nested_table_col_properties at the table level.
LOB_storage_clause

Use the **LOB_storage_clause** to specify the LOB storage characteristics for a newly added LOB column, LOB partition, or LOB subpartition, or when you are converting a LONG column into a LOB column. You cannot use this clause to modify an existing LOB. Instead, you must use the **modify_LOB_storage_clause** on page 12-69.

Unless otherwise noted in this section, all LOB parameters, in both the **LOB_storage_clause** and the **modify_LOB_storage_clause**, have the same semantics in an ALTER TABLE statement that they have in a CREATE TABLE statement. Refer to the CREATE TABLE **LOB_storage_clause** on page 16-57 for complete information on this clause.

Restriction on LOB Parameters   The only parameter of **LOB_parameters** you can specify for a hash partition or hash subpartition is **TABLESPACE**.

CACHE READS Clause   When you add a new LOB column, you can specify the logging attribute with **CACHE READS**, as you can when defining a LOB column at create time. Refer to the CREATE TABLE clause **CACHE READS** on page 16-81 for full information on this clause.

ENABLE | DISABLE STORAGE IN ROW   You cannot change **STORAGE IN ROW** once it is set. Therefore, you cannot specify this clause as part of the **modify_col_properties** clause. However, you can change this setting when adding a new column (**add_column_clause**) or when moving the table (**move_table_clause**). Refer to the CREATE TABLE clause **ENABLE STORAGE IN ROW** on page 16-58 for complete information on this clause.

CHUNK integer   You use cannot use the **modify_col_properties** clause to change the value of **CHUNK** after it has been set. If you require a different **CHUNK** value for a column after it has been created, use **ALTER TABLE ... MOVE**. Refer to the CREATE TABLE clause **CHUNK integer** on page 16-59 for more information.

RETENTION   For BasicFiles LOBs, if the database is in automatic undo mode, then you can specify **RETENTION** instead of **PCTVERSION** to instruct Oracle Database to retain old versions of this LOB. This clause overrides any prior setting of **PCTVERSION**. Refer to the CREATE TABLE clause **LOB_retention_clause** on page 16-59 for a full description of this parameter.

FREEPOOLS integer   For BasicFiles LOBs, if the database is in automatic undo mode, then you can use this clause to specify the number of freelist groups for this LOB. This clause overrides any prior setting of **FREELIST GROUPS**. Refer to the CREATE TABLE clause **FREEPOOLS integer** on page 16-60 for a full description of this parameter. The database ignores this parameter for SecureFiles LOBs.

LOB_partition_storage

You can specify only one list of **LOB_partition_storage clauses** in a single **ALTER TABLE** statement, and all **LOB_storage_clauses** and **varray_col_properties** clause must precede the list of **LOB_partition_storage clauses**. Refer to the CREATE TABLE clause **LOB_partition_storage** on page 16-61 for full information on this clause, including restrictions.

XMLType_column_properties   Refer to the CREATE TABLE clause **XMLType_column_properties** on page 16-64 for a full description of this clause.

**modify_column_clauses**

Use the `modify_column_clauses` to modify the properties of an existing column, the visibility of an existing column, or the substitutability of an existing object type column.

See Also:  "Modifying Table Columns: Examples" on page 12-108

**modify_col_properties**

Use this clause to modify the properties of the column. Any of the optional parts of the column definition (data type, default value, or constraint) that you omit from this clause remain unchanged.

**datatype**

You can change the data type of any column if all rows of the column contain nulls. However, if you change the data type of a column in a materialized view container table, then Oracle Database invalidates the corresponding materialized view.

You can omit the data type only if the statement also designates the column as part of the foreign key of a referential integrity constraint. The database automatically assigns the column the same data type as the corresponding column of the referenced key of the referential integrity constraint.

You can always increase the size of a character or raw column or the precision of a numeric column, whether or not all the rows contain nulls. You can reduce the size of a data type of a column as long as the change does not require data to be modified. The database scans existing data and returns an error if data exists that exceeds the new length limit.

When you increase the size of a `VARCHAR2`, `NVARCHAR2`, or `RAW` column to exceed 4000 bytes, Oracle Database performs an in-place length extension and does not migrate the inline storage to external LOB storage. This enables uninterrupted migration of large tables, especially after migration, to leverage extended data types. However, the inline storage of the column will not be preserved during table reorganization operations, such as `CREATE TABLE ... AS SELECT`, export, import, or online redefinition. To migrate to the new out-of-line storage of extended data type columns, you must recreate the table using one of the aforementioned methods. The inline storage of the column will be preserved during table or partition movement operations, such as `ALTER TABLE MOVE [ [SUB] PARTITION]`, and partition maintenance operations, such as `ALTER TABLE SPLIT [SUB] PARTITION, ALTER TABLE MERGE [SUB] PARTITIONS, and ALTER TABLE COALESCE [SUB] PARTITIONS.`
You can reduce the size of a data type of a column as long as the change does not require data to be modified. The database scans existing data and returns an error if data exists that exceeds the new length limit.

You can change a DATE column to a TIMESTAMP or TIMESTAMP WITH LOCAL TIME ZONE column, and you can change a TIMESTAMP or TIMESTAMP WITH LOCAL TIME ZONE column to a DATE column. The following rules apply:

- When you change a TIMESTAMP or TIMESTAMP WITH LOCAL TIME ZONE column to a DATE column, Oracle Database updates each column value that has non-zero fractional seconds by rounding the value to the nearest second. If, while updating such a value, Oracle Database encounters a minute field greater than or equal to 60 (which can occur in a boundary case when the daylight saving rule switches), then it updates the minute field by subtracting 60 from it.

- After you change a TIMESTAMP WITH LOCAL TIME ZONE column to a DATE column, the values in the column still represent the local time that they represented in the database time zone. However, the database time zone is no longer associated with the values. When queried in SQL*Plus, the values are no longer automatically adjusted to the session time zone. It is now the responsibility of applications processing the column values to interpret them in a particular time zone.

If the table is empty, then you can increase or decrease the leading field or the fractional second value of a datetime or interval column. If the table is not empty, then you can only increase the leading field or fractional second of a datetime or interval column.

You can use the TO_LOB function to change a LONG column to a CLOB or NCLOB column, and a LONG RAW column to a BLOB column. However, you cannot use the TO_LOB function from within a PL/SQL package. Instead use the TO_CLOB or TO_BLOB functions.

- The modified LOB column inherits all constraints and triggers that were defined on the original LONG column. If you want to change any constraints, then you must do so in a subsequent ALTER TABLE statement.

- If any domain indexes are defined on the LONG column, then you must drop them before modifying the column to a LOB.

- After the modification, you will have to rebuild all other indexes on all columns of the table.

You can use the TO_CLOB function to convert NCLOB columns CLOB columns.
ALTER TABLE

See Also:
- Oracle Database SecureFiles and Large Objects Developer’s Guide for information on LONG to LOB migration
- ALTER INDEX on page 10-107 for information on dropping and rebuilding indexes

For CHAR and VARCHAR2 columns, you can change the length semantics by specifying CHAR (to indicate character semantics for a column that was originally specified in bytes) or BYTE (to indicate byte semantics for a column that was originally specified in characters). To learn the length semantics of existing columns, query the CHAR_USED column of the ALL_. USER_. or DBA_TAB_COLUMNS data dictionary view.

See Also:
- Oracle Database Globalization Support Guide for information on byte and character semantics
- Oracle Database Reference for information on the data dictionary views

identity_clause Use identity_clause to modify the properties of an identity column. You cannot specify this clause on a column that is not an identity column. If you do not specify ALWAYS or BY DEFAULT, then the current generation type is retained. Refer to CREATE TABLE identity_clause on page 16-35 for more information on ALWAYS and BY DEFAULT.

identity_options Use the identity_options clause to configure the sequence generator. The identity_options clause has the same parameters as the CREATE SEQUENCE statement. Refer to CREATE SEQUENCE on page 15-96 for a full description of these parameters and characteristics. The exceptions are:

- START WITH LIMIT VALUE, which is specific to identity_options, can only be used with ALTER TABLE MODIFY. If you specify START WITH LIMIT VALUE, then Oracle Database locks the table and finds the maximum identity column value in the table (for increasing sequences) or the minimum identity column value (for decreasing sequences) and assigns the value as the sequence generator's high water mark. The next value returned by the sequence generator will be the high water mark + INCREMENT BY integer for increasing sequences, or the high water mark - INCREMENT BY integer for decreasing sequences.

- If you change the value of START WITH, then the default values will be used for all other parameters in this clause unless you specify otherwise.

DROP IDENTITY Use this clause to remove the identity property from a column, including the sequence generator and NOT NULL and NOT DEFERRABLE constraints. Identity column values in existing rows are not affected.

ENCRYPT encryption_spec | DECRYPT Use this clause to encrypt an encrypted column, to encrypt an unencrypted column, or to change the integrity algorithm or the SALT option of an encrypted column.

When encrypting an existing column, if you specify encryption_spec, it must match the encryption specification of any other encrypted columns in the same table. Refer to the CREATE TABLE clause encryption_spec on page 16-35 for additional information and restrictions on the encryption_spec.
If a materialized view log is defined on the table, then Oracle Database encrypts or decrypts in the materialized view log any columns you encrypt or decrypt in this clause.

Restrictions on ENCRYPT encryption_spec | DECRYPT: This clause is subject to the following restrictions:

- If the new or existing column is a LOB column, then it must be stored as a SecureFiles LOB, and you cannot specify the SALT option.
- You cannot encrypt or decrypt a column on which a fine-grained audit policy for the UPDATE statement is enabled. However, you can disable the fine-grained audit policy, encrypt or decrypt the column, and then enable the fine-grained audit policy.

See Also: "Data Encryption: Examples" on page 12-108

inline_constraint This clause lets you add a constraint to a column you are modifying. To change the state of existing constraints on existing columns, use the constraint_clauses.

LOB_storage_clause The LOB_storage_clause is permitted within modify_col_properties only if you are converting a LONG column to a LOB column. In this case only, you can specify LOB storage for the column using the LOB_storage_clause. However, you can specify only the single column as a LOB_item. Default LOB storage attributes are used for any attributes you omit in the LOB_storage_clause.

alter_XMLSchema_clause This clause is valid within modify_col_properties only for XMLType tables with BINARY XML storage. Refer to XMLSchema_spec on page 16-88 in the documentation on CREATE TABLE for more information on the ALLOW and DISALLOW clauses.

Restrictions on Modifying Column Properties The modification of column properties is subject to the following restrictions:

- You cannot change the data type of a LOB column.
- You cannot modify a column of a table if a domain index is defined on the column. You must first drop the domain index and then modify the column.
- You cannot modify the data type or length of a column that is part of the partitioning or subpartitioning key of a table or index.
- You can change a CHAR column to VARCHAR2 (or VARCHAR) and a VARCHAR2 (or VARCHAR) column to CHAR only if the BLANK_TRIMMING initialization parameter is set to TRUE and the column size stays the same or increases. If the BLANK_TRIMMING initialization parameter is set to TRUE, then you can also reduce the column size to any size greater than or equal to the maximum trimmed data value.
- You cannot change a LONG or LONG RAW column to a LOB if the table is part of a cluster. If you do change a LONG or LONG RAW column to a LOB, then the only other clauses you can specify in this ALTER TABLE statement are the DEFAULT clause and the LOB_storage_clause.
- You can specify the LOB_storage_clause as part of modify_col_properties only when you are changing a LONG or LONG RAW column to a LOB.
- You cannot specify a column of data type ROWID for an index-organized table, but you can specify a column of type UROWID.
You cannot change the data type of a column to REF.

**See Also**: ALTER MATERIALIZED VIEW on page 11-3 for information on revalidating a materialized view

**modify_virtcol_properties**
This clause is valid only for virtual columns that refer to editioned PL/SQL functions. You can use this clause to modify the evaluation edition or the unusable editions for the virtual column. The `evaluation_edition_clause` and the `unusable_editions_clause` have the same semantics when you modify a virtual column that they have when you create a virtual column. For complete information, refer to `evaluation_edition_clause` on page 16-37 and `unusable_editions_clause` on page 16-38 in the documentation on CREATE TABLE.

**Restriction on Modifying Virtual Columns** If an index is defined on a virtual column and you modify its evaluation edition or unusable editions, then the database will invalidate all indexes on the virtual column. If you attempt to modify any other properties of the virtual column, then an error occurs.

**modify_colVisibility**
Use this clause to change the visibility of column. For complete information, refer to "VISIBLE | INVISIBLE" on page 16-33 in the documentation on CREATE TABLE.

**Restriction on Modifying Column Visibility** You cannot change a VISIBLE column to INVISIBLE in a table owned by SYS.

**modify_col_substitutable**
Use this clause to set or change the substitutability of an existing object type column. The `FORCE` keyword drops any hidden columns containing typeid information or data for subtype attributes. You must specify `FORCE` if the column or any attributes of its type are not FINAL.

**Restrictions on Modifying Column Substitutability** The modification of column substitutability is subject to the following restrictions:

- You can specify this clause only once in any `ALTER TABLE` statement.
- You cannot modify the substitutability of a column in an object table if the substitutability of the table itself has been set.
- You cannot specify this clause if the column was created or added using the IS OF TYPE syntax, which limits the range of subtypes permitted in an object column or attribute to a particular subtype. Refer to `substitutable_column_clause` on page 16-56 in the documentation on CREATE TABLE for information on the IS OF TYPE syntax.
- You cannot change a varray column to NOT SUBSTITUTABLE, even by specifying `FORCE`, if any of its attributes are nested object types that are not FINAL.

**drop_column_clause**
The `drop_column_clause` lets you free space in the database by dropping columns you no longer need or by marking them to be dropped at a future time when the demand on system resources is less.

- If you drop a nested table column, then its storage table is removed.
If you drop a LOB column, then the LOB data and its corresponding LOB index segment are removed.

If you drop a BFILE column, then only the locators stored in that column are removed, not the files referenced by the locators.

If you drop or mark unused a column defined as an INCLUDING column, then the column stored immediately before this column will become the new INCLUDING column.

**SET UNUSED Clause**
Specify `SET UNUSED` to mark one or more columns as unused. For an internal heap-organized table, specifying this clause does not actually remove the target columns from each row in the table. It does not restore the disk space used by these columns. Therefore, the response time is faster than when you execute the `DROP` clause.

When you specify this clause for a column in an external table, the clause is transparently converted to an `ALTER TABLE ... DROP COLUMN` statement. The reason for this is that any operation on an external table is a metadata-only operation, so there is no difference in the performance of the two commands.

You can view all tables with columns marked `UNUSED` in the data dictionary views `USER UNUSED COL_TABS`, `DBA UNUSED COL_TABS`, and `ALL UNUSED COL_TABS`.

**See Also:** Oracle Database Reference for information on the data dictionary views

Unused columns are treated as if they were dropped, even though their column data remains in the table rows. After a column has been marked `UNUSED`, you have no access to that column. A `SELECT *` query will not retrieve data from unused columns. In addition, the names and types of columns marked `UNUSED` will not be displayed during a `DESCRIBE`, and you can add to the table a new column with the same name as an unused column.

---

**Note:** Until you actually drop these columns, they continue to count toward the absolute limit of 1000 columns in a single table. However, as with all DDL statements, you cannot roll back the results of this clause. You cannot issue `SET USED` counterpart to retrieve a column that you have `SET UNUSED`. Refer to `CREATE TABLE` on page 16-6 for more information on the 1000-column limit.

Also, if you mark a LONG column as `UNUSED`, then you cannot add another LONG column to the table until you actually drop the unused LONG column.

---

**ONLINE** Specify `ONLINE` to indicate that DML operations on the table will be allowed while marking the column or columns `UNUSED`.

**Restrictions on Marking Columns Unused** The following restrictions apply to the `SET UNUSED` clause:

- You cannot specify the `ONLINE` clause when marking a column with a `DEFERRABLE` constraint as `UNUSED`.
- Columns in tables owned by `SYS` cannot be marked as `UNUSED`.

---

SQL Statements: ALTER TABLE to ALTER TABLESPACE  12-65
DROP Clause
Specify DROP to remove the column descriptor and the data associated with the target column from each row in the table. If you explicitly drop a particular column, then all columns currently marked UNUSED in the target table are dropped at the same time.

When the column data is dropped:
- All indexes defined on any of the target columns are also dropped.
- All constraints that reference a target column are removed.
- If any statistics types are associated with the target columns, then Oracle Database disassociates the statistics from the column with the FORCE option and drops any statistics collected using the statistics type.

**Note:** If the target column is a parent key of a nontarget column, or if a check constraint references both the target and nontarget columns, then Oracle Database returns an error and does not drop the column unless you have specified the CASCADE CONSTRAINTS clause. If you have specified that clause, then the database removes all constraints that reference any of the target columns.

**See Also:** DISASSOCIATE STATISTICS on page 17-36 for more information on disassociating statistics types

DROP UNUSED COLUMNS Clause
Specify DROP UNUSED COLUMNS to remove from the table all columns currently marked as unused. Use this statement when you want to reclaim the extra disk space from unused columns in the table. If the table contains no unused columns, then the statement returns with no errors.

column Specify one or more columns to be set as unused or dropped. Use the COLUMN keyword only if you are specifying only one column. If you specify a column list, then it cannot contain duplicates.

CASCADE CONSTRAINTS Specify CASCADE CONSTRAINTS if you want to drop all foreign key constraints that refer to the primary and unique keys defined on the dropped columns as well as all multicolumn constraints defined on the dropped columns. If any constraint is referenced by columns from other tables or remaining columns in the target table, then you must specify CASCADE CONSTRAINTS. Otherwise, the statement aborts and an error is returned.

INVALIDATE The INVALIDATE keyword is optional. Oracle Database automatically invalidates all dependent objects, such as views, triggers, and stored program units. Object invalidation is a recursive process. Therefore, all directly dependent and indirectly dependent objects are invalidated. However, only local dependencies are invalidated, because the database manages remote dependencies differently from local dependencies.

An object invalidated by this statement is automatically revalidated when next referenced. You must then correct any errors that exist in that object before referencing it.

**See Also:** Oracle Database Concepts for more information on dependencies
CHECKPOINT  Specify CHECKPOINT if you want Oracle Database to apply a checkpoint for the DROP COLUMN operation after processing integer rows; integer is optional and must be greater than zero. If integer is greater than the number of rows in the table, then the database applies a checkpoint after all the rows have been processed. If you do not specify integer, then the database sets the default of 512. Checkpointing cuts down the amount of undo logs accumulated during the DROP COLUMN operation to avoid running out of undo space. However, if this statement is interrupted after a checkpoint has been applied, then the table remains in an unusable state. While the table is unusable, the only operations allowed on it are DROP TABLE, TRUNCATE TABLE, and ALTER TABLE DROP ... COLUMNS CONTINUE (described in sections that follow).

You cannot use this clause with SET UNUSED, because that clause does not remove column data.

DROP COLUMNS CONTINUE Clause
Specify DROP COLUMNS CONTINUE to continue the drop column operation from the point at which it was interrupted. Submitting this statement while the table is in an invalid state results in an error.

Restrictions on Dropping Columns  Dropping columns is subject to the following restrictions:

- Each of the parts of this clause can be specified only once in the statement and cannot be mixed with any other ALTER TABLE clauses. For example, the following statements are not allowed:

  ALTER TABLE t1 DROP COLUMN f1 DROP (f2);
  ALTER TABLE t1 DROP COLUMN f1 SET UNUSED (f2);
  ALTER TABLE t1 DROP (f1) ADD (f2 NUMBER);
  ALTER TABLE t1 SET UNUSED (f3)
      ADD (CONSTRAINT ck1 CHECK (f2 > 0));

- You can drop an object type column only as an entity. To drop an attribute from an object type column, use the ALTER TYPE ... DROP ATTRIBUTE statement with the CASCADE INCLUDING TABLE DATA clause. Be aware that dropping an attribute affects all dependent objects. See Oracle Database PL/SQL Language Reference for more information.

- You can drop a column from an index-organized table only if it is not a primary key column. The primary key constraint of an index-organized table can never be dropped, so you cannot drop a primary key column even if you have specified CASCADE CONSTRAINTS.

- You can export tables with dropped or unused columns. However, you can import a table only if all the columns specified in the export files are present in the table (none of those columns has been dropped or marked unused). Otherwise, Oracle Database returns an error.

- You can set unused a column from a table that uses COMPRESS BASIC, but you cannot drop the column. However, all clauses of the drop_column_clause are valid for tables that use ROW STORE COMPRESS ADVANCED. See the semantics for table_compression on page 16-45 for more information.

- You cannot drop a column on which a domain index has been built.

- You cannot drop a SCOPE table constraint or a WITH ROWID constraint on a REF column.

- You cannot use this clause to drop:
A pseudocolumn, cluster column, or partitioning column. You can drop nonpartitioning columns from a partitioned table if all the tablespaces where the partitions were created are online and in read/write mode.

- A column from a nested table, an object table, or a table owned by SYS.

See Also:  "Dropping a Column: Example" on page 12-103

**add_period_clause**

Use the **add_period_clause** to add a valid time dimension to table.

The **period_definition** clause of ALTER TABLE has the same semantics as in CREATE TABLE, with the following exceptions and additions:

- **valid_time_column** must not already exist in table.
- If you specify **start_time_column** and **end_time_column**, then these columns must already exist in table or you must specify the **add_column_clause** for each of these columns.
- If you specify **start_time_column** and **end_time_column** and these columns already exist in table and are populated with data, then for all rows where both columns have non-NULL values, the value of **start_time_column** must be earlier than the value of **end_time_column**.

See Also:  CREATE TABLE **period_definition** on page 16-40 for the full semantics of this clause

**drop_period_clause**

Use the **drop_period_clause** to drop a valid time dimension from table.

For **valid_time_column**, specify the name of the valid time dimension you want to drop.

This clause has the following effects:

- The **valid_time_column** will be dropped from table.
- If the start time column and end time column were automatically created by Oracle Database when the valid time dimension was created, either with CREATE TABLE ... **period_definition** or ALTER TABLE ... **add_period_clause**, then they will be dropped. Otherwise, these columns will remain in table and revert to regular table columns.

See Also:  CREATE TABLE **period_definition** on page 16-40 for more information on the **valid_time_column**, start time column, and end time column

**rename_column_clause**

Use the **rename_column_clause** to rename a column of table. The new column name must not be the same as any other column name in table.

When you rename a column, Oracle Database handles dependent objects as follows:

- Function-based indexes and check constraints that depend on the renamed column remain valid.
- Dependent views, triggers, functions, procedures, and packages are invalidated. Oracle Database attempts to revalidate them when they are next accessed, but you may need to alter these objects with the new column name if revalidation fails.
If a domain index is defined on the column being renamed, then the database invokes the ODCIIndexAlter method with the \texttt{RENAME} option. This operation establishes correspondence between the indextype metadata and the base table.

**Restrictions on Renaming Columns**

Renaming columns is subject to the following restrictions:

- You cannot combine this clause with any of the other column clauses in the same statement.
- You cannot rename a column that is used to define a join index. Instead you must drop the index, rename the column, and re-create the index.

**See Also:** "Renaming a Column: Example" on page 12-103

**modify\_collection\_retrieval**

Use the \texttt{modify\_collection\_retrieval} clause to change what Oracle Database returns when a collection item is retrieved from the database.

**collection\_item** Specify the name of a column-qualified attribute whose type is nested table or varray.

**RETURN AS** Specify what Oracle Database should return as the result of a query:

- \texttt{LOCATOR} specifies that a unique locator for the nested table is returned.
- \texttt{VALUE} specifies that a copy of the nested table itself is returned.

**See Also:** "Collection Retrieval: Example" on page 12-101

**modify\_LOB\_storage\_clause**

The \texttt{modify\_LOB\_storage\_clause} lets you change the physical attributes of \texttt{LOB\_item}. You can specify only one \texttt{LOB\_item} for each \texttt{modify\_LOB\_storage\_clause}.

The sections that follow describe the semantics of parameters specific to \texttt{modify\_LOB\_storage\_clause}. Unless otherwise documented in this section, the remaining LOB parameters have the same semantics when altering a table that they have when you are creating a table. Refer to the restrictions at the end of this section and to the \texttt{CREATE TABLE} clause \texttt{LOB\_storage\_parameters} on page 16-58 for more information.

**Notes:**

- You can modify LOB storage with an \texttt{ALTER TABLE} statement or with online redefinition by using the \texttt{DBMS\_REDEFINITION} package. If you have not enabled LOB encryption, compression, or deduplication at create time, Oracle recommends that you use online redefinition to enable them after creation, as this process is more disk space efficient for changes to these three parameters. See Oracle Database PL/SQL Packages and Types Reference for more information on \texttt{DBMS\_REDEFINITION}.

- You cannot convert a LOB from one type of storage to the other. Instead you must migrate to SecureFiles or BasicFiles by using online redefinition or partition exchange.

**PCTVERSION integer** Refer to the \texttt{CREATE TABLE} clause \texttt{PCTVERSION integer} on page 16-59 for information on this clause.
**LOB_retention_clause**  If the database is in automatic undo mode, then you can specify RETENTION instead of PCTVERSION to instruct Oracle Database to retain old versions of this LOB. This clause overrides any prior setting of PCTVERSION.

**FREEPOOLS integer**  For BasicFiles LOBs, if the database is in automatic undo mode, then you can use this clause to specify the number of freelist groups for this LOB. This clause overrides any prior setting of FREELIST GROUPS. Refer to the CREATE TABLE clause FREEPOOLS integer on page 16-60 for a full description of this parameter. The database ignores this parameter for SecureFiles LOBs.

**REBUILD FREEPOOLS**  This clause applies only to BasicFiles LOBs, not to SecureFiles LOBs. The REBUILD FREEPOOLS clause removes all the old versions of data from the LOB column. This clause is useful for removing all retained old version space in a LOB segment, freeing that space to be used immediately by new LOB data.

**LOB_deduplicate_clause**  This clause is valid only for SecureFiles LOBs. KEEP_DUPLICATES disables LOB deduplication. DEDUPLICATE enables LOB deduplication. All lobs in the segment are read, and any matching LOBs are deduplicated before returning.

**LOB_compression_clause**  This clause is valid only for SecureFiles LOBs. COMPRESS compresses all LOBs in the segment and then returns. NOCOMPRESS uncompresses all LOBs in the segment and then returns.

**ENCRYPT | DECRYPT**  LOB encryption has the same semantics as column encryption in general. See "ENCRYPT encryption_spec | DECRYPT" on page 12-62 for more information.

**CACHE, NOCACHE, CACHE READS**  When you modify a LOB column from CACHE or NOCACHE to CACHE READS, or from CACHE READS to CACHE or NOCACHE, you can change the logging attribute. If you do not specify LOGGING or NOLOGGING, then this attribute defaults to the current logging attribute of the LOB column. If you do not specify CACHE, NOCACHE, or CACHE READS, then Oracle Database retains the existing values of the LOB attributes.

**Restrictions on Modifying LOB Storage**  Modifying LOB storage is subject to the following restrictions:

- You cannot modify the value of the INITIAL parameter in the storage_clause when modifying the LOB storage attributes.
- You cannot specify both the allocate_extent_clause and the deallocate_unused_clause in the same statement.
- You cannot specify both the PCTVERSION and RETENTION parameters.
- You cannot specify the shrink_clause for SecureFiles LOBs.

See Also:  LOB_storage_clause on page 16-57 (in CREATE TABLE) for information on setting LOB parameters and "LOB Columns: Examples" on page 12-110

**alter_varray_col_properties**  The alter_varray_col_properties clause lets you change the storage characteristics of an existing LOB in which a varray is stored.
Restriction on Altering Varray Column Properties  You cannot specify the TABLESPACE clause of LOB_parameters as part of this clause. The LOB tablespace for a varray defaults to the tablespace of the containing table.

REKEY encryption_spec
The REKEY clause causes the database to generate a new encryption key. All encrypted columns in the table are reencrypted using the new key and, if you specify the USING clause of the encryption_spec, a new encryption algorithm. You cannot combine this clause with any other clauses in this ALTER TABLE statement.

See Also: Oracle Database Advanced Security Guide for more information on transparent column encryption

constraint_clauses
Use the constraint_clauses to add a new constraint using out-of-line declaration, modify the state of an existing constraint, or drop a constraint. Refer to constraint on page 8-4 for a description of all the keywords and parameters of out-of-line constraints and constraint_state.

Adding a Constraint
The ADD clause lets you add a new out-of-line constraint or out-of-line REF constraint to the table.

See Also: "Disabling a CHECK Constraint: Example" on page 12-102, "Specifying Object Identifiers: Example" on page 12-107, and "REF Columns: Examples" on page 12-111

Modifying a Constraint
The MODIFY CONSTRAINT clause lets you change the state of an existing constraint. The CASCADE keyword is valid only when you are disabling a unique or primary key constraint on which a foreign key constraint is defined. In this case, you must specify CASCADE so that the unique or primary key constraint and all of its dependent foreign key constraints are disabled.

Restrictions on Modifying Constraints  Modifying constraints is subject to the following restrictions:

- You cannot change the state of a NOT DEFERRABLE constraint to INITIALLY DEFERRED.
- If you specify this clause for an index-organized table, then you cannot specify any other clauses in the same statement.
- You cannot change the NOT NULL constraint on a foreign key column of a reference-partitioned table, and you cannot change the state of a partitioning referential constraint of a reference-partitioned table.

See Also: "Changing the State of a Constraint: Examples" on page 12-101

Renaming a Constraint
The RENAME CONSTRAINT clause lets you rename any existing constraint on table. The new constraint name cannot be the same as any existing constraint on any object in the same schema. All objects that are dependent on the constraint remain valid.
See Also: "Renaming Constraints: Example" on page 12-110

**drop_constraint_clause**
The *drop_constraint_clause* lets you drop an integrity constraint from the database. Oracle Database stops enforcing the constraint and removes it from the data dictionary. You can specify only one constraint for each *drop_constraint_clause*, but you can specify multiple *drop_constraint_clause* in one statement.

**PRIMARY KEY**  Specify **PRIMARY KEY** to drop the primary key constraint of **table**.

**UNIQUE**  Specify **UNIQUE** to drop the unique constraint on the specified columns.

If you drop the primary key or unique constraint from a column on which a bitmap join index is defined, then Oracle Database invalidates the index. See CREATE INDEX on page 14-73 for information on bitmap join indexes.

**CONSTRAINT**  Specify **CONSTRAINT constraint_name** to drop an integrity constraint other than a primary key or unique constraint.

**CASCADE**  Specify **CASCADE** if you want all other integrity constraints that depend on the dropped integrity constraint to be dropped as well.

**KEEP INDEX | DROP INDEX**  Specify **KEEP INDEX** or **DROP INDEX** to indicate whether Oracle Database should preserve or drop the index it has been using to enforce the **PRIMARY KEY** or **UNIQUE** constraint.

**ONLINE**  Specify **ONLINE** to indicate that DML operations on the table will be allowed while dropping the constraint.

**Restrictions on Dropping Constraints**  Dropping constraints is subject to the following restrictions:

- You cannot drop a primary key or unique key constraint that is part of a referential integrity constraint without also dropping the foreign key. To drop the referenced key and the foreign key together, use the **CASCADE** clause. If you omit **CASCADE**, then Oracle Database does not drop the primary key or unique constraint if any foreign key references it.

- You cannot drop a primary key constraint (even with the **CASCADE** clause) on a table that uses the primary key as its object identifier (OID).

- If you drop a referential integrity constraint on a **REF** column, then the **REF** column remains scoped to the referenced table.

- You cannot drop the scope of a **REF** column.

- You cannot drop the **NOT NULL** constraint on a foreign key column of a reference-partitioned table, and you cannot drop a partitioning referential constraint of a reference-partitioned table.

- You cannot drop the **NOT NULL** constraint on a column that is defined with a default column value using the **ON NULL** clause.

- You cannot specify the **ONLINE** clause when dropping a **DEFERRABLE** constraint.

See Also: "Dropping Constraints: Examples" on page 12-110
**alter_external_table**

Use the `alter_external_table` clauses to change the characteristics of an external table. This clause has no affect on the external data itself. The syntax and semantics of the `parallel_clause`, `enable_disable_clause`, `external_data_properties`, and `REJECT LIMIT` clause are the same as described for `CREATE TABLE`. See the `external_table_clause` on page 16-54 (in `CREATE TABLE`).

**PROJECT COLUMN Clause**  
This clause lets you determine how the access driver validates the rows of an external table in subsequent queries. The default is `PROJECT COLUMN ALL`, which means that the access driver processes all column values, regardless of which columns are selected, and validates only those rows with fully valid column entries. If any column value would raise an error, such as a data type conversion error, then the row is rejected even if that column was not referenced in the select list. If you specify `PROJECT COLUMN REFERENCED`, then the access driver processes only those columns in the select list.

The `ALL` setting guarantees consistent result sets. The `REFERENCED` setting can result in different numbers of rows returned, depending on the columns referenced in subsequent queries, but is faster than the `ALL` setting. If a subsequent query selects all columns of the external table, then the settings behave identically.

**Restrictions on Altering External Tables**  
Altering external tables is subject to the following restrictions:

- You cannot modify an external table using any clause outside of this clause.
- You cannot add a `LONG`, varray, or object type column to an external table, nor can you change the data type of an external table column to any of these data types.
- You cannot add a constraint to an external table.
- You cannot modify the storage parameters of an external table.

**alter_table_partitioning**

The clauses in this section apply only to partitioned tables. You cannot combine partition operations with other partition operations or with operations on the base table in the same `ALTER TABLE` statement.

**Notes on Changing Table Partitioning**  
The following notes apply when changing table partitioning:

- If you drop, exchange, truncate, move, modify, or split a partition on a table that is a master table for one or more materialized views, then existing bulk load information about the table will be deleted. Therefore, be sure to refresh all dependent materialized views before performing any of these operations.
- If a bitmap join index is defined on `table`, then any operation that alters a partition of `table` causes Oracle Database to mark the index `UNUSABLE`.
- The only `alter_table_partitioning` clauses you can specify for a reference-partitioned table are `modify_table_default_attrs`, `move_table_[sub]partition`, `truncate_partition_subpart`, and `exchange_partition_subpart`. None of these operations cascade to any child table of the reference-partitioned table. No other partition maintenance operations are valid on a reference-partitioned table, but you can specify the other partition maintenance operations on the parent table of a reference-partitioned table, and the operation will cascade to the child reference-partitioned table.
When adding partitions and subpartitions, bear in mind that you can specify up to a total of 1024K-1 partitions and subpartitions for each table.

When you add a table partition or subpartition and you omit the partition name, the database generates a name using the rules described in "Notes on Partitioning in General" on page 16-67.

When you move, add (hash only), coalesce, drop, merge, rename, or truncate a table partition or subpartition, the procedures, functions, packages, package bodies, views, type bodies, and triggers that reference the table remain valid. All other dependent objects are invalidated.

Deferred segment creation is not supported for partition maintenance operations that create new segments on tables with LOB columns; segments will always be created for the involved (sub)partitions.

For additional information on partition operations on tables with an associated CONTEXT domain index, refer to Oracle Text Reference.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to Oracle Database VLDB and Partitioning Guide for a discussion of these restrictions.

modify_table_default_attrs
The modify_table_default_attrs clause lets you specify new default values for the attributes of table. Only attributes named in the statement are affected. Partitions and LOB partitions you create subsequently will inherit these values unless you override them explicitly when creating the partition or LOB partition. Existing partitions and LOB partitions are not affected by this clause.

Only attributes named in the statement are affected, and the default values specified are overridden by any attributes specified at the individual partition or LOB partition level.

FOR partition_extended_name applies only to composite-partitioned tables. This clause specifies new default values for the attributes of the partition identified in partition_extended_name. Subpartitions and LOB subpartitions of that partition that you create subsequently will inherit these values unless you override them explicitly when creating the subpartition or LOB subpartition. Existing subpartitions are not affected by this clause.

PCTTHRESHOLD, prefix_compression, and the alter_overflow_clause are valid only for partitioned index-organized tables.

You can specify the prefix_compression clause only if prefix compression is already specified at the table level. Further, you cannot specify an integer after the COMPRESS keyword. Prefix length can be specified only when you create the table.

You cannot specify the PCTUSED parameter in segment_attributes for the index segment of an index-organized table.

The indexing_clause lets you modify the default indexing property for the table. The new default indexing property will be assigned to partitions or subpartitions that are subsequently added to the table, unless you override this behavior by specifying the indexing property for the new partition or subpartition. When you modify the default indexing property of a table, you do not change the indexing property of the existing partitions and subpartitions in the table. Refer to the indexing_clause of CREATE TABLE on page 16-65 for the full semantics of this clause.
**alter_interval_partitioning**

Use this clause:

- To convert an existing range-partitioned table to interval partitioning. The database automatically creates partitions of the specified numeric range or datetime interval as needed for data beyond the highest value allowed for the last range partition. If the table has reference-partitioned child tables, then the child tables are converted to interval reference-partitioned child tables.

- To change the interval of an existing interval-partitioned table. The database first converts existing interval partitions to range partitions and determines the high value of the defined range partitions. The database then automatically creates partitions of the specified numeric range or datetime interval as needed for data that is beyond that high value.

- To change the tablespace storage for an existing interval-partitioned table. If the table has interval reference-partitioned child tables, then the new tablespace storage is inherited by any child table that does not have its own table-level default tablespace.

- To change an interval-partitioned table back to a range-partitioned table. Use `SET INTERVAL()` to disable interval partitioning. The database converts existing interval partitions to range partitions, using the higher boundaries of created interval partitions as upper boundaries for the range partitions to be created. If the table has interval reference-partitioned child tables, then the child tables are converted to ordinary reference-partitioned child tables.

For `expr`, specify a valid number or interval expression.

**See Also:** The `CREATE TABLE "INTERVAL Clause"` on page 16-68 and Oracle Database VLDB and Partitioning Guide for more information on interval partitioning

**set_subpartition_template**

Use the `set_subpartition_template` clause to create or replace existing default range, list, or hash subpartition definitions for each table partition. This clause is valid only for composite-partitioned tables. It replaces the existing subpartition template or creates a new template if you have not previously created one. Existing subpartitions are not affected, nor are existing local and global indexes. However, subsequent partitioning operations (such as add and merge operations) will use the new template.

You can drop an existing subpartition template by specifying `ALTER TABLE table SET SUBPARTITION TEMPLATE ()`.

The `set_subpartition_template` clause has the same semantics as the `subpartition_template` clause of `CREATE TABLE`. Refer to the `subpartition_template` clause of `CREATE TABLE` on page 16-74 for more information.

**modify_table_partition**

The `modify_table_partition` clause lets you change the real physical attributes of a range, hash, list partition, or system partition. This clause optionally modifies the storage attributes of one or more LOB items for the partition. You can specify new values for physical attributes (with some restrictions, as noted in the sections that follow), logging, and storage parameters.

For all types of partitions, you can also specify how Oracle Database should handle local indexes that become unusable as a result of the modification to the partition. See "UNUSABLE LOCAL INDEXES Clauses" on page 12-95.
For partitioned index-organized tables, you can also update the mapping table in conjunction with partition changes. See the *alter_mapping_table_clauses* on page 12-54.

**indexing_clause**  Use the *indexing_clause* to modify the indexing property of a table partition. The indexing property determines whether the partition is included in partial indexes on the table. You can specify the *indexing_clause* in the *modify_range_partition*, *modify_hash_partition*, and *modify_list_partition* clauses.

Specify **INDEXING ON** to change the indexing property for a table partition to **ON**. This operation has no effect on full indexes on the table. It has the following effects on partial indexes on the table:

- Local partial indexes: The table partition is included in the index. The corresponding index partition is rebuilt and marked **USABLE**.
- Global partial indexes: The table partition is included in the index. Index entries for the table partition are added to the index as part of routine index maintenance.

Specify **INDEXING OFF** to change the indexing property for a table partition to **OFF**. This operation has no effect on full indexes on the table. It has the following effects on partial indexes on the table:

- Local partial indexes: The table partition is excluded from the index. The corresponding index partition is marked **UNUSABLE**.
- Global partial indexes: The table partition is excluded from the index. Index entries for the table partition are removed from the index. This is a metadata-only operation and the index entries will continue to be physically stored in the index. You can remove these orphaned index entries by specifying **COALESCE CLEANUP** in the *ALTER INDEX* statement or in the *modify_index_partition* clause.

**Restriction on the indexing_clause**  You can specify this clause only for partitions of a simple partitioned table. For composite-partitioned tables, you can specify the *indexing_clause* at the table subpartition level. Refer to *modify_table_subpartition* on page 12-78 for more information.

**Notes on Modifying Table Partitions**  The following notes apply to operations on range, list, and hash table partitions:

- For all types of table partition, in the *partition_attributes* clause, the *shrink_clause* lets you compact an individual partition segment. Refer to *shrink_clause* on page 12-51 for additional information on this clause.
- The syntax and semantics for modifying a system partition are the same as those for modifying a hash partition. Refer to *modify_hash_partition* on page 12-78.
- If *table* is composite partitioned, then:
  - If you specify the *allocate_extent_clause*, then Oracle Database allocates an extent for each subpartition of *partition*.
  - If you specify the *deallocate_unused_clause*, then Oracle Database deallocates unused storage from each subpartition of *partition*.
  - Any other attributes changed in this clause will be changed in subpartitions of *partition* as well, overriding existing values. To avoid changing the attributes of existing subpartitions, use the *FOR PARTITION* clause of *modify_table_default_attrs*.
- When you modify the *partition_attributes* of a table partition with equipartitioned nested tables, the changes do not apply to the nested table partitions corresponding to the table partition being modified. However, you can
modify the storage table of the nested table partition directly with an ALTER TABLE statement.

- Unless otherwise documented, the remaining clauses of partition_attributes have the same behavior they have when you are creating a partitioned table. Refer to the CREATE TABLE table_partitioning_clauses on page 16-67 for more information.

See Also: "Modifying Table Partitions: Examples" on page 12-106

modify_range_partition
Use this clause to modify the characteristics of a range partition.

add_range_subpartition This clause is valid only for range-range composite partitions. It lets you add one or more range subpartitions to partition.

Restriction on Adding Range Subpartitions If table is an index-organized table, then you can add only one range subpartition at a time.

add_hash_subpartition This clause is valid only for range-hash composite partitions. The add_hash_subpartition clause lets you add a hash subpartition to partition. Oracle Database populates the new subpartition with rows rehashed from the other subpartition(s) of partition as determined by the hash function. For optimal load balancing, the total number of subpartitions should be a power of 2.

In the partitioning_storage_clause, the only clause you can specify for subpartitions is the TABLESPACE clause. If you do not specify TABLESPACE, then the new subpartition will reside in the default tablespace of partition.

Oracle Database adds local index partitions corresponding to the selected partition.

Oracle Database marks UNUSABLE the local index partitions corresponding to the added partitions. The database invalidates any indexes on heap-organized tables. You can update these indexes during this operation using the update_index_clauses.

add_list_subpartition This clause is valid only for range-list and list-list composite partitions. It lets you add one or more list subpartitions to partition, and only if you have not already created a DEFAULT subpartition.

- The list_values_clause is required in this operation, and the values you specify in the list_values_clause cannot exist in any other subpartition of partition. However, these values can duplicate values found in subpartitions of other partitions.

- In the partitioning_storage_clause, the only clauses you can specify for subpartitions are the TABLESPACE clause and table compression.

For each added subpartition, Oracle Database also adds a subpartition with the same value list to all local index partitions of the table. The status of existing local and global index partitions of table are not affected.

Restrictions on Adding List Subpartitions The following restrictions apply to adding list subpartitions:

- You cannot specify this clause if you have already created a DEFAULT subpartition for this partition. Instead you must split the DEFAULT partition using the split_list_subpartition clause.

- If table is an index-organized table, then you can add only one list subpartition at a time.
**coalesce_table_subpartition**  
COALESCE SUBPARTITION applies only to hash subpartitions. Use the COALESCE SUBPARTITION clause if you want Oracle Database to select the last hash subpartition, distribute its contents into one or more remaining subpartitions (determined by the hash function), and then drop the last subpartition.

- Oracle Database drops local index partitions corresponding to the selected partition.
- Oracle Database marks UNUSABLE the local index partitions corresponding to one or more absorbing partitions. The database invalidates any global indexes on heap-organized tables. You can update these indexes during this operation using the update_index_clauses.

**modify_hash_partition**
When modifying a hash partition, in the partition_attributes clause, you can specify only the allocate_extent_clause and deallocate_unused_clause. All other attributes of the partition are inherited from the table-level defaults except TABLESPACE, which stays the same as it was at create time.

**modify_list_partition**
Clauses available to you when modifying a list partition have the same semantics as when you are modifying a range partition. When modifying a list partition, the following additional clauses are available:

**ADD | DROP VALUES Clauses**  
These clauses are valid only when you are modifying composite partitions. Local and global indexes on the table are not affected by either of these clauses.

- Use the ADD VALUES clause to extend the partition_key_value list of partition to include additional values. The added partition values must comply with all rules and restrictions listed in the CREATE TABLE clause list_partitions on page 16-71.
- Use the DROP VALUES clause to reduce the partition_key_value list of partition by eliminating one or more partition_key_value. When you specify this clause, Oracle Database checks to ensure that no rows with this value exist. If such rows do exist, then Oracle Database returns an error.

---

**Note:** ADD VALUES and DROP VALUES operations on a table with a DEFAULT list partition are enhanced if you have defined a local prefixed index on the table.

---

**Restrictions on Adding and Dropping List Values**  
Adding and dropping list values are subject to the following restrictions:

- You cannot add values to or drop values from a DEFAULT list partition.
- If table contains a DEFAULT partition and you attempt to add values to a nondefault partition, then Oracle Database will check that the values being added do not already exist in the DEFAULT partition. If the values do exist in the DEFAULT partition, then Oracle Database returns an error.

**modify_table_subpartition**

This clause applies only to composite-partitioned tables. Its subclauses let you modify the characteristics of an individual range, list, or hash subpartition.
ALTER TABLE

The `shrink_clause` lets you compact an individual subpartition segment. Refer to `shrink_clause` on page 12-51 for additional information on this clause.

You can also specify how Oracle Database should handle local indexes that become unusable as a result of the modification to the partition. See "UNUSABLE LOCAL INDEXES Clauses" on page 12-95.

Use the `indexing_clause` to modify the indexing property of a table subpartition. The indexing property determines whether the subpartition is included in partial indexes on the table. Modifying the indexing property of table subpartitions has the same effect on index subpartitions as modifying the indexing property of table partitions has on index partitions. Refer to the `indexing_clause` of `modify_table_partition` on page 12-76 for details.

**Restriction on Modifying Hash Subpartitions**

The only `modify_LOB_parameters` you can specify for `subpartition` are the `allocate_extent_clause` and `deallocate_unused_clause`.

**ADD | DROP VALUES Clauses**

These clauses are valid only when you are modifying list subpartitions. Local and global indexes on the table are not affected by either of these clauses.

- Use the `ADD VALUES` clause to extend the `subpartition_key_value` list of `subpartition` to include additional values. The added partition values must comply with all rules and restrictions listed in the `CREATE TABLE` clause `list_partitions` on page 16-71.

- Use the `DROP VALUES` clause to reduce the `subpartition_key_value` list of `subpartition` by eliminating one or more `subpartition_key_value`. When you specify this clause, Oracle Database checks to ensure that no rows with this value exist. If such rows do exist, then Oracle Database returns an error.

You can also specify how Oracle Database should handle local indexes that become unusable as a result of the modification to the partition. See "UNUSABLE LOCAL INDEXES Clauses" on page 12-95.

**Restriction on Modifying List Subpartitions**

The only `modify_LOB_parameters` you can specify for `subpartition` are the `allocate_extent_clause` and `deallocate_unused_clause`.

**move_table_partition**

Use the `move_table_partition` clause to move `partition` to another segment. You can move partition data to another tablespace, recluster data to reduce fragmentation, or change create-time physical attributes.

If the table contains LOB columns, then you can use the `LOB_storage_clause` to move the LOB data and LOB index segments associated with this partition. Only the LOBs named are affected. If you do not specify the `LOB_storage_clause` for a particular LOB column, then its LOB data and LOB index segments are not moved.

If the table contains nested table columns, then you can use the `nested_table_col_properties clause` of the `table_partition_description` to move the nested table segments associated with this partition. Only the nested table items named are affected. If you do not specify the `nested_table_col_properties clause` of the `table_partition_description` for a particular nested table column, then its segments are not moved.

Oracle Database moves local index partitions corresponding to the specified partition. If the moved partitions are not empty, then the database marks them `UNUSABLE`. The
database invalidates global indexes on heap-organized tables. You can update these indexes during this operation using the `update_index_clauses`.

When you move a LOB data segment, Oracle Database drops the old data segment and corresponding index segment and creates new segments even if you do not specify a new tablespace.

The move operation obtains its parallel attribute from the `parallel_clause`, if specified. When it is not specified, the default parallel attributes of the table, if any, are used. If neither is specified, then Oracle Database performs the move serially.

Specifying the `parallel_clause` in `MOVE PARTITION` does not change the default parallel attributes of `table`.

---

**Note:** For index-organized tables, Oracle Database uses the address of the primary key, as well as its value, to construct logical rowids. The logical rowids are stored in the secondary index of the table. If you move a partition of an index-organized table, then the address portion of the rowids will change, which can hamper performance. To ensure optimal performance, rebuild the secondary index(es) on the moved partition to update the rowids.

See Also: "Moving Table Partitions: Example" on page 12-106

**MAPPING TABLE** The `MAPPING TABLE` clause is relevant only for an index-organized table that already has a mapping table defined for it. Oracle Database moves the mapping table along with the moved index-organized table partition. The mapping table partition inherits the physical attributes of the moved index-organized table partition. This is the only way you can change the attributes of the mapping table partition. If you omit this clause, then the mapping table partition retains its original attributes.

Oracle Database marks `UNUSABLE` all corresponding bitmap index partitions.

Refer to the `mapping_table_clauses` on page 16-53 (in `CREATE TABLE`) for more information on this clause.

**ONLINE** Specify `ONLINE` to indicate that DML operations on the table partition will be allowed while moving the table partition.

**Restrictions on the ONLINE Clause** The `ONLINE` clause is subject to the following restrictions when moving table partitions:

- You cannot specify the `ONLINE` clause for tables owned by `SYS`.
- You cannot specify the `ONLINE` clause for index-organized tables.
- You cannot specify the `ONLINE` clause for heap-organized tables that contain object types or on which bitmap join indexes or domain indexes are defined.
- You cannot specify the `ONLINE` clause when database-level supplemental logging is enabled for the database. This restriction is removed starting with Oracle Database 12c Release 1 (12.1.0.2).
- Parallel DML and direct path `INSERT` operations require an exclusive lock on the table. Therefore, these operations are not supported concurrently with an ongoing online partition `MOVE`, due to conflicting locks.
Restrictions on Moving Table Partitions  Moving table partitions is subject to the following restrictions:

- If partition is a hash partition, then the only attribute you can specify in this clause is TABLESPACE.
- You cannot specify this clause for a partition containing subpartitions. However, you can move subpartitions using the move_table_subpartition clause.

move_table_subpartition

Use the move_table_subpartition clause to move the subpartition identified by subpartition_extended_name to another segment. If you do not specify TABLESPACE, then the subpartition remains in the same tablespace.

If the subpartition is not empty, then Oracle Database marks UNUSABLE all local index subpartitions corresponding to the subpartition being moved. You can update all indexes on heap-organized tables during this operation using the update_index_clauses.

If the table contains LOB columns, then you can use the LOB_storage_clause to move the LOB data and LOB index segments associated with this subpartition. Only the LOBs specified are affected. If you do not specify the LOB_storage_clause for a particular LOB column, then its LOB data and LOB index segments are not moved.

When you move a LOB data segment, Oracle Database drops the old data segment and corresponding index segment and creates new segments even if you do not specify a new tablespace.

ONLINE  Specify ONLINE to indicate that DML operations on the table subpartition will be allowed while moving the table subpartition.

Restrictions on the ONLINE Clause  The ONLINE clause for moving table subpartitions is subject to the same restrictions as the ONLINE clause for moving table partitions. Refer to "Restrictions on the ONLINE Clause" on page 12-80.

Restriction on Moving Table Subpartitions  The only clauses of the partitioning_storage_clause you can specify are the TABLESPACE clause and table_compression.

add_table_partition

Use the add_table_partition clause to add one or more range, list, or system partitions to table, or to add one hash partition to table.

For each partition added, Oracle Database adds to any local index defined on table a new partition with the same name as that of the base table partition. If the index already has a partition with such a name, then Oracle Database generates a partition name of the form SYS_Pn.

If table is index organized, then for each partition added Oracle Database adds a partition to any mapping table and overflow area defined on the table as well.

If table is the parent table of a reference-partitioned table, then you can use the dependent_tables_clause to propagate the partition maintenance operation you are specifying in this statement to all the reference-partitioned child tables.

The default indexing property of table is inherited by the new table partition(s). You can override this by setting the indexing property of a list, range, or system partition using the indexing_clause in the table_partition_description clause, or a hash partition using the indexing_clause in the add_hash_partition_clause.
For each partition added to a composite-partitioned table, Oracle Database adds a new index partition with the same subpartition descriptions to all local indexes defined on table. Global indexes defined on table are not affected. If you specify the indexing property for the new table partition, then the new subpartitions inherit the indexing property for the partition. Otherwise, the new subpartitions inherit the default indexing property for the table. You can override this by setting the indexing property of a subpartition using the indexing_clause in the range_subpartition_desc, individual_hash_subparts, and list_subpartition_desc clauses.

**BEFORE Clause**

You can specify the optional **BEFORE** clause only when adding system partitions to table. This clause lets you specify where the new partition(s) should be added in relation to existing partitions. You cannot split a system partition. Therefore, this clause is useful if you want to divide the contents of one existing partition among multiple new partitions. If you omit this clause, then the database adds the new partition(s) after the existing partitions.

**Restriction on Adding Table Partitions**

If table is an index-organized table, or if a local domain index is defined on table, then you can add only one partition at a time.

**See Also:** "Adding a Table Partition with a LOB and Nested Table Storage: Examples" on page 12-105 and "Adding Multiple Partitions to a Table: Example" on page 12-105

**add_range_partition_clause**

The **add_range_partition_clause** lets you add a new range partition to the high end of a range-partitioned or composite range-partitioned table (after the last existing partition).

If a domain index is defined on table, then the index must not be marked **IN PROGRESS** or **FAILED**.

**Restrictions on Adding Range Partitions**

Adding range partitions is subject to the following restrictions:

- If the upper partition bound of each partitioning key in the existing high partition is **MAXVALUE**, then you cannot add a partition to the table. Instead, use the **split_table_partition** clause to add a partition at the beginning or the middle of the table.

- The **prefix_compression** and **OVERFLOW** clauses, are valid only for a partitioned index-organized table. You can specify **prefix_compression** only if prefix compression is enabled at the table level. You can specify **OVERFLOW** only if the partitioned table already has an overflow segment.

- You cannot specify the **PCTUSED** parameter for the index segment of an index-organized table.

**range_values_clause**

Specify the upper bound for the new partition. The **value_list** is a comma-delimited, ordered list of literal values corresponding to the partitioning key columns. The **value_list** must collate greater than the partition bound for the highest existing partition in the table.

**table_partition_description**

Use this clause to specify any create-time physical attributes for the new partition. If the table contains LOB columns, then you can also specify partition-level attributes for one or more LOB items.
Subpartition Descriptions These clauses are valid only for composite-partitioned tables. Use the range_subpartition_desc, list_subpartition_desc, individual_hash_subparts, or hash_subparts_by_quantity clause as appropriate, if you want to specify subpartitions for the new partition. This clause overrides any subpartition descriptions defined in subpartition_template at the table level.

add_hash_partition_clause
The add_hash_partition_clause lets you add a new hash partition to the high end of a hash-partitioned table. Oracle Database populates the new partition with rows rehashed from other partitions of table as determined by the hash function. For optimal load balancing, the total number of partitions should be a power of 2.

You can specify a name for the partition, and optionally a tablespace where it should be stored. If you do not specify a name, then the database assigns a partition name of the form SYS_Pn. If you do not specify TABLESPACE, then the new partition is stored in the default tablespace of the table. Other attributes are always inherited from table-level defaults.

If this operation causes data to be rehashed among partitions, then the database marks UNUSABLE any corresponding local index partitions. You can update all indexes on heap-organized tables during this operation using the update_index_clauses.

Use the parallel_clause to specify whether to parallelize the creation of the new partition.

Use the indexing_clause to specify the indexing property for the partition. If you do not specify this clause, then the partition inherits the default indexing property of table.

See Also: CREATE TABLE on page 16-6 and Oracle Database VLDB and Partitioning Guide for more information on hash partitioning

add_list_partition_clause
The add_list_partition_clause lets you add a new partition to table using a new set of partition values. You can specify any create-time physical attributes for the new partition. If the table contains LOB columns, then you can also specify partition-level attributes for one or more LOB items.

Restrictions on Adding List Partitions You cannot add a list partition if you have already defined a DEFAULT partition for the table. Instead, you must use the split_table_partition clause to split the DEFAULT partition.

See Also:
- list_partitions of CREATE TABLE on page 16-71 for more information and restrictions on list partitions
- "Working with Default List Partitions: Example" on page 12-105

add_system_partition_clause
Use this clause to add a partition to a system-partitioned table. Oracle Database adds a corresponding index partition to all local indexes defined on the table.

The table_partition_description lets you specify partition-level attributes of the new partition. The values of any unspecified attributes are inherited from the table-level values.
**Restriction on Adding System Partitions**  You cannot specify the `OVERFLOW` clause when adding a system partition.

**See Also:**  The `CREATE TABLE` clause `system_partitioning` on page 16-77 for more information on system partitions

**coalesce_table_partition**

`COALESCE` applies only to hash partitions. Use the `coalesce_table_partition` clause to indicate that Oracle Database should select the last hash partition, distribute its contents into one or more remaining partitions as determined by the hash function, and then drop the last partition.

Oracle Database drops local index partitions corresponding to the selected partition. The database marks `UNUSABLE` the local index partitions corresponding to one or more absorbing partitions. The database invalidates any indexes on heap-organized tables. You can update all indexes during this operation using the `update_index_clauses`.

**Restriction on Coalescing Table Partitions**  If you update global indexes using the `update_all_indexes_clause`, then you can specify only the keywords `UPDATE INDEXES`, not the subclause.

**drop_table_partition**

The `drop_table_partition` clause removes partitions, and the data in those partitions, from a partitioned table. If you want to drop a partition but keep its data in the table, then you must merge the partition into one of the adjacent partitions.

**See Also:**  `merge_table_partitions` on page 12-91

Use the `partition_extended_names` clause to specify one or more partitions to be dropped. When specifying multiple partitions, you must specify all partitions by name, as shown in the upper branch of the syntax diagram, or all partitions using the `FOR` clause, as shown in the lower branch of the syntax diagram. You cannot use both types of syntax in one drop operation.

- If `table` has LOB columns, then Oracle Database also drops the LOB data and LOB index partitions and any subpartitions corresponding to the table partition(s) being dropped.
- If `table` has equipartitioned nested table columns, then Oracle Database also drops the nested table partitions corresponding to the table partition(s) being dropped.
- If `table` is index organized and has a mapping table defined on it, then the database drops the corresponding mapping table partition(s) as well.
- Oracle Database drops local index partitions and subpartitions corresponding to the dropped partition(s), even if they are marked `UNUSABLE`.

You can update indexes on `table` during this operation using the `update_index_clauses`. Updates to global indexes are metadata-only and the index entries for records that are dropped by the drop operation will continue to be physically stored in the index. You can remove these orphaned index entries by specifying `COALESCE CLEANUP` in the `ALTER INDEX` statement or in the `modify_index_partition` clause.

If you specify the `parallel_clause` with the `update_index_clauses`, then the database parallelizes the index update, not the drop operation.

If you drop a range partition and later insert a row that would have belonged to the dropped partition, then the database stores the row in the next higher partition.
However, if that partition is the highest partition, then the insert will fail, because the range of values represented by the dropped partition is no longer valid for the table.

**Restrictions on Dropping Table Partitions** Dropping table partitions is subject to the following restrictions:

- You cannot drop a partition of a hash-partitioned table. Instead, use the `coalesce_table_partition` clause.
- You cannot drop all of the partitions in a table. Instead, drop the table.
- If you update global indexes using the `update_all_indexes_clause`, then you can specify only the `UPDATE INDEXES` keywords but not the subclause.
- If `table` is an index-organized table, or if a local domain index is defined on `table`, then you can drop only one partition at a time.

See Also: "Dropping a Table Partition: Example" on page 12-106

**drop_table_subpartition**

Use this clause to drop range or list subpartitions from a range, list, or hash composite-partitioned table. Oracle Database deletes any rows in the dropped subpartition(s).

Use the `subpartition_extended_names` clause to specify one or more subpartitions to be dropped. When specifying multiple subpartitions, you must specify all subpartitions by name, as shown in the upper branch of the syntax diagram, or all subpartitions using the `FOR` clause, as shown in the lower branch of the syntax diagram. You cannot use both types of syntax in one drop operation.

Oracle Database drops the corresponding subpartition(s) of any local index. Other index subpartitions are not affected. Any global indexes are marked UNUSABLE unless you specify the `update_global_index_clause` or `update_all_indexes_clause`. Updates to global indexes are metadata-only and the index entries for records that are dropped by the drop operation will continue to be physically stored in the index. You can remove these orphaned index entries by specifying `COALESCE CLEANUP` in the `ALTER INDEX` statement or in the `modify_index_partition` clause.

**Restrictions on Dropping Table Subpartitions** Dropping table subpartitions is subject to the following restrictions:

- You cannot drop a hash subpartition. Instead use the `MODIFY PARTITION ... COALESCE SUBPARTITION` syntax.
- You cannot drop all of the subpartitions in a partition. Instead, use the `drop_table_partition` clause.
- If you update the global indexes, then you cannot specify the optional subclause of the `update_all_indexes_clause`.
- If `table` is an index-organized table, then you can drop only one subpartition at a time.
- When dropping multiple subpartitions, all of the subpartitions must be in the same partition.

**rename_partition_subpart**

Use the `rename_partition_subpart` clause to rename a table partition or subpartition to `new_name`. For both partitions and subpartitions, `new_name` must be different from all existing partitions and subpartitions of the same table.
If table is index organized, then Oracle Database assigns the same name to the corresponding primary key index partition as well as to any existing overflow partitions and mapping table partitions.

**See Also:** "Renaming Table Partitions: Examples" on page 12-106

**truncate_partition_subpart**

Specify TRUNCATE partition extended_names to remove all rows from the partition(s) identified by partition_extended_names or, if the table is composite partitioned, all rows from the subpartitions of those partitions. Specify TRUNCATE subpartition extended_names to remove all rows from individual subpartitions. If table is index organized, then Oracle Database also truncates any corresponding mapping table partitions and overflow area partitions.

When specifying multiple partitions, you must specify all partitions by name, as shown in the upper branch of the partition_extended_names syntax diagram, or all partitions using the FOR clause, as shown in the lower branch of the syntax diagram. You cannot use both types of syntax in one truncate operation. The same rule applies when specifying multiple subpartitions with the subpartition_extended_names clause.

For each specified partition or subpartition:

- If the partition or subpartition to be truncated contain data, then you must first disable any referential integrity constraints on the table. Alternatively, you can delete the rows and then truncate the partition.

- If table contains any LOB columns, then the LOB data and LOB index segments for the partition are also truncated. If table is composite partitioned, then the LOB data and LOB index segments for the subpartitions of the partition are truncated.

- If table contains any equipartitioned nested tables, then you cannot truncate the parent partition unless its corresponding nested table partition is empty.

- If a domain index is defined on table, then the index must not be marked IN_PROGRESS or FAILED, and the index partition corresponding to the table partition being truncated must not be marked IN_PROGRESS.

For each partition or subpartition truncated, Oracle Database also truncates corresponding local index partitions and subpartitions. If those index partitions or subpartitions are marked UNUSABLE, then the database truncates them and resets the UNSUSABLE marker to VALID.

You can update indexes on table during this operation using the update_index_clauses. Updates to global indexes are metadata-only and the index entries for records that are dropped by the truncate operation will continue to be physically stored in the index. You can remove these orphaned index entries by specifying COALESCE CLEANUP in the ALTER INDEX statement or in the modify_index_partition clause.

If you specify the parallel_clause with the update_index_clauses, then the database parallelizes the index update, not the truncate operation.

**DROP STORAGE** Specify DROP STORAGE to deallocate all space from the deleted rows, except the space allocated by the MINEXTENTS parameter. This space can subsequently be used by other objects in the tablespace.

**DROP ALL STORAGE** Specify DROP ALL STORAGE to deallocate all space from the deleted rows, including the space allocated by the MINEXTENTS parameter. All segments for the partition(s) or subpartition(s), as well as all segments for their dependent objects, will be deallocated.
Restrictions on DROP ALL STORAGE  This clause is subject to the same restrictions as described in "Restrictions on Deferred Segment Creation" on page 16-44.

REUSE STORAGE  Specify REUSE STORAGE to keep space from the deleted rows allocated to the partition(s) or subpartition(s). The space is subsequently available only for inserts and updates to the same partition(s) or subpartition(s).

CASCADE  Specify CASCADE to truncate the corresponding partition(s) or subpartition(s) in all reference-partitioned child tables of table.

Restrictions on Truncating Table Partitions and Subpartitions  Truncating table partitions and subpartitions is subject to the following restrictions:

- If you update global indexes using the update_all_indexes_clause, then you can specify only the UPDATE INDEXES keywords, not the subclause.
- If table is an index-organized table, or if a local domain index is defined on table, then you can truncate only one table partition or one table subpartition at a time.

See Also: "Truncating Table Partitions: Example" on page 12-107

split_table_partition  
The split_table_partition clause lets you create, from the partition identified by partition_extended_name, multiple new partitions, each with a new segment, new physical attributes, and new initial extents. The segment associated with the current partition is discarded.

The new partitions inherit all unspecified physical attributes from the current partition.

Note:  Oracle Database can optimize and speed up SPLIT PARTITION and SPLIT SUBPARTITION operations if specific conditions are met. Refer to Oracle Database VLDB and Partitioning Guide for information on optimizing these operations.

- If you split a DEFAULT list partition, then the last resulting partition will have the DEFAULT value. All other resulting partitions will have the specified split values.
- If table is index organized, then Oracle Database splits any corresponding mapping table partition and places it in the same tablespace as the parent index-organized table partition. The database also splits any corresponding overflow area, and you can use the OVERFLOW clause to specify segment attributes for the new overflow areas.
- If table contains LOB columns, then you can use the LOB_storage_clause to specify separate LOB storage attributes for the LOB data segments resulting from the split. The database drops the LOB data and LOB index segments of the current partition and creates new segments for each LOB column, for each partition, even if you do not specify a new tablespace.
- If table contains nested table columns, then you can use the split_nested_table_part clause to specify the storage table names and segment attributes of the nested table segments resulting from the split. The database drops the nested table segments of the current partition and creates new segments for each nested table column, for each partition. This clause allows for multiple nested table columns in the parent table as well as multilevel nested table columns.
Oracle Database splits the corresponding local index partition, even if it is marked UNUSABLE. The database marks UNUSABLE, and you must rebuild the local index partitions corresponding to the split partitions. The new index partitions inherit their attributes from the partition being split. The database stores the new index partitions in the default tablespace of the index partition being split. If that index partition has no default tablespace, then the database uses the tablespace of the new underlying table partitions.

**AT Clause** The AT clause applies only to range partitions and lets you split one range partition into two range partitions. Specify the new noninclusive upper bound for the first of the two new partitions. The value list must compare less than the original partition bound for the current partition and greater than the partition bound for the next lowest partition (if there is one).

**VALUES Clause** The VALUES clause applies only to list partitions and allows you to split one list partition into two list partitions. Specify the partition values you want to include in the first of the two new partitions. Oracle Database creates the first new partition using the partition value list you specify and creates the second new partition using the remaining partition values from the current partition. Therefore, the value list cannot contain all of the partition values of the current partition, nor can it contain any partition values that do not already exist for the current partition.

**INTO Clause** The INTO clause lets you describe the new partitions resulting from the split.

- The AT ... INTO clause lets you describe the partitions resulting from splitting one range partition into two range partitions. In `range_partition_desc`, the keyword PARTITION is required even if you do not specify the optional names and physical attributes of the two partitions resulting from the split. If you do not specify new partition names, then Oracle Database assigns names of the form `SYS_Pn`. Any attributes you do not specify are inherited from the current partition.

- The VALUES ... INTO clause lets you describe the partitions resulting from splitting one list partition into two list partitions. In `list_partition_desc`, the keyword PARTITION is required even if you do not specify the optional names and physical attributes of the two partitions resulting from the split. If you do not specify new partition names, then Oracle Database assigns names of the form `SYS_Pn`. Any attributes you do not specify are inherited from the current partition.

- The INTO clause lets you split one range partition into two or more range partitions, or one list partition into two or more list partitions. If you do not specify new partition names, then Oracle Database assigns names of the form `SYS_Pn`. Any attributes you do not specify are inherited from the current partition.

  - You must specify range partitions in ascending order of their partition bounds. The partition bound of the first specified range partition must be greater than the partition bound for the next lowest partition in the table (if there is one). Do not specify a partition bound for the last range partition; it will inherit the partition bound of the current partition.

  - For list partitions, all specified partition values for the new partitions must exist in the current partition. Do not specify any partition values for the last partition. Oracle Database creates the last partition using the remaining partition values from the current partition.

For range-hash composite-partitioned tables, if you specify subpartitioning for the new partitions, then you can specify only TABLESPACE and table compression for the subpartitions. All other attributes are inherited from the current partition. If you do
not specify subpartitioning for the new partitions, then their tablespace is also inherited from the current partition.

For range-list and list-list composite-partitioned tables, you cannot specify subpartitions for the new partitions at all. The list subpartitions of the split partition inherit the number of subpartitions and value lists from the current partition.

For all composite-partitioned tables for which you do not specify subpartition names for the newly created subpartitions, the newly created subpartitions inherit their names from the parent partition as follows:

- For those subpartitions in the parent partition with names of the form `partition_name underscore (_ subpartition_name` (for example, `P1_SUBP1`), Oracle Database generates corresponding names in the newly created subpartitions using the new partition names (for example `P1A_SUB1` and `P1B_SUB1`).

- For those subpartitions in the parent partition with names of any other form, Oracle Database generates subpartition names of the form `SYS_SUBPn`.

Oracle Database splits the corresponding partition(s) in each local index defined on `table`, even if the index is marked UNUSABLE.

Oracle Database invalidates any indexes on heap-organized tables. You can update these indexes during this operation using the `update_index_clauses`.

If `table` is the parent table of a reference-partitioned table, then you can use the `dependent_tables_clause` to propagate the partition maintenance operation you are specifying in this statement to all the reference-partitioned child tables.

The `parallel_clause` lets you parallelize the split operation but does not change the default parallel attributes of the table.

Restrictions on Splitting Table Partitions Splitting table partitions is subject to the following restrictions:

- You cannot specify this clause for a hash partition.

- You cannot specify the `parallel_clause` for index-organized tables.

- If `table` is an index-organized table, or if a local domain index is defined on `table`, then you can split the partition into only two new partitions.

See Also: "Splitting Table Partitions: Examples" on page 12-104

**split_table_subpartition**

Use this clause to split a subpartition into multiple new subpartitions with nonoverlapping value lists.

Note: Oracle Database can optimize and speed up `SPLIT PARTITION` and `SPLIT SUBPARTITION` operations if specific conditions are met. Refer to Oracle Database VLDB and Partitioning Guide for information on optimizing these operations.

**AT Clause** The `AT` clause is valid only for range subpartitions. Specify the new noninclusive upper bound for the first of the two new subpartitions. The value list must compare less than the original subpartition bound for the subpartition identified by `subpartition_extended_name` and greater than the partition bound for the next lowest subpartition (if there is one).

VALUES Clause  The VALUES clause is valid only for list subpartitions. Specify the subpartition values you want to include in the first of the two new subpartitions. You can specify NULL if you have not already specified NULL for another subpartition in the same partition. Oracle Database creates the first new subpartition using the subpartition value list you specify and creates the second new partition using the remaining partition values from the current subpartition. Therefore, the value list cannot contain all of the partition values of the current subpartition, nor can it contain any partition values that do not already exist for the current subpartition.

INTO Clause  The INTO clause lets you describe the new subpartitions resulting from the split.

- The AT ... INTO clause lets you describe the two subpartitions resulting from splitting one range partition into two range partitions. In range_subpartition_desc, the keyword SUBPARTITION is required even if you do not specify the optional names and attributes of the two new subpartitions. If you do not specify new subpartition names, then Oracle Database assigns names of the form SYS_SUBPn Any attributes you do not specify are inherited from the current subpartition.

- The VALUES ... INTO clause lets you describe the two subpartitions resulting from splitting one list partition into two list partitions. In list_subpartition_desc, the keyword SUBPARTITION is required even if you do not specify the optional names and attributes of the two new subpartitions. If you do not specify new subpartition names, then Oracle Database assigns names of the form SYS_SUBPn Any attributes you do not specify are inherited from the current subpartition.

- The INTO clause lets you split one range subpartition into two or more range subpartitions, or one list subpartition into two or more list subpartitions. If you do not specify new subpartition names, then Oracle Database assigns names of the form SYS_SUBPn. Any attributes you do not specify are inherited from the current subpartition.

- You must specify range subpartitions in ascending order of their subpartition bounds. The subpartition bound of the first specified range subpartition must be greater than the subpartition bound for the next lowest subpartition (if there is one). Do not specify a subpartition bound for the last range subpartition; it will inherit the partition bound of the current subpartition.

- For list subpartitions, all specified subpartition values for the new subpartitions must exist in the current subpartition. Do not specify any subpartition values for the last subpartition. Oracle Database creates the last subpartition using the remaining partition values from the current subpartition.

Oracle Database splits any corresponding local subpartition index, even if it is marked UNUSABLE. The new index subpartitions inherit the names of the new table subpartitions unless those names are already held by index subpartitions. In that case, the database assigns new index subpartition names of the form SYS_SUBPn. The new index subpartitions inherit physical attributes from the parent subpartition. However, if the parent subpartition does not have a default TABLESPACE attribute, then the new subpartitions inherit the tablespace of the corresponding new table subpartitions.

Oracle Database invalidates indexes on heap-organized tables. You can update these indexes by using the update_index_clauses.

Restrictions on Splitting Table Subpartitions  Splitting table subpartitions is subject to the following restrictions:
You cannot specify this clause for a hash subpartition.

In subpartition descriptions, the only clauses of partitioning_storage_clause you can specify are TABLESPACE and table compression.

You cannot specify the parallel_clause for index-organized tables.

If table is an index-organized table, then you can split the subpartition into only two new subpartitions.

merge_table_partitions

The merge_table_partitions clause lets you merge the contents of two or more range, list, or system partitions of table into one new partition and then drop the original partitions. This clause is not valid for hash partitions. Use the coalesce_table_partition clause instead.

Specify a comma-separated list of two or more range, list, or system partitions to be merged. You can use the TO clause to specify two or more adjacent range partitions to be merged.

For each partition, use partition to specify a partition name or the FOR clause to specify a partition without using its name. See "References to Partitioned Tables and Indexes" on page 2-128 for more information on the FOR clause.

The partitions to be merged must be adjacent and must be specified in ascending order of their partition bounds if they are range partitions. List partitions and system partitions need not be adjacent in order to be merged.

When you merge range partitions, the new partition inherits the partition bound of the highest of the original partitions.

When you merge list partitions, the resulting partition value list is the union of the set of the partition values lists of the partitions being merged. If you merge a DEFAULT list partition with other list partitions, then the resulting partition will be the DEFAULT partition and will have the DEFAULT value.

When you merge composite range partitions or composite list partitions, range-list or list-list composite partitions, you cannot specify subpartition descriptions. Oracle Database obtains the subpartitioning information from the subpartition template. If you have not specified a subpartition template, then the database creates one MAXVALUE subpartition from range subpartitions or one DEFAULT subpartition from list subpartitions.

Any attributes you do not specify explicitly for the new partition are inherited from table-level defaults. However, if you reuse one of the partition names for the new partition, then the new partition inherits values from the partition whose name is being reused rather than from table-level default values.

Oracle Database drops local index partitions corresponding to the selected partitions and marks UNUSABLE the local index partition corresponding to merged partition. The database also marks UNUSABLE any global indexes on heap-organized tables. You can update all these indexes during this operation using the update_index_clauses.

If table is the parent table of a reference-partitioned table, then you can use the dependent_tables_clause to propagate the partition maintenance operation you are specifying in this statement to all the reference-partitioned child tables.

Restriction on Merging Table Partitions  If table is an index-organized table, or if a local domain index is defined on table, then you can merge only two partitions at a time.
merge_table_subpartitions

The `merge_table_subpartitions` clause lets you merge the contents of two or more range or list subpartitions of `table` into one new subpartition and then drop the original subpartitions. This clause is not valid for hash subpartitions. Use the `coalesce_hash_subpartition` clause instead.

Specify a comma-separated list of two or more range or list subpartitions to be merged. You can use the `TO` clause to specify two or more adjacent range subpartitions to be merged.

For each subpartition, use `subpartition` to specify a subpartition name or the `FOR` clause to specify a subpartition without using its name. See "References to Partitioned Tables and Indexes" on page 2-128 for more information on the `FOR` clause.

The subpartitions to be merged must belong to the same partition. If they are range subpartitions, then they must be adjacent. If they are list subpartitions, then they need not be adjacent. The data in the resulting subpartition consists of the combined data from the merged subpartitions.

If you specify the `INTO` clause, then in the `range_subpartition_desc` or `list_subpartition_desc` you cannot specify the `range_values_clause` or `list_values_clause`, respectively. Further, the only clauses you can specify in the `partitioning_storage_clause` are the `TABLESPACE` clause and `table_compression`.

Any attributes you do not specify explicitly for the new subpartition are inherited from partition-level values. However, if you reuse one of the subpartition names for the new subpartition, then the new subpartition inherits values from the subpartition whose name is being reused rather than from partition-level default values.

Oracle Database merges corresponding local index subpartitions and marks the resulting index subpartition `UNUSABLE`. The database also marks `UNUSABLE` both partitioned and nonpartitioned global indexes on heap-organized tables. You can update all indexes during this operation using the `update_index_clauses`.

Restriction on Merging Table Subpartitions If `table` is an index-organized table, then you can merge only two subpartitions at a time.

echange_partition_subpart

Use the `EXCHANGE PARTITION` or `EXCHANGE SUBPARTITION` clause to exchange the data and index segments of:

- One nonpartitioned table with:
  - one range, list, or hash partition
  - one range, list, or hash subpartition

- One range-partitioned table with the range subpartitions of a range-range or list-range composite-partitioned table partition

- One hash-partitioned table with the hash subpartitions of a range-hash or list-hash composite-partitioned table partition

- One list-partitioned table with the list subpartitions of a range-list or hash-list composite-partitioned table partition

See Also: "Merging Two Table Partitions: Example" on page 12-105, "Merging Four Adjacent Range Partitions: Example" on page 12-105, and "Working with Default List Partitions: Example" on page 12-105
In all cases, the structure of the table and the partition or subpartition being exchanged, including their partitioning keys, must be identical. In the case of list partitions and subpartitions, the corresponding value lists must also match.

This clause facilitates high-speed data loading when used with transportable tablespaces.

**See Also:** *Oracle Database Administrator’s Guide* for information on transportable tablespaces

If `table` contains LOB columns, then for each LOB column Oracle Database exchanges LOB data and LOB index partition or subpartition segments with corresponding LOB data and LOB index segments of `table`.

If `table` has nested table columns, then for each such column Oracle Database exchanges nested table partition segments with corresponding nested table segments of the nonpartitioned table.

If `table` contains an identity column, then so must the partition or subpartition being exchanged, and vice versa. The sequence generators must both be increasing or decreasing. The sequence generators are not exchanged, so `table` and the partition or subpartition will continue to use the same sequence generators. The high water mark for both sequence generators will be adjusted so that new identity column values will not conflict with existing values.

All of the segment attributes of the two objects (including tablespace and logging) are also exchanged.

Existing statistics for the table being exchanged into the partitioned table will be exchanged. However, the global statistics for the partitioned table will not be altered. Use the `DBMS_STATS.GATHER_TABLE_STATS` procedure to re-create global statistics. You can set the `GRANULARITY` attribute equal to 'APPROX_GLOBAL AND PARTITION' to speed up the process and aggregate new global statistics based on the existing partition statistics. See *Oracle Database PL/SQL Packages and Types Reference* for more information on this packaged procedure.

Oracle Database invalidates any global indexes on the objects being exchanged. You can update the global indexes on the table whose partition is being exchanged by using either the `update_global_index_clause` or the `update_all_indexes_clause`. For the `update_all_indexes_clause`, you can specify only the keywords `UPDATE INDEXES`, not the subclause. Global indexes on the table being exchanged remain invalidated. The `update_global_index_clause` and `update_all_indexes_clause` do not update local indexes during an exchange operation. You can specify local index maintenance by using the `INCLUDING | EXCLUDING INDEXES` clause. If you specify the `parallel_clause` with either of these clauses, then the database parallelizes the index update, not the exchange operation.

**See Also:** “Notes on Exchanging Partitions and Subpartitions” on page 12-94

**WITH TABLE** Specify the `table` with which the partition or subpartition will be exchanged. If you omit `schema`, then Oracle Database assumes that `table` is in your own schema.

**INCLUDING | EXCLUDING INDEXES** Specify `INCLUDING INDEXES` if you want local index partitions or subpartitions to be exchanged with the corresponding table index (for a nonpartitioned table) or local indexes (for a hash-partitioned table). Specify `EXCLUDING INDEXES` if you want all index partitions or subpartitions corresponding to...
the partition and all the regular indexes and index partitions on the exchanged table to be marked UNUSABLE. If you omit this clause, then the default is EXCLUDING INDEXES.

**WITH | WITHOUT VALIDATION** Specify WITH VALIDATION if you want Oracle Database to return an error if any rows in the exchanged table do not map into partitions or subpartitions being exchanged. Specify WITHOUT VALIDATION if you do not want Oracle Database to check the proper mapping of rows in the exchanged table. If you omit this clause, then the default is WITH VALIDATION.

**exceptions_clause** See "Handling Constraint Exceptions" on page 8-18 for information on this clause. In the context of exchanging partitions, this clause is valid only if the partitioned table has been defined with a UNIQUE constraint, and that constraint must be in DISABLE VALIDATE state. This clause is valid only for exchanging partition, not subpartitions.

**CASCADE** Specify CASCADE to exchange the corresponding partition or subpartition in all reference-partitioned child tables of table. The reference-partitioned table hierarchies of the source and target must match.

**Restriction on CASCADE** You cannot specify CASCADE if a parent key in the reference-partitioned table hierarchy is referenced by multiple partitioning constraints.

**See Also:**
- The DBMS_IOT package in Oracle Database PL/SQL Packages and Types Reference for information on the SQL scripts
- Oracle Database Administrator's Guide for information on eliminating migrated and chained rows
- constraint on page 8-4 for more information on constraint checking and "Creating an Exceptions Table for Index-Organized Tables: Example" on page 12-102

**Notes on Exchanging Partitions and Subpartitions** The following notes apply when exchanging partitions and subpartitions:
- Both tables involved in the exchange must have the same primary key, and no validated foreign keys can be referencing either of the tables unless the referenced table is empty.
- When exchanging partitioned index-organized tables:
  - The source and target table or partition must have their primary key set on the same columns, in the same order.
  - If prefix compression is enabled, then it must be enabled for both the source and the target, and with the same prefix length.
  - Both the source and target must be index organized.
  - Both the source and target must have overflow segments, or neither can have overflow segments. Also, both the source and target must have mapping tables, or neither can have a mapping table.
  - Both the source and target must have identical storage attributes for any LOB columns.

**See Also:** "Exchanging Table Partitions: Example" on page 12-106
**dependent_tables_clause**
This clause is valid only when you are altering the parent table of a reference-partitioned table. The clause lets you specify attributes of partitions that are created by the operation for reference-partitioned child tables of the parent table.

- If the parent table is not composite partitioned, then specify one or more child tables, and for each child table specify one `partition_spec` for each partition created in the parent table.
- If the parent table is composite, then specify one or more child tables, and for each child table specify one `partition_spec` for each subpartition created in the parent table.

**See Also:** The `CREATE TABLE` clause `reference_partitioning` on page 16-76 for information on creating reference-partitioned tables and *Oracle Database VLDB and Partitioning Guide* for information on partitioning by reference in general

**UNUSABLE LOCAL INDEXES Clauses**
These two clauses modify the attributes of local index partitions and index subpartitions corresponding to `partition`, depending on whether you are modifying a partition or subpartition.

- `UNUSABLE LOCAL INDEXES` marks `UNUSABLE` the local index partition or index subpartition associated with `partition`.
- `REBUILD UNUSABLE LOCAL INDEXES` rebuilds the unusable local index partition or index subpartition associated with `partition`.

**Restrictions on UNUSABLE LOCAL INDEXES** This clause is subject to the following restrictions:

- You cannot specify this clause with any other clauses of the `modify_table_partition` clause.
- You cannot specify this clause in the `modify_table_partition` clause for a partition that has subpartitions. However, you can specify this clause in the `modify_table_subpartition` clause.

**update_index_clauses**
Use the `update_index_clauses` to update the indexes on `table` as part of the table partitioning operation. When you perform DDL on a table partition, if an index is defined on `table`, then Oracle Database invalidates the entire index, not just the partitions undergoing DDL. This clause lets you update the index partition you are changing during the DDL operation, eliminating the need to rebuild the index after the DDL.

The `update_index_clauses` are not needed, and are not valid, for partitioned index-organized tables. Index-organized tables are primary key based, so Oracle can keep global indexes `USABLE` during operations that move data but do not change its value.

**update_global_index_clause**
Use this clause to update only global indexes on `table`. Oracle Database marks `UNUSABLE` all local indexes on `table`.

SQL Statements: ALTER TABLE to ALTER TABLESPACE 12-95
**UPDATE GLOBAL INDEXES** Specify `UPDATE GLOBAL INDEXES` to update the global indexes defined on `table`.

**Restriction on Updating Global Indexes** If the global index is a global domain index defined on a LOB column, then Oracle Database marks the domain index `UNUSABLE` instead of updating it.

**INVALIDATE GLOBAL INDEXES** Specify `INVALIDATE GLOBAL INDEXES` to invalidate the global indexes defined on `table`.

If you specify neither, then Oracle Database invalidates the global indexes.

**Restrictions on Invalidating Global Indexes** This clause is supported only for global indexes. It is not supported for index-organized tables. In addition, this clause updates only indexes that are `USABLE` and `VALID`. `UNUSABLE` indexes are left unusable, and `INVALID` global indexes are ignored.

**update_all_indexes_clause**

Use this clause to update all indexes on `table`.

**update_index_partition** This clause is valid only for operations on table partitions and affects only local indexes.

- The `index_partition_description` lets you specify physical attributes, tablespace storage, and logging for each partition of each local index. If you specify only the `PARTITION` keyword, then Oracle Database updates the index partition as follows:
  - For operations on a single table partition (such as `MOVE PARTITION` and `SPLIT PARTITION`), the corresponding index partition inherits the attributes of the affected index table partition. Oracle Database does not generate names for new index partitions, so any new index partitions resulting from this operation inherit their names from the corresponding new table partition.
  - For `MERGE PARTITION` operations, the resulting local index partition inherits its name from the resulting table partition and inherits its attributes from the local index.

For a domain index, you can use the `PARAMETERS` clause to specify the parameter string that is passed uninterpreted to the appropriate ODCI indextype routine. The `PARAMETERS` clause is valid only for domain indexes, and is the only part of the `index_partition_description` you can specify for a domain index.

**See Also:** Oracle Database Data Cartridge Developer’s Guide for more information on domain indexes

- For a composite-partitioned index, the `index_subpartition_clause` lets you specify tablespace storage for each subpartition. Refer to the `index_subpartition_clause` on page 14-92 (in `CREATE INDEX`) for more information on this component of the `update_index_partition` clause.

For information on the `USABLE` and `UNUSABLE` keywords, refer to `ALTER INDEX ... USABLE | UNUSABLE` on page 10-120.

**update_index_subpartition** This clause is valid only for operations on subpartitions of composite-partitioned tables and affects only local indexes on composite-partitioned tables. It lets you specify tablespace storage for one or more subpartitions.
Restrictions on Updating All Indexes  The following restrictions apply to the `update_all_indexes_clause`:

■ You cannot specify this clause for index-organized tables.

■ When you exchange a partition or subpartition with the `exchange_partition_subpart` clause, the `update_all_indexes_clause` is applicable only to global indexes. Therefore, you cannot specify the `update_index_partition` or `update_index_subpartition` clauses. You can, however, specify local index maintenance during an exchange operation by using the `INCLUDING | EXCLUDING INDEXES` clause.

See Also:  "Updating Global Indexes: Example" on page 12-107 and "Updating Partitioned Indexes: Example" on page 12-107

**parallel_clause**
The `parallel_clause` lets you change the default degree of parallelism for queries and DML on the table.

For complete information on this clause, refer to `parallel_clause` on page 16-81 in the documentation on `CREATE TABLE`.

Restrictions on Changing Table Parallelization  Changing parallelization is subject to the following restrictions:

■ If `table` contains any columns of LOB or user-defined object type, then subsequent `INSERT, UPDATE, and DELETE` operations on `table` are executed serially without notification. Subsequent queries, however, are executed in parallel.

■ If you specify the `parallel_clause` in conjunction with the `move_table_clause`, then the parallelism applies only to the move, not to subsequent DML and query operations on the table.

See Also:  "Specifying Parallel Processing: Example" on page 12-101

**allow_disallow_clustering**
This clause is valid for tables that use attribute clustering. It lets you allow or disallow attribute clustering for data movement that occurs during the move table operation specified by the `move_table_clause`, and the table partition and subpartition maintenance operations specified by the `coalesce_table_[sub]partition, merge_table_[sub]partitions, move_table_[sub]partition, and split_table_[sub]partition` clauses.

■ Specify `ALLOW CLUSTERING` to allow attribute clustering for data movement. This clause overrides a `NO ON DATA MOVEMENT` setting in the DDL that created or altered the table.

■ Specify `DISALLOW CLUSTERING` to disallow attribute clustering for data movement. This clause overrides a `YES ON DATA MOVEMENT` setting in the DDL that created or altered the table.

The `allow_disallow_clustering` clause has no effect if you specify it for a table that does not use attribute clustering.

See Also:  `clustering_when clause of CREATE TABLE` on page 16-79 for more information on the `NO ON DATA MOVEMENT` and `YES ON DATA MOVEMENT` clauses
move_table_clause

The move_table_clause lets you relocate data of a nonpartitioned table or of a partition of a partitioned table into a new segment, optionally in a different tablespace, and optionally modify any of its storage attributes.

You can also move any LOB data segments associated with the table or partition using the LOB_storage_clause and varray_col_properties clause. LOB items not specified in this clause are not moved.

If you move the table to a different tablespace and the COMPATIBLE parameter is set to 10.0 or higher, then Oracle Database leaves the storage table of any nested table columns in the tablespace in which it was created. If COMPATIBLE is set to any value less than 10.0, then the database silently moves the storage table to the new tablespace along with the table.

ONLINE Clause  This clause is valid only for top-level index-organized tables and for nested table storage tables that are index organized. Specify ONLINE if you want DML operations on the index-organized table to be allowed during rebuilding of the primary key index of the table.

Restrictions on Moving Tables Online  Moving tables online is subject to the following restrictions:

- You cannot combine this clause with any other clause in the same statement.
- You cannot specify this clause for a partitioned index-organized table.
- Parallel DML and direct path INSERT operations require an exclusive lock on the table. Therefore, these operations are not supported concurrently with an ongoing online table MOVE, due to conflicting locks.
- You cannot specify this clause if the index-organized table contains any LOB, VARRAY, Oracle-supplied type, or user-defined object type columns.

index_org_table_clause

For an index-organized table, the index_org_table_clause of the move_table_clause lets you additionally specify overflow segment attributes. The move_table_clause rebuilds the primary key index of the index-organized table. The overflow data segment is not rebuilt unless the OVERFLOW keyword is explicitly stated, with two exceptions:

- If you alter the values of PCTTHRESHOLD or the INCLUDING column as part of this ALTER TABLE statement, then the overflow data segment is rebuilt.
- If you explicitly move any of out-of-line columns (LOBs, varrays, nested table columns) in the index-organized table, then the overflow data segment is also rebuilt.

The index and data segments of LOB columns are not rebuilt unless you specify the LOB columns explicitly as part of this ALTER TABLE statement.

mapping_table_clause  Specify MAPPING TABLE if you want Oracle Database to create a mapping table if one does not already exist. If it does exist, then the database moves the mapping table along with the index-organized table, and marks any bitmapped indexes UNUSABLE. The new mapping table is created in the same tablespace as the parent table.

Specify NOMAPPING to instruct the database to drop an existing mapping table.
ALTER TABLE

Refer to *mapping_table_clauses* on page 16-53 (in CREATE TABLE) for more information on this clause.

**Restriction on Mapping Tables** You cannot specify NOMAPPING if any bitmapped indexes have been defined on table.

**prefix_compression** Use the `prefix_compression` clause to enable or disable prefix compression in an index-organized table.

- **COMPRESS** enables prefix compression, which eliminates repeated occurrence of primary key column values in index-organized tables. Use `integer` to specify the prefix length (number of prefix columns to compress).
  
  The valid range of prefix length values is from 1 to the number of primary key columns minus 1. The default prefix length is the number of primary key columns minus 1.

- **NOCOMPRESS** disables prefix compression in index-organized tables. This is the default.

**TABLESPACE `tablespace`** Specify the tablespace into which the rebuilt index-organized table is to be stored.

**LOB_storage_clause** Use this clause to move a LOB segment to a different tablespace. You cannot use this clause to move a LOB segment if the table contains a LONG column. Instead, you must either convert the LONG column to a LOB, or you must export the table, re-create the table specifying the desired tablespace storage for the LOB column, and re-import the table data.

**Restrictions on Moving Tables** Moving tables is subject to the following restrictions:

- If you specify `MOVE`, then it must be the first clause in the `ALTER TABLE` statement, and the only clauses outside this clause that are allowed are the `physical_attributes_clause`, the `parallel_clause`, and the `LOB_storage_clause`.

- You cannot move a table containing a LONG or LONG RAW column.

- You cannot `MOVE` an entire partitioned table (either heap or index organized). You must move individual partitions or subpartitions.

---

**Notes Regarding LOBs:** For any LOB columns you specify in a `move_table_clause`:

- Oracle Database drops the old LOB data segment and corresponding index segment and creates new segments, even if you do not specify a new tablespace.

- If the LOB index in table resided in a different tablespace from the LOB data, then Oracle Database collocates the LOB index in the same tablespace with the LOB data after the move.

---

**See Also:** `move_table_partition` on page 12-79 and `move_table_subpartition` on page 12-81

**modify_opaque_type**

Use the `modify_opaque_type` clause to instruct the database to store the specified abstract data type or XMLType in an ANYDATA column using unpacked storage.
You can specify any abstract data type with this clause. However, it is primarily useful because it allows you to specify the following data types, which cannot be stored in an `ANYDATA` column using conventional storage:

- `XMLType`
- Abstract data types that contain one or more attributes of type `XMLType`, `CLOB`, `BLOB`, or `NCLOB`.

When you use **unpacked storage**, data types are stored in system-generated hidden columns that are associated with the `ANYDATA` column. You can insert and query these data types as you would data types that are stored in an `ANYDATA` column using conventional storage.

```sql
anydata_column Specify the name of a column of type `ANYDATA`. If `type_name` is an abstract data type that does not contain an attribute of type `XMLType`, `CLOB`, `BLOB`, or `NCLOB`, then `anydata_column` must be empty.

type_name Specify the name of one or more abstract data types or `XMLType`. The abstract data type can contain an attribute of type `XMLType`, `CLOB`, `BLOB`, or `NCLOB`. The type can be `EDITABLE`. When you subsequently insert these data types into `anydata_column`, they will use unpacked storage. If you previously specified this clause for the same `anydata_column`, then unpacked storage will continue to be used for the previously specified data types as well as the newly specified data types.

See Also: Oracle Database PL/SQL Packages and Types Reference for information on the `ANYDATA` type and "Unpacked Storage in `ANYDATA` Columns: Example" on page 12-112
```

**enable_disable_clause**

The `enable_disable_clause` lets you specify whether and how Oracle Database should apply an integrity constraint. The `DROP` and `KEEP` clauses are valid only when you are disabling a unique or primary key constraint.

See Also:

- The `enable_disable_clause` on page 16-82 (in `CREATE TABLE`) for a complete description of this clause, including notes and restrictions that relate to this statement
- "Using Indexes to Enforce Constraints" on page 8-17 for information on using indexes to enforce constraints

**TABLE LOCK** Oracle Database permits DDL operations on a table only if the table can be locked during the operation. Such table locks are not required during DML operations.

---

**Note:** Table locks are not acquired on temporary tables.

---

- Specify `ENABLE TABLE LOCK` to enable table locks, thereby allowing DDL operations on the table. All currently executing transactions must commit or roll back before Oracle Database enables the table lock.
ALTER TABLE

**Caution:** Oracle Database waits until active DML transactions in the database have completed before locking the table. Sometimes the resulting delay is considerable.

- Specify `DISABLE TABLE LOCK` to disable table locks, thereby preventing DDL operations on the table.

**Note:** Parallel DML operations are not performed when the table lock of the target table is disabled.

**ALL TRIGGERS** Use the `ALL TRIGGERS` clause to enable or disable all triggers associated with the table.

- Specify `ENABLE ALL TRIGGERS` to enable all triggers associated with the table. Oracle Database fires the triggers whenever their triggering condition is satisfied.
  
  To enable a single trigger, use the `enable_clause` of `ALTER TRIGGER`.

  **See Also:** `CREATE TRIGGER` on page 16-118, `ALTER TRIGGER` on page 13-2, and "Enabling Triggers: Example" on page 12-102

- Specify `DISABLE ALL TRIGGERS` to disable all triggers associated with the table. Oracle Database does not fire a disabled trigger even if the triggering condition is satisfied.

**Examples**

**Collection Retrieval: Example** The following statement modifies nested table column `ad_textdocs_ntab` in the sample table `sh.print_media` so that when queried it returns actual values instead of locators:

```sql
ALTER TABLE print_media MODIFY NESTED TABLE ad_textdocs_ntab RETURN AS VALUE;
```

**Specifying Parallel Processing: Example** The following statement specifies parallel processing for queries to the sample table `oe.customers`:

```sql
ALTER TABLE customers PARALLEL;
```

**Changing the State of a Constraint: Examples** The following statement places in `ENABLE VALIDATE` state an integrity constraint named `emp_manager_fk` in the `employees` table:

```sql
ALTER TABLE employees
  ENABLE VALIDATE CONSTRAINT emp_manager_fk
  EXCEPTIONS INTO exceptions;
```

Each row of the `employees` table must satisfy the constraint for Oracle Database to enable the constraint. If any row violates the constraint, then the constraint remains disabled. The database lists any exceptions in the table `exceptions`. You can also identify the exceptions in the `employees` table with the following statement:

```sql
SELECT e.*
FROM employees e, exceptions ex
WHERE e.rowid = ex.row_id
```
The following statement tries to place in ENABLE NOVALIDATE state two constraints on the employees table:

```
ALTER TABLE employees
    ENABLE NOVALIDATE PRIMARY KEY
    ENABLE NOVALIDATE CONSTRAINT emp_last_name_nn;
```

This statement has two ENABLE clauses:

- The first places a primary key constraint on the table in ENABLE NOVALIDATE state.
- The second places the constraint named `emp_last_name_nn` in ENABLE NOVALIDATE state.

In this case, Oracle Database enables the constraints only if both are satisfied by each row in the table. If any row violates either constraint, then the database returns an error and both constraints remain disabled.

Consider the foreign key constraint on the `location_id` column of the `departments` table, which references the primary key of the `locations` table. The following statement disables the primary key of the `locations` table:

```
ALTER TABLE locations
    MODIFY PRIMARY KEY DISABLE CASCADE;
```

The unique key in the `locations` table is referenced by the foreign key in the `departments` table, so you must specify `CASCADE` to disable the primary key. This clause disables the foreign key as well.

### Creating an Exceptions Table for Index-Organized Tables: Example

The following example creates the `except_table` table to hold rows from the index-organized table `hr.countries` that violate the primary key constraint:

```sql
EXECUTE DBMS_IOT.BUILD_EXCEPTIONS_TABLE ('hr', 'countries', 'except_table');
ALTER TABLE countries
    ENABLE PRIMARY KEY
    EXCEPTIONS INTO except_table;
```

To specify an exception table, you must have the privileges necessary to insert rows into the table. To examine the identified exceptions, you must have the privileges necessary to query the exceptions table.

### See Also: `INSERT` on page 18-62 and `SELECT` on page 19-4 for information on the privileges necessary to insert rows into tables

### Disabling a CHECK Constraint: Example

The following statement defines and disables a CHECK constraint on the `employees` table:

```
ALTER TABLE employees ADD CONSTRAINT check_comp
    CHECK (salary + (commission_pct * salary) <= 5000)
    DISABLE;
```

The constraint `check_comp` ensures that no employee's total compensation exceeds $5000. The constraint is disabled, so you can increase an employee's compensation above this limit.

### Enabling Triggers: Example

The following statement enables all triggers associated with the `employees` table:
ALTER TABLE employees
  ENABLE ALL TRIGGERS;

**Deallocating Unused Space: Example**  The following statement frees all unused space for reuse in table employees, where the high water mark is above MINEXTENTS:

ALTER TABLE employees
  DEALLOCATE UNUSED;

**Renaming a Column: Example**  The following example renames the credit_limit column of the sample table oe.customers to credit_amount:

ALTER TABLE customers
  RENAME COLUMN credit_limit TO credit_amount;

**Dropping a Column: Example**  This statement illustrates the drop_column_clause with CASCADE CONSTRAINTS. Assume table t1 is created as follows:

```
CREATE TABLE t1 {
  pk NUMBER PRIMARY KEY,
  fk NUMBER,
  c1 NUMBER,
  c2 NUMBER,
  CONSTRAINT ri FOREIGN KEY (fk) REFERENCES t1,
  CONSTRAINT ck1 CHECK (pk > 0 and c1 > 0),
  CONSTRAINT ck2 CHECK (c2 > 0)
};
```

An error will be returned for the following statements:

```
/* The next two statements return errors:
ALTER TABLE t1 DROP (pk);  -- pk is a parent key
ALTER TABLE t1 DROP (c1);  -- c1 is referenced by multicol
-- constraint ck1
```

Submitting the following statement drops column pk, the primary key constraint, the foreign key constraint, ri, and the check constraint, ck1:

```
ALTER TABLE t1 DROP (pk) CASCADE CONSTRAINTS;
```

If all columns referenced by the constraints defined on the dropped columns are also dropped, then CASCADE CONSTRAINTS is not required. For example, assuming that no other referential constraints from other tables refer to column pk, then it is valid to submit the following statement without the CASCADE CONSTRAINTS clause:

```
ALTER TABLE t1 DROP (pk, fk, c1);
```

**Modifying Index-Organized Tables: Examples**  This statement modifies the INITRANS parameter for the index segment of index-organized table countries_demo, which is based on hr.countries:

```
ALTER TABLE countries_demo INITRANS 4;
```

The following statement adds an overflow data segment to index-organized table countries:

```
ALTER TABLE countries_demo ADD OVERFLOW;
```

This statement modifies the INITRANS parameter for the overflow data segment of index-organized table countries:

```
ALTER TABLE countries_demo OVERFLOW INITRANS 4;
```
Splitting Table Partitions: Examples  The following statement splits the old partition sales_q4_2000 in the sample table sh.sales, creating two new partitions, naming one sales_q4_2000b and reusing the name of the old partition for the other:

```
ALTER TABLE sales SPLIT PARTITION SALES_Q4_2000
  AT (TO_DATE('15-NOV-2000','DD-MON-YYYY'))
  INTO (PARTITION SALES_Q4_2000, PARTITION SALES_Q4_2000b);
```

The following statement splits the old partition sales_q1_2002 into three new partitions sales_jan_2002, sales_feb_2002, and sales_mar_2002:

```
ALTER TABLE sales SPLIT PARTITION SALES_Q1_2002 INTO (
  PARTITION SALES_JAN_2002 VALUES LESS THAN (TO_DATE('01-FEB-2002','DD-MON-YYYY')),
  PARTITION SALES_FEB_2002 VALUES LESS THAN (TO_DATE('01-MAR-2002','DD-MON-YYYY')),
  PARTITION SALES_MAR_2002);
```

The following statements create a partitioned version of the pm.print_media table. The LONG column in the print_media table has been converted to LOB. The table is stored in tablespaces created in "Creating Oracle Managed Files: Examples" on page 16-117. The object types underlying the ad_textdocs_ntab and ad_header columns are created in the script that creates the pm sample schema:

```
CREATE TABLE print_media_part (  
  product_id NUMBER(6),  
  ad_id NUMBER(6),  
  ad_composite BLOB,  
  ad_sourcetext CLOB,  
  ad_finaltext CLOB,  
  ad_fltextn NCLOB,  
  ad_textdocs_ntab TEXTDOC_TAB,  
  ad_photo BLOB,  
  ad_graphic BFILE,  
  ad_header ADHEADER_TYP)  
NESTED TABLE ad_textdocs_ntab STORE AS textdoc_nt  
PARTITION BY RANGE (product_id)  
(PARTITION p1 VALUES LESS THAN (100),  
  PARTITION p2 VALUES LESS THAN (200));
```

The following statement splits partition p2 of that table into partitions p2a and p2b:

```
ALTER TABLE print_media_part
  SPLIT PARTITION p2 AT (150) INTO
  (PARTITION p2a TABLESPACE omf_ts1  
    LOB (ad_photo, ad_composite) STORE AS (TABLESPACE omf_ts2),
    PARTITION p2b  
    LOB (ad_photo, ad_composite) STORE AS (TABLESPACE omf_ts2))
NESTED TABLE ad_textdocs_ntab INTO (PARTITION nt_p2a, PARTITION nt_p2b);
```

In both partitions p2a and p2b, Oracle Database creates the LOB segments for columns ad_photo and ad_composite in tablespace omf_ts2. The LOB segments for the remaining columns in partition p2a are stored in tablespace omf_ts1. The LOB segments for the remaining columns in partition p2b remain in the tablespaces in which they resided prior to this ALTER statement. However, the database creates new segments for all the LOB data and LOB index segments, even if they are not moved to a new tablespace.

The database also creates new segments for nested table column ad_textdocs_ntab. The storage tables is those new segments are nt_p2a and nt_p2b.
Merging Two Table Partitions: Example  The following statement merges back into one partition the partitions created in "Splitting Table Partitions: Examples" on page 12-104:

```
ALTER TABLE sales
  MERGE PARTITIONS sales_q4_2000, sales_q4_2000b
  INTO PARTITION sales_q4_2000;
```

The next statement reverses the example in "Splitting Table Partitions: Examples" on page 12-104:

```
ALTER TABLE print_media_part
  MERGE PARTITIONS p2a, p2b INTO PARTITION p2ab TABLESPACE example
  NESTED TABLE ad_textdocs_ntab STORE AS nt_p2ab;
```

Merging Four Adjacent Range Partitions: Example  The following statement merges four adjacent range partitions, sales_q1_2000, sales_q2_2000, sales_q3_2000, and sales_q4_2000 into one partition sales_all_2000:

```
ALTER TABLE sales
  MERGE PARTITIONS sales_q1_2000 TO sales_q4_2000
  INTO PARTITION sales_all_2000;
```

Adding a Table Partition with a LOB and Nested Table Storage: Examples  The following statement adds a partition p3 to the print_media_part table (see preceding example) and specifies storage characteristics for the BLOB, CLOB, and nested table columns of that table:

```
ALTER TABLE print_media_part ADD PARTITION p3 VALUES LESS THAN (400)
  LOB(ad_photo, ad_composite) STORE AS (TABLESPACE omf_ts1)
  LOB(ad_sourcetext, ad_finaltext) STORE AS (TABLESPACE omf_ts2)
  NESTED TABLE ad_textdocs_ntab STORE AS nt_p3;
```

The LOB data and LOB index segments for columns ad_photo and ad_composite in partition p3 will reside in tablespace omf_ts1. The remaining attributes for these LOB columns will be inherited first from the table-level defaults, and then from the tablespace defaults.

The LOB data segments for columns ad_source_text and ad_finaltext will reside in the omf_ts2 tablespace, and will inherit all other attributes first from the table-level defaults, and then from the tablespace defaults.

The partition for the storage table for nested table storage column ad_textdocs_ntab corresponding to partition p3 of the base table is named nt_p3 and inherits all other attributes first from the table-level defaults, and then from the tablespace defaults.

Adding Multiple Partitions to a Table: Example  The following statement adds three partitions to the table print_media_part created in "Splitting Table Partitions: Examples" on page 12-104:

```
ALTER TABLE print_media_part ADD
  PARTITION p3 values less than (300),
  PARTITION p4 values less than (400),
  PARTITION p5 values less than (500);
```

Working with Default List Partitions: Example  The following statements use the list partitioned table created in "List Partitioning Example" on page 16-97. The first statement splits the existing default partition into a new south partition and a default partition:

```
ALTER TABLE list_customers SPLIT PARTITION rest
VALUES ('MEXICO', 'COLOMBIA')
INTO (PARTITION south, PARTITION rest);

The next statement merges the resulting default partition with the \texttt{asia} partition:

\begin{verbatim}
ALTER TABLE list_customers
MERGE PARTITIONS asia, rest INTO PARTITION rest;
\end{verbatim}

The next statement re-creates the \texttt{asia} partition by splitting the default partition:

\begin{verbatim}
ALTER TABLE list_customers SPLIT PARTITION rest
VALUES ('CHINA', 'THAILAND')
INTO (PARTITION asia, PARTITION rest);
\end{verbatim}

\textbf{Dropping a Table Partition: Example} \hspace{1em} The following statement drops partition \texttt{p3} created in "Adding a Table Partition with a LOB and Nested Table Storage: Examples" on page 12-105:

\begin{verbatim}
ALTER TABLE print_media_part DROP PARTITION p3;
\end{verbatim}

\textbf{Exchanging Table Partitions: Example} \hspace{1em} This example creates the table \texttt{exchange_table} with the same structure as the partitions of the \texttt{list_customers} table created in "List Partitioning Example" on page 16-97. It then replaces partition \texttt{rest} of table \texttt{list_customers} with table \texttt{exchange_table} without exchanging local index partitions with corresponding indexes on \texttt{exchange_table} and without verifying that data in \texttt{exchange_table} falls within the bounds of partition \texttt{rest}:

\begin{verbatim}
CREATE TABLE exchange_table (  
customer_id NUMBER(6),  
cust_first_name VARCHAR2(20),  
cust_last_name VARCHAR2(20),  
cust_address CUST_ADDRESS_TYP,  
nls_territory VARCHAR2(30),  
cust_email VARCHAR2(40));
\end{verbatim}

\begin{verbatim}
ALTER TABLE list_customers  
EXCHANGE PARTITION rest WITH TABLE exchange_table  
WITHOUT VALIDATION;
\end{verbatim}

\textbf{Modifying Table Partitions: Examples} \hspace{1em} The following statement marks all the local index partitions corresponding to the \texttt{asia} partition of the \texttt{list_customers} table \texttt{UNUSABLE}:

\begin{verbatim}
ALTER TABLE list_customers MODIFY PARTITION asia  
UNUSABLE LOCAL INDEXES;
\end{verbatim}

The following statement rebuilds all the local index partitions that were marked \texttt{UNUSABLE}:

\begin{verbatim}
ALTER TABLE list_customers MODIFY PARTITION asia  
REBUILD UNUSABLE LOCAL INDEXES;
\end{verbatim}

\textbf{Moving Table Partitions: Example} \hspace{1em} The following statement moves partition \texttt{p2b} (from "Splitting Table Partitions: Examples" on page 12-104) to tablespace \texttt{omf_ts1}:

\begin{verbatim}
ALTER TABLE print_media_part  
MOVE PARTITION p2b TABLESPACE omf_ts1;
\end{verbatim}

\textbf{Renaming Table Partitions: Examples} \hspace{1em} The following statement renames a partition of the \texttt{sh.sales} table:

\begin{verbatim}
ALTER TABLE sales RENAME PARTITION sales_q4_2003 TO sales_currentq;
\end{verbatim}
Truncating Table Partitions: Example The following statement uses the print_media_demo table created in "Partitioned Table with LOB Columns Example" on page 16-97. It deletes all the data in the p1 partition and deallocates the freed space:

```sql
ALTER TABLE print_media_demo
TRUNCATE PARTITION p1 DROP STORAGE;
```

Updating Global Indexes: Example The following statement splits partition sales_q1_2000 of the sample table sh.sales and updates any global indexes defined on it:

```sql
ALTER TABLE sales SPLIT PARTITION sales_q1_2000
AT (TO_DATE('16-FEB-2000','DD-MON-YYYY'))
INTO (PARTITION q1a_2000, PARTITION q1b_2000)
UPDATE GLOBAL INDEXES;
```

Updating Partitioned Indexes: Example The following statement splits partition costs_Q4_2003 of the sample table sh.costs and updates the local index defined on it. It uses the tablespaces created in "Creating Basic Tablespaces: Examples" on page 16-116.

```sql
CREATE INDEX cost_ix ON costs(channel_id) LOCAL;

ALTER TABLE costs
SPLIT PARTITION costs_q4_2003 at
(TO_DATE('01-Nov-2003','dd-mon-yyyy'))
INTO (PARTITION c_p1, PARTITION c_p2)
UPDATE INDEXES (cost_ix (PARTITION c_p1 tablespace tbs_02,
PARTITION c_p2 tablespace tbs_03));
```

Specifying Object Identifiers: Example The following statements create an object type, a corresponding object table with a primary-key-based object identifier, and a table having a user-defined REF column:

```sql
CREATE TYPE emp_t AS OBJECT (empno NUMBER, address CHAR(30));
CREATE TABLE emp OF emp_t (empno PRIMARY KEY)
OBJECT IDENTIFIER IS PRIMARY KEY;
CREATE TABLE dept (dno NUMBER, mgr_ref REF emp_t SCOPE is emp);

The next statements add a constraint and a user-defined REF column, both of which reference table emp
```

```sql
ALTER TABLE dept ADD CONSTRAINT mgr_cons FOREIGN KEY (mgr_ref)
REFERENCES emp;
ALTER TABLE dept ADD sr mgr REF emp_t REFERENCES emp;
```

Adding a Table Column: Example The following statement adds to the countries table a column named duty_pct of data type NUMBER and a column named visa_needed of data type VARCHAR2 with a size of 3 and a CHECK integrity constraint:

```sql
ALTER TABLE countries
ADD (duty_pct NUMBER(2,2) CHECK (duty_pct < 10.5),
    visa_needed VARCHAR2(3));
```

Adding a Virtual Table Column: Example The following statement adds to a copy of the hr.employees table a column named income, which is a combination of salary plus commission. Both salary and commission are NUMBER columns, so the database creates the virtual column as a NUMBER column even though the data type is not specified in the statement:
CREATE TABLE emp2 AS SELECT * FROM employees;

ALTER TABLE emp2 ADD (income AS (salary + (salary*commission_pct)));

**Modifying Table Columns: Examples**  
The following statement increases the size of the duty_pct column:

ALTER TABLE countries
    MODIFY (duty_pct NUMBER(3,2));

Because the MODIFY clause contains only one column definition, the parentheses around the definition are optional.

The following statement changes the values of the PCTFREE and PCTUSED parameters for the employees table to 30 and 60, respectively:

ALTER TABLE employees
    PCTFREE 30
    PCTUSED 60;

**Data Encryption: Examples**  
The following statement encrypts the salary column of the hr.employees table using the encryption algorithm AES256. As described in "Semantics" above, you must first enable Transparent Data Encryption:

ALTER TABLE employees
    MODIFY (salary ENCRYPT USING 'AES256' 'NOMAC');

The following statement adds a new encrypted column online_acct_pw to the oe.customers table, using the default encryption algorithm AES192. Specifying NO SALT will allow a B-tree index to be created on the column, if desired.

ALTER TABLE customers
    ADD (online_acct_pw VARCHAR2(8) ENCRYPT 'NOMAC' NO SALT);

The following example decrypts the customer.online_acct_pw column:

ALTER TABLE customers
    MODIFY (online_acct_pw DECRYPT);

**Allocating Extents: Example**  
The following statement allocates an extent of 5 kilobytes for the employees table and makes it available to instance 4:

ALTER TABLE employees
    ALLOCATE EXTENT (SIZE 5K INSTANCE 4);

Because this statement omits the DATAFILE parameter, Oracle Database allocates the extent in one of the data files belonging to the tablespace containing the table.

**Specifying a Default Column Value: Examples**  
This statement modifies the min_price column of the product_information table so that it has a default value of 10:

ALTER TABLE product_information
    MODIFY (min_price DEFAULT 10);

If you subsequently add a new row to the product_information table and do not specify a value for the min_price column, then the value of the min_price column is automatically 10:

INSERT INTO product_information (product_id, product_name,
    list_price)
    VALUES (300, 'left-handed mouse', 40.50);
To discontinue previously specified default values, so that they are no longer automatically inserted into newly added rows, replace the values with NULL, as shown in this statement:

```
ALTER TABLE product_information
    MODIFY (min_price DEFAULT NULL);
```

The `MODIFY` clause need only specify the column name and the modified part of the definition, rather than the entire column definition. This statement has no effect on any existing values in existing rows.

The following example adds a column defined with `DEFAULT ON NULL` to a table. The `DEFAULT` column value includes the sequence pseudocolumn `NEXTVAL`.

Create sequence `s1` and table `t1` as follows:

```
CREATE SEQUENCE s1 START WITH 1;
CREATE TABLE t1 (name VARCHAR2(10));
INSERT INTO t1 VALUES('Kevin');
INSERT INTO t1 VALUES('Julia');
INSERT INTO t1 VALUES('Ryan');
```

Add column `id`, which defaults to `s1.NEXTVAL`. The default column value for `id` is assigned to each existing row in the table. The order in which `s1.NEXTVAL` is assigned to each row is nondeterministic.

```
ALTER TABLE t1 ADD (id NUMBER DEFAULT ON NULL s1.NEXTVAL NOT NULL);
```

```
SELECT id, name FROM t1 ORDER BY id;
```

<table>
<thead>
<tr>
<th>ID</th>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Kevin</td>
</tr>
<tr>
<td>2</td>
<td>Julia</td>
</tr>
<tr>
<td>3</td>
<td>Ryan</td>
</tr>
</tbody>
</table>

If you subsequently add a new row to the table and specify a NULL value for the `id` column, then the `DEFAULT ON NULL` expression `s1.NEXTVAL` is inserted.

```
INSERT INTO t1(id, name) VALUES(NULL, 'Sean');
```

```
SELECT id, name FROM t1 ORDER BY id;
```

<table>
<thead>
<tr>
<th>ID</th>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Kevin</td>
</tr>
<tr>
<td>2</td>
<td>Julia</td>
</tr>
<tr>
<td>3</td>
<td>Ryan</td>
</tr>
<tr>
<td>4</td>
<td>Sean</td>
</tr>
</tbody>
</table>
Adding a Constraint to an XMLType Table: Example  The following example adds a primary key constraint to the xwarehouses table, created in "XMLType Examples" on page 16-94:

```
ALTER TABLE xwarehouses
  ADD (PRIMARY KEY(XMLDATA."WarehouseID"));
```

Refer to XMLDATA Pseudocolumn on page 3-11 for information about this pseudocolumn.

Renaming Constraints: Example  The following statement renames the cust_fname_nn constraint on the sample table oe.customers to cust_firstname_nn:

```
ALTER TABLE customers RENAME CONSTRAINT cust_fname_nn
  TO cust_firstname_nn;
```

Dropping Constraints: Examples  The following statement drops the primary key of the departments table:

```
ALTER TABLE departments
  DROP PRIMARY KEY CASCADE;
```

If you know that the name of the PRIMARY KEY constraint is pk_dept, then you could also drop it with the following statement:

```
ALTER TABLE departments
  DROP CONSTRAINT pk_dept CASCADE;
```

The CASCADE clause causes Oracle Database to drop any foreign keys that reference the primary key.

The following statement drops the unique key on the email column of the employees table:

```
ALTER TABLE employees
  DROP UNIQUE (email);
```

The DROP clause in this statement omits the CASCADE clause. Because of this omission, Oracle Database does not drop the unique key if any foreign key references it.

LOB Columns: Examples  The following statement adds CLOB column resume to the employee table and specifies LOB storage characteristics for the new column:

```
ALTER TABLE employees ADD (resume CLOB)
  LOB (resume) STORE AS resume_seg (TABLESPACE example);
```

To modify the LOB column resume to use caching, enter the following statement:

```
ALTER TABLE employees MODIFY LOB (resume) (CACHE);
```

The following statement adds a SecureFiles CLOB column resume to the employee table and specifies LOB storage characteristics for the new column. SecureFiles LOBs must be stored in tablespaces with automatic segment-space management. Therefore, the LOB data in this example is stored in the auto_seg_ts tablespace, which was created in "Specifying Segment Space Management for a Tablespace: Example" on page 16-117:

```
ALTER TABLE employees ADD (resume CLOB)
  LOB (resume) STORE AS SECUREFILE resume_seg (TABLESPACE auto_seg_ts);
```

To modify the LOB column resume so that it does not use caching, enter the following statement:
ALTER TABLE employees MODIFY LOB (resume) (NOCACHE);

**Nested Tables: Examples**  The following statement adds the nested table column skills to the employee table:

```
ALTER TABLE employees ADD (skills skill_table_type)
    NESTED TABLE skills STORE AS nested_skill_table;
```

You can also modify nested table storage characteristics. Use the name of the storage table specified in the `nested_table_col_properties` to make the modification. You cannot query or perform DML statements on the storage table. Use the storage table only to modify the nested table column storage characteristics.

The following statement creates table `vet_service` with nested table column `client` and storage table `client_tab`. Nested table `client_tab` is modified to specify constraints:

```
CREATE TYPE pet_t AS OBJECT
    (pet_id NUMBER, pet_name VARCHAR2(10), pet_dob DATE);
/
CREATE TYPE pet AS TABLE OF pet_t;
/
CREATE TABLE vet_service (vet_name VARCHAR2(30),
    client   pet)
    NESTED TABLE client STORE AS client_tab;

ALTER TABLE client_tab ADD UNIQUE (pet_id);
```

The following statement alters the storage table for a nested table of `REF` values to specify that the `REF` is scoped:

```
CREATE TYPE emp_t AS OBJECT (eno number, ename char(31));
CREATE TYPE emps_t AS TABLE OF REF emp_t;
CREATE TABLE emptab OF emp_t;
CREATE TABLE dept (dno NUMBER, employees emps_t)
    NESTED TABLE employees STORE AS deptemps;
ALTER TABLE deptemps ADD (SCOPE FOR (COLUMN_VALUE) IS emptab);
```

Similarly, to specify storing the `REF` with rowid:

```
ALTER TABLE deptemps ADD (REF(column_value) WITH ROWID);
```

In order to execute these `ALTER TABLE` statements successfully, the storage table `deptemps` must be empty. Also, because the nested table is defined as a table of scalar values (`REF` values), Oracle Database implicitly provides the column name `COLUMN_VALUE` for the storage table.

**See Also:**

- `CREATE TABLE` on page 16-6 for more information about nested table storage
- *Oracle Database Object-Relational Developer’s Guide* for more information about nested tables

**REF Columns: Examples**  The following statement creates an object type `dept_t` and then creates table `staff`:

```
CREATE TYPE dept_t AS OBJECT
    (deptno NUMBER, dname VARCHAR2(20));
```
CREATE TABLE staff
(name VARCHAR2(100),
salary NUMBER,
department REF dept_t);

An object table offices is created as:
CREATE TABLE offices OF dept_t;

The department column can store references to objects of dept_t stored in any table. If you would like to restrict the references to point only to objects stored in the departments table, then you could do so by adding a scope constraint on the department column as follows:

ALTER TABLE staff
  ADD (SCOPE FOR (department) IS offices);

The preceding ALTER TABLE statement will succeed only if the staff table is empty.

If you want the REF values in the department column of staff to also store the rowids, then issue the following statement:

ALTER TABLE staff
  ADD (REF(department) WITH ROWID);

Unpacked Storage in ANYDATA Columns: Example  This example creates a table with an ANYDATA column, stores opaque data types in the ANYDATA column using unpacked storage, and then queries the data types. This example assumes that you are connected to the database as user hr.

Create table t1, which contains a NUMBER column n and an ANYDATA column x:

CREATE TABLE t1 (n NUMBER, x ANYDATA);

Create an object type clob_typ, which contains a CLOB attribute:

CREATE OR REPLACE TYPE clob_typ AS OBJECT (c clob);
/

Enable unpacked storage of the opaque data types XMLType and clob_typ in ANYDATA column x of table t1:
ALTER TABLE t1 MODIFY OPAQUE TYPE x STORE (XMLType, clob_typ) UNPACKED;

Insert XMLType and clob_typ objects into table t1. These types will use unpacked storage:

INSERT INTO t1
  VALUES(1, anydata.convertobject(XMLType('<Test>This is test XML</Test>')));

INSERT INTO t1
  VALUES(2, anydata.convertobject(clob_typ(TO_CLOB('This is a test CLOB'))));

Query table t1 to view the names of the types stored in ANYDATA column x:
SELECT t1.*, anydata.getTypeName(t1.x) typename FROM t1;

<table>
<thead>
<tr>
<th>N</th>
<th>X()</th>
<th>TYPENAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ANYDATA()</td>
<td>SYS.XMLTYPE</td>
</tr>
<tr>
<td>2</td>
<td>ANYDATA()</td>
<td>HR.CLOB_TYP</td>
</tr>
</tbody>
</table>
Create functions that allow you to query the values stored in the XMLType and clob_typ data types:

```sql
CREATE FUNCTION get_xmltype (ad IN ANYDATA) RETURN VARCHAR2 AS
  rtn_val PLS_INTEGER;
  my_xmltype XMLType;
  string_val VARCHAR2(30);
BEGIN
  rtn_val := ad.getObject(my_xmltype);
  string_val := my_xmltype.getstringval();
  return (string_val);
END;
/

CREATE FUNCTION get_clob_typ (ad IN ANYDATA) RETURN VARCHAR2 AS
  rtn_val PLS_INTEGER;
  my_clob_typ clob_typ;
  string_val VARCHAR2(30);
BEGIN
  rtn_val := ad.getObject(my_clob_typ);
  string_val := (my_clob_typ.c);
  return (string_val);
END;
/
```

Query table `t1` to view the values stored in each data type in `ANYDATA` column `x`:

```sql
SELECT t1.*, anydata.getTypeName(t1.x) typename,
       CASE
           WHEN anydata.gettypename(t1.x) = 'SYS.XMLTYPE' THEN get_xmltype(t1.x)
           WHEN anydata.gettypename(t1.x) = 'HR.CLOB_TYP' THEN get_clob_typ(t1.x)
       END string_value
FROM t1;
```

<table>
<thead>
<tr>
<th>N</th>
<th>X()</th>
<th>TYPENAME</th>
<th>STRING_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ANYDATA()</td>
<td>SYS.XMLTYPE</td>
<td>&lt;Test&gt;This is test XML&lt;/Test&gt;</td>
</tr>
<tr>
<td>2</td>
<td>ANYDATA()</td>
<td>HR.CLOB_TYP</td>
<td>This is a test CLOB</td>
</tr>
</tbody>
</table>

Additional Examples  For examples of defining integrity constraints with the `ALTER TABLE` statement, see the `constraint` on page 8-4.

For examples of changing the storage parameters of a table, see the `storage_clause` on page 8-46.
ALTER TABLESPACE

Purpose

Use the ALTER TABLESPACE statement to alter an existing tablespace or one or more of its data files or temp files.

You cannot use this statement to convert a dictionary-managed tablespace to a locally managed tablespace. For that purpose, use the DBMS_SPACE_ADMIN package, which is documented in Oracle Database PL/SQL Packages and Types Reference.

See Also: Oracle Database Administrator’s Guide and CREATE TABLESPACE on page 16-102 for information on creating a tablespace

Prerequisites

To alter the SYSAUX tablespace, you must have the SYSDBA system privilege.

If you have the ALTER TABLESPACE system privilege, then you can perform any ALTER TABLESPACE operation. If you have the MANAGE TABLESPACE system privilege, then you can only perform the following operations:

- Take a tablespace online or offline
- Begin or end a backup
- Make a tablespace read only or read write
- Change the state of a tablespace to PERMANENT or TEMPORARY
- Set the default logging mode of a tablespace to LOGGING or NOLOGGING
- Put a tablespace in force logging mode or take it out of force logging mode
- Rename a tablespace or a tablespace data file
- Specify RETENTION GUARANTEE or RETENTION NOGUARANTEE for an undo tablespace
- Resize a data file for a tablespace
- Enable or disable autoextension of a data file for a tablespace
- Shrink the amount of space a temporary tablespace or a temp file is taking

Before you can make a tablespace read only, the following conditions must be met:

- The tablespace must be online.
- The tablespace must not contain any active rollback segments. For this reason, the SYSTEM tablespace can never be made read only, because it contains the SYSTEM rollback segment. Additionally, because the rollback segments of a read-only tablespace are not accessible, Oracle recommends that you drop the rollback segments before you make a tablespace read only.
- The tablespace must not be involved in an open backup, because the end of a backup updates the header file of all data files in the tablespace.

Performing this function in restricted mode may help you meet these restrictions, because only users with RESTRICTED SESSION system privilege can be logged on.
Syntax

```
alter_tablespace::= 

ALTER TABLESPACE [tablespace]
  DEFAULT table_compression
  inmemory_clause
  ilm_clause
  storage_clause

  MINIMUM EXTENT size_clause
  RESIZE size_clause
  COALESCE
  SHRINK SPACE KEEP size_clause
  RENAME TO new_tablespace_name
  BEGIN
  END
  BACKUP

  datafile_tempfile_clauses
  tablespace_logging_clauses
  tablespace_group_clause
  tablespace_state_clauses
  autoextend_clause
  flashback_mode_clause
  tablespace_retention_clause

```

**Note:** If you specify the DEFAULT clause, then you must specify at least one of the clauses `table_compression`, `inmemory_clause`, `ilm_clause`, or `storage_clause`.

(table_compression::= on page 12-5—part of ALTER TABLE, inmemory_clause::= on page 16-104—part of CREATE TABLESPACE, ilm_clause::= on page 12-7—part of ALTER TABLE, storage_clause::= on page 8-50, size_clause::= on page 8-47, datafile_tempfile_clauses::= on page 12-116, tablespace_logging_clauses::= on page 12-116, tablespace_group_clause::= on page 12-116, tablespace_state_clauses::= on page 12-116, autoextend_clause::= on page 12-117, flashback_mode_clause::= on page 12-117, tablespace_retention_clause::= on page 12-117)
**datafile tempfile clauses::=**

```
ADD DATAFILE TEMPFILE file_specification,
DROP DATAFILE TEMPFILE filename file_number,
SHRINK TEMPFILE filename file_number KEEP size_clause,
RENAMe DATAFILE TEMPFILE filename TO filename,
DATAFILE TEMPFILE ONLINE OFFLINE
```

*(file_specification::= on page 8-29).*

**tablespace logging clauses::=**

```
logging_clause
NO FORCE LOGGING
```

*(logging_clause::= on page 8-38)*

**tablespace group clause::=**

```
TABLESPACE GROUP tablespace_group_name

**flashback_mode_clause::=**

```
FLASHBACK
  ON
  OFF
```

**tablespace_retention_clause::=**

```
RETENTION
  GUARANTEE
  NOGUARANTEE
```

**Semantics**

**tablespace**
Specify the name of the tablespace to be altered.

**Restrictions on Altering Tablespace**
Altering tablespaces is subject to the following restrictions:

- If `tablespace` is an undo tablespace, then the only other clauses you can specify in this statement are `ADD DATAFILE`, `RENAME DATAFILE`, `RENAME TO` (renaming the tablespace), `DATAFILE ... ONLINE`, `DATAFILE ... OFFLINE`, `BEGIN BACKUP`, and `END BACKUP`.
- You cannot make the `SYSTEM` tablespace read only or temporary and you cannot take it offline.
- For locally managed temporary tablespaces, the only clause you can specify in this statement is the `ADD` clause.

**See Also:** Oracle Database Administrator’s Guide for information on automatic undo management and undo tablespaces

**DEFAULT Clause**
This clause lets you specify new default parameters for the tablespace. The new default parameters apply to objects subsequently created in the tablespace.

The clauses `table_compression`, `inmemory_clause`, `ilm_clause`, and `storage_clause` have the same semantics in `CREATE TABLESPACE` and `ALTER TABLESPACE`. For complete
MINIMUM EXTENT
This clause is valid only for permanent dictionary-managed tablespaces. The MINIMUM EXTENT clause lets you control free space fragmentation in the tablespace by ensuring that every used or free extent in a tablespace is at least as large as, and is a multiple of, the value specified in the size_clause.

Restriction on MINIMUM EXTENT You cannot specify this clause for a locally managed tablespace or for a dictionary-managed temporary tablespace.

See Also: size_clause on page 8-47 for information about that clause, Oracle Database Administrator's Guide for more information about using MINIMUM EXTENT to control space fragmentation

RESIZE Clause
This clause is valid only for bigfile tablespaces. It lets you increase or decrease the size of the single data file to an absolute size. Use K, M, G, or T to specify the size in kilobytes, megabytes, gigabytes, or terabytes, respectively.

To change the size of a newly added data file or temp file in smallfile tablespaces, use the ALTER DATABASE ... autoextend_clause (see database_file_clauses on page 10-51).

See Also: BIGFILE | SMALLFILE on page 16-106 for information on bigfile tablespaces

COALESCE
For each data file in the tablespace, this clause combines all contiguous free extents into larger contiguous extents.

SHRINK SPACE Clause
This clause is valid only for temporary tablespaces. It lets you reduce the amount of space the tablespace is taking. In the optional KEEP clause, the size_clause defines the lower bound that a tablespace can be shrunk to. It is the opposite of MAXSIZE for an autoextensible tablespace. If you omit the KEEP clause, then the database will attempt to shrink the tablespace as much as possible as long as other tablespace storage attributes are satisfied.

RENAME Clause
Use this clause to rename tablespace. This clause is valid only if tablespace and all its data files are online and the COMPATIBLE parameter is set to 10.0.0 or greater. You can rename both permanent and temporary tablespaces.

If tablespace is read only, then Oracle Database does not update the data file headers to reflect the new name. The alert log will indicate that the data file headers have not been updated.

Note: If you re-create the control file, and if the data files that Oracle Database uses for this purpose are restored backups whose headers reflect the old tablespace name, then the re-created control file will also reflect the old tablespace name. However, after the database is fully recovered, the control file will reflect the new name.
If `tablespace` has been designated as the undo tablespace for any instance in an Oracle Real Application Clusters (Oracle RAC) environment, and if a server parameter file was used to start up the database, then Oracle Database changes the value of the `UNDO_TABLESPACE` parameter for that instance in the server parameter file (SPFILE) to reflect the new tablespace name. If a single-instance database is using a parameter file (pfile) instead of an spfile, then the database puts a message in the alert log advising the database administrator to change the value manually in the pfile.

---

**Note:** The **RENAME** clause does not change the value of the `UNDO_TABLESPACE` parameter in the running instance. Although this does not affect the functioning of the undo tablespace, Oracle recommends that you issue the following statement to manually change the value of `UNDO_TABLESPACE` to the new tablespace name for the duration of the instance:

```sql
ALTER SYSTEM SET UNDO_TABLESPACE = new_tablespace_name SCOPE = MEMORY;
```

You only need to issue this statement once. If the `UNDO_TABLESPACE` parameter is set to the new tablespace name in the pfile or spfile, then the parameter will be set correctly when the instance is next restarted.

---

**Restriction on Renaming Tablespaces** You cannot rename the `SYSTEM` or `SYSAUX` tablespaces.

**BACKUP Clauses**

Use these clauses to move all data files in a tablespace into or out of online (sometimes called hot) backup mode.

---

**See Also:**

- *Oracle Database Administrator’s Guide* for information on restarting the database without media recovery
- `ALTER DATABASE "BACKUP Clauses"` on page 10-50 for information on moving all data files in the database into and out of online backup mode
- `ALTER DATABASE alter_datafile_clause` on page 10-52 for information on taking individual data files out of online backup mode

**BEGIN BACKUP**

Specify **BEGIN BACKUP** to indicate that an open backup is to be performed on the data files that make up this tablespace. This clause does not prevent users from accessing the tablespace. You must use this clause before beginning an open backup.

**Restrictions on Beginning Tablespace Backup** Beginning tablespace backup is subject to the following restrictions:

- You cannot specify this clause for a read-only tablespace or for a temporary locally managed tablespace.
- While the backup is in progress, you cannot take the tablespace offline normally, shut down the instance, or begin another backup of the tablespace.

---

**See Also:** "Backing Up Tablespaces: Examples" on page 12-125

---

SQL Statements: ALTER TABLE to ALTER TABLESPACE 12-119
END BACKUP
Specify END BACKUP to indicate that an online backup of the tablespace is complete. Use this clause as soon as possible after completing an online backup. Otherwise, if an instance failure or SHUTDOWN ABORT occurs, then Oracle Database assumes that media recovery (possibly requiring archived redo log) is necessary at the next instance startup.

Restriction on Ending Tablespace Backup You cannot use this clause on a read-only tablespace.

datafile_tempfile_clauses
The tablespace file clauses let you add or modify a data file or temp file.

ADD Clause
Specify ADD to add to the tablespace a data file or temp file specified by file_specification. Use the datafile_tempfile_spec form of file_specification (see file_specification on page 8-29) to list regular data files and temp files in an operating system file system or to list Oracle Automatic Storage Management disk group files.

For locally managed temporary tablespaces, this is the only clause you can specify at any time.

If you omit file_specification, then Oracle Database creates an Oracle Managed File of 100M with AUTOEXTEND enabled.

You can add a data file or temp file to a locally managed tablespace that is online or to a dictionary managed tablespace that is online or offline. Ensure the file is not in use by another database.

Restriction on Adding Data Files and Temp Files You cannot specify this clause for a bigfile (single-file) tablespace, as such a tablespace has only one data file or temp file.

Note: On some operating systems, Oracle does not allocate space for a temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. To avoid potential problems, before you create or resize a temp file, ensure that the available disk space exceeds the size of the new temp file or the increased size of a resized temp file. The excess space should allow for anticipated increases in disk space use by unrelated operations as well. Then proceed with the creation or resizing operation.

See Also: file_specification on page 8-29, "Adding and Dropping Data Files and Temp Files: Examples" on page 12-125, and "Adding an Oracle-managed Data File: Example" on page 12-126

DROP Clause
Specify DROP to drop from the tablespace an empty data file or temp file specified by filename or file_number. This clause causes the data file or temp file to be removed from the data dictionary and deleted from the operating system. The database must be open at the time this clause is specified.
ALTER TABLESPACE SQL Statements: ALTER TABLE to ALTER TABLESPACE 12-121

The ALTER TABLESPACE ... DROP TEMPFILE statement is equivalent to specifying the ALTER DATABASE TEMPFILE ... DROP INCLUDING DATAFILES.

Restrictions on Dropping Files  To drop a data file or temp file, the data file or temp file:

■ Must be empty.
■ Cannot be the first file that was created in the tablespace. In such cases, drop the tablespace instead.
■ Cannot be in a read-only tablespace that was migrated from dictionary managed to locally managed. Dropping a data file from all other read-only tablespaces is supported.
■ Cannot be offline.

See Also:
- ALTER DATABASE alter_tempfile_clause on page 10-53 for additional information on dropping temp files
- Oracle Database Administrator’s Guide for information on data file numbers and for guidelines on managing data files
- ”Adding and Dropping Data Files and Temp Files: Examples” on page 12-125

SHRINK TEMPFILE Clause
This clause is valid only when altering a temporary tablespace. It lets you reduce the amount of space the specified temp file is taking. In the optional KEEP clause, the size_clause defines the lower bound that the temp file can be shrunk to. It is the opposite of MAXSIZE for an autoextensible tablespace. If you omit the KEEP clause, then the database will attempt to shrink the temp file as much as possible as long as other storage attributes are satisfied.

RENAME DATAFILE Clause
Specify RENAME DATAFILE to rename one or more of the tablespace data files. The database must be open, and you must take the tablespace offline before renaming it. Each filename must fully specify a data file using the conventions for filenames on your operating system.

This clause merely associates the tablespace with the new file rather than the old one. This clause does not actually change the name of the operating system file. You must change the name of the file through your operating system.

See Also:  ”Moving and Renaming Tablespaces: Example” on page 12-125

ONLINE | OFFLINE Clauses
Use these clauses to take all data files or temp files in the tablespace offline or put them online. These clauses have no effect on the ONLINE or OFFLINE status of the tablespace itself.

The database must be mounted. If tablespace is SYSTEM, or an undo tablespace, or the default temporary tablespace, then the database must not be open.

tablespace_logging_clauses
Use these clauses to set or change the logging characteristics of the tablespace.

SQL Statements: ALTER TABLE to ALTER TABLESPACE 12-121
logging_clause
Specify LOGGING if you want logging of all tables, indexes, and partitions within the tablespace. The tablespace-level logging attribute can be overridden by logging specifications at the table, index, and partition levels.

When an existing tablespace logging attribute is changed by an ALTER TABLESPACE statement, all tables, indexes, and partitions created after the statement will have the new default logging attribute (which you can still subsequently override). The logging attribute of existing objects is not changed.

If the tablespace is in FORCE LOGGING mode, then you can specify NOLOGGING in this statement to set the default logging mode of the tablespace to NOLOGGING, but this will not take the tablespace out of FORCE LOGGING mode.

[NO] FORCE LOGGING
Use this clause to put the tablespace in force logging mode or take it out of force logging mode. The database must be open and in READ WRITE mode. Neither of these settings changes the default LOGGING or NOLOGGING mode of the tablespace.

Restriction on Force Logging Mode You cannot specify FORCE LOGGING for an undo or a temporary tablespace.

See Also: Oracle Database Administrator’s Guide for information on when to use FORCE LOGGING mode and "Changing Tablespace Logging Attributes: Example" on page 12-126

tablespace_group_clause
This clause is valid only for locally managed temporary tablespaces. Use this clause to add tablespace to or remove it from the tablespace_group_name tablespace group.

- Specify a group name to indicate that tablespace is a member of this tablespace group. If tablespace_group_name does not already exist, then Oracle Database implicitly creates it when you alter tablespace to be a member of it.

- Specify an empty string (" ") to remove tablespace from the tablespace_group_name tablespace group.

Restriction on Tablespace Groups You cannot specify a tablespace group for a permanent tablespace or for a dictionary-managed temporary tablespace.

See Also: Oracle Database Administrator’s Guide for more information on tablespace groups and "Assigning a Tablespace Group: Example" on page 13-14

tablespace_state_clauses
Use these clauses to set or change the state of the tablespace.

ONLINE | OFFLINE
Specify ONLINE to bring the tablespace online. Specify OFFLINE to take the tablespace offline and prevent further access to its segments. When you take a tablespace offline, all of its data files are also offline.
**Suggestion:** Before taking a tablespace offline for a long time, consider changing the tablespace allocation of any users who have been assigned the tablespace as either a default or temporary tablespace. While the tablespace is offline, such users cannot allocate space for objects or sort areas in the tablespace. See ALTER USER on page 13-6 for more information on allocating tablespace quota to users.

**Restriction on Taking Tablespaces Offline** You cannot take a temporary tablespace offline.

**OFFLINE NORMAL** Specify `NORMAL` to flush all blocks in all data files in the tablespace out of the system global area (SGA). You need not perform media recovery on this tablespace before bringing it back online. This is the default.

**OFFLINE TEMPORARY** If you specify `TEMPORARY`, then Oracle Database performs a checkpoint for all online data files in the tablespace but does not ensure that all files can be written. Files that are offline when you issue this statement may require media recovery before you bring the tablespace back online.

**OFFLINE IMMEDIATE** If you specify `IMMEDIATE`, then Oracle Database does not ensure that tablespace files are available and does not perform a checkpoint. You must perform media recovery on the tablespace before bringing it back online.

**Note:** The `FOR RECOVER` setting for `ALTER TABLESPACE ... OFFLINE` has been deprecated. The syntax is supported for backward compatibility. However, Oracle recommends that you use the transportable tablespaces feature for tablespace recovery.

**See Also:** *Oracle Database Backup and Recovery User’s Guide* for information on using transportable tablespaces to perform media recovery

**READ ONLY | READ WRITE**

Specify `READ ONLY` to place the tablespace in transition read-only mode. In this state, existing transactions can complete (commit or roll back), but no further DML operations are allowed to the tablespace except for rollback of existing transactions that previously modified blocks in the tablespace. You cannot make the SYSAUX, SYSTEM, or temporary tablespaces READ ONLY.

When a tablespace is read only, you can copy its files to read-only media. You must then rename the data files in the control file to point to the new location by using the SQL statement `ALTER DATABASE ... RENAME`.

**See Also:**
- *Oracle Database Concepts* for more information on read-only tablespaces
- `ALTER DATABASE` on page 10-32

Specify `READ WRITE` to indicate that write operations are allowed on a previously read-only tablespace.
PERMANENT | TEMPORARY
Specify `PERMANENT` to indicate that the tablespace is to be converted from a temporary to a permanent tablespace. A permanent tablespace is one in which permanent database objects can be stored. This is the default when a tablespace is created.

Specify `TEMPORARY` to indicate that the tablespace is to be converted from a permanent to a temporary tablespace. A temporary tablespace is one in which no permanent database objects can be stored. Objects in a temporary tablespace persist only for the duration of the session.

Restrictions on Temporary Tablespaces Temporary tablespaces are subject to the following restrictions:

- You cannot specify `TEMPORARY` for the `SYSAUX` tablespace.
- If `tablespace` was not created with a standard block size, then you cannot change it from permanent to temporary.
- You cannot specify `TEMPORARY` for a tablespace in `FORCE LOGGING` mode.

autoextend_clause
This clause is valid only for bigfile (single-file) tablespaces. Use this clause to enable or disable autoextension of the single data file in the tablespace. To enable or disable autoextension of a newly added data file or temp file in smallfile tablespaces, use the `autoextend_clause` of the `database_file_clauses` on page 10-51 in the `ALTER DATABASE` statement.

See Also:
- `Oracle Database Administrator’s Guide` for information about bigfile (single-file) tablespaces
- `file_specification` on page 8-29 for more information about the `autoextend_clause`

flashback_mode_clause
Use this clause to specify whether this tablespace should participate in any subsequent `FLASHBACK DATABASE` operation.

- For you to turn `FLASHBACK` mode on, the database must be mounted and closed.
- For you to turn `FLASHBACK` mode off, the database must be mounted, either open `READ WRITE` or closed.

This clause is not valid for temporary tablespaces.

Refer to `CREATE TABLESPACE` on page 16-102 for more complete information on this clause.

See Also: `Oracle Database Backup and Recovery User’s Guide` for more information about Flashback Database

tablespace_retention_clause
This clause has the same semantics in `CREATE TABLESPACE` and `ALTER TABLESPACE` statements. Refer to `tablespace_retention_clause` on page 16-114 in the documentation on `CREATE TABLESPACE`. 
Examples

**Backing Up Tablespaces: Examples**  The following statement signals to the database that a backup is about to begin:

```
ALTER TABLESPACE tbs_01
BEGIN BACKUP;
```

The following statement signals to the database that the backup is finished:

```
ALTER TABLESPACE tbs_01
END BACKUP;
```

**Moving and Renaming Tablespaces: Example**  This example moves and rename a data file associated with the tbs_02 tablespace, created in "Enabling Autoextend for a Tablespace: Example" on page 16-116, from diskb:tbs_f5.dbf to diska:tbs_f5.dbf:

1. Take the tablespace offline using an ALTER TABLESPACE statement with the OFFLINE clause:
   ```
   ALTER TABLESPACE tbs_02 OFFLINE NORMAL;
   ```

2. Copy the file from diskb:tbs_f5.dbf to diska:tbs_f5.dbf using your operating system commands.

3. Rename the data file using an ALTER TABLESPACE statement with the RENAME DATAFILE clause:
   ```
   ALTER TABLESPACE tbs_02
   RENAME DATAFILE 'diskb:tbs_f5.dbf'
   TO 'diska:tbs_f5.dbf';
   ```

4. Bring the tablespace back online using an ALTER TABLESPACE statement with the ONLINE clause:
   ```
   ALTER TABLESPACE tbs_02 ONLINE;
   ```

**Adding and Dropping Data Files and Temp Files: Examples**  The following statement adds a data file to the tablespace. When more space is needed, new 10-kilobytes extents will be added up to a maximum of 100 kilobytes:

```
ALTER TABLESPACE tbs_03
ADD DATAFILE 'tbs_f04.dbf'
SIZE 100K
AUTOEXTEND ON
NEXT 10K
MAXSIZE 100K;
```

The following statement drops the empty data file:

```
ALTER TABLESPACE tbs_03
DROP DATAFILE 'tbs_f04.dbf';
```

The following statements add a temp file to the temporary tablespace created in "Creating a Temporary Tablespace: Example" on page 16-115 and then drops the temp file:

```
ALTER TABLESPACE temp_demo ADD TEMPFILE 'temp05.dbf' SIZE 5 AUTOEXTEND ON;

ALTER TABLESPACE temp_demo DROP TEMPFILE 'temp05.dbf';
```
Managing Space in a Temporary Tablespace: Example  The following statement manages the space in the temporary tablespace created in "Creating a Temporary Tablespace: Example" on page 16-115 using the SHRINK SPACE clause. The KEEP clause is omitted, so the database will attempt to shrink the tablespace as much as possible as long as other tablespace storage attributes are satisfied.

```
ALTER TABLESPACE temp_demo SHRINK SPACE;
```

Adding an Oracle-managed Data File: Example  The following example adds an Oracle-managed data file to the omf_tsl tablespace (see "Creating Oracle Managed Files: Examples" on page 16-117 for the creation of this tablespace). The new data file is 100M and is autoextensible with unlimited maximum size:

```
ALTER TABLESPACE omf_tsl ADD DATAFILE;
```

Changing Tablespace Logging Attributes: Example  The following example changes the default logging attribute of a tablespace to NOLOGGING:

```
ALTER TABLESPACE tbs_03 NOLOGGING;
```

Altering a tablespace logging attribute has no affect on the logging attributes of the existing schema objects within the tablespace. The tablespace-level logging attribute can be overridden by logging specifications at the table, index, and partition levels.

Changing Undo Data Retention: Examples  The following statement changes the undo data retention for tablespace undots1 to normal undo data behavior:

```
ALTER TABLESPACE undots1
  RETENTION NOGUARANTEE;
```

The following statement changes the undo data retention for tablespace undots1 to behavior that preserves unexpired undo data:

```
ALTER TABLESPACE undots1
  RETENTION GUARANTEE;
```
This chapter contains the following SQL statements:

- ALTER TRIGGER
- ALTER TYPE
- ALTER USER
- ALTER VIEW
- ANALYZE
- ASSOCIATE STATISTICS
- AUDIT (Traditional Auditing)
- AUDIT (Unified Auditing)
- CALL
- COMMENT
- COMMIT
ALTERTRIGGER

Purpose

Triggers are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the ALTER TRIGGER statement to enable, disable, or compile a database trigger.

Note: This statement does not change the declaration or definition of an existing trigger. To redefine a trigger, use the CREATE TRIGGER statement with the OR REPLACE keywords.

See Also:
- CREATE TRIGGER on page 16-118 for information on creating a trigger
- DROP TRIGGER on page 18-12 for information on dropping a trigger
- Oracle Database Concepts for general information on triggers

Prerequisites

The trigger must be in your own schema or you must have ALTER ANY TRIGGER system privilege.

In addition, to alter a trigger on DATABASE, you must have the ADMINISTER DATABASE TRIGGER privilege.

See Also: CREATE TRIGGER on page 16-118 for more information on triggers based on DATABASE triggers

Syntax

```sql
alter_trigger ::= ALTER TRIGGER schema trigger_name trigger_compile_clause
                  ENABLE | DISABLE | RENAME TO new_name | EDITIONABLE | NONEDITIONABLE
```

(trigger_compile_clause: See Oracle Database PL/SQL Language Reference for the syntax of this clause.)
Semantics

**schema**
Specify the schema containing the trigger. If you omit `schema`, then Oracle Database assumes the trigger is in your own schema.

**trigger_name**
Specify the name of the trigger to be altered.

**trigger_compile_clause**
See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling triggers.

**ENABLE | DISABLE**
Specify `ENABLE` to enable the trigger. You can also use the `ENABLE ALL TRIGGERS` clause of `ALTER TABLE` to enable all triggers associated with a table. See `ALTER TABLE` on page 12-2.

Specify `DISABLE` to disable the trigger. You can also use the `DISABLE ALL TRIGGERS` clause of `ALTER TABLE` to disable all triggers associated with a table.

**RENAME Clause**
Specify `RENAME TO new_name` to rename the trigger. Oracle Database renames the trigger and leaves it in the same state it was in before being renamed.

When you rename a trigger, the database rebuilds the remembered source of the trigger in the `USER_SOURCE`, `ALL_SOURCE`, and `DBA_SOURCE` data dictionary views. As a result, comments and formatting may change in the `TEXT` column of those views even though the trigger source did not change.

**EDITIONABLE | NONEDITIONABLE**
Use these clauses to specify whether the trigger becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `TRIGGER` in `schema`. The default is `EDITIONABLE`. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

**Restriction on NONEDITIONABLE** You cannot specify `NONEDITIONABLE` for a crossedition trigger.
ALTER TYPE

Purpose

Object types are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the ALTER TYPE statement to add or drop member attributes or methods. You can change the existing properties (FINAL or INSTANTIABLE) of an object type, and you can modify the scalar attributes of the type.

You can also use this statement to recompile the specification or body of the type or to change the specification of an object type by adding new object member subprogram specifications.

Prerequisites

The object type must be in your own schema and you must have CREATE TYPE or CREATE ANY TYPE system privilege, or you must have ALTER ANY TYPE system privileges.

Syntax

\[alter\_type::=\]

```
ALTER TYPE schema.type_name alter_type_clause
```

(alter_type_clause: See Oracle Database PL/SQL Language Reference for the syntax of this clause.)

Semantics

\[schema\]
Specify the schema that contains the type. If you omit schema, then Oracle Database assumes the type is in your current schema.

\[type\_name\]
Specify the name of an object type, a nested table type, or a varray type.

Restriction on type_name

You cannot evolve an editioned object type. The ALTER TYPE statement fails with ORA-22348 if either of the following is true:

- The type is an editioned object type and the ALTER TYPE statement has no type_compile_clause. You can use the ALTER TYPE statement to recompile an editioned object type, but not for any other purpose.
- The type has a dependent that is an editioned object type and the ALTER TYPE statement has a CASCADE clause.

Refer to Oracle Database PL/SQL Language Reference for more information on the type_compile_clause and the CASCADE clause.
**alter_type_clause**

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling object types.

**EDITIONABLE | NONEDITIONABLE**

Use these clauses to specify whether the type becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `TYPE` in `schema`. The default is `EDITIONABLE`. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*. 
ALTER USER

Purpose

Use the ALTER USER statement:

■ To change the authentication or database resource characteristics of a database user
■ To permit a proxy server to connect as a client without authentication
■ In an Oracle Automatic Storage Management (Oracle ASM) cluster, to change the password of a user in the password file that is local to the Oracle ASM instance of the current node

See Also: Oracle Database Security Guide for detailed information about user authentication methods

Prerequisites

In general, you must have the ALTER USER system privilege. However, the current user can change his or her own password without this privilege.

You must be authenticated AS SYSASM to change the password of a user other than yourself in an Oracle ASM instance password file.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). If the current container is the root, then you can specify CONTAINER = ALL or CONTAINER = CURRENT. If the current container is a pluggable database (PDB), then you can specify only CONTAINER = CURRENT.

To set and modify CONTAINER_DATA attributes using the container_data_clause, you must be connected to a CDB and the current container must be the root.
Syntax

\textit{alter\_user::=}

\begin{verbatim}
ALTER
USER

BY
password
REPLACE
old\_password

IDENTIFIED
.EXTERNALLY
AS
certificate\_DN
kerberos\_principal\_name

GLOBALY
AS
directory\_DN

DEFAULT
ROLE

EXCEPT
role

PASSWORD
EXPIRE

ACCOUNT
LOCK
UNLOCK

ENABLE
EDITIONS

CONTAINER
CURRENT
ALL

container\_data\_clause

(size\_clause::= on page 8-47)
\end{verbatim}
ALTER USER

proxy_clause::=

db_user_proxy_clauses::=

container_data_clause::=

Semantics

The keywords, parameters, and clauses described in this section are unique to ALTER USER or have different semantics than they have in CREATE USER. Keywords, parameters, and clauses that do not appear here have the same meaning as in the CREATE USER statement.

Note: Oracle recommends that user names and passwords be encoded in ASCII or EBCDIC characters only, depending on your platform.

See Also: CREATE USER on page 17-7 for information on the keywords and parameters and CREATE PROFILE on page 15-77 for information on assigning limits on database resources to a user.
IDENTIFIED Clause

**BY password** Specify **BY password** to specify a new password for the user. Passwords are case sensitive. Any subsequent CONNECT string used to connect this user to the database must specify the password using the same case (upper, lower, or mixed) that is used in this ALTER USER statement. Passwords can contain single-byte, or multibyte characters, or both from your database character set.

**Note:** Oracle Database expects a different timestamp for each resetting of a particular password. If you reset one password multiple times within one second (for example, by cycling through a set of passwords using a script), then the database may return an error message that the password cannot be reused. For this reason, Oracle recommends that you avoid using scripts to reset passwords.

You can omit the REPLACE clause if you are setting your own password or you have the ALTER USER system privilege and you are changing another user's password. However, unless you have the ALTER USER system privilege, you must always specify the REPLACE clause if a password complexity verification function has been enabled, either by running the UTLPWDMG.SQL script or by specifying such a function in the PASSWORD_VERIFY_FUNCTION parameter of a profile that has been assigned to the user.

In an Oracle ASM cluster, you can use this clause to change the password of a user in the password file that is local to an Oracle ASM instance of the current node. You must be authenticated AS SYSASM to specify IDENTIFIED BY password without the REPLACE old_password clause. If you are not authenticated AS SYSASM, then you can only change your own password by specifying REPLACE old_password.

Oracle Database does not check the old password, even if you provide it in the REPLACE clause, unless you are changing your own existing password.

**See Also:** *Oracle Database Security Guide* for guidelines on creating passwords

**GLOBALLY** Refer to CREATE USER on page 17-7 for more information on this clause.

You can change a user's access verification method from IDENTIFIED GLOBALLY to either IDENTIFIED BY password or IDENTIFIED EXTERNALLY. You can change a user's access verification method to IDENTIFIED GLOBALLY from one of the other methods only if all external roles granted explicitly to the user are revoked.

**EXTERNALLY** Refer to CREATE USER on page 17-7 for more information on this clause.

**See Also:** *Oracle Database Enterprise User Security Administrator’s Guide* for more information on globally and externally identified users, "Changing User Identification: Example" on page 13-13, and "Changing User Authentication: Examples" on page 13-14

**DEFAULT TABLESPACE Clause**

Use this clause to assign or reassign a tablespace for the user's permanent segments. This clause overrides any default tablespace that has been specified for the database.
Restriction on Default Tablespaces  You cannot specify a locally managed temporary tablespace, including an undo tablespace, or a dictionary-managed temporary tablespace, as a user’s default tablespace.

TEMPORARY TABLESPACE Clause
Use this clause to assign or reassign a tablespace or tablespace group for the user’s temporary segments.

- Specify `tablespace` to indicate the user’s temporary tablespace. If you are connected to a CDB, then you can specify `CDB$DEFAULT` to use the CDB-wide default temporary tablespace.
- Specify `tablespace_group_name` to indicate that the user can save temporary segments in any tablespace in the tablespace group specified by `tablespace_group_name`.

Restriction on User Temporary Tablespace  Any individual tablespace you assign or reassign as the user’s temporary tablespace must be a temporary tablespace and must have a standard block size.

See Also:  "Assigning a Tablespace Group: Example" on page 13-14

DEFAULT ROLE Clause
Specify the roles granted by default to the user at logon. This clause can contain only roles that have been granted directly to the user with a `GRANT` statement, or roles created by the user with the `CREATE ROLE` privilege. You cannot use the DEFAULT ROLE clause to specify:

- Roles not granted to the user
- Roles granted through other roles
- Roles managed by an external service (such as the operating system), or by the Oracle Internet Directory
- Roles that are enabled by the `SET ROLE` statement, such as password-authenticated roles and secure application roles

See Also:  `CREATE ROLE` on page 15-87

Assigning Default Roles to Common Users in a CDB  You can modify the default role assigned to a common user both in the current container and across all containers in a CDB.

While assigning a default role to a common user across all containers, `role` must be a common role that was commonly granted to the common user.

While assigning a default role to a common user in the current container, `role` must be one of the following:

- A local role that was granted to the common user in the current container
- A common role that was granted to the common user, either commonly or locally in the current container

ENABLE EDITIONS
This clause is not reversible. Specify `ENABLE EDITIONS` to allow the user to create multiple versions of editionable objects in this schema using editions. Editionable objects in non-editions-enabled schemas cannot be editioned.
Use the FOR clause to specify one or more object types for which the user can create editionable objects. For a list of valid values for object_type, query the V$EDITIONABLE_TYPES dynamic performance view. If you omit the FOR clause, then the user can create editionable objects for all editionable object types.

See Also: Oracle Database Reference for more information about the V$EDITIONABLE_TYPES dynamic performance view

If the schema to be editions-enabled contains any objects that are not editionable and that depend on editionable type objects in the schema, then you must specify FORCE to enable editions for this schema. In this case, all the objects that are not editionable and that depend on the editionable type objects in the schema being editions-enabled become invalid.

CONTAINER Clause
If the current container is a PDB, then you can specify CONTAINER = CURRENT to change the attributes of a local user, or the container-specific attributes (such as the default tablespace) of a common user, in the current container. If the current container is the root, then you can specify CONTAINER = ALL to change the attributes of a common user across the entire CDB. If you omit this clause and the current container is a PDB, then CONTAINER = CURRENT is the default. If you omit this clause and the current container is the root, then CONTAINER = ALL is the default.

Restriction on Modifying Common Users in a CDB Certain attributes of a common user must be modified for all the containers in a CDB and not for only some containers. Therefore, when you use any of the following clauses to modify a common user, ensure that you modify all of the containers by connecting to the root and specifying CONTAINER = ALL:

- IDENTIFIED clause
- PASSWORD clause

container_data_clause
The container_data_clause allows you the set and modify CONTAINER_DATA attributes for a common user. Use the FOR clause to indicate whether to set or modify the default CONTAINER_DATA attribute or an object-specific CONTAINER_DATA attribute. These attributes determine the set of containers (which can never exclude the root) whose data will be visible via CONTAINER_DATA objects to the specified common user when the current session is the root.

To specify the container_data_clause, the current session must be the root and you must specify CONTAINER = CURRENT.

SET CONTAINER_DATA Use this clause to set the default CONTAINER_DATA attribute or an object-specific CONTAINER_DATA attribute for a common user. When you specify this clause, you replace the existing value, if any, of the CONTAINER_DATA attribute.

Use container_name to specify one or more containers that will be accessible to the user.

Use ALL to specify that all current and future containers in the CDB will be accessible to the user.

Use DEFAULT to specify the default behavior, which is as follows:

- For a default CONTAINER_DATA attribute, the current container, that is, the root, and the CDB as a whole will be accessible to the user.
For an object-specific CONTAINER_DATA attribute, the database will use the user’s default CONTAINER_DATA attribute.

---

Note: CONTAINER_DATA attributes that are set to DEFAULT are not visible in the DBA_CONTAINER_DATA view.

---

**ADD CONTAINER_DATA**

Use this clause to add containers to the default CONTAINER_DATA attribute or an object-specific CONTAINER_DATA attribute for a common user. Use `container_name` to specify one or more containers to add.

You cannot use this clause if the default CONTAINER_DATA attribute is set to ALL. If you use this clause when the default CONTAINER_DATA attribute is set to DEFAULT, then CDB$ROOT will automatically be added to the set of containers, unless the set already contains CDB$ROOT.

You cannot use this clause if the object-specific CONTAINER_DATA attribute is set to ALL or DEFAULT.

**REMOVE CONTAINER_DATA**

Use this clause to remove containers from the default CONTAINER_DATA attribute or an object-specific CONTAINER_DATA attribute for a common user. Use `container_name` to specify one or more containers to remove.

You cannot use this clause if the default CONTAINER_DATA attribute or object-specific CONTAINER_DATA attribute is set to ALL.

**FOR container_data_object**

If you specify the FOR clause, then you can set and modify the object-specific CONTAINER_DATA attribute for `container_data_object` for a common user. `container_data_object` must be a CONTAINER_DATA table or view. If you omit `schema`, then Oracle Database assumes that `container_data_object` is in your own schema.

If you omit the FOR clause, then you can set and modify the default CONTAINER_DATA attribute for a common user.

**See Also:** *Oracle Database Security Guide* for more information about enabling common users to view information about PDB objects

**proxy_clause**

The `proxy_clause` lets you control the ability of an enterprise user (a user outside the database) or a database proxy (another database user) to connect as the database user being altered.

**GRANT CONNECT THROUGH**

Specify GRANT CONNECT THROUGH to allow the connection.

**REVOKE CONNECT THROUGH**

Specify REVOKE CONNECT THROUGH to prohibit the connection.

**ENTERPRISE USER**

This clause lets you expose `user` to proxy use by enterprise users. The administrator working in Oracle Internet Directory must then grant privileges for appropriate enterprise users to act on behalf of `user`. 
**db_user_proxy**

This clause lets you expose *user* to proxy use by database user *db_user_proxy* (the proxy).

- The proxy will have all privileges that were directly granted to *user*.
- The proxy will have all roles associated with *user*, unless you specify the `WITH` clauses of *db_user_proxy_clauses* to limit the proxy to some or none of the roles of *user*. For each role associated with the proxy, if the role is enabled by default for *user* at login, then that role will also be enabled by default for the proxy at login.

**db_user_proxy_clauses**

Specify the `WITH` clauses to limit the proxy to some or none of the roles associated with *user*, and the `AUTHENTICATION REQUIRED` clause to specify whether authentication is required.

- **WITH ROLE**  
  `WITH ROLE role_name` permits the proxy to connect as the specified user and to activate only the roles that are specified by *role_name*. This clause can contain only roles that are associated with *user*.

- **WITH ROLE ALL EXCEPT**  
  `WITH ROLE ALL EXCEPT role_name` permits the proxy to connect as the specified user and to activate all roles associated with that user except those specified for *role_name*. This clause can contain only roles that are associated with *user*.

- **WITH NO ROLES**  
  `WITH NO ROLES` permits the proxy to connect as the specified user, but prohibits the proxy from activating any of that user's roles after connecting.

- **AUTHENTICATION REQUIRED**  
  Oracle Database does not expect the proxy to authenticate the user unless you specify the `AUTHENTICATION REQUIRED` clause. This clause ensures that authentication credentials for the user must be presented when the user is authenticated through the specified proxy. The credential is a password.

- **AUTHENTICATED USING**  
  The `AUTHENTICATED USING` clauses, which appeared in the syntax of earlier releases, have been deprecated and are no longer needed. If you specify the `AUTHENTICATED USING PASSWORD` clause, then Oracle Database converts it to the `AUTHENTICATION REQUIRED` clause. Specifying the `AUTHENTICATED USING CERTIFICATE` clause or the `AUTHENTICATED USING DISTINGUISHED NAME` clause is equivalent to omitting the `AUTHENTICATION REQUIRED` clause.

**Examples**

**Changing User Identification: Example**  
The following statement changes the password of the user *sidney* (created in "Creating a Database User: Example" on page 17-13) *second_2nd_pwd* and default tablespace to the tablespace *example*.

---

**SQL Statements: ALTER TRIGGER to COMMIT**  
13-13
ALTER USER sidney
  IDENTIFIED BY second_2nd_pwd
  DEFAULT TABLESPACE example;

The following statement assigns the new_profile profile (created in "Creating a Profile: Example" on page 15-82) to the sample user sh:

ALTER USER sh
  PROFILE new_profile;

In subsequent sessions, sh is restricted by limits in the new_profile profile.

The following statement makes all roles granted directly to sh default roles, except the dw_manager role:

ALTER USER sh
  DEFAULT ROLE ALL EXCEPT dw_manager;

At the beginning of sh's next session, Oracle Database enables all roles granted directly to sh except the dw_manager role.

Changing User Authentication: Examples  The following statement changes the authentication mechanism of user app_user1 (created in "Creating a Database User: Example" on page 17-13):

ALTER USER app_user1 IDENTIFIED GLOBALLY AS 'CN=tom,O=oracle,C=US';

The following statement causes user sidney's password to expire:

ALTER USER sidney PASSWORD EXPIRE;

If you cause a database user’s password to expire with PASSWORD EXPIRE, then the user (or the DBA) must change the password before attempting to log in to the database following the expiration. However, tools such as SQL*Plus allow the user to change the password on the first attempted login following the expiration.

Assigning a Tablespace Group: Example  The following statement assigns tbs_grp_01 (created in "Adding a Temporary Tablespace to a Tablespace Group: Example" on page 16-116) as the tablespace group for user sh:

ALTER USER sh
  TEMPORARY TABLESPACE tbs_grp_01;

Proxy Users: Examples  The following statement alters the user app_user1. The example permits the app_user1 to connect through the proxy user sh. The example also allows app_user1 to enable its warehouse_user role (created in "Creating a Role: Example" on page 15-89) when connected through the proxy sh:

ALTER USER app_user1
  GRANT CONNECT THROUGH sh
  WITH ROLE warehouse_user;

To show basic syntax, this example uses the sample database Sales History user (sh) as the proxy. Normally a proxy user would be an application server or middle-tier entity. For information on creating the interface between an application user and a database by way of an application server, refer to Oracle Call Interface Programmer’s Guide.
The following statement takes away the right of user `app_user1` to connect through the proxy user `sh`:

```
ALTER USER app_user1 REVOKE CONNECT THROUGH sh;
```

The following hypothetical examples show another method of proxy authentication:

```
ALTER USER sully GRANT CONNECT THROUGH OAS1
   AUTHENTICATED USING PASSWORD;
```

The following example exposes the user `app_user1` to proxy use by enterprise users. The enterprise users cannot act on behalf of `app_user1` until the Oracle Internet Directory administrator has granted them appropriate privileges:

```
ALTER USER app_user1
   GRANT CONNECT THROUGH ENTERPRISE USERS;
```
ALTER VIEW

Purpose

Use the `ALTER VIEW` statement to explicitly recompile a view that is invalid or to modify view constraints. Explicit recompilation lets you locate recompilation errors before runtime. You may want to recompile a view explicitly after altering one of its base tables to ensure that the alteration does not affect the view or other objects that depend on it.

You can also use `ALTER VIEW` to define, modify, or drop view constraints.

You cannot use this statement to change the definition of an existing view. Further, if DDL changes to the view’s base tables invalidate the view, then you cannot use this statement to compile the invalid view. In these cases, you must redefine the view using `CREATE VIEW` with the OR REPLACE keywords.

When you issue an `ALTER VIEW` statement, Oracle Database recompiles the view regardless of whether it is valid or invalid. The database also invalidates any local objects that depend on the view.

If you alter a view that is referenced by one or more materialized views, then those materialized views are invalidated. Invalid materialized views cannot be used by query rewrite and cannot be refreshed.

See Also:

- `CREATE VIEW` on page 17-15 for information on redefining a view and `ALTER MATERIALIZED VIEW` on page 11-3 for information on revalidating an invalid materialized view
- `Oracle Database Data Warehousing Guide` for general information on data warehouses
- `Oracle Database Concepts` for more about dependencies among schema objects

Prerequisites

The view must be in your own schema or you must have `ALTER ANY TABLE` system privilege.
ALTER VIEW

Syntax

\textit{alter\_view::=}

\begin{itemize}
  \item \textit{ADD out\_of\_line\_constraint}
  \item \textit{MODIFY CONSTRAINT constraint RELY NORELY}
  \item \textit{DROP PRIMARY KEY}
  \item \textit{UNIQUE column}
  \item \textit{COMPILE}
  \item \textit{READ ONLY}
  \item \textit{WRITE}
  \item \textit{EDITABLE}
  \item \textit{NONEDITABLE}
\end{itemize}

(out\_of\_line\_constraint::= on page 8-5—part of constraint::= syntax)

Semantics

\textit{schema}
Specify the schema containing the view. If you omit \textit{schema}, then Oracle Database assumes the view is in your own schema.

\textit{view}
Specify the name of the view to be recompiled.

\textbf{ADD Clause}
Use the \textit{ADD} clause to add a constraint to \textit{view}. Refer to \textit{constraint} on page 8-4 for information on view constraints and their restrictions.

\textbf{MODIFY CONSTRAINT Clause}
Use the \textit{MODIFY CONSTRAINT} clause to change the \textit{RELY} or \textit{NORELY} setting of an existing view constraint. Refer to "RELY Clause" on page 8-17 for information on the uses of these settings and to "Notes on View Constraints" on page 8-19 for general information on view constraints.

\textbf{Restriction on Modifying Constraints} You cannot change the setting of a unique or primary key constraint if it is part of a referential integrity constraint without dropping the foreign key or changing its setting to match that of \textit{view}.

\textbf{DROP Clause}
Use the \textit{DROP} clause to drop an existing view constraint.
Restriction on Dropping Constraints  You cannot drop a unique or primary key constraint if it is part of a referential integrity constraint on a view.

COMPILE
The COMPILE keyword directs Oracle Database to recompile the view.

{ READ ONLY | READ WRITE }
These clauses are valid only for editioning views.

■ Specify READ ONLY to indicate that the editioning view cannot be updated.
■ Specify READ WRITE to return a read-only editioning view to read/write status.

When you specify these clauses, the database does not invalidate dependent objects, but it may invalidate cursors.

EDITIONABLE | NONEDITIONABLE
Use these clauses to specify whether the view becomes an editioned or noneditioned object if editioning is later enabled for the schema object type VIEW in schema. The default is EDITIONABLE. For information about altering editioned and noneditioned objects, see Oracle Database Development Guide.

See Also: CREATE VIEW on page 17-15 for information about editioning views

Examples

Altering a View: Example  To recompile the view customer_ro (created in "Creating a Read-Only View: Example" on page 17-26), issue the following statement:

```
ALTER VIEW customer_ro
COMPILE;
```

If Oracle Database encounters no compilation errors while recompiling customer_ro, then customer_ro becomes valid. If recompiling results in compilation errors, then the database returns an error and customer_ro remains invalid.

Oracle Database also invalidates all dependent objects. These objects include any procedures, functions, package bodies, and views that reference customer_ro. If you subsequently reference one of these objects without first explicitly recompiling it, then the database recompiles it implicitly at run time.
ANALYZE

Purpose

Use the `ANALYZE` statement to collect statistics, for example, to:

- Collect or delete statistics about an index or index partition, table or table partition, index-organized table, cluster, or scalar object attribute.
- Validate the structure of an index or index partition, table or table partition, index-organized table, cluster, or object reference (REF).
- Identify migrated and chained rows of a table or cluster.

**Note:** For the collection of most statistics, use the `DBMS_STATS` package, which lets you collect statistics in parallel, collect global statistics for partitioned objects, and fine tune your statistics collection in other ways. See *Oracle Database PL/SQL Packages and Types Reference* for more information on the `DBMS_STATS` package.

Use the `ANALYZE` statement (rather than `DBMS_STATS`) for statistics collection not related to the cost-based optimizer:

- To use the `VALIDATE` or `LIST CHAINED ROWS` clauses
- To collect information on freelist blocks

Prerequisites

The schema object to be analyzed must be local, and it must be in your own schema or you must have the `ANALYZE ANY` system privilege.

If you want to list chained rows of a table or cluster into a list table, then the list table must be in your own schema, or you must have `INSERT` privilege on the list table, or you must have `INSERT ANY TABLE` system privilege.

If you want to validate a partitioned table, then you must have the `INSERT` object privilege on the table into which you list analyzed rowids, or you must have the `INSERT ANY TABLE` system privilege.
Syntax

```
analyze::=
  analyze
    . ANALYZE
      . TABLE
        . schema
          . table
            . partition_extension_clause
          . INDEX
            . schema
              . index
            . CLUSTER
              . schema
                . cluster
      . partition_extension_clause

partition_extension_clause::=
  PARTITION
    . partition
      . FOR
        . partition_key_value
      . SUBPARTITION
        . subpartition
          . FOR
            . subpartition_key_value
  VALIDATE
    . REF
      . UPDATE
        . SET
          . DANGLING
            . TO
              . NULL
            . CASCADE
              . FAST
                . COMPLETE
                  . OFFLINE
                    . ONLINE
                      . into_clause
  VALIDATE
    . STRUCTURE
      . INTO
        . schema
          . table
```

Semantics

**schema**
Specify the schema containing the table, index, or cluster. If you omit *schema*, then Oracle Database assumes the table, index, or cluster is in your own schema.
TABLE table

Specify a table to be analyzed. When you analyze a table, the database collects statistics about expressions occurring in any function-based indexes as well. Therefore, be sure to create function-based indexes on the table before analyzing the table. Refer to CREATE INDEX on page 14-73 for more information about function-based indexes.

When analyzing a table, the database skips all domain indexes marked LOADING or FAILED.

For an index-organized table, the database also analyzes any mapping table and calculates its PCT_ACCESSS_DIRECT statistics. These statistics estimate the accuracy of guess data block addresses stored as part of the local rowids in the mapping table.

Oracle Database collects the following statistics for a table. Statistics marked with an asterisk are always computed exactly. Table statistics, including the status of domain indexes, appear in the data dictionary views USER_TABLES, ALL_TABLES, and DBA_TABLES in the columns shown in parentheses.

- Number of rows (NUM_ROWS)
- * Number of data blocks below the high water mark—the number of data blocks that have been formatted to receive data, regardless whether they currently contain data or are empty (BLOCKS)
- * Number of data blocks allocated to the table that have never been used (EMPTY_BLOCKS)
- Average available free space in each data block in bytes (AVG_SPACE)
- Number of chained rows (CHAIN_COUNT)
- Average row length, including the row overhead, in bytes (AVG_ROW_LEN)

Restrictions on Analyzing Tables  Analyzing tables is subject to the following restrictions:

- You cannot use ANALYZE to collect statistics on data dictionary tables.
- You cannot use ANALYZE to collect statistics on an external table. Instead, you must use the DBMS_STATS package.
- You cannot use ANALYZE to collect default statistics on a temporary table. However, if you have already created an association between one or more columns of a temporary table and a user-defined statistics type, then you can use ANALYZE to collect the user-defined statistics on the temporary table.
- You cannot compute or estimate statistics for the following column types: REF column types, varrays, nested tables, LOB column types (LOB column types are not analyzed, they are skipped), LONG column types, or object types. However, if a statistics type is associated with such a column, then Oracle Database collects user-defined statistics.

See Also:
- ASSOCIATE STATISTICS on page 13-27
- Oracle Database Reference for information on the data dictionary views

partition_extension_clause

Specify the partition or subpartition, or the partition or subpartition value, on which you want statistics to be gathered. You cannot use this clause when analyzing clusters.
If you specify `PARTITION` and `table` is composite-partitioned, then Oracle Database analyzes all the subpartitions within the specified partition.

### INDEX `index`

Specify an index to be analyzed.

Oracle Database collects the following statistics for an index. Statistics marked with an asterisk are always computed exactly. For conventional indexes, when you compute or estimate statistics, the statistics appear in the data dictionary views `USER_INDEXES`, `ALL_INDEXES`, and `DBA_INDEXES` in the columns shown in parentheses.

- * Depth of the index from its root block to its leaf blocks (`BLEVEL`)
- Number of leaf blocks (`LEAF_BLOCKS`)
- Number of distinct index values (`DISTINCT_KEYS`)
- Average number of leaf blocks for each index value (`AVG_LEAF_BLOCKS_PER_KEY`)
- Average number of data blocks for each index value (for an index on a table) (`AVG_DATA_BLOCKS_PER_KEY`)
- Clustering factor (how well ordered the rows are about the indexed values) (`CLUSTERING_FACTOR`)

For domain indexes, this statement invokes the user-defined statistics collection function specified in the statistics type associated with the index (see `ASSOCIATE STATISTICS` on page 13-27). If no statistics type is associated with the domain index, then the statistics type associated with its index type is used. If no statistics type exists for either the index or its index type, then no user-defined statistics are collected. User-defined index statistics appear in the `STATISTICS` column of the data dictionary views `USER_USTATS`, `ALL_USTATS`, and `DBA_USTATS`.

---

**Notes:**

- When you analyze an index from which a substantial number of rows has been deleted, Oracle Database sometimes executes a `COMPUTE` statistics operation (which can entail a full table scan) even if you request an `ESTIMATE` statistics operation. Such an operation can be quite time consuming.

- In some cases, analyzing an index with the `ANALYZE` statement takes an inordinate amount of time to complete. In these cases, you can use a SQL query to validate the index. If the query determines that there is an inconsistency between a table and the index, then you can use the `ANALYZE` statement for a thorough analysis of the index. Refer to `Oracle Database Administrator’s Guide` for more information.

---

**Restriction on Analyzing Indexes** You cannot analyze a domain index that is marked `IN_PROGRESS` or `FAILED`. 
See Also:
- CREATE INDEX on page 14-73 for more information on domain indexes
- Oracle Database Reference for information on the data dictionary views
- "Analyzing an Index: Example" on page 13-26

**CLUSTER cluster**
Specify a cluster to be analyzed. When you collect statistics for a cluster, Oracle Database also automatically collects the statistics for all the tables in the cluster and all their indexes, including the cluster index.

For both indexed and hash clusters, the database collects the average number of data blocks taken up by a single cluster key (AVG_BLOCKS_PER_KEY). These statistics appear in the data dictionary views ALL_CLUSTERS, USER_CLUSTERS, and DBA_CLUSTERS.

See Also: Oracle Database Reference for information on the data dictionary views and "Analyzing a Cluster: Example" on page 13-26

**validation clauses**
The validation clauses let you validate REF values and the structure of the analyzed object.

See Also: Oracle Database Administrator’s Guide for more information about validating tables, indexes, clusters, and materialized views

**VALIDATE REF UPDATE Clause**
Specify VALIDATE REF UPDATE to validate the REF values in the specified table, check the rowid portion in each REF, compare it with the true rowid, and correct it, if necessary. You can use this clause only when analyzing a table.

If the owner of the table does not have the READ or SELECT object privilege on the referenced objects, then Oracle Database will consider them invalid and set them to null. Subsequently these REF values will not be available in a query, even if it is issued by a user with appropriate privileges on the objects.

**SET DANGLING TO NULL**
SET DANGLING TO NULL sets to null any REF values (whether or not scoped) in the specified table that are found to point to an invalid or nonexistent object.

**VALIDATE STRUCTURE**
Specify VALIDATE STRUCTURE to validate the structure of the analyzed object. The statistics collected by this clause are not used by the Oracle Database optimizer.

See Also: "Validating a Table: Example" on page 13-26

- For a table, Oracle Database verifies the integrity of each of the data blocks and rows. For an index-organized table, the database also generates compression statistics (optimal prefix compression count) for the primary key index on the table.
- For a cluster, Oracle Database automatically validates the structure of the cluster tables.
For a partitioned table, Oracle Database also verifies that each row belongs to the correct partition. If a row does not collate correctly, then its rowid is inserted into the `INVALID_ROWS` table.

For a temporary table, Oracle Database validates the structure of the table and its indexes during the current session.

For an index, Oracle Database verifies the integrity of each data block in the index and checks for block corruption. This clause does not confirm that each row in the table has an index entry or that each index entry points to a row in the table. You can perform these operations by validating the structure of the table with the `CASCADE` clause.

Oracle Database also computes compression statistics (optimal prefix compression count) for all normal indexes.

Oracle Database stores statistics about the index in the data dictionary views `INDEX_STATS` and `INDEX_HISTOGRAM`.

**See Also:** *Oracle Database Reference* for information on these views

If Oracle Database encounters corruption in the structure of the object, then an error message is returned. In this case, drop and re-create the object.

**CASCADE**  Specify `CASCADE` if you want Oracle Database to validate the structure of the indexes associated with the table or cluster. If you use this clause when validating a table, then the database also validates the indexes defined on the table. If you use this clause when validating a cluster, then the database also validates all the cluster tables indexes, including the cluster index.

By default, `CASCADE` performs a `COMPLETE` validation, which can be resource intensive. Specify `FAST` if you want the database to check for the existence of corruptions without reporting details about the corruption. If the `FAST` check finds a corruption, you can then use the `CASCADE` option without the `FAST` clause to locate and learn details about it.

If you use this clause to validate an enabled (but previously disabled) function-based index, then validation errors may result. In this case, you must rebuild the index.

**ONLINE | OFFLINE**  Specify `ONLINE` to enable Oracle Database to run the validation while DML operations are ongoing within the object. The database reduces the amount of validation performed to allow for concurrency.

**Note:**  When you validate the structure of an object `ONLINE`, Oracle Database does not collect any statistics, as it does when you validate the structure of the object `OFFLINE`.

Specify `OFFLINE`, to maximize the amount of validation performed. This setting prevents `INSERT`, `UPDATE`, and `DELETE` statements from concurrently accessing the object during validation but allows queries. This is the default.

**Restriction on ONLINE**  You cannot specify `ONLINE` when analyzing a cluster.

**INTO**  The `INTO` clause of `VALIDATE STRUCTURE` is valid only for partitioned tables. Specify a table into which Oracle Database lists the rowids of the partitions whose rows do not collate correctly. If you omit `schema`, then the database assumes the list is in your own schema. If you omit this clause altogether, then the database assumes that
the table is named INVALID_ROWS. The SQL script used to create this table is UTLVALID.SQL.

LIST CHAINED ROWS

LIST CHAINED ROWS lets you identify migrated and chained rows of the analyzed table or cluster. You cannot use this clause when analyzing an index.

In the INTO clause, specify a table into which Oracle Database lists the migrated and chained rows. If you omit schema, then the database assumes the chained-rows table is in your own schema. If you omit this clause altogether, then the database assumes that the table is named CHAINED_ROWS. The chained-rows table must be on your local database.

You can create the CHAINED_ROWS table using one of these scripts:

- UTLCHAIN.SQL uses physical rowids. Therefore it can accommodate rows from conventional tables but not from index-organized tables. (See the Note that follows.)
- UTLCHN1.SQL uses universal rowids, so it can accommodate rows from both conventional and index-organized tables.

If you create your own chained-rows table, then it must follow the format prescribed by one of these two scripts.

If you are analyzing index-organized tables based on primary keys (rather than universal rowids), then you must create a separate chained-rows table for each index-organized table to accommodate its primary-key storage. Use the SQL scripts DBMSIOTC.SQL and PRVTIOTC.PLB to define the BUILD_CHAIN_ROWS_TABLE procedure, and then execute this procedure to create an IOT_CHAINED_ROWS table for each such index-organized table.

See Also:

- The DBMS_IOT package in Oracle Database PL/SQL Packages and Types Reference for information on the packaged SQL scripts
- "Listing Chained Rows: Example" on page 13-26

DELETE STATISTICS

Specify DELETE STATISTICS to delete any statistics about the analyzed object that are currently stored in the data dictionary. Use this statement when you no longer want Oracle Database to use the statistics.

When you use this clause on a table, the database also automatically removes statistics for all the indexes defined on the table. When you use this clause on a cluster, the database also automatically removes statistics for all the cluster tables and all their indexes, including the cluster index.

Specify SYSTEM if you want Oracle Database to delete only system (not user-defined) statistics. If you omit SYSTEM, and if user-defined column or index statistics were collected for an object, then the database also removes the user-defined statistics by invoking the statistics deletion function specified in the statistics type that was used to collect the statistics.

See Also:  "Deleting Statistics: Example" on page 13-26
Examples

**Deleting Statistics: Example**  The following statement deletes statistics about the sample table `oe.orders` and all its indexes from the data dictionary:

```
ANALYZE TABLE orders DELETE STATISTICS;
```

**Analyzing an Index: Example**  The following statement validates the structure of the sample index `oe.inv_product_ix`:

```
ANALYZE INDEX inv_product_ix VALIDATE STRUCTURE;
```

**Validating a Table: Example**  The following statement analyzes the sample table `hr.employees` and all of its indexes:

```
ANALYZE TABLE employees VALIDATE STRUCTURE CASCADE;
```

For a table, the `VALIDATE REF UPDATE` clause verifies the `REF` values in the specified table, checks the rowid portion of each `REF`, and then compares it with the true rowid. If the result is an incorrect rowid, then the `REF` is updated so that the rowid portion is correct.

The following statement validates the `REF` values in the sample table `oe.customers`:

```
ANALYZE TABLE customers VALIDATE REF UPDATE;
```

The following statement validates the structure of the sample table `oe.customers` while allowing simultaneous DML:

```
ANALYZE TABLE customers VALIDATE STRUCTURE ONLINE;
```

**Analyzing a Cluster: Example**  The following statement analyzes the `personnel` cluster (created in "Creating a Cluster: Example" on page 14-17), all of its tables, and all of their indexes, including the cluster index:

```
ANALYZE CLUSTER personnel
    VALIDATE STRUCTURE CASCADE;
```

**Listing Chained Rows: Example**  The following statement collects information about all the chained rows in the table `orders`:

```
ANALYZE TABLE orders
    LIST CHAINED ROWS INTO chained_rows;
```

The preceding statement places the information into the table `chained_rows`. You can then examine the rows with this query (no rows will be returned if the table contains no chained rows):

```
SELECT owner_name, table_name, head_rowid, analyze_timestamp
 FROM chained_rows
 ORDER BY owner_name, table_name, head_rowid, analyze_timestamp;
```

<table>
<thead>
<tr>
<th>OWNER_NAME</th>
<th>TABLE_NAME</th>
<th>HEAD_ROWID</th>
<th>ANALYZE_TIMESTAMP</th>
</tr>
</thead>
<tbody>
<tr>
<td>OE</td>
<td>ORDERS</td>
<td>AAAAZzAABAAABrXAAA</td>
<td>25-SEP-2000</td>
</tr>
</tbody>
</table>
ASSOCIATE STATISTICS

Purpose

Use the ASSOCIATE STATISTICS statement to associate a statistics type (or default statistics) containing functions relevant to statistics collection, selectivity, or cost with one or more columns, standalone functions, packages, types, domain indexes, or indextypes.

For a listing of all current statistics type associations, query the USER_ASSOCIATIONS data dictionary view. If you analyze the object with which you are associating statistics, then you can also query the associations in the USER_USTATS view.

See Also: ANALYZE on page 13-19 for information on the order of precedence with which ANALYZE uses associations

Prerequisites

To issue this statement, you must have the appropriate privileges to alter the base object (table, function, package, type, domain index, or indextype). In addition, unless you are associating only default statistics, you must have execute privilege on the statistics type. The statistics type must already have been defined.

See Also: CREATE TYPE on page 17-3 for information on defining types

Syntax

associate_statistics::=

COLUMNs::=
function_association ::= 

FUNCTIONS schema function

PACKAGES schema package

TYPES schema type

INDEXES schema index

INDEXTYPES schema indextype

using_statistics_type ::= 

USING schema statistics_type NULL

default_cost_clause ::= 

DEFAULT COST cpu_cost io_cost network_cost

default_selectivity_clause ::= 

DEFAULT SELECTIVITY default_selectivity

storage_table_clause ::= 

WITH SYSTEM USER MANAGED STORAGE TABLES

Semantics

column_association
Specify one or more table columns. If you do not specify schema, then Oracle Database assumes the table is in your own schema.

function_association
Specify one or more standalone functions, packages, user-defined data types, domain indexes, or indextypes. If you do not specify schema, then Oracle Database assumes the object is in your own schema.
- **FUNCTIONS** refers only to standalone functions, not to method types or to built-in functions.

- **TYPES** refers only to user-defined types, not to built-in SQL data types.

**Restriction on function_association** You cannot specify an object for which you have already defined an association. You must first disassociate the statistics from this object.

**using_statistics_type**
Specify the statistics type (or a synonym for the type) being associated with column, function, package, type, domain index, or indextype. The **statistics_type** must already have been created.

The **NULL** keyword is valid only when you are associating statistics with a column or an index. When you associate a statistics type with an object type, columns of that object type inherit the statistics type. Likewise, when you associate a statistics type with an indextype, index instances of the indextype inherit the statistics type. You can override this inheritance by associating a different statistics type for the column or index. Alternatively, if you do not want to associate any statistics type for the column or index, then you can specify **NULL** in the **using_statistics_type** clause.

**Restriction on Specifying Statistics Type** You cannot specify **NULL** for functions, packages, types, or indextypes.

**See Also:** *Oracle Database Data Cartridge Developer’s Guide* for information on creating statistics collection functions

**default_cost_clause**
Specify default costs for standalone functions, packages, types, domain indexes, or indextypes. If you specify this clause, then you must include one number each for CPU cost, I/O cost, and network cost, in that order. Each cost is for a single execution of the function or method or for a single domain index access. Accepted values are integers of zero or greater.

**default_selectivity_clause**
Specify as a percent the default selectivity for predicates with standalone functions, types, packages, or user-defined operators. The **default_selectivity_clause** must be a number between 0 and 100. Values outside this range are ignored.

**Restriction on the default_selectivity_clause** You cannot specify **DEFAULT SELECTIVITY** for domain indexes or indextypes.

**See Also:** "Specifying Default Cost: Example" on page 13-30

**storage_table_clause**
This clause is relevant only for statistics on **INDEXTYPE**.

- Specify **WITH SYSTEM MANAGED STORAGE TABLES** to indicate that the storage of statistics data is to be managed by the system. The type you specify in **statistics_type** should be storing the statistics related information in tables that are maintained by the system. Also, the indextype you specify must already have been created or altered to support the **WITH SYSTEM MANAGED STORAGE TABLES** clause.
Specify WITH USER MANAGED STORAGE TABLES to indicate that the tables that store the user-defined statistics will be managed by the user. This is the default behavior.

Examples

**Associating Statistics: Example** This statement creates an association for the standalone package emp_mgmt. See Oracle Database PL/SQL Language Reference for the example that creates this package.

```
ASSOCIATE STATISTICS WITH PACKAGES emp_mgmt DEFAULT SELECTIVITY 10;
```

**Specifying Default Cost: Example** This statement specifies that using the domain index salary_index, created in "Using Extensible Indexing" on page F-1, to implement a given predicate always has a CPU cost of 100, I/O cost of 5, and network cost of 0.

```
ASSOCIATE STATISTICS WITH INDEXES salary_index DEFAULT COST (100,5,0);
```

The optimizer will use these default costs instead of calling a cost function.
AUDIT (Traditional Auditing)

This section describes the AUDIT statement for traditional auditing, which is the same auditing functionality used in releases earlier than Oracle Database 12c.

Beginning with Oracle Database 12c, Oracle introduces unified auditing, which provides a full set of enhanced auditing features. For backward compatibility, traditional auditing is still supported. However, Oracle recommends that you plan the migration of your existing audit settings to the new unified audit policy syntax. For new audit requirements, Oracle recommends that you use the new unified auditing. Traditional auditing may be desupported in a future major release.

See Also: AUDIT (Unified Auditing) on page 13-45 for a description of the AUDIT statement for unified auditing

Purpose

Use the AUDIT statement to:

■ Track the issuance of SQL statements in subsequent user sessions. You can track the issuance of a specific SQL statement or of all SQL statements authorized by a particular system privilege. Auditing operations on SQL statements apply only to subsequent sessions, not to current sessions.

■ Track operations on a specific schema object. Auditing operations on schema objects apply to current sessions as well as to subsequent sessions.

See Also:

■ Oracle Database PL/SQL Packages and Types Reference for information on the DBMS_FGA package, which lets you create and administer value-based auditing policies

■ NOAUDIT (Traditional Auditing) on page 18-87

Prerequisites

To audit issuances of a SQL statement, you must have the AUDIT SYSTEM system privilege. However, the AUDIT SYSTEM system privilege is not required when you use the IN SESSION CURRENT clause.

To collect auditing results, you must enable auditing by setting the initialization parameter AUDIT_TRAIL to a value other than the default setting of NONE. You can specify auditing options regardless of whether auditing is enabled. However, Oracle Database does not generate audit records until you enable auditing.

To audit operations on a schema object, the object you choose for auditing must be in your own schema or you must have AUDIT ANY system privilege. In addition, if the object you choose for auditing is a directory object, even if you created it, then you must have AUDIT ANY system privilege.

When you are connected to a multitenant container database (CDB), you must have the privileges described in this section, either granted locally in the current container or granted commonly.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = CURRENT, the current container must be a pluggable database (PDB). To specify CONTAINER = ALL, the current container must be the root.
Note: The AUDIT ANY system privileges allows the grantee to audit any object in any schema except the SYS schema. You can allow such a grantee to audit objects in the SYS schema by setting the 07_DICTONARY_ACCESSIBILITY initialization parameter to TRUE. For security reasons, Oracle recommends that you use this setting only with great caution.

See Also: Oracle Database Reference for information on the AUDIT_TRAIL parameter

Syntax

BY SESSION ACCESS

sql_statement_shortcut

ALL

ALL STATEMENTS

system_privilege

ALL PRIVILEGES

auditing_by_clause ::= 

BY

user
Notes on Using the AUDIT Statement in a CDB

When you issue the `AUDIT` statement in a CDB, the database performs auditing as follows:

- If you issue the `AUDIT` statement when the current container is a PDB, then the database performs auditing in that PDB. If you specify the `auditing_by_clause`, `user` must be a local user in the PDB or a common user. If you specify the `audit_schema_object_clause`, then the object must be a local object in the PDB.

- If you issue the `AUDIT` statement when the current container is the root, then the database performs auditing across the entire CDB, that is, in the root and all PDBs. If you specify the `auditing_by_clause`, then `user` must be a common user. If you omit the `auditing_by_clause`, then all local users in each PDB and all common users are audited. If you specify the `audit_schema_object_clause`, then the object must be a local object in the root or a common object.

`audit_operation_clause`

Use the `audit_operation_clause` to audit specified operations, regardless of the schema objects affected by the operations.

`sql_statementShortcut`

Specify a shortcut to audit the use of specific SQL statements. Table 13–1 on page 13-38 and Table 13–2 on page 13-40 list the shortcuts and the SQL statements they audit.
For each audited operation, Oracle Database produces an audit record containing this information:

- The user performing the operation
- The type of operation
- The object involved in the operation
- The date and time of the operation

Oracle Database writes audit records to the audit trail, which is a database table containing audit records. You can review database activity by examining the audit trail through data dictionary views.

See Also:

- *Oracle Database Security Guide 11g Release 2 (11.2)* for a listing of the audit trail data dictionary views. Refer to *Oracle Database Upgrade Guide* for instructions on how to locate the Oracle Database 11g Release 2 (11.2) documentation.
- *Oracle Database Reference* for detailed descriptions of the data dictionary views
- "Auditing SQL Statements Relating to Roles: Example" on page 13-42

**system privilege**

Specify a system privilege to audit SQL statements and other operations that are authorized by the specified system privilege.

Note: Auditing the use of a system privilege containing the **any** keyword is more restrictive than auditing the use of the same privilege without the **any** keyword. For example:

- **AUDIT CREATE PROCEDURE** audits the statements issued using either the **CREATE PROCEDURE** or **CREATE ANY PROCEDURE** privilege.
- **AUDIT CREATE ANY PROCEDURE** audits only those statements issued using the **CREATE ANY PROCEDURE** privilege.
Rather than specifying many individual system privileges, you can specify the roles CONNECT, RESOURCE, and DBA. Doing so is equivalent to auditing all of the system privileges granted to those roles.

Oracle Database also provides three shortcuts for specifying groups of system privileges and statement options at once:

**ALL** Specify ALL to audit all statements options shown in Table 13–1 but not the additional statement options shown in Table 13–2.

**ALL STATEMENTS** Specify ALL STATEMENTS to audit all top-level SQL statements executed. Top-level SQL statements are issued directly by a user. SQL statements run from within a PL/SQL procedure or function are not considered top-level statements. Therefore, this clause does not audit the statements executed within PL/SQL procedures or functions. However, the execution of the PL/SQL procedure or function itself is audited. This clause is useful if you want to audit all the statements in a specific environment, regardless of other auditing configurations that are system wide or user specific.

**ALL PRIVILEGES** Specify ALL PRIVILEGES to audit system privileges.

---

**Note:** Oracle recommends that you specify individual system privileges and statement options for auditing rather than roles or shortcuts. The specific system privileges and statement options encompassed by roles and shortcuts change from one release to the next and may not be supported in future versions of Oracle Database.

---

**See Also:**
- Table 18–1, "System Privileges (Organized by the Database Object Operated Upon)” on page 18-44 for a list of all system privileges and the operations that they authorize
- Oracle Database Security Guide for more information on the CONNECT, RESOURCE, and DBA roles

**auditing_by_clause**
Specify the auditing_by_clause to restrict auditing to only SQL statements issued by the specified users. If you omit this clause, then Oracle Database audits all users’ statements.

**IN SESSION CURRENT**
Use this clause to limit auditing to the current session. Auditing will persist until the end of the session and cannot be stopped using the NOAUDIT statement.

**audit_schema_object_clause**
Use the audit_schema_object_clause to audit operations on specific schema objects.

**Restriction on the audit_schema_object_clause** When connected to a CDB, you can specify the audit_schema_object_clause, but you cannot also specify the CONTAINER
clause. This restriction does not limit functionality because the only allowed values for the CONTAINER clause are the default values. Refer to "CONTAINER Clause" on page 13-38 for more information.

sql_operation
Specify the SQL operation to be audited. Table 13–3 on page 13-41 shows the types of objects that can be audited, and for each object the SQL statements that can be audited. For example, if you choose to audit a table with the ALTER operation, then Oracle Database audits all ALTER TABLE statements issued against the table. If you choose to audit a sequence with the SELECT operation, then the database audits all statements that use any values of the sequence.

ALL
Specify ALL as a shortcut equivalent to specifying all SQL operations applicable for the type of object.

auditing_on_clause
The auditing_on_clause lets you specify the particular schema object to be audited.

See Also: "Auditing Queries on a Table: Example" on page 13-43,
"Auditing Inserts and Updates on a Table: Example" on page 13-44,
and "Auditing Operations on a Sequence: Example" on page 13-44

schema
Specify the schema containing the object chosen for auditing. If you omit schema, then Oracle Database assumes the object is in your own schema.

object
Specify the name of the object to be audited. The object must be a table, view, sequence, stored procedure, stored function, package, materialized view, mining model, or library.

You can also specify a synonym for a table, view, sequence, stored procedure, stored function, package, materialized view, or user-defined type.

ON DIRECTORY
The ON DIRECTORY clause lets you specify the name of a directory chosen for auditing.

ON MINING MODEL
The ON MINING MODEL clause lets you specify the name of a mining model to be audited.

ON SQL TRANSLATION PROFILE
The ON SQL TRANSLATION PROFILE clause lets you specify the name of a SQL translation profile to be audited.

ON DEFAULT
Specify ON DEFAULT to establish the specified object options as default object options for subsequently created objects. After you have established these default auditing options, any subsequently created object is automatically audited with those options. The default auditing options for a view are always the union of the auditing options for the base tables of the view. You can see the current default auditing options by querying the ALL_DEF_AUDIT_OPTS data dictionary view.

When you change the default auditing options, the auditing options for previously created objects remain the same. You can change the auditing options for an existing object only by specifying the object in the ON clause of the AUDIT statement.

See Also: "Setting Default Auditing Options: Example" on page 13-44
NETWORK
Use this clause to detect internal failures in the network layer.

**See Also:** *Oracle Database Security Guide 11g Release 2 (11.2)* for information on network auditing. Refer to *Oracle Database Upgrade Guide* for instructions on how to locate the Oracle Database 11g Release 2 (11.2) documentation.

DIRECT_PATH LOAD
Use this clause to audit SQL*Loader direct path loads.

BY SESSION
In earlier releases, *BY SESSION* caused the database to write a single record for all SQL statements or operations of the same type executed on the same schema objects in the same session. Beginning with this release of Oracle Database, both *BY SESSION* and *BY ACCESS* cause Oracle Database to write one audit record for each audited statement and operation. *BY SESSION* continues to populate different values to the audit trail compared with *BY ACCESS*. Oracle recommends that you include the *BY ACCESS* clause for all *AUDIT* statements, which results in a more detailed audit record. If you specify neither clause, then *BY ACCESS* is the default.

**Note:** This change applies only to schema object audit options, statement options and system privileges that audit SQL statements other than data definition language (DDL) statements. The database has always audited *BY ACCESS* all SQL statements and system privileges that audit a DDL statement.

BY ACCESS
Specify *BY ACCESS* if you want Oracle Database to write one record for each audited statement and operation.

**Note:** If you specify either a SQL statement shortcut or a system privilege that audits a data definition language (DDL) statement, then the database always audits by access. In all other cases, the database honors the *BY SESSION* or *BY ACCESS* specification.

For statement options and system privileges that audit SQL statements other than DDL, you can specify either *BY SESSION* or *BY ACCESS*. *BY ACCESS* is the default.

WHENEVER [NOT] SUCCESSFUL
Specify *WHENEVER SUCCESSFUL* to audit only SQL statements and operations that succeed.

Specify *WHENEVER NOT SUCCESSFUL* to audit only SQL statements and operations that fail or result in errors.

If you omit this clause, then Oracle Database performs the audit regardless of success or failure.
CONTAINER Clause
The CONTAINER clause applies only when you are connected to a CDB. You can use this clause to specify the scope of the AUDIT statement. However, it is not necessary to specify the CONTAINER clause because its default values are the only allowed values.

- If you issue the AUDIT statement when the current container is a PDB, then you can optionally specify CONTAINER = CURRENT, which is the default.
- If you issue the AUDIT statement when the current container is the root, then you can optionally specify CONTAINER = ALL, which is the default.

</tr>
</tbody>
</table>

Notes:

- AUDIT USER audits these three SQL statements. Use AUDIT ALTER USER to audit statements that require the ALTER USER system privilege.
- An AUDIT ALTER USER statement does not audit a user changing his or her own password, as this activity does not require the ALTER USER system privilege.

| VIEW                   | CREATE VIEW                           |
|                       | DROP VIEW                             |

Note: Java schema objects (sources, classes, and resources) are considered the same as procedures for purposes of auditing SQL statements.

Table 13–3  Schema Object Auditing Options

<table>
<thead>
<tr>
<th>Object</th>
<th>SQL Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>ALTER AUDIT COMMENT DELETE FLASHBACK (Note 1) GRANT INDEX INSERT LOCK RENAME SELECT UPDATE</td>
</tr>
<tr>
<td>View</td>
<td>AUDIT COMMENT DELETE FLASHBACK (Note 1) GRANT INSERT LOCK RENAME SELECT UPDATE</td>
</tr>
<tr>
<td>Sequence</td>
<td>ALTER AUDIT GRANT</td>
</tr>
<tr>
<td>Procedure, Function, Package (Note 2)</td>
<td>AUDIT EXECUTE (Notes 3 and 4) GRANT</td>
</tr>
</tbody>
</table>
Note 1: The FLASHBACK audit object option applies only to flashback queries.

Note 2: Java schema objects (sources, classes, and resources) are considered the same as procedures, functions, and packages for purposes of auditing options.

Note 3: When you audit the EXECUTE operation on a PL/SQL stored procedure or stored function, the database considers only its ability to find the procedure or function and authorize its execution when determining the success or failure of the operation for the purposes of auditing. Therefore, if you specify the WHENEVER NOT SUCCESSFUL clause, then only invalid object errors, non-existent object errors, and authorization failures are audited; errors encountered during the execution of the procedure or function are not audited. If you specify the WHENEVER SUCCESSFUL clause, then all executions that are not blocked by invalid object errors, non-existent object errors, or authorization failures are audited, regardless of whether errors are encountered during execution.

Note 4: To audit the failure of a recursive SQL operation inside a PL/SQL stored procedure or stored function, configure auditing for the SQL operation.

Note 5: You can audit INSERT, UPDATE, and DELETE operations only on updatable materialized views.

Examples

Auditing SQL Statements Relating to Roles: Example To choose auditing for every SQL statement that creates, alters, drops, or sets a role, regardless of whether the statement completes successfully, issue the following statement:

AUDIT ROLE;

To choose auditing for every statement that successfully creates, alters, drops, or sets a role, issue the following statement:
AUDIT ROLE
WHENEVER SUCCESSFUL;

To choose auditing for every CREATE ROLE, ALTER ROLE, DROP ROLE, or SET ROLE statement that results in an Oracle Database error, issue the following statement:

AUDIT ROLE
WHENEVER NOT SUCCESSFUL;

Auditing Query and Update SQL Statements: Example To choose auditing for any statement that queries or updates any table, issue the following statement:

AUDIT SELECT TABLE, UPDATE TABLE;

To choose auditing for statements issued by the users hr and oe that query or update a table or view, issue the following statement

AUDIT SELECT TABLE, UPDATE TABLE
   BY hr, oe;

Auditing Deletions: Example To choose auditing for statements issued using the DELETE ANY TABLE system privilege, issue the following statement:

AUDIT DELETE ANY TABLE;

Auditing Statements Relating to Directories: Examples To choose auditing for statements issued using the CREATE ANY DIRECTORY system privilege, issue the following statement:

AUDIT CREATE ANY DIRECTORY;

To choose auditing for CREATE DIRECTORY (and DROP DIRECTORY) statements that do not use the CREATE ANY DIRECTORY system privilege, issue the following statement:

AUDIT DIRECTORY;

To choose auditing for every statement that reads files from the bfile_dir directory, issue the following statement:

AUDIT READ ON DIRECTORY bfile_dir;

Auditing Queries on a Table: Example To choose auditing for every SQL statement that queries the employees table in the schema hr, issue the following statement:

AUDIT SELECT
   ON hr.employees;

To choose auditing for every statement that successfully queries the employees table in the schema hr, issue the following statement:

AUDIT SELECT
   ON hr.employees
   WHENEVER SUCCESSFUL;

To choose auditing for every statement that queries the employees table in the schema hr and results in an Oracle Database error, issue the following statement:

AUDIT SELECT
   ON hr.employees
   WHENEVER NOT SUCCESSFUL;
**Auditing Inserts and Updates on a Table: Example** To choose auditing for every statement that inserts or updates a row in the `customers` table in the schema `oe`, issue the following statement:

```
AUDIT INSERT, UPDATE
    ON oe.customers;
```

**Auditing Operations on a Sequence: Example** To choose auditing for every statement that performs any operation on the `employees_seq` sequence in the schema `hr`, issue the following statement:

```
AUDIT ALL
    ON hr.employees_seq;
```

The preceding statement uses the `ALL` shortcut to choose auditing for the following statements that operate on the sequence:

- `ALTER SEQUENCE`
- `AUDIT`
- `GRANT`
- any statement that accesses the values of the sequence using the pseudocolumns `CURRVAL` or `NEXTVAL`

**Setting Default Auditing Options: Example** The following statement specifies default auditing options for objects created in the future:

```
AUDIT ALTER, GRANT, INSERT, UPDATE, DELETE
    ON DEFAULT;
```

Any objects created later are automatically configured for audit with the specified options that apply to them.

- If you create a table, then Oracle Database automatically configures audit options `ALTER`, `GRANT`, `INSERT`, `UPDATE`, or `DELETE` issued against the table.
- If you create a view, then Oracle Database automatically configures audit options `GRANT`, `INSERT`, `UPDATE`, or `DELETE` against the view.
- If you create a sequence, then Oracle Database automatically configures audit options `ALTER` or `GRANT` against the sequence.
- If you create a procedure, package, or function, then Oracle Database automatically configures audit options `ALTER` or `GRANT` against it.
AUDIT (Unified Auditing)

This section describes the AUDIT statement for unified auditing. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to Oracle Database Security Guide for more information on unified auditing.

Purpose

Use the AUDIT statement to:

- Enable a unified audit policy for all users or for specified users
- Specify whether an audit record is created if the audited event fails, succeeds, or both
- Specify application context attributes, whose values will be recorded in audit records

Operations performed with this statement take effect in subsequent user sessions, not in the current session.

See Also:

- NOAUDIT (Unified Auditing) on page 18-92
- CREATE AUDIT POLICY (Unified Auditing) on page 14-2
- ALTER AUDIT POLICY (Unified Auditing) on page 10-24
- DROP AUDIT POLICY (Unified Auditing) on page 17-38

Prerequisites

You must have the AUDIT SYSTEM system privilege or the AUDIT_ADMIN role.

If you are connected to a multitenant container database (CDB), then to enable a common unified audit policy, the current container must be the root and you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role. To enable a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT_ADMIN local role in the container.

To specify the AUDIT CONTEXT ... statement when connected to a CDB, you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT_ADMIN local role in the current session’s container.
Syntax

unified_audit ::= 

Semantics

policy
Specify the name of the unified audit policy to be enabled. The policy must have been created using the CREATE AUDIT POLICY statement.

You can find descriptions of all unified audit policies by querying the AUDIT_UNIFIED_POLICIES view and descriptions of all enabled unified audit policies by querying the AUDIT_UNIFIED_ENABLED_POLICIES view.

When you enable a unified audit policy, all SQL statements and operations that satisfy either a system privilege or action or role audit option specified in the enabled policy will be audited—that is, a unified audit record will be created in the UNIFIED_AUDIT_TRAIL view. If a single SQL statement or operation satisfies multiple enabled policies, then only one unified audit record will be created and all satisfied audit policy names will appear in a comma-separated list in the UNIFIED_AUDIT_POLICIES column of the UNIFIED_AUDIT_TRAIL view.

See Also:

- CREATE AUDIT POLICY (Unified Auditing) on page 14-2
- Oracle Database Reference for more information on the AUDIT_UNIFIED_POLICIES, AUDIT_UNIFIED_ENABLED_POLICIES, and UNIFIED_AUDIT_TRAIL views

BY | EXCEPT
Specify the BY clause to enable policy for only the specified users.

Specify the EXCEPT clause to enable policy for all users except the specified users.

If you omit the BY and EXCEPT clauses, then Oracle Database enables policy for all users.

If policy is a common unified audit policy, then user must be a common user. If policy is a local unified audit policy, then user must be a common user or a local user in the container to which you are connected.

Notes on the BY and EXCEPT Clauses
The following notes apply to the BY and EXCEPT clauses:

- If multiple AUDIT ... BY ... statements are specified for the same unified audit policy, then the policy is enabled for the union of the users specified in each statement.
If multiple `AUDIT ... EXCEPT ...` statements are specified for the same unified audit policy, then only the most recently specified statement takes effect. That is, the policy is enabled for all users except the users specified in the most recent `AUDIT ... EXCEPT ...` statement.

If a policy is enabled using the `BY` clause and you would like to instead enable it using the `EXCEPT` clause, then you must first use the `NOAUDIT ... BY ...` statement to disable the policy for all users for whom the policy is currently enabled, and then enable the policy with the `AUDIT ... EXCEPT ...` statement.

If a policy is enabled using the `EXCEPT` clause and you would like to instead enable it using the `BY` clause, then you must first use the `NOAUDIT` statement to disable the audit policy. Note that you cannot specify the `EXCEPT` clause with the `NOAUDIT` statement. You can then enable the policy with the `AUDIT ... BY ...` statement.

**Restriction on the BY and EXCEPT Clauses** You cannot specify an `AUDIT ... BY ...` statement and an `AUDIT ... EXCEPT ...` statement for the same unified audit policy. If you attempt to do so, then an error occurs.

**WHENEVER [NOT] SUCCESSFUL**
Specify `WHENEVER SUCCESSFUL` to audit only SQL statements and operations that succeed.

Specify `WHENEVER NOT SUCCESSFUL` to audit only SQL statements and operations that fail or result in errors.

If you omit this clause, then Oracle Database performs the audit regardless of success or failure.

**CONTEXT Clause**
Specify the `CONTEXT` clause to include the values of context attributes in audit records.

- For `namespace`, specify the context namespace.
- For `attribute`, specify one or more context attributes whose values you want to include in audit records.
- Use the optional `BY user` clause to include the values of the context attributes only in audit records for events executed by the specified users. If you omit the `BY` clause, then the values of the context attributes are included in all audit records.

If you specify the `CONTEXT` clause when the current container is the root of a CDB, then the values of context attributes will be included in audit records only for events executed in the root. If you specify the optional `BY` clause, then `user` must be a common user.

If you specify the `CONTEXT` clause when the current container is a pluggable database (PDB), then the values of context attributes will be included in audit records only for events executed in that PDB. If you specify the optional `BY` clause, then `user` must be a common user or a local user in that PDB.

You can find the application context attributes that are configured to be captured in the audit trail by querying the `AUDIT_UNIFIED_CONTEXTS` view.

**See Also:** *Oracle Database Reference* for more information on the `AUDIT_UNIFIED_CONTEXTS` view.
Examples

The following examples enable unified audit policies that were created in the CREATE AUDIT POLICY "Examples" on page 14-8.

**Enabling a Unified Audit Policy for All Users: Example**  The following statement enables unified audit policy `table_pol` for all users:

```sql
AUDIT POLICY table_pol;
```

The following statement verifies that `table_pol` is enabled for all users:

```sql
SELECT policy_name, enabled_opt, user_name
FROM audit_unified_enabled_policies
WHERE policy_name = 'TABLE_POL';
```

<table>
<thead>
<tr>
<th>POLICY_NAME</th>
<th>ENABLED_OPT</th>
<th>USER_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_POL</td>
<td>BY</td>
<td>ALL USERS</td>
</tr>
</tbody>
</table>

**Enabling a Unified Audit Policy for Specific Users: Examples**  The following statement enables unified audit policy `dml_pol` for only users `hr` and `sh`:

```sql
AUDIT POLICY dml_pol BY hr, sh;
```

The following statement verifies that `dml_pol` is enabled for only users `hr` and `sh`:

```sql
SELECT policy_name, enabled_opt, user_name
FROM audit_unified_enabled_policies
WHERE policy_name = 'DML_POL'
ORDER BY user_name;
```

<table>
<thead>
<tr>
<th>POLICY_NAME</th>
<th>ENABLED_OPT</th>
<th>USER_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>DML_POL</td>
<td>BY</td>
<td>HR</td>
</tr>
<tr>
<td>DML_POL</td>
<td>BY</td>
<td>SH</td>
</tr>
</tbody>
</table>

The following statement enables unified audit policy `read_dir_pol` for all users except `hr`:

```sql
AUDIT POLICY read_dir_pol EXCEPT hr;
```

The following statement verifies that `read_dir_pol` is enabled for all users except `hr`:

```sql
SELECT policy_name, enabled_opt, user_name
FROM audit_unified_enabled_policies
WHERE policy_name = 'READ_DIR_POL';
```

<table>
<thead>
<tr>
<th>POLICY_NAME</th>
<th>ENABLED_OPT</th>
<th>USER_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>READ_DIR_POL</td>
<td>EXCEPT</td>
<td>HR</td>
</tr>
</tbody>
</table>

The following statement enables unified audit policy `security_pol` for user `hr` and audits only the SQL statements and operations that fail:

```sql
AUDIT POLICY security_pol BY hr WHENEVER NOT SUCCESSFUL;
```

The following statement verifies that `security_pol` is enabled for only user `hr` and that only the SQL statements and operations that fail will be audited:

```sql
SELECT policy_name, enabled_opt, user_name, success, failure
FROM audit_unified_enabled_policies
WHERE policy_name = 'SECURITY_POL';
```
Including Values of Context Attributes in Audit Records: Example  

The following statement instructs the database to include the values of namespace `USERENV` attributes `CURRENT_USER` and `DB_NAME` in all audit records for user hr:

```
AUDIT CONTEXT NAMESPACE userenv
    ATTRIBUTES current_user, db_name
    BY hr;
```
CALL

Purpose

Use the CALL statement to execute a routine (a standalone procedure or function, or a procedure or function defined within a type or package) from within SQL.

Note: The restrictions on user-defined function expressions specified in "Function Expressions" on page 5-10 apply to the CALL statement as well.

See Also: Oracle Database PL/SQL Language Reference for information on creating such routine

Prerequisites

You must have EXECUTE privilege on the standalone routine or on the type or package in which the routine is defined.

Syntax

call ::= 

CALL object_access_expression 

INTO host_variable INDICATOR indicator_variable;

routine_clause ::= 

schema.type.package.function procedure method 

@dblink_name (argument)
**object_access_expression::=**

### Semantics
You can execute a routine in two ways. You can issue a call to the routine itself by name, by using the *routine_clause*, or you can invoke a routine inside the type of an expression, by using an *object_access_expression*.

#### schema
Specify the schema in which the standalone routine, or the package or type containing the routine, resides. If you do not specify *schema*, then Oracle Database assumes the routine is in your own schema.

#### type or package
Specify the type or package in which the routine is defined.

#### routine_clause
Specify the name of the function or procedure being called, or a synonym that resolves to a function or procedure.

When you call a member function or procedure of a type, if the first argument (*SELF*) is a null *IN OUT* argument, then Oracle Database returns an error. If *SELF* is a null *IN* argument, then the database returns null. In both cases, the function or procedure is not invoked.

#### Restriction on Functions
If the routine is a function, then the *INTO* clause is required.

#### @dblink
In a distributed database system, specify the name of the database containing the standalone routine, or the package or function containing the routine. If you omit *dblink*, then Oracle Database looks in your local database.

**See Also:** "Calling a Procedure: Example" on page 13-52 for an example of calling a routine directly

### object_access_expression
If you have an expression of an object type, such as a type constructor or a bind variable, then you can use this form of expression to call a routine defined within the type. In this context, the *object_access_expression* is limited to method invocations.

**See Also:** "Object Access Expressions" on page 5-15 for syntax and semantics of this form of expression, and "Calling a Procedure Using an Expression of an Object Type: Example" on page 13-52 for an example of calling a routine using an expression of an object type.
**argument**

Specify one or more arguments to the routine, if the routine takes arguments. You can use positional, named, or mixed notation for `argument`. For example, all of the following notations are correct:

```
CALL my_procedure(arg1 => 3, arg2 => 4)
CALL my_procedure(3, 4)
CALL my_procedure(3, arg2 => 4)
```

**Restrictions on Applying Arguments to Routines**

The `argument` is subject to the following restrictions:

- The data types of the parameters passed by the `CALL` statement must be SQL data types. They cannot be PL/SQL-only data types such as `BOOLEAN`.
- An `argument` cannot be a pseudocolumn or either of the object reference functions `VALUE` or `REF`.
- Any `argument` that is an IN OUT or OUT argument of the routine must correspond to a host variable expression.
- The number of arguments, including any return argument, is limited to 1000.
- You cannot bind arguments of character and raw data types (`CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, `RAW`, `LONG RAW`) that are larger than 4K.

**INTO :host_variable**

The `INTO` clause applies only to calls to functions. Specify which host variable will store the return value of the function.

**:indicator_variable**

Specify the value or condition of the host variable.

See Also: `Pro*C/C++ Programmer’s Guide` for more information on host variables and indicator variables

**Examples**

**Calling a Procedure: Example**

The following statement removes the Entertainment department (created in "Inserting Sequence Values: Example" on page 18-75) using uses the `remove_dept` procedure. See `Oracle Database PL/SQL Language Reference` for the example that creates this procedure.

```
CALL emp_mgmt.remove_dept(162);
```

**Calling a Procedure Using an Expression of an Object Type: Example**

The following examples show how call a procedure by using an expression of an object type in the `CALL` statement. The example uses the `warehouse_typ` object type in the order entry sample schema `OE`:

```
ALTER TYPE warehouse_typ
ADD MEMBER FUNCTION ret_name
RETURN VARCHAR2
CASCADE;

CREATE OR REPLACE TYPE BODY warehouse_typ
AS MEMBER FUNCTION ret_name
```
CALL
RETURN VARCHAR2
IS
BEGIN
    RETURN self.warehouse_name;
END;
END;
/
VARIABLE x VARCHAR2(25);

CALL warehouse_typ(456, 'Warehouse 456', 2236).ret_name()
    INTO :x;

PRINT x;
X
-----------------------------
Warehouse 456

The next example shows how to use an external function to achieve the same thing:

CREATE OR REPLACE FUNCTION ret_warehouse_typ(x warehouse_typ)
    RETURN warehouse_typ
IS
    BEGIN
        RETURN x;
    END;
/

CALL ret_warehouse_typ(warehouse_typ(234, 'Warehouse 234',
    2235)).ret_name()
    INTO :x;

PRINT x;
X
-----------------------------
Warehouse 234
COMMENT

Purpose

Use the comment statement to add to the data dictionary a comment about a table or table column, unified audit policy, edition, indextype, materialized view, mining model, operator, or view.

To drop a comment from the database, set it to the empty string ' '.

See Also:

- "Comments" on page 2-76 for more information on associating comments with SQL statements and schema objects
- Oracle Database Reference for information on the data dictionary views that display comments

Prerequisites

The object about which you are adding a comment must be in your own schema or:

- To add a comment to a table, view, or materialized view, you must have COMMENT ANY TABLE system privilege.
- To add a comment to a unified audit policy, you must have the AUDIT SYSTEM system privilege or the AUDIT_ADMIN role.
- To add a comment to an edition, you must have the CREATE ANY EDITION system privilege, granted either directly or through a role.
- To add a comment to an indextype, you must have the CREATE ANY INDEXTYPE system privilege.
- To add a comment to a mining model, you must have the COMMENT ANY MINING MODEL system privilege.
- To add a comment to an operator, you must have the CREATE ANY OPERATOR system privilege.
Syntax

`comment ::=`

```
\[
\text{AUDIT POLICY} \quad \text{policy} \\
\text{COLUMN} \quad \text{schema} \quad \text{table} \\
\text{COLUMN} \quad \text{view} \\
\text{COLUMN} \quad \text{column} \\
\text{EDITION} \quad \text{edition_name} \\
\text{INDEXTYPE} \quad \text{schema} \quad \text{indextype} \\
\text{MATERIALIZED VIEW} \quad \text{materialized_view} \\
\text{MINING MODEL} \quad \text{schema} \quad \text{model} \\
\text{OPERATOR} \quad \text{schema} \quad \text{operator} \\
\text{TABLE} \quad \text{schema} \quad \text{table} \\
\text{TABLE} \quad \text{view} \\
\text{IS} \quad \text{string} \\
\]
```

Semantics

**AUDIT POLICY Clause**

Specify the name of the unified audit policy to be commented.

You can view the comments on a particular unified audit policy by querying the `AUDIT_UNIFIED_POLICY_COMMENTS` data dictionary view.

**COLUMN Clause**

Specify the name of the column of a table, view, or materialized view to be commented. If you omit `schema`, then Oracle Database assumes the table, view, or materialized view is in your own schema.

You can view the comments on a particular table or column by querying the data dictionary views `USER_TAB_COMMENTS`, `DBA_TAB_COMMENTS`, or `ALL_TAB_COMMENTS` or `USER_COL_COMMENTS`, `DBA_COL_COMMENTS`, or `ALL_COL_COMMENTS`.

**EDITION Clause**

Specify the name of an existing edition to be commented.

You can query the data dictionary view `ALL_EDITION_COMMENTS` to view comments associated with editions that are accessible to the current user. You can query `DBA_EDITION_COMMENTS` to view comments associated with all editions in the database.

**TABLE Clause**

Specify the schema and name of the table or materialized view to be commented. If you omit `schema`, then Oracle Database assumes the table or materialized view is in your own schema.
INDEXTYPE Clause
Specify the name of the indextype to be commented. If you omit schema, then Oracle Database assumes the indextype is in your own schema.

You can view the comments on a particular indextype by querying the data dictionary views USER_INDEXTYPE_COMMENTS, DBA_INDEXTYPE_COMMENTS, or ALL_INDEXTYPE_COMMENTS.

MATERIALIZED VIEW Clause
Specify the name of the materialized view to be commented. If you omit schema, then Oracle Database assumes the materialized view is in your own schema.

You can view the comments on a particular materialized view by querying the data dictionary views USER_MVIEW_COMMENTS, DBA_MVIEW_COMMENTS, or ALL_MVIEW_COMMENTS.

MINING MODEL
Specify the name of the mining model to be commented.

You can view the comments on a particular mining model by querying the COMMENTS column of the data dictionary views USER_MINING_MODELS, DBA_MINING_MODELS, or ALL_MINING_MODELS.

OPERATOR Clause
Specify the name of the operator to be commented. If you omit schema, then Oracle Database assumes the operator is in your own schema.

You can view the comments on a particular operator by querying the data dictionary views USER_OPERATOR_COMMENTS, DBA_OPERATOR_COMMENTS, or ALL_OPERATOR_COMMENTS.

IS 'string'
Specify the text of the comment. Refer to "Text Literals" on page 2-48 for a syntax description of 'string'.

Examples
Creating Comments: Example To insert an explanatory remark on the job_id column of the employees table, you might issue the following statement:

```
COMMENT ON COLUMN employees.job_id
    IS 'abbreviated job title';
```

To drop this comment from the database, issue the following statement:

```
COMMENT ON COLUMN employees.job_id IS '';
```
COMMIT

Purpose

Use the COMMIT statement to end your current transaction and make permanent all changes performed in the transaction. A transaction is a sequence of SQL statements that Oracle Database treats as a single unit. This statement also erases all savepoints in the transaction and releases transaction locks.

Until you commit a transaction:

- You can see any changes you have made during the transaction by querying the modified tables, but other users cannot see the changes. After you commit the transaction, the changes are visible to other users' statements that execute after the commit.
- You can roll back (undo) any changes made during the transaction with the ROLLBACK statement (see ROLLBACK on page 18-110).

Oracle Database issues an implicit COMMIT under the following circumstances:

- Before any syntactically valid data definition language (DDL) statement, even if the statement results in an error
- After any data definition language (DDL) statement that completes without an error

You can also use this statement to:

- Commit an in-doubt distributed transaction manually
- Terminate a read-only transaction begun by a SET TRANSACTION statement

Oracle recommends that you explicitly end every transaction in your application programs with a COMMIT or ROLLBACK statement, including the last transaction, before disconnecting from Oracle Database. If you do not explicitly commit the transaction and the program terminates abnormally, then the last uncommitted transaction is automatically rolled back.

A normal exit from most Oracle utilities and tools causes the current transaction to be committed. A normal exit from an Oracle precompiler program does not commit the transaction and relies on Oracle Database to roll back the current transaction.

See Also:

- Oracle Database Concepts for more information on transactions
- SET TRANSACTION on page 19-84 for more information on specifying characteristics of a transaction

Prerequisites

You need no privileges to commit your current transaction.

To manually commit a distributed in-doubt transaction that you originally committed, you must have FORCE TRANSACTION system privilege. To manually commit a distributed in-doubt transaction that was originally committed by another user, you must have FORCE ANY TRANSACTION system privilege.
Syntax

commit ::= 

- COMMIT
- WORK
- COMMENT string
- WRITE
- WAIT
- NOWAIT
- IMMEDIATE
- BATCH
- FORCE string, integer

Semantics

COMMIT
All clauses after the COMMIT keyword are optional. If you specify only COMMIT, then the default is COMMIT WORK WRITE WAIT IMMEDIATE.

WORK
The WORK keyword is supported for compliance with standard SQL. The statements COMMIT and COMMIT WORK are equivalent.

COMMENT Clause
This clause is supported for backward compatibility. Oracle recommends that you use named transactions instead of commit comments.

See Also: SET TRANSACTION on page 19-84 and Oracle Database Concepts for more information on named transactions

Specify a comment to be associated with the current transaction. The 'text' is a quoted literal of up to 255 bytes that Oracle Database stores in the data dictionary view DBA_2PC_PEND along with the transaction ID if a distributed transaction becomes in doubt. This comment can help you diagnose the failure of a distributed transaction.

See Also: COMMENT on page 13-54 for more information on adding comments to SQL statements

WRITE Clause
Use this clause to specify the priority with which the redo information generated by the commit operation is written to the redo log. This clause can improve performance by reducing latency, thus eliminating the wait for an I/O to the redo log. Use this clause to improve response time in environments with stringent response time requirements where the following conditions apply:

- The volume of update transactions is large, requiring that the redo log be written to disk frequently.
- The application can tolerate the loss of an asynchronously committed transaction.
- The latency contributed by waiting for the redo log write to occur contributes significantly to overall response time.

You can specify the **WAIT | NOWAIT** and **IMMEDIATE | BATCH** clauses in any order.

---

**Note:** If you omit this clause, then the behavior of the commit operation is controlled by the `COMMIT_LOGGING` and `COMMIT_WAIT` initialization parameters, if they have been set.

---

**WAIT | NOWAIT** Use these clauses to specify when control returns to the user.

- The **WAIT** parameter ensures that the commit will return only after the corresponding redo is persistent in the online redo log. Whether in **BATCH** or **IMMEDIATE** mode, when the client receives a successful return from this `COMMIT` statement, the transaction has been committed to durable media. A crash occurring after a successful write to the log can prevent the success message from returning to the client. In this case the client cannot tell whether or not the transaction committed.

- The **NOWAIT** parameter causes the commit to return to the client whether or not the write to the redo log has completed. This behavior can increase transaction throughput. With the **WAIT** parameter, if the commit message is received, then you can be sure that no data has been lost.

---

**Caution:** With **NOWAIT**, a crash occurring after the commit message is received, but before the redo log record(s) are written, can falsely indicate to a transaction that its changes are persistent.

---

If you omit this clause, then the transaction commits with the **WAIT** behavior.

**IMMEDIATE | BATCH** Use these clauses to specify when the redo is written to the log.

- The **IMMEDIATE** parameter causes the log writer process (LGWR) to write the transaction’s redo information to the log. This operation option forces a disk I/O, so it can reduce transaction throughput.

- The **BATCH** parameter causes the redo to be buffered to the redo log, along with other concurrently executing transactions. When sufficient redo information is collected, a disk write of the redo log is initiated. This behavior is called “group commit”, as redo for multiple transactions is written to the log in a single I/O operation.

If you omit this clause, then the transaction commits with the **IMMEDIATE** behavior.

---

**See Also:** `Oracle Database Concepts` for more information on asynchronous commit

**FORCE Clause**

In a distributed database system, the `FORCE string [, integer]` clause lets you manually commit an in-doubt distributed transaction. The transaction is identified by the ‘string’ containing its local or global transaction ID. To find the IDs of such transactions, query the data dictionary view `DBA_2PC_PENDING`. You can use `integer` to specifically assign the transaction a system change number (SCN). If you omit `integer`, then the transaction is committed using the current SCN.
Examples

Committing an Insert: Example  This statement inserts a row into the hr.regions table and commits this change:

```
INSERT INTO regions VALUES (5, 'Antarctica');
COMMIT WORK;
```

To commit the same insert operation and instruct the database to buffer the change to the redo log, without initiating disk I/O, use the following COMMIT statement:

```
COMMIT WRITE BATCH;
```

Commenting on COMMIT: Example  The following statement commits the current transaction and associates a comment with it:

```
COMMIT
    COMMENT 'In-doubt transaction Code 36, Call (415) 555-2637';
```

If a network or machine failure prevents this distributed transaction from committing properly, then Oracle Database stores the comment in the data dictionary along with the transaction ID. The comment indicates the part of the application in which the failure occurred and provides information for contacting the administrator of the database where the transaction was committed.

Forcing an In-Doubt Transaction: Example  The following statement manually commits a hypothetical in-doubt distributed transaction. Query the V$CORRUPT_XID_LIST data dictionary view to find the transaction IDs of corrupt transactions. You must have DBA privileges to view the V$CORRUPT_XID_LIST and to issue this statement.

```
COMMIT FORCE '22.57.53';
```
SQL Statements: CREATE AUDIT POLICY to CREATE JAVA

This chapter contains the following SQL statements:

- CREATE AUDIT POLICY (Unified Auditing)
- CREATE CLUSTER
- CREATE CONTEXT
- CREATE CONTROLFILE
- CREATE DATABASE
- CREATE DATABASE LINK
- CREATE DIMENSION
- CREATE DIRECTORY
- CREATE DISKGROUP
- CREATE EDITION
- CREATE FLASHBACK ARCHIVE
- CREATE FUNCTION
- CREATE INDEX
- CREATE INDEXTYPE
- CREATE JAVA
CREATE AUDIT POLICY (Unified Auditing)

This section describes the CREATE AUDIT POLICY statement for unified auditing. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to Oracle Database Security Guide for more information on unified auditing.

Purpose

Use the CREATE AUDIT POLICY statement to create a unified audit policy.

See Also:
- ALTER AUDIT POLICY (Unified Auditing) on page 10-24
- DROP AUDIT POLICY (Unified Auditing) on page 17-38
- AUDIT (Unified Auditing) on page 13-45
- NOAUDIT (Unified Auditing) on page 18-92

Prerequisites

You must have the AUDIT SYSTEM system privilege or the AUDIT_ADMIN role.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To create a common unified audit policy, you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role. To create a local unified audit policy, you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT_ADMIN local role in the container to which you are connected.

Syntax

```
create_audit_policy ::= CREATE AUDIT POLICY policy privilege_audit_clause action_audit_clause role_audit_clause WHEN audit_condition EVALUATE PER STATEMENT SESSION INSTANCE CONTAINER = ALL CURRENT;
```

Note: You must specify at least one of the clauses privilege_audit_clause, action_audit_clause, or role_audit_clause.

(privilege_audit_clause ::= on page 14-3, action_audit_clause ::= on page 14-3, role_audit_clause ::= on page 14-3)
privilege_audit_clause ::= 

\[ \text{PRIVILEGES} \rightarrow \text{system\_privilege} \]

action_audit_clause ::= 

\[ \text{standard\_actions} \rightarrow \text{component\_actions} \]

\[ \text{role\_audit\_clause} ::= \]

\[ \text{PRIVILEGES} \rightarrow \text{system\_privilege} \]

Note: You can specify only the standard\_actions clause, only the component\_actions clause, or both clauses in either order, but you can specify each clause at most once.
Semantics

policy
Specify the name of the unified audit policy to be created. The name must satisfy the requirements listed in "Database Object Naming Rules" on page 2-119. You can find the names of all unified audit policies by querying the AUDIT_UNIFIED_POLICIES view.

See Also: Oracle Database Reference for more information on the AUDIT_UNIFIED_POLICIES view

privilege_audit_clause
Use this clause to audit one or more system privileges. SQL statements that require the system privilege(s) in order to succeed are audited. For system_privilege, specify a valid system privilege. To view all valid system privileges, query the NAME column of the SYSTEM_PRIVILEGE_MAP view.

Restriction on Auditing System Privileges You cannot audit the following system privileges: INHERIT ANY PRIVILEGES, SYSASM, SYSBACKUP, SYSDBA, SYSDG, SYSKM, SYSOPER, and TRANSLATE ANY SQL.

action_audit_clause
Use this clause to specify one or more actions to be audited. Use the standard_actions clause to audit actions on standard RDBMS objects and to audit standard RDBMS system actions for the database. Use the component_actions clause to audit actions for components.

standard_actions
Use this clause to audit actions on standard RDBMS objects and to audit standard RDBMS system actions for the database.

object_action ON Use this clause to audit an action on the specified object. For object_action, specify the action to be audited. Table 14–1 lists the actions that can be audited on each type of object.

ALL ON Use this clause to audit all actions on the specified object. All of the actions listed in Table 14–1 for the type of object that you specify in the ON clause will be audited.

ON Clause Use the ON clause to specify the object to be audited. Directories and data mining models are identified separately because they reside in separate namespaces. To audit actions on a directory, specify ON DIRECTORY directory_name. To audit actions on a data mining model, specify ON MINING MODEL object_name. To audit actions on the other types of objects listed in Table 14–1, specify ON object_name. If you do not qualify object_name with schema, then the database assumes the object is in your own schema.

<tr>
<td>View</td>
<td>AUDIT, DELETE, FLASHBACK, GRANT, INSERT, LOCK, RENAME, SELECT, UPDATE</td>
</tr>
</tbody>
</table>

Note 1: When you audit the EXECUTE operation on a PL/SQL stored procedure or stored function, the database considers only its ability to find the procedure or function and authorize its execution when determining the success or failure of the operation for the purposes of auditing. Therefore, if you specify the WHENEVER NOT SUCCESSFUL clause, then only invalid object errors, non-existent object errors, and authorization failures are audited; errors encountered during the execution of the procedure or function are not audited. If you specify the WHENEVER SUCCESSFUL clause, then all executions that are not blocked by invalid object errors, non-existent object errors, or authorization failures are audited, regardless of whether errors are encountered during execution.

Note 2: To audit the failure of a recursive SQL operation inside a PL/SQL stored procedure or stored function, configure auditing for the SQL operation.

**system_action** Use this clause to audit a system action for the database. To view the valid values for system_action, query the NAME column of the AUDITABLE_SYSTEM_ACTIONS view where COMPONENT is 'Standard'.

**ALL** Use this clause to audit all system actions for the database.

**component_actions**

Use this clause to audit actions for the following components: Oracle Data Pump, Oracle SQL*Loader Direct Path Load, Oracle Label Security, Oracle Database Real Application Security, and Oracle Database Vault.

**DATAPUMP** Use this clause to audit actions for Oracle Data Pump. For component_action, specify the action to be audited. To view the valid actions for Oracle Data Pump, query the NAME column of the AUDITABLE_SYSTEM_ACTIONS view where COMPONENT is Datapump. For example:

```
SELECT name FROM auditable_system_actions WHERE component = 'Datapump';
```

Refer to Oracle Database Security Guide for complete information on auditing Oracle Data Pump.

**DIRECT_LOAD** Use this clause to audit actions for Oracle SQL*Loader Direct Path Load. For component_action, specify the action to be audited. To view the valid
actions for Oracle SQL*Loader Direct Path Load, query the NAME column of the AUDITABLE_SYSTEM_ACTIONS view where COMPONENT is Direct path API. For example:

```sql
SELECT name FROM auditable_system_actions WHERE component = 'Direct path API';
```

Refer to Oracle Database Security Guide for complete information on auditing Oracle SQL*Loader Direct Path Load.

**OLS**  Use this clause to audit actions for Oracle Label Security. For component_action, specify the action to be audited. To view the valid actions for Oracle Label Security, query the NAME column of the AUDITABLE_SYSTEM_ACTIONS view where COMPONENT is Label Security. For example:

```sql
SELECT name FROM auditable_system_actions WHERE component = 'Label Security';
```

Refer to Oracle Database Security Guide for complete information on auditing Oracle Label Security.

**XS**  Use this clause to audit actions for Oracle Database Real Application Security. For component_action, specify the action to be audited. To view the valid actions for Oracle Database Real Application Security, query the NAME column of the AUDITABLE_SYSTEM_ACTIONS view where COMPONENT is XS. For example:

```sql
SELECT name FROM auditable_system_actions WHERE component = 'XS';
```

Refer to Oracle Database Security Guide for complete information on auditing Oracle Database Real Application Security.

**DV**  Use this clause to audit actions for Oracle Database Vault. For component_action, specify the action to be audited. To view the valid actions for Oracle Database Vault, query the NAME column of the AUDITABLE_SYSTEM_ACTIONS view where COMPONENT is Database Vault. For example:

```sql
SELECT name FROM auditable_system_actions WHERE component = 'Database Vault';
```

For object_name, specify the name of the Database Vault object to be audited.

Refer to Oracle Database Security Guide for complete information on auditing Oracle Database Vault.

**role_audit_clause**

Use this clause to specify one or more roles to be audited. When you audit a role, Oracle Database audits all system privileges that are granted directly to the role. SQL statements that require the system privileges in order to succeed are audited. For role, specify either a user-defined (local or external) or predefined role. For a list of predefined roles, refer to Oracle Database Security Guide.

**WHEN Clause**

Use this clause to control when the unified audit policy is enforced.

**audit_condition**  Specify a condition that determines if the unified audit policy is enforced. If audit_condition evaluates to TRUE, then the policy is enforced. If FALSE, then the policy is not enforced.

The audit_condition can have a maximum length of 4000 characters. It can contain expressions, as well as the following functions and conditions:

- Numeric functions: BITAND, CEIL, FLOOR, POWER
Character functions returning character values: CONCAT, LOWER, UPPER

Character functions returning number values: INSTR, LENGTH

Environment and identifier functions: SYS_CONTEXT, UID

Comparison conditions: =, !=, <>, <=, >=

Logical conditions: AND, OR

Null conditions: IS [NOT] NULL

[NOT] BETWEEN condition

[NOT] IN condition

The audit_condition must be enclosed in single quotation marks. If the audit_condition contains a single quotation mark, then specify two single quotation marks instead. For example, to specify the following condition:

SYS_CONTEXT('USERENV', 'CLIENT_IDENTIFIER') = 'myclient'

Specify the following for 'audit_condition':

'SYS_CONTEXT(''USERENV'', ''CLIENT_IDENTIFIER'') = ''myclient'''

EVALUATE PER STATEMENT Specify this clause to evaluate the audit_condition for each auditable statement. If the audit_condition evaluates to TRUE, then the unified audit policy is enforced for the statement. If FALSE, then the unified audit policy is not enforced for the statement.

EVALUATE PER SESSION Specify this clause to evaluate the audit_condition once during the session. The audit_condition is evaluated for the first auditable statement that is executed during the session. If the audit_condition evaluates to TRUE, then the unified audit policy is enforced for all applicable statements for the rest of the session. If FALSE, then the unified audit policy is not enforced for all applicable statements for the rest of the session.

EVALUATE PER INSTANCE Specify this clause to evaluate the audit_condition once during the lifetime of the instance. The audit_condition is evaluated for the first auditable statement that is executed during the instance lifetime. If the audit_condition evaluates to TRUE, then the unified audit policy is enforced for all applicable statements for the rest of the lifetime of the instance. If FALSE, then the unified audit policy is not enforced for all applicable statements for the rest of the lifetime of the instance.

CONTAINER Clause

Use the CONTAINER clause to specify the scope of the unified audit policy.

- Specify CONTAINER = ALL to create a common unified audit policy. This type of policy is available to all pluggable databases (PDBs) in the CDB. The current container must be the root. If you specify the ACTIONS object_action ON or ACTIONS ALL ON clause, then you must specify a common object.

- Specify CONTAINER = CURRENT to create a local unified audit policy in the current container. The current container can be the root or a PDB. If the current container is the root, then you cannot specify the clauses ACTIONS system_action, ACTIONS ALL, or privilege_audit_clause.

If you omit the CONTAINER clause and the current container is the root, then CONTAINER = ALL is the default. If you omit the CONTAINER clause and the current container is a pluggable database (PDB), then CONTAINER = CURRENT is the default.
Note: You cannot alter the scope of a unified audit policy after it has been created.

Examples

Auditing System Privileges: Example  The following statement creates unified audit policy `table_pol`, which audits the system privileges `CREATE ANY TABLE` and `DROP ANY TABLE`:

```sql
CREATE AUDIT POLICY table_pol
  PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE;
```

The following statement verifies that `table_pol` now appears in the `AUDIT_UNIFIED_POLICIES` view:

```sql
SELECT *
  FROM audit_unified_policies
  WHERE policy_name = 'TABLE_POL';
```

Auditing Actions on Objects: Examples  The following statement creates unified audit policy `dml_pol`, which audits `DELETE`, `INSERT`, and `UPDATE` actions on table `hr.employees`, and all auditable actions on table `hr.departments`:

```sql
CREATE AUDIT POLICY dml_pol
  ACTIONS DELETE on hr.employees,
    INSERT on hr.employees,
    UPDATE on hr.employees,
    ALL on hr.departments;
```

The following statement creates unified audit policy `read_dir_pol`, which audits `READ` actions on directory `bfile_dir` (created in "Creating a Directory: Examples" on page 14-55):

```sql
CREATE AUDIT POLICY read_dir_pol
  ACTIONS READ ON DIRECTORY bfile_dir;
```

Auditing System Actions: Examples  The following query displays the standard RDBMS system actions that can be audited for the database:

```sql
SELECT name FROM auditable_system_actions
  WHERE component = 'Standard'
  ORDER BY name;
```

<table>
<thead>
<tr>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADMINISTER KEY MANAGEMENT</td>
</tr>
<tr>
<td>ALL</td>
</tr>
<tr>
<td>ALTER ASSEMBLY</td>
</tr>
<tr>
<td>ALTER AUDIT POLICY</td>
</tr>
<tr>
<td>ALTER CLUSTER</td>
</tr>
<tr>
<td>...</td>
</tr>
</tbody>
</table>

The following statement creates unified audit policy `security_pol`, which audits the system action `ADMINISTER KEY MANAGEMENT`:

```sql
CREATE AUDIT POLICY security_pol
  ACTIONS ADMINISTER KEY MANAGEMENT;
```
The following statement creates unified audit policy `all_actions_pol`, which audits all standard RDBMS system actions for the database:

```
CREATE AUDIT POLICY all_actions_pol
  ACTIONS ALL;
```

**Auditing Component Actions: Example** The following query displays the actions that can be audited for Oracle Data Pump:

```
SELECT name FROM auditable_system_actions
  WHERE component = 'Datapump';
```

<table>
<thead>
<tr>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>----</td>
</tr>
<tr>
<td>EXPORT</td>
</tr>
<tr>
<td>IMPORT</td>
</tr>
<tr>
<td>ALL</td>
</tr>
</tbody>
</table>

The following statement creates unified audit policy `dp_actions_pol`, which audits `IMPORT` actions for Oracle Data Pump:

```
CREATE AUDIT POLICY dp_actions_pol
  ACTIONS COMPONENT = datapump IMPORT;
```

**Auditing Roles: Example** The following statement creates unified audit policy `java_pol`, which audits the predefined roles `java_admin` and `java_deploy`:

```
CREATE AUDIT POLICY java_pol
  ROLES java_admin, java_deploy;
```

**Auditing System Privileges, Actions, and Roles: Example** The following statement creates unified audit policy `hr_admin_pol`, which audits multiple system privileges, actions, and roles:

```
CREATE AUDIT POLICY hr_admin_pol
  PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE
  ACTIONS DELETE on hr.employees,
    INSERT on hr.employees,
    UPDATE on hr.employees,
    ALL on hr.departments,
    LOCK TABLE
  ROLES audit_admin, audit_viewer;
```

**Controlling When a Unified Audit Policy is Enforced: Examples** The following statement creates unified audit policy `order_updates_pol`, which audits `UPDATE` actions on table `oe.orders`. This policy is enforced only when the auditable statement is issued by an external user. The audit condition is checked once per session.

```
CREATE AUDIT POLICY order_updates_pol
  ACTIONS UPDATE ON oe.orders
  WHEN 'SYS_CONTEXT(''USERENV'', ''IDENTIFICATION_TYPE'') = ''EXTERNAL'''
  EVALUATE PER SESSION;
```

The following statement creates unified audit policy `emp_updates_pol`, which audits `DELETE`, `INSERT`, and `UPDATE` actions on table `hr.employees`. This policy is enforced only when the auditable statement is issued by a user who does not have a UID of 100, 105, or 107. The audit condition is checked for each auditable statement.

```
CREATE AUDIT POLICY emp_updates_pol
  ACTIONS DELETE on hr.employees,
    INSERT on hr.employees,
    UPDATE on hr.employees;
```
CREATE AUDIT POLICY (Unified Auditing)

UPDATE on hr.employees
  WHEN 'UID NOT IN (100, 105, 107)'
  EVALUATE PER STATEMENT;

Creating a Local Unified Audit Policy: Example  The following statement creates local
unified audit policy local_table_pol, which audits the system privileges CREATE ANY
TABLE and DROP ANY TABLE in the current container::

  CREATE AUDIT POLICY local_table_pol
    PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE
    CONTAINER = CURRENT;

Creating a Common Unified Audit Policy: Example  The following statement creates
common unified audit policy common_role1_pol, which audits the common role
c##role1 (created in CREATE ROLE "Examples" on page 15-89) across the entire CDB:

  CREATE AUDIT POLICY common_role1_pol
    ROLES c##role1
    CONTAINER = ALL;
CREATE CLUSTER

Purpose

Use the CREATE CLUSTER statement to create a cluster. A cluster is a schema object that contains data from one or more tables.

- An indexed cluster must contain more than one table, and all of the tables in the cluster have one or more columns in common. Oracle Database stores together all the rows from all the tables that share the same cluster key.
- In a hash cluster, which can contain one or more tables, Oracle Database stores together rows that have the same hash key value.

For information on existing clusters, query the USER_CLUSTERS, ALL_CLUSTERS, and DBA_CLUSTERS data dictionary views.

See Also:

- Oracle Database Concepts for general information on clusters
- Oracle Database SQL Tuning Guide for suggestions on when to use clusters
- Oracle Database Reference for information on the data dictionary views

Prerequisites

To create a cluster in your own schema, you must have CREATE CLUSTER system privilege. To create a cluster in another user’s schema, you must have CREATE ANY CLUSTER system privilege. Also, the owner of the schema to contain the cluster must have either space quota on the tablespace containing the cluster or the UNLIMITED TABLESPACE system privilege.

Oracle Database does not automatically create an index for a cluster when the cluster is initially created. Data manipulation language (DML) statements cannot be issued against cluster tables in an indexed cluster until you create a cluster index with a CREATE INDEX statement.
Syntax

create_cluster ::= CREATE CLUSTER schema.cluster (column datatype SORT, physical_attributes_clause SIZE size_clause TABLESPACE tablespace INDEX SINGLE TABLE HASHKEYS integer HASH IS expr parallel_clause).cluster_range_partitions);

(physical_attributes_clause ::= on page 14-12, size_clause ::= on page 8-47, cluster_range_partitions ::= on page 14-13)

physical_attributes_clause ::= PCTFREE integer, PCTUSED integer, INITTRANS integer, storage_clause

(storage_clause ::= on page 8-50)

parallel_clause ::= NOPARALLEL, PARALLEL integer

**cluster_range_partitions**:=

\[
\text{PARTITION BY RANGE (column)}
\]

\[
\text{PARTITION (partition range_values_clause table_partition_description)}
\]

\[(\text{range_values_clause::=} \text{on page 16-27, table_partition_description::=} \text{on page 16-27})\]

**Semantics**

**schema**

Specify the schema to contain the cluster. If you omit `schema`, then Oracle Database creates the cluster in your current schema.

**cluster**

Specify is the name of the cluster to be created.

After you create a cluster, you add tables to it. A cluster can contain a maximum of 32 tables. Object tables and tables containing LOB columns or columns of the Any* Oracle-supplied types cannot be part of a cluster. After you create a cluster and add tables to it, the cluster is transparent. You can access clustered tables with SQL statements just as you can access nonclustered tables.

**See Also:** `CREATE TABLE` on page 16-6 for information on adding tables to a cluster, "Creating a Cluster: Example" on page 14-17, and "Adding Tables to a Cluster: Example" on page 14-17

**column**

Specify one or more names of columns in the cluster key. You can specify up to 16 cluster key columns. These columns must correspond in both data type and size to columns in each of the clustered tables, although they need not correspond in name.

You cannot specify integrity constraints as part of the definition of a cluster key column. Instead, you can associate integrity constraints with the tables that belong to the cluster.

**See Also:** "Cluster Keys: Example" on page 14-17

**datatype**

Specify the data type of each cluster key column.

**Restrictions on Cluster Data Types** Cluster data types are subject to the following restrictions:

- You cannot specify a cluster key column of data type `LONG`, `LONG RAW`, `REP`, nested table, `varray`, `BLOB`, `CLOB`, `BFILE`, the Any* Oracle-supplied types, or user-defined object type.
- You can specify a column of type `ROWID`, but Oracle Database does not guarantee that the values in such columns are valid rowids.
SORT
The SORT keyword is valid only if you are creating a hash cluster. This clause instructs Oracle Database to sort the rows of the cluster on this column after applying the hash function when performing a DML operation. Doing so may improve response time during subsequent queries on the clustered data. See "HASHKEYS Clause" on page 14-15 for information on creating a hash cluster.

Restriction on Sorted Hash Clusters  Row dependency is not supported for sorted hash clusters.

physical_attributes_clause
The physical_attributes_clause lets you specify the storage characteristics of the cluster. Each table in the cluster uses these storage characteristics as well. If you do not specify values for these parameters, then Oracle Database uses the following defaults:

- PCTFREE: 10
- PCTUSED: 40
- INITRANS: 2 or the default value of the tablespace to contain the cluster, whichever is greater

See Also:  physical_attributes_clause on page 8-44 and storage_clause on page 8-46 for a complete description of these clauses

SIZE
Specify the amount of space in bytes reserved to store all rows with the same cluster key value or the same hash value. This space determines the maximum number of cluster or hash values stored in a data block. If SIZE is not a divisor of the data block size, then Oracle Database uses the next largest divisor. If SIZE is larger than the data block size, then the database uses the operating system block size, reserving at least one data block for each cluster or hash value.

The database also considers the length of the cluster key when determining how much space to reserve for the rows having a cluster key value. Larger cluster keys require larger sizes. To see the actual size, query the KEY_SIZE column of the USER_CLUSTERS data dictionary view. (This value does not apply to hash clusters, because hash values are not actually stored in the cluster.)

If you omit this parameter, then the database reserves one data block for each cluster key value or hash value.

TABLESPACE
Specify the tablespace in which the cluster is to be created.

INDEX Clause
Specify INDEX to create an indexed cluster. In an indexed cluster, Oracle Database stores together rows having the same cluster key value. Each distinct cluster key value is stored only once in each data block, regardless of the number of tables and rows in which it occurs. If you specify neither INDEX nor HASHKEYS, then Oracle Database creates an indexed cluster by default.
After you create an indexed cluster, you must create an index on the cluster key before you can issue any data manipulation language (DML) statements against a table in the cluster. This index is called the **cluster index**.

You cannot create a cluster index for a hash cluster, and you need not create an index on a hash cluster key.

**See Also:** CREATE INDEX on page 14-73 for information on creating a cluster index and Oracle Database Concepts for general information in indexed clusters

**HASHKEYS Clause**
Specify the **HASHKEYS** clause to create a **hash cluster** and specify the number of hash values for the hash cluster. In a hash cluster, Oracle Database stores together rows that have the same hash key value. The hash value for a row is the value returned by the hash function of the cluster.

Oracle Database rounds up the **HASHKEYS** value to the nearest prime number to obtain the actual number of hash values. The minimum value for this parameter is 2. If you omit both the **INDEX** clause and the **HASHKEYS** parameter, then the database creates an indexed cluster by default.

When you create a hash cluster, the database immediately allocates space for the cluster based on the values of the **SIZE** and **HASHKEYS** parameters.

**See Also:** Oracle Database Concepts for more information on how Oracle Database allocates space for clusters and "Hash Clusters: Examples" on page 14-17

**SINGLE TABLE** **SINGLE TABLE** indicates that the cluster is a type of hash cluster containing only one table. This clause can provide faster access to rows in the table.

**Restriction on Single-table Clusters** Only one table can be present in the cluster at a time. However, you can drop the table and create a different table in the same cluster.

**See Also:** "Single-Table Hash Clusters: Example" on page 14-17

**HASH IS expr** Specify an expression to be used as the hash function for the hash cluster. The expression:

- Must evaluate to a positive value
- Must contain at least one column, with referenced columns of any data type as long as the entire expression evaluates to a number of scale 0. For example: `number_column * LENGTH(varchar2_column)`
- Cannot reference user-defined PL/SQL functions
- Cannot reference the pseudocolumns **LEVEL** or **ROWNUM**
- Cannot reference the user-related functions **USERENV**, **UID**, or **USER** or the datetime functions **CURRENT_DATE**, **CURRENT_TIMESTAMP**, **DBTIMEZONE**, **EXTRACT** (**datetime**), **FROM_TZ**, **LOCALTIMESTAMP**, **NUMTODSINTERVAL**, **NUMTOYMINTERVAL**, **SESSIONTIMEZONE**, **SYSDATE**, **SYSTIMESTAMP**, **TO_DSINTERVAL**, **TO_TIMESTAMP**, **TO_DATE**, **TO_TIMESTAMP_TZ**, **TO_YMINTERVAL**, and **TZ_OFFSET**.
- Cannot evaluate to a constant
- Cannot be a scalar subquery expression
CREATE CLUSTER

- Cannot contain columns qualified with a schema or object name (other than the cluster name)

If you omit the HASH IS clause, then Oracle Database uses an internal hash function for the hash cluster.

For information on existing hash functions, query the USER_, ALL_, and DBA_CLUSTER_ HASH_EXPRESSIONS data dictionary tables.

The cluster key of a hash column can have one or more columns of any data type. Hash clusters with composite cluster keys or cluster keys made up of noninteger columns must use the internal hash function.

See Also: Oracle Database Reference for information on the data dictionary views

parallel_clause
The parallel_clause lets you parallelize the creation of the cluster.

For complete information on this clause, refer to parallel_clause on page 16-81 in the documentation on CREATE TABLE.

NOROWDEPENDENCIES | ROWDEPENDENCIES
This clause has the same behavior for a cluster that it has for a table. Refer to "NOROWDEPENDENCIES | ROWDEPENDENCIES" in CREATE TABLE on page 16-82 for information.

CACHE | NOCACHE

CACHE Specify CACHE if you want the blocks retrieved for this cluster to be placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This clause is useful for small lookup tables.

NOCACHE Specify NOCACHE if you want the blocks retrieved for this cluster to be placed at the least recently used end of the LRU list in the buffer cache when a full table scan is performed. This is the default behavior.

NOCACHE has no effect on clusters for which you specify KEEP in the storage_clause.

cluster_range_partitions
Beginning with Oracle Database 12c Release 1 (12.1.0.2), you can specify the cluster_range_partitions clause to create a range-partitioned hash cluster. If you specify this clause, then you must also specify the HASHKEYS clause.

Use the cluster_range_partitions clause to partition the cluster on ranges of values from the column list. When you add a table to a range-partitioned hash cluster, it is automatically partitioned on the same columns, with the same number of partitions, and on the same partition bounds as the cluster. Oracle Database assigns system-generated names to the table partitions.

The cluster_range_partitions clause has the same semantics as the range_partitions clause of CREATE TABLE, except that here you cannot specify the INTERVAL clause. For complete information, refer to range_partitions on page 16-68 in the documentation on CREATE TABLE.

See Also: "Range-Partitioned Hash Clusters: Example" on page 14-17
Examples

Creating a Cluster: Example The following statement creates a cluster named *personnel* with the cluster key column *department*, a cluster size of 512 bytes, and storage parameter values:

```sql
CREATE CLUSTER personnel
    (department NUMBER(4))
SIZE 512
STORAGE (initial 100K next 50K);
```

Cluster Keys: Example The following statement creates the cluster index on the cluster key of *personnel*:

```sql
CREATE INDEX idx_personnel ON CLUSTER personnel;
```

After creating the cluster index, you can add tables to the index and perform DML operations on those tables.

Adding Tables to a Cluster: Example The following statements create some departmental tables from the sample *hr.employees* table and add them to the *personnel* cluster created in the earlier example:

```sql
CREATE TABLE dept_10
    CLUSTER personnel (department_id)
    AS SELECT * FROM employees WHERE department_id = 10;
CREATE TABLE dept_20
    CLUSTER personnel (department_id)
    AS SELECT * FROM employees WHERE department_id = 20;
```

Hash Clusters: Examples The following statement creates a hash cluster named *language* with the cluster key column *cust_language*, a maximum of 10 hash key values, each of which is allocated 512 bytes, and storage parameter values:

```sql
CREATE CLUSTER language (cust_language VARCHAR2(3))
    SIZE 512 HASHKEYS 10
    STORAGE (INITIAL 100k next 50k);
```

Because the preceding statement omits the HASH IS clause, Oracle Database uses the internal hash function for the cluster.

The following statement creates a hash cluster named *address* with the cluster key made up of the columns *postal_code* and *country_id*, and uses a SQL expression containing these columns for the hash function:

```sql
CREATE CLUSTER address
    (postal_code NUMBER, country_id CHAR(2))
    HASHKEYS 20
    HASH IS MOD(postal_code + country_id, 101);
```

Single-Table Hash Clusters: Example The following statement creates a single-table hash cluster named *cust_orders* with the cluster key *customer_id* and a maximum of 100 hash key values, each of which is allocated 512 bytes:

```sql
CREATE CLUSTER cust_orders (customer_id NUMBER(6))
    SIZE 512 SINGLE TABLE HASHKEYS 100;
```

Range-Partitioned Hash Clusters: Example The following statement creates a range-partitioned hash cluster named *sales* with five range partitions based on the
amount sold. The cluster key is made up of the columns `amount_sold` and `prod_id`. The cluster uses the hash function `(amount_sold * 10 + prod_id)` and has a maximum of 100000 hash key values, each of which is allocated 300 bytes.

CREATE CLUSTER sales (amount_sold NUMBER, prod_id NUMBER)
    HASHKEYS 100000
    HASH IS (amount_sold * 10 + prod_id)
    SIZE 300
    TABLESPACE example
    PARTITION BY RANGE (amount_sold)
        (PARTITION p1 VALUES LESS THAN (2001),
         PARTITION p2 VALUES LESS THAN (4001),
         PARTITION p3 VALUES LESS THAN (6001),
         PARTITION p4 VALUES LESS THAN (8001),
         PARTITION p5 VALUES LESS THAN (MAXVALUE));
CREATE CONTEXT

Purpose

Use the CREATE CONTEXT statement to:

- Create a namespace for a context (a set of application-defined attributes that validates and secures an application)
- Associate the namespace with the externally created package that sets the context

You can use the DBMS_SESSION.SET_CONTEXT procedure in your designated package to set or reset the attributes of the context.

See Also:

- Oracle Database Security Guide for a discussion of contexts
- Oracle Database PL/SQL Packages and Types Reference for information on the DBMS_SESSION.SET_CONTEXT procedure

Prerequisites

To create a context namespace, you must have CREATE ANY CONTEXT system privilege.

Syntax

create_context::=

```
CREATE [OR REPLACE] CONTEXT namespace USING schema package
```

Semantics

**OR REPLACE**

Specify OR REPLACE to redefine an existing context namespace using a different package.

**namespace**

Specify the name of the context namespace to create or modify. Context namespaces are always stored in the schema SYS.

See Also: "Database Object Naming Rules" on page 2-119 for guidelines on naming a context namespace

**schema**

Specify the schema owning package. If you omit schema, then Oracle Database uses the current schema.
package
Specify the PL/SQL package that sets or resets the context attributes under the namespace for a user session.

To provide some design flexibility, Oracle Database does not verify the existence of the schema or the validity of the package at the time you create the context.

INITIALIZED Clause
The INITIALIZED clause lets you specify an entity other than Oracle Database that can initialize the context namespace.

EXTERNALLY  EXTERNALLY indicates that the namespace can be initialized using an OCI interface when establishing a session.

See Also:  Oracle Call Interface Programmer’s Guide for information on using OCI to establish a session

GLOBALLY  GLOBALLY indicates that the namespace can be initialized by the LDAP directory when a global user connects to the database.

After the session is established, only the designated PL/SQL package can issue commands to write to any attributes inside the namespace.

See Also:
- Oracle Database Security Guide for information on establishing globally initialized contexts
- Oracle Internet Directory Administrator’s Guide for information on the connecting to the database through the LDAP directory

ACCEDED GLOBALLY
This clause indicates that any application context set in namespace is accessible throughout the entire instance. This setting lets multiple sessions share application attributes.

Examples

Creating an Application Context: Example  This example uses a PL/SQL package emp_mgmt, which validates and secures a human resources application. See Oracle Database PL/SQL Language Reference for the example that creates that package. The following statement creates the context namespace hr_context and associates it with the package emp_mgmt:

CREATE CONTEXT hr_context USING emp_mgmt;

You can control data access based on this context using the SYS_CONTEXT function. For example, the emp_mgmt package has defined an attribute department_id as a particular department identifier. You can secure the base table employees by creating a view that restricts access based on the value of department_id, as follows:

CREATE VIEW hr_org_secure_view AS
SELECT * FROM employees
WHERE department_id = SYS_CONTEXT('hr_context', 'department_id');
See Also:  SYS_CONTEXT on page 7-334 and Oracle Database Security Guide for more information on using application contexts to retrieve user information
CREATE CONTROLFILE

Caution: Oracle recommends that you perform a full backup of all files in the database before using this statement. For more information, see Oracle Database Backup and Recovery User’s Guide.

Purpose

The CREATE CONTROLFILE statement should be used in only a few cases. Use this statement to re-create a control file if all control files being used by the database are lost and no backup control file exists. You can also use this statement to change the maximum number of redo log file groups, redo log file members, archived redo log files, data files, or instances that can concurrently have the database mounted and open.

To change the name of the database, Oracle recommends that you use the DBNEWID utility rather than the CREATE CONTROLFILE statement. DBNEWID is preferable because no OPEN RESETLOGS operation is required after changing the database name.

See Also:
- Oracle Database Utilities for more information about the DBNEWID utility
- ALTER DATABASE "BACKUP CONTROLFILE Clause" on page 10-59 for information creating a script based on an existing database control file

Prerequisites

To create a control file, you must have the SYSDBA or SYSBACKUP system privilege.

The database must not be mounted by any instance. After successfully creating the control file, Oracle mounts the database in the mode specified by the CLUSTER_DATABASE parameter. The DBA must then perform media recovery before opening the database. If you are using the database with Oracle Real Application Clusters (Oracle RAC), then you must then shut down and remount the database in SHARED mode (by setting the value of the CLUSTER_DATABASE initialization parameter to TRUE) before other instances can start up.
Syntax

\[ create\_controlfile::= \]

\[ (storage\_clause::= on page 8-50) \]

\[ logfile\_clause::= \]

\[ (file\_specification::= on page 8-29) \]

\[ character\_set\_clause::= \]

\[ (storage\_clause::= on page 8-50) \]

Semantics

When you issue a `CREATE CONTROLFILE` statement, Oracle Database creates a new control file based on the information you specify in the statement. The control file resides in the location specified in the `CONTROL_FILES` initialization parameter. If that parameter does not have a value, then the database creates an Oracle-managed control file in the default control file destination, which is one of the following (in order of precedence):

1. One or more control files as specified in the `DB_CREATE_ONLINE_LOG_DEST_n` initialization parameter. The file in the first directory is the primary control file. When `DB_CREATE_ONLINE_LOG_DEST_n` is specified, the database does not create a
control file in `DB_CREATE_FILE_DEST` or in `DB_RECOVERY_FILE_DEST` (the fast recovery area).

2. If no value is specified for `DB_CREATE_ONLINE_LOG_DEST_n`, but values are set for both the `DB_CREATE_FILE_DEST` and `DB_RECOVERY_FILE_DEST`, then the database creates one control file in each location. The location specified in `DB_CREATE_FILE_DEST` is the primary control file.

3. If a value is specified only for `DB_CREATE_FILE_DEST`, then the database creates one control file in that location.

4. If a value is specified only for `DB_RECOVERY_FILE_DEST`, then the database creates one control file in that location.

If no values are set for any of these parameters, then the database creates a control file in the default location for the operating system on which the database is running. This control file is not an Oracle Managed File.

If you omit any clauses, then Oracle Database uses the default values rather than the values for the previous control file. After successfully creating the control file, Oracle Database mounts the database in the mode specified by the initialization parameter `CLUSTER_DATABASE`. If that parameter is not set, then the default value is `FALSE`, and the database is mounted in `EXCLUSIVE` mode. Oracle recommends that you then shut down the instance and take a full backup of all files in the database.

**See Also:** *Oracle Database Backup and Recovery User’s Guide*

**REUSE**

Specify `REUSE` to indicate that existing control files identified by the initialization parameter `CONTROL_FILES` can be reused, overwriting any information they may currently contain. If you omit this clause and any of these control files already exists, then Oracle Database returns an error.

**DATABASE Clause**

Specify the name of the database. The value of this parameter must be the existing database name established by the previous `CREATE DATABASE` statement or `CREATE CONTROLFILE` statement.

**SET DATABASE Clause**

Use `SET DATABASE` to change the name of the database. The name of a database can be as long as eight bytes.

When you specify this clause, you must also specify `RESETLOGS`. If you want to rename the database and retain your existing log files, then after issuing this `CREATE CONTROLFILE` statement you must complete a full database recovery using an `ALTER DATABASE RECOVER USING BACKUP CONTROLFILE` statement.

**logfile_clause**

Use the `logfile_clause` to specify the redo log files for your database. You must list all members of all redo log file groups.

Use the `redo_log_file_spec` form of `file_specification` (see `file_specification` on page 8-29) to list regular redo log files in an operating system file system or to list Oracle ASM disk group redo log files. When using a form of `ASM_filename`, you cannot specify the `autoextend_clause` of the `redo_log_file_spec`. 
If you specify **RESETLOGS** in this clause, then you must use one of the file creation forms of *ASM_filename*. If you specify **NORESETLOGS**, then you must specify one of the reference forms of *ASM_filename*.

**See Also:** *ASM_filename* on page 8-32 for information on the different forms of syntax and *Oracle Automatic Storage Management Administrator’s Guide* for general information about using Oracle ASM.

**GROUP integer** Specify the logfile group number. If you specify **GROUP** values, then Oracle Database verifies these values with the **GROUP** values when the database was last open.

If you omit this clause, then the database creates logfiles using system default values. In addition, if either the **DB_CREATE_ONLINE_LOG_DEST_n** or **DB_CREATE_FILE_DEST** initialization parameter has been set, and if you have specified **RESETLOGS**, then the database creates two logs in the default logfile destination specified in the **DB_CREATE_ONLINE_LOG_DEST_n** parameter, and if it is not set, then in the **DB_CREATE_FILE_DEST** parameter.

**See Also:** *file_specification* on page 8-29 for a full description of this clause.

**RESETLOGS** Specify **RESETLOGS** if you want Oracle Database to ignore the contents of the files listed in the **LOGFILE** clause. These files do not have to exist. You must specify this clause if you have specified the **SET DATABASE** clause.

Each **redo_log_file_spec** in the **LOGFILE** clause must specify the **SIZE** parameter. The database assigns all online redo log file groups to thread 1 and enables this thread for public use by any instance. After using this clause, you must open the database using the **RESETLOGS** clause of the **ALTER DATABASE** statement.

**NORESETLOGS** Specify **NORESETLOGS** if you want Oracle Database to use all files in the **LOGFILE** clause as they were when the database was last open. These files must exist and must be the current online redo log files rather than restored backups. The database reassigns the redo log file groups to the threads that they were previously assigned and reenables the threads as they were previously enabled.

You cannot specify **NORESETLOGS** if you have specified the **SET DATABASE** clause to change the name of the database. Refer to "**SET DATABASE Clause**" on page 14-24 for more information.

**DATAFILE Clause**

Specify the data files of the database. You must list all data files. These files must all exist, although they may be restored backups that require media recovery.

Do not include in the **DATAFILE** clause any data files in read-only tablespaces. You can add these types of files to the database later. Also, do not include in this clause any temporary data files (temp files).

Use the **datafile_tempfile_spec** form of *file_specification* (see *file_specification* on page 8-29) to list regular data files and temp files in an operating system file system or to list Oracle ASM disk group files. When using a form of *ASM_filename*, you must use one of the reference forms of *ASM_filename*. Refer to *ASM_filename* on page 8-32 for information on the different forms of syntax.

**See Also:** *Oracle Automatic Storage Management Administrator’s Guide* for general information about using Oracle ASM.
Restriction on DATAFILE  You cannot specify the autoextend_clause of file_specification in this DATAFILE clause.

MAXLOGFILES Clause
Specify the maximum number of online redo log file groups that can ever be created for the database. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The default and maximum values depend on your operating system. The value that you specify should not be less than the greatest GROUP value for any redo log file group.

MAXLOGMEMBERS Clause
Specify the maximum number of members, or identical copies, for a redo log file group. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The minimum value is 1. The maximum and default values depend on your operating system.

MAXLOGHISTORY Clause
This parameter is useful only if you are using Oracle Database in ARCHIVELOG mode. Specify your current estimate of the maximum number of archived redo log file groups needed for automatic media recovery of the database. The database uses this value to determine how much space to allocate in the control file for the names of archived redo log files.

The minimum value is 0. The default value is a multiple of the MAXINSTANCES value and depends on your operating system. The maximum value is limited only by the maximum size of the control file. The database will continue to add additional space to the appropriate section of the control file as needed, so that you do not need to re-create the control file if your your original configuration is no longer adequate. As a result, the actual value of this parameter can eventually exceed the value you specify.

MAXDATAFILES Clause
Specify the initial sizing of the data files section of the control file at CREATE DATABASE or CREATE CONTROLFILE time. An attempt to add a file whose number is greater than MAXDATAFILES, but less than or equal to DB_FILES, causes the control file to expand automatically so that the data files section can accommodate more files.

The number of data files accessible to your instance is also limited by the initialization parameter DB_FILES.

MAXINSTANCES Clause
Specify the maximum number of instances that can simultaneously have the database mounted and open. This value takes precedence over the value of the initialization parameter INSTANCES. The minimum value is 1. The maximum and default values depend on your operating system.

ARCHIVELOG | NOARCHIVELOG
Specify ARCHIVELOG to archive the contents of redo log files before reusing them. This clause prepares for the possibility of media recovery as well as instance or system failure recovery.

If you omit both the ARCHIVELOG clause and NOARCHIVELOG clause, then Oracle Database chooses NOARCHIVELOG mode by default. After creating the control file, you can change between ARCHIVELOG mode and NOARCHIVELOG mode with the ALTER DATABASE statement.
FORCE LOGGING

Use this clause to put the database into FORCE LOGGING mode after control file creation. When the database is in this mode, Oracle Database logs all changes in the database except changes to temporary tablespaces and temporary segments. This setting takes precedence over and is independent of any NOLOGGING or FORCE LOGGING settings you specify for individual tablespaces and any NOLOGGING settings you specify for individual database objects. If you omit this clause, then the database will not be in FORCE LOGGING mode after the control file is created.

---

**Note:** FORCE LOGGING mode can have performance effects. Refer to Oracle Database Administrator’s Guide for information on when to use this setting.

---

**character_set_clause**

If you specify a character set, then Oracle Database reconstructs character set information in the control file. If media recovery of the database is subsequently required, then this information will be available before the database is open, so that tablespace names can be correctly interpreted during recovery. This clause is required only if you are using a character set other than the default, which depends on your operating system. Oracle Database prints the current database character set to the alert log in $ORACLE_HOME/log during startup.

If you are re-creating your control file and you are using Recovery Manager for tablespace recovery, and if you specify a different character set from the one stored in the data dictionary, then tablespace recovery will not succeed. However, at database open, the control file character set will be updated with the correct character set from the data dictionary.

You cannot modify the character set of the database with this clause.

**See Also:** Oracle Database Backup and Recovery User’s Guide for more information on tablespace recovery

---

**Examples**

**Creating a Controlfile: Example**  This statement re-creates a control file. In this statement, database demo was created with the WE8DEC character set. The example uses the word path where you would normally insert the path on your system to the appropriate Oracle Database directories.

```sql
STARTUP NOMOUNT
CREATE CONTROLFILE REUSE DATABASE "demo" NORESETPS NOARCHIVELOG
  MAXLOGFILES 32
  MAXLOGMEMBERS 2
  MAXDATAFILES 32
  MAXINSTANCES 1
  MAXLOGHISTORY 449
LOGFILE
  GROUP 1 '/path/oracle/dbs/t_log1.f' SIZE 500K,
  GROUP 2 '/path/oracle/dbs/t_log2.f' SIZE 500K
# STANDBY LOGFILE
DATAFILE
  '/path/oracle/dbs/t_db1.f',
  '/path/oracle/dbs/dbu19i.dbf',
```

---

SQL Statements: CREATE AUDIT POLICY to CREATE JAVA   14-27
CREATE CONTROLFILE

'path/oracle/dbs/tbs_11.f',
'path/oracle/dbs/smundo.dbf',
'path/oracle/dbs/demo.dbf'
CHARACTER SET WE8DEC
;

Oracle Database SQL Language Reference
CREATE DATABASE

Caution: This statement prepares a database for initial use and erases any data currently in the specified files. Use this statement only when you understand its ramifications.

Note Regarding Security Enhancements: In this release of Oracle Database and in subsequent releases, several enhancements are being made to ensure the security of default database user accounts. You can find a security checklist for this release in Oracle Database Security Guide. Oracle recommends that you read this checklist and configure your database accordingly.

Purpose

Use the CREATE DATABASE statement to create a database, making it available for general use.

This statement erases all data in any specified data files that already exist in order to prepare them for initial database use. If you use the statement on an existing database, then all data in the data files is lost.

After creating the database, this statement mounts it in either exclusive or parallel mode, depending on the value of the CLUSTER_DATABASE initialization parameter and opens it, making it available for normal use. You can then create tablespaces for the database.

See Also:

- ALTER DATABASE on page 10-32 for information on modifying a database
- Oracle Database Java Developer’s Guide for information on creating an Oracle Java virtual machine
- CREATE TABLESPACE on page 16-102 for information on creating tablespaces

Prerequisites

To create a database, you must have the SYSDBA system privilege. An initialization parameter file with the name of the database to be created must be available, and you must be in STARTUP NOMOUNT mode.
Syntax

```sql
create_database ::= CREATE DATABASE database

database::=

CREATE DATABASE database

USER SYS IDENTIFIED BY password
USER SYSTEM IDENTIFIED BY password
CONTROLFILE REUSE
MAXDATAFILES integer
MAXINSTANCES integer
CHARACTER SET charset
NATIONAL CHARACTER SET charset
SET DEFAULT BIGFILE SMALLFILE TABLESPACE

database_logging_clauses::=

LOGFILE GROUP integer file_specification

ARCHIVELOG
NOARCHIVELOG
FORCE LOGGING

(file_specification::= on page 8-29)

_ARCHIVELOG NOARCHIVELOG

ENABLE PLUGGABLE DATABASE

(datafile_tempfile_spec::= on page 8-29, enable_pluggable_database::= on page 14-32, datafile_tempfile_spec::= on page 8-29, enable_pluggable_database::= on page 14-32)

(database_logging_clauses::= on page 14-30, tablespace_clauses::= on page 14-31, set_time_zone_clause::= on page 14-32)
CREATE DATABASE

**tablespace_clauses::=**

(size_clause::= on page 8-47)

**undo_tablespace::=**

- BIGFILE SMALLFILE
- UNDO TABLESPACE tablespace DATAFILE file_specification

(file_specification::= on page 8-29)
**Semantics**

**database**
Specify the name of the database to be created. The name must match the value of the DB_NAME initialization parameter. The name can be up to 8 bytes long and can contain only ASCII characters. Oracle Database writes this name into the control file. If you subsequently issue an ALTER DATABASE statement that explicitly specifies a database name, then Oracle Database verifies that name with the name in the control file.

The database name is case insensitive and is stored in uppercase ASCII characters. If you specify the database name as a quoted identifier, then the quotation marks are silently ignored.

---

**Note:** You cannot use special characters from European or Asian character sets in a database name. For example, characters with umlauts are not allowed.

---

If you omit the database name from a CREATE DATABASE statement, then Oracle Database uses the name specified by the initialization parameter DB_NAME. The DB_NAME initialization parameter must be set in the database initialization parameter file, and if you specify a different name from the value of that parameter, then the database
returns an error. Refer to "Database Object Naming Rules" on page 2-119 for additional rules to which database names should adhere.

**USER SYS ..., USER SYSTEM ...**

Use these clauses to establish passwords for the **SYS** and **SYSTEM** users. These clauses are not mandatory in this release. However, if you specify either clause, then you must specify both clauses.

If you do not specify these clauses, then Oracle Database creates default passwords change_on_install for user **SYS** and manager for user **SYSTEM**. You can subsequently change these passwords using the **ALTER USER** statement. You can also use **ALTER USER** to add password management attributes after database creation.

*See Also:* [ALTER USER](#) on page 13-6

**CONTROLFILE REUSE Clause**

Specify **CONTROLFILE REUSE** to reuse existing control files identified by the initialization parameter **CONTROL_FILES**, overwriting any information they currently contain. Normally you use this clause only when you are re-creating a database, rather than creating one for the first time. When you create a database for the first time, Oracle Database creates a control file in the default destination, which is dependent on the value or several initialization parameters. See CREATE CONTROLFILE, “Semantics” on page 14-23.

You cannot use this clause if you also specify a parameter value that requires that the control file be larger than the existing files. These parameters are **MAXLOGFILES**, **MAXLOGMEMBERS**, **MAXLOGHISTORY**, **MAXDATAFILES**, and **MAXINSTANCES**.

If you omit this clause and any of the files specified by **CONTROL_FILES** already exist, then the database returns an error.

**MAXDATAFILES Clause**

Specify the initial sizing of the data files section of the control file at CREATE DATABASE or CREATE CONTROLFILE time. An attempt to add a file whose number is greater than **MAXDATAFILES**, but less than or equal to **DB_FILES**, causes the Oracle Database control file to expand automatically so that the data files section can accommodate more files.

The number of data files accessible to your instance is also limited by the initialization parameter **DB_FILES**.

**MAXINSTANCES Clause**

Specify the maximum number of instances that can simultaneously have this database mounted and open. This value takes precedence over the value of initialization parameter **INSTANCES**. The minimum value is 1. The maximum value is 1055. The default depends on your operating system.

**CHARACTER SET Clause**

Specify the character set the database uses to store data. The supported character sets and default value of this parameter depend on your operating system.

*Restriction on CHARACTER SET* You cannot specify the **AL16UTF16** character set as the database character set.

*See Also:* [Oracle Database Globalization Support Guide](#) for more information about choosing a character set
NATIONAL CHARACTER SET Clause
Specify the national character set used to store data in columns specifically defined as NCHAR, NCLOB, or NVARCHAR2. Valid values are AL16UTF16 and UTF8. The default is AL16UTF16.

See Also: Oracle Database Globalization Support Guide for information on Unicode data type support

SET DEFAULT TABLESPACE Clause
Use this clause to determine the default type of subsequently created tablespaces and of the SYSTEM and SYSAUX tablespace. Specify either BIGFILE or SMALLFILE to set the default type of subsequently created tablespaces as a bigfile or smallfile tablespace, respectively.

- A **bigfile tablespace** contains only one data file or temp file, which can contain up to approximately 4 billion \(2^{32}\) blocks. The maximum size of the single data file or temp file is 128 terabytes (TB) for a tablespace with 32K blocks and 32TB for a tablespace with 8K blocks.
- A **smallfile tablespace** is a traditional Oracle tablespace, which can contain 1022 data files or temp files, each of which can contain up to approximately 4 million \(2^{22}\) blocks.

If you omit this clause, then Oracle Database creates smallfile tablespaces by default.

See Also:
- Oracle Database Administrator’s Guide for more information about bigfile tablespaces
- "Setting the Default Type of Tablespaces: Example" on page 10-70 for an example using this syntax

database_logging_clauses
Use the `database_logging_clauses` to determine how Oracle Database will handle redo log files for this database.

LOGFILE Clause
Specify one or more files to be used as redo log files. Use the `redo_log_file_spec` form of `file_specification` to create regular redo log files in an operating system file system or to create Oracle ASM disk group redo log files. When using a form of `ASM_filename`, you cannot specify the `autoextend_clause` of `redo_log_file_spec`.

The `redo_log_file_spec` clause specifies a redo log file group containing one or more redo log file members (copies). All redo log files specified in a `CREATE DATABASE` statement are added to redo log thread number 1.

See Also: `file_specification` on page 8-29 for a full description of this clause

If you omit the `LOGFILE` clause, then Oracle Database creates an Oracle-managed log file member in the default destination, which is one of the following locations (in order of precedence):

- If `DB_CREATE_ONLINE_LOG_DEST_n` is set, then the database creates a log file member in each directory specified, up to the value of the `MAXLOGMEMBERS` initialization parameter.
If the `DB_CREATE_ONLINE_LOG_DEST_n` parameter is not set, but both the `DB_CREATE_FILE_DEST` and `DB_RECOVERY_FILE_DEST` initialization parameters are set, then the database creates one Oracle-managed log file member in each of those locations. The log file in the `DB_CREATE_FILE_DEST` destination is the first member.

If only the `DB_CREATE_FILE_DEST` initialization parameter is specified, then Oracle Database creates a log file member in that location.

If only the `DB_RECOVERY_FILE_DEST` initialization parameter is specified, then Oracle Database creates a log file member in that location.

In all these cases, the parameter settings must correctly specify operating system filenames or creation form Oracle ASM filenames, as appropriate.

If no values are set for any of these parameters, then the database creates a log file in the default location for the operating system on which the database is running. This log file is not an Oracle Managed File.

**GROUP integer**  Specify the number that identifies the redo log file group. The value of `integer` can range from 1 to the value of the `MAXLOGFILES` parameter. A database must have at least two redo log file groups. You cannot specify multiple redo log file groups having the same `GROUP` value. If you omit this parameter, then Oracle Database generates its value automatically. You can examine the `GROUP` value for a redo log file group through the dynamic performance view `V$LOG`.

**MAXLOGFILES Clause**
Specify the maximum number of redo log file groups that can ever be created for the database. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The default, minimum, and maximum values depend on your operating system.

**MAXLOGMEMBERS Clause**
Specify the maximum number of members, or copies, for a redo log file group. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The minimum value is 1. The maximum and default values depend on your operating system.

**MAXLOGHISTORY Clause**
This parameter is useful only if you are using Oracle Database in `ARCHIVELOG` mode with Oracle Real Application Clusters (Oracle RAC). Specify the maximum number of archived redo log files for automatic media recovery of Oracle RAC. The database uses this value to determine how much space to allocate in the control file for the names of archived redo log files. The minimum value is 0. The default value is a multiple of the `MAXINSTANCES` value and depends on your operating system. The maximum value is limited only by the maximum size of the control file.

**ARCHIVELOG**
Specify `ARCHIVELOG` if you want the contents of a redo log file group to be archived before the group can be reused. This clause prepares for the possibility of media recovery.

**NOARCHIVELOG**
Specify `NOARCHIVELOG` if the contents of a redo log file group need not be archived before the group can be reused. This clause does not allow for the possibility of media recovery.
The default is NOARCHIVELOG mode. After creating the database, you can change between ARCHIVELOG mode and NOARCHIVELOG mode with the ALTER DATABASE statement.

FORCE LOGGING
Use this clause to put the database into FORCE LOGGING mode. Oracle Database will log all changes in the database except for changes in temporary tablespaces and temporary segments. This setting takes precedence over and is independent of any NOLOGGING or FORCE LOGGING settings you specify for individual tablespaces and any NOLOGGING settings you specify for individual database objects.

FORCE LOGGING mode is persistent across instances of the database. If you shut down and restart the database, then the database is still in FORCE LOGGING mode. However, if you re-create the control file, then Oracle Database will take the database out of FORCE LOGGING mode unless you specify FORCE LOGGING in the CREATE CONTROLFILE statement.

Note: FORCE LOGGING mode can have performance effects. Refer to Oracle Database Administrator's Guide for information on when to use this setting.

See Also: CREATE CONTROLFILE on page 14-22

tablespace_clauses
Use the tablespace clauses to configure the SYSTEM and SYSAUX tablespaces and to specify a default temporary tablespace and an undo tablespace.

extent_management_clause
Use this clause to create a locally managed SYSTEM tablespace. If you omit this clause, then the SYSTEM tablespace will be dictionary managed.

Caution: When you create a locally managed SYSTEM tablespace, you cannot change it to be dictionary managed, nor can you create any other dictionary-managed tablespaces in this database.

If you specify this clause, then the database must have a default temporary tablespace, because a locally managed SYSTEM tablespace cannot store temporary segments.

- If you specify EXTENT MANAGEMENT LOCAL but you do not specify the DATAFILE clause, then you can omit the default_temp_tablespace clause. Oracle Database will create a default temporary tablespace called TEMP with one data file of size 10M with autoextend disabled.

- If you specify both EXTENT MANAGEMENT LOCAL and the DATAFILE clause, then you must also specify the default_temp_tablespace clause and explicitly specify a temp file for that temporary tablespace.

If you have opened the instance in automatic undo mode, similar requirements exist for the database undo tablespace:

- If you specify EXTENT MANAGEMENT LOCAL but you do not specify the DATAFILE clause, then you can omit the undo_tablespace clause. Oracle Database will create an undo tablespace named SYS_UNDOTBS.
If you specify both `EXTENT MANAGEMENT LOCAL` and the `DATAFILE` clause, then you must also specify the `undo_tablespace` clause and explicitly specify a data file for that tablespace.

**See Also:** *Oracle Database Administrator’s Guide* for more information on locally managed and dictionary-managed tablespaces

**DATAFILE Clause**

Specify one or more files to be used as data files. All these files become part of the `SYSTEM` tablespace. Use the data `file_tempfile_spec` form of `file_specification` to create regular data files and temp files in an operating system file system or to create Oracle ASM disk group files.

**Caution:** This clause is optional, as is the `DATAFILE` clause of the `undo_tablespace` clause. Therefore, to avoid ambiguity, if your intention is to specify a data file for the `SYSTEM` tablespace with this clause, then do not specify it immediately after an `undo_tablespace` clause that does not include the optional `DATAFILE` clause. If you do so, then Oracle Database will interpret the `DATAFILE` clause to be part of the `undo_tablespace` clause.

The syntax for specifying data files for the `SYSTEM` tablespace is the same as that for specifying data files during tablespace creation using the `CREATE TABLESPACE` statement, whether you are storing files using Oracle ASM or in a file system.

**See Also:** `CREATE TABLESPACE` on page 16-102 for information on specifying data files

If you are running the database in automatic undo mode and you specify a data file name for the `SYSTEM` tablespace, then Oracle Database expects to generate data files for all tablespaces. Oracle Database does this automatically if you are using Oracle Managed Files—you have set a value for the `DB_CREATE_FILE_DEST` initialization parameter. However, if you are not using Oracle Managed Files and you specify this clause, then you must also specify the `undo_tablespace` clause and the `default_temp_tablespace` clause.

If you omit this clause, then:

- If the `DB_CREATE_FILE_DEST` initialization parameter is set, then Oracle Database creates a 100 MB Oracle-managed data file with a system-generated name in the default file destination specified in the parameter.
- If the `DB_CREATE_FILE_DEST` initialization parameter is not set, then Oracle Database creates one data file whose name and size depend on your operating system.

**See Also:** `file_specification` on page 8-29 for syntax

**SYSAUX Clause**

Oracle Database creates both the `SYSTEM` and `SYSAUX` tablespaces as part of every database. Use this clause if you are not using Oracle Managed Files and you want to specify one or more data files for the `SYSAUX` tablespace.

You must specify this clause if you have specified one or more data files for the `SYSTEM` tablespace using the `DATAFILE` clause. If you are using Oracle Managed Files and you
omitting this clause, then the database creates the SYSAUX data files in the default location set up for Oracle Managed Files.

If you have enabled Oracle Managed Files and you omit the SYSAUX clause, then the database creates the SYSAUX tablespace as an online, permanent, locally managed tablespace with one data file of 100 MB, with logging enabled and automatic segment-space management.

The syntax for specifying data files for the SYSAUX tablespace is the same as that for specifying data files during tablespace creation using the CREATE TABLESPACE statement, whether you are storing files using Oracle ASM or in a file system.

**See Also:**
- CREATE TABLESPACE on page 16-102 for information on creating the SYSAUX tablespace during database upgrade and for information on specifying data files in a tablespace
- Oracle Database Administrator’s Guide for more information on creating the SYSAUX tablespace

**default_tablespace**

Specify this clause to create a default permanent tablespace for the database. Oracle Database creates a smallfile tablespace and subsequently will assign to this tablespace any non-SYSTEM users for whom you do not specify a different permanent tablespace. If you do not specify this clause, then the SYSTEM tablespace is the default permanent tablespace for non-SYSTEM users.

The DATAFILE clause and extent_management_clause have the same semantics they have in a CREATE TABLESPACE statement. Refer to "DATAFILE | TEMPFILE Clause" on page 16-107 and extent_management_clause on page 16-111 for information on these clauses.

**default_temp_tablespace**

Specify this clause to create a default temporary tablespace for the database. Oracle Database will assign to this temporary tablespace any users for whom you do not specify a different temporary tablespace. If you do not specify this clause, and if the database does not create a default temporary tablespace automatically in the process of creating a locally managed SYSTEM tablespace, then the SYSTEM tablespace is the default temporary tablespace.

Specify BIGFILE or SMALLFILE to determine whether the default temporary tablespace is a bigfile or smallfile tablespace. These clauses have the same semantics as in the "SET DEFAULT TABLESPACE Clause" on page 14-34.

The TEMPFILE clause part of this clause is optional if you have enabled Oracle Managed Files by setting the DB_CREATE_FILE_DEST initialization parameter. If you have not specified a value for this parameter, then the TEMPFILE clause is required. If you have specified BIGFILE, then you can specify only one temp file in this clause.

The syntax for specifying temp files for the default temporary tablespace is the same as that for specifying temp files during temporary tablespace creation using the CREATE TABLESPACE statement, whether you are storing files using Oracle ASM or in a file system.

**See Also:** CREATE TABLESPACE on page 16-102 for information on specifying temp files
**Note:** On some operating systems, Oracle does not allocate space for a temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. To avoid potential problems, before you create or resize a temp file, ensure that the available disk space exceeds the size of the new temp file or the increased size of a resized temp file. The excess space should allow for anticipated increases in disk space use by unrelated operations as well. Then proceed with the creation or resizing operation.

**Restrictions on Default Temporary Tablespaces** Default temporary tablespaces are subject to the following restrictions:

- You cannot specify the `SYSTEM` tablespace in this clause.
- The default temporary tablespace must have a standard block size.

The `extent_management_clause` clause has the same semantics in `CREATE DATABASE` and `CREATE TABLESPACE` statements. For complete information, refer to the `CREATE TABLESPACE` ... `extent_management_clause` on page 16-111.

**undo_tablespace**

If you have opened the instance in automatic undo mode (the `UNDO_MANAGEMENT` initialization parameter is set to `AUTO`, which is the default), then you can specify the `undo_tablespace` to create a tablespace to be used for undo data. Oracle strongly recommends that you use automatic undo mode. However, if you want undo space management to be handled by way of rollback segments, then you must omit this clause. You can also omit this clause if you have set a value for the `UNDO_TABLESPACE` initialization parameter. If that parameter has been set, and if you specify this clause, then `tablespace` must be the same as that parameter value.

- Specify `BIGFILE` if you want the undo tablespace to be a bigfile tablespace. A bigfile tablespace contains only one data file, which can be up to 8 exabytes (8 million terabytes) in size.
- Specify `SMALLFILE` if you want the undo tablespace to be a smallfile tablespace. A smallfile tablespace is a traditional Oracle Database tablespace, which can contain 1022 data files or temp files, each of which can contain up to approximately 4 million ($2^{22}$) blocks.
- The `DATAFILE` clause part of this clause is optional if you have enabled Oracle Managed Files by setting the `DB_CREATE_FILE_DEST` initialization parameter. If you have not specified a value for this parameter, then the `DATAFILE` clause is required. If you have specified `BIGFILE`, then you can specify only one data file in this clause.

The syntax for specifying data files for the undo tablespace is the same as that for specifying data files during tablespace creation using the `CREATE TABLESPACE` statement, whether you are storing files using Oracle ASM or in a file system.

**See Also:** `CREATE TABLESPACE` on page 16-102 for information on specifying data files

If you specify this clause, then Oracle Database creates an undo tablespace named `tablespace`, creates the specified data file(s) as part of the undo tablespace, and
assigns this tablespace as the undo tablespace of the instance. Oracle Database will manage undo data using this undo tablespace. The DATAFILE clause of this clause has the same behavior as described in "DATAFILE Clause" on page 14-37.

If you have specified a value for the UNDO_TABLESPACE initialization parameter in your initialization parameter file before mounting the database, then you must specify the same name in this clause. If these names differ, then Oracle Database will return an error when you open the database.

If you omit this clause, then Oracle Database creates a default database with a default smallfile undo tablespace named SYS_UNDOTBS and assigns this default tablespace as the undo tablespace of the instance. This undo tablespace allocates disk space from the default files used by the CREATE DATABASE statement, and it has an initial extent of 10M. Oracle Database handles the system-generated data file as described in "DATAFILE Clause" on page 14-37. If Oracle Database is unable to create the undo tablespace, then the entire CREATE DATABASE operation fails.

See Also:
- Oracle Database Administrator’s Guide for information on automatic undo management and undo tablespaces
- CREATE TABLESPACE on page 16-102 for information on creating an undo tablespace after database creation

**set_time_zone_clause**

Use the SET TIME_ZONE clause to set the time zone of the database. You can specify the time zone in two ways:

- By specifying a displacement from UTC (Coordinated Universal Time—formerly Greenwich Mean Time). The valid range of \( hh:mm \) is -12:00 to +14:00.
- By specifying a time zone region. To see a listing of valid time zone region names, query the TZNAME column of the V$TIMEZONE_NAMES dynamic performance view.

---

**Note:** Oracle recommends that you set the database time zone to UTC (0:00). Doing so can improve performance, especially across databases, as no conversion of time zones will be required.

---

See Also: Oracle Database Reference for information on the dynamic performance views

Oracle Database normalizes all TIMESTAMP WITH LOCAL TIME ZONE data to the time zone of the database when the data is stored on disk. If you do not specify the SET TIME_ ZONE clause, then the database uses the operating system time zone of the server. If the operating system time zone is not a valid Oracle Database time zone, then the database time zone defaults to UTC.

**USER_DATA TABLESPACE Clause**

This clause lets you create a tablespace that is used for storing user data and database options such as Oracle XML DB.

- If you specify this clause when creating a multitenant container database (CDB), then the tablespace is created as part of the seed. Pluggable databases (PDBs) subsequently created using the seed will include this tablespace and its data file. The tablespace and data file specified in this clause are not used by the root.
If you specify this clause when creating a non-CDB, then the tablespace is created as part of the non-CDB.

Specify `BIGFILE` or `SMALLFILE` to determine whether the tablespace is a bigfile or smallfile tablespace. If you omit these clauses, then Oracle Database creates a tablespace of the type that you specify with the `SET DEFAULT TABLESPACE` clause. If you do not specify the `SET DEFAULT TABLESPACE` clause, then Oracle Database creates a smallfile tablespace. These clauses have the same semantics as in the "SET DEFAULT TABLESPACE Clause" on page 14-34.

Use the `datafile_tempfile_spec` clause to specify one or more data files for the tablespace. Refer to `datafile_tempfile_spec` on page 8-31 for the full semantics of this clause.

**enable_pluggable_database**

Specify this clause to create a CDB. Before issuing the `CREATE DATABASE` statement, you must set the `ENABLE_PLUGGABLE_DATABASE` initialization parameter to `TRUE`. The `CREATE DATABASE` statement will create a CDB that contains a root and a seed container. You can then create PDBs in the CDB by using the `CREATE PLUGGABLE DATABASE` statement. If you omit the `enable_pluggable_database` clause, then a non-CDB is created and it can never contain any containers.

**See Also:**

- *Oracle Database Administrator’s Guide* for the complete steps for creating a CDB
- `CREATE PLUGGABLE DATABASE` on page 15-61
- "Creating a CDB: Example" on page 14-42

**file_name_convert**

Use the `file_name_convert` clause to determine how the database generates the names of files (such as data files and wallet files) associated with the seed by using the names of files associated with the root.

- For `filename_pattern`, specify a string found in file names associated with the root.
- For `replacement_filename_pattern`, specify a replacement string.

Oracle Database will replace `filename_pattern` with `replacement_filename_pattern` when generating the names of files associated with the seed.

File name patterns cannot match files or directories managed by Oracle Managed Files.

You can specify `FILE_NAME_CONVERT = NONE`, which is the same as omitting this clause. If you omit this clause, then the database first attempts to use Oracle Managed Files to generate seed file names. If you are not using Oracle Managed Files, then the database uses the `PDB_FILE_NAME_CONVERT` initialization parameter to generate file names. If this parameter is not set, then an error occurs.

**tablespace_datafile_clauses**

Use these clauses to specify attributes for all data files comprising the `SYSTEM` and `SYSAUX` tablespaces in the seed PDB. If you do not specify `SIZE size_clause`, then the data file size for a given tablespace will be set to a predetermined fraction of the size of the corresponding root data file. If you do not specify the `autoextend_clause`, then those values are inherited from the root.
CREATE DATABASE

Refer to size_clause on page 8-47 and autoextend_clause on page 8-35 for the full semantics of these clauses.

Examples

Creating a Database: Example  The following statement creates a database and fully specifies each argument:

```sql
CREATE DATABASE sample
    CONTROLFILE REUSE
    LOGFILE
        GROUP 1 ('diskx:log1.log', 'disky:log1.log') SIZE 50K,
        GROUP 2 ('diskx:log2.log', 'disky:log2.log') SIZE 50K
    MAXLOGFILES 5
    MAXLOGHISTORY 100
    MAXDATAFILES 10
    MAXINSTANCES 2
    ARCHIVELOG
    CHARACTER SET AL32UTF8
    NATIONAL CHARACTER SET AL16UTF16
    DATAFILE
        'disk1:df1.dbf' AUTOEXTEND ON,
        'disk2:df2.dbf' AUTOEXTEND ON NEXT 10M MAXSIZE UNLIMITED
    DEFAULT TEMPORARY TABLESPACE temp_ts
    UNDO TABLESPACE undo_ts
    SET TIME_ZONE = '+02:00';
```

This example assumes that you have enabled Oracle Managed Files by specifying a value for the DB_CREATE_FILE_DEST parameter in your initialization parameter file. Therefore no file specification is needed for the DEFAULT TEMPORARY TABLESPACE and UNDO TABLESPACE clauses.

Creating a CDB: Example  The following statement creates a CDB newcdb. The ENABLE PLUGGABLE DATABASE clause indicates that a CDB is being created. The CDB will contain a root (CDB$ROOT) and a seed (PDB$SEED). The FILE_NAME_CONVERT clause specifies that names of files for the seed will be generated by replacing /u01/app/oracle/oradata/newcdb in the names of files associated with the root with /u01/app/oracle/oradata/pdbseed.

```sql
CREATE DATABASE newcdb
    USER SYS IDENTIFIED BY sys_password
    USER SYSTEM IDENTIFIED BY system_password
    LOGFILE GROUP 1 ('/u01/logs/my/redo01a.log','/u02/logs/my/redo01b.log')
        SIZE 100M BLOCKSIZE 512,
        GROUP 2 ('/u01/logs/my/redo02a.log','/u02/logs/my/redo02b.log')
        SIZE 100M BLOCKSIZE 512,
        GROUP 3 ('/u01/logs/my/redo03a.log','/u02/logs/my/redo03b.log')
        SIZE 100M BLOCKSIZE 512
    MAXLOGFILES 16
    MAXLOGMEMBERS 3
    MAXDATAFILES 1024
    CHARACTER SET AL32UTF8
    NATIONAL CHARACTER SET AL16UTF16
    EXTENT MANAGEMENT LOCAL
    DATAFILE '/u01/app/oracle/oradata/newcdb/system01.dbf'
        SIZE 700M REUSE AUTOEXTEND ON NEXT 10240K MAXSIZE UNLIMITED
    SYSAUX DATAFILE '/u01/app/oracle/oradata/newcdb/sysaux01.dbf'
        SIZE 550M REUSE AUTOEXTEND ON NEXT 10240K MAXSIZE UNLIMITED
```

14-42  Oracle Database SQL Language Reference
CREATE DATABASE

SQL Statements: CREATE AUDIT POLICY to CREATE JAVA

DEFAULT TABLESPACE deftbs
  DATAFILE '/u01/app/oracle/oradata/newcdb/deftbs01.dbf'
  SIZE 500M REUSE AUTOEXTEND ON MAXSIZE UNLIMITED

SQL Statements: CREATE AUDIT POLICY to CREATE JAVA   14-43
CREATE DATABASE LINK

Purpose

Use the CREATE DATABASE LINK statement to create a database link. A database link is a schema object in one database that enables you to access objects on another database. The other database need not be an Oracle Database system. However, to access non-Oracle systems you must use Oracle Heterogeneous Services.

After you have created a database link, you can use it in SQL statements to refer to tables, views, and PL/SQL objects in the other database by appending @dblink to the table, view, or PL/SQL object name. You can query a table or view in the other database with the SELECT statement. You can also access remote tables and views using any INSERT, UPDATE, DELETE, or LOCK TABLE statement.

See Also:

- Oracle Database Development Guide for information about accessing remote tables or views with PL/SQL functions, procedures, packages, and data types
- Oracle Database Administrator’s Guide for information on distributed database systems
- Oracle Database Reference for descriptions of existing database links in the ALL_DB_LINKS, DBA_DB_LINKS, and USER_DB_LINKS data dictionary views and for information on monitoring the performance of existing links through the V$DBLINK dynamic performance view
- ALTER DATABASE LINK on page 10-73 for information on altering a database link when the password of a connection or authentication user changes.
- DROP DATABASE LINK on page 17-44 for information on dropping existing database links
- INSERT on page 18-62, UPDATE on page 19-93, DELETE on page 17-28, and LOCK TABLE on page 18-79 for using links in DML operations

Prerequisites

To create a private database link, you must have the CREATE DATABASE LINK system privilege. To create a public database link, you must have the CREATE PUBLIC DATABASE LINK system privilege. Also, you must have the CREATE SESSION system privilege on the remote Oracle Database.

Oracle Net must be installed on both the local and remote Oracle Databases.
Syntax

```
create_database_link ::= 
CREATE [SHARED] [PUBLIC] DATABASE LINK dblink

  dblink_authentication ::= 
  CONNECT TO CURRENT_USER
  user [IDENTIFIED BY password] dblink_authentication

  USING connect_string

(dblink ::= on page 2-126)
```

Semantics

**PUBLIC**
Specify `PUBLIC` to create a public database link visible to all users. If you omit this clause, then the database link is private and is available only to you.

The data accessible on the remote database depends on the identity the database link uses when connecting to the remote database:

- If you specify `CONNECT TO user IDENTIFIED BY password`, then the database link connects with the specified user and password.
- If you specify `CONNECT TO CURRENT_USER`, then the database link connects with the user in effect based on the scope in which the link is used.
- If you omit both of those clauses, then the database link connects to the remote database as the locally connected user.

See Also: "Defining a Public Database Link: Example" on page 14-47

**SHARED**
Specify `SHARED` to create a database link that can be shared by multiple sessions using a single network connection from the source database to the target database. In a shared server configuration, shared database links can keep the number of connections into the remote database from becoming too large. Shared links are typically also public database links. However, a shared private database link can be useful when many clients access the same local schema, and therefore use the same private database link.

In a shared database link, multiple sessions in the source database share the same connection to the target database. Once a session is established on the target database, that session is disassociated from the connection, to make the connection available to another session on the source database. To prevent an unauthorized session from
attempting to connect through the database link, when you specify SHARED you must also specify the `dblink_authentication` clause for the users authorized to use the database link.

**See Also:**  *Oracle Database Administrator’s Guide* for more information about shared database links

**dblink**
Specify the complete or partial name of the database link. If you specify only the database name, then Oracle Database implicitly appends the database domain of the local database.

Use only ASCII characters for `dblink`. Multibyte characters are not supported. The database link name is case insensitive and is stored in uppercase ASCII characters. If you specify the database name as a quoted identifier, then the quotation marks are silently ignored.

If the value of the `GLOBAL_NAMES` initialization parameter is `TRUE`, then the database link must have the same name as the database to which it connects. If the value of `GLOBAL_NAMES` is `FALSE`, and if you have changed the global name of the database, then you can specify the global name.

The maximum number of database links that can be open in one session or one instance of an Oracle RAC configuration depends on the value of the `OPEN_LINKS` and `OPEN_LINKS_PER_INSTANCE` initialization parameters.

**Restriction on Creating Database Links**  You cannot create a database link in another user's schema, and you cannot qualify `dblink` with the name of a schema. Periods are permitted in names of database links, so Oracle Database interprets the entire name, such as `ralph.linktosales`, as the name of a database link in your schema rather than as a database link named `linktosales` in the schema `ralph`.)

**See Also:**  
- "References to Objects in Remote Databases" on page 2-126 for guidelines for naming database links
- *Oracle Database Reference* for information on the `GLOBAL_NAMES`, `OPEN_LINKS`, and `OPEN_LINKS_PER_INSTANCE` initialization parameters
- "RENAME GLOBAL_NAME Clause" on page 10-67 (an ALTER `DATABASE` clause) for information on changing the database global name

**CONNECT TO Clause**
The `CONNECT TO` clause lets you specify the user and credentials, if any, to be used to connect to the remote database.

**CURRENT_USER Clause**
Specify `CURRENT_USER` to create a current user database link. The current user must be a global user with a valid account on the remote database.

If the database link is used directly rather than from within a stored object, then the current user is the same as the connected user.

When executing a stored object (such as a procedure, view, or trigger) that initiates a database link, `CURRENT_USER` is the name of the user that owns the stored object, and...
not the name of the user that called the object. For example, if the database link
appears inside procedure \texttt{scott.p} (created by \texttt{scott}), and user \texttt{jane} calls procedure
\texttt{scott.p}, then \texttt{the current user is scott}.

However, if the stored object is an invoker-rights function, procedure, or package, then
the invoker’s authorization ID is used to connect as a remote user. For example, if the
privileged database link appears inside procedure \texttt{scott.p} (an invoker-rights
procedure created by \texttt{scott}), and user \texttt{jane} calls procedure \texttt{scott.p}, then \texttt{CURRENT_USER is jane} and the procedure executes with Jane's privileges.

\textbf{See Also:}

- \texttt{CREATE FUNCTION on page 14-71} for more information on
  invoker-rights functions
- "Defining a CURRENT_USER Database Link: Example" on
  page 14-48

\texttt{user IDENTIFIED BY password}

Specify the user name and password used to connect to the remote database using a
\textbf{fixed user database link}. If you omit this clause, then the database link uses the user
name and password of each user who is connected to the database. This is called a
\textbf{connected user database link}.

\textbf{See Also:}  "Defining a Fixed-User Database Link: Example" on
page 14-48

\texttt{dblink_authentication}

You can specify this clause only if you are creating a shared database link—that is, you
have specified the \texttt{SHARED} clause. Specify the username and password on the target
instance. This clause authenticates the user to the remote server and is required for
security. The specified username and password must be a valid username and
password on the remote instance. The username and password are used only for
authentication. No other operations are performed on behalf of this user.

\texttt{USING 'connect string'}

Specify the service name of a remote database. If you specify only the database name,
then Oracle Database implicitly appends the database domain to the connect string to
create a complete service name. Therefore, if the database domain of the remote
database is different from that of the current database, then you must specify the
complete service name.

\textbf{See Also:}  \textit{Oracle Database Administrator’s Guide} for information on
specifying remote databases

\textbf{Examples}

The examples that follow assume two databases, one with the database name \texttt{local}
and the other with the database name \texttt{remote}. The examples use the Oracle Database
domain. Your database domain will be different.

\textbf{Defining a Public Database Link: Example}  The following statement defines a shared
public database link named \texttt{remote} that refers to the database specified by the service
name \texttt{remote}:

\begin{verbatim}
CREATE PUBLIC DATABASE LINK remote
   USING 'remote';
\end{verbatim}
This database link allows user hr on the local database to update a table on the remote database (assuming hr has appropriate privileges):

```
UPDATE employees@remote
    SET salary=salary*1.1
WHERE last_name = 'Baer';
```

**Defining a Fixed-User Database Link: Example**  In the following statement, user hr on the remote database defines a fixed-user database link named local to the hr schema on the local database:

```
CREATE DATABASE LINK local
    CONNECT TO hr IDENTIFIED BY password
    USING 'local';
```

After this database link is created, hr can query tables in the schema hr on the local database in this manner:

```
SELECT * FROM employees@local;
```

User hr can also use DML statements to modify data on the local database:

```
INSERT INTO employees@local
    (employee_id, last_name, email, hire_date, job_id)
VALUES (999, 'Claus', 'sclaus@example.com', SYSDATE, 'SH_CLERK');
```

```
UPDATE jobs@local SET min_salary = 3000
WHERE job_id = 'SH_CLERK';
```

```
DELETE FROM employees@local
    WHERE employee_id = 999;
```

Using this fixed database link, user hr on the remote database can also access tables owned by other users on the same database. This statement assumes that user hr has the READ or SELECT privilege on the oe.customers table. The statement connects to the user hr on the local database and then queries the oe.customers table:

```
SELECT * FROM oe.customers@local;
```

**Defining a CURRENT_USER Database Link: Example** The following statement defines a current-user database link to the remote database, using the entire service name as the link name:

```
CREATE DATABASE LINK remote.us.example.com
    CONNECT TO CURRENT_USER
    USING 'remote';
```

The user who issues this statement must be a global user registered with the LDAP directory service.

You can create a synonym to hide the fact that a particular table is on the remote database. The following statement causes all future references to emp_table to access the employees table owned by hr on the remote database:

```
CREATE SYNONYM emp_table
    FOR oe.employees@remote.us.example.com;
```
CREATE DIMENSION

Purpose

Use the CREATE DIMENSION statement to create a dimension. A dimension defines a parent-child relationship between pairs of column sets, where all the columns of a column set must come from the same table. However, columns in one column set (called a level) can come from a different table than columns in another set. The optimizer uses these relationships with materialized views to perform query rewrite. The SQL Access Advisor uses these relationships to recommend creation of specific materialized views.

Note: Oracle Database does not automatically validate the relationships you declare when creating a dimension. To validate the relationships specified in the hierarchy_clause and the dimension_join_clause of CREATE DIMENSION, you must run the DBMS_OLAP.VALIDATE_DIMENSION procedure.

See Also:
- CREATE MATERIALIZED VIEW on page 15-4 for more information on materialized views
- Oracle Database SQL Tuning Guide for more information on query rewrite, the optimizer and the SQL Access Advisor

Prerequisites

To create a dimension in your own schema, you must have the CREATE DIMENSION system privilege. To create a dimension in another user’s schema, you must have the CREATE ANY DIMENSION system privilege. In either case, you must have the READ or SELECT object privilege on any objects referenced in the dimension.

Syntax

```sql
create_dimension ::= 
```

```sql
level_clause ::= 
```

SQL Statements: CREATE AUDIT POLICY to CREATE JAVA  14-49
**hierarchy_clause**:=

```
HIERARCHY hierarchy (child_level CHILD OF parent_level)
```

**dimension_join_clause**:=

```
JOIN KEY child_key_column REFERENCES parent_level
```

**attribute_clause**:=

```
ATTRIBUTE level DETERMINES dependent_column
```

**extended_attribute_clause**:=

```
ATTRIBUTE attribute LEVEL level DETERMINES dependent_column
```

**Semantics**

**schema**
Specify the schema in which the dimension will be created. If you do not specify `schema`, then Oracle Database creates the dimension in your own schema.

**dimension**
Specify the name of the dimension. The name must be unique within its schema and satisfy the requirements listed in "Database Object Naming Rules" on page 2-119.

**level_clause**
The `level_clause` defines a level in the dimension. A level defines dimension hierarchies and attributes.

**level** Specify the name of the level.

**level_table . level_column** Specify the columns in the level. You can specify up to 32 columns. The tables you specify in this clause must already exist.

**SKIP WHEN NULL** Specify this clause to indicate that if the specified level is NULL, then the level is to be skipped. This clause lets you preserve the hierarchical chain of parent-child relationship by an alternative path that skips over the specified level. See `hierarchy_clause` on page 14-51.
Restrictions on Dimension Level Columns  Dimension level columns are subject to the following restrictions:

- All of the columns in a level must come from the same table.
- If columns in different levels come from different tables, then you must specify the `dimension_join_clause`.
- The set of columns you specify must be unique to this level.
- The columns you specify cannot be specified in any other dimension.
- Each `level_column` must be non-null unless the level is specified with `SKIP WHEN NULL`. The non-null columns need not have `NOT NULL` constraints. The column for which you specify `SKIP WHEN NULL` cannot have a `NOT NULL` constraint).

**hierarchy_clause**
The `hierarchy_clause` defines a linear hierarchy of levels in the dimension. Each hierarchy forms a chain of parent-child relationships among the levels in the dimension. Hierarchies in a dimension are independent of each other. They may, but need not, have columns in common.

Each level in the dimension should be specified at most once in this clause, and each level must already have been named in the `level_clause`.

**hierarchy**  Specify the name of the hierarchy. This name must be unique in the dimension.

**child_level**  Specify the name of a level that has an n:1 relationship with a parent level. The `level_columns` of `child_level` cannot be null, and each `child_level` value uniquely determines the value of the next named `parent_level`.

If the child `level_table` is different from the parent `level_table`, then you must specify a join relationship between them in the `dimension_join_clause`.

**parent_level**  Specify the name of a level.

**dimension_join_clause**
The `dimension_join_clause` lets you specify an inner equijoin relationship for a dimension whose columns are contained in multiple tables. This clause is required and permitted only when the columns specified in the hierarchy are not all in the same table.

**child_key_column**
Specify one or more columns that are join-compatible with columns in the parent level.

If you do not specify the schema and table of each `child_column`, then the schema and table are inferred from the `CHILD OF` relationship in the `hierarchy_clause`. If you do specify the schema and column of a `child_key_column`, then the schema and table must match the schema and table of columns in the child of `parent_level` in the `hierarchy_clause`.

**parent_level**  Specify the name of a level.

Restrictions on Join Dimensions  Join dimensions are subject to the following restrictions:
CREATE DIMENSION

- You can specify only one `dimension_join_clause` for a given pair of levels in the same hierarchy.
- The `child_key_columns` must be non-null, and the parent key must be unique and non-null. You need not define constraints to enforce these conditions, but queries may return incorrect results if these conditions are not true.
- Each child key must join with a key in the `parent_level` table.
- Self-joins are not permitted. The `child_key_columns` cannot be in the same table as `parent_level`.
- All of the child key columns must come from the same table.
- The number of child key columns must match the number of columns in `parent_level`, and the columns must be joinable.
- You cannot specify multiple child key columns unless the parent level consists of multiple columns.

**attribute_clause**

The `attribute_clause` lets you specify the columns that are uniquely determined by a hierarchy level. The columns in `level` must all come from the same table as the `dependent_columns`. The `dependent_columns` need not have been specified in the `level_clause`.

For example, if the hierarchy levels are `city`, `state`, and `country`, then `city` might determine `mayor`, `state` might determine `governor`, and `country` might determine `president`.

**extended_attribute_clause**

This clause lets you specify an attribute name for one or more level-to-column relations. The type of attribute you create with this clause is not different from the type of attribute created using the `attribute_clause`. The only difference is that this clause lets you assign a name to the attribute that is different from the level name.

**Examples**

**Creating a Dimension: Examples**  
This statement was used to create the `customers_dim` dimension in the sample schema `sh`:

```sql
CREATE DIMENSION customers_dim
    LEVEL customer IS (customers.cust_id)
    LEVEL city IS (customers.cust_city)
    LEVEL state IS (customers.cust_state_province)
    LEVEL country IS (countries.country_id)
    LEVEL subregion IS (countries.country_subregion)
    LEVEL region IS (countries.country_region)
    HIERARCHY geog_rollup {
        customer CHILD OF
        city     CHILD OF
        state    CHILD OF
        country  CHILD OF
        subregion CHILD OF
        region   CHILD OF
    }
    JOIN KEY (customers.country_id) REFERENCES country
    ATTRIBUTE customer DETERMINES
        (cust_first_name, cust_last_name, cust_gender,
```
CREATE DIMENSION

ALTER SQL Statements: CREATE AUDIT POLICY to CREATE JAVA

CREATE DIMENSION customers_dim
LEVEL customer IS (customers.cust_id)
LEVEL status IS (customers.cust_marital_status) SKIP WHEN NULL
LEVEL city IS (customers.cust_city)
LEVEL state IS (customers.cust_state_province)
LEVEL country IS (countries.country_id)
LEVEL subregion IS (countries.country_subregion) SKIP WHEN NULL
LEVEL region IS (countries.country_region)
HIERARCHY geog_rollup {
    customer CHILD OF
city CHILD OF
state CHILD OF
country CHILD OF
subregion CHILD OF
region
JOIN KEY (customers.country_id) REFERENCES country
}
ATTRIBUTE customer_info LEVEL customer DETERMINES (cust_first_name, cust_last_name, cust_gender,
cust_marital_status, cust_year_of_birth,
cust_income_level, cust_credit_limit)
ATTRIBUTE country DETERMINES (countries.country_name);

Creating a Dimension with Extended Attributes: Example

Alternatively, the extended_attribute_clause could have been used instead of the attribute_clause, as shown in the following example:

CREATE DIMENSION customers_dim
LEVEL customer IS (customers.cust_id)
LEVEL city IS (customers.cust_city)
LEVEL state IS (customers.cust_state_province)
LEVEL country IS (countries.country_id)
LEVEL subregion IS (countries.country_subregion)
LEVEL region IS (countries.country_region)
HIERARCHY geog_rollup {
    customer CHILD OF
city CHILD OF
state CHILD OF
country CHILD OF
subregion CHILD OF
region
JOIN KEY (customers.country_id) REFERENCES country
}
ATTRIBUTE customer_info LEVEL customer DETERMINES (cust_first_name, cust_last_name, cust_gender,
cust_marital_status, cust_year_of_birth,
cust_income_level, cust_credit_limit)
ATTRIBUTE country DETERMINES (countries.country_name);

Creating a Dimension with NULL Column Values: Example

The following example shows how to create the dimension if one of the level columns is null and you want to preserve the hierarchical chain. The example uses the cust_marital_status column for simplicity because it is not a NOT NULL column. If it had such a constraint, then you would have to disable the constraint before using the SKIP WHEN NULL clause.

CREATE DIMENSION customers_dim
LEVEL customer IS (customers.cust_id)
LEVEL status IS (customers.cust_marital_status) SKIP WHEN NULL
LEVEL city IS (customers.cust_city)
LEVEL state IS (customers.cust_state_province)
LEVEL country IS (countries.country_id)
LEVEL subregion IS (countries.country_subregion) SKIP WHEN NULL
LEVEL region IS (countries.country_region)
HIERARCHY geog_rollup {
    customer CHILD OF
city CHILD OF
state CHILD OF
country CHILD OF
subregion CHILD OF
region
JOIN KEY (customers.country_id) REFERENCES country
}
ATTRIBUTE customer_info LEVEL customer DETERMINES (cust_first_name, cust_last_name, cust_gender,
cust_marital_status, cust_year_of_birth,
cust_income_level, cust_credit_limit)
ATTRIBUTE country DETERMINES (countries.country_name);

SQL Statements: CREATE AUDIT POLICY to CREATE JAVA
CREATE DIRECTORY

Purpose

Use the CREATE DIRECTORY statement to create a directory object. A directory object specifies an alias for a directory on the server file system where external binary file LOBs (BFILEs) and external table data are located. You can use directory names when referring to BFILEs in your PL/SQL code and OCI calls, rather than hard coding the operating system path name, for management flexibility.

All directories are created in a single namespace and are not owned by an individual schema. You can secure access to the BFILEs stored within the directory structure by granting object privileges on the directories to specific users.

See Also:
- "Large Object (LOB) Data Types" on page 2-26 for more information on BFILE objects
- GRANT on page 18-35 for more information on granting object privileges
- external_table_clause::= of CREATE TABLE on page 16-21

Prerequisites

You must have the CREATE ANY DIRECTORY system privilege to create directories.

When you create a directory, you are automatically granted the READ, WRITE, and EXECUTE object privileges on the directory, and you can grant these privileges to other users and roles. The DBA can also grant these privileges to other users and roles.

WRITE privileges on a directory are useful in connection with external tables. They let the grantee determine whether the external table agent can write a log file or a bad file to the directory.

For file storage, you must also create a corresponding operating system directory, an Oracle Automatic Storage Management (Oracle ASM) disk group, or a directory within an Oracle ASM disk group. Your system or database administrator must ensure that the operating system directory has the correct read and write permissions for Oracle Database processes.

Privileges granted for the directory are created independently of the permissions defined for the operating system directory, and the two may or may not correspond exactly. For example, an error occurs if sample user hr is granted READ privilege on the directory object but the corresponding operating system directory does not have READ permission defined for Oracle Database processes.

Syntax

create_directory ::= 

\[
\text{CREATE} \quad \text{OR} \quad \text{REPLACE} \quad \text{DIRECTORY} \quad \text{directory} \quad \text{AS} \quad \text{path_name}\]

14-54 Oracle Database SQL Language Reference
Semantics

**OR REPLACE**
Specify **OR REPLACE** to re-create the directory database object if it already exists. You can use this clause to change the definition of an existing directory without dropping, re-creating, and regranting database object privileges previously granted on the directory.

Users who had previously been granted privileges on a redefined directory can still access the directory without being regranted the privileges.

**See Also:** **DROP DIRECTORY** on page 17-46 for information on removing a directory from the database

**directory**
Specify the name of the directory object to be created. The maximum length of **directory** is 30 bytes. You cannot qualify a directory object with a schema name.

Oracle Database does not verify that the directory you specify actually exists. Therefore, take care that you specify a valid directory in your operating system. In addition, if your operating system uses case-sensitive path names, then be sure you specify the directory in the correct format. You need not include a trailing slash at the end of the path name.

Do not refer to a parent directory in the directory name. For example, the following syntax is valid:

```
CREATE DIRECTORY mydir AS '/scratch/data/file_data';
```

However, the following syntax is not valid:

```
CREATE DIRECTORY mydir AS '/scratch/./file_data';
```

**path_name**
Specify the full path name of the operating system directory of the server where the files are located. The single quotation marks are required, with the result that the path name is case sensitive.

Examples

**Creating a Directory: Examples** The following statement creates a directory database object that points to a directory on the server:

```
CREATE DIRECTORY admin AS '/disk1/oracle/admin';
```

The following statement redefines directory database object **bfile_dir** to enable access to **BFILEs** stored in the operating system directory **/usr/bin/bfile_dir**:

```
CREATE OR REPLACE DIRECTORY bfile_dir AS '/usr/bin/bfile_dir';
```
CREATE DISKGROUP

Purpose

Use the CREATE DISKGROUP clause to name a group of disks and specify that Oracle Database should manage the group for you. Oracle Database manages a disk group as a logical unit and evenly spreads each file across the disks to balance I/O. Oracle Database also automatically distributes database files across all available disks in disk groups and rebalances storage automatically whenever the storage configuration changes.

This statement creates a disk group, assigns one or more disks to the disk group, and mounts the disk group for the first time. Note that CREATE DISKGROUP only mounts a disk group on the local node. If you want Oracle ASM to mount the disk group automatically in subsequent instances, then you must add the disk group name to the value of the ASM_DISKGROUPS initialization parameter in the initialization parameter file. If you use an SPFILE, then the disk group is added to the initialization parameter automatically.

See Also:

- ALTER DISKGROUP on page 10-78 for information on modifying disk groups
- Oracle Automatic Storage Management Administrator’s Guide for information on Oracle ASM and using disk groups to simplify database administration
- ASM_DISKGROUPS for more information about adding disk group names to the initialization parameter file
- V$ASM_OPERATION for information on monitoring Oracle ASM operations
- DROP DISKGROUP on page 17-47 for information on dropping a disk group

Prerequisites

You must have the SYSASM system privilege to issue this statement.

Before issuing this statement, you must format the disks using an operating system format utility. Also ensure that the Oracle Database user has read/write permission and the disks can be discovered using the ASM_DISKSTRING.

When you store your database files in Oracle ASM disk groups, rather than in a file system, before the database instance can access your files in the disk groups, you must configure and start up an Oracle ASM instance to manage the disk groups.
Each database instance communicates with a single Oracle ASM instance on the same node as the database. Multiple database instances on the same node can communicate with a single Oracle ASM instance.

**Syntax**

```sql
create_diskgroup ::= 
```

```sql
cREATE DISKGROUP diskgroup_name
```

```sql
<table>
<thead>
<tr>
<th>REDUNDANCY</th>
<th>HIGH</th>
<th>NORMAL</th>
<th>EXTERNAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUORUM</td>
<td>REGULAR</td>
<td>FAILGROUP</td>
<td>failgroup_name</td>
</tr>
<tr>
<td>DISK</td>
<td>qualified_disk_clause</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ATTRIBUTE</td>
<td>attribute_name</td>
<td>attribute_value</td>
<td></td>
</tr>
<tr>
<td>search_string</td>
<td>NAME</td>
<td>disk_name</td>
<td>SIZE</td>
</tr>
<tr>
<td>FORCE</td>
<td>NOFORCE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

*(size_clause ::= on page 8-47)*

**Semantics**

**diskgroup_name**

Specify the name of the disk group. Disk groups are subject to the same naming conventions and restrictions as database schema objects. Refer to "Database Object Naming Rules" on page 2-119 for information on database object names. However, disk groups are not schema objects. Disk group names are not case sensitive, even if you specify them with quotation marks. They are always stored internally as uppercase.

**Note:** Oracle does not recommend using quoted identifiers for disk group names. These quoted identifiers are accepted when issuing the `CREATE DISKGROUP` statement in SQL*Plus, but they may not be valid when using other tools that manage disk groups.

**REdundancy Clause**

The `REdundancy` clause lets you specify the redundancy level of the disk group.
NORMAL REDUNDANCY requires the existence of at least two failure groups (see the FAILGROUP clause that follows). Oracle ASM provides redundancy for all files in the disk group according to the attributes specified in the disk group templates. NORMAL REDUNDANCY disk groups can tolerate the loss of one group. Refer to ALTER DISKGROUP ... diskgroup_template_clauses on page 10-91 for more information on disk group templates.

NORMAL REDUNDANCY is the default if you omit the REDUNDANCY clause. Therefore, if you omit this clause, you must create at least two failure groups, or the create operation will fail.

HIGH REDUNDANCY requires the existence of at least three failure groups. Oracle ASM fixes mirroring at 3-way mirroring, with each extent getting two mirrored copies. HIGH REDUNDANCY disk groups can tolerate the loss of two failure groups.

EXTERNAL REDUNDANCY indicates that Oracle ASM does not provide any redundancy for the disk group. The disks within the disk group must provide redundancy (for example, using a storage array), or you must be willing to tolerate loss of the disk group if a disk fails (for example, in a test environment). You cannot specify the FAILGROUP clause if you specify EXTERNAL REDUNDANCY.

You cannot change the redundancy level after the disk group has been created.

QUORUM | REGULAR
Use these keywords to qualify either failure group or disk specifications.

- REGULAR disks, or disks in non-quorum failure groups, can contain any files.
- QUORUM disks, or disks in quorum failure groups, cannot contain any database files, the Oracle Cluster Registry (OCR), or dynamic volumes. However, QUORUM disks can contain the voting file for Cluster Synchronization Services (CSS). Oracle ASM uses quorum disks or disks in quorum failure groups for voting files whenever possible.

Disks in quorum failure groups are not considered when determining redundancy requirements.

If you specify neither keyword, then REGULAR is the default.

Specify either QUORUM or REGULAR before the keyword FAILGROUP if you are explicitly specifying the failure group. If you are creating a disk group with implicitly created failure groups, then specify these keywords before the keyword DISK.

See Also: Oracle Automatic Storage Management Administrator’s Guide for more information about quorum and regular disks and failure groups

FAILGROUP Clause
Use this clause to specify a name for one or more failure groups. If you omit this clause, and you have specified NORMAL or HIGH REDUNDANCY, then Oracle Database automatically adds each disk in the disk group to its own failure group. The implicit name of the failure group is the same as the operating system independent disk name (see "NAME Clause" on page 14-59).

You cannot specify this clause if you are creating an EXTERNAL REDUNDANCY disk group.

qualified_disk_clause
Specify DISK qualified_disk_clause to add a disk to a disk group.
**search_string** For each disk you are adding to the disk group, specify the operating system dependent search string that Oracle ASM will use to find the disk. The search_string must point to a subset of the disks returned by discovery using the strings in the `ASM_DISKSTRING` initialization parameter. If search_string does not point to any disks the Oracle Database user has read/write access to, then Oracle ASM returns an error. If it points to one or more disks that have already been assigned to a different disk group, then Oracle Database returns an error unless you also specify `FORCE`.

For each valid candidate disk, Oracle ASM formats the disk header to indicate that it is a member of the new disk group.

**See Also:** The `ASM_DISKSTRING` initialization parameter for more information on specifying the search string

**NAME Clause** The `NAME` clause is valid only if the search_string points to a single disk. This clause lets you specify an operating system independent name for the disk. The name can be up to 30 alphanumeric characters. The first character must be alphabetic. If you omit this clause and you assigned a label to a disk through ASMLIB, then that label is used as the disk name. If you omit this clause and you did not assign a label through ASMLIB, then Oracle ASM creates a default name of the form `diskgroupname_####`, where #### is the disk number. You use this name to refer to the disk in subsequent Oracle ASM operations.

**SIZE Clause** Use this clause to specify in bytes the size of the disk. If you specify a size greater than the capacity of the disk, then Oracle ASM returns an error. If you specify a size less than the capacity of the disk, then you limit the disk space Oracle ASM will use. The size value must be identical for all disks in a disk group. If you omit this clause, then Oracle ASM attempts programmatically to determine the size of the disk.

**FORCE** Specify `FORCE` if you want Oracle ASM to add the disk to the disk group even if the disk is already a member of a different disk group.

---

**Caution:** Using `FORCE` in this way may destroy existing disk groups.

For this clause to be valid, the disk must already be a member of a disk group and the disk cannot be part of a mounted disk group.

**NOFORCE** Specify `NOFORCE` if you want Oracle ASM to return an error if the disk is already a member of a different disk group. `NOFORCE` is the default.

**ATTRIBUTE Clause** Use this clause to set attribute values for the disk group. You can view the current attribute values by querying the `V$ASM_ATTRIBUTE` view. Table 14–2 lists the attributes you can set with this clause. All attribute values are strings.
### Disk Group Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Valid Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS_CONTROL.ENABLED</td>
<td>true or false</td>
<td>Specifies whether Oracle ASM File Access Control is enabled for a disk group. If set to true, accessing Oracle ASM files is subject to access control. If false, any user can access every file in the disk group. All other operations behave independently of this attribute. The default value is false. If both the compatible.rdbms and compatible.asm attributes are set to at least 11.2, you can set this attribute in an ALTER_DISKGROUP ... SET ATTRIBUTE statement. You cannot set this attribute when creating a disk group. When you set up file access control on an existing disk group, the files previously created remain accessible by everyone, unless you run the ALTER_DISKGROUP SET PERMISSION statement to restrict the permissions. <strong>Note:</strong> This attribute is used in conjunction with ACCESS_CONTROL.UMASK to manage Oracle ASM File Access Control. After setting the ACCESS_CONTROL.ENABLED disk attribute, you must set permissions with the ACCESS_CONTROL.UMASK attribute.</td>
</tr>
<tr>
<td>ACCESS_CONTROL.UMASK</td>
<td>A three-digit number where each digit is 0, 2, or 6.</td>
<td>Determines which permissions are masked out on the creation of an Oracle ASM file for the user that owns the file (first digit), users in the same user group (second digit), and others not in the user group (third digit). This attribute applies to all files on a disk group. Setting 0 masks out nothing. Setting to 2 masks out write permission. Setting to 6 masks out both read and write permissions. The default value is 066. If both the compatible.rdbms and compatible.asm attributes are set to at least 11.2, you can set this attribute in an ALTER_DISKGROUP ... SET ATTRIBUTE statement. You cannot set this attribute when creating a disk group. When you set up file access control on an existing disk group, the files previously created remain accessible by everyone, unless you run the ALTER_DISKGROUP SET PERMISSION statement to restrict the permissions. <strong>Note:</strong> This attribute is used in conjunction with ACCESS_CONTROL.ENABLED to manage Oracle ASM File Access Control. Before setting ACCESS_CONTROL.UMASK, you must set ACCESS_CONTROL.ENABLED to true.</td>
</tr>
<tr>
<td>AU_SIZE</td>
<td>Size in bytes. Valid values are powers of 2 from 1M to 64M. Examples '4M', '4194304'.</td>
<td>Specifies the allocation unit size. This attribute can be set only during disk group creation; it cannot be modified with an ALTER_DISKGROUP statement.</td>
</tr>
<tr>
<td>COMPATIBLE.ADVM</td>
<td>Valid Oracle Database version number¹</td>
<td>Determines whether the disk group can contain Oracle ADVM volumes. The value must be set to 11.2 or higher. Before setting this attribute, the COMPATIBLE.ASM value must be 11.2 or higher. Also, the Oracle ADVM volume drivers must be loaded. By default, the value of the COMPATIBLE.ADVM attribute is empty until set.</td>
</tr>
</tbody>
</table>
**Table 14–2 (Cont.) Disk Group Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Valid Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPATIBLE.ASM</td>
<td>Valid Oracle Database version number 1</td>
<td>Determines the minimum software version for an Oracle ASM instance that can use the disk group. This setting also affects the format of the data structures for the Oracle ASM metadata on the disk. For Oracle ASM in Oracle Database 11g, 10.1 is the default setting for the COMPATIBLE.ASM attribute when using the SQL CREATE DISKGROUP statement, the ASMCMD mkdg command, and Oracle Enterprise Manager Create Disk Group page. When creating a disk group with ASMCA, the default setting is 11.2.</td>
</tr>
<tr>
<td>COMPATIBLE.RDBMS</td>
<td>Valid Oracle Database version number 1</td>
<td>Determines the minimum COMPATIBLE database initialization parameter setting for any database instance that is allowed to use the disk group. Before advancing the COMPATIBLE.RDBMS attribute, ensure that the values for the COMPATIBLE initialization parameter for all of the databases that access the disk group are set to at least the value of the new setting for COMPATIBLE.RDBMS. For example, if the COMPATIBLE initialization parameters of the databases are set to either 11.1 or 11.2, then COMPATIBLE.RDBMS can be set to any value between 10.1 and 11.1 inclusively. For Oracle ASM in Oracle Database 11g, 10.1 is the default setting for the COMPATIBLE.RDBMS attribute when using the SQL CREATE DISKGROUP statement, the ASMCMD mkdg command, ASMCA Create Disk Group page, and Oracle Enterprise Manager Create Disk Group page.</td>
</tr>
<tr>
<td>CONTENT.CHECK</td>
<td>true or false</td>
<td>Enables (true) or disables (false) content checking when performing data copy operations for rebalancing a disk group. The default value is false. You cannot set this attribute when creating a disk group.</td>
</tr>
<tr>
<td>DISK_REPAIR_TIME</td>
<td>0 to 136 years</td>
<td>When disks are taken offline, Oracle ASM drops them after a default period of time. If both the compatible.rdbms and compatible.asm attributes are set to at least 11.1, you can set the disk_repair_time attribute in an ALTER DISKGROUP ... SET ATTRIBUTE statement to change that default period of time so that the disk can be repaired and brought back online. You cannot set this attribute when creating a disk group. The time can be specified in units of minute (M) or hour (H). The specified time elapses only when the disk group is mounted. If you omit the unit, then the default is H. If you omit this attribute, and both compatible.rdbms and compatible.asm are set to at least 11.1, then the default is 3.6 H. Otherwise the disk is dropped immediately. You can override this attribute with an ALTER DISKGROUP ... OFFLINE DISK statement and the DROP AFTER clause. <strong>Note:</strong> If a disk is taken offline using the current value of disk_repair_time, and the value of this attribute is subsequently changed, then the changed value is used by Oracle ASM in the disk offline logic. <strong>See Also:</strong> The ALTER DISKGROUP ... disk_offline_clause on page 10-89 and Oracle Automatic Storage Management Administrator’s Guide for more information</td>
</tr>
<tr>
<td>FAILGROUP_REPAIR_TIME</td>
<td>&lt;number&gt;m</td>
<td>Specifies a default repair time for the failure groups in the disk group. The failure group repair time is used if Oracle ASM determines that an entire failure group has failed. The default value is 24 hours (24h). If there is a repair time specified for a disk, such as with the DROP AFTER clause of the ALTER DISKGROUP OFFLINE DISK statement, then that disk repair time overrides the failure group repair time. This attribute can only be set when altering a disk group and is only applicable to normal and high redundancy disk groups.</td>
</tr>
</tbody>
</table>

SQL Statements: CREATE AUDIT POLICY to CREATE JAVA  14-61
CREATE DISKGROUP

Table 14–2  (Cont.) Disk Group Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Valid Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PHYS_META_REPLICATED</td>
<td>true or false</td>
<td>Tracks the replication status of a disk group. When the Oracle ASM compatibility of a disk group is advanced to 12.0 or higher, the physical metadata of each disk, including its disk header, free space table blocks and allocation table blocks, is replicated. The replication is performed online asynchronously. PHYS_META_REPLICATED is set to true by Oracle ASM if the physical metadata of every disk in the disk group has been replicated. This disk group attribute is only defined in a disk group with the Oracle ASM disk group compatibility (COMPATIBLE.ASM) set to 12.0 and higher. This attribute is read-only and is intended for information only. You cannot set or change its value.</td>
</tr>
<tr>
<td>SECTOR_SIZE</td>
<td></td>
<td>All disks in the disk group must have a sector size equal to the attribute value specified. When processing the CREATE DISKGROUP statement, Oracle ASM queries the operating system for the sector size of every disk specified in this statement before it is added to the disk group, ensuring that a disk group is made up of disks with identical sector size. If a disk is found to have a different sector size than is specified for this attribute, then the statement fails. Similar checks are performed when mounting the disk group. If you omit this attribute in the CREATE DISKGROUP statement, then Oracle ASM proceeds with the create operation as long as all specified disks are found to have identical sector size, and that value is assumed as the disk group sector size. When new disks are added to an existing disk group, using the ALTER DISKGROUP ... ADD DISK statement, the new disks must also have sector size value identical to the disk group attribute. Oracle ASM verifies this and the ALTER DISKGROUP statement fails if any of the disks to be added are found to be of a different sector size. By setting a value for this attribute, you can establish the sector size you intend for the disk group, rather than letting Oracle ASM assume a value for all the disks in the disk group. As a result, users can query the SECTOR_SIZE column of the V$ASM_ATTRIBUTE view to determine the intended sector size before attempting to add a new disk to the disk group.</td>
</tr>
<tr>
<td>THIN_PROVISIONED</td>
<td>true or false</td>
<td>Enables (true) or disables (false) the functionality to discard unused storage space after a disk group rebalance is completed. The default value is false.</td>
</tr>
</tbody>
</table>

1 Specify at least the first two digits of a valid Oracle Database release number. Refer to Oracle Database Administrator’s Guide for information on specifying valid version numbers. For example, you can specify compatibility as '11.2' or '12.1'.

See Also: Oracle Automatic Storage Management Administrator’s Guide for more information on managing these attribute settings.

Examples

The following example assumes that the ASM_DISKSTRING parameter is a superset of /devices/disks/c*,/devices/disks/c* points to at least one device to be used as an Oracle ASM disk, and the Oracle Database user has read/write permission to the disks.

See Also: Oracle Automatic Storage Management Administrator’s Guide for information on Oracle ASM and using disk groups to simplify database administration.
Creating a Diskgroup: Example  The following statement creates an Oracle ASM disk group dgroup_01 where no redundancy for the disk group is provided by Oracle ASM and includes all disks that match the search_string:

```
CREATE DISKGROUP dgroup_01
  EXTERNAL REDUNDANCY
  DISK '/devices/disks/c*';
```
CREATE EDITION

Purpose

This statement creates a new edition as a child of an existing edition. An edition makes it possible to have two or more versions of the same editionable objects in the database. When you create an edition, it immediately inherits all of the editionable objects of its parent edition. The following object types are editionable:

- Synonym
- View
- Function
- Procedure
- Package (specification and body)
- Type (specification and body)
- Library
- Trigger

An editionable object is an object of one of the above editionable object types in an editions-enabled schema. The ability to have multiple versions of these objects in the database greatly facilitates online application upgrades.

Note: All database object types not listed above are not editionable. Changes to object types that are not editionable are immediately visible across all editions in the database.

Every newly created or upgraded Oracle Database has one default edition named ORA$BASE, which serves as the parent of the first edition created with a CREATE EDITION statement. You can subsequently designate a user-defined edition as the database default edition using an ALTER DATABASE DEFAULT EDITION statement.

See Also:

- Oracle Database Development Guide for a more complete discussion of editionable object types and editions
- The ALTER DATABASE "DEFAULT EDITION Clause" on page 10-65 for information on designating an edition as the default edition for the database

Prerequisites

To create an edition, you must have the CREATE ANY EDITION system privilege, granted either directly or through a role. To create an edition as a child of another edition, you must have the USE object privilege on the parent edition.
Syntax

create_edition ::= 

Semantics

edition

Specify the name of the edition to be created. The name must satisfy the rules listed in "Database Object Naming Rules" on page 2-119. To learn the editions that have been created for the database, query the EDITION_NAME column of the DBA_OBJECTS or ALL_OBJECTS data dictionary view.

When you create an edition, the system automatically grants you the USE object privilege WITH GRANT OPTION on the edition you create.

Note: Oracle strongly recommends that you do not name editions with the prefixes ORA, ORACLE, SYS, DBA, and DBMS, as these prefixes are reserved for internal use.

AS CHILD OF Clause

If you use this clause, then the new edition is created as a child of parent_edition. If you omit this clause, then the new edition is created as a child of the leaf edition. At the time of its creation, the new edition inherits all editioned objects from its parent edition.

Restriction on Editions An edition can have only one child edition. If you specify for parent_edition an edition that already has a child edition, then an error is returned.

Examples

The following very simple examples are intended to show the syntax for creating and working with an edition. For realistic examples of using editions refer to Oracle Database Development Guide.

In the following statements, the user HR is given the privileges needed to create and use an edition:

GRANT CREATE ANY EDITION, DROP ANY EDITION to HR;
Grant succeeded.

ALTER USER hr ENABLE EDITIONS;
User altered.

HR creates a new edition TEST_ED for testing purposes:

CREATE EDITION test_ed;

HR then creates an editioning view ed_view in the default edition ORA$BASE for testing purposes, first verifying that the current edition is the default edition:

SELECT SYS_CONTEXT('userenv', 'current_edition_name') FROM DUAL;
SYS_CONTEXT('USERENV', 'CURRENT_EDITION_NAME')

---------------------------------------------
CREATE EDITIONING VIEW e_view AS
  SELECT last_name, first_name, email FROM employees;
View created.

DESCRIBE e_view
Name                                      Null?    Type
----------------------------------------- -------- ----------------------------
LAST_NAME                                 NOT NULL VARCHAR2(25)
FIRST_NAME                                      VARCHAR2(20)
EMAIL                                     NOT NULL VARCHAR2(25)

The view is then actualized in the TEST_ED edition when HR uses the TEST_ED edition and re-creates the view in a different form:
ALTER SESSION SET EDITION = TEST_ED;
Session altered.

CREATE OR REPLACE EDITIONING VIEW e_view AS
  SELECT last_name, first_name, email, salary FROM employees;
View created.

The view in the TEST_ED edition has an additional column:
DESCRIBE e_view
Name                                      Null?    Type
----------------------------------------- -------- ----------------------------
LAST_NAME                                 NOT NULL VARCHAR2(25)
FIRST_NAME                                      VARCHAR2(20)
EMAIL                                     NOT NULL VARCHAR2(25)
SALARY                                             NUMBER(8,2)

The view in the ORA$BASE edition remains isolated from the test environment:
ALTER SESSION SET EDITION = ora$base;
Session altered.

DESCRIBE e_view;
Name                                      Null?    Type
----------------------------------------- -------- ----------------------------
LAST_NAME                                 NOT NULL VARCHAR2(25)
FIRST_NAME                                      VARCHAR2(20)
EMAIL                                     NOT NULL VARCHAR2(25)

Even if the view is dropped in the test environment, it remains in the ORA$BASE edition:
ALTER SESSION SET EDITION = TEST_ED;
Session altered.

DROP VIEW e_view;
View dropped.

ALTER SESSION SET EDITION = ORA$BASE;
Session altered.

DESCRIBE e_view;
Name                                      Null?    Type
----------------------------------------- -------- ----------------------------
LAST_NAME         NOT NULL VARCHAR2(25)
FIRST_NAME        VARCHAR2(20)
EMAIL             NOT NULL VARCHAR2(25)

When the testing of upgrade that necessitated the TEST_ED edition is complete, the edition can be dropped:

DROP EDITION TEST_ED;
CREATE FLASHBACK ARCHIVE

Purpose

Use the CREATE FLASHBACK ARCHIVE statement to create a flashback data archive, which provides the ability to automatically track and archive transactional data changes to specified database objects. A flashback data archive consists of multiple tablespaces and stores historic data from all transactions against tracked tables. The data is stored in internal history tables.

Flashback data archives retain historical data for the time duration specified using the RETENTION parameter. Historical data can be queried using the Flashback Query AS OF clause. Archived historic data that has aged beyond the specified retention period is automatically purged.

Flashback data archives retain historical data across data definition language (DDL) changes to tables enabled for flashback data archive. Flashback data archives supports many common DDL statements, including some DDL statements that alter table definitions or incur data movement. DDL statements that are not supported result in error ORA-55610.

See Also:
- Oracle Database Development Guide for general information on using flashback data archives
- The CREATE TABLE flashback_archive_clause on page 16-84 for information on designating a table as a tracked table
- ALTER FLASHBACK ARCHIVE on page 10-103 for information on changing the quota and retention attributes of the flashback data archive, as well as adding or changing tablespace storage for the flashback data archive

Prerequisites

You must have the FLASHBACK ARCHIVE ADMINISTER system privilege to create a flashback data archive. In addition, you must have the CREATE TABLESPACE system privilege to create a flashback data archive, as well as sufficient quota on the tablespace in which the historical information will reside. To designate a flashback data archive as the system default flashback data archive, you must be logged in as SYSDBA.

Syntax

create_flashback_archive::=

\[\text{CREATE}\ \text{FLASHBACK}\ \text{ARCHIVE}\ \text{DEFAULT}\ \text{FLASHBACK}\ \text{ARCHIVE}\ \text{TABLESPACE}\ \text{tablespace}\\]

\[\text{flashback_archive_quota}\ \text{NO}\ \text{OPTIMIZE}\ \text{DATA}\ \text{flashback_archive_retention}\ \text{clause}\]
CREATE FLASHBACK ARCHIVE

**flashback_archive_quota**: ::= 

```
QUOTA  integer
```

**flashback_archive_retention**: ::= 

```
RETENTION  integer
```

**Semantics**

**DEFAULT**
You must be logged in as SYSDBA to specify `DEFAULT`. Use this clause to designate this flashback data archive as the default flashback data archive for the database. When a `CREATE TABLE` or `ALTER TABLE` statement specifies the `flashback_archive_clause` without specifying a flashback data archive name, the database uses the default flashback data archive to store data from that table.

You cannot specify this clause if a default flashback data archive already exists. However, you can replace an existing default flashback data archive using the `ALTER FLASHBACK ARCHIVE` ... `SET DEFAULT` clause.

**See Also:** The `CREATE TABLE` `flashback_archive_clause` on page 16-84 for more information

**flashback_archive**
Specify the name of the flashback data archive. The name must satisfy the requirements specified in "Database Object Naming Rules" on page 2-119.

**TABLESPACE Clause**
Specify the tablespace where the archived data for this flashback data archive is to be stored. You can specify only one tablespace with this clause. However, you can subsequently add tablespaces to the flashback data archive with an `ALTER FLASHBACK ARCHIVE` statement.

**flashback_archive_quota**
Specify the amount of space in the initial tablespace to be reserved for the archived data. If the space for archiving in a flashback data archive becomes full, then DML operations on tracked tables that use this flashback data archive will fail. The database issues an out-of-space alert when the content of the flashback data archive is 90% of the specified quota, to allow time to purge old data or add additional quota. If you omit this clause, then the flashback data archive has unlimited quota on the specified tablespace.
[NO] OPTIMIZE DATA
Specify OPTIMIZE DATA to enable optimization for flashback data archive history tables. This instructs the database to optimize the storage of data in history tables using any of the following features: Advanced Row Compression, Advanced LOB Compression, Advanced LOB Deduplication, segment-level compression tiering, and row-level compression tiering. To specify this clause, you must have a license for the Advanced Compression option.

Specify NO OPTIMIZE DATA to instruct the database not to optimize the storage of data in history tables. This is the default.

flashback_archive_retention
Specify the length of time in months, days, or years that the archived data should be retained in the flashback data archive. If the length of time causes the flashback data archive to become full, then the database responds as described in flashback_archive_quota on page 14-69.

Examples
The following statement creates two flashback data archives for testing purposes. The first is designated as the default for the database. For both of them, the space quota is 1 megabyte, and the archive retention is one day.

```
CREATE FLASHBACK ARCHIVE DEFAULT test_archive1
   TABLESPACE example
   QUOTA 1 M
   RETENTION 1 DAY;

CREATE FLASHBACK ARCHIVE test_archive2
   TABLESPACE example
   QUOTA 1 M
   RETENTION 1 DAY;
```

The next statement alters the default flashback data archive to extend the retention period to 1 month:
```
ALTER FLASHBACK ARCHIVE test_archive1
   MODIFY RETENTION 1 MONTH;
```

The next statement specifies tracking for the oe.customers table. The flashback data archive is not specified, so data will be archived in the default flashback data archive, test_archive1:
```
ALTER TABLE oe.customers
   FLASHBACK ARCHIVE;
```

The next statement specifies tracking for the oe.orders table. In this case, data will be archived in the specified flashback data archive, test_archive2:
```
ALTER TABLE oe.orders
   FLASHBACK ARCHIVE test_archive2;
```

The next statement drops test_archive2 flashback data archive:
```
DROP FLASHBACK ARCHIVE test_archive2;
```
CREATE FUNCTION

Purpose

Functions are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the CREATE FUNCTION statement to create a standalone stored function or a call specification.

- A stored function (also called a user function or user-defined function) is a set of PL/SQL statements you can call by name. Stored functions are very similar to procedures, except that a function returns a value to the environment in which it is called. User functions can be used as part of a SQL expression.

- A call specification declares a Java method or a third-generation language (3GL) routine so that it can be called from PL/SQL. You can also use the CALL SQL statement to call such a method or routine. The call specification tells Oracle Database which Java method, or which named function in which shared library, to invoke when a call is made. It also tells the database what type conversions to make for the arguments and return value.

---

**Note:** You can also create a function as part of a package using the CREATE PACKAGE statement.

---

See Also:

- CREATE PROCEDURE on page 15-75 for a general discussion of procedures and functions, CREATE PACKAGE on page 15-55 for information on creating packages, ALTER FUNCTION on page 10-106 and DROP FUNCTION on page 17-52 for information on modifying and dropping a function

- CREATE LIBRARY on page 15-2 for information on shared libraries

- Oracle Database Development Guide for more information about registering external functions

Prerequisites

To create or replace a function in your own schema, you must have the CREATE PROCEDURE system privilege. To create or replace a function in another user’s schema, you must have the CREATE ANY PROCEDURE system privilege.

Syntax

Functions are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to Oracle Database PL/SQL Language Reference for the PL/SQL syntax, semantics, and examples.
CREATE FUNCTION

create_function::= 

(PLSQL_function_source: See Oracle Database PL/SQL Language Reference.)

Semantics

OR REPLACE
Specify OR REPLACE to re-create the function if it already exists. Use this clause to change the definition of an existing function without dropping, re-creating, and regranting object privileges previously granted on the function. If you redefine a function, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined function can still access the function without being regranted the privileges.

If any function-based indexes depend on the function, then Oracle Database marks the indexes DISABLED.

See Also: ALTER FUNCTION for information on recompiling functions using SQL

[ EDITIONABLE | NONEDITIONABLE ]
Use these clauses to specify whether the function is an editioned or noneditioned object if editioning is enabled for the schema object type FUNCTION in schema. The default is EDITIONABLE. For information about editioned and noneditioned objects, see Oracle Database Development Guide.

PLSQL_function_source
See Oracle Database PL/SQL Language Reference for the syntax and semantics of the PLSQL_function_source, including examples.
CREATE INDEX

Purpose

Use the CREATE INDEX statement to create an index on:

- One or more columns of a table, a partitioned table, an index-organized table, or a cluster
- One or more scalar typed object attributes of a table or a cluster
- A nested table storage table for indexing a nested table column

An index is a schema object that contains an entry for each value that appears in the indexed column(s) of the table or cluster and provides direct, fast access to rows. The maximum size of a single index entry is dependent on the block size of the database.

Oracle Database supports several types of index:

- Normal indexes. (By default, Oracle Database creates B-tree indexes.)
- Bitmap indexes, which store rowids associated with a key value as a bitmap.
- Partitioned indexes, which consist of partitions containing an entry for each value that appears in the indexed column(s) of the table.
- Function-based indexes, which are based on expressions. They enable you to construct queries that evaluate the value returned by an expression, which in turn may include built-in or user-defined functions.
- Domain indexes, which are instances of an application-specific index of type indextype.

See Also:

- Oracle Database Concepts for a discussion of indexes
- Oracle Database Reference for more information about the limits related to index size
- ALTER INDEX on page 10-107 and DROP INDEX on page 17-54

Prerequisites

To create an index in your own schema, one of the following conditions must be true:

- The table or cluster to be indexed must be in your own schema.
- You must have the INDEX object privilege on the table to be indexed.
- You must have the CREATE ANY INDEX system privilege.

To create an index in another schema, you must have the CREATE ANY INDEX system privilege. Also, the owner of the schema to contain the index must have either the UNLIMITED TABLESPACE system privilege or space quota on the tablespaces to contain the index or index partitions.

To create a domain index in your own schema, in addition to the prerequisites for creating a conventional index, you must also have the EXECUTE object privilege on the indextype. If you are creating a domain index in another user's schema, then the index owner also must have the EXECUTE object privilege on the indextype and its underlying implementation type. Before creating a domain index, you should first define the indextype.
To create a function-based index, in addition to the prerequisites for creating a conventional index, if the index is based on user-defined functions, then those functions must be marked `DETERMINISTIC`. Also, you must have the `EXECUTE` object privilege on any user-defined function(s) used in the function-based index if those functions are owned by another user.

**Syntax**

`create_index ::=`
**CREATE INDEX**

\[
\text{bitmap_join_index_clause} := \\
\text{schema} \rightarrow \text{table} \rightarrow \text{t_alias} \rightarrow \text{column} \\

Semantics

**UNIQUE**
Specify **UNIQUE** to indicate that the value of the column (or columns) upon which the index is based must be unique.

**Restrictions on Unique Indexes**
Unique indexes are subject to the following restrictions:
- You cannot specify both **UNIQUE** and **BITMAP**.
- You cannot specify **UNIQUE** for a domain index.

**BITMAP**
Specify **BITMAP** to indicate that index is to be created with a bitmap for each distinct key, rather than indexing each row separately. Bitmap indexes store the rowids associated with a key value as a bitmap. Each bit in the bitmap corresponds to a possible rowid. If the bit is set, then it means that the row with the corresponding rowid contains the key value. The internal representation of bitmaps is best suited for applications with low levels of concurrent transactions, such as data warehousing.

**Note:** Oracle does not index table rows in which all key columns are null except in the case of bitmap indexes. Therefore, if you want an index on all rows of a table, then you must either specify **NOT NULL** constraints for the index key columns or create a bitmap index.

**Restrictions on Bitmap Indexes**
Bitmap indexes are subject to the following restrictions:
- You cannot specify **BITMAP** when creating a global partitioned index.
- You cannot create a bitmap secondary index on an index-organized table unless the index-organized table has a mapping table associated with it.
- You cannot specify both **UNIQUE** and **BITMAP**.
- You cannot specify **BITMAP** for a domain index.
- A bitmap index can have a maximum of 30 columns.

**See Also:**
- Oracle Database Concepts and Oracle Database SQL Tuning Guide for more information about using bitmap indexes
- CREATE TABLE on page 16-6 for information on mapping tables
- "Bitmap Index Examples" on page 14-100

**schema**
Specify the schema to contain the index. If you omit **schema**, then Oracle Database creates the index in your own schema.
CREATE INDEX

**index**
Specify the name of the index to be created. The name must satisfy the requirements listed in "Database Object Naming Rules" on page 2-119.

**See Also:** "Creating an Index: Example" on page 14-96 and "Creating an Index on an XMLType Table: Example" on page 14-97

**cluster_index_clause**
Use the `cluster_index_clause` to identify the cluster for which a cluster index is to be created. If you do not qualify `cluster` with `schema`, then Oracle Database assumes the cluster is in your current schema. You cannot create a cluster index for a hash cluster.

**See Also:** CREATE CLUSTER on page 14-11 and "Creating a Cluster Index: Example" on page 14-97

**table_index_clause**
Specify the table on which you are defining the index. If you do not qualify `table` with `schema`, then Oracle Database assumes the table is contained in your own schema.

You create an index on a nested table column by creating the index on the nested table storage table. Include the `NESTED_TABLE_ID` pseudocolumn of the storage table to create a `UNIQUE` index, which effectively ensures that the rows of a nested table value are distinct.

**See Also:** "Indexes on Nested Tables: Example" on page 14-101

You can perform DDL operations (such as ALTER TABLE, DROP TABLE, CREATE INDEX) on a temporary table only when no session is bound to it. A session becomes bound to a temporary table by performing an INSERT operation on the table. A session becomes unbound to the temporary table by issuing a TRUNCATE statement or at session termination, or, for a transaction-specific temporary table, by issuing a COMMIT or ROLLBACK statement.

**Restrictions on the table_index_clause**
This clause is subject to the following restrictions:

- If `index` is locally partitioned, then `table` must be partitioned.
- If `table` is index-organized, then this statement creates a secondary index. The index contains the index key and the logical rowid of the index-organized table. The logical rowid excludes columns that are also part of the index key. You cannot specify `REVERSE` for this secondary index, and the combined size of the index key and the logical rowid should be less than the block size.
- If `table` is a temporary table, then `index` will also be temporary with the same scope (session or transaction) as `table`. The following restrictions apply to indexes on temporary tables:
  - The only part of `index_properties` you can specify is `index_attributes`.
  - Within `index_attributes`, you cannot specify the `physical_attributes_clause`, the `parallel_clause`, the `logging_clause`, or `TABLESPACE`.
  - You cannot create a domain index or a partitioned index on a temporary table.
- You cannot create an index on an external table.

**See Also:** CREATE TABLE on page 16-6 and Oracle Database Concepts for more information on temporary tables.
**t_alias**
Specify a correlation name (alias) for the table upon which you are building the index.

---

**Note:** This alias is required if the index_expr references any object type attributes or object type methods. See “Creating a Function-based Index on a Type Method: Example” on page 14-98 and “Indexing on Substitutable Columns: Examples” on page 14-102.

---

**index_expr**
For index_expr, specify the column or column expression upon which the index is based.

You can create multiple indexes on the same set of columns, column expressions, or both if the following conditions are met:

- The indexes are of different types, use different partitioning, or have different uniqueness properties.
- Only one of the indexes is **VISIBLE** at any given time.

**See Also:** *Oracle Database Administrator's Guide* for more information on creating multiple indexes

**column**
Specify the name of one or more columns in the table. A bitmap index can have a maximum of 30 columns. Other indexes can have as many as 32 columns. These columns define the **index key**.

If a unique index is local nonprefixed (see *local_partitioned_index*), then the index key must contain the partitioning key.

**See Also:** *Oracle Database VLDB and Partitioning Guide* for information on prefixed and nonprefixed indexes

You can create an index on a scalar object attribute column or on the system-defined NESTED_TABLE_ID column of the nested table storage table. If you specify an object attribute column, then the column name must be qualified with the table name. If you specify a nested table column attribute, then it must be qualified with the outermost table name, the containing column name, and all intermediate attribute names leading to the nested table column attribute.

**Creating an Index on an Extended Data Type Column**
If column is an extended data type column, then you may receive a "maximum key length exceeded" error when attempting to create the index. The maximum key length for an index varies depending on the database block size and some additional index metadata stored in a block. For example, for databases that use the Oracle standard 8K block size, the maximum key length is approximately 6400 bytes.

To work around this situation, you must shorten the length of the values you want to index, using one of the following methods:

- Create a function-based index to shorten the values stored in the extended data type column as part of the expression used for the index definition.
- Create a virtual column to shorten the values stored in the extended data type column as part of the expression used for the virtual column definition and build a normal index on the virtual column. Using a virtual column also enables you to
leverage functionality for regular columns, such as collecting statistics and using constraint and triggers.

For both methods you can use either the \texttt{SUBSTR} or \texttt{STANDARD_HASH} function to shorten the values of the extended data type column to build an index. These methods have the following advantages and disadvantages:

- Use the \texttt{SUBSTR} function to return a substring, or prefix, of \texttt{column} that is an acceptable length for the index key. This type of index can be used for equality, IN-list, and range predicates on the original column without the need to specify the \texttt{SUBSTR} column as part of the predicate. Refer to \texttt{SUBSTR} on page 7-329 for more information.

- Using the \texttt{STANDARD_HASH} function is likely to create an index that is more compact than the substring-based index and may result in fewer unnecessary index accesses. This type of index can be used for equality and IN-list predicates on the original column without the need to specify the \texttt{SUBSTR} column as part of the predicate. Refer to \texttt{STANDARD_HASH} on page 7-304 for more information.

The following example shows how to create a function-based index on an extended data type column:

\begin{verbatim}
CREATE INDEX index ON table (SUBSTR(column, 0, n));
\end{verbatim}

For \texttt{n}, specify a prefix length that is large enough to differentiate between values in \texttt{column}.

The following example shows how to create a virtual column for an extended data type column, and then create an index on the virtual column:

\begin{verbatim}
ALTER TABLE table ADD (new_hash_column AS (STANDARD_HASH(column)));
CREATE INDEX index ON table (new_hash_column);
\end{verbatim}

\textbf{See Also:} "Extended Data Types" on page 2-29 for more information on extended data types

\textbf{Restrictions on Index Columns} The following restrictions apply to index columns:

- You cannot create an index on columns or attributes whose type is user-defined, \texttt{LONG}, \texttt{LONG_RAW}, \texttt{LOB}, or \texttt{REF}, except that Oracle Database supports an index on \texttt{REF} type columns or attributes that have been defined with a \texttt{SCOPE} clause.

- Only normal (B-tree) indexes can be created on encrypted columns, and they can only be used for equality searches.

\texttt{column_expression} Specify an expression built from columns of \texttt{table}, constants, SQL functions, and user-defined functions. When you specify \texttt{column_expression}, you create a \textbf{function-based index}.

\textbf{See Also:} "Column Expressions" on page 5-7, "Notes on Function-based Indexes" on page 14-85, "Restrictions on Function-based Indexes" on page 14-86, and "Function-Based Index Examples" on page 14-97

Name resolution of the function is based on the schema of the index creator. User-defined functions used in \texttt{column_expression} are fully name resolved during the \texttt{CREATE INDEX} operation.

After creating a function-based index, collect statistics on both the index and its base table using the \texttt{DBMS_STATS} package. Such statistics will enable Oracle Database to correctly decide when to use the index.
Function-based unique indexes can be useful in defining a conditional unique constraint on a column or combination of columns. Refer to "Using a Function-based Index to Define Conditional Uniqueness: Example" on page 14-99 for an example.

See Also:  Oracle Database PL/SQL Packages and Types Reference for more information on the DBMS_STATS package

Notes on Function-based Indexes  The following notes apply to function-based indexes:

- When you subsequently query a table that uses a function-based index, Oracle Database will not use the index unless the query filters out nulls. However, Oracle Database will use a function-based index in a query even if the columns specified in the WHERE clause are in a different order than their order in the column_expression that defined the function-based index.

  See Also:  "Function-Based Index Examples" on page 14-97

- If the function on which the index is based becomes invalid or is dropped, then Oracle Database marks the index DISABLED. Queries on a DISABLED index fail if the optimizer chooses to use the index. DML operations on a DISABLED index fail unless the index is also marked UNUSABLE and the parameter SKIP_UNUSABLE_INDEXES is set to true. Refer to ALTER SESSION on page 11-65 for more information on this parameter.

- If a public synonym for a function, package, or type is used in column_expression, and later an actual object with the same name is created in the table owner’s schema, then Oracle Database disables the function-based index. When you subsequently enable the function-based index using ALTER INDEX ... ENABLE or ALTER INDEX ... REBUILD, the function, package, or type used in the column_expression continues to resolve to the function, package, or type to which the public synonym originally pointed. It will not resolve to the new function, package, or type.

- If the definition of a function-based index generates internal conversion to character data, then use caution when changing NLS parameter settings. Function-based indexes use the current database settings for NLS parameters. If you reset these parameters at the session level, then queries using the function-based index may return incorrect results. Two exceptions are the collation parameters (NLS_SORT and NLS_COMP). Oracle Database handles the conversions correctly even if these have been reset at the session level.

- Oracle Database cannot convert data in all cases, even when conversion is explicitly requested. For example, an attempt to convert the string '105 lbs' from VARCHAR2 to NUMBER using the TO_NUMBER function fails with an error. Therefore, if column_expression contains a data conversion function such as TO_NUMBER or TO_DATE, and if a subsequent INSERT or UPDATE statement includes data that the conversion function cannot convert, then the index will cause the INSERT or UPDATE statement to fail.

- If column_expression contains a datetime format model, then the function-based index expression defining the column may contain format elements that are different from those specified. For example, define a function-based index using the yyyy datetime format element:

  CREATE INDEX cust_eff_ix ON customers
  (NVL(cust_eff_to, TO_DATE('9000-01-01 00:00:00', 'yyyy-mm-dd hh24:mi:ss')));

SQL Statements: CREATE AUDIT POLICY to CREATE JAVA  14-85
Query the ALL_IND_EXPRESSIONS view to see that the function-based index expression defining the column uses the syyyy datetime format element:

```
SELECT column_expression
  FROM all_ind_expressions
  WHERE index_names='CUST_EFF_IX';
```

<table>
<thead>
<tr>
<th>COLUMN_EXPRESSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>NVL(&quot;CUST_EFF_TO&quot;,TO_DATE(' 9000-01-01 00:00:00', 'syyyy-mm-dd hh24:mi:ss'))</td>
</tr>
</tbody>
</table>

**Restrictions on Function-based Indexes** Function-based indexes are subject to the following restrictions:

- The value returned by the function referenced in `column_expression` is subject to the same restrictions as are the index columns of a B-tree index. Refer to "Restrictions on Index Columns" on page 14-84.
- Any user-defined function referenced in `column_expression` must be declared as `DETERMINISTIC`.
- For a function-based globally partitioned index, the `column_expression` cannot be the partitioning key.
- The `column_expression` can be any of the forms of expression described in Column Expressions on page 5-7.
- All functions must be specified with parentheses, even if they have no parameters. Otherwise Oracle Database interprets them as column names.
- Any function you specify in `column_expression` must return a repeatable value. For example, you cannot specify the `SYSDATE` or `USER` function or the `ROWNUM` pseudocolumn.

**See Also:** CREATE FUNCTION on page 14-71 and Oracle Database PL/SQL Language Reference

**ASC | DESC**

Use `ASC` or `DESC` to indicate whether the index should be created in ascending or descending order. Indexes on character data are created in ascending or descending order of the character values in the database character set.

Oracle Database treats descending indexes as if they were function-based indexes. As with other function-based indexes, the database does not use descending indexes until you first analyze the index and the table on which the index is defined. See the `column_expression` clause of this statement.

Ascending unique indexes allow multiple `NULL` values. However, in descending unique indexes, multiple `NULL` values are treated as duplicate values and therefore are not permitted.

**Restriction on Ascending and Descending Indexes** You cannot specify either of these clauses for a domain index. You cannot specify `DESC` for a reverse index. Oracle Database ignores `DESC` if `index` is bitmapped or if the `COMPATIBLE` initialization parameter is set to a value less than 8.1.0.

**index_attributes**

Specify the optional index attributes.
physical_attributes_clause  Use the physical_attributes_clause to establish values for physical and storage characteristics for the index.

If you omit this clause, then Oracle Database sets PCTFREE to 10 and INITRANS to 2.

Restriction on Index Physical Attributes  You cannot specify the PCTUSED parameter for an index.

See Also:  physical_attributes_clause on page 8-44 and storage_clause on page 8-46 for a complete description of these clauses

TABLESPACE  For tablespace, specify the name of the tablespace to hold the index, index partition, or index subpartition. If you omit this clause, then Oracle Database creates the index in the default tablespace of the owner of the schema containing the index.

For a local index, you can specify the keyword DEFAULT in place of tablespace. New partitions or subpartitions added to the local index will be created in the same tablespace(s) as the corresponding partitions or subpartitions of the underlying table.

index_compression  The index_compression clauses let you enable or disable index compression for the index. Specify the COMPRESS clause of prefix_compression to enable prefix compression for the index, specify the COMPRESS ADVANCED LOW clause of advanced_index_compression to enable advanced index compression for the index, or specify the NOCOMPRESS clause of either prefix_compression or advanced_index_compression to disable compression for the index. The default is NOCOMPRESS.

Oracle Database compresses indexes that are nonunique or unique indexes of at least two columns. If you want to use compression for a partitioned index, then you must create the index with compression enabled at the index level. You can subsequently enable and disable the compression setting for individual partitions of such a partitioned index. You can also enable and disable compression when rebuilding individual partitions. You can modify an existing non-partitioned index to enable or disable compression only when rebuilding the index.

prefix_compression  Specify COMPRESS to enable prefix compression, also known as key compression, which eliminates repeated occurrence of key column values. Use integer to specify the prefix length (number of prefix columns to compress).

- For unique indexes, the range of valid prefix length values is from 1 to the number of key columns minus 1. The default prefix length is the number of key columns minus 1.
- For nonunique indexes, the range of valid prefix length values is from 1 to the number of key columns. The default prefix length is number of key columns.

advanced_index_compression  Specify COMPRESS ADVANCED LOW to enable advanced index compression. Advanced index compression improves compression ratios significantly while still providing efficient access to indexes. Therefore, advanced index compression works well on all supported indexes, including those indexes that are not good candidates for prefix compression.

Restrictions on Index Compression  The following restrictions apply to index compression:

- You cannot specify prefix compression or advanced index compression for a bitmap index or on a single-column unique index.
You cannot specify advanced index compression for index-organized tables.

See Also:
- Oracle Database Administrator’s Guide for more information on prefix compression and advanced index compression
- "Compressing an Index: Example" on page 14-97

**partial_index_clause** You can specify this clause only when creating an index on a partitioned table. Specify `INDEXING FULL` to create a full index. Specify `INDEXING PARTIAL` to create a partial index. The default is `INDEXING FULL`.

A full index includes all partitions in the underlying table, regardless of their indexing properties. A partial index includes only partitions in the underlying table with an indexing property of `ON`.

If a partial index is a local partitioned index, then index partitions that correspond with table partitions with an indexing property of `ON` are marked `USABLE`. Index partitions that correspond with table partitions with an indexing property of `OFF` are marked `UNUSABLE`.

If the underlying table is a composite-partitioned table, then the preceding conditions for index partitions and table partitions apply instead to index subpartitions and table subpartitions.

**Restrictions on Partial Indexes** Partial indexes are subject to the following restrictions:
- The underlying table of a partial index cannot be a nonpartitioned table.
- Unique indexes cannot be partial indexes. This applies to indexes created with the `CREATE UNIQUE INDEX` statement and indexes that are implicitly created when you specify a unique constraint on one or more columns.

See Also: CREATE TABLE `indexing_clause` on page 16-65 for information on the indexing property

**SORT | NOSORT** By default, Oracle Database sorts indexes in ascending order when it creates the index. You can specify `NOSORT` to indicate to the database that the rows are already stored in the database in ascending order, so that Oracle Database does not have to sort the rows when creating the index. If the rows of the indexed column or columns are not stored in ascending order, then the database returns an error. For greatest savings of sort time and space, use this clause immediately after the initial load of rows into a table. If you specify neither of these keywords, then `SORT` is the default.

**Restrictions on NOSORT** This parameter is subject to the following restrictions:
- You cannot specify `REVERSE` with this clause.
- You cannot use this clause to create a cluster index partitioned or bitmap index.
- You cannot specify this clause for a secondary index on an index-organized table.

**REVERSE** Specify `REVERSE` to store the bytes of the index block in reverse order, excluding the rowid.

**Restrictions on Reverse Indexes** Reverse indexes are subject to the following restrictions:
CREATE INDEX

You cannot specify NOSORT with this clause.

You cannot reverse a bitmap index or an index on an index-organized table.

**VISIBLE | INVISIBLE**  Use this clause to specify whether the index is visible or invisible to the optimizer. An invisible index is maintained by DML operations, but it is not be used by the optimizer during queries unless you explicitly set the parameter OPTIMIZER_USE_INVISIBLE_INDEXES to TRUE at the session or system level.

To determine whether an existing index is visible or invisible to the optimizer, you can query the VISIBILITY column of the USER_, DBA_, ALL_INDEXES data dictionary views.

See Also:  *Oracle Database Administrator’s Guide* for more information on this feature

**logging clause**  Specify whether the creation of the index will be logged (LOGGING) or not logged (NOLOGGING) in the redo log file. This setting also determines whether subsequent Direct Loader (SQL*Loader) and direct-path INSERT operations against the index are logged or not logged. LOGGING is the default.

If *index* is nonpartitioned, then this clause specifies the logging attribute of the index.

If *index* is partitioned, then this clause determines:

- The default value of all partitions specified in the CREATE statement, unless you specify the *logging clause* in the PARTITION description clause
- The default value for the segments associated with the index partitions
- The default value for local index partitions or subpartitions added implicitly during subsequent ALTER TABLE ... ADD PARTITION operations

The logging attribute of the index is independent of that of its base table.

If you omit this clause, then the logging attribute is that of the tablespace in which it resides.

See Also:

- *logging clause* on page 8-38 for a full description of this clause
- *Oracle Database VLDB and Partitioning Guide* for more information about logging and parallel DML
- "Creating an Index in NOLOGGING Mode: Example" on page 14-97

**ONLINE**  Specify ONLINE to indicate that DML operations on the table will be allowed during creation of the index.

**Restrictions on Online Index Building**  Online index building is subject to the following restrictions:

- Parallel DML is not supported during online index building. If you specify ONLINE and then issue parallel DML statements, then Oracle Database returns an error.
- You cannot specify ONLINE for a bitmap index or a cluster index.
- You cannot specify ONLINE for a conventional index on a UROWID column.
- For a nonunique secondary index on an index-organized table, the number of index key columns plus the number of primary key columns that are included in
the logical rowid in the index-organized table cannot exceed 32. The logical rowid
excludes columns that are part of the index key.

**See Also:** Oracle Database Concepts for a description of online index
building and rebuilding

**parallel_clause**
Specify the `parallel_clause` if you want creation of the index to be parallelized.

For complete information on this clause, refer to `parallel_clause` on page 16-81 in the
documentation on `CREATE TABLE`.

**Index Partitioning Clauses**
Use the `global_partitioned_index` clause and the `local_partitioned_index` clauses
to partition index.

The storage of partitioned database entities in tablespaces of different block sizes is
subject to several restrictions. Refer to Oracle Database VLDB and Partitioning Guide for
a discussion of these restrictions.

**See Also:** "Partitioned Index Examples" on page 14-99

**global_partitioned_index**
The `global_partitioned_index` clause lets you specify that the partitioning of the
index is user defined and is not equipartitioned with the underlying table. By default,
nonpartitioned indexes are global indexes.

You can partition a global index by range or by hash. In both cases, you can specify up
to 32 columns as partitioning key columns. The partitioning column list must specify a
left prefix of the index column list. If the index is defined on columns `a`, `b`, and `c`, then
for the columns you can specify `(a, b, c)`, or `(a, b)`, or `(a, c)`, but you cannot specify `(b, c)`
or `(c)` or `(b, a)`. If you omit the partition names, then Oracle Database assigns
names of the form `SYS_Pn`.

**GLOBAL PARTITION BY RANGE** Use this clause to create a range-partitioned global
index. Oracle Database will partition the global index on the ranges of values from the
table columns you specify in the column list.

**See Also:** "Creating a Range-Partitioned Global Index: Example" on
page 14-99

**GLOBAL PARTITION BY HASH** Use this clause to create a hash-partitioned global
index. Oracle Database assigns rows to the partitions using a hash function on values
in the partitioning key columns.

**See Also:** The `CREATE TABLE` clause `hash_partitions` on page 16-71 for
information on the two methods of hash partitioning and "Creating a
Hash-Partitioned Global Index: Example" on page 14-99

**Restrictions on Global Partitioned Indexes** Global partitioned indexes are subject to
the following restrictions:

- The partitioning key column list cannot contain the `ROWID` pseudocolumn or a
column of type `ROWID`. 
The only property you can specify for hash partitions is tablespace storage. Therefore, you cannot specify LOB or varray storage clauses in the `partitioning_storage_clause` of `individual_hash_partitions`.

You cannot specify the `OVERFLOW` clause of `hash_partitions_by_quantity`, as that clause is valid only for index-organized table partitions.

In the `partitioning_storage_clause`, you cannot specify `table_compression` or the `inmemory_clause`, but you can specify `index_compression`.

---

**Note:** If your enterprise has or will have databases using different character sets, then use caution when partitioning on character columns. The sort sequence of characters is not identical in all character sets.

---

**See Also:** *Oracle Database Globalization Support Guide* for more information on character set support

**index_partitioning_clause**  Use this clause to describe the individual index partitions. The number of repetitions of this clause determines the number of partitions. If you omit `partition`, then Oracle Database generates a name with the form `SYS_Pn`.

For `VALUES LESS THAN (value_list)`, specify the noninclusive upper bound for the current partition in a global index. The value list is a comma-delimited, ordered list of literal values corresponding to the column list in the `global_partitioned_index` clause. Always specify `MAXVALUE` as the value of the last partition.

---

**Note:** If the index is partitioned on a `DATE` column, and if the date format does not specify the first two digits of the year, then you must use the `TO_DATE` function with a 4-character format mask for the year. The date format is determined implicitly by `NLS_TERRITORY` or explicitly by `NLS_DATE_FORMAT`. Refer to *Oracle Database Globalization Support Guide* for more information on these initialization parameters.

---

**See Also:** "Range Partitioning Example" on page 16-96

**local_partitioned_index**  The `local_partitioned_index` clauses let you specify that the index is partitioned on the same columns, with the same number of partitions and the same partition bounds as `table`. For composite-partitioned tables, this clause lets you specify that the index is subpartitioned on the same columns, with the same number of subpartitions and the same subpartition bounds as `table`. Oracle Database automatically maintains local index partitioning as the underlying table is repartitioned.

If you specify only the keyword `LOCAL` and do not specify a subclause, then Oracle Database creates each index partition in the same tablespace as its corresponding table partition and assigns it the same name as its corresponding table partition. If `table` is a composite-partitioned table, then Oracle Database creates each index subpartition in the same tablespace as its corresponding table subpartition and assigns it the same name as its corresponding table subpartition.

**on_range_partitioned_table**  This clause lets you specify the names and attributes of index partitions on a range-partitioned table. If you specify this clause, then the number of `PARTITION` clauses must be equal to the number of table partitions, and in
the same order. If you omit partition, then Oracle Database generates a name that is consistent with the corresponding table partition. If the name conflicts with an existing index partition name, then the database uses the form SYS_Pn.

You cannot specify prefix compression for an index partition unless you have specified prefix compression for the index.

For more information on the USABLE and UNUSABLE clauses, refer to USABLE | UNUSABLE on page 14-95.

**on_list_partitioned_table**  
The on_list_partitioned_table clause is identical to on_range_partitioned_table on page 14-91.

**on_hash_partitioned_table**  
This clause lets you specify names and tablespace storage for index partitions on a hash-partitioned table.

If you specify any PARTITION clauses, then the number of these clauses must be equal to the number of table partitions. If you omit partition, then Oracle Database generates a name that is consistent with the corresponding table partition. If the name conflicts with an existing index partition name, then the database uses the form SYS_Pn. You can optionally specify tablespace storage for one or more individual partitions.

If you do not specify tablespace storage either here or in the STORE IN clause, then the database stores each index partition in the same tablespace as the corresponding table partition.

The STORE IN clause lets you specify one or more tablespaces across which Oracle Database will distribute all the index hash partitions. The number of tablespaces need not equal the number of index partitions. If the number of index partitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

For more information on the USABLE and UNUSABLE clauses, refer to USABLE | UNUSABLE on page 14-95.

**on_comp_partitioned_table**  
This clause lets you specify the name and attributes of index partitions on a composite-partitioned table.

The STORE IN clause is valid only for range-hash or list-hash composite-partitioned tables. It lets you specify one or more default tablespaces across which Oracle Database will distribute all index hash subpartitions for all partitions. You can override this storage by specifying different default tablespace storage for the subpartitions of an individual partition in the second STORE IN clause in the index_subpartition_clause.

For range-range, range-list, and list-list composite-partitioned tables, you can specify default attributes for the range or list subpartitions in the PARTITION clause. You can override this storage by specifying different attributes for the range or list subpartitions of an individual partition in the SUBPARTITION clause of the index_subpartition_clause.

You cannot specify prefix compression for an index partition unless you have specified prefix compression for the index.

For more information on the USABLE and UNUSABLE clauses, refer to USABLE | UNUSABLE on page 14-95.

**index_subpartition_clause**  
This clause lets you specify names and tablespace storage for index subpartitions in a composite-partitioned table.
The `STORE IN` clause is valid only for hash subpartitions of a range-hash and list-hash composite-partitioned table. It lets you specify one or more tablespaces across which Oracle Database will distribute all the index hash subpartitions. The `SUBPARTITION` clause is valid for all subpartition types.

If you specify any `SUBPARTITION` clauses, then the number of those clauses must be equal to the number of table subpartitions. If you omit `subpartition`, then the database generates a name that is consistent with the corresponding table subpartition. If the name conflicts with an existing index subpartition name, then the database uses the form `SYS_SUBPn`.

The number of tablespaces need not equal the number of index subpartitions. If the number of index subpartitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

If you do not specify tablespace storage for subpartitions either in the `on_comp_partitioned_table` clause or in the `index_subpartition_clause`, then Oracle Database uses the tablespace specified for `index`. If you also do not specify tablespace storage for `index`, then the database stores the subpartition in the corresponding table subpartition.

For more information on the `USABLE` and `UNUSABLE` clauses, refer to `CREATE INDEX ... USABLE | UNUSABLE` on page 14-95.

`domain_index_clause`

Use the `domain_index_clause` to indicate that `index` is a domain index, which is an instance of an application-specific index of type `indextype`.

Creating a domain index requires a number of preceding operations. You must first create an implementation type for an `indextype`. You must also create a functional implementation and then create an operator that uses the function. Next you create an `indextype`, which associates the implementation type with the operator. Finally, you create the domain index using this clause. Refer to Appendix F, "Extended Examples", which contains an example of creating a simple domain index, including all of these operations.

`index_expr` In the `index_expr` (in `table_index_clause`), specify the table columns or object attributes on which the index is defined. You can define multiple domain indexes on a single column only if the underlying `indextypes` are different and the `indextypes` support a disjoint set of user-defined operators.

Restrictions on Domain Indexes Domain indexes are subject to the following restrictions:

- The `index_expr` (in `table_index_clause`) can specify only a single column, and the column cannot be of data type `REF`, `varray`, nested table, `LONG`, or `LONG RAW`.
- You cannot create a bitmap or unique domain index.
- You cannot create a domain index on a temporary table.
- You can create a local domain index only on a range-, list-, hash-, or interval-partitioned table.

`indextype` For `indextype`, specify the name of the `indextype`. This name should be a valid schema object that has already been created.

If you have installed Oracle Text, then you can use various built-in `indextypes` to create Oracle Text domain indexes. For more information on Oracle Text and the indexes it uses, refer to Oracle Text Reference.
See Also:  CREATE INDEXTYPE on page 14-103

local_domain_index_clause  Use this clause to specify that the index is a local index on a partitioned table.

- The PARTITIONS clause lets you specify names for the index partitions. The number of partitions you specify must match the number of partitions in the base table. If you omit this clause, then the database creates the partitions with system-generated names of the form SYS_Pn.

- The PARAMETERS clause lets you specify the parameter string specific to an individual partition. If you omit this clause, then the parameter string associated with the index is also associated with the partition.

parallel_clause  Use the parallel_clause to parallelize creation of the domain index. For a nonpartitioned domain index, Oracle Database passes the explicit or default degree of parallelism to the ODCIIndexCreate cartridge routine, which in turn establishes parallelism for the index. For local domain indexes, this clause causes the index partitions to be created in parallel.

See Also:  Oracle Database Data Cartridge Developer’s Guide for complete information on the Oracle Data Cartridge Interface (ODCI) routines

PARAMETERS  In the PARAMETERS clause, specify the parameter string that is passed uninterpreted to the appropriate ODCI indextype routine. The maximum length of the parameter string is 1000 characters.

When you specify this clause at the top level of the syntax, the parameters become the default parameters for the index partitions. If you specify this clause as part of the local_domain_index_clause, then you override any default parameters with parameters for the individual partition.

After the domain index is created, Oracle Database invokes the appropriate ODCI routine. If the routine does not return successfully, then the domain index is marked FAILED. The only operations supported on an failed domain index are DROP INDEX and (for non-local indexes) REBUILD INDEX.

See Also:  Oracle Database Data Cartridge Developer’s Guide for information on the Oracle Data Cartridge Interface (ODCI) routines

XMLIndex_clause  The XMLIndex_clause lets you define an XMLIndex index, typically on a column contain XML data. An XMLIndex index is a type of domain index designed specifically for the domain of XML data.

XMLIndex_parameters_clause  This clause lets you specify information about the path table and about the secondary indexes corresponding to the components of XMLIndex. This clause also lets you specify information about the structured component of the index. The maximum length of the parameter string is 1000 characters.

When you specify this clause at the top level of the syntax, the parameters become the parameters of the index and the default parameters for the index partitions. If you specify this clause as part of the local_xmlindex_clause clause, then you override any default parameters with parameters for the individual partition.
CREATE INDEX

**See Also:** Oracle XML DB Developer’s Guide for the syntax and semantics of the `XMLIndex_parameters_clause`, as well as detailed information about the use of `XMLIndex`.

**bitmap_join_index_clause**

Use the `bitmap_join_index_clause` to define a **bitmap join index**. A bitmap join index is defined on a single table. For an index key made up of dimension table columns, it stores the fact table rowids corresponding to that key. In a data warehousing environment, the table on which the index is defined is commonly referred to as a **fact table**, and the tables with which this table is joined are commonly referred to as **dimension tables**. However, a star schema is not a requirement for creating a join index.

**ON** In the **ON** clause, first specify the fact table, and then inside the parentheses specify the columns of the dimension tables on which the index is defined.

**FROM** In the **FROM** clause, specify the joined tables.

**WHERE** In the **WHERE** clause, specify the join condition.

If the underlying fact table is partitioned, then you must also specify one of the `local_partitioned_index` clauses (see `local_partitioned_index` on page 14-91).

**Restrictions on Bitmap Join Indexes** In addition to the restrictions on bitmap indexes in general (see BITMAP on page 14-81), the following restrictions apply to bitmap join indexes:

- You cannot create a bitmap join index on a temporary table.
- No table may appear twice in the **FROM** clause.
- You cannot create a function-based join index.
- The dimension table columns must be either primary key columns or have unique constraints.
- If a dimension table has a composite primary key, then each column in the primary key must be part of the join.
- You cannot specify the `local_partitioned_index` clause unless the fact table is partitioned.

**See Also:** Oracle Database Data Warehousing Guide for information on fact and dimension tables and on using bitmap indexes in a data warehousing environment.

**USABLE | UNUSABLE**

You can specify the **USABLE** and **UNUSABLE** keywords:

- For an index, in the **CREATE INDEX** statement
- For an index partition, in the `on_range_partitioned_table`, `on_list_partitioned_table`, `on_hash_partitioned_table`, and `on_comp_partitioned_table` clauses
- For an index subpartition, in the **index_subpartition_clause**

For nonpartitioned indexes, specify **UNUSABLE** to create an index in an unusable state. An unusable index must be rebuilt, or dropped and re-created, before it can be used. Specify **USABLE** to create an index in a usable state. **USABLE** is the default.

See Also: Oracle XML DB Developer’s Guide for the syntax and semantics of the `XMLIndex_parameters_clause`, as well as detailed information about the use of `XMLIndex`.
For partitioned indexes, specify **USABLE** or **UNUSABLE** as follows:

- If you specify **UNUSABLE** for the index, then all index partitions are marked **UNUSABLE**.
- If you specify **USABLE** for the index, then all index partitions are marked **USABLE**.
- If you do not specify **USABLE** or **UNUSABLE** for the index, then all index partitions are marked **USABLE**. The exception is a local partial index. If you specify the **LOCAL** and **INDEXING PARTIAL** clauses, and do not specify **USABLE** or **UNUSABLE**, then each index partition is marked **USABLE** if the indexing property of its corresponding table partition is **ON**, or **UNUSABLE** if the indexing property of its corresponding table partition is **OFF**.

You can override the preceding conditions by specifying **USABLE** or **UNUSABLE** for a specific index partition.

If the underlying table is a composite-partitioned table, then the preceding conditions for index partitions and table partitions apply instead to index subpartitions and table subpartitions.

After you create a partitioned index, you can choose to rebuild specific index partitions or subpartitions to make them **USABLE**. Doing so can be useful if you want to maintain indexes only on some index partitions or subpartitions—for example, if you want to enable index access for new partitions but not for old partitions.

When an index, or some partitions or subpartitions of an index, are created **UNUSABLE**, no segment is allocated for the unusable object. The unusable index or index partition consumes no space in the database.

If an index, or some partitions or subpartitions of the index, are marked **UNUSABLE**, then the index will be considered as an access path by the optimizer only under the following circumstances: the optimizer must know at compile time which partitions are to be accessed, and all of those partitions to be accessed must be marked **USABLE**. Therefore, the query cannot contain any bind variables.

**Restrictions on USABLE | UNUSABLE**  The following restrictions apply when marking an index **USABLE** or **UNUSABLE**:

- You cannot specify this clause for an index on a temporary table.
- Unusable indexes or index partitions will still have a segment under the following conditions:
  - The index (or index partition) is owned by **SYS**, **SYSTEM**, **PUBLIC**, **OUTLN**, or **XDB**
  - The index (or index partition) is stored in dictionary-managed tablespace
  - The global partitioned or nonpartitioned index on a partitioned table becomes unusable due to a partition maintenance operation

**Examples**

**General Index Examples**

**Creating an Index: Example**  The following statement shows how the sample index `ord_customer_ix` on the `customer_id` column of the sample table `oe.orders` was created:

```sql
CREATE INDEX ord_customer_ix
ON orders (customer_id);
```
**Compressing an Index: Example** To create the `ord_customer_ix_demo` index with the `COMPRESS` clause, you might issue the following statement:

```sql
CREATE INDEX ord_customer_ix_demo
    ON orders (customer_id, sales_rep_id)
    COMPRESS 1;
```

The index will compress repeated occurrences of `customer_id` column values.

**Creating an Index in NOLOGGING Mode: Example** If the sample table `orders` had been created using a fast parallel load (so all rows were already sorted), then you could issue the following statement to quickly create an index.

```sql
/* Unless you first sort the table oe.orders, this example fails
   because you cannot specify NOSORT unless the base table is
   already sorted.
*/
CREATE INDEX ord_customer_ix_demo
    ON orders (order_mode)
    NOSORT
    NOLOGGING;
```

**Creating a Cluster Index: Example** To create an index for the `personnel` cluster, which was created in "Creating a Cluster: Example" on page 14-17, issue the following statement:

```sql
CREATE INDEX idx_personnel ON CLUSTER personnel;
```

No index columns are specified, because cluster indexes are automatically built on all the columns of the cluster key. For cluster indexes, all rows are indexed.

**Creating an Index on an XMLType Table: Example** The following example creates an index on the area element of the `xwarehouses` table (created in "XMLType Table Examples" on page 16-94):

```sql
CREATE INDEX area_index ON xwarehouses e
    (EXTRACTVALUE(VALUE(e),'/Warehouse/Area'));
```

Such an index would greatly improve the performance of queries that select from the table based on, for example, the square footage of a warehouse, as shown in this statement:

```sql
SELECT e.getClobVal() AS warehouse
    FROM xwarehouses e
    WHERE EXISTSNODE(VALUE(e),'/Warehouse[Area>50000]') = 1;
```

**See Also:** `EXISTSNODE` on page 7-104 and `VALUE` on page 7-398

**Function-Based Index Examples**

The following examples show how to create and use function-based indexes.

**Creating a Function-Based Index: Example** The following statement creates a function-based index on the `employees` table based on an uppercase evaluation of the `last_name` column:

```sql
CREATE INDEX upper_ix ON employees (UPPER(last_name));
```

See the "Prerequisites" on page 14-73 for the privileges and parameter settings required when creating function-based indexes.
To increase the likelihood that Oracle Database will use the index rather than performing a full table scan, be sure that the value returned by the function is not null in subsequent queries. For example, this statement will use the index, unless some other condition exists that prevents the optimizer from doing so:

```sql
SELECT first_name, last_name
FROM employees WHERE UPPER(last_name) IS NOT NULL
ORDER BY UPPER(last_name);
```

Without the `WHERE` clause, Oracle Database may perform a full table scan.

In the next statements showing index creation and subsequent query, Oracle Database will use index `income_ix` even though the columns are in reverse order in the query:

```sql
CREATE INDEX income_ix
ON employees(salary + (salary*commission_pct));

SELECT first_name||' '||last_name "Name"
FROM employees
WHERE (salary*commission_pct) + salary > 15000
ORDER BY employee_id;
```

**Creating a Function-Based Index on a LOB Column: Example** The following statement uses the `text_length` function to create a function-based index on a LOB column in the sample `pm` schema. See *Oracle Database PL/SQL Language Reference* for the example that creates this function. The example selects rows from the sample table `print_media` where that CLOB column has fewer than 1000 characters.

```sql
CREATE INDEX src_idx ON print_media(text_length(ad_sourcetext));

SELECT product_id FROM print_media
WHERE text_length(ad_sourcetext) < 1000
ORDER BY product_id;
```

**Creating a Function-based Index on a Type Method: Example** This example entails an object type `rectangle` containing two number attributes: `length` and `width`. The `area()` method computes the area of the rectangle.

```sql
CREATE TYPE rectangle AS OBJECT
( length   NUMBER,
  width    NUMBER,
  MEMBER FUNCTION area RETURN NUMBER DETERMINISTIC
);

CREATE OR REPLACE TYPE BODY rectangle AS
MEMBER FUNCTION area RETURN NUMBER IS
  BEGIN
    RETURN (length*width);
  END;
END;
```

Now, if you create a table `rect_tab` of type `rectangle`, you can create a function-based index on the `area()` method as follows:
CREATE TABLE rect_tab OF rectangle;
CREATE INDEX area_idx ON rect_tab x (x.area());

You can use this index efficiently to evaluate a query of the form:
SELECT * FROM rect_tab x WHERE x.area() > 100;

Using a Function-based Index to Define Conditional Uniqueness: Example  
The following statement creates a unique function-based index on the oe.orders table that prevents a customer from taking advantage of promotion ID 2 ("blowout sale") more than once:

```
CREATE UNIQUE INDEX promo_ix ON orders
    (CASE WHEN promotion_id = 2 THEN customer_id ELSE NULL END,
    CASE WHEN promotion_id = 2 THEN promotion_id ELSE NULL END);
```

```
INSERT INTO orders (order_id, order_date, customer_id, order_total, promotion_id)
    VALUES (2459, systimestamp, 106, 251, 2);
1 row created.

INSERT INTO orders (order_id, order_date, customer_id, order_total, promotion_id)
    VALUES (2460, systimestamp+1, 106, 110, 2);
insert into orders (order_id, order_date, customer_id, order_total, promotion_id) *
ERROR at line 1:
ORA-00001: unique constraint (OE.PROMO_IX) violated
```

The objective is to remove from the index any rows where the promotion_id is not equal to 2. Oracle Database does not store in the index any rows where all the keys are NULL. Therefore, in this example, both customer_id and promotion_id are mapped to NULL unless promotion_id is equal to 2. The result is that the index constraint is violated only if promotion_id is equal to 2 for two rows with the same customer_id value.

Partitioned Index Examples

Creating a Range-Partitioned Global Index: Example  
The following statement creates a global prefixed index cost_ix on the sample table sh.sales with three partitions that divide the range of costs into three groups:

```
CREATE INDEX cost_ix ON sales (amount_sold)
    GLOBAL PARTITION BY RANGE (amount_sold)
    (PARTITION p1 VALUES LESS THAN (1000),
    PARTITION p2 VALUES LESS THAN (2500),
    PARTITION p3 VALUES LESS THAN (MAXVALUE));
```

Creating a Hash-Partitioned Global Index: Example  
The following statement creates a hash-partitioned global index cust_last_name_ix on the sample table sh.customers with four partitions:

```
CREATE INDEX cust_last_name_ix ON customers (cust_last_name)
    GLOBAL PARTITION BY HASH (cust_last_name)
    PARTITIONS 4;
```

Creating an Index on a Hash-Partitioned Table: Example  
The following statement creates a local index on the category_id column of the hash_products partitioned table (which was created in "Hash Partitioning Example" on page 16-98). The STORE IN clause immediately following LOCAL indicates that hash_products is hash partitioned.
Oracle Database will distribute the hash partitions between the tbs1 and tbs2 tablespaces:

```
CREATE INDEX prod_idx ON hash_products(category_id) LOCAL
   STORE IN (tbs_01, tbs_02);
```

The creator of the index must have quota on the tablespaces specified. See CREATE TABLESPACE on page 16-102 for examples that create tablespaces tbs_01 and tbs_02.

### Creating an Index on a Composite-Partitioned Table: Example

The following statement creates a local index on the composite_sales table, which was created in "Composite-Partitioned Table Examples" on page 16-99. The STORAGE clause specifies default storage attributes for the index. However, this default is overridden for the five subpartitions of partitions q3_2000 and q4_2000, because separate TABLESPACE storage is specified.

The creator of the index must have quota on the tablespaces specified. See CREATE TABLESPACE on page 16-102 for examples that create tablespaces tbs_02 and tbs_03.

```
CREATE INDEX sales_ix ON composite_sales(time_id, prod_id)
   STORAGE (INITIAL 1M)
   LOCAL
   (PARTITION q1_1998,
    PARTITION q2_1998,
    PARTITION q3_1998,
    PARTITION q4_1998,
    PARTITION q1_1999,
    PARTITION q2_1999,
    PARTITION q3_1999,
    PARTITION q4_1999,
    PARTITION q1_2000,
    PARTITION q2_2000
      (SUBPARTITION pq2001, SUBPARTITION pq2002,
       SUBPARTITION pq2003, SUBPARTITION pq2004,
       SUBPARTITION pq2005, SUBPARTITION pq2006,
       SUBPARTITION pq2007, SUBPARTITION pq2008),
    PARTITION q3_2000
      (SUBPARTITION c1 TABLESPACE tbs_02,
       SUBPARTITION c2 TABLESPACE tbs_02,
       SUBPARTITION c3 TABLESPACE tbs_02,
       SUBPARTITION c4 TABLESPACE tbs_02,
       SUBPARTITION c5 TABLESPACE tbs_02),
    PARTITION q4_2000
      (SUBPARTITION pq4001 TABLESPACE tbs_03,
       SUBPARTITION pq4002 TABLESPACE tbs_03,
       SUBPARTITION pq4003 TABLESPACE tbs_03,
       SUBPARTITION pq4004 TABLESPACE tbs_03)
   );
```

### Bitmap Index Examples

The following creates a bitmap index on the table oe.hash_products, which was created in “Hash Partitioning Example” on page 16-98:

```
CREATE BITMAP INDEX product_bm_ix
   ON hash_products(list_price)
   LOCAL(PARTITION ix_p1 TABLESPACE tbs_01,
     PARTITION ix_p2,
     PARTITION ix_p3 TABLESPACE tbs_02,
     PARTITION ix_p4 TABLESPACE tbs_03)
   TABLESPACE tbs_04;
```
Because `hash_products` is a partitioned table, the bitmap join index must be locally partitioned. In this example, the user must have quota on tablespaces specified. See `CREATE TABLESPACE` on page 16-102 for examples that create tablespaces `tbs_01`, `tbs_02`, `tbs_03`, and `tbs_04`.

The next series of statements shows how one might create a bitmap join index on a fact table using a join with a dimension table.

```sql
CREATE TABLE hash_products
(
    product_id          NUMBER(6)
  , product_name        VARCHAR2(50)
  , product_description VARCHAR2(2000)
  , category_id         NUMBER(2)
  , weight_class        NUMBER(1)
  , warranty_period     INTERVAL YEAR TO MONTH
  , supplier_id         NUMBER(6)
  , product_status      VARCHAR2(20)
  , list_price          NUMBER(8,2)
  , min_price           NUMBER(8,2)
  , catalog_url         VARCHAR2(50)
  , CONSTRAINT          pk_product_id PRIMARY KEY (product_id)
  , CONSTRAINT          product_status_lov_demo
    CHECK (product_status in ('orderable'
                                , 'planned'
                                , 'under development'
                                , 'obsolete'))
) PARTITION BY HASH (product_id)
PARTITIONS 5
STORE IN (example);

CREATE TABLE sales_quota
(
    product_id          NUMBER(6)
  , customer_name       VARCHAR2(50)
  , order_qty           NUMBER(6)
) CONSTRAINT u_product_id UNIQUE(product_id);

CREATE BITMAP INDEX product_bm_ix
ON hash_products
FROM hash_products h, sales_quota s
WHERE h.product_id = s.product_id
LOCAL(PARTITION ix_p1 TABLESPACE example,
      PARTITION ix_p2,
      PARTITION ix_p3 TABLESPACE example,
      PARTITION ix_p4,
      PARTITION ix_p5 TABLESPACE example)
STORE IN (example);

Indexes on Nested Tables: Example

The sample table `pm.print_media` contains a nested table column `ad_textdocs_ntab`, which is stored in storage table `textdocs_nestedtab`. The following example creates a unique index on storage table `textdocs_nestedtab`:

```sql
CREATE UNIQUE INDEX nested_tab_ix
ON textdocs_nestedtab
(NESTED_TABLE_ID, document_typ);
```

Including pseudocolumn `NESTED_TABLE_ID` ensures distinct rows in nested table column `ad_textdocs_ntab`. 
Indexing on Substitutable Columns: Examples

You can build an index on attributes of the declared type of a substitutable column. In addition, you can reference the subtype attributes by using the appropriate `TREAT` function. The following example uses the table `books`, which is created in "Substitutable Table and Column Examples" on page 16-91. The statement creates an index on the `salary` attribute of all employee authors in the `books` table:

```
CREATE INDEX salary_i
  ON books (TREAT(author AS employee_t).salary);
```

The target type in the argument of the `TREAT` function must be the type that added the attribute being referenced. In the example, the target of `TREAT` is `employee_t`, which is the type that added the `salary` attribute.

If this condition is not satisfied, then Oracle Database interprets the `TREAT` function as any functional expression and creates the index as a function-based index. For example, the following statement creates a function-based index on the `salary` attribute of part-time employees, assigning nulls to instances of all other types in the type hierarchy.

```
CREATE INDEX salary_func_i ON persons p
  (TREAT(VALUE(p) AS part_time_emp_t).salary);
```

You can also build an index on the type-discriminant column underlying a substitutable column by using the `SYS_TYPEID` function.

```
CREATE BITMAP INDEX typeid_i ON books (SYS_TYPEID(author));
```

Note: Oracle Database uses the type-discriminant column to evaluate queries that involve the `IS OF type` condition. The cardinality of the `typeid` column is normally low, so Oracle recommends that you build a bitmap index in this situation.

The following statement creates a bitmap index on the `typeid` of the author column of the `books` table:

```
CREATE BITMAP INDEX typeid_i ON books (SYS_TYPEID(author));
```

See Also:

- *Oracle Database PL/SQL Language Reference* to see the creation of the type hierarchy underlying the `books` table
- the functions `TREAT` on page 7-385 and `SYS_TYPEID` on page 7-346 and the condition "IS OF type Condition" on page 6-34
CREATE INDEXTYPE

Purpose
Use the CREATE INDEXTYPE statement to create an indextype, which is an object that specifies the routines that manage a domain (application-specific) index. Indextypes reside in the same namespace as tables, views, and other schema objects. This statement binds the indextype name to an implementation type, which in turn specifies and refers to user-defined index functions and procedures that implement the indextype.

See Also: Oracle Database Data Cartridge Developer’s Guide for more information on implementing indextypes

Prerequisites
To create an indextype in your own schema, you must have the CREATE INDEXTYPE system privilege. To create an indextype in another schema, you must have the CREATE ANY INDEXTYPE system privilege. In either case, you must have the EXECUTE object privilege on the implementation type and the supported operators.

An indextype supports one or more operators, so before creating an indextype, you must first design the operator or operators to be supported and provide functional implementation for those operators.

See Also: CREATE OPERATOR on page 15-49

Syntax

\[
\text{create\_indextype::=} \\
\text{CREATE OR REPLACE INDEXTYPE schema.\text{indextype}\ FOR schema.\text{operator}(parameter\_type)}, \text{using\_type\_clause;}
\]

\[
\text{\textit{using\_type\_clause::=} \\
\text{USING schema.\text{implementation\_type} array\_DML\_clause}}
\]
array_DML_clause ::= 

\[
\text{WITH} \quad \text{WITHOUT} \quad \text{ARRAY} \quad \text{DML}
\]

storage_table_clause ::= 

\[
\text{WITH} \quad \text{SYSTEM} \quad \text{USER} \quad \text{MANAGED} \quad \text{STORAGE} \quad \text{TABLES}
\]

Semantics

**schema**
Specify the name of the schema in which the indextype resides. If you omit `schema`, then Oracle Database creates the indextype in your own schema.

**index_type**
Specify the name of the indextype to be created.

**FOR Clause**
Use the **FOR** clause to specify the list of operators supported by the indextype.

- For `schema`, specify the schema containing the operator. If you omit `schema`, then Oracle assumes the operator is in your own schema.
- For `operator`, specify the name of the operator supported by the indextype.
  All the operators listed in this clause must be valid operators.
- For `parameter_type`, list the types of parameters to the operator.

**using_type_clause**
The **USING** clause lets you specify the type that provides the implementation for the new indextype.

For `implementation_type`, specify the name of the type that implements the appropriate Oracle Data Cartridge Interface (ODCI).

- You must specify a valid type that implements the routines in the ODCI.
- The implementation type must reside in the same schema as the indextype.

**See Also:** *Oracle Database Data Cartridge Developer’s Guide* for additional information on this interface.
WITH LOCAL PARTITION

Use this clause to indicate that the indextype can be used to create local domain indexes on range-, list-, hash-, and interval-partitioned tables. You use this clause in combination with the `storage_table_clause` in several ways (see `storage_table_clause` on page 14-105).

- The recommended method is to specify `WITH LOCAL PARTITION WITH SYSTEM MANAGED STORAGE TABLES`. This combination uses system-managed storage tables, which are the preferred storage management, and lets you create local domain indexes on range-, list-, hash-, and interval-partitioned tables. In this case the `RANGE` keyword is optional and ignored, because it is no longer needed if you specify `WITH LOCAL PARTITION WITH SYSTEM MANAGED STORAGE TABLES`.

- You can specify `WITH LOCAL RANGE PARTITION` (including the `RANGE` keyword) and omit the `storage_table` clause. Local domain indexes on range-partitioned tables are supported with user-managed storage tables for backward compatibility. Oracle does not recommend this combination because it uses the less efficient user-managed storage tables.

If you omit this clause entirely, then you cannot subsequently use this indextype to create a local domain index on a range, list-, hash-, or interval-partitioned table.

`storage_table_clause`

Use this clause to specify how storage tables and partition maintenance operations for indexes built on this indextype are managed:

- Specify `WITH SYSTEM MANAGED STORAGE TABLES` to indicate that the storage of statistics data is to be managed by the system. The type you specify in `statistics_type` should be storing the statistics related information in tables that are maintained by the system. Also, the indextype you specify must already have been created or altered to support the `WITH SYSTEM MANAGED STORAGE TABLES` clause.

- Specify `WITH USER MANAGED STORAGE TABLES` to indicate that the tables that store the user-defined statistics will be managed by the user. This is the default behavior.

See Also: `Oracle Database Data Cartridge Developer’s Guide` for more information about storage tables for domain indexes

`array_DML_clause`

Use this clause to let the indextype support the array interface for the ODCIIndexInsert method.

`type and varray_type` If the data type of the column to be indexed is a user-defined object type, then you must specify this clause to identify the varray `varray_type` that Oracle should use to hold column values of `type`. If the indextype supports a list of types, then you can specify a corresponding list of varray types. If you omit `schema` for either `type` or `varray_type`, then Oracle assumes the type is in your own schema.

If the data type of the column to be indexed is a built-in system type, then any varray type specified for the indextype takes precedence over the ODCI types defined by the system.

See Also: `Oracle Database Data Cartridge Developer’s Guide` for more information on the ODCI array interface
Examples

Creating an Indextype: Example  The following statement creates an indextype named position_indextype and specifies the position_between operator that is supported by the indextype and the position_im type that implements the index interface. Refer to "Using Extensible Indexing" on page F-1 for an extensible indexing scenario that uses this indextype:

```
CREATE INDEXTYPE position_indextype
  FOR position_between(NUMBER, NUMBER, NUMBER)
  USING position_im;
```
CREATE JAVA

Purpose

Use the CREATE JAVA statement to create a schema object containing a Java source, class, or resource.

See Also:
- Oracle Database Java Developer’s Guide for Java concepts and information about Java stored procedures
- Oracle Database JDBC Developer’s Guide for information on JDBC

Prerequisites

To create or replace a schema object containing a Java source, class, or resource in your own schema, you must have CREATE PROCEDURE system privilege. To create or replace such a schema object in another user’s schema, you must have CREATE ANY PROCEDURE system privilege.

Syntax

\[ create_{\text{java}} ::= \]

```sql
CREATE [OR REPLACE] [AND] [RESOLVE] [NOFORCE] [COMPILE]

JAVA [SOURCE | RESOURCE | CLASS] [SCHEMA schema] [NAMED primary_name]

invoker_rights_clause

RESOLVER (match_string, schema_name)

USING \( [\text{BFILE} (directory_object_name, server_file_name)] | \text{CLOB} \) \( \text{AS} \) source_char
```

```
create_java ::= 
```
invoker_rights_clause ::= 

AUTHID CURRENT_USER DEFINER

Semantics

**OR REPLACE**
Specify **OR REPLACE** to re-create the schema object containing the Java class, source, or resource if it already exists. Use this clause to change the definition of an existing object without dropping, re-creating, and regranting object privileges previously granted.

If you redefine a Java schema object and specify **RESOLVE** or **COMPILE**, then Oracle Database recompiles or resolves the object. Whether or not the resolution or compilation is successful, the database invalidates classes that reference the Java schema object.

Users who had previously been granted privileges on a redefined function can still access the function without being regranted the privileges.

**See Also:**  *ALTER JAVA* on page 10-130 for additional information

**RESOLVE | COMPILE**
**RESOLVE** and **COMPILE** are synonymous keywords. They specify that Oracle Database should attempt to resolve the Java schema object that is created if this statement succeeds.

- When applied to a class, resolution of referenced names to other class schema objects occurs.
- When applied to a source, source compilation occurs.

**Restriction on RESOLVE and COMPILE** You cannot specify these keywords for a Java resource.

**NOFORCE**
Specify **NOFORCE** to roll back the results of this **CREATE** command if you have specified either **RESOLVE** or **COMPILE** and the resolution or compilation fails. If you do not specify this option, then Oracle Database takes no action if the resolution or compilation fails, and the created schema object remains.

**JAVA SOURCE Clause**
Specify **JAVA SOURCE** to load a Java source file.

**JAVA CLASS Clause**
Specify **JAVA CLASS** to load a Java class file.

**JAVA RESOURCE Clause**
Specify **JAVA RESOURCE** to load a Java resource file.
NAMED Clause

The NAMED clause is required for a Java source or resource. The primary_name must be enclosed in double quotation marks and its length must not exceed 4000 bytes in the database character set.

- For a Java source, this clause specifies the name of the schema object in which the source code is held. A successful CREATE JAVA SOURCE statement will also create additional schema objects to hold each of the Java classes defined by the source.
- For a Java resource, this clause specifies the name of the schema object to hold the Java resource.

Use double quotation marks to preserve a lower- or mixed-case primary_name.

If you do not specify schema, then Oracle Database creates the object in your own schema.

Restrictions on NAMED Java Classes

The NAMED clause is subject to the following restrictions:

- You cannot specify NAMED for a Java class.
- The primary_name cannot contain a database link.

SCHEMA Clause

The SCHEMA clause applies only to a Java class. This optional clause specifies the schema in which the object containing the Java file will reside. If you do not specify this clause, then Oracle Database creates the object in your own schema.

invoker_rights_clause

Use the invoker_rights_clause to indicate whether the methods of the class execute with the privileges and in the schema of the user who owns the class or with the privileges and in the schema of CURRENT_USER.

This clause also determines how Oracle Database resolves external names in queries, DML operations, and dynamic SQL statements in the member functions and procedures of the type.

AUTHID CURRENT_USER

CURRENT_USER indicates that the methods of the class execute with the privileges of CURRENT_USER. This clause is the default and creates an invoker-rights class.

This clause also specifies that external names in queries, DML operations, and dynamic SQL statements resolve in the schema of CURRENT_USER. External names in all other statements resolve in the schema in which the methods reside.

AUTHID DEFINER

DEFINER indicates that the methods of the class execute with the privileges of the owner of the schema in which the class resides, and that external names resolve in the schema where the class resides. This clause creates a definer-rights class.

See Also:

- Oracle Database Java Developer’s Guide
- Oracle Database PL/SQL Language Reference for information on how CURRENT_USER is determined
RESOLVER Clause

The RESOLVER clause lets you specify a mapping of the fully qualified Java name to a Java schema object, where:

- `match_string` is either a fully qualified Java name, a wildcard that can match such a Java name, or a wildcard that can match any name.
- `schema_name` designates a schema to be searched for the corresponding Java schema object.
- A dash (-) as an alternative to `schema_name` indicates that if `match_string` matches a valid Java name, Oracle Database can leave the name unresolved. The resolution succeeds, but the name cannot be used at run time by the class.

This mapping is stored with the definition of the schema objects created in this command for use in later resolutions (either implicit or in explicit `ALTER JAVA ... RESOLVE` statements).

USING Clause

The USING clause determines a sequence of character data (CLOB or BFILE) or binary data (BLOB or BFILE) for the Java class or resource. Oracle Database uses the sequence of characters to define one file for a Java class or resource, or one source file and one or more derived classes for a Java source.

BFILE Clause

Specify the directory and filename of a previously created file on the operating system (`directory_object_name`) and server file (`server_file_name`) containing the sequence.

BFILE is usually interpreted as a character sequence by `CREATE JAVA SOURCE` and as a binary sequence by `CREATE JAVA CLASS` or `CREATE JAVA RESOURCE`.

CLOB | BLOB | BFILE subquery

Specify a subquery that selects a single row and column of the type specified (CLOB, BLOB, or BFILE). The value of the column makes up the sequence of characters.

---

**Note:** In earlier releases, the USING clause implicitly supplied the keyword SELECT. This is no longer the case. However, the subquery without the keyword SELECT is still supported for backward compatibility.

---

`key_for_BLOB`

The `key_for_BLOB` clause supplies the following implicit query:

```
SELECT LOB FROM CREATE$JAVA$LOB$TABLE
    WHERE NAME = 'key_for_BLOB';
```

**Restriction on the key_for_BLOB Clause** For you to use this case, the table `CREATE$JAVA$LOB$TABLE` must exist in the current schema and must have a column LOB of type BLOB and a column NAME of type VARCHAR2.

**AS source_char**

Specify a sequence of characters for a Java source.
Examples

**Creating a Java Class Object: Example**  The following statement creates a schema object containing a Java class using the name found in a Java binary file:

```sql
CREATE JAVA CLASS USING BFILE (java_dir, 'Agent.class')
```

This example assumes the directory object `java_dir`, which points to the operating system directory containing the Java class `Agent.class`, already exists. In this example, the name of the class determines the name of the Java class schema object.

**Creating a Java Source Object: Example**  The following statement creates a Java source schema object:

```sql
CREATE JAVA SOURCE NAMED "Welcome" AS
   public class Welcome {
       public static String welcome() {
           return "Welcome World";
       }
   }
```

**Creating a Java Resource Object: Example**  The following statement creates a Java resource schema object named `appText` from a `bfile`:

```sql
CREATE JAVA RESOURCE NAMED "appText"
   USING BFILE (java_dir, 'textBundle.dat')
```
This chapter contains the following SQL statements:

- CREATE LIBRARY
- CREATE MATERIALIZED VIEW
- CREATE MATERIALIZED VIEW LOG
- CREATE MATERIALIZED ZONEMAP
- CREATE OPERATOR
- CREATE OUTLINE
- CREATE PACKAGE
- CREATE PACKAGE BODY
- CREATE PFILE
- CREATE PLUGGABLE DATABASE
- CREATE PROCEDURE
- CREATE PROFILE
- CREATE RESTORE POINT
- CREATE ROLE
- CREATE ROLLBACK SEGMENT
- CREATE SCHEMA
- CREATE SEQUENCE
- CREATE SPFILE
CREATE LIBRARY

Purpose

Use the CREATE LIBRARY statement to create a schema object associated with an operating-system shared library. The name of this schema object can then be used in the call_spec of CREATE FUNCTION or CREATE PROCEDURE statements, or when declaring a function or procedure in a package or type, so that SQL and PL/SQL can call to third-generation-language (3GL) functions and procedures.

See Also: CREATE FUNCTION on page 14-71 and Oracle Database PL/SQL Language Reference for more information on functions and procedures

Prerequisites

The CREATE LIBRARY statement is valid only on platforms that support shared libraries and dynamic linking.

To create a library in your own schema, you must have the CREATE LIBRARY system privilege. To create a library in another user's schema, you must have the CREATE ANY LIBRARY system privilege.

To use the library in the call_spec of a CREATE FUNCTION statement, or when declaring a function in a package or type, you must have the EXECUTE object privilege on the library and the CREATE FUNCTION system privilege. Refer to Oracle Database PL/SQL Language Reference for information on the call_spec of a CREATE FUNCTION statement.

To use the library in the call_spec of a CREATE PROCEDURE statement, or when declaring a procedure in a package or type, you must have the EXECUTE object privilege on the library and the CREATE PROCEDURE system privilege. Refer to Oracle Database PL/SQL Language Reference for information on the call_spec of a CREATE PROCEDURE statement.

To execute a procedure or function defined with the call_spec (including a procedure or function defined within a package or type), you must have the EXECUTE object privilege on the procedure or function (but you do not need the EXECUTE object privilege on the library).

Syntax

Libraries are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to Oracle Database PL/SQL Language Reference for the PL/SQL syntax, semantics, and examples.

create_library ::=  

(create | OR | REPLACE | EDITIONABLE) LIBRARY plsql_library_source  

(plsql_library_source: See Oracle Database PL/SQL Language Reference.)
Semantics

**OR REPLACE**
Specify **OR REPLACE** to re-create the library if it already exists. Use this clause to change the definition of an existing library without dropping, re-creating, and regranting object privileges granted on it.

Users who had previously been granted privileges on a redefined library can still access the library without being regranted the privileges.

**[ EDITIONABLE | NONEDITIONABLE ]**
Use these clauses to specify whether the library is an editioned or noneditioned object if editioning is enabled for the schema object type LIBRARY in `schema`. The default is EDITIONABLE. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

**plsql_library_source**
See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the `plsql_library_source`. 
CREATE MATERIALIZED VIEW

Purpose

Use the CREATE MATERIALIZED VIEW statement to create a materialized view. A materialized view is a database object that contains the results of a query. The FROM clause of the query can name tables, views, and other materialized views. Collectively these objects are called master tables (a replication term) or detail tables (a data warehousing term). This reference uses "master tables" for consistency. The databases containing the master tables are called the master databases.

Note: The keyword SNAPSHOT is supported in place of MATERIALIZED VIEW for backward compatibility.

For replication purposes, materialized views allow you to maintain copies of remote data on your local node. The copies can be updatable with the Advanced Replication feature and are read-only without this feature. You can select data from a materialized view as you would from a table or view. In replication environments, the materialized views commonly created are primary key, rowid, object, and subquery materialized views.

See Also: Oracle Database Advanced Replication for information on the types of materialized views used to support replication

For data warehousing purposes, the materialized views commonly created are materialized aggregate views, single-table materialized aggregate views, and materialized join views. All three types of materialized views can be used by query rewrite, an optimization technique that transforms a user request written in terms of master tables into a semantically equivalent request that includes one or more materialized views.

See Also:
- ALTER MATERIALIZED VIEW on page 11-3
- Oracle Database Data Warehousing Guide for information on the types of materialized views used to support data warehousing

Prerequisites

The privileges required to create a materialized view should be granted directly rather than through a role.

To create a materialized view in your own schema:
- You must have been granted the CREATE MATERIALIZED VIEW system privilege and either the CREATE TABLE or CREATE ANY TABLE system privilege.
- You must also have access to any master tables of the materialized view that you do not own, either through a READ or SELECT object privilege on each of the tables or through the READ ANY TABLE or SELECT ANY TABLE system privilege.

To create a materialized view in another user's schema:
- You must have the CREATE ANY MATERIALIZED VIEW system privilege.
- The owner of the materialized view must have the CREATE TABLE system privilege. The owner must also have access to any master tables of the materialized view.
that the schema owner does not own (for example, if the master tables are on a remote database) and to any materialized view logs defined on those master tables, either through a READ or SELECT object privilege on each of the tables or through the READ ANY TABLE or SELECT ANY TABLE system privilege.

To create a refresh-on-commit materialized view (REFRESH ON COMMIT clause), in addition to the preceding privileges, you must have the ON COMMIT REFRESH object privilege on any master tables that you do not own or you must have the ON COMMIT REFRESH system privilege.

To create the materialized view with query rewrite enabled, in addition to the preceding privileges:

- If the schema owner does not own the master tables, then the schema owner must have the GLOBAL QUERY REWRITE privilege or the QUERY REWRITE object privilege on each table outside the schema.
- If you are defining the materialized view on a prebuilt container (ON PREBUILT TABLE clause), then you must have the READ or SELECT privilege WITH GRANT OPTION on the container table.

The user whose schema contains the materialized view must have sufficient quota in the target tablespace to store the master table and index of the materialized view or must have the UNLIMITED TABLESPACE system privilege.

When you create a materialized view, Oracle Database creates one internal table and at least one index, and may create one view, all in the schema of the materialized view. Oracle Database uses these objects to maintain the materialized view data. You must have the privileges necessary to create these objects.

You can create the following types of local materialized views (including both ON COMMIT and ON DEMAND) on master tables with commit SCN-based materialized view logs:

- Materialized aggregate views, including materialized aggregate views on a single table
- Materialized join views
- Primary-key-based and rowid-based single table materialized views
- UNION ALL materialized views, where each UNION ALL branch is one of the above materialized view types

You cannot create remote materialized views on master tables with commit SCN-based materialized view logs.

Creating a materialized view on master tables with different types of materialized view logs (that is, a master table with timestamp-based materialized view logs and a master table with commit SCN-based materialized view logs) is not supported and causes ORA-32414.

To specify an edition in the evaluation_edition_clause or the unusable_editions_clause, you must have the USE privilege on the edition.

**Semantics**

**schema**
Specify the schema to contain the materialized view. If you omit `schema`, then Oracle Database creates the materialized view in your schema.

**materialized_view**
Specify the name of the materialized view to be created. The name must satisfy the requirements listed in "Database Object Naming Rules" on page 2-119. Oracle Database generates names for the table and indexes used to maintain the materialized view by adding a prefix or suffix to the materialized view name.

**column_alias**
You can specify a column alias for each column of the materialized view. The column alias list explicitly resolves any column name conflict, eliminating the need to specify aliases in the `SELECT` clause of the materialized view. If you specify any column alias in this clause, then you must specify an alias for each data source referenced in the `SELECT` clause.

**ENCRYPT clause**
Use this clause to encrypt this column of the materialized view. Refer to the `CREATE TABLE` clause encryption_spec on page 16-35 for more information on column encryption.

**OF object_type**
The `OF object_type` clause lets you explicitly create an object materialized view of type `object_type`. 

---

15-14  Oracle Database SQL Language Reference
See Also: See CREATE TABLE ... object_table on page 16-8 for more information on the OF type_name clause

**scoped_table_ref_constraint**

Use the SCOPE FOR clause to restrict the scope of references to a single object table. You can refer either to the table name with scope_table_name or to a column alias. The values in the REF column or attribute point to objects in scope_table_name or c_alias, in which object instances of the same type as the REF column are stored. If you specify aliases, then they must have a one-to-one correspondence with the columns in the SELECT list of the defining query of the materialized view.

See Also: "SCOPE REF Constraints" on page 8-13 for more information

**ON PREBUILT TABLE Clause**

The ON PREBUILT TABLE clause lets you register an existing table as a preinitialized materialized view. This clause is particularly useful for registering large materialized views in a data warehousing environment. The table must have the same name and be in the same schema as the resulting materialized view.

If the materialized view is dropped, then the preexisting table reverts to its identity as a table.

---

**Caution:** This clause assumes that the table object reflects the materialization of a subquery. Oracle strongly recommends that you ensure that this assumption is true in order to ensure that the materialized view correctly reflects the data in its master tables.

---

The ON PREBUILT TABLE clause could be useful in the following scenarios:

- You have a table representing the result of a query. Creating the table was an expensive operation that possibly took a long time. You want to create a materialized view on the query. You can use the ON PREBUILT TABLE clause to avoid the expense of executing the query and populating the container for the materialized view.

- You temporarily discontinue having a materialized view, but keep its container table, using the DROP MATERIALIZED VIEW ... PRESERVE TABLE statement. You then decide to recreate the materialized view and you know that the master tables of the view have not changed. You can create the materialized view using the ON PREBUILT TABLE clause. This avoids the expense and time of creating and populating the container table for the materialized view.

If you specify ON PREBUILT TABLE, then Oracle database does not create the I_SNAPS index. This index improves fast refresh performance. If you want the benefits of this index, then you can create it manually. Refer to Oracle Database Data Warehousing Guide for more information.

**WITH REDUCED PRECISION** Specify WITH REDUCED PRECISION to authorize the loss of precision that will result if the precision of the table or materialized view columns do not exactly match the precision returned by subquery.

**WITHOUT REDUCED PRECISION** Specify WITHOUT REDUCED PRECISION to require that the precision of the table or materialized view columns match exactly the precision returned by subquery, or the create operation will fail. This is the default.
**Restrictions on Using Prebuilt Tables**  Prebuilt tables are subject to the following restrictions:

- Each column alias in *subquery* must correspond to a column in the prebuilt table, and corresponding columns must have matching data types.
- If you specify this clause, then you cannot specify a *NOT NULL* constraint for any column that is not referenced in *subquery* unless you also specify a default value for that column.
- You cannot specify the **ON PREBUILT TABLE** clause when creating a rowid materialized view.

**See Also:**  "Creating Prebuilt Materialized Views: Example" on page 15-28

**physical_properties_clause**

The components of the **physical_properties_clause** have the same semantics for materialized views that they have for tables, with exceptions and additions described in the sections that follow.

**Restriction on the physical_properties_clause**  You cannot specify **ORGANIZATION EXTERNAL** for a materialized view.

**deferred_segment_creation**

Use this clause to determine when the segment for this materialized view should be created. See the **CREATE TABLE** clause **deferred_segment_creation** on page 16-43 for more information.

**segment_attributes_clause**

Use the **segment_attributes_clause** to establish values for the **PCTFREE**, **PCTUSED**, and **INTEGRITY** parameters, the storage characteristics for the materialized view, to assign a tablespace, and to specify whether logging is to occur. In the **USING INDEX** clause, you cannot specify **PCTFREE** or **PCTUSED**.

**TABLESPACE Clause**  Specify the tablespace in which the materialized view is to be created. If you omit this clause, then Oracle Database creates the materialized view in the default tablespace of the schema containing the materialized view.

**See Also:**  **physical_attributes_clause** on page 8-44 and **storage_clause** on page 8-46 for a complete description of these clauses, including default values

**logging_clause**  Specify **LOGGING** or **NOLGOGING** to establish the logging characteristics for the materialized view. The logging characteristic affects the creation of the materialized view and any nonatomic refresh that is initiated by way of the **DBMS_REFRESH** package. The default is the logging characteristic of the tablespace in which the materialized view resides.

**See Also:**  **logging_clause** on page 8-38 for a full description of this clause and Oracle Database PL/SQL Packages and Types Reference for more information on atomic and nonatomic refresh

**table_compression**

Use the **table_compression** clause to instruct the database whether to compress data segments to reduce disk and memory use. This clause has the same semantics in
CREATE MATERIALIZED VIEW and CREATE TABLE. Refer to the *table_compression* clause on page 16-45 in the documentation on CREATE TABLE for the full semantics of this clause.

**innmemory_table_clause**

Use the *innmemory_table_clause* to enable or disable the materialized view for the In-Memory Column Store (IM column store). This clause has the same semantics as the *innmemory_table_clause* on page 16-48 in the CREATE TABLE documentation.

**innmemory_column_clause**

Use the *innmemory_column_clause* to disable specific materialized view columns for the IM column store, and to specify the data compression method for specific columns. In order to specify this clause, the materialized view must be enabled for the IM column store. This clause has the same semantics as the *innmemory_column_clause* on page 16-50 in the CREATE TABLE documentation, with the following addition: If you specify the *innmemory_column_clause*, then you must also specify a *column_alias* for each column in the materialized view.

**index_org_table_clause**

The *ORGANIZATION INDEX* clause lets you create an index-organized materialized view. In such a materialized view, data rows are stored in an index defined on the primary key of the materialized view. You can specify index organization for the following types of materialized views:

- Read-only and updatable object materialized views. You must ensure that the master table has a primary key.
- Read-only and updatable primary key materialized views.
- Read-only rowid materialized views.

The keywords and parameters of the *index_org_table_clause* have the same semantics as described in CREATE TABLE, with the restrictions that follow.

**See Also:** The *index_org_table_clause* of CREATE TABLE on page 16-52

**Restrictions on Index-Organized Materialized Views** Index-organized materialized views are subject to the following restrictions:

- You cannot specify the following CREATE MATERIALIZED VIEW clauses: CACHE or NOCACHE, CLUSTER, or ON PREBUILT TABLE.
- In the *index_org_table_clause*:
  - You cannot specify the *mapping_table_clause*.
  - You can specify COMPRESS only for a materialized view based on a composite primary key. You can specify NOCOMPRESS for a materialized view based on either a simple or composite primary key.

**CLUSTER Clause**

The *CLUSTER* clause lets you create the materialized view as part of the specified cluster. A cluster materialized view uses the space allocation of the cluster. Therefore, you do not specify physical attributes or the TABLESPACE clause with the CLUSTER clause.

**Restriction on Cluster Materialized Views** If you specify CLUSTER, then you cannot specify the *table_partitioning_clauses* in materialized_view_props.
**materialized_view_props**

Use these property clauses to describe a materialized view that is not based on an existing table. To create a materialized view that is based on an existing table, use the `ON PREBUILT TABLE` clause.

**column_properties**

The `column_properties` clause lets you specify the storage characteristics of a LOB, nested table, varray, or `XMLType` column. The `object_type_col_properties` are not relevant for a materialized view.

See Also:  `CREATE TABLE` on page 16-6 for detailed information about specifying the parameters of this clause

**table_partitioning_clauses**

The `table_partitioning_clauses` let you specify that the materialized view is partitioned on specified ranges of values or on a hash function. Partitioning of materialized views is the same as partitioning of tables.

See Also:  `table_partitioning_clauses` on page 16-67 in the `CREATE TABLE` documentation

**CACHE | NOCACHE**

For data that will be accessed frequently, `CACHE` specifies that the blocks retrieved for this table are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables. `NOCACHE` specifies that the blocks are placed at the least recently used end of the LRU list.

---

**Note:**  `NOCACHE` has no effect on materialized views for which you specify `KEEP` in the `storage_clause`.

See Also:  `CREATE TABLE` on page 16-6 for information about specifying `CACHE` or `NOCACHE`

**parallel_clause**

The `parallel_clause` lets you indicate whether parallel operations will be supported for the materialized view and sets the default degree of parallelism for queries and DML on the materialized view after creation.

For complete information on this clause, refer to `parallel_clause` on page 16-81 in the documentation on `CREATE TABLE`.

**build_clause**

The `build_clause` lets you specify when to populate the materialized view.

**IMMEDIATE**  Specify `IMMEDIATE` to indicate that the materialized view is to be populated immediately. This is the default.

**DEFERRED**  Specify `DEFERRED` to indicate that the materialized view is to be populated by the next `REFRESH` operation. The first (deferred) refresh must always be a complete refresh. Until then, the materialized view has a staleness value of `UNUSABLE`, so it cannot be used for query rewrite.
USING INDEX Clause
The USING INDEX clause lets you establish the value of the INITRANS and STORAGE parameters for the default index Oracle Database uses to maintain the materialized view data. If USING INDEX is not specified, then default values are used for the index. Oracle Database uses the default index to speed up incremental (FAST) refresh of the materialized view.

Restriction on USING INDEX clause  You cannot specify the PCTUSED parameter in this clause.

USING NO INDEX Clause
Specify USING NO INDEX to suppress the creation of the default index. You can create an alternative index explicitly by using the CREATE INDEX statement. You should create such an index if you specify USING NO INDEX and you are creating the materialized view with the fast refresh method (REFRESH FAST).

create_mv_refresh
Use the create_mv_refresh clause to specify the default methods, modes, and times for the database to refresh the materialized view. If the master tables of a materialized view are modified, then the data in the materialized view must be updated to make the materialized view accurately reflect the data currently in its master tables. This clause lets you schedule the times and specify the method and mode for the database to refresh the materialized view.

Restriction on Synchronous Refresh  If you are using the synchronous refresh method, then you must specify ON DEMAND and USING TRUSTED CONSTRAINTS.

Note:  This clause only sets the default refresh options. For instructions on actually implementing the refresh, refer to Oracle Database Advanced Replication and Oracle Database Data Warehousing Guide.

See Also:
- Oracle Database PL/SQL Packages and Types Reference for more information on refresh methods

FAST Clause
Specify FAST to indicate the fast refresh method, which performs the refresh according to the changes that have occurred to the master tables. The changes for conventional DML changes are stored in the materialized view log associated with the master table. The changes for direct-path INSERT operations are stored in the direct loader log.

If you specify REFRESH FAST, then the CREATE statement will fail unless materialized view logs already exist for the materialized view master tables. Oracle Database creates the direct loader log automatically when a direct-path INSERT takes place. No user intervention is needed.

For both conventional DML changes and for direct-path INSERT operations, other conditions may restrict the eligibility of a materialized view for fast refresh.
Restrictions on FAST Refresh

FAST refresh is subject to the following restrictions:

- When you specify FAST refresh at create time, Oracle Database verifies that the materialized view you are creating is eligible for fast refresh. When you change the refresh method to FAST in an ALTER MATERIALIZED VIEW statement, Oracle Database does not perform this verification. If the materialized view is not eligible for fast refresh, then Oracle Database returns an error when you attempt to refresh this view.

- Materialized views are not eligible for fast refresh if the defining query contains an analytic function or the XMLTable function.

- Materialized views are not eligible for fast refresh if the defining query references a table on which an XMLIndex index is defined.

- You cannot fast refresh a materialized view if any of its columns is encrypted.

See Also:
- Oracle Database Advanced Replication for restrictions on fast refresh in replication environments
- Oracle Database Data Warehousing Guide for restrictions on fast refresh in data warehousing environments
- The EXPLAIN_MVIEW procedure of the DBMS_MVIEW package for help diagnosing problems with fast refresh and the TUNE_MVIEW procedure of the DBMS_MVIEW package for correction of fast refresh problems
- "Analytic Functions" on page 7-12
- "Creating a Fast Refreshable Materialized View: Example" on page 15-29

COMPLETE Clause

Specify COMPLETE to indicate the complete refresh method, which is implemented by executing the defining query of the materialized view. If you request a complete refresh, then Oracle Database performs a complete refresh even if a fast refresh is possible.

FORCE Clause

Specify FORCE to indicate that when a refresh occurs, Oracle Database will perform a fast refresh if one is possible or a complete refresh if fast refresh is not possible. If you do not specify a refresh method (FAST, COMPLETE, or FORCE), then FORCE is the default.

ON COMMIT Clause

Specify ON COMMIT to indicate that a refresh is to occur whenever the database commits a transaction that operates on a master table of the materialized view. This clause may increase the time taken to complete the commit, because the database performs the refresh operation as part of the commit process.

You cannot specify both ON COMMIT and ON DEMAND. If you specify ON COMMIT, then you cannot also specify START WITH or NEXT.

Restrictions on Refreshing ON COMMIT

- This clause is not supported for materialized views containing object types or Oracle-supplied types.
- This clause is not supported for materialized views with remote tables.
If you specify this clause, then you cannot subsequently execute a distributed transaction on any master table of this materialized view. For example, you cannot insert into the master by selecting from a remote table. The ON DEMAND clause does not impose this restriction on subsequent distributed transactions on master tables.

**ON DEMAND Clause**
Specify `ON DEMAND` to indicate that database will not refresh the materialized view unless the user manually launches a refresh through one of the three `DBMS_MVIEW` refresh procedures.

You cannot specify both `ON COMMIT` and `ON DEMAND`. If you omit both `ON COMMIT` and `ON DEMAND`, then `ON DEMAND` is the default. You can override this default setting by specifying the `START WITH` or `NEXT` clauses, either in the same `CREATE MATERIALIZED VIEW` statement or a subsequent `ALTER MATERIALIZED VIEW` statement.

`START WITH` and `NEXT` take precedence over `ON DEMAND`. Therefore, in most circumstances it is not meaningful to specify `ON DEMAND` when you have specified `START WITH` or `NEXT`.

**See Also:**
- Oracle Database PL/SQL Packages and Types Reference for information on these procedures
- Oracle Database Data Warehousing Guide on the types of materialized views you can create by specifying `REFRESH ON DEMAND`

**START WITH Clause**
Specify a datetime expression for the first automatic refresh time.

**NEXT Clause**
Specify a datetime expression for calculating the interval between automatic refreshes.

Both the `START WITH` and `NEXT` values must evaluate to a time in the future. If you omit the `START WITH` value, then the database determines the first automatic refresh time by evaluating the `NEXT` expression with respect to the creation time of the materialized view. If you specify a `START WITH` value but omit the `NEXT` value, then the database refreshes the materialized view only once. If you omit both the `START WITH` and `NEXT` values, or if you omit the `create_mv_refresh` entirely, then the database does not automatically refresh the materialized view.

**WITH PRIMARY KEY Clause**
Specify `WITH PRIMARY KEY` to create a primary key materialized view. This is the default and should be used in all cases except those described for `WITH ROWID`. Primary key materialized views allow materialized view master tables to be reorganized without affecting the eligibility of the materialized view for fast refresh. The master table must contain an enabled primary key constraint, and the defining query of the materialized view must specify all of the primary key columns directly. In the defining query, the primary key columns cannot be specified as the argument to a function such as `UPPER`.

**Restriction on Primary Key Materialized Views** You cannot specify this clause for an object materialized view. Oracle Database implicitly refreshes objects materialized `WITH OBJECT ID`. 

---

SQL Statements: CREATE LIBRARY to CREATE SPFILE 15-21
WITH ROWID Clause
Specify WITH ROWID to create a rowid materialized view. Rowid materialized views are useful if the materialized view does not include all primary key columns of the master tables. Rowid materialized views must be based on a single table and cannot contain any of the following:

- Distinct or aggregate functions
- GROUP BY or CONNECT BY clauses
- Subqueries
- Joins
- Set operations

The WITH ROWID clause has no effect if there are multiple master tables in the defining query.

Rowid materialized views are not eligible for fast refresh after a master table reorganization until a complete refresh has been performed.

Restriction on Rowid Materialized Views
You cannot specify this clause for an object materialized view. Oracle Database implicitly refreshes objects materialized WITH OBJECT ID.

See Also: Oracle Database Advanced Replication for detailed information about primary key materialized views and "Creating Primary Key Materialized Views: Example" on page 15-28

USING ROLLBACK SEGMENT Clause
This clause is not valid if your database is in automatic undo mode, because in that mode Oracle Database uses undo tablespaces instead of rollback segments. Oracle strongly recommends that you use automatic undo mode. This clause is supported for backward compatibility with replication environments containing older versions of Oracle Database that still use rollback segments.

For rollback_segment, specify the remote rollback segment to be used during materialized view refresh.

DEFAULT DEFAULT specifies that Oracle Database will choose automatically which rollback segment to use. If you specify DEFAULT, then you cannot specify rollback_segment. DEFAULT is most useful when modifying, rather than creating, a materialized view.

See Also: ALTER MATERIALIZED VIEW on page 11-3

MASTER MASTER specifies the remote rollback segment to be used at the remote master site for the individual materialized view.

LOCAL LOCAL specifies the remote rollback segment to be used for the local refresh group that contains the materialized view. This is the default.
CREATE MATERIALIZED VIEW

SQL Statements: CREATE LIBRARY to CREATE SPFILE

... ...

If you omit `rollback_segment`, then the database automatically chooses the rollback segment to be used. One master rollback segment is stored for each materialized view and is validated during materialized view creation and refresh. If the materialized view is complex, then the database ignores any master rollback segment you specify.

**USING ... CONSTRAINTS Clause**

The `USING ... CONSTRAINTS` clause lets Oracle Database choose more rewrite options during the refresh operation, resulting in more efficient refresh execution. The clause lets Oracle Database use unenforced constraints, such as dimension relationships or constraints in the `RELY` state, rather than relying only on enforced constraints during the refresh operation.

The `USING TRUSTED CONSTRAINTS` clause enables you to create a materialized view on top of a table that has a non-NULL Virtual Private Database (VPD) policy on it. In this case, you must ensure that the materialized view behaves correctly. Materialized view results are computed based on the rows and columns filtered by VPD policy. Therefore, you must coordinate the materialized view definition with the VPD policy to ensure the correct results. Without the `USING TRUSTED CONSTRAINTS` clause, any VPD policy on a master table will prevent a materialized view from being created.

---

**Caution:** The `USING TRUSTED CONSTRAINTS` clause lets Oracle Database use dimension and constraint information that has been declared trustworthy by the database administrator but that has not been validated by the database. If the dimension and constraint information is valid, then performance may improve. However, if this information is invalid, then the refresh procedure may corrupt the materialized view even though it returns a success status.

---

If you omit this clause, then the default is `USING ENFORCED CONSTRAINTS`.

**NEVER REFRESH Clause**

Specify `NEVER REFRESH` to prevent the materialized view from being refreshed with any Oracle Database refresh mechanism or packaged procedure. Oracle Database will ignore any `REFRESH` statement on the materialized view issued from such a procedure. If you specify this clause, then you can perform DML operations on the materialized view. To reverse this clause, you must issue an `ALTER MATERIALIZED VIEW ... REFRESH` statement.

**FOR UPDATE Clause**

Specify `FOR UPDATE` to allow a subquery, primary key, object, or rowid materialized view to be updated. When used in conjunction with Advanced Replication, these updates will be propagated to the master.

**evaluation_edition_clause**

You must specify this clause if `subquery` references an editioned object. Use this clause to specify the edition that is searched during name resolution of the editioned object—the evaluation edition.
CREATE MATERIALIZED VIEW

- Specify CURRENT EDITION to search the edition in which this DDL statement is executed.
- Specifying NULL EDITION is equivalent to omitting the evaluation_edition_clause.

If you omit the evaluation_edition_clause, then editioned objects are invisible during name resolution and an error will result. Dropping the evaluation edition invalidates the materialized view.

See Also: Oracle Database Development Guide for more information on specifying the evaluation edition for a materialized view

**query_rewrite_clause**

The query_rewrite_clause lets you specify whether the materialized view is eligible to be used for query rewrite.

**ENABLE Clause** Specify ENABLE to enable the materialized view for query rewrite. If you also specify the unusable_editions_clause, then the materialized view is not enabled for query rewrite in the unusable editions.

**Restrictions on Enabling Query Rewrite** Enabling of query rewrite is subject to the following restrictions:

- You can enable query rewrite only if all user-defined functions in the materialized view are DETERMINISTIC.
- You can enable query rewrite only if expressions in the statement are repeatable. For example, you cannot include CURRENT_TIME or USER, sequence values (such as the CURRVAL or NEXTVAL pseudocolumns), or the SAMPLE clause (which may sample different rows as the contents of the materialized view change).

---

**Notes:**

- Query rewrite is disabled by default, so you must specify this clause to make materialized views eligible for query rewrite.
- After you create the materialized view, you must collect statistics on it using the DBMS_STATS package. Oracle Database needs the statistics generated by this package to optimize query rewrite.

---

See Also:

- Oracle Database Data Warehousing Guide for more information on query rewrite
- Oracle Database PL/SQL Packages and Types Reference for information about the DBMS_STATS package
- The EXPLAIN_MVIEW procedure of the DBMS_MVIEW package for help diagnosing problems with query rewrite and the TUNE_MVIEW procedure of the DBMS_MVIEW package correction of query rewrite problems
- CREATE FUNCTION on page 14-71
DISABLE Clause Specify DISABLE to indicate that the materialized view is not eligible for use by query rewrite. A disabled materialized view can be refreshed.

unusable_editions_clause This clause lets you specify that the materialized view is not eligible for query rewrite in one or more editions. You can specify this clause regardless of whether you specify the ENABLE or DISABLE clause. If you specify the DISABLE clause, then this clause will take effect if the materialized view is subsequently enabled for query rewrite using the ALTER MATERIALIZED VIEW ... ENABLE QUERY REWRITE statement.

UNUSABLE BEFORE Clause This clause lets you specify that the materialized view is not eligible for query rewrite in the ancestors of an edition.

- If you specify CURRENT EDITION, then the materialized view is not eligible for query rewrite in the ancestors of the current edition.
- If you specify EDITION edition, then the materialized view is not eligible for query rewrite in the ancestors of the specified edition.

UNUSABLE BEGINNING WITH Clause This clause lets you specify that the materialized view is not eligible for query rewrite in an edition and its descendants.

- If you specify CURRENT EDITION, then the materialized view is not eligible for query rewrite in the current edition and its descendants.
- If you specify EDITION edition, then the materialized view is not eligible for query rewrite in the specified edition and its descendants.
- Specifying NULL EDITION is equivalent to omitting the UNUSABLE BEGINNING WITH clause.

The materialized view has a dependency on each edition in which it is not eligible for query rewrite. If such an edition is subsequently dropped, then the dependency is removed. However, the materialized view is not invalidated.

AS subquery Specify the defining query of the materialized view. When you create the materialized view, Oracle Database executes this subquery and places the results in the materialized view. This subquery is any valid SQL subquery. However, not all subqueries are fast refreshable, nor are all subqueries eligible for query rewrite.

Notes on the Defining Query of a Materialized View The following notes apply to materialized views:

- Oracle Database does not execute the defining query immediately if you specify BUILD DEFERRED.
- Oracle recommends that you qualify each table and view in the FROM clause of the defining query of the materialized view with the schema containing it.
- In order to create a materialized view whose defining query selects from a master table that has a Virtual Private Database (VPD) policy, you must specify the REFRESH USING TRUSTED CONSTRAINTS clause.

Restrictions on the Defining Query of a Materialized View The materialized view query is subject to the following restrictions:

- The defining query of a materialized view can select from tables, views, or materialized views owned by the user SYS, but you cannot enable QUERY REWRITE on such a materialized view.
The defining query of a materialized view cannot select from a \$V\$ view or a \$GV\$ view.

You cannot define a materialized view with a subquery in the select list of the defining query. You can, however, include subqueries elsewhere in the defining query, such as in the \$WHERE\$ clause.

You cannot use the \$AS\$ of clause of the \$flashback\_query\_clause\$ in the defining query of a materialized view.

Materialized join views and materialized aggregate views with a \$GROUP\$ BY clause cannot select from an index-organized table.

Materialized views cannot contain columns of data type \$LONG\$ or \$LONG\$ RAW.

Materialized views cannot contain virtual columns.

You cannot create a materialized view log on a temporary table. Therefore, if the defining query references a temporary table, then this materialized view will not be eligible for \$FAST\$ refresh, nor can you specify the \$QUERY\$ \$REWRITE\$ clause in this statement.

If the \$FROM\$ clause of the defining query references another materialized view, then you must always refresh the materialized view referenced in the defining query before refreshing the materialized view you are creating in this statement.

Materialized views with join expressions in the defining query cannot have XML data type columns. The XML data types include \$XMLType\$ and URI data type columns.

If you are creating a materialized view enabled for query rewrite, then:

- The defining query cannot contain, either directly or through a view, references to \$ROWNUM\$, \$USER\$, \$SYSDATE\$, remote tables, sequences, or PL/SQL functions that write or read database or package state.

- Neither the materialized view nor the master tables of the materialized view can be remote.

If you want the materialized view to be eligible for fast refresh using a materialized view log, or synchronous refresh using a staging log, then some additional restrictions apply.

See Also:
- \$Oracle Database Data Warehousing Guide\$ for restrictions relating to using fast refresh and synchronous refresh
- \$Oracle Database Advanced Replication\$ for more information on restrictions relating to replication

Examples

The following examples require the materialized logs that are created in the "Examples" section of \$CREATE\$ \$MATERIALIZED\$ \$VIEW\$ \$LOG\$ on page 15-31.

Creating a Simple Materialized View: Example  The following statement creates a very simple materialized view based on the \$employees\$ and table in the \$hr\$ schema:
CREATE MATERIALIZED VIEW mv1 AS SELECT * FROM hr.employees;

By default, Oracle Database creates a primary key materialized view with refresh on demand only. If a materialized view log exists on employees, then mv1 can be altered to be capable of fast refresh. If no such log exists, then only full refresh of mv1 is possible. Oracle Database uses default storage properties for mv1. The only privileges required for this operation are the CREATE MATERIALIZED VIEW system privilege, and the READ or SELECT object privilege on hr.employees.

Creating Subquery Materialized Views: Example  The following statement creates a subquery materialized view based on the customers and countries tables in the sh schema at the remote database:

CREATE MATERIALIZED VIEW foreign_customers FOR UPDATE
AS SELECT * FROM sh.customers@remote cu
WHERE EXISTS
    (SELECT * FROM sh.countries@remote co
    WHERE co.country_id = cu.country_id);

Creating Materialized Aggregate Views: Example  The following statement creates and populates a materialized aggregate view on the sample sh.sales table and specifies the default refresh method, mode, and time. It uses the materialized view log created in "Creating a Materialized View Log for Fast Refresh: Examples" on page 15-39, as well as the two additional logs shown here:

CREATE MATERIALIZED VIEW LOG ON times
    WITH ROWID, SEQUENCE (time_id, calendar_year)
    INCLUDING NEW VALUES;

CREATE MATERIALIZED VIEW LOG ON products
    WITH ROWID, SEQUENCE (prod_id)
    INCLUDING NEW VALUES;

CREATE MATERIALIZED VIEW sales_mv
    BUILD IMMEDIATE
    REFRESH FAST ON COMMIT
    AS SELECT t.calendar_year, p.prod_id,
        SUM(s.amount_sold) AS sum_sales
    FROM times t, products p, sales s
    WHERE t.time_id = s.time_id AND p.prod_id = s.prod_id
    GROUP BY t.calendar_year, p.prod_id;

Creating Materialized Join Views: Example  The following statement creates and populates the materialized aggregate view sales_by_month_by_state using tables in the sample sh schema. The materialized view will be populated with data as soon as the statement executes successfully. By default, subsequent refreshes will be accomplished by reexecuting the defining query of the materialized view:

CREATE MATERIALIZED VIEW sales_by_month_by_state
    TABLESPACE example
    PARALLEL 4
    BUILD IMMEDIATE
    REFRESH COMPLETE
    ENABLE QUERY REWRITE
    AS SELECT t.calendar_month_desc, c.cust_state_province,
        SUM(s.amount_sold) AS sum_sales
    FROM times t, sales s, customers c
    WHERE s.time_id = t.time_id AND s.cust_id = c.cust_id
    GROUP BY t.calendar_month_desc, c.cust_state_province;
Creating Prebuilt Materialized Views: Example  The following statement creates a materialized aggregate view for the preexisting summary table, `sales_sum_table`:

```
CREATE TABLE sales_sum_table
    (month VARCHAR2(8), state VARCHAR2(40), sales NUMBER(10,2));

CREATE MATERIALIZED VIEW sales_sum_table
    ON PREBUILT TABLE WITH REDUCED PRECISION
    ENABLE QUERY REWRITE
    AS SELECT t.calendar_month_desc AS month,
                c.cust_state_province AS state,
                SUM(s.amount_sold) AS sales
    FROM times t, customers c, sales s
    WHERE s.time_id = t.time_id AND s.cust_id = c.cust_id
    GROUP BY t.calendar_month_desc, c.cust_state_province;
```

In the preceding example, the materialized view has the same name and also has the same number of columns with the same data types as the prebuilt table. The `WITH REDUCED PRECISION` clause allows for differences between the precision of the materialized view columns and the precision of the values returned by the subquery.

Creating Primary Key Materialized Views: Example  The following statement creates the primary key materialized view `catalog` on the sample table `oe.product_information`:

```
CREATE MATERIALIZED VIEW catalog
    REFRESH FAST START WITH SYSDATE NEXT SYSDATE + 1/4096
    WITH PRIMARY KEY
    AS SELECT * FROM product_information;
```

Creating Rowid Materialized Views: Example  The following statement creates a rowid materialized view on the sample table `oe.orders`:

```
CREATE MATERIALIZED VIEW order_data REFRESH WITH ROWID
    AS SELECT * FROM orders;
```

Periodic Refresh of Materialized Views: Example  The following statement creates the primary key materialized view `emp_data` and populates it with data from the sample table `hr.employees`:

```
CREATE MATERIALIZED VIEW LOG ON employees
    WITH PRIMARY KEY
    INCLUDING NEW VALUES;

CREATE MATERIALIZED VIEW emp_data
    PCTFREE 5 PCTUSED 60
    TABLESPACE example
    STORAGE (INITIAL 50K)
    REFRESH FAST NEXT sysdate + 7
    AS SELECT * FROM employees;
```

The preceding statement does not include a `START WITH` parameter, so Oracle Database determines the first automatic refresh time by evaluating the `NEXT` value using the current `SYSDATE`. A materialized view log was created for the employee table, so Oracle Database performs a fast refresh of the materialized view every 7 days, beginning 7 days after the materialized view is created.

Because the materialized view conforms to the conditions for fast refresh, the database will perform a fast refresh. The preceding statement also establishes storage characteristics that the database uses to maintain the materialized view.
Automatic Refresh Times for Materialized Views: Example  
The following statement creates the complex materialized view `all_customers` that queries the employee tables on the remote and local databases:

```sql
CREATE MATERIALIZED VIEW all_customers
  PCTFREE 5 PCTUSED 60
  TABLESPACE example
  STORAGE (INITIAL 50K)
  USING INDEX STORAGE (INITIAL 25K)
  REFRESH START WITH ROUND(SYSDATE + 1) + 11/24
  NEXT NEXT_DAY(TRUNC(SYSDATE), 'MONDAY') + 15/24
AS SELECT * FROM sh.customers@remote
  UNION
  SELECT * FROM sh.customers@local;
```

Oracle Database automatically refreshes this materialized view tomorrow at 11:00 a.m. and subsequently every Monday at 3:00 p.m. The default refresh method is `FORCE`. The defining query contains a `UNION` operator, which is not supported for fast refresh, so the database will automatically perform a complete refresh.

The preceding statement also establishes storage characteristics for both the materialized view and the index that the database uses to maintain it:

- The first `STORAGE` clause establishes the sizes of the first and second extents of the materialized view as 50 kilobytes each.

- The second `STORAGE` clause, appearing with the `USING INDEX` clause, establishes the sizes of the first and second extents of the index as 25 kilobytes each.

Creating a Fast Refreshable Materialized View: Example  
The following statement creates a fast-refreshable materialized view that selects columns from the `order_items` table in the sample `oe` schema, using the `UNION` set operator to restrict the rows returned from the `product_information` and `inventories` tables using `WHERE` conditions. The materialized view logs for `order_items` and `product_information` were created in the "Examples" section of CREATE MATERIALIZED VIEW LOG on page 15-39. This example also requires a materialized view log on `oe.inventories`.

```sql
CREATE MATERIALIZED VIEW LOG ON inventories
  WITH (quantity_on_hand);
CREATE MATERIALIZED VIEW warranty_orders REFRESH FAST AS
  SELECT order_id, line_item_id, product_id FROM order_items o
  WHERE EXISTS
    (SELECT * FROM inventories i WHERE o.product_id = i.product_id
     AND i.quantity_on_hand IS NOT NULL)
  UNION
  SELECT order_id, line_item_id, product_id FROM order_items
  WHERE quantity > 5;
```

The materialized view `warranty_orders` requires that materialized view logs be defined on `order_items` (with `product_id` as a join column) and on `inventories` (with `quantity_on_hand` as a filter column). See "Specifying Filter Columns for Materialized View Logs: Example" and "Specifying Join Columns for Materialized View Logs: Example" on page 15-40.

Creating a Nested Materialized View: Example  
The following example uses the materialized view from the preceding example as a master table to create a materialized view tailored for a particular sales representative in the sample `oe` schema:
CREATE MATERIALIZED VIEW my_warranty_orders
AS SELECT w.order_id, w.line_item_id, o.order_date
FROM warranty_orders w, orders o
WHERE o.order_id = o.order_id
AND o.sales_rep_id = 165;
CREATE MATERIALIZED VIEW LOG

Purpose

Use the CREATE MATERIALIZED VIEW LOG statement to create a materialized view log, which is a table associated with the master table of a materialized view.

---

**Note:** The keyword SNAPSHOT is supported in place of MATERIALIZED VIEW for backward compatibility.

---

Materialized view logs are used for two types of materialized view refreshes: fast refresh and synchronous refresh.

**Fast refresh** uses a conventional materialized view log. During a fast refresh (also called an incremental refresh), when DML changes are made to master table data, Oracle Database stores rows describing those changes in the materialized view log and then uses the materialized view log to refresh materialized views based on the master table.

**Synchronous refresh** uses a special type of materialized view log called a staging log. During a synchronous refresh, DML changes are first described in the staging log and then applied to the master tables and the materialized views simultaneously. This guarantees that the master table data and materialized view data are in sync throughout the refresh process. This refresh method is useful in data warehousing environments.

Without a materialized view log, Oracle Database must reexecute the materialized view query to refresh the materialized view. This process is called a complete refresh. Usually, a complete refresh takes more time to complete than a fast refresh or a synchronous refresh.

A materialized view log is located in the master database in the same schema as the master table. A master table can have only one materialized view log defined on it.

To fast refresh or synchronous refresh a materialized join view, you must create a materialized view log for each of the tables referenced by the materialized view.

Fast refresh supports two types of materialized view logs: timestamp-based materialized view logs and commit SCN-based materialized view logs. Timestamp-based materialized view logs use timestamps and require some setup operations when preparing to refresh the materialized view. Commit SCN-based materialized view logs use commit SCN data rather than timestamps, which removes the need for the setup operations and thus can improve the speed of the materialized view refresh. If you specify the COMMIT SCN clause, then a commit SCN-based materialized view log is created. Otherwise, a time-stamp based materialized view log is created. Note that only new materialized view logs can take advantage of COMMIT SCN. Existing materialized view logs cannot be altered to add COMMIT SCN unless they are dropped and recreated. Refer to Oracle Database Data Warehousing Guide for more information.

Synchronous refresh supports only timestamp-based staging logs.
Prerequisites

The privileges required to create a materialized view log directly relate to the
privileges necessary to create the underlying objects associated with a materialized
view log.

- If you own the master table, then you can create an associated materialized view
  log if you have the CREATE TABLE privilege.

- If you are creating a materialized view log for a table in another user’s schema,
  then you must have the CREATE ANY TABLE and COMMENT ANY TABLE system
  privileges, as well as either the READ or SELECT object privilege on the master table
  or the READ ANY TABLE or SELECT ANY TABLE system privilege.

In either case, the owner of the materialized view log must have sufficient quota in the
namespace intended to hold the materialized view log or must have the UNLIMITED
TABLESPACE system privilege.

See Also: Oracle Database Data Warehousing Guide for more
information about the prerequisites for creating a materialized view
log.
Syntax

create_materialized_vw_log ::=

  USING staging_log_name

Semantics

schema
Specify the schema containing the materialized view log master table. If you omit schema, then Oracle Database assumes the master table is contained in your own schema. Oracle Database creates the materialized view log in the schema of its master table. You cannot create a materialized view log for a table in the schema of the user SYS.

table
Specify the name of the master table for which the materialized view log is to be created. Oracle Database encrypts any columns in the materialized view log that are encrypted in the master table, using the same encryption algorithm.

Restrictions on Master Tables of Materialized View Logs
The following restrictions apply to master tables of materialized view logs:

- You cannot create a materialized view log for a temporary table or for a view.
- You cannot create a materialized view log for a master table with a virtual column.
physical_attributes_clause
Use the `physical_attributes_clause` to define physical and storage characteristics for the materialized view log.

See Also: `physical_attributes_clause` on page 8-44 and `storage_clause` on page 8-46 for a complete description of these clauses, including default values.

TABLESPACE Clause
Specify the tablespace in which the materialized view log is to be created. If you omit this clause, then the database creates the materialized view log in the default tablespace of the schema of the materialized view log.

logging_clause
Specify either `LOGGING` or `NOLOGGING` to establish the logging characteristics for the materialized view log. The default is the logging characteristic of the tablespace in which the materialized view log resides.

See Also: `logging_clause` on page 8-38 for a full description of this clause.

CACHE | NOCACHE
For data that will be accessed frequently, `CACHE` specifies that the blocks retrieved for this log are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables.

`NOCACHE` specifies that the blocks are placed at the least recently used end of the LRU list. The default is `NOCACHE`.

---

Note: `NOCACHE` has no effect on materialized view logs for which you specify `KEEP` in the `storage_clause`.

See Also: `CREATE TABLE` on page 16-6 for information about specifying `CACHE` or `NOCACHE`.

parallel_clause
The `parallel_clause` lets you indicate whether parallel operations will be supported for the materialized view log.

For complete information on this clause, refer to `parallel_clause` on page 16-81 in the documentation on `CREATE TABLE`.

table_partitioning_clauses
Use the `table_partitioning_clauses` to indicate that the materialized view log is partitioned on specified ranges of values or on a hash function. Partitioning of materialized view logs is the same as partitioning of tables.

See Also: `table_partitioning_clauses` on page 16-67 in the `CREATE TABLE` documentation.
WITH Clause

Use the WITH clause to indicate whether the materialized view log should record the primary key, rowid, object ID, or a combination of these row identifiers when rows in the master are changed. You can also use this clause to add a sequence to the materialized view log to provide additional ordering information for its records.

This clause also specifies whether the materialized view log records additional columns that might be referenced as filter columns, which are non-primary-key columns referenced by subquery materialized views, or join columns, which are non-primary-key columns that define a join in the subquery WHERE clause.

If you omit this clause, or if you specify the clause without PRIMARY KEY, ROWID, or OBJECT ID, then the database stores primary key values by default. However, the database does not store primary key values implicitly if you specify only OBJECT ID or ROWID at create time. A primary key log, created either explicitly or by default, performs additional checking on the primary key constraint.

OBJECT ID Specify OBJECT ID to indicate that the system-generated or user-defined object identifier of every modified row should be recorded in the materialized view log.

Restriction on OBJECT ID You can specify OBJECT ID only when creating a log on an object table, and you cannot specify it for storage tables.

PRIMARY KEY Specify PRIMARY KEY to indicate that the primary key of all rows changed should be recorded in the materialized view log.

ROWID Specify ROWID to indicate that the rowid of all rows changed should be recorded in the materialized view log.

SEQUENCE Specify SEQUENCE to indicate that a sequence value providing additional ordering information should be recorded in the materialized view log. Sequence numbers are necessary to support fast refresh after some update scenarios.

See Also: Oracle Database Data Warehousing Guide for more information on the use of sequence numbers in materialized view logs and for examples that use this clause

COMMIT SCN Without the COMMIT SCN clause, the materialized view log is based on timestamps and requires some setup operations when preparing to refresh the materialized view. Specify COMMIT SCN to instruct the database to use commit SCN data rather than timestamps. This setting removes the need for the setup operations and thus can improve the speed of the materialized view refresh.

You can create the following types of local materialized views (including both ON COMMIT and ON DEMAND) on master tables with commit SCN-based materialized view logs:

- Materialized aggregate views, including materialized aggregate views on a single table
- Materialized join views
- Primary-key-based and rowid-based single table materialized views
- UNION ALL materialized views, where each UNION ALL branch is one of the above materialized view types
You cannot create remote materialized views on master tables with commit SCN-based materialized view logs.

**Restrictions on COMMIT SCN**  The following restrictions apply to COMMIT SCN:

- Use of COMMIT SCN on a table with one or more LOB columns is not supported and causes ORA-32421.
- Creating a materialized view on master tables with different types of materialized view logs (that is, a master table with timestamp-based materialized view logs and a master table with commit SCN-based materialized view logs) is not supported and causes ORA-32414.
- If you specify COMMIT SCN, then you cannot specify **FOR SYNCHRONOUS REFRESH**.

**column** Specify the columns whose values you want to be recorded in the materialized view log for all rows that are changed. Typically these columns are filter columns and join columns.

**Restrictions on the WITH Clause**  This clause is subject to the following restrictions:

- You can specify only one **PRIMARY KEY**, one **ROWID**, one **OBJECT ID**, one **SEQUENCE**, and one column list for each materialized view log.
- Primary key columns are implicitly recorded in the materialized view log. Therefore, you cannot specify any of the following combinations if column contains one of the primary key columns:

```
WITH ... PRIMARY KEY ... (column)
WITH ... (column) ... PRIMARY KEY
WITH (column)
```

**NEW VALUES Clause**

The **NEW VALUES** clause lets you determine whether Oracle Database saves both old and new values for update DML operations in the materialized view log.

**See Also:**

- CREATE MATERIALIZED VIEW on page 15-4 for information on explicit and implicit inclusion of materialized view log values
- Oracle Database Advanced Replication for more information about filter columns and join columns

**INCLUDING**  Specify **INCLUDING** to save both new and old values in the log. If this log is for a table on which you have a single-table materialized aggregate view, and if you want the materialized view to be eligible for fast refresh, then you must specify INCLUDING.

**EXCLUDING**  Specify **EXCLUDING** to disable the recording of new values in the log. This is the default. You can use this clause to avoid the overhead of recording new values. Do not use this clause if you have a fast-refreshable single-table materialized aggregate view defined on the master table.
**mv_log_purge_clause**

Use this clause to specify the purge time for the materialized view log.

- **IMMEDIATE SYNCHRONOUS**: the materialized view log is purged immediately after refresh. This is the default.
- **IMMEDIATE ASYNCHRONOUS**: the materialized view log is purged in a separate Oracle Scheduler job after the refresh operation.
- **START WITH, NEXT, and REPEAT INTERVAL** set up a scheduled purge that is independent of the materialized view refresh and is initiated during CREATE or ALTER MATERIALIZED VIEW LOG statement. This is very similar to scheduled refresh syntax in a CREATE or ALTER MATERIALIZED VIEW statement:
  - The **START WITH** datetime expression specifies when the purge starts.
  - The **NEXT** datetime expression computes the next run time for the purge.

If you specify **REPEAT INTERVAL**, then the next run time will be: `SYSDATE + interval_expr`.

A CREATE MATERIALIZED VIEW LOG statement with a scheduled purge creates an Oracle Scheduler job to perform log purge. The job calls the `DBMS_SNAPSHOT.PURGE_LOG` procedure to purge the materialized view logs. This process allows you to amortize the purging costs over several materialized view refreshes.

** Restriction on mv_log_purge_clause**  This clause is not valid for materialized view logs on temporary tables.

**See Also:** Oracle Database Data Warehousing Guide for more information on purging materialized view logs

**for_refresh_clause**

Use this clause to specify the refresh method for which the materialized view log will be used. You can specify only one refresh method for any given master table.

**FOR SYNCHRONOUS REFRESH** Specify this clause to create a staging log that can be used for synchronous refresh. Use **staging_log_name** to specify the name of the staging log to be created. The staging log will be created in the schema in which the master table resides.

After you create the staging log, you cannot perform DML operations directly on the master table. You must use the procedures in the `DBMS_SYNC_REFRESH` package to prepare and execute change data operations.

**Restrictions on Synchronous Refresh** The following restrictions apply to synchronous refresh:

- If you specify **FOR SYNCHRONOUS REFRESH**, then you cannot specify **COMMIT SCN**.
- To be eligible for synchronous refresh, the master table must satisfy the following criteria:
  - If the master table is a fact table, then it must be partitioned.
  - The master table must have a key. If the master table is a dimension table, then it must have a primary key defined on it. If the master table is a fact table, then the set of columns that are the foreign keys of the dimension tables joined to the fact table are deemed to be the key.
- The master table cannot have a non-NULL Virtual Private Database (VPD) policy or a trigger defined on it.

Oracle Database may allow you to create a staging log on a master table even if all of the preceding criteria are not met. However, the master table will not be eligible for synchronous refresh.

- Any existing materialized views on the master table must be refresh-on-demand materialized views. If an existing materialized view is a refresh-on-commit materialized view, then you must change it to a refresh-on-demand materialized view with the `alter_mv_refresh` clause of `ALTER MATERIALIZED VIEW` on page 11-14 before you create the staging log.

**See Also:**

- Oracle Database Data Warehousing Guide for the complete steps for using synchronous refresh
- Oracle Database PL/SQL Packages and Types Reference for information on the `DBMS_SYNC_REFRESH` package

**FOR FAST REFRESH** Specify this clause to create a materialized view log that can be used for fast refresh. The materialized view log will be created in the same schema in which the master table resides. This is the default.

**Examples**

---

**Creating a Materialized View Log for Fast Refresh: Examples**  The following statement creates a materialized view log on the `oe.customers` table that specifies physical and storage characteristics:

```sql
CREATE MATERIALIZED VIEW LOG ON customers
  PCTFREE 5
  TABLESPACE example
  STORAGE (INITIAL 10K);
```

The materialized view log on `customers` supports fast refresh for primary key materialized views only.

The following statement creates another version of the materialized view log with the `ROWID` clause, which enables fast refresh for more types of materialized views:

```sql
CREATE MATERIALIZED VIEW LOG ON customers WITH PRIMARY KEY, ROWID;
```

This materialized view log on `customers` makes fast refresh possible for rowid materialized views and for materialized join views. To provide for fast refresh of materialized aggregate views, you must also specify the `SEQUENCE` and `INCLUDING NEW VALUES` clauses, as shown in the example that follows.

**Specify a Purge Repeat Interval for a Materialized View Log: Example**  The following statement creates a materialized view log on the `oe.orders` table. The contents of the log will be purged once every five days, beginning five days after the creation date of the materialized view log:

```sql
CREATE MATERIALIZED VIEW LOG ON orders
  PCTFREE 5
  TABLESPACE example
  STORAGE (INITIAL 10K)
  PURGE REPEAT INTERVAL '5' DAY;
```
Specifying Filter Columns for Materialized View Logs: Example  The following statement creates a materialized view log on the sh.sales table and is used in "Creating Materialized Aggregate Views: Example" on page 15-27. It specifies as filter columns all of the columns of the table referenced in that materialized view.

```
CREATE MATERIALIZED VIEW LOG ON sales
  WITH ROWID, SEQUENCE(amount_sold, time_id, prod_id)
  INCLUDING NEW VALUES;
```

Specifying Join Columns for Materialized View Logs: Example  The following statement creates a materialized view log on the order_items table of the sample oe schema. The log records primary keys and product_id, which is used as a join column in "Creating a Fast Refreshable Materialized View: Example" on page 15-29.

```
CREATE MATERIALIZED VIEW LOG ON order_items WITH (product_id);
```

Including New Values in Materialized View Logs: Example  The following example creates a materialized view log on the oe.product_information table that specifies INCLUDING NEW VALUES:

```
CREATE MATERIALIZED VIEW LOG ON product_information
  WITH ROWID, SEQUENCE (list_price, min_price, category_id), PRIMARY KEY
  INCLUDING NEW VALUES;
```

You could create the following materialized aggregate view to use the product_information log:

```
CREATE MATERIALIZED VIEW products_mv
  REFRESH FAST ON COMMIT
  AS SELECT SUM(list_price - min_price), category_id
  FROM product_information
  GROUP BY category_id;
```

This materialized view is eligible for fast refresh because the log defined on its master table includes both old and new values.

Creating a Staging Log for Synchronous Refresh: Example  The following statement creates a staging log on the sh.sales fact table. The staging log is named mystage_log and is stored in the sh schema. It can be used for synchronous refresh.

```
CREATE MATERIALIZED VIEW LOG ON sales
  PCTFREE 5
  TABLESPACE example
  STORAGE (INITIAL 10K)
  FOR SYNCHRONOUS REFRESH USING mystage_log;
```
CREATE MATERIALIZED ZONEMAP

Note: The CREATE MATERIALIZED ZONEMAP statement is available starting with Oracle Database 12c Release 1 (12.1.0.2).

Purpose

Use the CREATE MATERIALIZED ZONEMAP statement to create a zone map.

A zone map is a special type of materialized view that stores information about zones. A zone is a set of contiguous data blocks on disk that stores the values of one or more table columns. Multiple zones are usually required to store all of the values of the table columns. A zone map tracks the minimum and maximum table column values stored in each zone.

Zone maps enable you to reduce the I/O and CPU costs of table scans. When a SQL statement contains predicates on columns in a zone map, the database compares the predicate values to the minimum and maximum table column values stored in each zone to determine which zones to read during SQL execution.

Oracle Database supports the following types of zone maps:

- **A basic zone map** is defined on a single table and maintains zone information for specified columns in that table.

  You can create a basic zone map either by specifying the create_zonemap_on_table clause, or by specifying the create_zonemap_as_subquery clause where the FROM clause of the defining subquery specifies a single table.

- **A join zone map** is defined on two or more joined tables and maintains zone information for specified columns in any of the joined tables.

  You can create a join zone map by specifying the create_zonemap_as_subquery clause. The FROM clause of the defining subquery must specify a table that is left outer joined with one or more other tables.

Zone maps are commonly used with star schemas in data warehousing environments. However, a star schema is not a requirement for creating a zone map. In either case, this reference uses star schema terminology to refer to the tables in a zone map. In a join zone map, the outer table of the join(s) is referred to as the fact table, and the tables with which this table is joined are referred to as dimension tables. Collectively these tables are called the base tables of the zone map. In a basic zone map, the single table on which the zone map is defined is referred to as both the fact table and the base table of the zone map.

A base table of a zone map can be a partitioned or composite-partitioned table. In this case, the zone map maintains minimum and maximum column values for each partition (and subpartition) as well as for each zone.

You can create zone maps for use with or without attribute clustering:

- To create a zone map for use with attribute clustering, use either of the following methods:
  
    - Use the CREATE MATERIALIZED ZONEMAP statement and include attribute clustered columns in the zone map. Refer to the attribute_clustering_clause of CREATE TABLE on page 16-78 and the attribute_clustering_clause clause of ALTER TABLE on page 12-52 for more information.
– Specify the WITH MATERIALIZED ZONEMAP clause while creating or modifying an attribute clustered table. Refer to the zonemap_clause of CREATE TABLE on page 16-79 and the MODIFY CLUSTERING clause of ALTER TABLE on page 12-52 for more information.

To create a zone map for use without attribute clustering, use the CREATE MATERIALIZED ZONEMAP statement and include columns that are not attribute clustered in the zone map.

See Also: Oracle Database Data Warehousing Guide for more information on zone maps

Prerequisites

To create a zone map in your own schema:

■ You must have the CREATE MATERIALIZED VIEW system privilege and either the CREATE TABLE or CREATE ANY TABLE system privilege.

■ You must also have access to any base tables of the zone map that you do not own, either through a READ or SELECT object privilege on each of the tables or through the READ ANY TABLE or SELECT ANY TABLE system privilege.

To create a zone map in another user’s schema:

■ You must have the CREATE ANY MATERIALIZED VIEW system privilege.

■ The owner of the zone map must have the CREATE TABLE system privilege. The owner must also have access to any base tables of the zone map that the schema owner does not own, either through a READ or SELECT object privilege on each of the tables or through the READ ANY TABLE or SELECT ANY TABLE system privilege.

To create a refresh-on-commit zone map (REFRESH ON COMMIT clause), in addition to the preceding privileges, you must have the ON COMMIT REFRESH object privilege on any base tables that you do not own or you must have the ON COMMIT REFRESH system privilege. Unlike materialized views, you can create a refresh-on-commit zone map even if there are no materialized view logs on the base tables.

When you create a zone map, Oracle Database creates one internal table and at least one index, all in the schema of the zone map. Oracle Database uses these objects to maintain the zone map data. You must have the privileges necessary to create these objects, and you must have sufficient quota in the target tablespace to store these objects or you must have the UNLIMITED TABLESPACE system privilege.

Syntax

create_materialized_zonemap ::= 

create_zonemap_on_table | create_zonemap_as_subquery
CREATE MATERIALIZED ZONEMAP

create_zonemap_on_table ::= CREATE MATERIALIZED ZONEMAP schema zonemap_name zonemap_attributes zonemap_refresh_clause

create_zonemap_as_subquery ::= CREATE MATERIALIZED ZONEMAP schema zonemap_name column alias zonemap_attributes zonemap_refresh_clause

zonemap_attributes ::= TABLESPACE tablespace SCALE integer PCTFREE integer PCTUSED integer CACHE NOCACHE

zonemap_refresh_clause ::= ON REFRESH COMPLETE FORCE LOAD DATA MOVEMENT

ON COMMIT LOAD DATA MOVEMENT
CREATE MATERIALIZED ZONEMAP

Semantics

create_zonemap_on_table
Use this clause to create a basic zone map.

ON Clause In the ON clause, first specify the fact table for the zone map, and then inside the parentheses specify one or more columns of the fact table to be included in the zone map.

For each specified fact table column, Oracle creates two columns in the zone map. These two columns contain the minimum and maximum values of the fact table column in each zone. Oracle generates names for the zone map columns of the form MIN_1_column and MAX_1_column for the first specified fact table column, MIN_2_column and MAX_2_column for the second specified fact table column, and so on.

If you omit schema, then Oracle assumes the fact table is in your own schema. The fact table can be a table or a materialized view.

create_zonemap_as_subquery
Use this clause to create a basic zone map or a join zone map. To create a basic zone map, specify a single base table in the FROM clause of the defining subquery. To create a join zone map, specify a table that is left outer joined to one or more other tables in the FROM clause of the defining subquery.

column_alias You can specify a column alias for each table column to be included in the zone map. The column alias list explicitly resolves any column name conflict, eliminating the need to specify aliases in the SELECT list of the defining subquery. If you specify any column alias in this clause, then you must specify an alias for each column in the SELECT list of the defining subquery. The first column alias you specify must be ZONE_ID$, which corresponds to the first column in the SELECT list, the SYS_OP_ZONE_ID function expression.

AS query_block Specify the defining subquery of the zone map. The subquery must consist of a single query_block. You can specify only the SELECT, FROM, WHERE, and GROUP BY clauses of query_block, and those clauses must satisfy the following requirements:

■ The first column in the SELECT list must be the SYS_OP_ZONE_ID function expression. Refer to SYS_OP_ZONE_ID on page 7-344 for more information.

■ The remaining columns in the SELECT list must be function expressions that return minimum and maximum values for the columns you want to include in the zone map. For each column, specify a pair of function expressions of the following form:

\[ \text{MIN}([\text{table.}]\text{column}), \text{MAX}([\text{table.}]\text{column}) \]

For table, specify the name or table alias for the table that contains the column. The table can be a fact table or dimension table. For column, specify the name or column alias for the column.

■ The FROM clause can specify a fact table alone, or a fact table and one or more dimension tables with each dimension table left outer joined to the fact table.

Note: When specifying the zonemap_refresh_clause, you must specify at least one clause after the REFRESH keyword.
can specify **LEFT [OUTER] JOIN** syntax in the **FROM** clause, or apply the outer join operator (+) to dimension table columns in the join condition in the **WHERE** clause. You can optionally specify a table alias for any of the tables in the **FROM** clause. Fact tables and dimension tables can be tables or materialized views.

- In the **WHERE** clause, you can specify only left outer join conditions using the outer join operator (+).
- You must specify a **GROUP BY** clause with the same **SYS_OP_ZONE_ID** function expression that you specified for the first column of the **SELECT** list.

**schema**

Specify the schema to contain the zone map. If you omit **schema**, then Oracle Database creates the zone map in your schema.

**zonemap_name**

Specify the name of the zone map to be created. The name must satisfy the requirements listed in "Database Object Naming Rules" on page 2-119.

**zonemap_attributes**

Use this clause to specify the following attributes for the zone map: **TABLESPACE**, **SCALE**, **PCTFREE**, **PCTUSED**, and **CACHE** or **NOCACHE**.

**TABLESPACE** Specify the **tablespace** in which the zone map is to be created. If you omit this clause, then Oracle Database creates the zone map in the default tablespace of the schema containing the zone map.

**SCALE** This clause lets you specify the zone map scale, which determines the number of contiguous disk blocks that form a zone. The scale is an integer value that represents a power of 2. For example, a scale of 10 means up to 2 raised to the 10th power, or 1024, contiguous disk blocks will form a zone. For **integer**, specify a value between 4 and 16, inclusive. The recommended value is 10; this is the default.

**PCTFREE** Specify an **integer** representing the percentage of space in each data block of the zone map reserved for future updates to rows of the zone map. The integer value must be between 0 and 99, inclusive. The default value is 10. Refer to **physical_attributes_clause** on page 8-44 for more information on the **PCTFREE** parameter.

**PCTUSED** Specify an **integer** representing the minimum percentage of used space that Oracle maintains for each data block of the zone map. The integer value must be between 0 and 99, inclusive. The default value is 40. Refer to **physical_attributes_clause** on page 8-44 for more information on the **PCTUSED** parameter.

**CACHE | NOCACHE** For data that will be accessed frequently, **CACHE** specifies that the blocks retrieved for this zone map are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. **NOCACHE** specifies that the blocks are placed at the least recently used end of the LRU list. The default is **NOCACHE**.

**zonemap_refresh_clause**

Use this clause to specify the default refresh method and mode for the zone map. If you do not specify a refresh method (**FAST**, **COMPLETE**, or **FORCE**), then **FORCE** is the default method. If you do not specify a refresh mode (**ON** clauses), then **ON LOAD DATA MOVEMENT** is the default mode.
FAST Specify FAST to indicate the fast refresh method, which performs the refresh according to the changes that have occurred to the base tables. While zone maps are internally implemented as a type of materialized view, materialized view logs on base tables are not needed to perform a fast refresh of a zone map.

COMPLETE Specify COMPLETE to indicate the complete refresh method, which is implemented by executing the defining query of the zone map. If you request a complete refresh, then Oracle Database performs a complete refresh even if a fast refresh is possible.

FORCE Specify FORCE to indicate that when a refresh occurs, Oracle Database will perform a fast refresh if one is possible or a complete refresh if fast refresh is not possible. This is the default.

ON DEMAND Specify ON DEMAND to indicate that database will not refresh the zone map unless you manually issue an ALTER MATERIALIZED ZONEMAP...REBUILD statement. If you specify this clause, then the zone map is referred to as a refresh-on-demand zone map. Refer to REBUILD on page 11-29 in the documentation on ALTER MATERIALIZED ZONEMAP for more information on rebuilding a zone map.

ON COMMIT Specify ON COMMIT to indicate that a refresh is to occur whenever the database commits a transaction that operates on a base table of the zone map. If you specify this clause, then the zone map is referred to as a refresh-on-commit zone map. This clause may increase the time taken to complete the commit, because the database performs the refresh operation as part of the commit process.

ON LOAD Specify ON LOAD to indicate that a refresh is to occur at the end of a direct-path insert (serial or parallel) resulting either from an INSERT or a MERGE operation.

ON DATA MOVEMENT Specify ON DATA MOVEMENT to indicate that a refresh is to occur at the end of the following data movement operations:

- Data redefinition using the DBMS_REDEFINITION package
- Table partition maintenance operations that are specified by the following clauses of ALTER TABLE: coalesce_table, merge_table_partitions, move_table_partition, and split_table_partition

ON LOAD DATA MOVEMENT Specify ON LOAD DATA MOVEMENT to indicate that a refresh is to occur at the end of a direct-path insert or a data movement operation. This is the default.

ENABLE | DISABLE PRUNING
This clause lets you control the use of the zone map for pruning.

- Specify ENABLE PRUNING to enable use of the zone map for pruning. This is the default.
- Specify DISABLE PRUNING to disable use of the zone map for pruning. The optimizer will not use the zone map for pruning, but the database will continue to maintain the zone map.

If the setting is ENABLE PRUNING, then the optimizer will consider using the zone map for pruning during SQL operations that include any of the following conditions:

- Comparison conditions: =, <=, <, >, >=, >
The condition must be a simple comparison condition that has a column name on one side and a literal or bind variable on the other side. For example:

```
WHERE country_name = 'United States of America'
WHERE country_name = :country1
WHERE 10000 >= salary
```

- **IN condition**
  
  The IN condition must have a column name on the left side and an expression list of literals or bind variables on the right side. For example:

  ```
  WHERE country_name IN ('Germany', 'India', 'United Kingdom')
  WHERE country_name IN (:country1, :country2, :country3)
  WHERE prod_id IN (20, 48, 132, 143)
  ```

- **LIKE condition**
  
  The LIKE condition must have a column name on the left side and a text literal on the right side. The text literal is the pattern for the LIKE condition and it must contain at least one pattern matching character. Valid pattern matching characters are the underscore (_), which matches exactly one character, and the percent sign (%), which matches zero or more characters. The first character of the pattern cannot be a pattern matching character. For example:

  ```
  WHERE prod_name LIKE 'DVD'
  WHERE prod_name LIKE 'Model%Cordless%Battery'
  WHERE prod_name LIKE 'CD%Pack of _'
  ```

**See Also:** Chapter 6, “Conditions” on page 6-1 for more information on conditions

**Restrictions on Zone Maps** Zone maps are subject to the following restrictions:

- A table can be a fact table for at most one zone map. A table can be a dimension table for multiple zone maps. A table can be a fact table for one zone map and a dimension table for other zone maps.
- A base table of a zone map cannot be an external table, an index-organized table, a remote table, a temporary table, or a view.
- A base table of a zone map cannot be in the schema of the user SYS.
- A zone map cannot be partitioned.
- You can define a zone map on a column of any scalar data type other than BFILE, BLOB, CLOB, LONG, LONG RAW, or NCLOB.
- All joins specified in the defining subquery of a zone map must be left outer equijoins with the fact table on the left side.
- If the FROM clause of the defining subquery for a zone map references a materialized view, then you must refresh that materialized view before refreshing the zone map.
- You cannot perform DML operations directly on a zone map.

**Examples**

The following statement creates a basic zone map called sales_zmap. The zone map tracks columns cust_id and prod_id in the table sales.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
  ON sales(cust_id, prod_id);
```

SQL Statements: CREATE LIBRARY to CREATE SPFILE  15-47
The following statement creates a basic zone map called `sales_zmap` that is similar to the zone map created in the previous example. However, this statement uses a defining subquery to create the zone map.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
AS SELECT SYS_OP_ZONE_ID(rowid),
       MIN(cust_id), MAX(cust_id),
       MIN(prod_id), MAX(prod_id)
FROM sales
GROUP BY SYS_OP_ZONE_ID(rowid);
```

The following statement creates a join zone map called `sales_zmap`. The fact table for the zone map is `sales` and the zone map has one dimension table: `customers`. The zone map tracks two columns in the dimension table: `cust_state_province` and `cust_city`.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
AS SELECT SYS_OP_ZONE_ID(s.rowid),
       MIN(cust_state_province), MAX(cust_state_province),
       MIN(cust_city), MAX(cust_city)
FROM sales s
LEFT OUTER JOIN customers c ON s.cust_id = c.cust_id
GROUP BY SYS_OP_ZONE_ID(s.rowid);
```

The following statement creates a join zone map called `sales_zmap`. The fact table for the zone map is `sales` and the zone map has two dimension tables: `products` and `customers`. The zone map tracks five columns in the dimension tables: `prod_category` and `prod_subcategory` in the `products` table, and `country_id`, `cust_state_province`, and `cust_city` in the `customers` table.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
AS SELECT SYS_OP_ZONE_ID(s.rowid),
       MIN(prod_category), MAX(prod_category),
       MIN(prod_subcategory), MAX(prod_subcategory),
       MIN(country_id), MAX(country_id),
       MIN(cust_state_province), MAX(cust_state_province),
       MIN(cust_city), MAX(cust_city)
FROM sales s
LEFT OUTER JOIN products p ON s.prod_id = p.prod_id
LEFT OUTER JOIN customers c ON s.cust_id = c.cust_id
GROUP BY sys_op_zone_id(s.rowid);
```

The following statement creates a join zone map that is identical to the zone map created in the previous example. The only difference is that the previous example uses the `LEFT OUTER JOIN` syntax in the `FROM` clause and the following example uses the outer join operator (+) in the `WHERE` clause.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
AS SELECT SYS_OP_ZONE_ID(s.rowid),
       MIN(prod_category), MAX(prod_category),
       MIN(prod_subcategory), MAX(prod_subcategory),
       MIN(country_id), MAX(country_id),
       MIN(cust_state_province), MAX(cust_state_province),
       MIN(cust_city), MAX(cust_city)
FROM sales s, products p, customers c
WHERE s.prod_id = p.prod_id(+) AND
  s.cust_id = c.cust_id(+)
GROUP BY sys_op_zone_id(s.rowid);
```
CREATE OPERATOR

Purpose

Use the create operator statement to create a new operator and define its bindings. Operators can be referenced by index types and by SQL queries and DML statements. The operators, in turn, reference functions, packages, types, and other user-defined objects.

See Also: Oracle Database Data Cartridge Developer’s Guide and Oracle Database Concepts for a discussion of these dependencies and of operators in general

Prerequisites

To create an operator in your own schema, you must have the CREATE OPERATOR system privilege. To create an operator in another schema, you must have the CREATE ANY OPERATOR system privilege. In either case, you must also have the EXECUTE object privilege on the functions and operators referenced.

Syntax

create_operator ::= 

binding_clause ::= 

implementation_clause ::= 

context_clause ::= 

SQL Statements: CREATE LIBRARY to CREATE SPFILE 15-49
using_function_clause ::= 

Semantics

OR REPLACE
Specify OR REPLACE to replace the definition of the operator schema object.

Restriction on Replacing an Operator  You can replace the definition only if the operator has no dependent objects, such as indextypes supporting the operator.

schema
Specify the schema containing the operator. If you omit schema, then the database creates the operator in your own schema.

operator
Specify the name of the operator to be created. The name must satisfy the requirements listed in “Database Object Naming Rules” on page 2-119.

binding_clause
Use the binding_clause to specify one or more parameter data types (parameter_type) for binding the operator to a function. The signature of each binding—the sequence of the data types of the arguments to the corresponding function—must be unique according to the rules of overloading.

The parameter_type can itself be an object type. If it is, then you can optionally qualify it with its schema.

Restriction on Binding Operators  You cannot specify a parameter_type of REF, LONG, or LONG RAW.

See Also:  Oracle Database PL/SQL Language Reference for more information about overloading

RETURN Clause
Specify the return data type for the binding.

The return_type can itself be an object type. If so, then you can optionally qualify it with its schema.

Restriction on Binding Return Data Type  You cannot specify a return_type of REF, LONG, or LONG RAW.

implementation_clause
Use this clause to describe the implementation of the binding.
ANCILLARY TO Clause

Use the ANCILLARY TO clause to indicate that the operator binding is ancillary to the specified primary operator binding (primary_operator). If you specify this clause, then do not specify a previous binding with just one number parameter.

context_clause

Use the context_clause to describe the functional implementation of a binding that is not ancillary to a primary operator binding.

WITH INDEX CONTEXT, SCAN CONTEXT  Use this clause to indicate that the functional evaluation of the operator uses the index and a scan context that is specified by the implementation type.

COMPUTE ANCILLARY DATA  Specify COMPUTE ANCILLARY DATA to indicate that the operator binding computes ancillary data.

WITH COLUMN CONTEXT  Specify WITH COLUMN CONTEXT to indicate that Oracle Database should pass the column information to the functional implementation for the operator.

If you specify this clause, then the signature of the function implemented must include one extra ODCIFuncCallInfo structure.

See Also:  Oracle Database Data Cartridge Developer’s Guide for instructions on using the ODCIFuncCallInfo routine

using_function_clause

The using_function_clause lets you specify the function that provides the implementation for the binding. The function_name can be a standalone function, packaged function, type method, or a synonym for any of these.

If the function is subsequently dropped, then the database marks all dependent objects INVALID, including the operator. However, if you then subsequently issue an ALTER OPERATOR ... DROP BINDING statement to drop the binding, then subsequent queries and DML will revalidate the dependent objects.

Examples

Creating User-Defined Operators: Example  This example creates a very simple functional implementation of equality and then creates an operator that uses the function. For a more complete set of examples, see Oracle Database Data Cartridge Developer’s Guide.

CREATE FUNCTION eq_f(a VARCHAR2, b VARCHAR2) RETURN NUMBER AS
BEGIN
  IF a = b THEN RETURN 1;
  ELSE RETURN 0;
  END IF;
END;
/

CREATE OPERATOR eq_op
  BINDING (VARCHAR2, VARCHAR2)
  RETURN NUMBER
  USING eq_f;
CREATE OUTLINE

Purpose

**Note:** Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. SQL plan management creates SQL plan baselines, which offer superior SQL performance stability compared with stored outlines.

You can migrate existing stored outlines to SQL plan baselines by using the `MIGRATE_STORED_OUTLINE` function of the `DBMS_SPM` package or Enterprise Manager Cloud Control. When the migration is complete, the stored outlines are marked as migrated and can be removed. You can drop all migrated stored outlines on your system by using the `DROP_MIGRATED_STORED_OUTLINE` function of the `DBMS_SPM` package.

See Also: Oracle Database SQL Tuning Guide for more information about SQL plan management and Oracle Database PL/SQL Packages and Types Reference for information about the `DBMS_SPM` package

Use the `CREATE OUTLINE` statement to create a **stored outline**, which is a set of attributes used by the optimizer to generate an execution plan. You can then instruct the optimizer to use a set of outlines to influence the generation of execution plans whenever a particular SQL statement is issued, regardless of changes in factors that can affect optimization. You can also modify an outline so that it takes into account changes in these factors.

**Note:** The SQL statement you want to affect must be an exact string match of the statement specified when creating the outline.

**See Also:**
- Oracle Database SQL Tuning Guide for information on execution plans
- `ALTER OUTLINE` on page 11-34 for information on modifying an outline
- `ALTER SESSION` on page 11-65 and `ALTER SYSTEM` on page 11-81 for information on the `USE_STORED_OUTLINES` and `USE_PRIVATE_OUTLINES` parameters

**Prerequisites**

To create a public or private outline, you must have the `CREATE ANY OUTLINE` system privilege.

If you are creating a clone outline from a source outline, then you must also have the `SELECT_CATALOG_ROLE` role.

You can enable or disable the use of stored outlines dynamically for an individual session or for the system:
CREATE OUTLINE

- Enable the `USE_STORED_OUTLINES` parameter to use public outlines.
- Enable the `USE_PRIVATE_OUTLINES` parameter to use private stored outlines.

Syntax

```
create_outline ::= CREATE [OR REPLACE] PUBLIC | PRIVATE OUTLINE outline [FROM source_outline] [FOR CATEGORY category] [ON statement];
```

Semantics

**OR REPLACE**
Specify `OR REPLACE` to replace an existing outline with a new outline of the same name.

**PUBLIC | PRIVATE**
Specify `PUBLIC` if you are creating an outline for use by `PUBLIC`. This is the default.
Specify `PRIVATE` to create an outline for private use by the current session only. The data of this outline is stored in the current schema.

**outline**
Specify the unique name to be assigned to the stored outline. If you do not specify `outline`, then the database generates an outline name.

**See Also:** "Creating an Outline: Example" on page 15-54

**FROM source_outline Clause**
Use the `FROM` clause to create a new outline by copying an existing one. By default, Oracle Database looks for `source_category` in the public area. If you specify `PRIVATE`, then the database looks for the outline in the current schema.

**Restriction on Copying an Outline** If you specify the `FROM` clause, then you cannot specify the `ON` clause.
FOR CATEGORY Clause
Specify an optional name used to group stored outlines. For example, you could specify a category of outlines for end-of-week use and another for end-of-quarter use. If you do not specify `category`, then the outline is stored in the `DEFAULT` category.

ON Clause
Specify the SQL statement for which the database will create an outline when the statement is compiled. This clause is optional only if you are creating a copy of an existing outline using the `FROM` clause.

You can specify any one of the following statements: `SELECT`, `DELETE`, `UPDATE`, `INSERT` ...

`SELECT`, `CREATE TABLE` ... `AS SELECT`.

Restrictions on the ON Clause
This clause is subject to the following restrictions:

- If you specify the `ON` clause, then you cannot specify the `FROM` clause.
- You cannot create an outline on a multitable `INSERT` statement.
- The SQL statement in the `ON` clause cannot include any DML operation on a remote object.

Note: In subsequent statements, you can specify additional outlines for the same SQL statement, but each outline for the same statement must specify a different category in the `CATEGORY` clause.

Examples

Creating an Outline: Example
The following statement creates a stored outline by compiling the `ON` statement. The outline is called `salaries` and is stored in the category `special`.

```
CREATE OUTLINE salaries FOR CATEGORY special
    ON SELECT last_name, salary FROM employees;
```

When this same `SELECT` statement is subsequently compiled, if the `USE_STORED_OUTLINES` parameter is set to `special`, the database generates the same execution plan as was generated when the outline `salaries` was created.

Creating a Private Clone Outline: Example
The following statement creates a stored private outline `my_salaries` based on the public category `salaries` created in the preceding example.

```
CREATE OR REPLACE PRIVATE OUTLINE my_salaries
    FROM salaries;
```

Publicizing a Private Outline to the Public Area: Example
The following statement copies back (publicizes) a private outline to the public area after private editing:

```
CREATE OR REPLACE OUTLINE public_salaries
    FROM PRIVATE my_salaries;
```
CREATE PACKAGE

Purpose

Packages are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the CREATE PACKAGE statement to create the specification for a stored package, which is an encapsulated collection of related procedures, functions, and other program objects stored together in the database. The package specification declares these objects. The package body, specified subsequently, defines these objects.

See Also:
- CREATE PACKAGE BODY on page 15-57 for information on specifying the implementation of the package
- CREATE FUNCTION on page 14-71 and CREATE PROCEDURE on page 15-75 for information on creating standalone functions and procedures
- ALTER PACKAGE on page 11-36 and DROP PACKAGE on page 17-66 for information on modifying and dropping a package
- Oracle Database Development Guide and Oracle Database PL/SQL Packages and Types Reference for detailed discussions of packages and how to use them

Prerequisites

To create or replace a package in your own schema, you must have the CREATE PROCEDURE system privilege. To create or replace a package in another user’s schema, you must have the CREATE ANY PROCEDURE system privilege.

To embed a CREATE PACKAGE statement inside an Oracle Database precompiler program, you must terminate the statement with the keyword END-EXEC followed by the embedded SQL statement terminator for the specific language.

See Also: Oracle Database PL/SQL Language Reference for more information

Syntax

Packages are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to Oracle Database PL/SQL Language Reference for the PL/SQL syntax, semantics, and examples.

\[
\text{create\_package}::= \\
\text{CREATE} \text{ OR REPLACE} \text{ EDITIONABLE} \text{ NONEDITIONABLE} \text{ PACKAGE } \text{plsql\_package\_source} \\
\]

(plsql_package_source: See Oracle Database PL/SQL Language Reference.)
Semantics

**OR REPLACE**
Specify **OR REPLACE** to re-create the package specification if it already exists. Use this clause to change the specification of an existing package without dropping, re-creating, and regranting object privileges previously granted on the package. If you change a package specification, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined package can still access the package without being regranted the privileges.

If any function-based indexes depend on the package, then the database marks the indexes **DISABLED**.

**See Also:** ALTER PACKAGE for information on recompiling package specifications

**[ EDITIONABLE | NONEDITIONABLE ]**
Use these clauses to specify whether the package is an editioned or noneditioned object if editioning is enabled for the schema object type **PACKAGE** in **schema**. The default is **EDITIONABLE**. For information about editioned and noneditioned objects, see Oracle Database Development Guide.

**plsql_package_source**
See Oracle Database PL/SQL Language Reference for the syntax and semantics of the **plsql_package_source**, including examples.
CREATE PACKAGE BODY

Purpose

Package bodies are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the CREATE PACKAGE BODY statement to create the body of a stored package, which is an encapsulated collection of related procedures, stored functions, and other program objects stored together in the database. The package body defines these objects. The package specification, defined in an earlier CREATE PACKAGE statement, declares these objects.

Packages are an alternative to creating procedures and functions as standalone schema objects.

See Also:

- CREATE FUNCTION on page 14-71 and CREATE PROCEDURE on page 15-75 for information on creating standalone functions and procedures
- CREATE PACKAGE on page 15-55 for a discussion of packages, including how to create packages
- ALTER PACKAGE on page 11-36 for information on modifying a package
- DROP PACKAGE on page 17-66 for information on removing a package from the database

Prerequisites

To create or replace a package in your own schema, you must have the CREATE PROCEDURE system privilege. To create or replace a package in another user's schema, you must have the CREATE ANY PROCEDURE system privilege. In both cases, the package body must be created in the same schema as the package.

To embed a CREATE PACKAGE BODY statement inside an Oracle Database precompiler program, you must terminate the statement with the keyword END-EXEC followed by the embedded SQL statement terminator for the specific language.

See Also: Oracle Database PL/SQL Language Reference

Syntax

Package bodies are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to Oracle Database PL/SQL Language Reference for the PL/SQL syntax, semantics, and examples.

create_package_body ::= CREATE OR REPLACE EDITIONABLE NONEDITIONABLE PACKAGE BODY plsql_package_body_source

(plsql_package_body_source: See Oracle Database PL/SQL Language Reference.)
Semantics

**OR REPLACE**
Specify **OR REPLACE** to re-create the package body if it already exists. Use this clause to change the body of an existing package without dropping, re-creating, and regranting object privileges previously granted on it. If you change a package body, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined package can still access the package without being regranted the privileges.

**See Also:** ALTER PACKAGE on page 11-36 for information on recompiling package bodies

[ EDITIONABLE | NONEDITIONABLE ]
If you do not specify this clause, then the package body inherits EDITIONABLE or NONEDITIONABLE from the package specification. If you do specify this clause, then it must match that of the package specification.

**plsql_package_body_source**
See Oracle Database PL/SQL Language Reference for the syntax and semantics of the plsql_package_body_source.
CREATE PFILE

Purpose

Use the CREATE PFILE statement to export either a binary server parameter file or the current in-memory parameter settings into a text initialization parameter file. Creating a text parameter file is a convenient way to get a listing of the current parameter settings being used by the database, and it lets you edit the file easily in a text editor and then convert it back into a server parameter file using the CREATE SPFILE statement.

Upon successful execution of this statement, Oracle Database creates a text parameter file on the server. In an Oracle Real Application Clusters environment, it will contain all parameter settings of all instances. It will also contain any comments that appeared on the same line with a parameter setting in the server parameter file.

Note on Creating Text Parameter Files in a CDB When you create a text parameter file in a multitenant container database (CDB), the current container can be the root or a PDB.

- If the current container is the root, then the database creates a text file that contains the parameter settings for the root.
- Starting with Oracle Database 12c Release 1 (12.1.0.2), you can create a text parameter file when the current container is a PDB. In this case you must specify a pfile_name. The database creates a text file that contains the parameter settings for the PDB.

See Also:

- CREATE SPFILE on page 15-101 for information on server parameter files
- Oracle Database Administrator’s Guide for additional information on text initialization parameter files and binary server parameter files
- Oracle Real Application Clusters Administration and Deployment Guide for information on using server parameter files in an Oracle Real Application Clusters environment

Prerequisites

You must have the SYSBACKUP, SYSDBA, SYSDG, or SYSOPER system privilege to execute this statement. You can execute this statement either before or after instance startup.

Syntax

create_pfile::=
CREATE PFILE

Semantics

pfile_name
Specify the name of the text parameter file you want to create. If you do not specify pfile_name, then Oracle Database uses the platform-specific default initialization parameter file name. pfile_name can include a path prefix. If you do not specify such a path prefix, then the database adds the path prefix for the default storage location, which is platform dependent.

spfile_name
Specify the name of the binary server parameter from which you want to create a text file.

- If you specify spfile_name, then the file must exist on the server. If the file does not reside in the default directory for server parameter files on your operating system, then you must specify the full path.
- If you do not specify spfile_name, then the database uses the spfile that is currently associated with the instance, usually the one that was used a startup. If no spfile is associated with the instance, then the database looks for the platform-specific default server parameter file name. If that file does not exist, then the database returns an error.

See Also: the appropriate operating-system-specific documentation for default parameter file names

MEMORY
Specify MEMORY to create a pfile using the current system-wide parameter settings. In an Oracle RAC environment, the created file will contain the parameter settings from each instance.

Examples

Creating a Parameter File: Example
The following example creates a text parameter file my_init.ora from a binary server parameter file s_params.ora:

CREATE PFILE = 'my_init.ora' FROM SPFILE = 's_params.ora';

Note: Typically you will need to specify the full path and filename for parameter files on your operating system. Refer to your Oracle operating system documentation for path information.
CREATE PLUGGABLE DATABASE

Purpose

Use the `CREATE PLUGGABLE DATABASE` statement to create a pluggable database (PDB).

This statement enables you to perform the following tasks:

- Create a PDB by using the seed as a template
  
  Use the `create_pdb_from_seed` clause to create a PDB by using the seed in the multitenant container database (CDB) as a template. The files associated with the seed are copied to a new location and the copied files are then associated with the new PDB.

- Create a PDB by cloning an existing PDB or non-CDB
  
  Use the `create_pdb_clone` clause to create a PDB by copying an existing PDB or non-CDB and then plugging the copy into the CDB. The files associated with the existing PDB or non-CDB are copied to a new location and the copied files are associated with the new PDB.

  **Note:** Creating a PDB by cloning a non-CDB is available starting with Oracle Database 12c Release 1 (12.1.0.2).

- Create a PDB by plugging an unplugged PDB or a non-CDB into a CDB
  
  Use the `create_pdb_from_xml` clause to plug an unplugged PDB or a non-CDB into a CDB, using an XML metadata file.

  **Note:** When a new PDB is established in a CDB, it is possible that the name of a service offered by the new PDB will collide with an existing service name. The namespace in which a collision can occur is that of the listener that gives access to the CDB. Within that namespace, collisions are possible among the names of non-CDB’s default services, CDB’s default services, PDB’s default services, and user-defined services. For example, if two or more CDBs on the same computer system use the same listener, and the newly established PDB has the same service name as another PDB in these CDBs, then a collision occurs.

  You must not attempt to operate a PDB that causes a collision with an existing service name. If the colliding name is that of the PDB’s default service, then you must rename the PDB. If the colliding name is that of a user-created service within the PDB, then you must drop that service and create one in its place, with a non-colliding name, that has the same purpose and properties.
CREATE PLUGGABLE DATABASE

Prerequisites

You must be connected to a CDB and the current container must be the root.

You must have the CREATE PLUGGABLE DATABASE system privilege.

The CDB in which the PDB is being created must be in READ WRITE mode.

To specify the create_pdb_clone clause:

■ If src_pdb_name refers to a PDB in the same CDB, then you must have the CREATE PLUGGABLE DATABASE system privilege in the root of the CDB in which the new PDB will be created and in the PDB being cloned.

■ If src_pdb_name refers to a PDB in a remote database or a non-CDB, then you must have the CREATE PLUGGABLE DATABASE system privilege in the root of the CDB in which the new PDB will be created and the remote user must have the CREATE PLUGGABLE DATABASE system privilege in the PDB or non-CDB to which src_pdb_name refers.

Syntax

create_pluggable_database::=

( create_pdb_from_seed::= on page 15-62, create_pdb_clone::= on page 15-64, create_pdb_from_xml::= on page 15-65 )
CREATE PLUGGABLE DATABASE

pdb_dba_roles ::= 

default_tablespace ::= 

(file_name_convert ::= on page 8-29, extent_management_clause ::= on page 14-31)

file_name_convert ::= 

pdb_storage_clause ::= 

(path_prefix_clause ::= 

 tempfile_reuse_clause ::=
CREATE PLUGGABLE DATABASE

user_tablespace_clause ::= 

standbys_clause ::= 

logging_clause ::= 

create_file_dest_clause ::= 

create_pdb_clone ::= 

(pdb_storage_clause ::= on page 15-63, file_name_convert ::= on page 15-63, path_prefix_clause ::= on page 15-63, tempfile_reuse_clause ::= on page 15-63, user_tablespace_clause ::= on page 15-64, standbys_clause ::= on page 15-64, logging_clause ::= on page 15-64, create_file_dest_clause ::= on page 15-64)
**CREATE PLUGGABLE DATABASE**

**create_pdb_from_xml::=**

[source_file_name_convert::= on page 15-65, source_file_directory::= on page 15-65, file_name_convert::= on page 15-63, pdb_storage_clause::= on page 15-63, path_prefix_clause::= on page 15-63, tempfile_reuse_clause::= on page 15-63, user_tablespaces_clause::= on page 15-64, standbys_clause::= on page 15-64, logging_clause::= on page 15-64, create_file_dest_clause::= on page 15-64)

**source_file_name_convert::=**

**source_file_directory::=**

**Semantics**

**pdb_name**

Specify the name of the PDB to be created. The first character of a PDB name must be alphanumeric and the remaining characters can be alphanumeric or the underscore character (_).

The PDB name must be unique in the CDB, and it must be unique within the scope of all the CDBs whose instances are reached through a specific listener.

**create_pdb_from_seed**

This clause enables you to create a PDB by using the seed in the CDB as a template.

**See Also:** Oracle Database Administrator’s Guide for the complete steps for creating a PDB using the seed

**ADMIN USER Clause**

Use this clause to create an administrative user who can be granted the privileges required to perform administrative tasks on the PDB. For admin_user_name, specify name of the user to be created. Use the IDENTIFIED BY clause to specify the password
for admin_user_name. Oracle Database creates a local user in the PDB and grants the PDB_DBA local role to that user.

**pdb_dba_roles**
This clause lets you grant one or more roles to the PDB_DBA role. Use this clause to grant roles that have the privileges required by the administrative user of the PDB. For role, specify a predefined role. For a list of predefined roles, refer to Oracle Database Security Guide.

You can also use the GRANT statement to grant roles to the PDB_DBA role after the PDB has been created. Until you have granted the appropriate privileges to the PDB_DBA role, the SYS and SYSTEM users can perform administrative tasks on a PDB.

**default_tablespace**
Specify this clause to create a default permanent tablespace for the PDB. The default_tablespace clause has the same semantics that it has for the CREATE DATABASE statement. For full information, refer to default_tablespace on page 14-38 in the documentation on CREATE DATABASE.

**file_name_convert**
Use this clause to determine how the database generates the names of files (such as data files and wallet files) for the PDB.

- For filename_pattern, specify a string found in names of files associated with the seed (when creating a PDB by using the seed), associated with the source PDB (when cloning a PDB), or listed in the XML file (when plugging a PDB into a CDB).
- For replacement_filename_pattern, specify a replacement string.

Oracle Database will replace filename_pattern with replacement_filename_pattern when generating the names of files associated with the new PDB.

File name patterns cannot match files or directories managed by Oracle Managed Files. You can specify FILE_NAME_CONVERT = NONE, which is the same as omitting this clause. If you omit this clause, then the database first attempts to use Oracle Managed Files to generate file names. If you are not using Oracle Managed Files, then the database uses the PDB_FILE_NAME_CONVERT initialization parameter to generate file names. If this parameter is not set, then an error occurs.

**pdb_storage_clause**
Use this clause to specify storage limits for the PDB.

- Use MAXSIZE to limit the amount of storage that can be used by all tablespaces in the PDB to the value specified with size_clause. This limit includes the size of data files and temporary files for tablespaces belonging to the PDB. Specify MAXSIZE UNLIMITED to enforce no limit.
- Use MAX_SHARED_TEMP_SIZE to limit the amount of storage in the shared temporary tablespace that can be used by sessions connected to the PDB to the value specified with size_clause. Specify MAX_SHARED_TEMP_SIZE UNLIMITED to enforce no limit.

If you omit this clause, or specify STORAGE UNLIMITED, then there are no storage limits for the PDB. This is equivalent to specifying STORAGE (MAXSIZE UNLIMITED MAX_SHARED_TEMP_SIZE UNLIMITED).
**path_prefix_clause**

Use this clause to ensure that file paths for directory objects associated with the PDB are restricted to the specified directory or its subdirectories. You cannot modify the setting of this clause after you create the PDB. This clause does not affect files created by Oracle Managed Files.

- For `path_name`, specify the absolute path name of an operating system directory. The single quotation marks are required, with the result that the path name is case sensitive. Oracle Database uses `path_name` as a prefix to the relative paths for directory objects associated with the PDB. If a directory object has an absolute path, then the `path_prefix_clause` is ignored.

  Be sure to specify `path_name` so that the resulting path name will be properly formed when relative paths are appended to it. For example, on UNIX systems, be sure to end `path_name` with a forward slash (`/`), such as:

  `PATH_PREFIX = '/disk1/oracle/dba/salespdb/'`

- If you specify `PATH_PREFIX = NONE`, then the relative paths for directory objects associated with the PDB are treated as absolute paths and are not restricted to a particular directory.

Omitting the `path_prefix_clause` is equivalent to specifying `PATH_PREFIX = NONE`.

**tempfile_reuse_clause**

When you create a PDB, Oracle Database associates temp files with the new PDB. Depending on how you create the PDB, the temp files may already exist and may have been previously used.

Specify `TEMPFILE REUSE` to instruct the database to format and reuse a temp file associated with the new PDB if it already exists. If you specify this clause and a temp file does not exist, then the database creates the temp file.

If you do not specify `TEMPFILE REUSE` and a temp file to be associated with the new PDB already exists, then the database returns an error and does not create the PDB.

**user_tablespaces_clause**

**Note:** The `user_tablespaces_clause` is available starting with Oracle Database 12c Release 1 (12.1.0.2).

This clause lets you specify the tablespaces to be made available in the new PDB. The `SYSTEM`, `SYSAUX`, and `TEMP` tablespaces are available in all PDBs and cannot be specified in this clause.

- Specify `tablespace` to make the tablespace available in the new PDB. You can specify more than one tablespace in a comma-separated list.
- Specify `NONE` to make only the `SYSTEM`, `SYSAUX`, and `TEMP` tablespaces available in the new PDB.
- Specify `ALL` to make all tablespaces available in the new PDB. This is the default.
- Specify `ALL EXCEPT` to make all tablespaces available in the new PDB, except the specified tablespaces.

Tablespaces that are unavailable in a PDB are offline in the PDB, and all data files that belong to those tablespaces are unnamed and offline in the PDB.
**standbys_clause**

Use this clause to specify whether the new PDB is included in standby CDBs.

- Specify **ALL** to include the new PDB in all standby CDBs. During standby recovery, the standby CDB will search for the data files for the PDB. If the data files are not found, then standby recovery will stop and you must copy the data files to the correct location before you can restart recovery. This is the default.

- Specify **NONE** to exclude the new PDB from all standby CDBs. When a PDB is excluded from all standby CDBs, the PDB's data files are unnamed and marked offline on all of the standby CDBs. Standby recovery will not stop if the data files for the PDB are not found on the standby. If you instantiate a new standby CDB after the PDB is created, then you must explicitly disable the PDB for recovery on the new standby CDB.

You can enable a PDB on a standby CDB after it was excluded on that standby CDB by copying the data files to the correct location, bringing the PDB online, and marking it as enabled for recovery.

**logging_clause**

Use this clause to specify the default logging attribute for tablespaces created within the PDB. The logging attribute controls whether certain DML operations are logged in the redo log file (**logging** or **NOlogging**). The default is **logging**.

When creating a tablespace, you can override the default logging attribute by specifying the **logging** clause of the CREATE TABLESPACE statement on page 16-109.

Refer to **logging** clause on page 8-38 for a full description of this clause.

**create_file_dest_clause**

By default, a newly created PDB inherits its Oracle Managed Files settings from the root. If the root uses Oracle Managed Files, then the PDB also uses Oracle Managed Files. The PDB shares the same base file system directory for Oracle Managed Files with the root and has its own subdirectory named with the GUID of the PDB. If the root does not use Oracle Managed Files, then the PDB also does not use Oracle Managed Files.

This clause lets you override the default behavior. You can enable or disable Oracle Managed Files for the PDB and you specify a different base file system directory or Oracle ASM disk group for the PDB's files.
CREATE PLUGGABLE DATABASE

- Specify `NONE` to disable Oracle Managed Files for the PDB.
- Specify either `directory_path_name` or `diskgroup_name` to enable Oracle Managed Files for the PDB.

Specify `directory_path_name` to designate the base file system directory for the PDB's files. Specify the full path name of the operating system directory. The directory must exist and Oracle processes must have appropriate permissions on the directory. The single quotation marks are required, with the result that the path name is case sensitive.

Specify `diskgroup_name` to designate the default Oracle ASM disk group for the PDB's files.

If you specify a value other than `NONE`, then the database implicitly sets the `DB_CREATE_FILE_DEST` initialization parameter with `SCOPE=SPFILE` in the PDB.

`create_pdb_clone`

This clause enables you to create a new PDB by cloning a source to a target PDB. The source can be a PDB in the local CDB, a PDB in a remote CDB, or a non-CDB. The target PDB is the clone of the source.

If the source is a PDB in the local CDB, then the source PDB can be plugged in or unplugged. If the source is a PDB in a remote CDB, then the source PDB must be plugged in.

If the source is a non-CDB or a PDB in a remote CDB, then the source and the CDB that contains the target PDB must meet the following requirements:

- They must have the same endian format.
- They must have compatible character sets and national character sets, which means:
  - Every character in the source character set is available in the local CDB character set.
  - Every character in the source character set has the same code point value in the local CDB character set.
- They must have the same set of database options installed.

Users in the PDB who used the default temporary tablespace of the source non-CDB or PDB use the default temporary tablespace of the new PDB. Users who used non-default temporary tablespaces in the non-CDB or PDB continue to use the same local temporary tablespaces in the new PDB.

**See Also:** Oracle Database Administrator's Guide for the complete steps for creating a PDB by cloning an existing PDB

FROM Clause

Use this clause to specify the source PDB or non-CDB. The source must be open with open mode `READ ONLY`. The files associated with the source are copied to a new location and these copied files are then associated with the new PDB.

- If the source is a PDB in the local CDB, then use `src_pdb_name` to specify the name of the source PDB. You cannot specify `PDB$SEED` for `src_pdb_name`. Instead, use the `create_pdb_from_seed` clause on page 15-65 to create a PDB by using the seed as a template.
If the source is a PDB in a remote CDB, then use `src_pdb_name` to specify the name of the source PDB and `dblink` to specify the name of the database link to use to connect to the remote CDB.

If the source is a non-CDB, then specify `NON$CDB@dblink`, where `dblink` is the name of the database link to use to connect to the non-CDB.

**pdb_storage_clause**

Use this clause to specify storage limits for the new PDB. Refer to `pdb_storage_clause` on page 15-66 for the full semantics of this clause.

**file_name_convert**

Use this clause to determine how the database generates the names of files for the new PDB. Refer to `file_name_convert` on page 15-66 for the full semantics of this clause.

**path_prefix_clause**

Use this clause to ensure that all directory object paths associated with the PDB are restricted to the specified directory or its subdirectories. Refer to `path_prefix_clause` on page 15-67 for the full semantics of this clause.

**tempfile_reuse_clause**

Specify `TEMPFILE REUSE` to instruct the database to format and reuse a temp file associated with the new PDB if it already exists. Refer to `tempfile_reuseClause` on page 15-67 for the full semantics of this clause.

**SNAPSHOT COPY**

You can specify `SNAPSHOT COPY` only when cloning a PDB. This clause is not supported when cloning a non-CDB. The source PDB can be in the local CDB or a remote CDB. The `SNAPSHOT COPY` clause instructs the database to clone the source PDB using storage snapshots. This reduces the time required to create the clone because the database does not need to make a complete copy of the source data files.

When you use the `SNAPSHOT COPY` clause to create a clone of a source PDB and the `CLONEDB` initialization parameter is set to `FALSE`, the underlying file system for the source PDB’s files must support storage snapshots. Such file systems include Oracle Automatic Storage Management Cluster File System (Oracle ACFS) and Direct NFS Client storage.

When you use the `SNAPSHOT COPY` clause to create a clone of a source PDB and the `CLONEDB` initialization parameter is set to `TRUE`, the underlying file system for the source PDB’s files can be any local file system, network file system (NFS), or clustered file system that has Direct NFS enabled. However, the source PDB must remain in open read-only mode as long as any clones exist.

Direct NFS Client enables an Oracle database to access network attached storage (NAS) devices directly, rather than using the operating system kernel NFS client. If the PDB files are stored on Direct NFS Client storage, then the following additional requirements must be met:

- The source PDB files must be located on an NFS volume.
- Storage credentials must be stored in a Transparent Data Encryption keystore.
- The storage user must have the privileges required to create and destroy snapshots on the volume that hosts the source PDB files.
- Credentials must be stored in the keystore using an `ADMINISTER KEY MANAGEMENT ADD SECRET` SQL statement.
When you use the `SNAPSHOT COPY` clause to create a clone of a source PDB, the following restrictions apply to the source PDB as long as any clones exist:

- It cannot be unplugged.
- It cannot be dropped.

PDB clones created using the `SNAPSHOT COPY` clause cannot be unplugged. They can only be dropped. Attempting to unplug a clone created using the `SNAPSHOT COPY` clause results in an error.

For a PDB created using the `SNAPSHOT COPY` clause in an Oracle Real Application Clusters (Oracle RAC) environment, each node that must access the PDB's files must be mounted. For Oracle RAC databases running on Linux or UNIX platforms, the underlying NFS volumes must be mounted. If the Oracle RAC database is running on a Windows platform and using Direct NFS for shared storage, then you must update the `orafstab` file on all nodes with the created volume `export` and `mount` entries.

Storage clones are named and tagged using the new PDB GUID. You can query the `CLONETAG` column of `DBA_PDB_HISTORY` view to view clone tags for storage clones.

**NO DATA**

| Note: | The NO DATA clause is available starting with Oracle Database 12c Release 1 (12.1.0.2). |

The NO DATA clause applies only when cloning a PDB. This clause specifies that the source PDB's data model definition is cloned, but not the PDB's data. The dictionary data in the source PDB is cloned, but all user-created table and index data from the source PDB is discarded.

**Restrictions on the NO DATA Clause** The following restrictions apply to the NO DATA clause:

- You cannot specify NO DATA when cloning a non-CDB.
- You cannot specify NO DATA if the source PDB contains clustered tables, Advanced Queuing (AQ) tables, index-organized tables, or tables that contain abstract data type columns.

**create_pdb_from_xml**

This clause enables you to create a PDB by plugging an unplugged PDB or a non-CDB (the source database) into a CDB (the target CDB). If the source database is an unplugged PDB, then it may have been unplugged from the target CDB or a different CDB.

The source database and the target CDB must meet the following requirements:

- They must have the same endian format.
- They must have compatible character sets and national character sets, which means:
  - Every character in the source database character set is available in the target CDB character set.
  - Every character in the source database character set has the same code point value in the target CDB character set.
They must have the same set of database options installed.

See Also:

- *Oracle Database Administrator’s Guide* for the complete steps for creating a PDB by plugging an unplugged PDB into a CDB and creating a PDB using a non-CDB
- *Oracle Database PL/SQL Packages and Types Reference* for more information on the DBMS_PDB package

**AS CLONE Clause**

Specify this clause only if the target CDB already contains a PDB that was created using the same set of data files. The source files remain as an unplugged PDB and can be used again. Specifying *AS CLONE* also ensures that Oracle Database generates new identifiers, such as DBID and GUID, for the new PDB.

**USING Clause**

Use `filename` to specify the name of the XML file that contains the metadata that describes the source database that you are plugging in. The XML file and the files associated with the source database must exist in a location that is accessible to the CDB. You can obtain this file as follows:

- If the source database is an unplugged PDB, then the XML metadata file was created by the `pdb_unplug_clause` of `ALTER PLUGGABLE DATABASE`.
- If the source database is a non-CDB, then you must create the XML metadata file using the DBMS_PDB package.

**source_file_name_convert**

Specify this clause only if the contents of the XML file do not accurately describe the locations of the source files. If the files that must be used to plug in the source database are no longer in the location specified in the XML file, then use this clause to map the specified file names to the actual file names.

- For `filename_pattern`, specify the string for the location of the files as specified in the XML file.
- For `replacement_filename_pattern`, specify the string for the actual location that contains the files that must be used to create the PDB.

Oracle Database will replace `filename_pattern` with `replacement_filename_pattern` when searching for the source database files.

File name patterns cannot match files or directories managed by Oracle Managed Files.

If the files that must be used to create the PDB exist in the location specified in the XML file, you can either omit this clause or specify `SOURCE_FILE_NAME_CONVERT=NONE`.

**source_file_directory**

---

**Note:** The `source_file_directory` clause is available starting with Oracle Database 12c Release 1 (12.1.0.2).

---

Specify this clause only if the contents of the XML file do not accurately describe the locations of the source files and the source files are all present in a single directory. This clause is convenient when you have a large number of data files and specifying a
replacement file name pattern for each file using the _source_file_name_convert_ clause is not feasible.

- For _directory_path_name_, specify the absolute path of the directory that contains the source files. The directory is scanned to find the appropriate files based on the unplugged PDB's XML file.

You can specify this clause for configurations that use Oracle Managed Files and for configurations that do not use Oracle Managed Files.

If the files that must be used to create the PDB exist in the location specified in the XML file, you can either omit this clause or specify _SOURCE_FILE_DIRECTORY=NONE_.

**COPY Clause**

Specify _COPY_ if you want the files listed in the XML file to be copied to the new location and used for the new PDB. This is the default. You can use the optional _file_name_convert_ clause to use pattern replacement in the new file names. Refer to _file_name_convert_ on page 15-66 for the full semantics of this clause.

**MOVE Clause**

Specify _MOVE_ if you want the files listed in the XML file to be moved, rather than copied, to the new location and used for the new PDB. You can use the optional _file_name_convert_ clause to use pattern replacement in the new file names. Refer to _file_name_convert_ on page 15-66 for the full semantics of this clause.

**NOCOPY Clause**

Specify _NOCOPY_ if you want the files for the PDB to remain in their current locations. Use this clause if there is no need to copy or move the files required to plug in the PDB.

**pdb_storage_clause**

Use this clause to specify storage limits for the new PDB. Refer to _pdb_storage_clause_ on page 15-66 for the full semantics of this clause.

**path_prefix_clause**

Use this clause to ensure that all directory object paths associated with the PDB are restricted to the specified directory or its subdirectories. Refer to _path_prefix_clause_ on page 15-67 for the full semantics of this clause.

**tempfile_reuse_clause**

Specify _TEMPFILE_REUSE_ to instruct the database to format and reuse a temp file associated with the new PDB if it already exists. Refer to _tempfile_reuse_clause_ on page 15-67 for the full semantics of this clause.

**Examples**

**Creating a PDB by Using the Seed: Example**  
The following statement creates a PDB `salespdb` by using the seed in the CDB as a template. The administrative user `salesadm` is created and granted the `dba` role. The default tablespace assigned to any non-`SYSTEM` users for whom no permanent tablespace is assigned is `sales`. File names for the new PDB will be constructed by replacing `/disk1/oracle/dbs/pdbseed/` in the file names in the seed with `/disk1/oracle/dbs/salespdb/`. All tablespaces that belong to `sales` must not exceed 2G. The location of all directory object paths associated with `salespdb` are restricted to the directory `/disk1/oracle/dbs/salespdb/`.  

```sql
CREATE PLUGGABLE DATABASE
```
CREATE PLUGGABLE DATABASE salespdb
   ADMIN USER salesadm IDENTIFIED BY password
   ROLES = (dba)
   DEFAULT TABLESPACE sales
      DATAFILE '/disk1/oracle/dbs/salespdb/sales01.dbf' SIZE 250M AUTOEXTEND ON
      FILE_NAME_CONVERT = ('/disk1/oracle/dbs/pdbseed/',
                            '/disk1/oracle/dbs/salespdb/')
      STORAGE (MAXSIZE 2G)
      PATH_PREFIX = '/disk1/oracle/dbs/salespdb/';

Cloning a PDB From an Existing PDB: Example  The following statement creates a
PDB newpdb by cloning PDB salespdb. PDBs newpdb and salespdb are in the same
CDB. Because no storage limits are explicitly specified, there is no limit on the amount
of storage for newpdb. The files are copied from /disk1/oracle/dbs/salespdb/ to
/disk1/oracle/dbs/newpdb/. The location of all directory object paths associated with
newpdb are restricted to the directory /disk1/oracle/dbs/newpdb/.

CREATE PLUGGABLE DATABASE newpdb FROM salespdb
   FILE_NAME_CONVERT = ('/disk1/oracle/dbs/salespdb/', '/disk1/oracle/dbs/newpdb/')
   PATH_PREFIX = '/disk1/oracle/dbs/newpdb';

Plugging a PDB into a CDB: Example  The following statement plugs the PDB
salespdb, which was previously unplugged, into the CDB. The details about the
metadata describing salespdb are stored in the XML file /disk1/usr/salespdb.xml.
The XML file does not accurately describe the current locations of the files. Therefore,
the SOURCE_FILE_NAME_CONVERT clause is used to indicate that the files are in
/disk2/oracle/dbs/salespdb/, not /disk1/oracle/dbs/salespdb/. The NOCOPY
clause indicates that the files are already in the correct location. All tablespaces that
belong to sales must not exceed 2G. A file with the same name as the temp file
specified in the XML file exists in the target location. Therefore, the TEMPFILE REUSE
clause is required.

CREATE PLUGGABLE DATABASE salespdb
   USING '/disk1/usr/salespdb.xml'
   SOURCE_FILE_NAME_CONVERT =
      ('/disk1/oracle/dbs/salespdb/', '/disk2/oracle/dbs/salespdb/')
   NOCOPY
   STORAGE (MAXSIZE 2G)
   TEMPFILE REUSE;
CREATE PROCEDURE

Purpose

Procedures are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the CREATE PROCEDURE statement to create a standalone stored procedure or a call specification.

A procedure is a group of PL/SQL statements that you can call by name. A call specification (sometimes called call spec) declares a Java method or a third-generation language (3GL) routine so that it can be called from SQL and PL/SQL. The call spec tells Oracle Database which Java method to invoke when a call is made. It also tells the database what type conversions to make for the arguments and return value.

Stored procedures offer advantages in the areas of development, integrity, security, performance, and memory allocation.

See Also:
- Oracle Database Development Guide for more information on stored procedures, including how to call stored procedures and for information about registering external procedures.
- CREATE FUNCTION on page 14-71 for information specific to functions, which are similar to procedures in many ways.
- CREATE PACKAGE on page 15-55 for information on creating packages. The CREATEPROCEDURE statement creates a procedure as a standalone schema object. You can also create a procedure as part of a package.
- ALTER PROCEDURE on page 11-50 and DROP PROCEDURE on page 17-70 for information on modifying and dropping a standalone procedure.
- CREATE LIBRARY on page 15-2 for more information about shared libraries.

Prerequisites

To create or replace a procedure in your own schema, you must have the CREATE PROCEDURE system privilege. To create or replace a procedure in another user's schema, you must have the CREATE ANY PROCEDURE system privilege.

To invoke a call spec, you may need additional privileges, for example, the EXECUTE object privilege on the C library for a C call spec.

To embed a CREATE PROCEDURE statement inside an Oracle precompiler program, you must terminate the statement with the keyword END-EXEC followed by the embedded SQL statement terminator for the specific language.

See Also: Oracle Database PL/SQL Language Reference or Oracle Database Java Developer's Guide for more information.
Syntax

Procedures are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to Oracle Database PL/SQL Language Reference for the PL/SQL syntax, semantics, and examples.

create_procedure ::= (plsql_procedure_source: See Oracle Database PL/SQL Language Reference.)

Semantics

OR REPLACE

Specify OR REPLACE to re-create the procedure if it already exists. Use this clause to change the definition of an existing procedure without dropping, re-creating, and re-granting object privileges previously granted on it. If you redefine a procedure, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined procedure can still access the procedure without being re-granted the privileges.

If any function-based indexes depend on the procedure, then Oracle Database marks the indexes DISABLED.

See Also: ALTER PROCEDURE on page 11-50 for information on recompiling procedures

[ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the procedure is an editioned or noneditioned object if editioning is enabled for the schema object type PROCEDURE in schema. The default is EDITIONABLE. For information about editioned and noneditioned objects, see Oracle Database Development Guide.

plsql_procedure_source

See Oracle Database PL/SQL Language Reference for the syntax and semantics of the plsql_procedure_source.
CREATE PROFILE

**Note:** Oracle recommends that you use the Database Resource Manager rather than this SQL statement to establish resource limits. The Database Resource Manager offers a more flexible means of managing and tracking resource use. For more information on the Database Resource Manager, refer to Oracle Database Administrator’s Guide.

**Purpose**

Use the `CREATE PROFILE` statement to create a profile, which is a set of limits on database resources. If you assign the profile to a user, then that user cannot exceed these limits.

**See Also:** Oracle Database Security Guide for a detailed description and explanation of how to use password management and protection

**Prerequisites**

To create a profile, you must have the `CREATE PROFILE` system privilege.

To specify resource limits for a user, you must:

- Enable resource limits dynamically with the `ALTER SYSTEM` statement or with the initialization parameter `RESOURCE_LIMIT`. This parameter does not apply to password resources. Password resources are always enabled.
- Create a profile that defines the limits using the `CREATE PROFILE` statement
- Assign the profile to the user using the `CREATE USER` or `ALTER USER` statement

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root. To specify `CONTAINER = CURRENT`, the current container must be a pluggable database (PDB).

**See Also:**

- `ALTER SYSTEM` on page 11-81 for information on enabling resource limits dynamically
- Oracle Database Reference for information on the `RESOURCE_LIMIT` parameter
- `CREATE USER` on page 17-7 and `ALTER USER` on page 13-6 for information on profiles

**Syntax**

```
create_profile::=
```

SQL Statements: CREATE LIBRARY to CREATE SPFILE  15-77
**resource_parameters**: ::= 

```
SESSIONS_PER_USER
CPU_PER_SESSION
CPU_PER_CALL
CONNECT_TIME
IDLE_TIME
LOGICAL_READS_PER_SESSION
LOGICAL_READS_PER_CALL
COMPOSITE_LIMIT
PRIVATE_SGA
```

(size_clause ::= on page 8-47)

**password_parameters**: ::= 

```
FAILED_LOGIN_ATTEMPTS
PASSWORD_LIFE_TIME
PASSWORD_REUSE_TIME
PASSWORD_REUSE_MAX
PASSWORD_LOCK_TIME
PASSWORD_GRACE_TIME
```

(expr ::= UNLIMITED
 DEFAULT)

```
PASSWORD_VERIFY_FUNCTION
```

(function ::= NULL
 DEFAULT)

**Semantics**

**profile**

Specify the name of the profile to be created. The name must satisfy the requirements listed in "Database Object Naming Rules" on page 2-119. Use profiles to limit the database resources available to a user for a single call or a single session.

In a non-CDB, a profile name cannot begin with C## or c##.

In a CDB, the requirements for a profile name are as follows:

- In Oracle Database 12c Release 1 (12.1.0.1), the name of a **common profile** must begin with C## or c## and the name of a **local profile** must not begin with C## or c##.
- Starting with Oracle Database 12c Release 1 (12.1.0.2):
The name of a **common profile** must begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. By default, the prefix is `C##`.

The name of a **local profile** must **not** begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. Regardless of the value of `COMMON_USER_PREFIX`, the name of a local profile can never begin with `C##` or `c##`.

---

**Note:** If the value of `COMMON_USER_PREFIX` is an empty string, then there are no requirements for common or local profile names with one exception: the name of a local profile can never begin with `C##` or `c##`. Oracle recommends against using an empty string value because it might result in conflicts between the names of local and common profiles when a PDB is plugged into a different CDB, or when opening a PDB that was closed when a common user was created.

Oracle Database enforces resource limits in the following ways:

- If a user exceeds the `CONNECT_TIME` or `IDLE_TIME` session resource limit, then the database rolls back the current transaction and ends the session. When the user process next issues a call, the database returns an error.
- If a user attempts to perform an operation that exceeds the limit for other session resources, then the database aborts the operation, rolls back the current statement, and immediately returns an error. The user can then commit or roll back the current transaction, and must then end the session.
- If a user attempts to perform an operation that exceeds the limit for a single call, then the database aborts the operation, rolls back the current statement, and returns an error, leaving the current transaction intact.

---

**Notes:**

- You can use fractions of days for all parameters that limit time, with days as units. For example, 1 hour is 1/24 and 1 minute is 1/1440.
- You can specify resource limits for users regardless of whether the resource limits are enabled. However, Oracle Database does not enforce the limits until you enable them.

---

**See Also:** "Creating a Profile: Example" on page 15-82

**UNLIMITED**

When specified with a resource parameter, `UNLIMITED` indicates that a user assigned this profile can use an unlimited amount of this resource. When specified with a password parameter, `UNLIMITED` indicates that no limit has been set for the parameter.

**DEFAULT**

Specify `DEFAULT` if you want to omit a limit for this resource in this profile. A user assigned this profile is subject to the limit for this resource specified in the `DEFAULT` profile. The `DEFAULT` profile initially defines unlimited resources. You can change those limits with the `ALTER PROFILE` statement.
Any user who is not explicitly assigned a profile is subject to the limits defined in the DEFAULT profile. Also, if the profile that is explicitly assigned to a user omits limits for some resources or specifies DEFAULT for some limits, then the user is subject to the limits on those resources defined by the DEFAULT profile.

resource_parameters

SECTIONS_PER_USER Specify the number of concurrent sessions to which you want to limit the user.

CPU_PER_SESSION Specify the CPU time limit for a session, expressed in hundredths of seconds.

CPU_PER_CALL Specify the CPU time limit for a call (a parse, execute, or fetch), expressed in hundredths of seconds.

CONNECT_TIME Specify the total elapsed time limit for a session, expressed in minutes.

IDLE_TIME Specify the permitted periods of continuous inactive time during a session, expressed in minutes. Long-running queries and other operations are not subject to this limit.

LOGICAL_READS_PER_SESSION Specify the permitted number of data blocks read in a session, including blocks read from memory and disk.

LOGICAL_READS_PER_CALL Specify the permitted number of data blocks read for a call to process a SQL statement (a parse, execute, or fetch).

PRIVATE_SGA Specify the amount of private space a session can allocate in the shared pool of the system global area (SGA). Refer to size_clause on page 8-47 for information on that clause.

---

Note: This limit applies only if you are using shared server architecture. The private space for a session in the SGA includes private SQL and PL/SQL areas, but not shared SQL and PL/SQL areas.

---

COMPOSITE_LIMIT Specify the total resource cost for a session, expressed in service units. Oracle Database calculates the total service units as a weighted sum of CPU_PER_SESSION, CONNECT_TIME, LOGICAL_READS_PER_SESSION, and PRIVATE_SGA.

See Also:
- ALTER RESOURCE COST on page 11-55 for information on how to specify the weight for each session resource
- "Setting Profile Resource Limits: Example" on page 15-82

password_parameters

Use the following clauses to set password parameters. Parameters that set lengths of time—that is, all the password parameters except FAILED_LOGIN_ATTEMPTS and PASSWORD_REUSE_MAX—are interpreted in number of days. For testing purposes you can specify minutes (n/1440) or even seconds (n/86400) for these parameters. You can also use a decimal value for this purpose (for example .0833 for approximately one
hour). The minimum value is 1 second. The maximum value is 24855 days. For FAILED_LOGIN_ATTEMPTS and PASSWORD_REUSE_MAX, you must specify an integer.

**FAILED_LOGIN_ATTEMPTS** Specify the number of consecutive failed attempts to log in to the user account before the account is locked. If you omit this clause, then the default is 10 times.

**PASSWORD_LIFE_TIME** Specify the number of days the same password can be used for authentication. If you also set a value for PASSWORD_GRACE_TIME, then the password expires if it is not changed within the grace period, and further connections are rejected. If you omit this clause, then the default is 180 days.

**PASSWORD_REUSE_TIME** and **PASSWORD_REUSE_MAX** These two parameters must be set in conjunction with each other. PASSWORD_REUSE_TIME specifies the number of days before which a password cannot be reused. PASSWORD_REUSE_MAX specifies the number of password changes required before the current password can be reused. For these parameter to have any effect, you must specify a value for both of them.

- If you specify a value for both of these parameters, then the user cannot reuse a password until the password has been changed the number of times specified for PASSWORD_REUSE_MAX during the number of days specified for PASSWORD_REUSE_TIME.

  For example, if you specify PASSWORD_REUSE_TIME to 30 and PASSWORD_REUSE_MAX to 10, then the user can reuse the password after 30 days if the password has already been changed 10 times.

- If you specify a value for either of these parameters and specify UNLIMITED for the other, then the user can never reuse a password.

- If you specify DEFAULT for either parameter, then Oracle Database uses the value defined in the DEFAULT profile. By default, all parameters are set to UNLIMITED in the DEFAULT profile. If you have not changed the default setting of UNLIMITED in the DEFAULT profile, then the database treats the value for that parameter as UNLIMITED.

- If you set both of these parameters to UNLIMITED, then the database ignores both of them. This is the default if you omit both parameters.

**PASSWORD_LOCK_TIME** Specify the number of days an account will be locked after the specified number of consecutive failed login attempts. If you omit this clause, then the default is 1 day.

**PASSWORD_GRACE_TIME** Specify the number of days after the grace period begins during which a warning is issued and login is allowed. If you omit this clause, then the default is 7 days.

**PASSWORD_VERIFY_FUNCTION** The PASSWORD_VERIFY_FUNCTION clause lets a PL/SQL password complexity verification script be passed as an argument to the CREATE PROFILE statement. Oracle Database provides a default script, but you can create your own routine or use third-party software instead.

- For function, specify the name of the password complexity verification routine. The function must exist in the SYS schema and you must have EXECUTE privilege on the function.

See Also: Oracle Database Security Guide for information on setting PASSWORD_LIFE_TIME to a low value.
### Examples

#### Creating a Profile: Example

The following statement creates the profile `new_profile`:

```sql
CREATE PROFILE new_profile
  LIMIT PASSWORD_REUSE_MAX 10
  PASSWORD_REUSE_TIME 30;
```

#### Setting Profile Resource Limits: Example

The following statement creates the profile `app_user`:

```sql
CREATE PROFILE app_user LIMIT
  SESSIONS_PER_USER UNLIMITED
  CPU_PER_SESSION UNLIMITED
  CPU_PER_CALL 3000
  CONNECT_TIME 45
  LOGICAL_READS_PER_SESSION DEFAULT
  LOGICAL_READS_PER_CALL 1000
  PRIVATE_SGA 15K
  COMPOSITE_LIMIT 5000000;
```

If you assign the `app_user` profile to a user, then the user is subject to the following limits in subsequent sessions:

- The user can have any number of concurrent sessions.
- In a single session, the user can consume an unlimited amount of CPU time.
- A single call made by the user cannot consume more than 30 seconds of CPU time.
- A single session cannot last for more than 45 minutes.
- In a single session, the number of data blocks read from memory and disk is subject to the limit specified in the `DEFAULT` profile.
- A single call made by the user cannot read more than 1000 data blocks from memory and disk.
- A single session cannot allocate more than 15 kilobytes of memory in the SGA.

### See Also:

- "Setting Profile Password Limits: Example" on page 15-83
In a single session, the total resource cost cannot exceed 5 million service units. The formula for calculating the total resource cost is specified by the `ALTER RESOURCE COST` statement.

Since the `app_user` profile omits a limit for `IDLE_TIME` and for password limits, the user is subject to the limits on these resources specified in the `DEFAULT` profile.

**Setting Profile Password Limits: Example**  The following statement creates the `app_user2` profile with password limits values set:

```
CREATE PROFILE app_user2 LIMIT
  FAILED_LOGIN_ATTEMPTS 5
  PASSWORD_LIFE_TIME 60
  PASSWORD_REUSE_TIME 60
  PASSWORD_REUSE_MAX 5
  PASSWORD_VERIFY_FUNCTION verify_function
  PASSWORD_LOCK_TIME 1/24
  PASSWORD_GRACE_TIME 10;
```

This example uses the default Oracle Database password verification function, `verify_function`. Refer to *Oracle Database Security Guide* for information on using this verification function provided or designing your own verification function.
CREATE RESTORE POINT

Purpose

Use the CREATE RESTORE POINT statement to create a **restore point**, which is a name associated with a timestamp or an SCN of the database. A restore point can be used to flash back a table or the database to the time specified by the restore point without the need to determine the SCN or timestamp. Restore points are also useful in various RMAN operations, including backups and database duplication. You can use RMAN to create restore points in the process of implementing an archival backup.

**See Also:**
- *Oracle Database Backup and Recovery User’s Guide* for more information on creating and using restore points and guaranteed restore points, for information on database duplication, and for information on archival backups
- **FLASHBACK DATABASE** on page 18-26, **FLASHBACK TABLE** on page 18-29, and **DROP RESTORE POINT** on page 17-72 for information on using and dropping restore points

**Prerequisites**

To create a normal restore point, you must have the **SELECT ANY DICTIONARY**, **FLASHBACK ANY TABLE**, **SYSDBA**, **SYSBACKUP**, or **SYSDG** system privilege. To create a guaranteed restore point, you must have the **SYSDBA**, **SYSBACKUP**, or **SYSDG** system privilege.

To view or use a restore point, you must have the **SELECT ANY DICTIONARY**, **FLASHBACK ANY TABLE**, **SYSDBA**, **SYSBACKUP**, or **SYSDG** system privilege or the **SELECT_CATALOG_ROLE** role.

You can create a restore point on a primary or standby database. The database can be open, or mounted but not open. If the database is mounted, then it must have been shut down consistently before being mounted unless it is a physical standby database.

You must have created a fast recovery area before creating a guaranteed restore point. You need not enable flashback database before you create the restore point. The database must be in **ARCHIVELOG** mode if you are creating a guaranteed restore point.

**Syntax**

```sql
CREATE RESTORE POINT restore_point AS OF TIMESTAMP expr
```

The **PRESERVE** or **GUARANTEE** and **FLASHBACK DATABASE** keywords must be specified in any of the following ways when creating a guaranteed restore point:

- **PRESERVE**
- **GUARANTEE**
- **FLASHBACK DATABASE**

- **PRESERVE**
- **GUARANTEE**
- **FLASHBACK DATABASE**

**Notes:**

- The **AS** keyword is implied when creating a guaranteed restore point.
- The **OF** keyword is implied when creating a normal restore point.
- The **TIMESTAMP** and **SCN** keywords are implied when creating a guaranteed restore point.

**Examples:**

- To create a guaranteed restore point:
  ```sql
  CREATE RESTORE POINT rp AS OF TIMESTAMP sysctime;
  ```

- To create a normal restore point:
  ```sql
  CREATE RESTORE POINT rp AS OF SCN 1234567890;
  ```

- To create a guaranteed restore point with flashback database enabled:
  ```sql
  CREATE RESTORE POINT rp AS OF TIMESTAMP sysctime WITH FLASHBACK DATABASE;
  ```

- To create a guaranteed restore point with flashback database disabled:
  ```sql
  CREATE RESTORE POINT rp AS OF SCN 1234567890 NO FLASHBACK DATABASE;
  ```
Semantics

**restore_point**
Specify the name of the restore point. The name is a character value of up to 128 characters.

The database can retain at least 2048 normal restore points. Normal restore points are retained in the database for at least the number of days specified for the `CONTROL_FILE_RECORD_KEEP_TIME` initialization parameter. The default value of that parameter is 7 days. Guaranteed restore points are retained in the database until explicitly dropped by the user.

If you specify neither `PRESERVE` nor `GUARANTEE FLASHBACK DATABASE`, then the resulting restore point enables you to flash the database back to a restore point within the time period determined by the `DB_FLASHBACK_RETENTION_TARGET` initialization parameter. The database automatically manages such restore points. When the maximum number of restore points is reached, according to the rules described in `restore_point` above, the database automatically drops the oldest restore point.

Under some circumstances the restore points will be retained in the RMAN recovery catalog for use in restoring long-term backups. You can explicitly drop a restore point using the `DROP RESTORE POINT` statement.

**AS OF Clause**
Use this clause to create a restore point at a specified datetime or SCN in the past. If you specify `TIMESTAMP`, then `expr` must be a valid datetime expression resolving to a time in the past. If you specify `SCN`, then `expr` must be a valid SCN in the database in the past. In either case, `expr` must refer to a datetime or SCN in the current incarnation of the database.

**PRESERVE**
Specify `PRESERVE` to indicate that the restore point must be explicitly deleted. Such restore points are useful for preserving a flashback database.

**GUARANTEE FLASHBACK DATABASE**
A guaranteed restore point enables you to flash the database back deterministically to the restore point regardless of the `DB_FLASHBACK_RETENTION_TARGET` initialization parameter setting. The guaranteed ability to flash back depends on sufficient space being available in the fast recovery area.

Guaranteed restore points guarantee only that the database will maintain enough flashback logs to flashback the database to the guaranteed restore point. It does not guarantee that the database will have enough undo to flashback any table to the same restore point.

Guaranteed restore points are always preserved. They must be dropped explicitly by the user using the `DROP RESTORE POINT` statement. They do not age out. Guaranteed restore points can use considerable space in the fast recovery area. Therefore, Oracle recommends that you create guaranteed restore points only after careful consideration.

**Examples**

**Creating and Using a Restore Point: Example**  The following example creates a normal restore point, updates a table, and then flashes back the altered table to the restore point. The example assumes the user `hr` has the appropriate system privileges to use each of the statements.
CREATE RESTORE POINT good_data;

SELECT salary FROM employees WHERE employee_id = 108;

   SALARY
         ----------
           12000

UPDATE employees SET salary = salary*10
       WHERE employee_id = 108;

SELECT salary FROM employees
       WHERE employee_id = 108;

   SALARY
         ----------
           120000

COMMIT;

FLASHBACK TABLE employees TO RESTORE POINT good_data;

SELECT salary FROM employees
       WHERE employee_id = 108;

   SALARY
         ----------
           12000
CREATE ROLE

Purpose

Use the CREATE ROLE statement to create a role, which is a set of privileges that can be granted to users or to other roles. You can use roles to administer database privileges. You can add privileges to a role and then grant the role to a user. The user can then enable the role and exercise the privileges granted by the role.

A role contains all privileges granted to the role and all privileges of other roles granted to it. A new role is initially empty. You add privileges to a role with the GRANT statement.

If you create a role that is NOT IDENTIFIED or is IDENTIFIED EXTERNALLY or BY password, then Oracle Database grants you the role with ADMIN OPTION. However, if you create a role IDENTIFIED GLOBALLY, then the database does not grant you the role. A global role cannot be granted to a user or role directly. Global roles can be granted only through enterprise roles.

See Also:

- GRANT on page 18-35 for information on granting roles
- ALTER USER on page 13-6 for information on enabling roles
- ALTER ROLE on page 11-58 and DROP ROLE on page 17-73 for information on modifying or removing a role from the database
- SET ROLE on page 19-81 for information on enabling and disabling roles for the current session
- Oracle Database Security Guide for general information about roles
- Oracle Database Enterprise User Security Administrator’s Guide for details on enterprise roles

Prerequisites

You must have the CREATE ROLE system privilege.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root. To specify CONTAINER = CURRENT, the current container must be a pluggable database (PDB).
Syntax

```
create_role ::= 
```

Semantics

**role**

Specify the name of the role to be created. Oracle recommends that the role contain at least one single-byte character regardless of whether the database character set also contains multibyte characters. The maximum length of the role name is 30 bytes. The maximum number of user-defined roles that can be enabled for a single user at one time is 148.

In a non-CDB, a role name cannot begin with `C##` or `c##`.

In a CDB, the requirements for a role name are as follows:

- In Oracle Database 12c Release 1 (12.1.0.1), the name of a **common role** must begin with `C##` or `c##` and the name of a **local role** must not begin with `C##` or `c##`.
- Starting with Oracle Database 12c Release 1 (12.1.0.2):
  - The name of a **common role** must begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. By default, the prefix is `C##`.
  - The name of a **local role** must not begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. Regardless of the value of `COMMON_USER_PREFIX`, the name of a local role can never begin with `C##` or `c##`.

**Note:** If the value of `COMMON_USER_PREFIX` is an empty string, then there are no requirements for common or local role names with one exception: the name of a local role can never begin with `C##` or `c##`. Oracle recommends against using an empty string value because it might result in conflicts between the names of local and common roles when a PDB is plugged into a different CDB, or when opening a PDB that was closed when a common user was created.

Some roles are defined by SQL scripts provided on your distribution media.
See Also:  GRANT on page 18-35 for a list of these predefined roles and SET ROLE on page 19-81 for information on enabling and disabling roles for a user

NOT IDENTIFIED Clause
Specify NOT IDENTIFIED to indicate that this role is authorized by the database and that no password is required to enable the role.

IDENTIFIED Clause
Use the IDENTIFIED clause to indicate that a user must be authorized by the specified method before the role is enabled with the SET ROLE statement.

BY password  The BY password clause lets you create a local role and indicates that the user must specify the password to the database when enabling the role. The password can contain only single-byte characters from your database character set regardless of whether this character set also contains multibyte characters.

USING package  The USING package clause lets you create a secure application role, which is a role that can be enabled only by applications using an authorized package. If you do not specify schema, then the database assumes the package is in your own schema.

See Also:  Oracle Database Security Guide for information on creating a secure application role

EXTERNALLY  Specify EXTERNALLY to create an external role. An external user must be authorized by an external service, such as an operating system or third-party service, before enabling the role.

Depending on the operating system, the user may have to specify a password to the operating system before the role is enabled.

GLOBALLY  Specify GLOBALLY to create a global role. A global user must be authorized to use the role by the enterprise directory service before the role is enabled at login.

If you omit both the NOT IDENTIFIED clause and the IDENTIFIED clause, then the role defaults to NOT IDENTIFIED.

CONTAINER Clause
The CONTAINER clause applies when you are connected to a CDB. However, it is not necessary to specify the CONTAINER clause because its default values are the only allowed values.

- To create a common role, you must be connected to the root. You can optionally specify CONTAINER = ALL, which is the default when you are connected to the root.
- To create a local role, you must be connected to a PDB. You can optionally specify CONTAINER = CURRENT, which is the default when you are connected to a PDB.

Examples

Creating a Role: Example  The following statement creates the role dw_manager:

```
CREATE ROLE dw_manager;
```
Users who are subsequently granted the `dw_manager` role will inherit all of the privileges that have been granted to this role.

You can add a layer of security to roles by specifying a password, as in the following example:

```sql
CREATE ROLE dw_manager
    IDENTIFIED BY warehouse;
```

Users who are subsequently granted the `dw_manager` role must specify the password `warehouse` to enable the role with the `SET ROLE` statement.

The following statement creates global role `warehouse_user`:

```sql
CREATE ROLE warehouse_user IDENTIFIED GLOBALLY;
```

The following statement creates the same role as an external role:

```sql
CREATE ROLE warehouse_user IDENTIFIED EXTERNALLY;
```

The following statement creates local role `role1` in the current PDB. The current container must be a PDB when you issue this statement:

```sql
CREATE ROLE role1 CONTAINER = CURRENT;
```

The following statement creates common role `c##role1`. The current container must be the root when you issue this statement:

```sql
CREATE ROLE c##role1 CONTAINER = ALL;
```
CREATE ROLLBACK SEGMENT

**Purpose**

Use the `CREATE ROLLBACK SEGMENT` statement to create a **rollback segment**, which is an object that Oracle Database uses to store data necessary to reverse, or undo, changes made by transactions.

The information in this section assumes that your database is not running in automatic undo mode (the `UNDO_MANAGEMENT` initialization parameter is set to `MANUAL` or not set at all). If your database is running in automatic undo mode (the `UNDO_MANAGEMENT` initialization parameter is set to `AUTO`, which is the default), then rollback segments are not permitted. However, errors generated in rollback segment operations are suppressed.

Further, if your database has a locally managed `SYSTEM` tablespace, then you cannot create rollback segments in any dictionary-managed tablespace. Instead, you must either use the automatic undo management feature or create locally managed tablespaces to hold the rollback segments.

**Note:** A tablespace can have multiple rollback segments. Generally, multiple rollback segments improve performance.

- The tablespace must be online for you to add a rollback segment to it.
- When you create a rollback segment, it is initially offline. To make it available for transactions by your Oracle Database instance, bring it online using the `ALTER ROLLBACK SEGMENT` statement. To bring it online automatically whenever you start up the database, add the segment name to the value of the `ROLLBACK_SEGMENT` initialization parameter.

To use objects in a tablespace other than the `SYSTEM` tablespace:

- If you are using rollback segments for undo, then at least one rollback segment (other than the `SYSTEM` rollback segment) must be online.
- If you are running the database in automatic undo mode, then at least one `UNDO` tablespace must be online.

---

**Note:** Oracle strongly recommends that you run your database in automatic undo management mode instead of using rollback segments. Do not use rollback segments unless you must do so for compatibility with earlier versions of Oracle Database. Refer to *Oracle Database Administrator’s Guide* for information on automatic undo management.

---

**Note:** A tablespace can have multiple rollback segments. Generally, multiple rollback segments improve performance.

- The tablespace must be online for you to add a rollback segment to it.
- When you create a rollback segment, it is initially offline. To make it available for transactions by your Oracle Database instance, bring it online using the `ALTER ROLLBACK SEGMENT` statement. To bring it online automatically whenever you start up the database, add the segment name to the value of the `ROLLBACK_SEGMENT` initialization parameter.

To use objects in a tablespace other than the `SYSTEM` tablespace:

- If you are using rollback segments for undo, then at least one rollback segment (other than the `SYSTEM` rollback segment) must be online.
- If you are running the database in automatic undo mode, then at least one `UNDO` tablespace must be online.
CREATE ROLLBACK SEGMENT

See Also:

- ALTER ROLLBACK SEGMENT on page 11-60 for information on altering a rollback segment
- DROP ROLLBACK SEGMENT on page 17-74 for information on removing a rollback segment
- Oracle Database Reference for information on the UNDO_MANAGEMENT parameter
- Oracle Database Administrator’s Guide for information on automatic undo mode

Prerequisites

To create a rollback segment, you must have the CREATE ROLLBACK SEGMENT system privilege.

Syntax

```
create_rollback_segment ::= 
CREATE PUBLIC ROLLBACK SEGMENT rollback_segment 
```  

(\textit{storage clause} on page 8-48)

Semantics

PUBLIC

Specify \texttt{PUBLIC} to indicate that the rollback segment is public and is available to any instance. If you omit this clause, then the rollback segment is private and is available only to the instance naming it in its initialization parameter \texttt{ROLLBACK_SEGMENTS}.

\textit{rollback_segment}

Specify the name of the rollback segment to be created.

TABLESPACE

Use the \texttt{TABLESPACE} clause to identify the tablespace in which the rollback segment is created. If you omit this clause, then the database creates the rollback segment in the \texttt{SYSTEM} tablespace.
**Note:** Oracle Database must access rollback segments frequently. Therefore, Oracle strongly recommends that you do not create rollback segments in the `SYSTEM` tablespace, either explicitly or implicitly by omitting this clause. In addition, to avoid high contention for the tablespace containing the rollback segment, it should not contain other objects such as tables and indexes, and it should require minimal extent allocation and deallocation.

To achieve these goals, create rollback segments in locally managed tablespaces with autoallocation disabled—in tablespaces created with the `EXTENT MANAGEMENT LOCAL` clause with the `UNIFORM` setting. The `AUTOALLOCATE` setting is not supported.

---

**See Also:** [CREATE TABLESPACE](page:16-102)

**storage_clause**

The `storage_clause` lets you specify storage characteristics for the rollback segment.

- The `OPTIMAL` parameter of the `storage_clause` is of particular interest, because it applies only to rollback segments.
- You cannot specify the `PCTINCREASE` parameter of the `storage_clause` with `CREATE ROLLBACK SEGMENT`.

**See Also:** [storage_clause](page:8-48)

---

**Examples**

**Creating a Rollback Segment: Example** The following statement creates a rollback segment with default storage values in an appropriately configured tablespace:

```sql
CREATE TABLESPACE rbs_ts
  DATAFILE 'rbs01.dbf' SIZE 10M
  EXTENT MANAGEMENT LOCAL UNIFORM SIZE 100K;
/* This example and the next will fail if your database is in automatic undo mode. */
CREATE ROLLBACK SEGMENT rbs_one
  TABLESPACE rbs_ts;
```

The preceding statement is equivalent to the following:

```sql
CREATE ROLLBACK SEGMENT rbs_one
  TABLESPACE rbs_ts
  STORAGE
  ( INITIAL 10K );
```
CREATE SCHEMA

Purpose

Use the CREATE SCHEMA statement to create multiple tables and views and perform multiple grants in your own schema in a single transaction.

To execute a CREATE SCHEMA statement, Oracle Database executes each included statement. If all statements execute successfully, then the database commits the transaction. If any statement results in an error, then the database rolls back all the statements.

Note: This statement does not actually create a schema. Oracle Database automatically creates a schema when you create a user (see CREATE USER on page 17-7). This statement lets you populate your schema with tables and views and grant privileges on those objects without having to issue multiple SQL statements in multiple transactions.

Prerequisites

The CREATE SCHEMA statement can include CREATE TABLE, CREATE VIEW, and GRANT statements. To issue a CREATE SCHEMA statement, you must have the privileges necessary to issue the included statements.

Syntax

create_schema ::=  

create_schema

CREATE SCHEMA AUTHORIZATION schema create_table_statement create_view_statement grant_statement ;

Semantics

schema

Specify the name of the schema. The schema name must be the same as your Oracle Database username.

create_table_statement

Specify a CREATE TABLE statement to be issued as part of this CREATE_SCHEMA statement. Do not end this statement with a semicolon (or other terminator character).

See Also: CREATE TABLE on page 16-6

create_view_statement

Specify a CREATE VIEW statement to be issued as part of this CREATE_SCHEMA statement. Do not end this statement with a semicolon (or other terminator character).

See Also: CREATE VIEW on page 17-15
grant_statement

Specify a GRANT statement to be issued as part of this CREATE SCHEMA statement. Do not end this statement with a semicolon (or other terminator character). You can use this clause to grant object privileges on objects you own to other users. You can also grant system privileges to other users if you were granted those privileges WITH ADMIN OPTION.

See Also: GRANT on page 18-35

The CREATE SCHEMA statement supports the syntax of these statements only as defined by standard SQL, rather than the complete syntax supported by Oracle Database.

The order in which you list the CREATE TABLE, CREATE VIEW, and GRANT statements is unimportant. The statements within a CREATE SCHEMA statement can reference existing objects or objects you create in other statements within the same CREATE SCHEMA statement.

Restriction on Granting Privileges to a Schema  The syntax of the parallel_clause is allowed for a CREATE TABLE statement in CREATE SCHEMA, but parallelism is not used when creating the objects.

See Also: The parallel_clause on page 16-81 in the CREATE TABLE documentation

Examples

Creating a Schema: Example  The following statement creates a schema named oe for the sample order entry user oe, creates the table new_product, creates the view new_product_view, and grants the SELECT object privilege on new_product_view to the sample human resources user hr.

CREATE SCHEMA AUTHORIZATION oe
CREATE TABLE new_product
  (color VARCHAR2(10) PRIMARY KEY, quantity NUMBER)
CREATE VIEW new_product_view
  AS SELECT color, quantity FROM new_product WHERE color = 'RED'
GRANT select ON new_product_view TO hr;
CREATE SEQUENCE

Purpose

Use the CREATE SEQUENCE statement to create a sequence, which is a database object from which multiple users may generate unique integers. You can use sequences to automatically generate primary key values.

When a sequence number is generated, the sequence is incremented, independent of the transaction committing or rolling back. If two users concurrently increment the same sequence, then the sequence numbers each user acquires may have gaps, because sequence numbers are being generated by the other user. One user can never acquire the sequence number generated by another user. After a sequence value is generated by one user, that user can continue to access that value regardless of whether the sequence is incremented by another user.

Sequence numbers are generated independently of tables, so the same sequence can be used for one or for multiple tables. It is possible that individual sequence numbers will appear to be skipped, because they were generated and used in a transaction that ultimately rolled back. Additionally, a single user may not realize that other users are drawing from the same sequence.

After a sequence is created, you can access its values in SQL statements with the CURRVAL pseudocolumn, which returns the current value of the sequence, or the NEXTVAL pseudocolumn, which increments the sequence and returns the new value.

Note on Using Sequences with Deferred Segments If you attempt to insert a sequence value into a table that uses deferred segment creation, the first value that the sequence returns will be skipped.

See Also:
- Chapter 3, "Pseudocolumns" for more information on using the CURRVAL and NEXTVAL pseudocolumns
- "How to Use Sequence Values" on page 3-4 for information on using sequences
- ALTER SEQUENCE on page 11-63 or DROP SEQUENCE on page 18-2 for information on modifying or dropping a sequence

Prerequisites

To create a sequence in your own schema, you must have the CREATE SEQUENCE system privilege.

To create a sequence in another user's schema, you must have the CREATE ANY SEQUENCE system privilege.
Syntax

create_sequence::=

Semantics

**schema**
Specify the schema to contain the sequence. If you omit *schema*, then Oracle Database creates the sequence in your own schema.

**sequence**
Specify the name of the sequence to be created. The name must satisfy the requirements listed in "Database Object Naming Rules" on page 2-119.

If you specify none of the following clauses, then you create an ascending sequence that starts with 1 and increases by 1 with no upper limit. Specifying only `INCREMENT BY -1` creates a descending sequence that starts with -1 and decreases with no lower limit.

- To create a sequence that increments without bound, for ascending sequences, omit the `MAXVALUE` parameter or specify `NOMAXVALUE`. For descending sequences, omit the `MINVALUE` parameter or specify the `NOMINVALUE`.

- To create a sequence that stops at a predefined limit, for an ascending sequence, specify a value for the `MAXVALUE` parameter. For a descending sequence, specify a value for the `MINVALUE` parameter. Also specify `NOCYCLE`. Any attempt to generate a sequence number once the sequence has reached its limit results in an error.
To create a sequence that restarts after reaching a predefined limit, specify values for both the MAXVALUE and MINVALUE parameters. Also specify CYCLE.

INCREMENT BY Specify the interval between sequence numbers. This integer value can be any positive or negative integer, but it cannot be 0. This value can have 28 or fewer digits for an ascending sequence and 27 or fewer digits for a descending sequence. The absolute of this value must be less than the difference of MAXVALUE and MINVALUE. If this value is negative, then the sequence descends. If the value is positive, then the sequence ascends. If you omit this clause, then the interval defaults to 1.

START WITH Specify the first sequence number to be generated. Use this clause to start an ascending sequence at a value greater than its minimum or to start a descending sequence at a value less than its maximum. For ascending sequences, the default value is the minimum value of the sequence. For descending sequences, the default value is the maximum value of the sequence. This integer value can have 28 or fewer digits for positive values and 27 or fewer digits for negative values.

MAXVALUE Specify the maximum value the sequence can generate. This integer value can have 28 or fewer digits for positive values and 27 or fewer digits for negative values. MAXVALUE must be equal to or greater than START WITH and must be greater than MINVALUE.

NOMAXVALUE Specify NOMAXVALUE to indicate a maximum value of $10^{28}-1$ for an ascending sequence or -1 for a descending sequence. This is the default.

MINVALUE Specify the minimum value of the sequence. This integer value can have 28 or fewer digits for positive values and 27 or fewer digits for negative values. MINVALUE must be less than or equal to START WITH and must be less than MAXVALUE.

NOMINVALUENOMINVALUE Specify NOMINVALUENOMINVALUE to indicate a minimum value of 1 for an ascending sequence or -(10^{27} -1) for a descending sequence. This is the default.

CYCLE Specify CYCLE to indicate that the sequence continues to generate values after reaching either its maximum or minimum value. After an ascending sequence reaches its maximum value, it generates its minimum value. After a descending sequence reaches its minimum, it generates its maximum value.

NOCYCLE Specify NOCYCLE to indicate that the sequence cannot generate more values after reaching its maximum or minimum value. This is the default.

CACHE Specify how many values of the sequence the database preallocates and keeps in memory for faster access. This integer value can have 28 or fewer digits. The minimum value for this parameter is 2. For sequences that cycle, this value must be less than the number of values in the cycle. You cannot cache more values than will fit in a given cycle of sequence numbers. Therefore, the maximum value allowed for CACHE must be less than the value determined by the following formula:

\[(\text{CEIL} (\text{MAXVALUE} - \text{MINVALUE})) / \text{ABS} (\text{INCREMENT})\]
If a system failure occurs, then all cached sequence values that have not been used in committed DML statements are lost. The potential number of lost values is equal to the value of the **CACHE** parameter.

**Note:** Oracle recommends using the **CACHE** setting to enhance performance if you are using sequences in an Oracle Real Application Clusters environment.

**NOCACHE** Specify **NOCACHE** to indicate that values of the sequence are not preallocated. If you omit both **CACHE** and **NOCACHE**, then the database caches 20 sequence numbers by default.

**ORDER** Specify **ORDER** to guarantee that sequence numbers are generated in order of request. This clause is useful if you are using the sequence numbers as timestamps. Guaranteeing order is usually not important for sequences used to generate primary keys.

**ORDER** is necessary only to guarantee ordered generation if you are using Oracle Real Application Clusters. If you are using exclusive mode, then sequence numbers are always generated in order.

**NOORDER** Specify **NOORDER** if you do not want to guarantee sequence numbers are generated in order of request. This is the default.

**KEEP** Specify **KEEP** if you want **NEXTVAL** to retain its original value during replay for Application Continuity. This behavior will occur only if the user running the application is the owner of the schema containing the sequence. This clause is useful for providing bind variable consistency at replay after recoverable errors. Refer to *Oracle Database Development Guide* for more information on Application Continuity.

**NOKEEP** Specify **NOKEEP** if you do not want **NEXTVAL** to retain its original value during replay for Application Continuity. This is the default.

**SESSION** Specify **SESSION** to create a session sequence, which is a special type of sequence that is specifically designed to be used with global temporary tables that have session visibility. Unlike the existing regular sequences (referred to as "global" sequences for the sake of comparison), a session sequence returns a unique range of sequence numbers only within a session, but not across sessions. Another difference is that session sequences are not persistent. If a session goes away, so does the state of the session sequences that were accessed during the session.

Session sequences must be created by a read-write database but can be accessed on any read-write or read-only databases (either a regular database temporarily open read-only or a standby database).

The **CACHE**, **NOCACHE**, **ORDER**, or **NOORDER** clauses are ignored when specified with the **SESSION** clause.
CREATE SEQUENCE

**GLOBAL** Specify **GLOBAL** to create a global, or regular, sequence. This is the default.

**Examples**

**Creating a Sequence: Example** The following statement creates the sequence `customers_seq` in the sample schema `oe`. This sequence could be used to provide customer ID numbers when rows are added to the `customers` table.

```sql
CREATE SEQUENCE customers_seq
START WITH 1000
INCREMENT BY 1
NOCACHE
NOCYCLE;
```

The first reference to `customers_seq.nextval` returns 1000. The second returns 1001. Each subsequent reference will return a value 1 greater than the previous reference.

**See Also:** *Oracle Data Guard Concepts and Administration* for more information on session sequences.
CREATE SPFILE

Purpose

Use the `CREATE SPFILE` statement to create a server parameter file either from a traditional plain-text initialization parameter file or from the current system-wide settings. Server parameter files are binary files that exist only on the server and are called from client locations to start up the database.

Server parameter files let you make persistent changes to individual parameters. When you use a server parameter file, you can specify in an `ALTER SYSTEM SET parameter` statement that the new parameter value should be persistent. This means that the new value applies not only in the current instance, but also to any instances that are started up subsequently. Traditional plain-text parameter files do not let you make persistent changes to parameter values.

Server parameter files are located on the server, so they allow for automatic database tuning by Oracle Database and for backup by Recovery Manager (RMAN).

To use a server parameter file when starting up the database, you must create it using the `CREATE SPFILE` statement.

All instances in an Oracle Real Application Clusters environment must use the same server parameter file. However, when otherwise permitted, individual instances can have different settings of the same parameter within this one file. Instance-specific parameter definitions are specified as `SID.parameter = value`, where `SID` is the instance identifier.

The method of starting up the database with a server parameter file depends on whether you create a default or nondefault server parameter file. Refer to “Creating a Server Parameter File: Examples” on page 15-103 for examples of how to use server parameter files.

Note on Creating Server Parameter Files in a CDB  When you create a server parameter file in a multitenant container database (CDB), the current container can be the root or a PDB.

- If the current container is the root, then the values that you set for initialization parameters in the root are used as default values for all other containers.
- Starting with Oracle Database 12c Release 1 (12.1.0.2), you can issue the `CREATE SPFILE` statement when the current container is a PDB. In this case, the database stores the PDB’s initialization parameter values internally, rather than in a file. Therefore, you cannot specify an `spfile_name`. The values that you set for initialization parameters in the PDB are persistent and override any values set for those parameters in the root.

You can subsequently use the `ALTER SYSTEM` statement to modify initialization parameter values for the root or a PDB.
CREATE SPFILE

Prerequisites

You must have the SYSBACKUP, SYSDBA, SYSDG, or SYSOPER system privilege to execute this statement. You can execute this statement before or after instance startup. However, if you have already started an instance using spfile_name, you cannot specify the same spfile_name in this statement.

To create a server parameter file in a CDB, the current container must be the root and you must have the commonly granted SYSBACKUP, SYSDBA, SYSDG, or SYSOPER system privilege.

Syntax

create_spfile::=

\[ CREATE SPFILE \{ spfile_name \} | FROM PFILE \{ pfile_name \} | MEMORY \]

Semantics

spfile_name

This clause lets you specify a name for the server parameter file you are creating.

If you specify spfile_name, then Oracle Database creates a nondefault server parameter file.

- For spfile_name, you can specify a traditional filename, a file in an Oracle ACFS file system, or an Oracle Storage Management (Oracle ASM) filename.
- If you specify a traditional filename or a file in an Oracle ACFS file system, then spfile_name can include a path prefix. If you do not specify such a path prefix, then the database adds the path prefix for the default storage location, which is platform dependent.
- If you specify the Oracle ASM filename syntax, then the database creates the spfile in an Oracle ASM disk group.
- When using a nondefault server parameter file, you must specify the server parameter filename in the STARTUP command when you start up the database. An exception to this rule is as follows:
  - If you specify both the spfile_name and the FROM PFILE clause, the instance from which the command is issued is running, and the database is defined as a resource in Oracle Clusterware, then this statement automatically updates the
SPFILE in the database resource. In this case, you can start up the database without referring to the server parameter file by name. If the instance from which the command is issued is not running, then the SPFILE in the database resource must be updated manually using `srvctl modify database -d dbname -spfile spfile_path`.

If you omit `spfile_name`, then Oracle Database uses the platform-specific default server parameter filename. If such a file already exists on the server, then this statement overwrites it. When using a default server parameter file, you can start up the database without referring to the file by name.

**Restriction on `spfile_name`** You cannot specify `spfile_name` when creating a server parameter file while connected to a PDB.

### See Also:

- "Creating a Server Parameter File: Examples" on page 15-103 for information on starting up the database with default and nondefault server parameter files
- `file_specification` on page 8-29 for the syntax of traditional and Oracle ASM filenames and `ALTER DISKGROUP` on page 10-78 for information on modifying the characteristics of an Oracle ASM file
- The appropriate operating-system-specific documentation for default parameter file names

### `pfile_name`

Specify the traditional plain-text initialization parameter file from which you want to create a server parameter file. The traditional parameter file must reside on the server.

- If you specify `pfile_name` and the traditional parameter file does not reside in the default directory for parameter files on your operating system, then you must specify the full path.
- If you do not specify `pfile_name`, then Oracle Database looks in the default directory for parameter files on your operating system for the default parameter filename and uses that file. If that file does not exist in the expected directory, then the database returns an error.

#### Note:

In an Oracle Real Application Clusters environment, you must first combine all instance parameter files into one file before specifying that filename in this statement to create a server parameter file. For information on accomplishing this step, see *Oracle Real Application Clusters Administration and Deployment Guide*.

### MEMORY

Specify `MEMORY` to create an spfile using the current system-wide parameter settings. In an Oracle RAC environment, the created file will contain the parameter settings from each instance.

### Examples

**Creating a Server Parameter File: Examples** The following example creates a default server parameter file from a traditional plain-text parameter file named `t_init1.ora`:
CREATE SPFILE
FROM PFILE = '$ORACLE_HOME/work/t_init1.ora';

**Note:** Typically you will need to specify the full path and filename for parameter files on your operating system.

When you create a default server parameter file, you subsequently start up the database using that server parameter file by using the SQL*Plus command `STARTUP` without the `PFILE` parameter, as follows:

```
STARTUP
```

The following example creates a nondefault server parameter file `s_params.ora` from a traditional plain-text parameter file named `t_init1.ora`:

```
CREATE SPFILE = 's_params.ora'
    FROM PFILE = '$ORACLE_HOME/work/t_init1.ora';
```

When you create a nondefault server parameter file, you subsequently start up the database by first creating a traditional parameter file containing the following single line:

```
spfile = 's_params.ora'
```

The name of this parameter file must comply with the naming conventions of your operating system. You then use the single-line parameter file in the `STARTUP` command. The following example shows how to start up the database, assuming that the single-line parameter file is named `new_param.ora`:

```
STARTUP PFILE=new_param.ora
```
This chapter contains the following SQL statements:

- CREATE SYNONYM
- CREATE TABLE
- CREATE TABLESPACE
- CREATE TRIGGER
CREATE SYNONYM

Purpose

Use the CREATE SYNONYM statement to create a synonym, which is an alternative name for a table, view, sequence, operator, procedure, stored function, package, materialized view, Java class schema object, user-defined object type, or another synonym. A synonym places a dependency on its target object and becomes invalid if the target object is changed or dropped.

Synonyms provide both data independence and location transparency. Synonyms permit applications to function without modification regardless of which user owns the table or view and regardless of which database holds the table or view. However, synonyms are not a substitute for privileges on database objects. Appropriate privileges must be granted to a user before the user can use the synonym.

You can refer to synonyms in the following DML statements: SELECT, INSERT, UPDATE, DELETE, FLASHBACK TABLE, EXPLAIN PLAN, and LOCK TABLE.

You can refer to synonyms in the following DDL statements: AUDIT, NOAUDIT, GRANT, REVOKE, and COMMENT.

See Also: Oracle Database Concepts for general information on synonyms

Prerequisites

To create a private synonym in your own schema, you must have the CREATE SYNONYM system privilege.

To create a private synonym in another user’s schema, you must have the CREATE ANY SYNONYM system privilege.

To create a PUBLIC synonym, you must have the CREATE PUBLIC SYNONYM system privilege.

Syntax

```
create_synonym ::= CREATE SYNONYM
```

```
create_synonym ::= CREATE SYNONYM
               | CREATE SYNONYM OR REPLACE
               | CREATE SYNONYM OR REPLACE EDITIONABLE
               | CREATE SYNONYM OR REPLACE NONEDITIONABLE
               | CREATE SYNONYM PUBLIC
```

Semantics

**OR REPLACE**

Specify OR REPLACE to re-create the synonym if it already exists. Use this clause to change the definition of an existing synonym without first dropping it.
Restriction on Replacing a Synonym  You cannot use the OR REPLACE clause for a type synonym that has any dependent tables or dependent valid user-defined object types.

[ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the synonym is an editioned or noneditioned object if editioning is enabled for the schema object type SYNONYM in schema. For private synonyms, the default is EDITIONABLE. For public synonyms, the default is NONEDITIONABLE. For information about editioned and noneditioned objects, see Oracle Database Development Guide.

PUBLIC

Specify PUBLIC to create a public synonym. Public synonyms are accessible to all users. However each user must have appropriate privileges on the underlying object in order to use the synonym.

When resolving references to an object, Oracle Database uses a public synonym only if the object is not prefaced by a schema and is not followed by a database link.

If you omit this clause, then the synonym is private. A private synonym name must be unique in its schema. A private synonym is accessible to users other than the owner only if those users have appropriate privileges on the underlying database object and specify the schema along with the synonym name.

Notes on Public Synonyms  The following notes apply to public synonyms:

- If you create a public synonym and it subsequently has dependent tables or dependent valid user-defined object types, then you cannot create another database object of the same name as the synonym in the same schema as the dependent objects.
- Take care not to create a public synonym with the same name as an existing schema. If you do so, then all PL/SQL units that use that name will be invalidated.

schema

Specify the schema to contain the synonym. If you omit schema, then Oracle Database creates the synonym in your own schema. You cannot specify a schema for the synonym if you have specified PUBLIC.

synonym

Specify the name of the synonym to be created. The name must satisfy the requirements listed in "Database Object Naming Rules" on page 2-119.

Note:   Synonyms longer than 30 bytes can be created and dropped. However, unless they represent a Java name they will not work in any other SQL command. Names longer than 30 bytes are transformed into an obscure shorter string for storage in the data dictionary.

See Also:  "CREATE SYNONYM: Examples" on page 16-4 and "Oracle Database Resolution of Synonyms: Example" on page 16-5

FOR Clause

Specify the object for which the synonym is created. The schema object for which you are creating the synonym can be of the following types:
CREATE SYNONYM

- Table or object table
- View or object view
- Sequence
- Stored procedure, function, or package
- Materialized view
- Java class schema object
- User-defined object type
- Synonym

The schema object need not currently exist and you need not have privileges to access the object.

**Restriction on the FOR Clause**  The schema object cannot be contained in a package.

**schema**  Specify the schema in which the object resides. If you do not qualify object with **schema**, then the database assumes that the schema object is in your own schema.

If you are creating a synonym for a procedure or function on a remote database, then you must specify **schema** in this CREATE statement. Alternatively, you can create a local public synonym on the database where the object resides. However, the database link must then be included in all subsequent calls to the procedure or function.

**dblink**  You can specify a complete or partial database link to create a synonym for a schema object on a remote database where the object is located. If you specify **dblink** and omit **schema**, then the synonym refers to an object in the schema specified by the database link. Oracle recommends that you specify the schema containing the object in the remote database.

If you omit **dblink**, then Oracle Database assumes the object is located on the local database.

**Restriction on Database Links**  You cannot specify **dblink** for a Java class synonym.

**See Also:**
- "References to Objects in Remote Databases" on page 2-126 for more information on referring to database links
- **CREATE DATABASE LINK** on page 14-44 for more information on creating database links

**Examples**

**CREATE SYNONYM: Examples**  To define the synonym **offices** for the table **locations** in the schema **hr**, issue the following statement:

```
CREATE SYNONYM offices
    FOR hr.locations;
```

To create a PUBLIC synonym for the **employees** table in the schema **hr** on the remote database, you could issue the following statement:

```
CREATE PUBLIC SYNONYM emp_table
    FOR hr.employees@remote.us.example.com;
```
A synonym may have the same name as the underlying object, provided the underlying object is contained in another schema.

**Oracle Database Resolution of Synonyms: Example**  Oracle Database attempts to resolve references to objects at the schema level before resolving them at the PUBLIC synonym level. For example, the schemas oe and sh both contain tables named customers. In the next example, user SYSTEM creates a PUBLIC synonym named customers for oe.customers:

CREATE PUBLIC SYNONYM customers FOR oe.customers;

If the user sh then issues the following statement, then the database returns the count of rows from sh.customers:

SELECT COUNT(*) FROM customers;

To retrieve the count of rows from oe.customers, the user sh must preface customers with the schema name. (The user sh must have select permission on oe.customers as well.)

SELECT COUNT(*) FROM oe.customers;

If the user hr’s schema does not contain an object named customers, and if hr has select permission on oe.customers, then hr can access the customers table in oe’s schema by using the public synonym customers:

SELECT COUNT(*) FROM customers;
CREATE TABLE

Purpose

Use the CREATE TABLE statement to create one of the following types of tables:

- A relational table, which is the basic structure to hold user data.
- An object table, which is a table that uses an object type for a column definition. An object table is explicitly defined to hold object instances of a particular type.

You can also create an object type and then use it in a column when creating a relational table.

Tables are created with no data unless a subquery is specified. You can add rows to a table with the INSERT statement. After creating a table, you can define additional columns, partitions, and integrity constraints with the ADD clause of the ALTER TABLE statement. You can change the definition of an existing column or partition with the MODIFY clause of the ALTER TABLE statement.

See Also:

- Oracle Database Administrator's Guide and CREATE TYPE on page 17-3 for more information about creating objects
- ALTER TABLE on page 12-2 and DROP TABLE on page 18-5 for information on modifying and dropping tables

Prerequisites

To create a relational table in your own schema, you must have the CREATE TABLE system privilege. To create a table in another user's schema, you must have the CREATE ANY TABLE system privilege. Also, the owner of the schema to contain the table must have either space quota on the tablespace to contain the table or the UNLIMITED TABLESPACE system privilege.

In addition to these table privileges, to create an object table or a relational table with an object type column, the owner of the table must have the EXECUTE object privilege in order to access all types referenced by the table, or you must have the EXECUTE ANY TYPE system privilege. These privileges must be granted explicitly and not acquired through a role.

Additionally, if the table owner intends to grant access to the table to other users, then the owner must have been granted the EXECUTE object privilege on the referenced types WITH GRANT OPTION, or have the EXECUTE ANY TYPE system privilege WITH ADMIN OPTION. Without these privileges, the table owner has insufficient privileges to grant access to the table to other users.

To enable a unique or primary key constraint, you must have the privileges necessary to create an index on the table. You need these privileges because Oracle Database creates an index on the columns of the unique or primary key in the schema containing the table.

To specify an edition in the evaluation_edition_clause or the unusableEditions_clause, you must have the USE privilege on the edition.

To specify the zonemap_clause, you must have the permissions necessary to create a zone map. Refer to the "Prerequisites" section on page 15-42 in the documentation on CREATE MATERIALIZED ZONEMAP.
To create an **external table**, you must have the required read and write operating system privileges on the appropriate operating system directories. You must have the `READ` object privilege on the database directory object corresponding to the operating system directory in which the external data resides. You must also have the `WRITE` object privilege on the database directory in which the files will reside if you specify a log file or bad file in the `opaque_format_spec` or if you unload data into an external table from a database table by specifying the `AS subquery` clause.

To create an **XMLType table** in a different database schema from your own, you must have not only privilege `CREATE ANY TABLE` but also privilege `CREATE ANY INDEX`. This is because a unique index is created on column `OBJECT_ID` when you create the table. Column `OBJECT_ID` stores a system-generated object identifier.

**See Also:**
- `CREATE INDEX` on page 14-73
- Oracle Database Administrator’s Guide for more information about the privileges required to create tables using types

**Syntax**

```sql
create_table ::= 
```

(see page 16-7, `object_table ::=` on page 16-8, `XMLType_table ::=` on page 16-8)

```sql
relational_table ::= 
```

(see page 16-7, `physical_properties ::=` on page 16-11, `table_properties ::=` on page 16-15)

---

**Note:** Each of the clauses following the table name is optional for any given relational table. However, for every table you must at least specify either column names and data types using the `relational_properties` clause or an `AS subquery` clause using the `table_properties` clause.
Note: You can specify these clauses in any order with the following exception: You must specify at least one column_definition or virtual_column_definition before you specify period_definition. You can specify period_definition only once.
CREATE TABLE

Semantics

relational_table

GLOBAL TEMPORARY
Specify GLOBAL TEMPORARY to indicate that the table is temporary and that its definition is visible to all sessions with appropriate privileges. The data in a temporary table is visible only to the session that inserts the data into the table.

When you first create a temporary table, its table metadata is stored in the data dictionary, but no space is allocated for table data. Space is allocated for the table segment at the time of the first DML operation on the table. The temporary table definition persists in the same way as the definitions of regular tables, but the table segment and any data the table contains are either session-specific or transaction-specific data. You specify whether the table segment and data are session- or transaction-specific with the ON COMMIT keywords.

You can perform DDL operations (such as ALTER TABLE, DROP TABLE, CREATE INDEX) on a temporary table only when no session is bound to it. A session becomes bound to a temporary table by performing an INSERT operation on the table. A session becomes unbound to the temporary table by issuing a TRUNCATE statement or at session termination, or, for a transaction-specific temporary table, by issuing a COMMIT or ROLLBACK statement.

See Also: Oracle Database Concepts for information on temporary tables and "Creating a Table: Temporary Table Example" on page 16-91

Restrictions on Temporary Tables
Temporary tables are subject to the following restrictions:

- Temporary tables cannot be partitioned, clustered, or index organized.
- You cannot specify any foreign key constraints on temporary tables.
- Temporary tables cannot contain columns of nested table.
- You cannot specify the following clauses of the LOB_storage_clause: TABLESPACE, storage_clause, or logging_clause.
- Parallel UPDATE, DELETE and MERGE are not supported for temporary tables.
- The only part of the segment_attributes_clause you can specify for a temporary table is TABLESPACE, which allows you to specify a single temporary table.
- Distributed transactions are not supported for temporary tables.
- A temporary table cannot contain INVISIBLE columns.

schema
Specify the schema to contain the table. If you omit schema, then the database creates the table in your own schema.

table
Specify the name of the table or object table to be created. The name must satisfy the requirements listed in "Database Object Naming Rules" on page 2-119.

See Also: "Creating Tables: General Examples" on page 16-89
**relational_properties**

The relational properties describe the components of a relational table.

**column_definition**

The *column_definition* clause lets you define the characteristics of the column.

**Specifying column_definition with AS subquery**

If you specify the *AS subquery* clause, and each column returned by *subquery* has a column name or is an expression with a specified column alias, then you can omit the *column_definition* clause. In this case, the names of the columns of table are the same as the names of the columns returned by *subquery*. The exception is creating an index-organized table, for which you must specify the *column_definition* clause, because you must designate a primary key column.Regardless of the table type, if you specify the *column_definition* clause and the *AS subquery* clause, then you must omit *datatype* from the *column_definition* clause.

**column**

Specify the name of a column of the table.

If you also specify *AS subquery*, then you can omit *column* and *datatype* unless you are creating an index-organized table. If you specify *AS subquery* when creating an index-organized table, then you must specify *column*, and you must omit *datatype*.

The absolute maximum number of columns in a table is 1000. When you create an object table or a relational table with columns of object, nested table, varray, or REF type, Oracle Database maps the columns of the user-defined types to relational columns, in effect creating hidden columns that count toward the 1000-column limit.

**datatype**

Specify the data type of a column.

In general, you must specify *datatype*. However, the following exceptions apply:

- You must omit *datatype* if you specify the *AS subquery* clause.
- You can also omit *datatype* if the statement designates the column as part of a foreign key in a referential integrity constraint. Oracle Database automatically assigns to the column the data type of the corresponding column of the referenced key of the referential integrity constraint.

**Restrictions on Table Column Data Types**

The following restrictions apply to the data types of table columns:

- Do not create a table with *LONG* columns. Use LOB columns (*CLOB, NCLOB, BLOB*) instead. *LONG* columns are supported only for backward compatibility.
- You can specify a column of type *ROWID*, but Oracle Database does not guarantee that the values in such columns are valid rowids.

**See Also:** "Data Types" on page 2-1 for information on *LONG* columns and on Oracle-supplied data types

**SORT**

The *SORT* keyword is valid only if you are creating this table as part of a hash cluster and only for columns that are also cluster columns.
This clause instructs the database to sort the rows of the cluster on this column after applying the hash function when performing a DML operation. Doing so may improve response time during subsequent operations on the clustered data.

See Also: "CLUSTER Clause" on page 16-56 for information on creating a cluster table

VISIBLE | INVISIBLE
Use this clause to specify whether column is VISIBLE or INVISIBLE. The default is VISIBLE.

INVISIBLE columns are user-specified hidden columns. To display or assign a value to an INVISIBLE column, you must specify its name explicitly. For example:

- The SELECT * syntax will not display an INVISIBLE column. However, if you include an INVISIBLE column in the select list of a SELECT statement, then the column will be displayed.
- You cannot implicitly specify a value for an INVISIBLE column in the VALUES clause of an INSERT statement. You must specify the INVISIBLE column in the column list.
- You must explicitly specify an INVISIBLE column in Oracle Call Interface (OCI) describes.
- You can configure SQL*Plus to allow INVISIBLE column information to be viewed with the DESCRIBE command. Refer to SQL*Plus User’s Guide and Reference for more information.

Notes on VISIBLE and INVISIBLE Columns
The following notes apply to VISIBLE and INVISIBLE columns:

- An INVISIBLE column can be used as a partitioning key when specified as part of CREATE TABLE.
- You can specify INVISIBLE columns in a column_expression.
- A virtual column can be an INVISIBLE column.
- PL/SQL %ROWTYPE attributes do not show INVISIBLE columns.
- The COLUMN_ID column of the ALL_.*, DBA_.*, and USER_TAB_COLUMNS data dictionary views determines the order in which a SELECT * query returns columns for a table, view, or materialized view. The value of COLUMN_ID is NULL for INVISIBLE columns. When you make an invisible column visible, it will be assigned the next highest available COLUMN_ID value. When you make a visible column invisible, its COLUMN_ID value is set to NULL and COLUMN_ID is decremented by 1 for any columns with a higher COLUMN_ID.

Restrictions on VISIBLE and INVISIBLE Columns
The following restrictions apply to VISIBLE and INVISIBLE columns:

- INVISIBLE columns are not supported in external tables, cluster tables, or temporary tables.
- You cannot make a system-generated hidden column visible.
DEFAULT

The `DEFAULT` clause lets you specify a value to be assigned to the column if a subsequent `INSERT` statement omits a value for the column. The data type of the expression must match the data type specified for the column. The column must also be large enough to hold this expression.

The `DEFAULT` expression can include any SQL function as long as the function does not return a literal argument, a column reference, or a nested function invocation.

The `DEFAULT` expression can include the sequence pseudocolumns `CURRVAL` and `NEXTVAL`, as long as the sequence exists and you have the privileges necessary to access it. Users who perform subsequent inserts that use the `DEFAULT` expression must have the `INSERT` privilege on the table and the `SELECT` privilege on the sequence. If the sequence is later dropped, then subsequent `INSERT` statements where the `DEFAULT` expression is used will result in an error. If you do not fully qualify the sequence by specifying the sequence owner, for example, `SCOTT.SEQ1`, then Oracle Database will default the sequence owner to be the user who issues the `CREATE TABLE` statement. For example, if user `MARY` creates `SCOTT.TABLE` and refers to a sequence that is not fully qualified, such as `SEQ2`, then the column will use sequence `MARY.SEQ2`. Synonyms on sequences undergo a full name resolution and are stored as the fully qualified sequence in the data dictionary; this is true for public and private synonyms. For example, if user `BETH` adds a column referring to public or private synonym `SYN1` and the synonym refers to `PETER.SEQ7`, then the column will store `PETER.SEQ7` as the default.

**Restrictions on Default Column Values**

Default column values are subject to the following restrictions:

- A `DEFAULT` expression cannot contain references to PL/SQL functions or to other columns, the pseudocolumns `LEVEL`, `PRIOR`, and `ROWNUM`, or date constants that are not fully specified.
- The expression can be of any form except a scalar subquery expression.

See Also: "About SQL Expressions" on page 5-1 for the syntax of `expr`.

**ON NULL**

If you specify the `ON NULL` clause, then Oracle Database assigns the `DEFAULT` column value when a subsequent `INSERT` statement attempts to assign a value that evaluates to `NULL`.

When you specify `ON NULL`, the `NOT NULL` constraint and `NOT DEFERRABLE` constraint state are implicitly specified. If you specify an inline constraint that conflicts with `NOT NULL` and `NOT DEFERRABLE`, then an error is raised.

**Restriction on the ON NULL Clause**

You cannot specify this clause for an object type column or a `REF` column.

See Also: "Creating a Table with a DEFAULT ON NULL Column Value: Example" on page 90
**identity_clause**

Use this clause to specify an identity column. The identity column will be assigned an increasing or decreasing integer value from a sequence generator for each subsequent INSERT statement. You can use the identity_options clause to configure the sequence generator.

**ALWAYS** If you specify ALWAYS, then Oracle Database always uses the sequence generator to assign a value to the column. If you attempt to explicitly assign a value to the column using INSERT or UPDATE, then an error will be returned. This is the default.

**BY DEFAULT** If you specify BY DEFAULT, then Oracle Database uses the sequence generator to assign a value to the column by default, but you can also explicitly assign a specified value to the column. If you specify ON NULL, then Oracle Database uses the sequence generator to assign a value to the column when a subsequent INSERT statement attempts to assign a value that evaluates to NULL.

**identity_options**

Use the identity_options clause to configure the sequence generator. The identity_options clause has the same parameters as the CREATE SEQUENCE statement. Refer to CREATE SEQUENCE on page 15-96 for a full description of these parameters and characteristics. The exception is START WITH LIMIT VALUE, which is specific to identity_options and can only be used with ALTER TABLE MODIFY. Refer to identity_options on page 12-62 for more information.

**Restrictions on Identity Columns**

Identity columns are subject to the following restrictions:

- You can specify only one identity column per table.
- If you specify identity_clause, then you must specify a numeric data type for datatype in the column_definition clause. You cannot specify a user-defined data type.
- If you specify identity_clause, then you cannot specify the DEFAULT clause in the column_definition clause.
- When you specify identity_clause, the NOT NULL constraint and NOT DEFERRABLE constraint state are implicitly specified. If you specify an inline constraint that conflicts with NOT NULL and NOT DEFERRABLE, then an error is raised.
- If an identity column is encrypted, then the encryption algorithm may be inferred. Oracle recommends that you use a strong encryption algorithm on identity columns.
- CREATE TABLE AS SELECT will not inherit the identity property on a column.

**See Also:** "Creating a Table with an Identity Column: Examples" on page 16-90

**encryption_spec**

The ENCRYPT clause lets you use the Transparent Data Encryption (TDE) feature to encrypt the column you are defining. You can encrypt columns of type CHAR, NCHAR,
CREATE TABLE

VARCHAR2, NVARCHAR2, NUMBER, DATE, LOB, and RAW. The data does not appear in its encrypted form to authorized users, such as the user who encrypts the column.

---

**Note:** Column encryption requires that a system administrator with appropriate privileges has initialized the security module, opened a keystore, and set an encryption key. Refer to Oracle Database Advanced Security Guide for general information about column encryption and to security_clauses on page 11-93 for related ALTER SYSTEM statements.

---

**USING 'encrypt_algorithm'** Use this clause to specify the name of the algorithm to be used. Valid algorithms are AES256, AES192, AES128 and 3DES168. If you omit this clause, then the database uses AES192. If you encrypt more than one column in the same table, and if you specify the USING clause for one of the columns, then you must specify the same encryption algorithm for all the encrypted columns.

**IDENTIFIED BY password** If you specify this clause, then the database derives the column key from the specified password.

**'integrity_algorithm'** Use this clause to specify the integrity algorithm to be used. Valid integrity algorithms are SHA-1 and NOMAC.

- If you specify SHA-1, then TDE uses the Secure Hash Algorithm (SHA-1) and adds a 20-byte Message Authentication Code (MAC) to each encrypted value for integrity checking. This is the default.
- If you specify NOMAC, then TDE does not add a MAC and does not perform the integrity check. This saves 20 bytes of disk space per encrypted value. Refer to Oracle Database Advanced Security Guide for more information on using NOMAC to save disk space and improve performance.

All encrypted columns in a table must use the same integrity algorithm. If you already have a table column using the SHA-1 algorithm, then you cannot use the NOMAC parameter to encrypt another column in the same table. Refer to the REKEY encryption_spec clause of ALTER TABLE on page 12-52 to learn how to change the integrity algorithm used by all encrypted columns in a table.

**SALT | NO SALT** Specify SALT to instruct the database to append a random string, called "salt," to the clear text of the column before encrypting it. This is the default. Specify NO SALT to prevent the database from appending salt to the clear text of the column before encrypting it.

The following considerations apply when specifying SALT or NO SALT for encrypted columns:

- If you want to use the column as an index key, then you must specify NO SALT. Refer to Oracle Database Advanced Security Guide for a description of "salt" in this context.
- If you specify table compression for the table, then the database does not compress the data in encrypted columns with SALT.

You cannot specify SALT or NO SALT for LOB encryption.

**Restrictions on encryption_spec:** The following restrictions apply to column encryption:
Transparent Data Encryption is not supported by the traditional import and export utilities or by transportable-tablespace-based export. Use the Data Pump import and export utilities with encrypted columns instead.

To encrypt a column in an external table, the table must use ORACLE_DATAPUMP as its access type.

You cannot encrypt a column in tables owned by SYS.

You cannot encrypt a foreign key column.

**See Also:** Oracle Database Advanced Security Guide for more information about Transparent Data Encryption

### virtual_column_definition

The `virtual_column_definition` clause lets you create a virtual column. A virtual column is not stored on disk. Rather, the database derives the values in a virtual column on demand by computing a set of expressions or functions. Virtual columns can be used in queries, DML, and DDL statements. They can be indexed, and you can collect statistics on them. Thus, they can be treated much as other columns. Exceptions and restrictions are listed below in "Notes on Virtual Columns" on page 16-38 and "Restrictions on Virtual Columns" on page 16-39.

- **column** For `column`, specify the name of the virtual column.
- **datatype** You can optionally specify the data type of the virtual column. If you omit `datatype`, then the database determines the data type of the column based on the data type of the underlying expressions. All Oracle scalar data types and XMLType are supported.
- **VISIBLE | INVISIBLE** Use this clause to specify whether virtual column is VISIBLE or INVISIBLE. The default is VISIBLE. For complete information, refer to "VISIBLE | INVISIBLE" on page 16-33.
- **GENERATED ALWAYS** The optional keywords GENERATED ALWAYS are provided for semantic clarity. They indicate that the column is not stored on disk, but is evaluated on demand.
- **column_expression** The `AS column_expression` clause determines the content of the column. Refer to "Column Expressions" on page 5-7 for more information on column_expression.
- **VIRTUAL** The optional keyword VIRTUAL is provided for semantic clarity.
- **evaluation_edition_clause** You must specify this clause if `column_expression` refers to an editioned PL/SQL function. Use this clause to specify the edition that is searched during name resolution of the editioned PL/SQL function—the evaluation edition.
  - Specify CURRENT EDITION to search the edition in which this DDL statement is executed.
  - Specifying NULL EDITION is equivalent to omitting the evaluation_edition_clause.

If you omit the evaluation_edition_clause, then editioned objects are invisible during name resolution and an error will result. If the evaluation edition is dropped, then a subsequent query on the virtual column will result in an error.
The database does not maintain dependencies on the functions referenced by a virtual column. Therefore, if a virtual column refers to a noneditioned function, and the function becomes editioned, then the following operations may raise an error:

- Querying the virtual column
- Updating a row that includes the virtual column
- Firing a trigger that accesses the virtual column

**See Also:** *Oracle Database Development Guide* for more information on specifying the evaluation edition for a virtual column

**unusable_editions_clause** This clause lets you specify that the virtual column expression is unusable for evaluating queries in one or more editions. The remaining editions form a range of editions in which it is safe for the optimizer to use the virtual column expression to evaluate queries.

For example, suppose you define a function-based index on the virtual column. The optimizer can use the function-based index to evaluate queries that contain the virtual column expression in their `WHERE` clause. If a query is compiled in an edition that is in the usable range of editions for the virtual column, then the optimizer will consider using the index to evaluate the query. If a query is compiled in an edition outside the usable range of editions for the virtual column, then the optimizer will not consider using the index.

**See Also:** *Oracle Database Concepts* for more information on optimization with function-based indexes

**UNUSABLE BEFORE Clause** This clause lets you specify that the virtual column expression is unusable for evaluating queries in the ancestors of an edition.

- If you specify `CURRENT EDITION`, then the virtual column expression is unusable in the ancestors of the edition in which this DDL statement is executed.
- If you specify `EDITION edition`, then the virtual column expression is unusable in the ancestors of the specified `edition`.

**UNUSABLE BEGINNING WITH Clause** This clause lets you specify that the virtual column expression is unusable for evaluating queries in an edition and its descendants.

- If you specify `CURRENT EDITION`, then the virtual column expression is unusable in the edition in which this DDL statement is executed and its descendants.
- If you specify `EDITION edition`, then the virtual column expression is unusable in the specified `edition` and its descendants.
- Specifying `NULL EDITION` is equivalent to omitting the `UNUSABLE BEGINNING WITH` clause.

If an edition specified in this clause is subsequently dropped, there is no effect on the virtual column.

**Notes on Virtual Columns**

- If `column_expression` refers to a column on which column-level security is implemented, then the virtual column does not inherit the security rules of the base column. In such a case, you must ensure that data in the virtual column is protected, either by duplicating a column-level security policy on the virtual column or by applying a function that implicitly masks the data. For example, it is
common for credit card numbers to be protected by a column-level security policy, while still allowing call center employees to view the last four digits of the credit card number for validation purposes. In such a case, you could define the virtual column to take a substring of the last four digits of the credit card number.

- A table index defined on a virtual column is equivalent to a function-based index on the table.

- You cannot directly update a virtual column. Thus, you cannot specify a virtual column in the SET clause of an UPDATE statement. However, you can specify a virtual column in the WHERE clause of an UPDATE statement. Likewise, you can specify a virtual column in the WHERE clause of a DELETE statement to delete rows from a table based on the derived value of the virtual column.

- A query that specifies in its FROM clause a table containing a virtual column is eligible for result caching. Refer to "RESULT_CACHE Hint" on page 2-113 for more information on result caching.

- The column_expression can refer to a PL/SQL function if the function is explicitly designated DETERMINISTIC during its creation. However, if the function is subsequently replaced, definitions dependent on the virtual column are not invalidated. In such a case, if the table contains data, queries that reference the virtual column may return incorrect results if the virtual column is used in the definition of constraints, indexes, or materialized views or for result caching. Therefore, in order to replace the deterministic PL/SQL function for a virtual column.
  - Disable and re-enable any constraints on the virtual column.
  - Rebuild any indexes on the virtual column.
  - Fully refresh materialized views accessing the virtual column.
  - Flush the result cache if cached queries have accessed the virtual column.
  - Regather statistics on the table.

- A virtual column can be an INVISIBLE column. The column_expression can contain INVISIBLE columns.

Restrictions on Virtual Columns

- You can create virtual columns only in relational heap tables. Virtual columns are not supported for index-organized, external, object, cluster, or temporary tables.

- The column_expression in the AS clause has the following restrictions:
  - It cannot refer to another virtual column by name.
  - Any columns referenced in column_expression must be defined on the same table.
  - It can refer to a deterministic user-defined function, but if it does, then you cannot use the virtual column as a partitioning key column.
  - The output of column_expression must be a scalar value.

  See Also: "Column Expressions" on page 5-7 for additional information and restrictions on column_expression

- The virtual column cannot be an Oracle supplied data type, a user-defined type, or LOB or LONG RAW.
You cannot specify a call to a PL/SQL function in the defining expression for a virtual column that you want to use as a partitioning column.

**See Also:** "Adding a Virtual Table Column: Example" on page 12-107 and Oracle Database Administrator’s Guide for examples of creating tables with virtual columns

### period_definition

Use the `period_definition` clause to create a valid time dimension for `table`. This clause implements Temporal Validity support for `table`. If you specify this clause, then one column in `table`, the start time column, contains a start date or timestamp, and another column in `table`, the end time column, contains an end date or timestamp. These two columns define a valid time dimension for `table`—that is, a period of time for which each row is considered valid. You can use Oracle Flashback Query to retrieve rows from `table` based on whether they are considered valid as of a specified time, before a specified time, or during a specified time period.

You can specify at most one valid time dimension when you create a table. You can subsequently add additional valid time dimensions to a table with the `add_period_clause` of `ALTER TABLE` on page 12-68.

### valid_time_column

Specify the name of the valid time dimension. The name must satisfy the requirements listed in "Database Object Naming Rules" on page 2-119. Oracle Database creates an INVISIBLE virtual column with this name of data type `NUMBER` in `table`.

### start_time_column and end_time_column

You can optionally specify these clauses as follows:

- Use `start_time_column` to specify the name of the start time column, which contains the start date or timestamp.
- Use `end_time_column` to specify the name of the end time column, which contains the end date or timestamp.

The names you specify for `start_time_column` and `end_time_column` must satisfy the requirements listed in "Database Object Naming Rules" on page 2-119.

If you specify these clauses, then you must define `start_time_column` and `end_time_column` in the `column_definition` clause of `CREATE TABLE`. Each column must be of a datatime data type `(DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, or TIMESTAMP WITH LOCAL TIME ZONE)` and can be VISIBLE or INVISIBLE.

If you do not specify these clauses, then Oracle Database creates a start time column named `valid_time_column_STARTED`, and an end time column named `valid_time_column_ENDED`. These columns are of data type `TIMESTAMP WITH TIME ZONE` and are INVISIBLE.

You can insert and update values in the start time column and end time column as you would any column, with the following considerations:

- If the value of the start time column is NULL, then the row is considered valid for all time values that occur before, but not including, the value of the end time column.
- If the value of the end time column is NULL, then the row is considered valid for all time values that occur on or after the value of the start time column.
- If the value of neither column is NULL, then the value of the start time column must be earlier than the value of the end time column. The row is considered valid...
for all time values that occur on or after the value of the start time column, and up to, but not including, the value of the end time column.

- If the value of both columns is NULL, then the row is considered valid for all time values.

**Restrictions on Valid Time Dimension Columns**

The following restrictions apply to valid time dimension columns:

- The valid_time_column is for internal use only. You cannot perform DDL or DML operations on it with one exception: You can drop the column by using the drop_period_clause of ALTER TABLE.

- You can drop the start time column and end time column only by using the drop_period_clause of ALTER TABLE.

- If the start time column and end time column are automatically created by Oracle Database, then they are INVISIBLE and you cannot subsequently make them VISIBLE.

**See Also:**

- *Oracle Database Development Guide* for more information on Temporal Validity
- *SELECT flashback_query_clause* on page 19-22 for more information on Oracle Flashback Query
- *ALTER TABLE add_period_clause* on page 12-68 and *drop_period_clause* on page 12-68 for information how to add and drop a valid time dimension

**Constraint Clauses**

Use these clauses to create constraints on the table columns. You must specify a PRIMARY KEY constraint for an index-organized table, and it cannot be DEFERRABLE. Refer to constraint on page 8-4 for syntax and description of these constraints as well as examples.

**inline_ref_constraint and out_of_line_ref_constraint**

These clauses let you describe a column of type REF. The only difference between these clauses is that you specify out_of_line_ref_constraint from the table level, so you must identify the REF column or attribute you are defining. Specify inline_ref_constraint as part of the definition of the REF column or attribute.

**See Also:** "REF Constraint Examples" on page 8-25

**inline_constraint**

Use the inline_constraint to define an integrity constraint as part of the column definition.

You can create UNIQUE, PRIMARY KEY, and REFERENCES constraints on scalar attributes of object type columns. You can also create NOT NULL constraints on object type columns and CHECK constraints that reference object type columns or any attribute of an object type column.

**out_of_line_constraint**

Use the out_of_line_constraint syntax to define an integrity constraint as part of the table definition.
**supplemental_logging_props**

The `supplemental_logging_props` clause lets you instruct the database to put additional data into the log stream to support log-based tools.

**supplemental_log_grp_clause**  Use this clause to create a named log group.

- The `NO LOG` clause lets you omit from the redo log one or more columns that would otherwise be included in the redo for the named log group. You must specify at least one fixed-length column without `NO LOG` in the named log group.
- If you specify `ALWAYS`, then during an update, the database includes in the redo all columns in the log group. This is called an unconditional log group (sometimes called an "always log group"), because Oracle Database supplementally logs all the columns in the log group when the associated row is modified. If you omit `ALWAYS`, then the database supplementally logs all the columns in the log group only if any column in the log group is modified. This is called a conditional log group.

You can query the appropriate `USER_`, `ALL_`, or `DBA_LOG_GROUPS` data dictionary view to determine whether any supplemental logging has already been specified.

**supplemental_id_key_clause**  Use this clause to specify that all or a combination of the primary key, unique key, and foreign key columns should be supplementally logged. Oracle Database will generate either an unconditional log group or a conditional log group. With an unconditional log group, the database supplementally logs all the columns in the log group when the associated row is modified. With a conditional log group, the database supplementally logs all the columns in the log group only if any column in the log group is modified.

- If you specify `ALL_COLUMNS`, then the database includes in the redo log all the fixed-length maximum size columns of that row. Such a redo log is a system-generated unconditional log group.
- If you specify `PRIMARY_KEY_COLUMNS`, then for all tables with a primary key, the database places into the redo log all columns of the primary key whenever an update is performed. Oracle Database evaluates which columns to supplementally log as follows:
  - First the database chooses columns of the primary key constraint, if the constraint is validated or marked `RELY` and is not marked as `DISABLED` or `INITIALLY DEFERRED`.
  - If no primary key columns exist, then the database looks for the smallest `UNIQUE` index with at least one `NOT NULL` column and uses the columns in that index.
  - If no such index exists, then the database supplementally logs all scalar columns of the table.
- If you specify `UNIQUE_COLUMNS`, then for all tables with a unique key or a bitmap index, if any of the unique key or bitmap index columns are modified, the database places into the redo log all other columns belonging to the unique key or bitmap index. Such a log group is a system-generated conditional log group.
- If you specify `FOREIGN_KEY_COLUMNS`, then for all tables with a foreign key, if any foreign key columns are modified, the database places into the redo log all other columns belonging to the foreign key. Such a redo log is a system-generated conditional log group.

If you specify this clause multiple times, then the database creates a separate log group for each specification. You can query the appropriate `USER_`, `ALL_`, or `DBA_LOG_GROUPS`
data dictionary view to determine whether any supplemental logging data has already been specified.

**ON COMMIT**
The **ON COMMIT** clause is relevant only if you are creating a temporary table. This clause specifies whether the data in the temporary table persists for the duration of a transaction or a session.

**DELETE ROWS** Specify **DELETE ROWS** for a transaction-specific temporary table. This is the default. Oracle Database will truncate the table (delete all its rows) after each commit.

**PRESERVE ROWS** Specify **PRESERVE ROWS** for a session-specific temporary table. Oracle Database will truncate the table (delete all its rows) when you terminate the session.

**physical_properties**
The physical properties relate to the treatment of extents and segments and to the storage characteristics of the table.

**deferred_segment_creation**
Use this clause to determine when the database should create the segment(s) for this table:

- **SEGMENT CREATION DEFERRED**: This clause defers creation of the table segment — as well as segments for any LOB columns of the table, any indexes created implicitly as part of table creation, and any indexes subsequently explicitly created on the table — until the first row of data is inserted into the table. At that time, the segments for the table, LOB columns and indexes, and explicitly created indexes are all materialized and inherit any storage properties specified in this CREATE TABLE statement or, in the case of explicitly created indexes, the CREATE INDEX statement. These segments are created regardless whether the initial insert operation is uncommitted or rolled back. This is the default value.

  **Caution**: When creating many tables with deferred segment creation, ensure that you allocate enough space for your database so that when the first rows are inserted, there is enough space for all the new segments.

- **SEGMENT CREATION IMMEDIATE**: The table segment is created as part of this CREATE TABLE statement.

Immediate segment creation is useful, for example, if your application depends upon the object appearing in the **DBA_**, **USER_**, and **ALL_SEGMENTS** data dictionary views, because the object will not appear in those views until the segment is created. This clause overrides the setting of the **DEFERRED_SEGMENT_CREATION** initialization parameter.

To determine whether a segment has been created for an existing table or its LOB columns or indexes, query the **SEGMENT_CREATED** column of **USER_TABLES**, **USER_INDEXES**, or **USER_LOBS**.

**Notes on Tables Without Segments** The following rules apply to a table whose segment has not yet been materialized:
If you create this table with `CREATE TABLE ... AS subquery`, then if the source table has no rows, segment creation of the new table is deferred. If the source table has rows, then segment creation of the new table is not deferred.

If you specify `ALTER TABLE ... ALLOCATE EXTENT` before the segment is materialized, then the segment is materialized and then an extent is allocated. However the `ALLOCATE EXTENT` clause in a DDL statement on any indexes of the table will return an error.

In a DDL statement on the table or its LOB columns or indexes, any specification of `DEALLOCATE UNUSED` is silently ignored.

ONLINE operations on indexes of a table or table partition without a segment will silently be disabled; that is, they will proceed `OFFLINE`.

If any of the following DDL statements are executed on a table with one or more LOB columns, then the resulting partition(s) or subpartition(s) will be materialized:
- `ALTER TABLE SPLIT [SUB]PARTITION`
- `ALTER TABLE MERGE [SUB]PARTITIONS`
- `ALTER TABLE ADD [SUB]PARTITION (hash partitions only)`
- `ALTER TABLE COALESCE [SUB]PARTITION (hash partitions only)`

### Restrictions on Deferred Segment Creation
This clause is subject to the following restrictions:

- You cannot defer segment creation for the following types of tables: index-organized tables, clustered tables, global temporary tables, session-specific temporary tables, internal tables, object tables, `XMLType` tables, AQ tables, external tables, and tables owned by `SYS`, `SYSTEM`, `PUBLIC`, `OUTLN`, or `XDB`.
- Deferred segment creation is not supported for bitmap join indexes and domain indexes.
- Deferred segment creation is not supported in dictionary-managed tablespaces.
- Deferred segment creation is not supported in the `SYSTEM` tablespace.
- Serializable transactions do not work with deferred segment creation. Trying to insert data into an empty table with no segment created causes an error.
- When a global index is marked `UNUSABLE` during a partition maintenance operation, the database does not drop the unusable index segments.

**See Also:** Oracle Database Concepts for general information on segment allocation and Oracle Database Reference for more information about the `DEFERRED_SEGMENT_CREATION` initialization parameter

### segment_attributes_clause
The `segment_attributes_clause` lets you specify physical attributes and tablespace storage for the table.

### physical_attributes_clause
The `physical_attributes_clause` lets you specify the value of the `PCTFREE`, `PCTUSED`, and `INITRANS` parameters and the storage characteristics of the table.

- For a nonpartitioned table, each parameter and storage characteristic you specify determines the actual physical attribute of the segment associated with the table.
CREATE TABLE

For partitioned tables, the value you specify for the parameter or storage characteristic is the default physical attribute of the segments associated with all partitions specified in this CREATE statement (and in subsequent ALTER TABLE ... ADD PARTITION statements), unless you explicitly override that value in the PARTITION clause of the statement that creates the partition.

If you omit this clause, then Oracle Database sets PCTFREE to 10, PCTUSED to 40, and INITRANS to 1.

See Also:
- physical_attributes_clause on page 8-44 and storage_clause on page 8-46 for a description of these clauses
- "Creating a Table: Storage Example" on page 16-89

TABLESPACE Specify the tablespace in which Oracle Database creates the table, object table, partition, LOB data segment, LOB index segment, or index-organized table overflow data segment. If you omit TABLESPACE, then the database creates that item in the default tablespace of the owner of the schema containing the table.

For a heap-organized table with one or more LOB columns, if you omit the TABLESPACE clause for LOB storage, then the database creates the LOB data and index segments in the tablespace where the table is created.

For an index-organized table with one or more LOB columns, if you omit TABLESPACE, then the LOB data and index segments are created in the tablespace in which the primary key index segment of the index-organized table is created.

For nonpartitioned tables, the value specified for TABLESPACE is the actual physical attribute of the segment associated with the table. For partitioned tables, the value specified for TABLESPACE is the default physical attribute of the segments associated with all partitions specified in the CREATE statement and on subsequent ALTER TABLE ... ADD PARTITION statements, unless you specify TABLESPACE in the PARTITION description.

See Also: CREATE TABLESPACE on page 16-102 for more information on tablespaces

logging_clause

Specify whether the creation of the table and of any indexes required because of constraints, partition, or LOB storage characteristics will be logged in the redo log file (LOGGING) or not (NOLOGGING). The logging attribute of the table is independent of that of its indexes.

This attribute also specifies whether subsequent direct loader (SQL*Loader) and direct-path INSERT operations against the table, partition, or LOB storage are logged (LOGGING) or not logged (NOLOGGING).

Refer to logging_clause on page 8-38 for a full description of this clause.

table_compression

The table_compression clause is valid only for heap-organized tables. Use this clause to instruct the database whether to compress data segments to reduce disk use. The COMPRESS clauses enable table compression. The NOCOMPRESS clause disables table compression. The default is NOCOMPRESS.
COMPRESS  Specifying only the keyword COMPRESS is equivalent to specifying ROW STORE COMPRESS BASIC and enables basic table compression.

ROW STORE COMPRESS BASIC  When you enable table compression by specifying either ROW STORE COMPRESS or ROW STORE COMPRESS BASIC, you enable basic table compression. Oracle Database attempts to compress data during direct-path INSERT operations when it is productive to do so. The original import utility (imp) does not support direct-path INSERT, and therefore cannot import data in a compressed format.

Tables with basic table compression use a PCTFREE value of 0 to maximize compression, unless you explicitly set a value for PCTFREE in the physical_attributes_clause.

In earlier releases, basic table compression was enabled using COMPRESS BASIC. This syntax is still supported for backward compatibility.

See Also: "Conventional and Direct-Path INSERT" on page 18-62 for information on direct-path INSERT operations, including restrictions

ROW STORE COMPRESS ADVANCED  When you enable table compression by specifying ROW STORE COMPRESS ADVANCED, you enable Advanced Row Compression. Oracle Database compresses data during all DML operations on the table. This form of compression is recommended for OLTP environments.

Tables with ROW STORE COMPRESS ADVANCED or NOCOMPRESS use the PCTFREE default value of 10, to maximize compress while still allowing for some future DML changes to the data, unless you override this default explicitly.

In earlier releases, Advanced Row Compression was called OLTP table compression and was enabled using COMPRESS FOR OLTP. This syntax is still supported for backward compatibility.

COLUMN STORE COMPRESS FOR { QUERY I ARCHIVE }  When you specify COLUMN STORE COMPRESS FOR QUERY or COLUMN STORE COMPRESS FOR ARCHIVE, you enable Hybrid Columnar Compression. With Hybrid Columnar Compression, data can be compressed during bulk load operations. During the load process, data is transformed into a column-oriented format and then compressed. Oracle Database uses a compression algorithm appropriate for the level you specify. In general, the higher the level, the greater the compression ratio. Hybrid Columnar Compression can result in higher compression ratios, at a greater CPU cost. Therefore, this form of compression is recommended for data that is not frequently updated.

COLUMN STORE COMPRESS FOR QUERY is useful in data warehousing environments. Valid values are LOW and HIGH, with HIGH providing a higher compression ratio. The default is HIGH.

COLUMN STORE COMPRESS FOR ARCHIVE uses higher compression ratios than COLUMN STORE COMPRESS FOR QUERY, and is useful for compressing data that will be stored for long periods of time. Valid values are LOW and HIGH, with HIGH providing the highest possible compression ratio. The default is LOW.

Specifying COLUMN STORE COMPRESS is equivalent to specifying COLUMN STORE COMPRESS FOR QUERY HIGH.

Tables with COLUMN STORE COMPRESS FOR QUERY or COLUMN STORE COMPRESS FOR ARCHIVE use a PCTFREE value of 0 to maximize compression, unless you explicitly set a value for PCTFREE in the physical_attributes_clause. For these tables, PCTFREE has no effect for blocks loaded using direct-path INSERT. PCTFREE is honored for blocks loaded
using conventional `INSERT`, and for blocks created as a result of DML operations on blocks originally loaded using direct-path `INSERT`.

**[NO] ROW LEVEL LOCKING** If you specify `ROW LEVEL LOCKING`, then Oracle Database uses row-level locking during DML operations. This improves the performance of these operations when accessing Hybrid Columnar Compressed data. If you specify `NO ROW LEVEL LOCKING`, then row-level locking is not used. The default is `NO ROW LEVEL LOCKING`.

In earlier releases, Hybrid Columnar Compression was enabled using `COMPRESS FOR QUERY` and `COMPRESS FOR ARCHIVE`. This syntax is still supported for backward compatibility.

**See Also:** *Oracle Database Concepts* for more information on Hybrid Columnar Compression, which is a feature of certain Oracle storage systems.

**Notes on Table Compression:** You can specify table compression for the following portions of a heap-organized table:

- For an entire table, in the `physical_properties` clause of `relational_table` or `object_table`
- For a range partition, in the `table_partition_description` of the `range_partitions` clause
- For a composite range partition, in the `table_partition_description` of the `range_partition_desc` clause
- For a composite list partition, in the `table_partition_description` of the `list_partition_desc` clause
- For a list partition, in the `table_partition_description` of the `list_partitions` clause
- For a system or reference partition, in the `table_partition_description` of the `reference_partition_desc` clause
- For the storage table of a nested table, in the `nested_table_col_properties` clause

**See Also:** *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_COMPRESSION` package, which helps you choose the correct compression level for an application, and *Oracle Database Administrator’s Guide* for more information about table compression, including examples.

**Restrictions on Table Compression** Table compression is subject to the following restrictions:

- Data segments of BasicFiles LOBs are not compressed. For information on compression of SecureFiles LOBs, see `LOB_compression_clause` on page 16-60.
- You cannot drop a column from a table that uses `COMPRESS BASIC`, although you can set such a column as unused. All of the operations of the `ALTER TABLE ... drop_column_clause` are valid for tables that use `ROW STORE COMPRESS ADVANCED`, `COLUMN STORE COMPRESS FOR QUERY`, and `COLUMN STORE COMPRESS FOR ARCHIVE`.
- You cannot specify any type of table compression for an index-organized table, any overflow segment or partition of an overflow segment, or any mapping table segment of an index-organized table.
You cannot specify any type of table compression for external tables or for tables that are part of a cluster.

You cannot specify any type of table compression for tables with `LONG` or `LONG RAW` columns, tables that are owned by the `SYS` schema and reside in the `SYSTEM` tablespace, or tables with `ROWDEPENDENCIES` enabled.

You cannot specify Hybrid Columnar Compression on tables that are enabled for flashback archiving.

You cannot specify Hybrid Columnar Compression on the following object-relational features: object tables, `XMLType` tables, columns with abstract data types, collections stored as tables, or OPAQUE types, including `XMLType` columns stored as objects.

When you update a row in a table compressed with Hybrid Columnar Compression, the `ROWID` of the row may change.

In tables compressed with Hybrid Columnar Compression, updates to a single row may result in locks on multiple rows. Concurrency for write transactions may therefore be affected.

If a table compressed with Hybrid Columnar Compression has a foreign key constraint, and you insert data using `INSERT` with the `APPEND` hint, then the data will be compressed to a lesser level than is typical with Hybrid Columnar Compression. To compress the data with Hybrid Columnar Compression, disable the foreign key constraint, insert the data using `INSERT` with the `APPEND` hint, and then reenable the foreign key constraint.

---

**inmemory_table_clause**

Use this clause to enable or disable the table for the In-Memory Column Store (IM column store). The IM column store is an optional, static SGA pool that stores copies of tables and partitions in a special columnar format optimized for rapid scans. The IM column store does not replace the buffer cache, but acts as a supplement so that both memory areas can store the same data in different formats. The IM column store is available starting with Oracle Database 12c Release 1 (12.1.0.2).

Specify `INMEMORY` to enable the table for the IM column store.

You can optionally use the `inmemory_parameters` clause to specify how table data is stored in the IM column store. This clause enables you to specify the data compression method and the data population priority. In an Oracle RAC environment, it also enables you to specify how the data is distributed and duplicated across Oracle RAC instances. Refer to the `inmemory_parameters` clause on page 16-49 for more information.

You can optionally use the `inmemory_column_clause` to disable specific table columns for the IM column store, and to specify the data compression method for specific columns. Refer to the `inmemory_column_clause` on page 16-50 for more information.

Specify `NO INMEMORY` to disable the table for the IM column store.

If you omit this clause, then the table is assigned the default IM column store settings for the tablespace in which it is created. Refer to the `inmemory_clause` of `CREATE TABLESPACE` on page 16-110 for more information on specifying the default IM column store settings for a tablespace.
Restrictions on the In-Memory Column Store The following restrictions apply to the In-Memory Column Store:

- You cannot specify the `INMEMORY` clause for tables that are owned by the `SYS` schema and reside in the `SYSTEM` or `SYSAUX` tablespace.
- The IM column store does not support `LONG` or `LONG RAW` columns, out-of-line columns (LOBs, varrays, nested table columns), virtual columns, or extended data type columns. If you enable a table for the IM column store and it contains any of these types of columns, then the columns will not be populated in the IM column store.

See Also:
- Oracle Database Concepts for an overview of the IM column store
- Oracle Database Administrator’s Guide to learn how to use the IM column store

`inmemory_parameters`
Use the `inmemory_memcompress`, `inmemory_priority`, `inmemory_distribute`, and `inmemory_duplicate` clauses to specify how table data is stored in the IM column store.

`inmemory_memcompress` Use this clause to specify the compression method for table data stored in the IM column store. This data is called in-memory data. To instruct the database to not compress in-memory data, specify `NO MEMCOMPRESS`. To instruct the database to compress in-memory data, specify `MEMCOMPRESS FOR` followed by one of the following methods:

- DML - This method is optimized for DML operations and performs little or no data compression.
- QUERY - Specifying `QUERY` is equivalent to specifying `QUERY LOW`.
- QUERY LOW - This method compresses in-memory data the least (except for DML) and results in the best query performance. This is the default.
- QUERY HIGH - This method compresses in-memory data more than `QUERY LOW`, but less than `CAPACITY LOW`.
- CAPACITY - Specifying `CAPACITY` is equivalent to specifying `CAPACITY LOW`.
- CAPACITY LOW - This method compresses in-memory data more than `QUERY HIGH`, but less than `CAPACITY HIGH`, and results in excellent query performance.
- CAPACITY HIGH - This method compresses in-memory data the most and results in good query performance.

`inmemory_priority` Use the `PRIORITY` clause to specify the data population priority for table data in the IM column store. This clause controls the priority of population, but not the speed of population.
CREA TE TABLE

- Specify **NONE** for **on-demand population**. In this case, the database populates table data in the IM column store when the table it is accessed through a full table scan. If the table is never accessed, or if it is accessed only through an index scan or fetch by rowid, then population never occurs. This is the default.

- Specify one of the following priority levels for **priority-based population**: **LOW, MEDIUM, HIGH, or CRITICAL**. In this case, the database automatically populates table data in the IM column store using an internally managed priority queue; a full scan is not a necessary condition for population. The database queues population of the table data based on the specified priority level. For example, a table with the setting **INMEMORY PRIORITY CRITICAL** takes precedence over a table with the setting **INMEMORY PRIORITY HIGH**, which in turn takes precedence over a table with the setting **INMEMORY PRIORITY LOW**, and so on. If the IM column store has insufficient space, then the database does not populate additional table data until space is available.

**inmemory_distribute** The **DISTRIBUTE** clause is applicable only if you are using Oracle Real Application Clusters (Oracle RAC). It controls how table data in the IM column store is distributed across Oracle RAC instances. You can specify the following options:

- **AUTO** - Oracle Database controls how data is distributed across Oracle RAC instances. Large tables are distributed across Oracle RAC instances depending on their access patterns. Smaller tables may be distributed between instances. If you specify only the **DISTRIBUTE** keyword or omit the **inmemory_distribute** clause entirely, then **AUTO** is the default.

- **BY ROWID RANGE** - Data in certain ranges of rowids is distributed to different Oracle RAC instances.

- **BY PARTITION** - Data in partitions is distributed to different Oracle RAC instances.

- **BY SUBPARTITION** - Data in subpartitions is distributed to different Oracle RAC instances.

**inmemory_duplicate** The **DUPLICATE** clause is applicable only if you are using Oracle Real Application Clusters (Oracle RAC) on an engineered system. It controls how table data in the IM column store is duplicated across Oracle RAC instances. You can specify the following options:

- **DUPLICATE** - Data is duplicated on one Oracle RAC instance, resulting in the data existing on a total of two Oracle RAC instances.

- **DUPLICATE ALL** - Data is duplicated across all Oracle RAC instances. If you specify **DUPLICATE ALL**, then the database uses the **DISTRIBUTE AUTO** setting, regardless of whether or how you specify the **inmemory_distribute** clause.

- **NO DUPLICATE** - Data is not duplicated across Oracle RAC instances. This is the default.

**inmemory_column_clause** Use this clause to disable specific table columns for the IM column store, and to specify the data compression method for specific columns. In order to specify this clause, the table must be enabled for the IM column store.

- Specify **INMEMORY** to enable the specified table columns for the IM column store. You can optionally use the **inmemory_memcompress** clause to specify the data compression method for specific columns. See **inmemory_memcompress** on page 16-49. If you omit the **inmemory_memcompress** clause, then the table column
uses the data compression method for the table. You cannot specify the PRIORITY, DISTRIBUTE, or DUPLICATE settings for a specific table column. These settings are the same for all table columns as they are for the table.

- Specify NO INMEMORY to disable the specified table columns for the IM column store.

If you omit the inmemory_column_clause, then all table columns use the IM column store settings for the table.

**Restriction on inmemory_column_clause** You cannot specify this clause for a LONG or LONG RAW column, an out-of-line column (LOB, varray, nested table column), a virtual column, or an extended data type column.

**inmemory_clause**

Use this clause to enable or disable a table partition for the IM column store. In order to specify this clause, the table must be enabled for the IM column store. If you omit this clause, then the table partition uses the IM column store settings for the table.

The inmemory_parameters clause has the same semantics for table partitions as for tables. Refer to the inmemory_parameters clause on page 16-49 for full information.

**ilm_clause**

Use this clause to add an Automatic Data Optimization policy to table.

This clause has the same semantics in CREATE TABLE and ALTER TABLE, with the following additional restriction: You can specify only the ADD POLICY clause for CREATE TABLE. Refer to the ilm_clause on page 12-45 for the full semantics of this clause.

**Restrictions on Automatic Data Optimization** Automatic Data Optimization is subject to the following restrictions:

- Automatic Data Optimization is not supported for tables that contain object types, index-organized tables, clustered tables, or materialized views.
- Automatic Data Optimization is not supported in multitenant container databases (CDBs).
- Row-level policies are not supported for tables that support Temporal Validity or tables that are enabled for row archiving for In-Database Archiving.

**ilm_policy_clause**

Use this clause to describe the Automatic Data Optimization policy.

This clause has the same semantics in CREATE TABLE and ALTER TABLE. Refer to ilm_policy_clause on page 12-46 for the full semantics of this clause.

**RECOVERABLE | UNRECOVERABLE**

These keywords are deprecated and have been replaced with LOGGING and NOLOGGING, respectively. Although RECOVERABLE and UNRECOVERABLE are supported for backward compatibility, Oracle strongly recommends that you use the LOGGING and NOLOGGING keywords.

**Restrictions on [UN]RECOVERABLE** This clause is subject to the following restrictions:
CREATE TABLE

- You cannot specify RECOVERABLE for partitioned tables or LOB storage characteristics.
- You cannot specify UNRECOVERABLE for partitioned or index-organized tables.
- You can specify UNRECOVERABLE only with AS subquery.

**ORGANIZATION**
The ORGANIZATION clause lets you specify the order in which the data rows of the table are stored.

**HEAP**  HEAP indicates that the data rows of table are stored in no particular order. This is the default.

**INDEX**  INDEX indicates that table is created as an index-organized table. In an index-organized table, the data rows are held in an index defined on the primary key for the table.

**EXTERNAL**  EXTERNAL indicates that table is a read-only table located outside the database.

See Also:  "External Table Example" on page 16-94

**index_org_table_clause**
Use the index_org_table_clause to create an index-organized table. Oracle Database maintains the table rows, both primary key column values and nonkey column values, in an index built on the primary key. Index-organized tables are therefore best suited for primary key-based access and manipulation. An index-organized table is an alternative to:

- A noncluster table indexed on the primary key by using the CREATE INDEX statement
- A cluster table stored in an indexed cluster that has been created using the CREATE CLUSTER statement that maps the primary key for the table to the cluster key

You must specify a primary key for an index-organized table, because the primary key uniquely identifies a row. The primary key cannot be DEFERRABLE. Use the primary key instead of the rowid for directly accessing index-organized rows.

If an index-organized table is partitioned and contains LOB columns, then you should specify the index_org_table_clause first, then the LOB_storage_clause, and then the appropriate table_partitioning_clauses.

You cannot use the TO_LOB function to convert a LONG column to a LOB column in the subquery of a CREATE TABLE ... AS SELECT statement if you are creating an index-organized table. Instead, create the index-organized table without the LONG column, and then use the TO_LOB function in an INSERT ... AS SELECT statement.

The ROWID pseudocolumn of an index-organized table returns logical rowids instead of physical rowids. A column that you create with the data type ROWID cannot store the logical rowids of the IOT. The only data you can store in a column of type ROWID is rowids from heap-organized tables. If you want to store the logical rowids of an IOT, then create a column of type UROWID instead. A column of type UROWID can store both physical and logical rowids.

See Also:  "Index-Organized Table Example" on page 16-93
**Restrictions on Index-Organized Tables**  Index-organized tables are subject to the following restrictions:

- You cannot define a virtual column for an index-organized table.
- You cannot specify the `composite_range_partitions`, `composite_list_partitions`, or `composite_hash_partitions` clauses for an index-organized table.
- If the index-organized table is a nested table or varray, then you cannot specify `table_partitioning_clauses`.

**PCTTHRESHOLD integer**  Specify the percentage of space reserved in the index block for an index-organized table row. PCTTHRESHOLD must be large enough to hold the primary key. All trailing columns of a row, starting with the column that causes the specified threshold to be exceeded, are stored in the overflow segment. PCTTHRESHOLD must be a value from 1 to 50. If you do not specify PCTTHRESHOLD, then the default is 50.

**Restriction on PCTTHRESHOLD**  You cannot specify PCTTHRESHOLD for individual partitions of an index-organized table.

**mapping_table_clauses**  Specify MAPPING TABLE to instruct the database to create a mapping of local to physical ROWIDs and store them in a heap-organized table. This mapping is needed in order to create a bitmap index on the index-organized table. If the index-organized table is partitioned, then the mapping table is also partitioned and its partitions have the same name and physical attributes as the base table partitions.

Oracle Database creates the mapping table or mapping table partition in the same tablespace as its parent index-organized table or partition. You cannot query, perform DML operations on, or modify the storage characteristics of the mapping table or its partitions.

**prefix_compression**  The prefix_compression clauses let you enable or disable prefix compression for index-organized tables.

- Specify COMPRESS to enable prefix compression, also known as key compression, for an index-organized table, which eliminates repeated occurrence of primary key column values in index-organized tables. Use integer to specify the prefix length, which is the number of prefix columns to compress.

  The valid range of prefix length values is from 1 to the number of primary key columns minus 1. The default prefix length is the number of primary key columns minus 1.

- Specify NOCOMPRESS to disable prefix compression in index-organized tables. This is the default.

**Restriction on Prefix Compression of Index-organized Tables**  At the partition level, you can specify COMPRESS, but you cannot specify the prefix length with integer.

**index_org_overflow_clause**  The index_org_overflow_clause lets you instruct the database that index-organized table data rows exceeding the specified threshold are placed in the data segment specified in this clause.

- When you create an index-organized table, Oracle Database evaluates the maximum size of each column to estimate the largest possible row. If an overflow segment is needed but you have not specified OVERFLOW, then the database raises an error and does not execute the CREATE TABLE statement. This checking function
guarantees that subsequent DML operations on the index-organized table will not fail because an overflow segment is lacking.

- All physical attributes and storage characteristics you specify in this clause after the `OVERFLOW` keyword apply only to the overflow segment of the table. Physical attributes and storage characteristics for the index-organized table itself, default values for all its partitions, and values for individual partitions must be specified before this keyword.

- If the index-organized table contains one or more LOB columns, then the LOBs will be stored out-of-line unless you specify `OVERFLOW`, even if they would otherwise be small enough be to stored inline.

- If `table` is partitioned, then the database equipartitions the overflow data segments with the primary key index segments.

**INCLUDING column_name** Specify a column at which to divide an index-organized table row into index and overflow portions. The primary key columns are always stored in the index. `column_name` can be either the last primary key column or any non primary key column. All non primary key columns that follow `column_name` are stored in the overflow data segment.

If an attempt to divide a row at `column_name` causes the size of the index portion of the row to exceed the specified or default `PCTTHRESHOLD` value, then the database breaks up the row based on the `PCTTHRESHOLD` value.

**Restriction on the INCLUDING Clause** You cannot specify this clause for individual partitions of an index-organized table.

**external_table_clause**

Use the `external_table_clause` to create an external table, which is a read-only table whose metadata is stored in the database but whose data in stored outside the database. Among other capabilities, external tables let you query data without first loading it into the database.

See Also: Oracle Database Data Warehousing Guide, Oracle Database Administrator’s Guide, and Oracle Database Utilities for information on the uses for external tables.

Because external tables have no data in the database, you define them with a small subset of the clauses normally available when creating tables.

- Within the `relational_properties` clause, you can specify only `column` and `datatype`.

- Within the `physical_properties` clause, you can specify only the organization of the table (ORGANIZATION EXTERNAL `external_table_clause`).

- Within the `table_properties` clause, you can specify only the `parallel_clause`. The `parallel_clause` lets you parallelize subsequent queries on the external data and subsequent operations that populate the external table.

- You can populate the external table at create time by using the `AS subquery` clause.

No other clauses are permitted in the same `CREATE TABLE` statement.
Restrictions on External Tables  
External tables are subject to the following restrictions:

- An external table cannot be a temporary table.
- You cannot specify constraints on an external table.
- You cannot create an index on an external table.
- An external table cannot contain virtual columns or INVISIBLE columns.
- An external table cannot have object type, varray, or LONG columns. However, you can populate LOB columns of an external table with varray or LONG data from an internal database table.

**TYPE**  
`TYPE access_driver_type` indicates the access driver of the external table. The access driver is the API that interprets the external data for the database. Oracle Database provides two access drivers: `ORACLE_LOADER` and `ORACLE_DATAPUMP`. If you do not specify `TYPE`, then the database uses `ORACLE_LOADER` as the default access driver. You must specify the `ORACLE_DATAPUMP` access driver if you specify the `AS subquery` clause to unload data from one Oracle Database and reload it into the same or a different Oracle Database.

**See Also:** Oracle Database Utilities for information about the `ORACLE_LOADER` and `ORACLE_DATAPUMP` access drivers

**DEFAULT DIRECTORY**  
`DEFAULT DIRECTORY` lets you specify a default directory object corresponding to a directory on the file system where the external data sources may reside. The default directory can also be used by the access driver to store auxiliary files such as error logs.

**ACCESS PARAMETERS**  
The optional `ACCESS PARAMETERS` clause lets you assign values to the parameters of the specific access driver for this external table.

- The `opaque_format_spec` specifies all access parameters for the `ORACLE_LOADER` and `ORACLE_DATAPUMP` access drivers. See Oracle Database Utilities for descriptions of these parameters.
  
  Field names specified in the `opaque_format_spec` must match columns in the table definition. Oracle Database ignores any field in the `opaque_format_spec` that is not matched by a column in the table definition.

- `USING CLOB subquery` lets you derive the parameters and their values through a subquery. The subquery cannot contain any set operators or an `ORDER BY` clause. It must return one row containing a single item of data type CLOB.

Whether you specify the parameters in an `opaque_format_spec` or derive them using a subquery, the database does not interpret anything in this clause. It is up to the access driver to interpret this information in the context of the external data.

**LOCATION**  
The `LOCATION` clause lets you specify one or more external data sources. Usually the `location_specifier` is a file, but it need not be. Oracle Database does not
interpret this clause. It is up to the access driver to interpret this information in the context of the external data.

**REJECT LIMIT** The **REJECT LIMIT** clause lets you specify how many conversion errors can occur during a query of the external data before an Oracle Database error is returned and the query is aborted. The default value is 0.

**CLUSTER Clause**
The **CLUSTER** clause indicates that the table is to be part of cluster. The columns listed in this clause are the table columns that correspond to the cluster columns. Generally, the cluster columns of a table are the column or columns that make up its primary key or a portion of its primary key. Refer to CREATE CLUSTER on page 14-11 for more information.

Specify one column from the table for each column in the cluster key. The columns are matched by position, not by name.

A cluster table uses the space allocation of the cluster. Therefore, do not use the **PCTFREE**, **PCTUSED**, or **INITRANS** parameters, the **TABLESPACE** clause, or the **storage_clause** with the **CLUSTER** clause.

**Restrictions on Cluster Tables** Cluster tables are subject to the following restrictions:

- Object tables and tables containing LOB columns or columns of the Any* Oracle-supplied types cannot be part of a cluster.
- You cannot specify the **parallel_clause** or **CACHE** or **NOCACHE** for a table that is part of a cluster.
- You cannot specify **CLUSTER** with either **ROWDEPENDENCIES** or **NOROWDEPENDENCIES** unless the cluster has been created with the same **ROWDEPENDENCIES** or **NOROWDEPENDENCIES** setting.
- A cluster table cannot contain **INVISIBLE** columns.

**table_properties**
The **table_properties** further define the characteristics of the table.

**column_properties**
Use the **column_properties** clauses to specify the storage attributes of a column.

**object_type_col_properties**
The **object_type_col_properties** determine storage characteristics of an object column or attribute or of an element of a collection column or attribute.

**column** For **column**, specify an object column or attribute.

**substitutable_column_clause** The **substitutable_column_clause** indicates whether object columns or attributes in the same hierarchy are substitutable for each other. You can specify that a column is of a particular type, or whether it can contain instances of its subtypes, or both.

- If you specify **ELEMENT**, then you constrain the element type of a collection column or attribute to a subtype of its declared type.
- The **IS OF [TYPE] (ONLY type)** clause constrains the type of the object column to a subtype of its declared type.
- **NOT SUBSTITUTABLE AT ALL LEVELS** indicates that the object column cannot hold instances corresponding to any of its subtypes. Also, substitution is disabled for any embedded object attributes and elements of embedded nested tables and varrays. The default is **SUBSTITUTABLE AT ALL LEVELS**.

**Restrictions on the substitutable_column_clause**  This clause is subject to the following restrictions:

- You cannot specify this clause for an attribute of an object column. However, you can specify this clause for a object type column of a relational table and for an object column of an object table if the substitutability of the object table itself has not been set.

- For a collection type column, the only part of this clause you can specify is **[NOT] SUBSTITUTABLE AT ALL LEVELS**.

**LOB_storage_clause**

The **LOB_storage_clause** lets you specify the storage attributes of LOB data segments. You must specify at least one clause after the **STORE AS** keywords. If you specify more than one clause, then you must specify them in the order shown in the syntax diagram, from top to bottom.

For a nonpartitioned table, this clause specifies the storage attributes of LOB data segments of the table.

For a partitioned table, Oracle Database implements this clause depending on where it is specified:

- For a partitioned table specified at the table level—when specified in the **physical_properties** clause along with one of the partitioning clauses—this clause specifies the default storage attributes for LOB data segments associated with each partition or subpartition. These storage attributes apply to all partitions or subpartitions unless overridden by a **LOB_storage_clause** at the partition or subpartition level.

- For an individual partition of a partitioned table—when specified as part of a **table_partition_description**—this clause specifies the storage attributes of the data segments of the partition or the default storage attributes of any subpartitions of the partition. A partition-level **LOB_storage_clause** overrides a table-level **LOB_storage_clause**.

- For an individual subpartition of a partitioned table—when specified as part of **subpartition_by_hash** or **subpartition_by_list**—this clause specifies the storage attributes of the data segments of the subpartition. A subpartition-level **LOB_storage_clause** overrides both partition-level and table-level **LOB_storage_clauses**.

**Restriction on the LOB_storage_clause:**  Only the **TABLESPACE** clause is allowed when specifying the **LOB_storage_clause** in a subpartition.

**See Also:**

- Oracle Database SecureFiles and Large Objects Developer’s Guide for detailed information about LOBs, including guidelines for creating gigabyte LOBs

- "Creating a Table: LOB Column Example” on page 16-93
**LOB_item**

Specify the LOB column name or LOB object attribute for which you are explicitly defining tablespace and storage characteristics that are different from those of the table. Oracle Database automatically creates a system-managed index for each LOB_item you create.

**SECUREFILE | BASICFILE**

Use this clause to specify the type of LOB storage, either high-performance LOB (SecureFiles), or the traditional LOB (BasicFiles).

**See Also:** Oracle Database SecureFiles and Large Objects Developer’s Guide for more information about SecureFiles LOBs

---

**Note:** You cannot convert a LOB from one type of storage to the other. Instead you must migrate to SecureFiles or BasicFiles by using online redefinition or partition exchange.

---

**LOB_segname**

Specify the name of the LOB data segment. You cannot use LOB_segname if you specify more than one LOB_item.

**LOB_storage_parameters**

The LOB_storage_parameters clause lets you specify various elements of LOB storage.

**TABLESPACE Clause**

Use this clause to specify the tablespace in which LOB data is to be stored.

**storage_clause**

Use the storage_clause to specify various aspects of LOB segment storage. Of particular interest in the context of LOB storage is the MAXSIZE clause of the storage_clause, which can be used in combination with the LOB_retention_clause of LOB_parameters. Refer to storage_clause on page 8-48 for more information.

**LOB_parameters**

Several of the LOB_parameters are no longer needed if you are using SecureFiles for LOB storage. The PCTVERSION and FREEPOOLS parameters are valid and useful only if you are using BasicFiles LOB storage.

**ENABLE STORAGE IN ROW**

If you enable storage in row, then the LOB value is stored in the row (inline) if its length is less than approximately 4000 bytes minus system control information. This is the default.

**Restriction on Enabling Storage in Row**

For an index-organized table, you cannot specify this parameter unless you have specified an OVERFLOW segment in the index_org_table_clause.

**DISABLE STORAGE IN ROW**

If you disable storage in row, then the LOB value is stored outside of the row out of line regardless of the length of the LOB value. The LOB locator is always stored inline regardless of where the LOB value is stored. You cannot change the value of STORAGE IN ROW once it is set except by moving the table. See the move_table_clause on page 12-98 in the ALTER TABLE documentation for more information.
**CHUNK integer** Specify the number of bytes to be allocated for LOB manipulation. If integer is not a multiple of the database block size, then the database rounds up in bytes to the next multiple. For example, if the database block size is 2048 and integer is 2050, then the database allocates 4096 bytes (2 blocks). The maximum value is 32768 (32K), which is the largest Oracle Database block size allowed. The default CHUNK size is one Oracle Database block.

The value of CHUNK must be less than or equal to the value of NEXT, either the default value or that specified in the storage_clause. If CHUNK exceeds the value of NEXT, then the database returns an error. You cannot change the value of CHUNK once it is set.

**PCTVERSION integer** Specify the maximum percentage of overall LOB storage space used for maintaining old versions of the LOB. If the database is running in manual undo mode, then the default value is 10, meaning that older versions of the LOB data are not overwritten until they consume 10% of the overall LOB storage space.

You can specify the PCTVERSION parameter whether the database is running in manual or automatic undo mode. PCTVERSION is the default in manual undo mode. RETENTION is the default in automatic undo mode. You cannot specify both PCTVERSION and RETENTION.

This clause is not valid if you have specified SECUREFILE. If you specify both SECUREFILE and PCTVERSION, then the database silently ignores the PCTVERSION parameter.

**LOB_retention_clause** Use this clause to specify whether you want the LOB segment retained for flashback purposes, consistent-read purposes, both, or neither.

You can specify the RETENTION parameter only if the database is running in automatic undo mode. Oracle Database uses the value of the UNDO_RETENTION initialization parameter to determine the amount of committed undo data to retain in the database. In automatic undo mode, RETENTION is the default value unless you specify PCTVERSION. You cannot specify both PCTVERSION and RETENTION.

You can specify the optional settings after RETENTION only if you are using SecureFiles. The SECUREFILE parameter of the LOB_storage_clause indicates that the database will use SecureFiles to manage storage dynamically, taking into account factors such as the undo mode of the database.

- Specify MAX to signify that the undo should be retained until the LOB segment has reached MAXSIZE. If you specify MAX, then you must also specify the MAXSIZE clause in the storage_clause.
- Specify MIN if the database is in flashback mode to limit the undo retention duration for the specific LOB segment to n seconds.
- Specify AUTO if you want to retain undo sufficient for consistent read purposes only.
- Specify NONE if no undo is required for either consistent read or flashback purposes.

If you do not specify the RETENTION parameter, or you specify RETENTION with no optional settings, then RETENTION is set to DEFAULT, which is functionally equivalent to AUTO.

- Oracle Database SecureFiles and Large Objects Developer’s Guide for more information on using SecureFiles
- flashback_mode_clause on page 10-68 of ALTER DATABASE for information on putting a database in flashback mode
- "Creating an Undo Tablespace: Example" on page 16-115

FREEPOOLS integer Specify the number of groups of free lists for the LOB segment. Normally integer will be the number of instances in an Oracle Real Application Clusters environment or 1 for a single-instance database.

You can specify this parameter only if the database is running in automatic undo mode. In this mode, FREEPOOLS is the default unless you specify the FREELIST GROUPS parameter of the storage_clause. If you specify neither FREEPOOLS nor FREELIST GROUPS, then the database uses a default of FREEPOOLS 1 if the database is in automatic undo management mode and a default of FREELIST GROUPS 1 if the database is in manual undo management mode.

This clause is not valid if you have specified SECUREFILE. If you specify both SECUREFILE and FREEPOOLS, then the database silently ignores the FREEPOOLS parameter.

Restriction on FREEPOOLS You cannot specify both FREEPOOLS and the FREELIST GROUPS parameter of the storage_clause.

LOB_deduplicate_clause This clause is valid only for SecureFiles LOBs. Use the LOB_deduplicate_clause to enable or disable LOB deduplication, which is the elimination of duplicate LOB data.

The DEDUPLICATE keyword instructs the database to eliminate duplicate copies of LOBs. Using a secure hash index to detect duplication, the database coalesces LOBs with identical content into a single copy, reducing storage consumption and simplifying storage management.

If you omit this clause, then LOB deduplication is disabled by default.

This clause implements LOB deduplication for the entire LOB segment. To enable or disable deduplication for an individual LOB, use the DBMS_LOB.SETOPTIONS procedure.

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for more information about LOB deduplication and Oracle Database PL/SQL Packages and Types Reference for information about the DBMS_LOB package

LOB_compression_clause This clause is valid only for SecureFiles LOBs, not for BasicFiles LOBs. Use the LOB_compression_clause to instruct the database to enable or disable server-side LOB compression. Random read/write access is possible on server-side compressed LOB segments. LOB compression is independent from table compression or index compression. If you omit this clause, then the default is NOCOMPRESS.

You can specify HIGH, MEDIUM, or LOW to vary the degree of compression. The HIGH degree of compression incurs higher latency than MEDIUM but provides better compression. The LOW degree results in significantly higher decompression and
CREATE TABLE

SQL Statements: CREATE SYNONYM to CREATE TRIGGER

16-61

compression speeds, at the cost of slightly lower compression ratio than either HIGH or MEDIUM. If you omit this optional parameter, then the default is MEDIUM.

This clause implements server-side LOB compression for the entire LOB segment. To enable or disable compression on an individual LOB, use the DBMS_LOB.SETOPTIONS procedure.

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for more information on server-side LOB storage and Oracle Database PL/SQL Packages and Types Reference for information about client-side LOB compression using the UTL_COMPRESS supplied package and for information about the DBMS_LOB package

ENCRYPT | DECRYPT These clauses are valid only for LOBs that are using SecureFiles for LOB storage. Specify ENCRYPT to encrypt all LOBs in the column. Specify DECRYPT to keep the LOB in cleartext. If you omit this clause, then DECRYPT is the default.

Refer to encryption_spec on page 16-35 for general information on that clause. When applied to a LOB column, encryption_spec is specific to the individual LOB column, so the encryption algorithm can differ from that of other LOB columns and other non-LOB columns. Use the encryption_spec as part of the column_definition to encrypt the entire LOB column. Use the encryption_spec as part of the LOB_storage_clause in the table_partition_description to encrypt a LOB partition.

Restriction on encryption_spec for LOBs You cannot specify the SALT or NO SALT clauses of encryption_spec for LOB encryption.

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for more information on LOB encryption and Oracle Database PL/SQL Packages and Types Reference for information the DBMS_LOB package

CACHE | NOCACHE | CACHE READS Refer to CACHE | NOCACHE | CACHE READS on page 16-80 for information on these clauses.

LOB_partition_storage The LOB_partition_storage clause lets you specify a separate LOB_storage_clause or varray_col_properties clause for each partition. You must specify the partitions in the order of partition position. You can find the order of the partitions by querying the PARTITION_NAME and PARTITION_POSITION columns of the USER_IND_PARTITIONS view.

If you do not specify a LOB_storage_clause or varray_col_properties clause for a particular partition, then the storage characteristics are those specified for the LOB item at the table level. If you also did not specify any storage characteristics for the LOB item at the table level, then Oracle Database stores the LOB data partition in the same tablespace as the table partition to which it corresponds.

Restrictions on LOB_partition_storage: LOB_partition_storage is subject to the following restrictions:

- In the LOB_parameters of the LOB_storage_clause, you cannot specify encryption_spec, because it is invalid to specify an encryption algorithm for partitions and subpartitions.
- You can only specify the TABLESPACE clause for hash partitions and all types of subpartitions.
**varray_col_properties**

The `varray_col_properties` let you specify separate storage characteristics for the LOB in which a varray will be stored. If `varray_item` is a multilevel collection, then the database stores all collection items nested within `varray_item` in the same LOB in which `varray_item` is stored.

- For a nonpartitioned table—when specified in the `physical_properties` clause without any of the partitioning clauses—this clause specifies the storage attributes of the LOB data segments of the varray.

- For a partitioned table specified at the table level—when specified in the `physical_properties` clause along with one of the partitioning clauses—this clause specifies the default storage attributes for the varray LOB data segments associated with each partition (or its subpartitions, if any).

- For an individual partition of a partitioned table—when specified as part of a `table_partition_description`—this clause specifies the storage attributes of the varray LOB data segments of that partition or the default storage attributes of the varray LOB data segments of any subpartitions of this partition. A partition-level `varray_col_properties` overrides a table-level `varray_col_properties`.

- For an individual subpartition of a partitioned table—when specified as part of `subpartition_by_hash` or `subpartition_by_list`—this clause specifies the storage attributes of the varray data segments of this subpartition. A subpartition-level `varray_col_properties` overrides both partition-level and table-level `varray_col_properties`.

**STORE AS [SECUREFILE | BASICFILE] LOB Clause**

If you specify `STORE AS LOB`, then:

- If the maximum varray size is less than approximately 4000 bytes, then the database stores the varray as an inline LOB unless you have disabled storage in row.

- If the maximum varray size is greater than approximately 4000 bytes or if you have disabled storage in row, then the database stores in the varray as an out-of-line LOB.

If you do not specify `STORE AS LOB`, then storage is based on the maximum possible size of the varray rather than on the actual size of a varray column. The maximum size of the varray is the number of elements times the element size, plus a small amount for system control information. If you omit this clause, then:

- If the maximum size of the varray is less than approximately 4000 bytes, then the database does not store the varray as a LOB, but as inline data.

- If the maximum size is greater than approximately 4000 bytes, then the database always stores the varray as a LOB.
  - If the actual size is less than approximately 4000 bytes, then it is stored as an inline LOB
  - If the actual size is greater than approximately 4000 bytes, then it is stored as an out-of-line LOB, as is true for other LOB columns.

**substitutable_column_clause**

The `substitutable_column_clause` has the same behavior as described for `object_type_col_properties` on page 16-56.

**See Also:** "Substitutable Table and Column Examples" on page 16-91
Restriction on Varray Column Properties  You cannot specify this clause on an interval partitioned table.

**nested_table_col_properties**

The `nested_table_col_properties` let you specify separate storage characteristics for a nested table, which in turn enables you to define the nested table as an index-organized table. Unless you explicitly specify otherwise in this clause:

- For a nonpartitioned table, the storage table is created in the same schema and the same tablespace as the parent table.
- For a partitioned table, the storage table is created in the default tablespace of the schema. By default, nested tables are equipartitioned with the partitioned base table.
- In either case, the storage table uses default storage characteristics, and stores the nested table values of the column for which it was created.

You must include this clause when creating a table with columns or column attributes whose type is a nested table. Clauses within `nested_table_col_properties` that function the same way they function for the parent table are not repeated here.

**nested_item**  Specify the name of a column, or of a top-level attribute of the object type of the tables, whose type is a nested table.

**COLUMN_VALUE**  If the nested table is a multilevel collection, then the inner nested table or varray may not have a name. In this case, specify `COLUMN_VALUE` in place of the `nested_item` name.

See Also:  "Creating a Table: Multilevel Collection Example" on page 16-92 for examples using `nested_item` and `COLUMN_VALUE`

**LOCAL | GLOBAL**  Specify `LOCAL` to equipartition the nested table with the base table. This is the default. Oracle Database automatically creates a local partitioned index for the partitioned nested table.

Specify `GLOBAL` to indicate that the nested table is a nonpartitioned nested table of a partitioned base table.

**storage_table**  Specify the name of the table where the rows of `nested_item` reside.

You cannot query or perform DML statements on `storage_table` directly, but you can modify its storage characteristics by specifying its name in an `ALTER TABLE` statement.

See Also:  `ALTER TABLE` on page 12-2 for information about modifying nested table column storage characteristics

**RETURN [AS]**  Specify what Oracle Database returns as the result of a query.

- `VALUE` returns a copy of the nested table itself.
- `LOCATOR` returns a collection locator to the copy of the nested table.

  The locator is scoped to the session and cannot be used across sessions. Unlike a LOB locator, the collection locator cannot be used to modify the collection instance.

If you do not specify the `segment_attributes_clause` or the `LOB_storage_clause`, then the nested table is heap organized and is created with default storage characteristics.
Restrictions on Nested Table Column Properties  Nested table column properties are subject to the following restrictions:

- You cannot specify this clause for a temporary table.
- You cannot specify this clause on an interval partitioned table.
- You cannot specify the oid_clause.
- At create time, you cannot use object_properties to specify an out_of_line_ref_constraint, inline_ref_constraint, or foreign key constraint for the attributes of a nested table. However, you can modify a nested table to add such constraints using ALTER TABLE.

See Also:
- ALTER TABLE on page 12-2 for information about modifying nested table column storage characteristics
- ”Nested Table Example” on page 16-92 and ”Creating a Table: Multilevel Collection Example” on page 16-92

XMLType_column_properties
The XMLType_column_properties let you specify storage attributes for an XMLTYPE column.

XMLType_storage  XMLType data can be stored in binary XML, CLOB, or object-relational columns.

- Specify BINARY XML to store the XML data in compact binary XML format.
  Any LOB parameters you specify are applied to the underlying BLOB column created for storing the binary XML encoded value.

  In earlier releases, binary XML data is stored by default in a BasicFiles LOB. Beginning with Oracle Database 11g Release 2 (11.2.0.2), if the COMPATIBLE initialization parameter is 11.2 or higher and you do not specify BASICFILE or SECUREFILE, then binary XML data is stored in a SecureFiles LOB whenever possible. If SecureFiles LOB storage is not possible then the binary XML data is stored in a BasicFiles LOB. This can occur if either of the following is true:
    - The tablespace for the XMLType table does not use automatic segment space management.
    - A setting in file init.ora prevents SecureFiles LOB storage. For example, see parameter DB_SECUREFILE in Oracle Database Reference.

- Specify CLOB if you want the database to store the XMLType data in a CLOB column. Storing data in a CLOB column preserves the original content and enhances retrieval time.

  If you specify LOB storage, then you can specify either LOB parameters or the XMLSchema_spec clause, but not both. Specify the XMLSchema_spec clause if you want to restrict the table or column to particular schema-based XML instances.

  If you do not specify BASICFILE or SECUREFILE with this clause, then the CLOB column is stored in a BasicFiles LOB.

Note: Oracle recommends against storing XMLType data in a CLOB column. CLOB storage of XMLType is deprecated. Use binary XML storage of XMLType instead.
Specify **OBJECT RELATIONAL** if you want the database to store the **XMLType** data in object-relational columns. Storing data objects relationally lets you define indexes on the relational columns and enhances query performance.

If you specify object-relational storage, then you must also specify the **XMLSchema_spec** clause.

Use the **ALL VARRAYS AS** clause if you want the database to store all varrays in an **XMLType** column.

In earlier releases, **XMLType** data is stored in a **CLOB** column in a BasicFiles LOB by default. Beginning with Oracle Database 11g Release 2 (11.2.0.2), if the **COMPATIBLE** initialization parameter is 11.2 or higher and you do not specify the **XMLType_storage** clause, then **XMLType** data is stored in a binary XML column in a SecureFiles LOB. If SecureFiles LOB storage is not possible, then it is stored in a binary XML column in a BasicFiles LOB.

**See Also:** *Oracle Database SecureFiles and Large Objects Developer’s Guide* for more information on SecureFiles LOBs

**XMLSchema_spec**  Refer to the **XMLSchema_spec** on page 16-88 for the full semantics of this clause.

**See Also:**

- **LOB_storage_clause** on page 12-59 for information on the **LOB_segnname** and **LOB_parameters** clauses
- "**XMLType Column Examples**" on page 16-95 for examples of **XMLType** columns in object-relational tables and "**Using XML in SQL Statements**" on page F-8 for an example of creating an **XMLSchema**
- *Oracle XML DB Developer’s Guide* for more information on **XMLType** columns and tables and on creating **XMLSchemas**
- *Oracle Database PL/SQL Packages and Types Reference* for information on the **DBMS_XMLSCHEMA** package

**XMLType_virtual_columns**

This clause is valid only for **XMLType** tables with binary XML storage, which you designate in the **XMLType_storage** clause. Specify the **VIRTUAL COLUMNS** clause to define virtual columns, which can be used as in a function-based index or in the definition of a constraint. You cannot define a constraint on such a virtual column during creation of the table, but you can use a subsequent **ALTER TABLE** statement to add a constraint to the column.

**See Also:** *Oracle XML DB Developer’s Guide* for examples of how to use this clause in an XML environment

**indexing_clause**

The **indexing_clause** is valid only for partitioned tables. Use this clause to set the **indexing property** for a table, table partition, or table subpartition.

- Specify **INDEXING ON** to set the indexing property to **ON**. This is the default.
- Specify **INDEXING OFF** to set the indexing property to **OFF**.

The indexing property determines whether table partitions and subpartitions are included in partial indexes on the table.
For simple partitioned tables, partitions with an indexing property of `ON` are included in partial indexes on the table. Partitions with an indexing property of `OFF` are excluded.

For composite-partitioned tables, subpartitions with an indexing property of `ON` are included in partial indexes on the table. Subpartitions with an indexing property of `OFF` are excluded.

You can specify the `indexing_clause` at the table, partition, or subpartition level. When you specify the `indexing_clause` at the table level, in the `table_properties` clause, you set the default indexing property for the table. Interval partitions, which are automatically created by the database, always inherit the default indexing property for the table. Other types of partitions and subpartitions inherit the default indexing property as follows:

For simple partitioned tables, partitions inherit the default indexing property for the table. You can override this behavior by specifying the `indexing_clause` for an individual partition:

- For a range partition, in the `table_partition_description` of the `range_partitions` clause
- For a hash partition, in the `individual_hash_partitions` clause of the `hash_partitions` clause
- For a list partition, in the `table_partition_description` of the `list_partitions` clause
- For a reference partition, in the `table_partition_description` of the `reference_partition_desc` clause of the `reference_partitioning` clause
- For a system partition, in the `table_partition_description` of the `reference_partition_desc` clause of the `system_partitioning` clause

For composite-partitioned tables, subpartitions inherit the default indexing property for the table. You can override this behavior by specifying the `indexing_clause` for an individual partition or subpartition.

If you specify the `indexing_clause` for a partition, then its subpartitions inherit the indexing property of the partition:

- For composite range partitions, in the `table_partition_description` of the `composite_range_partitions` clause
- For composite list partitions, in the `table_partition_description` of the `composite_list_partitions` clause
- For composite hash partitions, in the `individual_hash_partitions` clause of the `composite_hash_partitions` clause

You can set the indexing property of a subpartition by specifying the `indexing_clause` for the subpartition:

- For range subpartitions, in the `range_subpartition_desc` clause of the `composite_range_partitions` clause
- For list subpartitions, in the `list_subpartition_desc` clause of the `composite_list_partitions` clause
- For hash subpartitions, in the `individual_hash_subparts` clause of the `composite_hash_partitions` clause
Restrictions on the `indexing_clause` The `indexing_clause` is subject to the following restrictions:

- You cannot specify the `indexing_clause` for nonpartitioned tables.
- You cannot specify the `indexing_clause` for index-organized tables.

**See Also:** The `partial_index_clause` of `CREATE INDEX` on page 14-88 for more information on partial indexes

`table_partitioning_clauses`
Use the `table_partitioning_clauses` to create a partitioned table.

**Notes on Partitioning in General** The following notes pertain to all types of partitioning:

- You can specify up to a total of 1024K-1 partitions and subpartitions.
- You can create a partitioned table with just one partition. A table with one partition is different from a nonpartitioned table. For example, you cannot add a partition to a nonpartitioned table.
- You can specify a name for every table and LOB partition and for every table and LOB subpartition, but you need not do so. If you omit the name, then the database generates names as follows:
  - If you omit a partition name, then the database generates a name of the form `SYS_Pn`. System-generated names for LOB data and LOB index partitions take the form `SYS_LOB_Pn` and `SYS_IL_Pn`, respectively.
  - If you specify a subpartition name in `subpartition_template`, then for each subpartition created with that template, the database generates a name by concatenating the partition name with the template subpartition name. For LOB subpartitions, the generated LOB subpartition name is a concatenation of the partition name and the template LOB segment name. In either case, if the concatenation exceeds 30 characters, then the database returns an error and the statement fails.
  - If you omit a subpartition name when specifying an individual subpartition, and you have not specified `subpartition_template`, then the database generates a name of the form `SYS_SUBPn`. The corresponding system-generated names for LOB data and index subpartitions are `SYS_LOB_SUBPn` and `SYS_IL_SUBPn`, respectively.
- Tablespace storage can be specified at various levels in the `CREATE TABLE` statement for both table segments and LOB segments. The number of tablespaces does not have to equal the number of partitions or subpartitions. If the number of partitions or subpartitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

**See Also:** `Oracle Database Reference` for information on viewing the indexing property of a table, table partition, or table subpartition.

- To view the default indexing property of a table, query the `DEF_INDEXING` column of the `*PART_TABLES` views.
- To view the indexing property of a table partition, query the `INDEXING` column of the `*TAB_PARTITIONS` views.
- To view the indexing property of a table subpartition, query the `INDEXING` column of the `*TAB_SUBPARTITIONS` views.
The database evaluates tablespace storage in the following order of descending priority:

- Tablespace storage specified at the individual table subpartition or LOB subpartition level has the highest priority, followed by storage specified for the partition or LOB in the subpartition_template.
- Tablespace storage specified at the individual table partition or LOB partition level. Storage parameters specified here take precedence over the subpartition_template.
- Tablespace storage specified for the table
- Default tablespace storage specified for the user

By default, nested tables are equipartitioned with the partitioned base table.

**Restrictions on Partitioning in General**

All partitioning is subject to the following restrictions:

- You cannot partition a table that is part of a cluster.
- You cannot partition a nested table or varray that is defined as an index-organized table.
- You cannot partition a table containing any LONG or LONG RAW columns.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to Oracle Database VLDB and Partitioning Guide for a discussion of these restrictions.

See Also: "Partitioning Examples" on page 16-96

**range_partitions**

Use the `range_partitions` clause to partition the table on ranges of values from the column list. For an index-organized table, the column list must be a subset of the primary key columns of the table.

**column**

Specify an ordered list of columns used to determine into which partition a row belongs. These columns are the **partitioning key**. You can specify virtual columns and INVISIBLE columns as partitioning key columns.

**INTERVAL Clause**

Use this clause to establish **interval partitioning** for the table. Interval partitions are partitions based on a numeric range or datetime interval. They extend range partitioning by instructing the database to create partitions of the specified range or interval automatically when data inserted into the table exceeds all of the range partitions. For each automatically created partition, the database generates a name of the form `SYS_Pn`. The database guarantees that automatically generated partition names are unique and do not violate namespace rules.

- For `expr`, specify a valid number or interval expression.
- The optional `STORE IN` clause lets you specify one or more tablespaces into which the database will store interval partition data.
- You must also specify at least one range partition using the `PARTITION` clause of `range_partitions`. The range partition key value determines the high value of the
range partitions, which is called the **transition point**, and the database creates interval partitions for data beyond that transition point.

**Restrictions on Interval Partitioning**  The `INTERVAL` clause is subject to the restrictions listed in "Restrictions on Partitioning in General" on page 16-68 and "Restrictions on Range Partitioning" on page 16-70. The following additional restrictions apply:

- You can specify only one partitioning key column, and it must be of type `NUMBER`, `DATE`, `FLOAT`, or `TIMESTAMP`.
- This clause is not supported for index-organized tables.
- This clause is not supported for tables containing nested table columns, varray columns, or `XMLType` columns.
- Interval partitioning is not supported at the subpartition level.
- Serializable transactions do not work with interval partitioning. Trying to insert data into a partition of an interval partitioned table that does not yet have a segment causes an error.
- In the `VALUES` clause:
  - You cannot specify `MAXVALUE` (an infinite upper bound), because doing so would defeat the purpose of the automatic addition of partitions as needed.
  - You cannot specify `NULL` values for the partitioning key column.

**See Also:** *Oracle Database VLDB and Partitioning Guide* for more information on interval partitioning

**PARTITION partition**

If you specify a partition name, then the name `partition` must conform to the rules for naming schema objects and their part as described in "Database Object Naming Rules" on page 2-119. If you omit `partition`, then the database generates a name as described in "Notes on Partitioning in General" on page 16-67.

**range_values_clause**

Specify the noninclusive upper bound for the current partition. The value list is an ordered list of literal values corresponding to the column list in the `range_partitions` clause. You can substitute the keyword `MAXVALUE` for any literal in the value list. `MAXVALUE` specifies a maximum value that will always sort higher than any other value, including null.

Specifying a value other than `MAXVALUE` for the highest partition bound imposes an implicit integrity constraint on the table.

---

**Note:**  If `table` is partitioned on a `DATE` column, and if the date format does not specify the first two digits of the year, then you must use the `TO_DATE` function with the `YYYY` 4-character format mask for the year. The `RRRR` format mask is not supported in this clause. The date format is determined implicitly by `NLS_TERRITORY` or explicitly by `NLS_DATE_FORMAT`. Refer to *Oracle Database Globalization Support Guide* for more information on these initialization parameters.

**See Also:** *Oracle Database Concepts* for more information about partition bounds and "Range Partitioning Example" on page 16-96
table_partition_description

Use the table_partition_description to define the physical and storage characteristics of the table.

The clauses deferred_segment_creation, segment_attributes_clause, table_compression, inmemory_clause, and ilm_clause have the same function as described for the physical_properties of the table as a whole.

Use the indexingClause to set the indexing property for a range, list, system, or reference table partition. Refer to the indexingClause on page 16-65 for more information.

The prefix_compression clause and OVERFLOW clause, have the same function as described for the index_org_table_clause.

LOB_storage_clause

The LOB_storage_clause lets you specify LOB storage characteristics for one or more LOB items in this partition or in any range or list subpartitions of this partition. If you do not specify the LOB_storage_clause for a LOB item, then the database generates a name for each LOB data partition as described in "Notes on Partitioning in General" on page 16-67.

varray_col_properties

The varray_col_properties let you specify storage characteristics for one or more varray items in this partition or in any range or list subpartitions of this partition.

nested_table_col_properties

The nested_table_col_properties let you specify storage characteristics for one or more nested table storage table items in this partition or in any range or list subpartitions of this partition. Storage characteristics specified in this clause override any storage attributes specified at the table level.

partitioning_storage_clause

Use the partitioning_storage_clause to specify storage characteristics for hash partitions and for range, hash, and list subpartitions.

Restrictions on partitioning_storage_clause

This clause is subject to the following restrictions:

- The OVERFLOW clause is relevant only for index-organized partitioned tables and is valid only within the individual_hash_partitions clause. It is not valid for range or hash partitions or for subpartitions of any type.
- You cannot specify the advanced_index_compression clause of the index_compression clause.
- You can specify the prefix_compression clause of the indexing_clause only for partitions of index-organized tables and you can specify COMPRESS or NOCOMPRESS, but you cannot specify the prefix length with integer.

Restrictions on Range Partitioning

Range partitioning is subject to the restrictions listed in "Restrictions on Partitioning in General" on page 16-68. The following additional restrictions apply:

- You cannot specify more than 16 partitioning key columns.
- Partitioning key columns must be of type CHAR, NCHAR, VARCHAR2, NVARCHAR2, VARCHAR, NUMBER, FLOAT, DATE, TIMESTAMP, TIMESTAMP WITH LOCAL TIMEZONE, or RAW.
- You cannot specify NULL in the VALUES clause.
### list_partitions
Use the `list_partitions` clause to partition the table on lists of literal values from `column`. List partitioning is useful for controlling how individual rows map to specific partitions.

#### list_values_clause
The `list_values_clause` of each partition must have at least one value. No value, including `NULL`, can appear in more than one partition. List partitions are not ordered.

If you specify the literal `NULL` for a partition value in the `VALUES` clause, then to access data in that partition in subsequent queries, you must use an `IS NULL` condition in the `WHERE` clause, rather than a comparison condition.

The `DEFAULT` keyword creates a partition into which the database will insert any row that does not map to another partition. Therefore, you can specify `DEFAULT` for only one partition, and you cannot specify any other values for that partition. Further, the default partition must be the last partition you define. The use of `DEFAULT` is similar to the use of `MAXVALUE` for range partitions.

The string comprising the list of values for each partition can be up to 4K bytes. The total number of values for all partitions cannot exceed 64K-1.

The partitioning key column for a list partition can be an extended data type column, which has a maximum size of 32767 bytes. In this case, the list of values that you want to specify for a partition may exceed the 4K byte limit. You can work around this limitation by using one of the following methods:

- Use the `DEFAULT` partition for values that exceed the 4K byte limit.
- Use a hash function, such as `STANDARD_HASH`, in the partition key column to create unique identifiers of lengths less than 4K bytes. See `STANDARD_HASH` on page 7-304 for more information.

**See Also:** "Extended Data Types" on page 2-29 for more information on extended data types

### table_partition_description
The subclauses of the `table_partition_description` have the same behavior as described for range partitions in `table_partition_description` on page 16-70.

### Restrictions on List Partitioning
List partitioning is subject to the restrictions listed in "Restrictions on Partitioning in General" on page 16-68. The following additional restrictions apply:

- You can specify only one partitioning key column.
- The partitioning key column must be of type `CHAR`, `NCHAR`, `VARCHAR2`, `NVARCHAR2`, `VARCHAR`, `NUMBER`, `FLOAT`, `DATE`, `TIMESTAMP`, `TIMESTAMP WITH LOCAL TIMEZONE`, or `RAW`.

### hash_partitions
Use the `hash_partitions` clause to specify that the table is to be partitioned using the hash method. Oracle Database assigns rows to partitions using a hash function on values found in columns designated as the partitioning key. You can specify individual hash partitions, or you can specify how many hash partitions the database should create.

#### column
Specify an ordered list of columns used to determine into which partition a row belongs (the partitioning key).
individual_hash_partitions  Use this clause to specify individual partitions by name. Use the indexing_clause to set the indexing property for a hash partition. Refer to the indexing_clause on page 16-65 for more information.

Restriction on Specifying Individual Hash Partitions  The only clauses you can specify in the partitioning_storage_clause are the TABLESPACE clause and table compression.

Note: If your enterprise has or will have databases using different character sets, then use caution when partitioning on character columns. The sort sequence of characters is not identical in all character sets. Refer to Oracle Database Globalization Support Guide for more information on character set support.

hash_partitions_by_quantity  An alternative to defining individual partitions is to specify the number of hash partitions. In this case, the database assigns partition names of the form SYS_Pn. The STORE IN clause lets you specify one or more tablespaces where the hash partition data is to be stored. The number of tablespaces need not equal the number of partitions. If the number of partitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

For both methods of hash partitioning, for optimal load balancing you should specify a number of partitions that is a power of 2. When you specify individual hash partitions, you can specify both TABLESPACE and table compression in the partitioning_storage_clause. When you specify hash partitions by quantity, you can specify only TABLESPACE. Hash partitions inherit all other attributes from table-level defaults.

The table_compression clause has the same function as described for the table_properties of the table as a whole.

The prefix_compression clause and the OVERFLOW clause have the same function as described for the index_org_table_clause.

Tablespace storage specified at the table level is overridden by tablespace storage specified at the partition level, which in turn is overridden by tablespace storage specified at the subpartition level.

In the individual_hash_partitions clause, the TABLESPACE clause of the partitioning_storage_clause determines tablespace storage only for the individual partition being created. In the hash_partitions_by_quantity clause, the STORE IN clause determines placement of partitions as the table is being created and the default storage location for subsequently added partitions.

Restriction on Specifying Hash Partitions by Quantity  You cannot specify the advanced_index_compression clause of the index_compression clause.

See Also: Oracle Database VLDB and Partitioning Guide for more information on hash partitioning

Restrictions on Hash Partitioning  Hash partitioning is subject to the restrictions listed in "Restrictions on Partitioning in General" on page 16-68. The following additional restrictions apply:

- You cannot specify more than 16 partitioning key columns.
Partitioning key columns must be of type CHAR, NCHAR, VARCHAR2, NVARCHAR2, VARCHAR, NUMBER, FLOAT, DATE, TIMESTAMP, TIMESTAMP WITH LOCAL TIMEZONE, or RAW.

**composite_range_partitions**

Use the `composite_range_partitions` clause to first partition table by range, and then partition the partitions further into range, hash, or list subpartitions.

The `INTERVAL` clause has the same semantics for composite range partitioning that it has for range partitioning. Refer to "INTERVAL Clause" on page 16-68 for more information.

Specify `subpartition_by_range`, `subpartition_by_hash` or `subpartition_by_list` to indicate the type of subpartitioning you want for each composite range partition. Within these clauses you can specify a subpartition template, which establishes default subpartition characteristics for subpartitions created as part of this statement or subsequently created subpartitions.

After establishing the type of subpartitioning you want for the table, and optionally a subpartition template, you must define at least one range partition.

- You must specify the `range_values_clause`, which has the same requirements as for noncomposite range partitions.
- Use the `table_partition_description` to define the physical and storage characteristics of the each partition.
- In the `range_partition_desc`, `use range_subpartition_desc, list_subpartition_desc, individual_hash_subparts, or hash_subparts_by_quantity` to specify characteristics for the individual subpartitions of the partition. The values you specify in these clauses supersede for these subpartitions any values you have specified in the `subpartition_template`.
- The only characteristics you can specify for a hash or list subpartition or any LOB subpartition are TABLESPACE and `table_compression`.

**Restrictions on Composite Range Partitioning**  Regardless of the type of subpartitioning, composite range partitioning is subject to the following restrictions:

- The only physical attributes you can specify at the subpartition level are TABLESPACE and table compression.
- You cannot specify composite partitioning for an index-organized table. Therefore, the `OVERFLOW` clause of the `table_partition_description` is not valid for composite-partitioned tables.
- You cannot specify composite partitioning for tables containing XMLType columns.

**See Also:** "Composite-Partitioned Table Examples" on page 16-99 for examples of composite range partitioning and Oracle Database VLDB and Partitioning Guide for examples of composite list partitioning

**composite_list_partitions**

Use the `composite_list_partitions` clause to first partition table by list, and then partition the partitions further into range, hash, or list subpartitions.

Specify `subpartition_by_range`, `subpartition_by_hash` or `subpartition_by_list` to indicate the type of subpartitioning you want for each composite list partition. Within these clauses you can specify a subpartition template, which establishes default subpartition characteristics for subpartitions created as part of this statement and for subsequently created subpartitions.
After establishing the type of subpartitioning you want for each composite partition, and optionally defining a subpartition template, you must define at least one list partition.

- In the `list_partition_desc`, you must specify the `list_values_clause`, which has the same requirements as for noncomposite list partitions.
- Use the `table_partition_description` to define the physical and storage characteristics of the each partition.
- In the `list_partition_desc`, use `range_subpartition_desc`, `list_subpartition_desc`, `individual_hash_subparts`, or `hash_subparts_by_quantity` to specify characteristics for the individual subpartitions of the partition. The values you specify in these clauses supersede the for these subpartitions any values you have specified in the `subpartition_template`.

**Restrictions on Composite List Partitioning**  Composite list partitioning is subject to the same restrictions as described in "Restrictions on Composite Range Partitioning" on page 16-73.

**composite_hash_partitions**

Use the `composite_hash_partitions` clause to first partition the table using the hash method, and then partition the partitions further into range, hash, or list subpartitions.

Specify `subpartition_by_range`, `subpartition_by_hash` or `subpartition_by_list` to indicate the type of subpartitioning you want for each composite range partition. Within these clauses you can specify a subpartition template, which establishes default subpartition characteristics for subpartitions created as part of this statement or subsequently created subpartitions.

After establishing the type of subpartitioning you want for the table, you must specify `individual_hash_partitions` or `hash_partitions_by_quantity`.

**Restrictions on Composite Hash Partitioning**  Composite hash partitioning is subject to the same restrictions as described in "Restrictions on Composite Range Partitioning" on page 16-73.

**subpartition_template**  The `subpartition_template` is an optional element of range, list, and hash subpartitioning. The template lets you define default subpartitions for each table partition. Oracle Database will create these default subpartition characteristics in any partition for which you do not explicitly define subpartitions. This clause is useful for creating symmetric partitions. You can override this clause by explicitly defining subpartitions at the partition level, in the `range_subpartition_desc`, `list_subpartition_desc`, `individual_hash_subparts`, or `hash_subparts_by_quantity` clause.

When defining subpartitions with a template, you can explicitly define range, list, or hash subpartitions, or you can define a quantity of hash subpartitions.

- To explicitly define subpartitions, use `range_subpartition_desc`, `list_subpartition_desc`, or `individual_hash_subparts`. You must specify a name for each subpartition. If you specify the `LOB_partitioning_clause` of the `partitioning_storage_clause`, then you must specify `LOB_segname`.

- To define a quantity of hash subpartitions, specify a positive integer for `hash_subpartition_quantity`. The database creates that number of subpartitions in each partition and assigns subpartition names of the form SYS_SUBPn.
Restrictions on Subpartition Templates  Subpartition templates are subject to the following restrictions:

- If you specify TABLESPACE for one LOB subpartition, then you must specify TABLESPACE for all of the LOB subpartitions of that LOB column. You can specify the same tablespace for more than one LOB subpartition.

- If you specify separate LOB storage for list subpartitions using the partitioning_storage_clause, either in the subpartition_template or when defining individual subpartitions, then you must specify LOB_segname for both LOB and varray columns.

subpartition_by_range

Use the subpartition_by_range clause to indicate that the database should subpartition by range each partition in table. The subpartitioning column list is unrelated to the partitioning key but is subject to the same restrictions (see column on page 16-68).

You can use the subpartition_template to specify default subpartition characteristic values. See subpartition_template on page 16-74. The database uses these values for any subpartition in this partition for which you do not explicitly specify the characteristic.

You can also define range subpartitions individually for each partition using the range_subpartition_desc of range_partition_desc or list_partition_desc. If you omit both subpartition_template and the range_subpartition_desc, then the database creates a single MAXVALUE subpartition.

subpartition_by_list

Use the subpartition_by_list clause to indicate that the database should subpartition each partition in table by literal values from column. You can specify only one list subpartitioning key column.

You can use the subpartition_template to specify default subpartition characteristic values. See subpartition_template on page 16-74. The database uses these values for any subpartition in this partition for which you do not explicitly specify the characteristic.

You can also define list subpartitions individually for each partition using the list_subpartition_desc of range_partition_desc or list_partition_desc. If you omit both subpartition_template and the list_subpartition_desc, then the database creates a single DEFAULT subpartition.

Restrictions on List Subpartitioning  List subpartitioning is subject to the same restrictions as described in Restrictions on Composite Range Partitioning on page 16-73.
**subpartition_by_hash**

Use the `subpartition_by_hash` clause to indicate that the database should subpartition by hash each partition in `table`. The subpartitioning column list is unrelated to the partitioning key but is subject to the same restrictions (see `column` on page 16-71).

You can define the subpartitions using the `subpartition_template` or the `SUBPARTITIONS integer` clause. See `subpartition_template` on page 16-74. In either case, for optimal load balancing you should specify a number of partitions that is a power of 2.

If you specify `SUBPARTITIONS integer`, then you determine the default number of subpartitions in each partition of `table`, and optionally one or more tablespaces in which they are to be stored. The default value is 1. If you omit both this clause and `subpartition_template`, then the database will create each partition with one hash subpartition.

**Notes on Composite Partitions**  
The following notes apply to composite partitions:

- For all subpartitions, you can use the `range_subpartition_desc`, `list_subpartition_desc`, `individual_hash_subparts`, or `hash_subparts_by_quantity` to specify individual subpartitions by name, and optionally some other characteristics.
- Alternatively, for hash and list subpartitions:
  - You can specify the number of subpartitions and optionally one or more tablespaces where they are to be stored. In this case, Oracle Database assigns subpartition names of the form `SYS_SUBPn`.
  - If you omit the subpartition description and if you have created a subpartition template, then the database uses the template to create subpartitions. If you have not created a subpartition template, then the database creates one hash subpartition or one `DEFAULT` list subpartition.
- For all types of subpartitions, if you omit the subpartitions description entirely, then the database assigns subpartition names as follows:
  - If you have specified a subpartition template and you have specified partition names, then the database generates subpartition names of the form `partition_name underscore (_) subpartition_name` (for example, `P1_SUB1`).
  - If you have not specified a subpartition template or if you have specified a subpartition template but did not specify partition names, then the database generates subpartition names of the form `SYS_SUBPn`.

**reference_partitioning**

Use this clause to partition the table by reference. Partitioning by reference is a method of equipartitioning the table being created (the child table) by a referential constraint to an existing partitioned table (the parent table). When you partition a table by reference, partition maintenance operations subsequently performed on the parent table automatically cascade to the child table. Therefore, you cannot perform partition maintenance operations on a reference-partitioned table directly.

If the parent table is an interval-partitioned table, then partitions in the reference-partitioned child table that correspond to interval partitions in the parent table will be created during inserts into the child table. When an interval partition in a child table is created, the partition name is inherited from the associated parent table partition. If the child table has a table-level default tablespace, then it will be used as the tablespace for the new interval partition. Otherwise, the tablespace will be
inherited from the parent table partition. Refer to Oracle Database VLDB and Partitioning Guide for more information on referencing an interval-partitioned table.

**constraint**  The partitioning referential constraint must meet the following conditions:

- You must specify a referential integrity constraint defined on the table being created, which must refer to a primary key or unique constraint on the parent table. The constraint must be in **ENABLE VALIDATE NOT DEFERRABLE** state, which is the default when you specify a referential integrity constraint during table creation.
- All foreign key columns referenced in the constraint must be **NOT NULL**.
- When you specify the constraint, you cannot specify the **ON DELETE SET NULL** clause of the references_clause.
- The parent table referenced in the constraint must be an existing partitioned table. It can be partitioned by any method.
- The foreign and parent keys cannot contain any virtual columns that reference PL/SQL functions or LOB columns.

**reference_partition_desc**  Use this optional clause to specify partition names and to define the physical and storage characteristics of the partition. The subclauses of the table_partition_description have the same behavior as described for range partitions in table_partition_description on page 16-71.

If you specify this clause when creating a reference-partitioned child table whose parent is an interval-partitioned table, then the partition descriptors are used for the child table's non-interval partitions. Partition descriptors cannot be specified for interval partitions.

**Restrictions on Reference Partitioning**  Reference partitioning is subject to the restrictions listed in "Restrictions on Partitioning in General" on page 16-68. The following additional restrictions apply:

- Restrictions for reference partitioning are derived from the partitioning strategy of the parent table.
- You cannot specify this clause for an index-organized table, an external table, or a domain index storage table.
- The parent table can be partitioned by reference, but constraint cannot be self-referential. The table being created cannot be partitioned based on a reference to itself.
- If **ROW MOVEMENT** is enabled for the parent table, it must also be enabled for the child table.

**See Also:** Oracle Database VLDB and Partitioning Guide for more information on partitioning by reference and "Reference Partitioning Example" on page 16-98

**system_partitioning**

Use this clause to create system partitions. System partitioning does not entail any partitioning key columns, nor do system partitions have any range or list bounds or hash algorithms. Rather, they provide a way to equipartition dependent tables such as nested table or domain index storage tables with partitioned base tables.
If you specify only `PARTITION BY SYSTEM`, then the database creates one partition with a system-generated name of the form `SYS_Pn`.

If you specify `PARTITION BY SYSTEM PARTITIONS integer`, then the database creates as many partitions as you specify in `integer`, which can range from 1 to 1024K-1.

The description of the partition takes the same syntax as reference partitions, so they share the `reference_partition_desc`. You can specify additional partition attributes with the `reference_partition_desc` syntax. However, within the `table_partition_description`, you cannot specify the `OVERFLOW` clause.

**Restrictions on System Partitioning**

System partitioning is subject to the following restrictions:

- You cannot system partition an index-organized table or a table that is part of a cluster.
- Composite partitioning is not supported with system partitioning.
- You cannot split a system partition.
- You cannot specify system partitioning in a `CREATE TABLE ... AS SELECT` statement.
- To insert data into a system-partitioned table using an `INSERT INTO ... AS subquery` statement, you must use partition-extended syntax to specify the partition into which the values returned by the subquery will be inserted.

**See Also:** Refer to *Oracle Database Data Cartridge Developer’s Guide* for information on the uses for system partitioning and "References to Partitioned Tables and Indexes" on page 2-128

---

**attribute_clustering_clause**

---

**Note:** The `attribute_clustering_clause` is available starting with Oracle Database 12c Release 1 (12.1.0.2).

Use this clause to enable the table for attribute clustering. Attribute clustering lets you cluster data in close physical proximity based on the content of specified columns.

Attribute clustering can be based only on columns in `table` or on joined values from other tables. The latter is called join attribute clustering.

**See Also:** *Oracle Database Data Warehousing Guide* for more information on attribute clustering

---

**clustering_join**

Use this clause to specify join attribute clustering. Use the `JOIN` clause to specify the joined values from other tables on which to base the attribute clustering. You can specify a maximum of four `JOIN` clauses.

---

**cluster_clause**

Use this clause to specify the type of ordering to use for the table: linear ordering or interleaved ordering. If you do not specify the `LINEAR` or `INTERLEAVED` keyword, then the default is `LINEAR`.

**BY LINEAR ORDER**

Use this clause to specify linear ordering. This type of ordering stores data according to the order of the specified columns. If you specify this clause,
then you can specify only one clustering column group, which can contain at most 10 columns.

**BY INTERLEAVED ORDER** Use this clause to specify interleaved ordering. This type of ordering uses a special multidimensional clustering technique, similar to z-ordering, that permits multicolunm clustering. If you specify this clause, then you can specify at most four clustering column groups, with a maximum of 40 columns across all groups.

**clustering_columns**
Use this clause to specify one or more clustering column groups.

**clustering_column_group**
Use this clause to specify one or more columns to be included in the clustering column group.

**clustering_when**
Use these clauses to allow or disallow attribute clustering during direct-path insert operations and data movement operations.

**ON LOAD** Specify **YES ON LOAD** to allow, or **NO ON LOAD** to disallow, attribute clustering during direct-path inserts (serial or parallel) resulting either from an **INSERT** or a **MERGE** operation. The default is **NO ON LOAD**.

**ON DATA MOVEMENT** Specify **YES ON DATA MOVEMENT** to allow, or **NO ON DATA MOVEMENT** to disallow, attribute clustering for data movement that occurs during the following operations:

- Data redefinition using the **DBMS_REDEFINITION** package
- Table partition maintenance operations that are specified by the following clauses of **ALTER TABLE**: **coalesce_table, merge_table_partitions, move_table_partition, and split_table_partition**

The default is **NO ON DATA MOVEMENT**.

**zonemap_clause**
Use this clause to create a zone map on the table. The zone map tracks the columns specified in the **clustering_columns** clause.

- Specify **WITH MATERIALIZED ZONEMAP** to create a zone map. For **zonemap_name**, specify the name of the zone map to be created. If you omit **zonemap_name**, then the name of the zone map is **ZMAP$_table$**.
- Specify **WITHOUT MATERIALIZED ZONEMAP** to not create a zone map. This is the default.

If you subsequently drop the table or use the **ALTER TABLE** statement to **DROP CLUSTERING** or **MODIFY CLUSTERING ... WITHOUT MATERIALIZED ZONEMAP**, then the zone map will be dropped.

**See Also:** [CREATE MATERIALIZED ZONEMAP](#) on page 15-41 for more information on zone maps

**Restrictions on Attribute Clustering** The following restrictions apply to attribute clustering:

- Attribute clustering is not supported for temporary tables or external tables.
The table being created must be a heap-organized table. However, tables specified in the `clustering_join` clause can be heap-organized or index-organized tables.

Clustering columns must be of a scalar data type and cannot be encrypted.

If you specify `BY LINEAR ORDER`, then you can specify only one clustering column group, which can contain at most 10 columns.

If you specify `BY INTERLEAVED ORDER`, then you can specify at most four clustering column groups, with a maximum of 40 columns across all groups.

For join attribute clustering:
- The number of dimension tables cannot exceed four.
- The join to the table or tables providing the attribute clustering columns must be on a unique key or primary key column to avoid row duplication.

Attribute clustering will not order rows that are inserted using `MERGE` statements or multitable insert operations.

**CACHE | NOCACHE | CACHE READS**

Use these clauses to indicate how Oracle Database should store blocks in the buffer cache. For LOB storage, you can specify `CACHE`, `NOCACHE`, or `CACHE READS`. For other types of storage, you can specify only `CACHE` or `NOCACHE`.

If you omit these clauses, then:

- In a `CREATE TABLE` statement, `NOCACHE` is the default.
- In an `ALTER TABLE` statement, the existing value is not changed.

The behavior of `CACHE` and `NOCACHE` described in this section does not apply when Oracle Database chooses to use direct reads or to perform table scans using parallel query.

**CACHE** For data that is accessed frequently, this clause indicates that the blocks retrieved for this table are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables.

**See Also:** Oracle Database Concepts for more information on how the database maintains the least recently used (LRU) list

As a parameter in the `LOB_storage_clause`, `CACHE` specifies that the database places LOB data values in the buffer cache for faster access. The database evaluates this parameter in conjunction with the `logging_clause`. If you omit this clause, then the default value for both BasicFiles and SecureFiles LOBs is `NOCACHE LOGGING`.

**Restriction on CACHE** You cannot specify `CACHE` for an index-organized table. However, index-organized tables implicitly provide `CACHE` behavior.

**NOCACHE** For data that is not accessed frequently, this clause indicates that the blocks retrieved for this table are placed at the least recently used end of the LRU list in the buffer cache when a full table scan is performed. `NOCACHE` is the default for LOB storage.

As a parameter in the `LOB_storage_clause`, `NOCACHE` specifies that the LOB values are not brought into the buffer cache. `NOCACHE` is the default for LOB storage.

**Restriction on NOCACHE** You cannot specify `NOCACHE` for an index-organized table.
CACHE READS  CACHE READS applies only to LOB storage. It specifies that LOB values are brought into the buffer cache only during read operations but not during write operations.

logging_clause  Use this clause to indicate whether the storage of data blocks should be logged or not.

See Also:  logging_clause on page 8-38 for a description of the logging_clause when specified as part of LOB_parameters

RESULT_CACHE Clause
Use this clause to determine whether the results of statements or query blocks that name this table are considered for storage in the result cache. Two modes of result caching are available:

- DEFAULT: Result caching is not determined at the table level. The query is considered for result caching if the RESULT_CACHE_MODE initialization parameter is set to FORCE, or if that parameter is set to MANUAL and the RESULT_CACHE hint is specified in the query. This is the default if you omit this clause.

- FORCE: If all tables names in the query have this setting, then the query is always considered for caching unless the NO_RESULT_CACHE hint is specified for the query. If one or more tables named in the query are set to DEFAULT, then the effective table annotation for that query is considered to be DEFAULT, with the semantics described above.

You can query the RESULT_CACHE column of the DBA_, ALL_, and USER_TABLES data dictionary views to learn the result cache mode of the table.

The RESULT_CACHE and NO_RESULT_CACHE SQL hints take precedence over these result cache table annotations and the RESULT_CACHE_MODE initialization parameter. The RESULT_CACHE_MODE setting of FORCE in turn takes precedence over this table annotation clause.

Note:  The RESULT_CACHE_MODE setting of FORCE is not recommended, as it can cause significant performance and latching overhead, as database and clients will try to cache all queries.

See Also:
- Oracle Call Interface Programmer’s Guide and Oracle Database Concepts for general information about result caching
- Oracle Database Performance Tuning Guide for information about using this clause
- Oracle Database Reference for information about the RESULT_CACHE_MODE initialization parameter and the *_TABLES data dictionary views
- "RESULT_CACHE Hint" on page 2-113 and "NO_RESULT_CACHE Hint" on page 2-102 for information about the hints

parallel_clause
The parallel_clause lets you parallelize creation of the table and set the default degree of parallelism for queries and the DML INSERT, UPDATE, DELETE, and MERGE after table creation.
**NOPARALLEL** Specify `NOPARALLEL` for serial execution. This is the default.

**PARALLEL** Specify `PARALLEL` if you want Oracle to select a degree of parallelism equal to the number of CPUs available on all participating instances times the value of the `PARALLEL_THREADS_PER_CPU` initialization parameter.

**PARALLEL integer** Specification of `integer` indicates the degree of parallelism, which is the number of parallel threads used in the parallel operation. Each parallel thread may use one or two parallel execution servers. Normally Oracle calculates the optimum degree of parallelism, so it is not necessary for you to specify `integer`.

See Also: `parallel_clause` on page 8-41 for more information on this clause

**NOROWDEPENDENCIES | ROWDEPENDENCIES**
This clause lets you specify whether `table` will use row-level dependency tracking. With this feature, each row in the table has a system change number (SCN) that represents a time greater than or equal to the commit time of the last transaction that modified the row. You cannot change this setting after `table` is created.

**ROWDEPENDENCIES** Specify `ROWDEPENDENCIES` if you want to enable row-level dependency tracking. This setting is useful primarily to allow for parallel propagation in replication environments. It increases the size of each row by 6 bytes.

Restriction on the ROWDEPENDENCIES Clause  Oracle does not support table compression for tables that use row-level dependency tracking. If you specify both the `ROWDEPENDENCIES` clause and the `table_compression` clause, then the `table_compression` clause is ignored. To remove the `ROWDEPENDENCIES` attribute, you must redefine the table using the `DBMS_REDEFINITION` package or recreate the table.

**NOROWDEPENDENCIES** Specify `NOROWDEPENDENCIES` if you do not want `table` to use the row-level dependency tracking feature. This is the default.

See Also: `Oracle Database Advanced Replication` for information about the use of row-level dependency tracking in replication environments

**enable_disable_clause**
The `enable_disable_clause` lets you specify whether Oracle Database should apply a constraint. By default, constraints are created in `ENABLE VALIDATE` state.

Restrictions on Enabling and Disabling Constraints  Enabling and disabling constraints are subject to the following restrictions:

- To enable or disable any integrity constraint, you must have defined the constraint in this or a previous statement.
- You cannot enable a foreign key constraint unless the referenced unique or primary key constraint is already enabled.

---

Note: The syntax of the `parallel_clause` supersedes syntax appearing in earlier releases of Oracle. Superseded syntax is still supported for backward compatibility but may result in slightly different behavior from that documented.
In the `index_properties` clause of the `using_index_clause`, the `INDEXTYPE IS ...` clause is not valid in the definition of a constraint.

See Also: `constraint` on page 8-4 for more information on constraints and "Creating a Table: ENABLE/DISABLE Examples" on page 16-92

**ENABLE Clause** Use this clause if you want the constraint to be applied to the data in the table. This clause is described fully in "ENABLE Clause" on page 8-16 in the documentation on constraints.

**DISABLE Clause** Use this clause if you want to disable the integrity constraint. This clause is described fully in "DISABLE Clause" on page 8-16 in the documentation on constraints.

**UNIQUE** The `UNIQUE` clause lets you enable or disable the unique constraint defined on the specified column or combination of columns.

**PRIMARY KEY** The `PRIMARY KEY` clause lets you enable or disable the primary key constraint defined on the table.

**CONSTRAINT** The `CONSTRAINT` clause lets you enable or disable the integrity constraint named `constraint_name`.

**KEEP | DROP INDEX** This clause lets you either preserve or drop the index Oracle Database has been using to enforce a unique or primary key constraint.

**Restriction on Preserving and Dropping Indexes** You can specify this clause only when disabling a unique or primary key constraint.

**using_index_clause** The `using_index_clause` lets you specify an index for Oracle Database to use to enforce a unique or primary key constraint, or lets you instruct the database to create the index used to enforce the constraint. This clause is discussed fully in `using_index_clause` on page 8-17 in the documentation on constraints.

See Also:
- `CREATE INDEX` on page 14-73 for a description of `index_attributes`, the `global_partitioned_index` and `local_partitioned_index` clauses, `NOSORT`, and the `logging_clause` in relation to indexes
- `constraint` on page 8-4 for information on the `using_index_clause` and on `PRIMARY KEY` and `UNIQUE` constraints
- "Explicit Index Control Example" on page 8-26 for an example of using an index to enforce a constraint

**CASCADE** Specify `CASCADE` to disable any integrity constraints that depend on the specified integrity constraint. To disable a primary or unique key that is part of a referential integrity constraint, you must specify this clause.

**Restriction on CASCADE** You can specify `CASCADE` only if you have specified `DISABLE`.

**row_movement_clause** The `row_movement_clause` lets you specify whether the database can move a table row. It is possible for a row to move, for example, during table compression or an update operation on partitioned data.
Caution: If you need static rowids for data access, then do not enable row movement. For a normal (heap-organized) table, moving a row changes the rowid of the row. For a moved row in an index-organized table, the logical rowid remains valid, although the physical guess component of the logical rowid becomes inaccurate.

- Specify `ENABLE` to allow the database to move a row, thus changing the rowid.
- Specify `DISABLE` if you want to prevent the database from moving a row, thus preventing a change of rowid.

If you omit this clause, then the database disables row movement.

Restriction on Row Movement You cannot specify this clause for a nonpartitioned index-organized table.

`flashback_archive_clause`

You must have the `FLASHBACK ARCHIVE` object privilege on the specified flashback data archive to specify this clause. Use this clause to enable or disable historical tracking for the table.

- Specify `FLASHBACK ARCHIVE` to enable tracking for the table. You can specify `flashback_archive` to designate a particular flashback data archive for this table. The flashback data archive you specify much already exist.

  If you omit `flashback_archive`, then the database uses the default flashback data archive designated for the system. If no default flashback data archive has been designated for the system, then you must specify `flashback_archive`.

- Specify `NO FLASHBACK ARCHIVE` to disable tracking for the table. This is the default.

Restrictions on `flashback_archive_clause` Flashback data archives are subject to the following restrictions:

- You cannot specify this clause for a nested table, clustered table, temporary table, remote table, or external table.
- You cannot specify this clause for a table compressed with Hybrid Columnar Compression.
- The table for which you are specifying this clause cannot contain any `LONG` or nested table columns.
- If you specify this clause and subsequently copy the table to a different database—using the export and import utilities or the transportable tablespace feature—then the copied table will not be enabled for tracking and the archived data for the original table will not be available for the copied table.

See Also:

- Oracle Database Development Guide for general information on using flashback data archives
- `ALTER FLASHBACK ARCHIVE` on page 10-103 for information on changing the quota and retention attributes of the flashback data archive, as well as adding or changing tablespace storage for the flashback data archive
**ROW ARCHIVAL**

Specify this clause to enable table for row archival. This clause lets you implement In-Database Archiving, which allows you to designate table rows as active or archived. You can then perform queries on only the active rows within the table.

When you specify this clause, a hidden column ORA_ARCHIVE_STATE is created in the table. The column is of data type VARCHAR2. You can specify a value of 0 or 1 for this column to indicate whether a row is active (0) or archived (1). If you do not specify a value for ORA_ARCHIVE_STATE when inserting data into the table, then the value is set to 0.

- If ROW_ARCHIVE_VISIBILITY = ACTIVE for the session, then the database will consider only active rows when performing queries on the table.
- If ROW_ARCHIVE_VISIBILITY = ALL for the session, then the database will consider all rows when performing queries on the table.

**See Also:**
- The `ALTER SESSION ROW ARCHIVAL VISIBILITY` clause on page 11-70 to learn how to configure row archival visibility for a session
- The `ALTER TABLE [NO] ROW ARCHIVAL` clause on page 12-52 to learn how to enable or disable an existing table for row archival
- *Oracle Database VLDB and Partitioning Guide* for more information on In-Database Archiving

**AS subquery**

Specify a subquery to determine the contents of the table. The rows returned by the subquery are inserted into the table upon its creation.

For object tables, subquery can contain either one expression corresponding to the table type, or the number of top-level attributes of the table type. Refer to *SELECT* on page 19-4 for more information.

If subquery returns the equivalent of part or all of an existing materialized view, then the database may rewrite the query to use the materialized view in place of one or more tables specified in subquery.

**See Also:** *Oracle Database Data Warehousing Guide* for more information on materialized views and query rewrite

Oracle Database derives data types and lengths from the subquery. Oracle Database follows the following rules for integrity constraints and other column and table attributes:

- Oracle Database automatically defines on columns in the new table any NOT NULL constraints that have a state of NOT DEFERRABLE and VALIDATE, and were explicitly created on the corresponding columns of the selected table if the subquery selects the column rather than an expression containing the column. If any rows violate the constraint, then the database does not create the table and returns an error.

- NOT NULL constraints that were implicitly created by Oracle Database on columns of the selected table (for example, for primary keys) are not carried over to the new table.
In addition, primary keys, unique keys, foreign keys, check constraints, partitioning criteria, indexes, and column default values are not carried over to the new table.

If the selected table is partitioned, then you can choose whether the new table will be partitioned the same way, partitioned differently, or not partitioned. Partitioning is not carried over to the new table. Specify any desired partitioning as part of the CREATE TABLE statement before the AS subquery clause.

A column that is encrypted using Transparent Data Encryption in the selected table will not be encrypted in the new table unless you define the column in the new table as encrypted at create time.

Note: Oracle recommends that you encrypt sensitive columns before populating them with data. This will avoid creating clear text copies of sensitive data.

If each column returned by subquery has a column name or is an expression with a specified column alias, then you can omit the columns from the table definition entirely. In this case, the names of the columns of table are the same as the columns in subquery. The exception is creating an index-organized table, for which you must specify the columns in the table definition because you must specify a primary key column.

You can use subquery in combination with the TO_LOB function to convert the values in a LONG column in another table to LOB values in a column of the table you are creating.

See Also:
- Oracle Database SecureFiles and Large Objects Developer’s Guide for a discussion of why and when to copy LONG data to a LOB
- "Conversion Functions" on page 7-6 for a description of how to use the TO_LOB function
- SELECT on page 19-4 for more information on the order_by_clause
- Oracle Database SQL Tuning Guide for information on statistics gathering when using the AS subquery clause

parallel_clause If you specify the parallel_clause in this statement, then the database will ignore any value you specify for the INITIAL storage parameter and will instead use the value of the NEXT parameter.

See Also: storage_clause on page 8-46 for information on these parameters

ORDER BY The ORDER BY clause lets you order rows returned by the subquery.

When specified with CREATE TABLE, this clause does not necessarily order data across the entire table. For example, it does not order across partitions. Specify this clause if you intend to create an index on the same key as the ORDER BY key column. Oracle Database will cluster data on the ORDER BY key so that it corresponds to the index key.

Restrictions on the Defining Query of a Table The table query is subject to the following restrictions:
■ The number of columns in the table must equal the number of expressions in the subquery.

■ The column definitions can specify only column names, default values, and integrity constraints, not data types.

■ You cannot define a foreign key constraint in a CREATE TABLE statement that contains AS subquery unless the table is reference partitioned and the constraint is the table's partitioning referential constraint. In all other cases, you must create the table without the constraint and then add it later with an ALTER TABLE statement.

**object_table**

The **OF** clause lets you explicitly create an **object table** of type **object_type**. The columns of an object table correspond to the top-level attributes of type **object_type**. Each row will contain an object instance, and each instance will be assigned a unique, system-generated object identifier when a row is inserted. If you omit **schema**, then the database creates the object table in your own schema.

Object tables, as well as **XMLType** tables, object views, and **XMLType** views, do not have any column names specified for them. Therefore, Oracle defines a system-generated pseudocolumn **OBJECT_ID**. You can use this column name in queries and to create object views with the **WITH OBJECT IDENTIFIER** clause.

**See Also:** "Object Column and Table Examples" on page 16-100

**object_table_substitution**

Use the **object_table_substitution** clause to specify whether row objects corresponding to subtypes can be inserted into this object table.

**NOT SUBSTITUTABLE AT ALL LEVELS**  **NOT SUBSTITUTABLE AT ALL LEVELS** indicates that the object table being created is not substitutable. In addition, substitution is disabled for all embedded object attributes and elements of embedded nested tables and arrays. The default is **SUBSTITUTABLE AT ALL LEVELS**.

**See Also:**

■ **CREATE TYPE** on page 17-3 for more information about creating object types

■ "User-Defined Types" on page 2-33, "About User-Defined Functions" on page 7-438, "About SQL Expressions" on page 5-1, **CREATE TYPE** on page 17-3, and *Oracle Database Object-Relational Developer’s Guide* for more information about using **REF** types

**object_properties**

The properties of object tables are essentially the same as those of relational tables. However, instead of specifying columns, you specify attributes of the object.

For **attribute**, specify the qualified column name of an item in an object.

**oid_clause**

The **oid_clause** lets you specify whether the object identifier of the object table should be system generated or should be based on the primary key of the table. The default is **SYSTEM GENERATED**.

**Restrictions on the oid_clause**  This clause is subject to the following restrictions:
You cannot specify **OBJECT IDENTIFIER IS PRIMARY KEY** unless you have already specified a **PRIMARY KEY** constraint for the table.

You cannot specify this clause for a nested table.

---

**Note:** A primary key object identifier is locally unique but not necessarily globally unique. If you require a globally unique identifier, then you must ensure that the primary key is globally unique.

---

**oid_index_clause**

This clause is relevant only if you have specified the **oid_clause** as **SYSTEM GENERATED**. It specifies an index, and optionally its storage characteristics, on the hidden object identifier column.

For **index**, specify the name of the index on the hidden system-generated object identifier column. If you omit **index**, then the database generates a name.

**physical_properties and table_properties**

The semantics of these clauses are documented in the corresponding sections under relational tables. See **physical_properties** on page 16-43 and **table_properties** on page 16-56.

**XMLType_table**

Use the **XMLType_table** syntax to create a table of data type **XMLType**. Most of the clauses used to create an **XMLType** table have the same semantics that exist for object tables. The clauses specific to **XMLType** tables are described in this section.

Object tables, as well as **XMLType** tables, object views, and **XMLType** views, do not have any column names specified for them. Therefore, Oracle defines a system-generated pseudocolumn **OBJECT_ID**. You can use this column name in queries and to create object views with the **WITH OBJECT IDENTIFIER** clause.

**XMLSchema_spec**

This clause lets you specify the URL of a registered XMLSchema, either in the **XMLSCHEMA** clause or as part of the **ELEMENT** clause, and an XML element name.

You must specify an element, although the XMLSchema URL is optional. If you do specify an XMLSchema URL, then you must already have registered the XMLSchema using the **DBMS_XMLSCHEMA** package.

The optional **STORE ALL VARRAYS AS** clause lets you specify how all varrays in the **XMLType** table or column are to be stored.

- **STORE ALL VARRAYS AS LOBS** indicates that all varrays are to be stored as LOBs.
- **STORE ALL VARRAYS AS TABLES** indicates that all varrays are to be stored as tables.

The optional **ALLOW | DISALLOW** clauses are valid only if you have specified **BINARY XML** storage.

- **ALLOW NONSCHEMA** indicates that non-schema-based documents can be stored in the **XMLType** column.
- **DISALLOW NONSCHEMA** indicates that non-schema-based documents cannot be stored in the **XMLType** column. This is the default.
- **ALLOW ANYSCHEMA** indicates that any schema-based document can be stored in the **XMLType** column.
CREATE TABLE

■ DISALLOW ANYSCHEMA indicates that any schema-based document cannot be stored in the XMLType column. This is the default.

■ "XMLType Table Examples" on page 16-94

Examples

Creating Tables: General Examples

This statement shows how the employees table owned by the sample human resources (hr) schema was created. A hypothetical name is given to the table and constraints so that you can duplicate this example in your test database:

```
CREATE TABLE employees_demo
(   employee_id    NUMBER(6)
,   first_name     VARCHAR2(20)
,   last_name      VARCHAR2(25)
   CONSTRAINT emp_last_name_nn_demo NOT NULL
,   email          VARCHAR2(25)
   CONSTRAINT emp_email_nn_demo NOT NULL
,   phone_number   VARCHAR2(20)
,   hire_date      DATE  DEFAULT SYSDATE
   CONSTRAINT emp_hire_date_nn_demo  NOT NULL
,   job_id         VARCHAR2(10)
   CONSTRAINT emp_job_nn_demo NOT NULL
,   salary         NUMBER(8,2)
   CONSTRAINT emp_salary_nn_demo NOT NULL
,   commission_pct NUMBER(2,2)
,   manager_id     NUMBER(6)
,   department_id  NUMBER(4)
,   dn             VARCHAR2(300)
   CONSTRAINT emp_salary_min_demo
       CHECK (salary > 0)
,   email          VARCHAR2(25)
   CONSTRAINT emp_email_uk_demo
       UNIQUE (email)
) ;
```

This table contains twelve columns. The employee_id column is of data type NUMBER. The hire_date column is of data type DATE and has a default value of SYSDATE. The last_name column is of type VARCHAR2 and has a NOT NULL constraint, and so on.

Creating a Table: Storage Example  To define the same employees_demo table in the example tablespace with a small storage capacity, issue the following statement:

```
CREATE TABLE employees_demo
(   employee_id    NUMBER(6)
,   first_name     VARCHAR2(20)
,   last_name      VARCHAR2(25)
   CONSTRAINT emp_last_name_nn_demo NOT NULL
,   email          VARCHAR2(25)
   CONSTRAINT emp_email_nn_demo NOT NULL
,   phone_number   VARCHAR2(20)
,   hire_date      DATE  DEFAULT SYSDATE
```
**Creating a Table with a DEFAULT ON NULL Column Value: Example**

The following statement creates a table `myemp`, which can be used to store employee data. The `department_id` column is defined with a DEFAULT ON NULL column value of 50. Therefore, if a subsequent INSERT statement attempts to assign a NULL value to `department_id`, then the value of 50 will be assigned instead.

```sql
CREATE TABLE myemp (employee_id number, last_name varchar2(25),
department_id NUMBER DEFAULT ON NULL 50 NOT NULL);
```

In the `employees` table, `employee_id` 178 has a NULL value for `department_id`:

```sql
SELECT employee_id, last_name, department_id
FROM employees
WHERE department_id IS NULL;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>DEPARTMENT_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>178</td>
<td>Grant</td>
<td></td>
</tr>
</tbody>
</table>

Populate the `myemp` table with the `employee_id`, `last_name`, and `department_id` column data from the `employees` table:

```sql
INSERT INTO myemp (employee_id, last_name, department_id)
(SELECT employee_id, last_name, department_id from employees);
```

In the `myemp` table, `employee_id` 178 has a value of 50 for `department_id`:

```sql
SELECT employee_id, last_name, department_id
FROM myemp
WHERE employee_id = 178;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>DEPARTMENT_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>178</td>
<td>Grant</td>
<td>50</td>
</tr>
</tbody>
</table>

**Creating a Table with an Identity Column: Examples**

The following statement creates a table `t1` with an identity column `id`. The sequence generator will always assign increasing integer values to `id`, starting with 1.

```sql
CREATE TABLE t1 (id NUMBER GENERATED AS IDENTITY);
```

The following statement creates a table `t2` with an identity column `id`. The sequence generator will, by default, assign increasing integer values to `id` in increments of 10 starting with 100.
CREATE TABLE t2 (id NUMBER GENERATED BY DEFAULT AS IDENTITY (START WITH 100 INCREMENT BY 10));

Creating a Table: Temporary Table Example  The following statement creates a temporary table `today_sales` for use by sales representatives in the sample database. Each sales representative session can store its own sales data for the day in the table. The temporary data is deleted at the end of the session.

```sql
CREATE GLOBAL TEMPORARY TABLE today_sales
  ON COMMIT PRESERVE ROWS
  AS SELECT * FROM orders WHERE order_date = SYSDATE;
```

Creating a Table with Deferred Segment Creation: Example  The following statement creates a table with deferred segment creation. Oracle Database will not create a segment for the data of this table until data is inserted into the table:

```sql
CREATE TABLE later (col1 NUMBER, col2 VARCHAR2(20))
  SEGMENT CREATION DEFERRED;
```

Substitutable Table and Column Examples  The following statements create a type hierarchy, which can be used to create a substitutable table. Type `employee_t` inherits the name and ssn attributes from type `person_t` and in addition has department_id and salary attributes. Type `part_time_emp_t` inherits all of the attributes from `employee_t` and, through `employee_t`, those of `person_t` and in addition has a num_hrs attribute. Type `part_time_emp_t` is final by default, so no further subtypes can be created under it.

```sql
CREATE TYPE person_t AS OBJECT (name VARCHAR2(100), ssn NUMBER)
  NOT FINAL;
/

CREATE TYPE employee_t UNDER person_t
  (department_id NUMBER, salary NUMBER) NOT FINAL;
/

CREATE TYPE part_time_emp_t UNDER employee_t (num_hrs NUMBER);
/

The following statement creates a substitutable table from the `person_t` type:

```sql
CREATE TABLE persons OF person_t;
```

The following statement creates a table with a substitutable column of type `person_t`:

```sql
CREATE TABLE books (title VARCHAR2(100), author person_t);
```

When you insert into `persons` or `books`, you can specify values for the attributes of `person_t` or any of its subtypes. Examples of insert statements appear in "Inserting into a Substitutable Tables and Columns: Examples" on page 18-75.

You can extract data from such tables using built-in functions and conditions. For examples, see the functions `TREAT` on page 7-385 and `SYS_TYPEID` on page 7-346, and the "IS OF type Condition" condition on page 6-34.

Creating a Table: Parallelism Examples  The following statement creates a table using an optimum number of parallel execution servers to scan `employees` and to populate `dept_80`:

```sql
CREATE TABLE dept_80
  PARALLEL
  AS SELECT * FROM employees
```
WHERE department_id = 80;

Using parallelism speeds up the creation of the table, because the database uses parallel execution servers to create the table. After the table is created, querying the table is also faster, because the same degree of parallelism is used to access the table.

The following statement creates the same table serially. Subsequent DML and queries on the table will also be serially executed.

```sql
CREATE TABLE dept_80
    AS SELECT * FROM employees
    WHERE department_id = 80;
```

**Creating a Table: ENABLE/DISABLE Examples**  
The following statement shows how the sample table *departments* was created. The example defines a `NOT NULL` constraint, and places it in ENABLE VALIDATE state. A hypothetical name is given to the table so that you can duplicate this example in your test database:

```sql
CREATE TABLE departments_demo
    ( department_id    NUMBER(4)
    , department_name  VARCHAR2(30)
        CONSTRAINT dept_name_nn  NOT NULL
    , manager_id       NUMBER(6)
    , location_id      NUMBER(4)
    , dn               VARCHAR2(300)
    ) ;
```

The following statement creates the same *departments_demo* table but also defines a disabled primary key constraint:

```sql
CREATE TABLE departments_demo
    ( department_id    NUMBER(4)   PRIMARY KEY DISABLE
    , department_name  VARCHAR2(30)
        CONSTRAINT dept_name_nn  NOT NULL
    , manager_id       NUMBER(6)
    , location_id      NUMBER(4)
    , dn               VARCHAR2(300)
    ) ;
```

**Nested Table Example**  
The following statement shows how the sample table *pm.print_media* was created with a nested table column *ad_textdocs_ntab*:

```sql
CREATE TABLE print_media
    ( product_id        NUMBER(6)
    , ad_id             NUMBER(6)
    , ad_composite      BLOB
    , ad_sourcetext     CLOB
    , ad_finaltext      CLOB
    , ad_fltextn        NCLOB
    , ad_textdocs_ntab  textdoc_tab
    , ad_photo          BLOB
    , ad_graphic        BFILE
    , ad_header         adheader_typ
    ) NESTED TABLE ad_textdocs_ntab STORE AS textdocs_nestedtab;
```

**Creating a Table: Multilevel Collection Example**  
The following example shows how an account manager might create a table of customers using two levels of nested tables:

```sql
CREATE TYPE phone AS OBJECT (telephone NUMBER);
/
```
CREATE TYPE phone_list AS TABLE OF phone;
/
CREATE TYPE my_customers AS OBJECT {
    cust_name VARCHAR2(25),
    phones phone_list);
/
CREATE TABLE business_contacts ( {
    company_name VARCHAR2(25),
    company_reps customer_list)
    NESTED TABLE company_reps STORE AS outer_ntab
    (NESTED TABLE phones STORE AS inner_ntab);

The following variation of this example shows how to use the COLUMN_VALUE keyword if the inner nested table has no column or attribute name:

CREATE TYPE phone AS TABLE OF NUMBER;
/
CREATE TYPE phone_list AS TABLE OF phone;
/
CREATE TABLE my_customers ( {
    name VARCHAR2(25),
    phone_numbers phone_list)
    NESTED TABLE phone_numbers STORE AS outer_ntab
    (NESTED TABLE COLUMN_VALUE STORE AS inner_ntab);

Creating a Table: LOB Column Example  The following statement is a variation of the statement that created the pm.print_media table with some added LOB storage characteristics:

CREATE TABLE print_media_new
( product_id        NUMBER(6)
, ad_id             NUMBER(6)
, ad_composite      BLOB
, ad_sourcetext     CLOB
, ad_finaltext      CLOB
, ad_fltextn        NCLOB
, ad_textdocs_ntab  textdoc_tab
, ad_photo          BLOB
, ad_graphic        BFILE
, ad_header         adheader_typ
) NESTED TABLE ad_textdocs_ntab STORE AS textdocs_nestedtab_new
LOB (ad_sourcetext, ad_finaltext) STORE AS
|TABLESPACES example
|STORAGE (INITIAL 6144)
|CHUNK 4000
|NOCACHE LOGGING);

In the example, the database rounds the value of CHUNK up to 4096 (the nearest multiple of the block size of 2048).

Index-Organized Table Example  The following statement is a variation of the sample table hr.countries, which is index organized:

CREATE TABLE countries_demo
( country_id      CHAR(2)
, constraint country_id_nn_demo NOT NULL

External Table Example  The following statement creates an external table that represents a subset of the sample table hr.departments. The TYPE clause specifies that the access driver type for the table is ORACLE_LOADER. The ACCESS PARAMETERS() clause specifies parameter values for the ORACLE_LOADER access driver. These parameters are shown in italics and form the opaque_format_spec. The syntax for opaque_format_spec depends on the access driver type and is outside the scope of this document. Refer to Oracle Database Utilities for details on the ORACLE_LOADER access driver and the opaque_format_spec syntax.

CREATE TABLE dept_external (  deptno     NUMBER(6),
  dname      VARCHAR2(20),
  loc        VARCHAR2(25) )
ORGANIZATION EXTERNAL
  (TYPE ORACLE_LOADER
    DEFAULT DIRECTORY admin
    ACCESS PARAMETERS  
      (RECORDS DELIMITED BY newline
       BADFILE 'ulcasel.bad'
       DISCARDFILE 'ulcasel.dis'
       LOGFILE 'ulcasel.log'
       SKIP 20
       FIELDS TERMINATED BY *"* OPTIONALLY ENCLOSED BY '"'
      (deptno     INTEGER EXTERNAL(6),
       dname      CHAR(20),
       loc        CHAR(25) )
    )
  )
LOCATION ('ulcasel.ctl')
REJECT LIMIT UNLIMITED;

See Also:  "Creating a Directory: Examples" on page 14-55 to see how the admin directory was created

XMLType Examples
This section contains brief examples of creating an XMLType table or XMLType column. For a more expanded version of these examples, refer to "Using XML in SQL Statements" on page F-8.

XMLType Table Examples  The following example creates a very simple XMLType table with one implicit binary XML column:

CREATE TABLE xwarehouses OF XMLTYPE;

See Also:  "Creating a Directory: Examples" on page 14-55 to see how the admin directory was created

XMLType Examples
This section contains brief examples of creating an XMLType table or XMLType column. For a more expanded version of these examples, refer to "Using XML in SQL Statements" on page F-8.

XMLType Table Examples  The following example creates a very simple XMLType table with one implicit binary XML column:

CREATE TABLE xwarehouses OF XMLTYPE;
The following example creates an XMLSchema-based table. The XMLSchema must already have been created (see “Using XML in SQL Statements” on page F-8 for more information):

```
CREATE TABLE xwarehouses OF XMLTYPE
    XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
    ELEMENT "Warehouse";
```

You can define constraints on an XMLSchema-based table, and you can also create indexes on XMLSchema-based tables, which greatly enhance subsequent queries. You can create object-relational views on XMLType tables, and you can create XMLType views on object-relational tables.

**See Also:**
- ”Using XML in SQL Statements” on page F-8 for an example of adding a constraint
- ”Creating an Index on an XMLType Table: Example” on page 14-97 for an example of creating an index
- ”Creating an XMLType View: Example” on page 17-27 for an example of creating an XMLType view

**XMLType Column Examples**  The following example creates a table with an XMLType column stored as a CLOB. This table does not require an XMLSchema, so the content structure is not predetermined:

```
CREATE TABLE xwarehouses {
    warehouse_id NUMBER,
    warehouse_spec XMLTYPE)
    XMLTYPE warehouse_spec STORE AS CLOB
    (TABLESPACE example
    STORAGE (INITIAL 6144)
    CHINK 4000
    NOCACHE LOGGING);
```

The following example creates a similar table, but stores XMLType data in an object relational XMLType column whose structure is determined by the specified schema:

```
CREATE TABLE xwarehouses {
    warehouse_id NUMBER,
    warehouse_spec XMLTYPE)
    XMLTYPE warehouse_spec STORE AS OBJECT RELATIONAL
    XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
    ELEMENT "Warehouse";
```

The following example creates another similar table with an XMLType column stored as a SecureFiles CLOB. This table does not require an XMLSchema, so the content structure is not predetermined. SecureFiles LOBs require a tablespace with automatic segment-space management, so the example uses the tablespace created in “Specifying Segment Space Management for a Tablespace: Example” on page 16-117.

```
CREATE TABLE xwarehouses {
    warehouse_id NUMBER,
    warehouse_spec XMLTYPE)
    XMLTYPE warehouse_spec STORE AS SECUREFILE CLOB
    (TABLESPACE auto_seg_ts
    STORAGE (INITIAL 6144)
    CACHE);
```
Partitioning Examples

**Range Partitioning Example**  The `sales` table in the sample schema `sh` is partitioned by range. The following example shows an abbreviated variation of the `sales` table. Constraints and storage elements have been omitted from the example.

```plaintext
CREATE TABLE range_sales
( prod_id        NUMBER(6),
  cust_id        NUMBER,
  time_id        DATE,
  channel_id     CHAR(1),
  promo_id       NUMBER(6),
  quantity_sold  NUMBER(3),
  amount_sold    NUMBER(10,2)
)
PARTITION BY RANGE (time_id)
(PARTITION SALES_Q1_1998 VALUES LESS THAN (TO_DATE('01-APR-1998','DD-MON-YYYY')),
 PARTITION SALES_Q2_1998 VALUES LESS THAN (TO_DATE('01-JUL-1998','DD-MON-YYYY')),
 PARTITION SALES_Q3_1998 VALUES LESS THAN (TO_DATE('01-OCT-1998','DD-MON-YYYY')),
 PARTITION SALES_Q4_1998 VALUES LESS THAN (TO_DATE('01-JAN-1999','DD-MON-YYYY')),
 PARTITION SALES_Q1_1999 VALUES LESS THAN (TO_DATE('01-APR-1999','DD-MON-YYYY')),
 PARTITION SALES_Q2_1999 VALUES LESS THAN (TO_DATE('01-JUL-1999','DD-MON-YYYY')),
 PARTITION SALES_Q3_1999 VALUES LESS THAN (TO_DATE('01-OCT-1999','DD-MON-YYYY')),
 PARTITION SALES_Q4_1999 VALUES LESS THAN (TO_DATE('01-JAN-2000','DD-MON-YYYY')),
 PARTITION SALES_Q1_2000 VALUES LESS THAN (TO_DATE('01-APR-2000','DD-MON-YYYY')),
 PARTITION SALES_Q2_2000 VALUES LESS THAN (TO_DATE('01-JUL-2000','DD-MON-YYYY')),
 PARTITION SALES_Q3_2000 VALUES LESS THAN (TO_DATE('01-OCT-2000','DD-MON-YYYY')),
 PARTITION SALES_Q4_2000 VALUES LESS THAN (MAXVALUE))
;
```

For information about partitioned table maintenance operations, see *Oracle Database VLDB and Partitioning Guide*.

**Interval Partitioning Example**  The following example creates a variation of the `oe.customers` table that is partitioned by interval on the `credit_limit` column. One range partition is created to establish the transition point. All of the original data in the table is within the bounds of the range partition. Then data is added that exceeds the range partition, and the database creates a new interval partition.

```plaintext
CREATE TABLE customers_demo
( customer_id number(6),
  cust_first_name varchar2(20),
  cust_last_name varchar2(20),
  credit_limit number(9,2))
PARTITION BY RANGE (credit_limit)
INTERVAL (1000)
(PARTITION p1 VALUES LESS THAN (5001));

INSERT INTO customers_demo
( select customer_id, cust_first_name, cust_last_name, credit_limit
  from customers);

Query the `USER_TAB_PARTITIONS` data dictionary view before the database creates the interval partition:

```sql
SELECT partition_name, high_value FROM user_tab_partitions
WHERE table_name = 'CUSTOMERS_DEMO';
```

<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>HIGH_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>----------------</td>
<td>-----------</td>
</tr>
</tbody>
</table>
```
P1 5001

Insert data into the table that exceeds the high value of the range partition:

```sql
INSERT INTO customers_demo
    VALUES (699, 'Fred', 'Flintstone', 5500);
```

Query the USER_TAB_PARTITIONS view again after the insert to learn the system-generated name of the interval partition created to accommodate the inserted data. (The system-generated name will vary for each session.)

```sql
SELECT partition_name, high_value FROM user_tab_partitions
WHERE table_name = 'CUSTOMERS_DEMO'
ORDER BY partition_name;
```

<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>HIGH_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>P1</td>
<td>5001</td>
</tr>
<tr>
<td>SYS_P44</td>
<td>6001</td>
</tr>
</tbody>
</table>

**List Partitioning Example**  The following statement shows how the sample table oe.customers might have been created as a list-partitioned table. Some columns and all constraints of the sample table have been omitted in this example.

```sql
CREATE TABLE list_customers
    ( customer_id             NUMBER(6)
    , cust_first_name         VARCHAR2(20)
    , cust_last_name          VARCHAR2(20)
    , cust_address            CUST_ADDRESS_TYP
    , nls_territory           VARCHAR2(30)
    , cust_email              VARCHAR2(40)
    ) PARTITION BY LIST (nls_territory) {
    PARTITION asia VALUES ('CHINA', 'THAILAND'),
    PARTITION europe VALUES ('GERMANY', 'ITALY', 'SWITZERLAND'),
    PARTITION west VALUES ('AMERICA'),
    PARTITION east VALUES ('INDIA'),
    PARTITION rest VALUES (DEFAULT));
```

**Partitioned Table with LOB Columns Example**  This statement creates a partitioned table print_media_demo with two partitions p1 and p2, and a number of LOB columns. The statement uses the sample table pm.print_media.

```sql
CREATE TABLE print_media_demo
    ( product_id NUMBER(6)
    , ad_id NUMBER(6)
    , ad_composite BLOB
    , ad_sourcetext CLOB
    , ad_finaltext CLOB
    , ad_fltextn NCLOB
    , ad_textdocs_ntab textdoc_tab
    , ad_photo BLOB
    , ad_graphic BFILE
    , ad_header adheader_typ
    ) NESTED TABLE ad_textdocs_ntab STORE AS textdocs_nestedtab_demo
    LOB (ad_composite, ad_photo, ad_finaltext)
    STORE AS(STORAGE (INITIAL 20M))
    PARTITION BY RANGE (product_id)
    (PARTITION p1 VALUES LESS THAN (3000) TABLESPACE tbs_01
    LOB (ad_composite, ad_photo)
    STORE AS (TABLESPACE tbs_02 STORAGE (INITIAL 10M))
    NESTED TABLE ad_textdocs_ntab STORE AS nt_p1 (TABLESPACE example),
```
CREATE TABLE

    PARTITION P2 VALUES LESS THAN (MAXVALUE)
    LOB (ad_composite, ad_finaltext)
    STORE AS SECUREFILE (TABLESPACE auto_seg_ts)
    NESTED TABLE ad_textdocs_ntab STORE AS nt_p2

    TABLESPACE tbs_03;

Partition p1 will be in tablespace tbs_01. The LOB data partitions for ad_composite and ad_photo will be in tablespace tbs_02. The LOB data partition for the remaining LOB columns will be in tablespace tbs_01. The storage attribute INITIAL is specified for LOB columns ad_composite and ad_photo. Other attributes will be inherited from the default table-level specification. The default LOB storage attributes not specified at the table level will be inherited from the tablespace tbs_02 for columns ad_composite and ad_photo and from tablespace tbs_01 for the remaining LOB columns. LOB index partitions will be in the same tablespaces as the corresponding LOB data partitions. Other storage attributes will be based on values of the corresponding attributes of the LOB data partitions and default attributes of the tablespace where the index partitions reside. The nested table partition for ad_textdocs_ntab will be stored as nt_p1 in tablespace example.

Partition p2 will be in the default tablespace tbs_03. The LOB data for ad_composite and ad_finaltext will be in tablespace auto_seg_ts as SecureFiles LOBs. The LOB data for the remaining LOB columns will be in tablespace tbs_01. The LOB index for columns ad_composite and ad_finaltext will be in tablespace auto_seg_ts. The LOB index for the remaining LOB columns will be in tablespace tbs_03. The nested table partition for ad_textdocs_ntab will be stored as nt_p2 in the default tablespace tbs_03.

Hash Partitioning Example  The sample table oe.product_information is not partitioned. However, you might want to partition such a large table by hash for performance reasons, as shown in this example. The tablespace names are hypothetical in this example.

CREATE TABLE hash_products

( product_id          NUMBER(6)   PRIMARY KEY
, product_name        VARCHAR2(50)
, product_description VARCHAR2(2000)
, category_id         NUMBER(2)
, weight_class        NUMBER(1)
, warranty_period     INTERVAL YEAR TO MONTH
, supplier_id         NUMBER(6)
, product_status      VARCHAR2(20)
, list_price          NUMBER(8,2)
, min_price           NUMBER(8,2)
, catalog_url         VARCHAR2(50)
, CONSTRAINT          product_status_lov_demo
    CHECK (product_status in ('orderable'
                                ,'planned'
                                ,'under development'
                                ,'obsolete'))
)
PARTITION BY HASH (product_id)
PARTITIONS 4
STORE IN (tbs_01, tbs_02, tbs_03, tbs_04);

Reference Partitioning Example  The next statement uses the hash_products partitioned table created in the preceding example. It creates a variation of the oe.order_items table that is partitioned by reference to the hash partitioning on the product id of hash_products. The resulting child table will be created with five
partitions. For each row of the child table `part_order_items`, the database evaluates
the foreign key value (`product_id`) to determine the partition number of the parent
table `hash_products` to which the referenced key belongs. The `part_order_items` row
is placed in its corresponding partition.

```
CREATE TABLE part_order_items
(
  order_id        NUMBER(12) PRIMARY KEY,
  line_item_id    NUMBER(3),
  product_id      NUMBER(6) NOT NULL,
  unit_price      NUMBER(8,2),
  quantity        NUMBER(8),
  CONSTRAINT product_id_fk
    FOREIGN KEY (product_id) REFERENCES hash_products(product_id))
PARTITION BY REFERENCE (product_id_fk);
```

**Composite-Partitioned Table Examples**  

The table created in the "Range Partitioning Example" on page 16-96 divides data by time of sale. If you plan to access recent data according to distribution channel as well as time, then composite partitioning might be more appropriate. The following example creates a copy of that `range_sales` table but specifies range-hash composite partitioning. The partitions with the most recent data are subpartitioned with both system-generated and user-defined subpartition names. Constraints and storage attributes have been omitted from the example.

```
CREATE TABLE composite_sales
( prod_id        NUMBER(6),
  cust_id        NUMBER,
  time_id        DATE,
  channel_id     CHAR(1),
  promo_id       NUMBER(6),
  quantity_sold  NUMBER(3),
  amount_sold    NUMBER(10,2)
)
PARTITION BY RANGE (time_id)
SUBPARTITION BY HASH (channel_id)
(PARTITION SALES_Q1_1998 VALUES LESS THAN (TO_DATE('01-APR-1998','DD-MON-YYYY'))),
PARTITION SALES_Q2_1998 VALUES LESS THAN (TO_DATE('01-JUL-1998','DD-MON-YYYY'))),
PARTITION SALES_Q3_1998 VALUES LESS THAN (TO_DATE('01-OCT-1998','DD-MON-YYYY'))),
PARTITION SALES_Q4_1998 VALUES LESS THAN (TO_DATE('01-JAN-1999','DD-MON-YYYY'))),
PARTITION SALES_Q1_1999 VALUES LESS THAN (TO_DATE('01-APR-1999','DD-MON-YYYY'))),
PARTITION SALES_Q2_1999 VALUES LESS THAN (TO_DATE('01-JUL-1999','DD-MON-YYYY'))),
PARTITION SALES_Q3_1999 VALUES LESS THAN (TO_DATE('01-OCT-1999','DD-MON-YYYY'))),
PARTITION SALES_Q4_1999 VALUES LESS THAN (TO_DATE('01-JAN-2000','DD-MON-YYYY'))),
PARTITION SALES_Q1_2000 VALUES LESS THAN (TO_DATE('01-APR-2000','DD-MON-YYYY'))),
PARTITION SALES_Q2_2000 VALUES LESS THAN (TO_DATE('01-JUL-2000','DD-MON-YYYY')))
SUBPARTITIONS 8,
PARTITION SALES_Q3_2000 VALUES LESS THAN (TO_DATE('01-OCT-2000','DD-MON-YYYY'))
  (SUBPARTITION ch_c,
   SUBPARTITION ch_i,
   SUBPARTITION ch_p,
   SUBPARTITION ch_s,
   SUBPARTITION ch_t),
PARTITION SALES_Q4_2000 VALUES LESS THAN (MAXVALUE)
  SUBPARTITIONS 4)
```

The following examples creates a partitioned table of customers based on the sample
table `oe.customers`. In this example, the table is partitioned on the `credit_limit`
column and list subpartitioned on the `nls_territory` column. The subpartition
template determines the subpartitioning of any subsequently added partitions, unless
you override the template by defining individual subpartitions. This composite
partitioning makes it possible to query the table based on a credit limit range within a specified region:

```
CREATE TABLE customers_part {
    customer_id        NUMBER(6),
    cust_first_name    VARCHAR2(20),
    cust_last_name     VARCHAR2(20),
    nls_territory      VARCHAR2(30),
    credit_limit       NUMBER(9,2))
PARTITION BY RANGE (credit_limit)
SUBPARTITION BY LIST (nls_territory)
SUBPARTITION TEMPLATE
    (SUBPARTITION east VALUES
        ('CHINA', 'JAPAN', 'INDIA', 'THAILAND'),
    SUBPARTITION west VALUES
        ('AMERICA', 'GERMANY', 'ITALY', 'SWITZERLAND'),
    SUBPARTITION other VALUES (DEFAULT))
(PARTITION p1 VALUES LESS THAN (1000),
PARTITION p2 VALUES LESS THAN (2500),
PARTITION p3 VALUES LESS THAN (MAXVALUE));
```

Object Column and Table Examples

Creating Object Tables: Examples  Consider object type `department_typ`:

```
CREATE TYPE department_typ AS OBJECT
    ( d_name   VARCHAR2(100),
    d_address VARCHAR2(200) );
/
```

Object table `departments_obj_t` holds department objects of type `department_typ`:

```
CREATE TABLE departments_obj_t OF department_typ;
```

The following statement creates object table `salesreps` with a user-defined object type, `salesrep_typ`:

```
CREATE OR REPLACE TYPE salesrep_typ AS OBJECT
    ( repId   NUMBER,
    repName  VARCHAR2(64));
/
```

```
CREATE TABLE salesreps OF salesrep_typ;
```

Creating a Table with a User-Defined Object Identifier: Example  This example creates an object type and a corresponding object table whose object identifier is primary key based:

```
CREATE TYPE employees_typ AS OBJECT
    (e_no   NUMBER, e_address CHAR(30));
/
```

```
CREATE TABLE employees_obj_t OF employees_typ (e_no PRIMARY KEY)
    OBJECT IDENTIFIER IS PRIMARY KEY;
```

You can subsequently reference the `employees_obj_t` object table using either `inline_ref_constraint` or `out_of_line_ref_constraint` syntax:

```
CREATE TABLE departments_t
    (d_no   NUMBER,
    mgr_ref REF employees_typ SCOPE IS employees_obj_t);
```
CREATE TABLE departments_t {
  d_no NUMBER,
  mgr_ref REF employees_typ
       CONSTRAINT mgr_in_emp REFERENCES employees_obj_t);

**Specifying Constraints on Type Columns: Example**  The following example shows how to define constraints on attributes of an object type column:

CREATE TYPE address_t AS OBJECT
  { hno NUMBER,
    street VARCHAR2(40),
    city VARCHAR2(20),
    zip VARCHAR2(5),
    phone VARCHAR2(10) )
  /

CREATE TYPE person AS OBJECT
  { name VARCHAR2(40),
    dateofbirth DATE,
    homeaddress address_t,
    manager REF person }
  /

CREATE TABLE persons OF person
  { homeaddress NOT NULL,
    UNIQUE (homeaddress.phone),
    CHECK (homeaddress.zip IS NOT NULL),
    CHECK (homeaddress.city <> 'San Francisco') );
CREATE TABLESPACE

Purpose
Use the CREATE TABLESPACE statement to create a **tablespace**, which is an allocation of space in the database that can contain schema objects.

- A **permanent tablespace** contains persistent schema objects. Objects in permanent tablespaces are stored in **data files**.
- An **undo tablespace** is a type of permanent tablespace used by Oracle Database to manage undo data if you are running your database in automatic undo management mode. Oracle strongly recommends that you use automatic undo management mode rather than using rollback segments for undo.
- A **temporary tablespace** contains schema objects only for the duration of a session. Objects in temporary tablespaces are stored in **temp files**.

When you create a tablespace, it is initially a read/write tablespace. You can subsequently use the ALTER TABLESPACE statement to take the tablespace offline or online, add data files or temp files to it, or make it a read-only tablespace.

You can also drop a tablespace from the database with the DROP TABLESPACE statement.

**See Also:**
- *Oracle Database Concepts* for information on tablespaces
- ALTER TABLESPACE on page 12-114 and DROP TABLESPACE on page 18-9 for information on modifying and dropping tablespaces

Prerequisites
You must have the CREATE TABLESPACE system privilege. To create the SYSAUX tablespace, you must have the SYSDBA system privilege.

Before you can create a tablespace, you must create a database to contain it, and the database must be open.

**See Also:** CREATE DATABASE on page 14-29

To use objects in a tablespace other than the SYSTEM tablespace:

- If you are running the database in automatic undo management mode, then at least one UNDO tablespace must be online.
- If you are running the database in manual undo management mode, then at least one rollback segment other than the SYSTEM rollback segment must be online.

---

**Note:** Oracle strongly recommends that you run your database in automatic undo management mode. For more information, refer to Oracle Database Administrator’s Guide.
Syntax

create_tablespace::=

(CREATE TABLESPACE SQL Statements: CREATE SYNONYM to CREATE TRIGGER 16-103

permanent_tablespace_clause::=

Note: If you specify the DEFAULT clause, then you must specify at least one of the clauses table_compression, inmemory_clause, ilm_clause, or storage_clause.

(file_specification::= on page 8-29, size_clause::= on page 8-47, logging_clause::= on page 16-104, tablespace_encryption_spec::= on page 16-104, table_compression::= on page 16-12—part of CREATE TABLE, inmemory_clause::= on page 16-104, ilm_clause::= on page 16-14—part of CREATE TABLE, storage_clause::= on page 8-50, extent_management_clause::= on page 16-105, segment_management_clause::= on page 16-105, flashback_mode_clause::= on page 16-105)

SQL Statements: CREATE SYNONYM to CREATE TRIGGER 16-103
logging_clause::=

```
                   LOGGING
                      NOLOGGING
                        FILESYSTEMLIKELOGGING
```
**inmemory_distribute::=**

```
DISTRIBUTE
  | AUTO
  | ROWID
  | BY
  | PARTITION
  | SUBPARTITION
```

**inmemory_duplicate::=**

```
DUPLICATE
  | ALL
  | NO
  | DUPLICATE
```

**extent_management_clause::=**

```
MANAGEMENT
  | LOCAL
  | AUTOALLOCATE
  | UNIFORM
  | SIZE
  | size_clause
```

(size_clause::= on page 8-47)

**segment_management_clause::=**

```

  (file_specification::= on page 8-29, extent_management_clause::= on page 16-105,
  tablespace_retention_clause::= on page 16-106)

tablespace_retention_clause::=

  RETENTION  GUARANTEE

  NOGUARANTEE
```

Semantics

**BIGFILE | SMALLFILE**

Use this clause to determine whether the tablespace is a bigfile or smallfile tablespace. This clause overrides any default tablespace type setting for the database.

- A **bigfile tablespace** contains only one data file or temp file, which can contain up to approximately 4 billion \(2^{32}\) blocks. The minimum size of the single data file or temp file is 12 megabytes (MB) for a tablespace with 32K blocks and 7MB for a tablespace with 8K blocks. The maximum size of the single data file or temp file is 128 terabytes (TB) for a tablespace with 32K blocks and 32TB for a tablespace with 8K blocks.

- A **smallfile tablespace** is a traditional Oracle tablespace, which can contain 1022 data files or temp files, each of which can contain up to approximately 4 million \(2^{22}\) blocks.

If you omit this clause, then Oracle Database uses the current default tablespace type of permanent or temporary tablespace set for the database. If you specify **BIGFILE** for a permanent tablespace, then the database by default creates a locally managed tablespace with automatic segment-space management.

**Restriction on Bigfile Tablespaces** You can specify only one data file in the **DATAFILE** clause or one temp file in the **TEMPFILE** clause.

**See Also:**

- *Oracle Database Administrator’s Guide* for more information on using bigfile tablespaces
- "Creating a Bigfile Tablespace: Example" on page 16-115
permanent_tablespace_clause

Use the following clauses to create a permanent tablespace. (Some of these clauses are also used to create a temporary or undo tablespace.)

tablespace

Specify the name of the tablespace to be created. The name must satisfy the requirements listed in "Database Object Naming Rules" on page 2-119.

Note on the SYSAUX Tablespace

SYSAUX is a required auxiliary system tablespace. You must use the CREATE TABLESPACE statement to create the SYSAUX tablespace if you are upgrading from a release earlier than Oracle Database 11g. You must have the SYSDBA system privilege to specify this clause, and you must have opened the database in UPGRADE mode.

You must specify EXTENT MANAGEMENT LOCAL and SEGMENT SPACE MANAGEMENT AUTO for the SYSAUX tablespace. The DATAFILE clause is optional only if you have enabled Oracle Managed Files. See "DATAFILE | TEMPFILE Clause" on page 16-107 for the behavior of the DATAFILE clause.

Take care to allocate sufficient space for the SYSAUX tablespace. For guidelines on creating this tablespace, refer to Oracle Database Upgrade Guide.

Restrictions on the SYSAUX Tablespace

You cannot specify OFFLINE or TEMPORARY for the SYSAUX tablespace.

DATAFILE | TEMPFILE Clause

Specify the data files to make up the permanent tablespace or the temp files to make up the temporary tablespace. Use the datafile_tempfile_spec form of file specification to create regular data files and temp files in an operating system file system or to create Oracle Automatic Storage Management (Oracle ASM) disk group files.

You must specify the DATAFILE or TEMPFILE clause unless you have enabled Oracle Managed Files by setting a value for the DB_CREATE_FILE_DEST initialization parameter. For Oracle ASM disk group files, the parameter must be set to a multiple file creation form of Oracle ASM filenames. If this parameter is set, then the database creates a system-named 100 MB file in the default file destination specified in the parameter. The file has AUTOEXTEND enabled and an unlimited maximum size.

---

**Note:** Media recovery does not recognize temp files.

---

See Also:

- Oracle Automatic Storage Management Administrator’s Guide for more information on using Oracle ASM
- file specification on page 8-29 for a full description, including the AUTOEXTEND parameter and the multiple file creation form of Oracle ASM filenames

Notes on Specifying Data Files and Temp Files

- You can create a tablespace within an Oracle ASM disk group by providing only the disk group name in the datafile_tempfile_spec. In this case, Oracle ASM creates a data file in the specified disk group with a system-generated filename.
The data file is auto-extensible with an unlimited maximum size and a default size of 100 MB. You can use the autoextend_clause to override the default size.

■ If you use one of the reference forms of the ASM_filename, which refers to an existing file, then you must also specify REUSE.

---

**Note:** On some operating systems, Oracle does not allocate space for a temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. To avoid potential problems, before you create or resize a temp file, ensure that the available disk space exceeds the size of the new temp file or the increased size of a resized temp file. The excess space should allow for anticipated increases in disk space use by unrelated operations as well. Then proceed with the creation or resizing operation.

---

**See Also:**

■ **file_specification** on page 8-29 for a full description, including the AUTOEXTEND parameter

■ "Enabling Autoextend for a Tablespace: Example" on page 16-116 and "Creating Oracle Managed Files: Examples" on page 16-117

---

**MINIMUM EXTENT Clause**

This clause is valid only for a dictionary-managed tablespace. Specify the minimum size of an extent in the tablespace. This clause lets you control free space fragmentation in the tablespace by ensuring that the size of every used or free extent in a tablespace is at least as large as, and is a multiple of, the value specified in the size_clause.

**See Also:**  
**size_clause** on page 8-47 for information on that clause and Oracle Database VLDB and Partitioning Guide for more information about using MINIMUM EXTENT to control fragmentation

---

**BLOCKSIZE Clause**

Use the BLOCKSIZE clause to specify a nonstandard block size for the tablespace. In order to specify this clause, the DB_CACHE_SIZE and at least one DB_nK_CACHE_SIZE parameter must be set, and the integer you specify in this clause must correspond with the setting of one DB_nK_CACHE_SIZE parameter setting.

**Restriction on BLOCKSIZE**  
You cannot specify nonstandard block sizes for a temporary tablespace or if you intend to assign this tablespace as the temporary tablespace for any users.

---

**Note:**  
Oracle recommend that you do not store tablespaces with a 2K block size on 4K sector size disks, because performance degradation can result.

---

**See Also:**  
*Oracle Database Reference* for information on the DB_nK_CACHE_SIZE parameter and *Oracle Database Concepts* for information on multiple block sizes
logging_clause
Specify the default logging attributes of all tables, indexes, materialized views, materialized view logs, and partitions within the tablespace. This clause is not valid for a temporary or undo tablespace.

If you omit this clause, then the default is LOGGING. The exception is creating a tablespace in a PDB. In this case, if you omit this clause, then the tablespace uses the logging attribute of the PDB. Refer to the logging_clause of CREATE PLUGGABLE DATABASE on page 15-68 for more information.

The tablespace-level logging attribute can be overridden by logging specifications at the table, index, materialized view, materialized view log, and partition levels.

See Also: logging_clause on page 8-38 for a full description of this clause

FORCE LOGGING
Use this clause to put the tablespace into FORCE LOGGING mode. Oracle Database will log all changes to all objects in the tablespace except changes to temporary segments, overriding any NOLOGGING setting for individual objects. The database must be open and in READ WRITE mode.

This setting does not exclude the NOLOGGING attribute. You can specify both FORCE LOGGING and NOLOGGING. In this case, NOLOGGING is the default logging mode for objects subsequently created in the tablespace, but the database ignores this default as long as the tablespace or the database is in FORCE LOGGING mode. If you subsequently take the tablespace out of FORCE LOGGING mode, then the NOLOGGING default is once again enforced.

Note: FORCE LOGGING mode can have performance effects. Refer to Oracle Database Administrator’s Guide for information on when to use this setting.

Restriction on Forced Logging You cannot specify FORCE LOGGING for an undo or temporary tablespace.

ENCRYPTION Clause
Use this clause to specify the encryption properties of the tablespace. This clause does not actually encrypt the tablespace. You must also specify the ENCRYPT keyword as part of the DEFAULT storage_clause in this statement in order for the tablespace to be encrypted. In addition, you must already have used ALTER SYSTEM SET ENCRYPTION WALLET OPEN IDENTIFIED BY ... to load the TDE master key into database memory for the duration of the instance, or establish a connection to the HSM to send the encrypted table and tablespace keys to the HSM and receive them back decrypted. For more information, see "SET ENCRYPTION WALLET Clause" on page 11-93.

Note: You cannot decrypt a tablespace that has been created encrypted. You must create an unencrypted tablespace and re-create the database objects in the unencrypted tablespace.

tablespace_encryption_spec Specify USING 'encrypt_algorithm' to indicate the name of the encryption algorithm to be used. Valid algorithms are AES256, AES192, AES128 and 3DES168. If you omit this clause, then the database uses AES128.
DEFAULT Clause
The DEFAULT clause lets you specify default parameters for the tablespace.

**table compression** Use the `table_compression` clause to specify default compression of data for all tables created in the tablespace. This clause is not valid for a temporary tablespace. Refer to the `table_compression` clause of `CREATE TABLE` on page 16-45 for the full semantics of this clause.

**inmemory_clause** Use the `inmemory_clause` to specify the default In-Memory Column Store (IM column store) settings for all tables and materialized views created in the tablespace. This clause is not valid for a temporary tablespace.

- Specify `INMEMORY` to enable all tables and materialized views for the IM column store.
  
  You can optionally use the `inmemory_parameters` clause to specify how the table or materialized view data is stored in the IM column store. The `inmemory_parameters` clause has the same semantics in `CREATE TABLE` and `CREATE TABLESPACE`. Refer to the `inmemory_parameters` clause of `CREATE TABLE` on page 16-49 for the full semantics of this clause.

- Specify `NO INMEMORY` to disable all tables and materialized views for the IM column store. This is the default.

**ilm_clause** Use the `ilm_clause` to specify default Automatic Data Optimization settings for all tables created in the tablespace. This clause is not valid for a temporary tablespace. Refer to the `ilm_clause` of `CREATE TABLE` on page 16-51 for the full semantics of this clause.

**storage_clause** Use the `storage_clause` to specify storage parameters for all objects created in the tablespace. This clause is not valid for a temporary tablespace or a locally managed tablespace. For a dictionary-managed tablespace, you can specify the following storage parameters with this clause: `ENCRYPT`, `INITIAL`, `NEXT`, `MINEXTENTS`, `MAXEXTENTS`, `MAXSIZE`, and `PCTINCREASE`. Refer to `storage_clause` on page 8-48 for more information.

See Also: "Creating Encrypted Tablespaces: Example" on page 16-117

ONLINE | OFFLINE Clauses
Use these clauses to determine whether the tablespace is online or offline. This clause is not valid for a temporary tablespace.

**ONLINE** Specify `ONLINE` to make the tablespace available immediately after creation to users who have been granted access to the tablespace. This is the default.

**OFFLINE** Specify `OFFLINE` to make the tablespace unavailable immediately after creation.

The data dictionary view `DBA_TABLESPACES` indicates whether each tablespace is online or offline.
**extent_management_clause**

The **extent_management_clause** lets you specify how the extents of the tablespace will be managed.

---

**Note:** After you have specified extent management with this clause, you can change extent management only by migrating the tablespace.

---

- **AUTOALLOCATE** specifies that the tablespace is system managed. Users cannot specify an extent size. You cannot specify **AUTOALLOCATE** for a temporary tablespace.

- **UNIFORM** specifies that the tablespace is managed with uniform extents of **SIZE** bytes. The default **SIZE** is 1 megabyte. All extents of temporary tablespaces are of uniform size, so this keyword is optional for a temporary tablespace. However, you must specify **UNIFORM** in order to specify **SIZE**. You cannot specify **UNIFORM** for an undo tablespace.

If you do not specify **AUTOALLOCATE** or **UNIFORM**, then the default is **UNIFORM** for temporary tablespaces and **AUTOALLOCATE** for all other types of tablespaces.

If you do not specify the **extent_management_clause**, then Oracle Database interprets the **MINIMUM EXTENT** clause and the **DEFAULT storage_clause** to determine extent management.

---

**Note:** The **DICTIONARY** keyword is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you create locally managed tablespaces. Locally managed tablespaces are much more efficiently managed than dictionary-managed tablespaces. The creation of new dictionary-managed tablespaces is scheduled for desupport.

---

**See Also:** *Oracle Database Concepts* for a discussion of locally managed tablespaces

**Restrictions on Extent Management** Extent management is subject to the following restrictions:

- A permanent locally managed tablespace can contain only permanent objects. If you need a locally managed tablespace to store temporary objects, for example, if you will assign it as a user’s temporary tablespace, then use the **temporary_tablespace_clause**.

- If you specify this clause, then you cannot specify **DEFAULT storage_clause**, **MINIMUM EXTENT**, or the **temporary_tablespace_clause**.

  **See Also:** *Oracle Database Administrator’s Guide* for information on changing extent management by migrating tablespaces and “Creating a Locally Managed Tablespace: Example” on page 16-116

**segment_management_clause**

The **segment_management_clause** is relevant only for permanent, locally managed tablespaces. It lets you specify whether Oracle Database should track the used and free
space in the segments in the tablespace using free lists or bitmaps. This clause is not valid for a temporary tablespace.

**AUTO** Specify **AUTO** if you want the database to manage the free space of segments in the tablespace using a bitmap. If you specify **AUTO**, then the database ignores any specification for **PCTUSED**, **FREELIST**, and **FREELIST GROUPS** in subsequent storage specifications for objects in this tablespace. This setting is called **automatic segment-space management** and is the default.

**MANUAL** Specify **MANUAL** if you want the database to manage the free space of segments in the tablespace using free lists. Oracle strongly recommends that you do not use this setting and that you create tablespaces with automatic segment-space management.

To determine the segment management of an existing tablespace, query the **SEGMENT_SPACE_MANAGEMENT** column of the **DBA_TABLESPACES** or **USER_TABLESPACES** data dictionary view.

---

**Notes:** If you specify **AUTO** segment management, then:

- If you set extent management to **LOCAL UNIFORM**, then you must ensure that each extent contains at least 5 database blocks.
- If you set extent management to **LOCAL AUTOALLOCATE**, and if the database block size is 16K or greater, then Oracle manages segment space by creating extents with a minimum size of 5 blocks rounded up to 64K.

---

**Restrictions on Automatic Segment-Space Management** This clause is subject to the following restrictions:

- You can specify this clause only for a permanent, locally managed tablespace.
- You cannot specify this clause for the **SYSTEM** tablespace.

**See Also:**

- *Oracle Automatic Storage Management Administrator’s Guide* for information on automatic segment-space management and when to use it
- *Oracle Database Reference* for information on the data dictionary views
- "Specifying Segment Space Management for a Tablespace: Example" on page 16-117

**flashback_mode_clause**

Use this clause in conjunction with the **ALTER DATABASE FLASHBACK** clause to specify whether the tablespace can participate in **FLASHBACK DATABASE** operations. This clause is useful if you have the database in **FLASHBACK** mode but you do not want Oracle Database to maintain Flashback log data for this tablespace.

This clause is not valid for temporary or undo tablespaces.

**FLASHBACK ON** Specify **FLASHBACK ON** to put the tablespace in **FLASHBACK** mode. Oracle Database will save Flashback log data for this tablespace and the tablespace can
participate in a FLASHBACK DATABASE operation. If you omit the flashback_mode_clause, then FLASHBACK ON is the default.

FLASHBACK OFF Specify FLASHBACK OFF to take the tablespace out of FLASHBACK mode. Oracle Database will not save any Flashback log data for this tablespace. You must take the data files in this tablespace offline or drop them prior to any subsequent FLASHBACK DATABASE operation. Alternatively, you can take the entire tablespace offline. In either case, the database does not drop existing Flashback logs.

---

Note: The FLASHBACK mode of a tablespace is independent of the FLASHBACK mode of an individual table.

---

See Also:
- Oracle Database Backup and Recovery User's Guide for information on Oracle Flashback Database
- ALTER DATABASE on page 10-32 and FLASHBACK DATABASE on page 18-26 for information on setting the FLASHBACK mode of the entire database and reverting the database to an earlier version
- FLASHBACK TABLE on page 18-29 and flashback_query_clause on page 19-22

**temporary_tablespace_clause**

Use this clause to create a locally managed temporary tablespace, which is an allocation of space in the database that can contain transient data that persists only for the duration of a session. This transient data cannot be recovered after process or instance failure.

The transient data can be user-generated schema objects such as temporary tables or system-generated data such as temp space used by hash joins and sort operations. When a temporary tablespace, or a tablespace group of which this tablespace is a member, is assigned to a particular user, then Oracle Database uses the tablespace for sorting operations in transactions initiated by that user.

The TEMPFILE clause is described in "DATAFILE | TEMPFILE Clause" on page 16-107. The extent_management_clause is described in extent_management_clause on page 16-111.

See Also: Oracle Database Security Guide for information on assigning temporary tablespaces to users

**tablespace_group_clause**

This clause is relevant only for temporary tablespaces. Use this clause to determine whether tablespace is a member of a tablespace group. A tablespace group lets you assign multiple temporary tablespaces to a single user and increases the addressability of temporary tablespaces.

- Specify a group name to indicate that tablespace is a member of this tablespace group. The group name cannot be the same as tablespace or any other existing tablespace. If the tablespace group already exists, then Oracle Database adds the new tablespace to that group. If the tablespace group does not exist, then the database creates the group and adds the new tablespace to that group.
- Specify an empty string (""") to indicate that tablespace is not a member of any tablespace group.
See Also:

- `ALTER TABLESPACE` on page 12-114 and "Adding a Temporary Tablespace to a Tablespace Group: Example" on page 16-116 for information on adding a tablespace to a tablespace group
- `CREATE USER` on page 17-7 for information on assigning a temporary tablespace to a user
- `Oracle Database Administrator's Guide` for more information on tablespace groups

Restrictions on Temporary Tablespaces  The data stored in temporary tablespaces persists only for the duration of a session. Therefore, only a subset of the `CREATE TABLESPACE` clauses are relevant for temporary tablespaces. The only clauses you can specify for a temporary tablespace are the `TEMPFILE` clause, the `tablespace_group_clause`, and the `extent_management_clause`.

`undo_tablespace_clause`  Specify `UNDO` to create an undo tablespace. When you run the database in automatic undo management mode, Oracle Database manages undo space using the undo tablespace instead of rollback segments. This clause is useful if you are now running in automatic undo management mode but your database was not created in automatic undo management mode.

Oracle Database always assigns an undo tablespace when you start up the database in automatic undo management mode. If no undo tablespace has been assigned to this instance, then the database uses the `SYSTEM` rollback segment. You can avoid this by creating an undo tablespace, which the database will implicitly assign to the instance if no other undo tablespace is currently assigned.

The `DATAFILE` clause is described in "DATAFILE | TEMPFILE Clause" on page 16-107.

`extent_management_clause`  It is unnecessary to specify the `extent_management_clause` when creating an undo tablespace, because undo tablespaces must be locally managed tablespaces that use `AUTOALLOCATE` extent management. If you do specify this clause, then you must specify `EXTENT MANAGEMENT LOCAL` or `EXTENT MANAGEMENT LOCAL AUTOALLOCATE`, both of which are the same as omitting this clause. Refer to `extent_management_clause` on page 16-111 for the full semantics of this clause.

`tablespace_retention_clause`  This clause is valid only for undo tablespaces.

- `RETENTION GUARANTEE` specifies that Oracle Database should preserve unexpired undo data in all undo segments of `tablespace` even if doing so forces the failure of ongoing operations that need undo space in those segments. This setting is useful if you need to issue an Oracle Flashback Query or an Oracle Flashback Transaction Query to diagnose and correct a problem with the data.

- `RETENTION NOGUARANTEE` returns the undo behavior to normal. Space occupied by unexpired undo data in undo segments can be consumed if necessary by ongoing transactions. This is the default.

Restrictions on Undo Tablespaces  Undo tablespaces are subject to the following restrictions:
CREATE TABLESPACE

SQL Statements: CREATE SYNONYM to CREATE TRIGGER

You cannot create database objects in this tablespace. It is reserved for system-managed undo data.

The only clauses you can specify for an undo tablespace are the DATAFILE clause and the extent_management_clause to specify local AUTOALLOCATE extent management. You cannot specify local UNIFORM extent management or dictionary extent management using the extent_management_clause. All undo tablespaces are created permanent, read/write, and in logging mode. Values for MINIMUM EXTENT and DEFAULT STORAGE are system generated.

See Also:

- Oracle Database Administrator’s Guide for information on automatic undo management and undo tablespaces and Oracle Database Reference for information on the UNDO_MANAGEMENT parameter
- CREATE DATABASE on page 14-29 for information on creating an undo tablespace during database creation, and ALTER TABLESPACE on page 12-114 and DROP TABLESPACE on page 18-9
- ”Creating an Undo Tablespace: Example” on page 16-115

Examples

These examples assume that your database is using 8K blocks.

Creating a Bigfile Tablespace: Example The following example creates a bigfile tablespace bigtbs_01 with a data file bigtbs_f1.dbf of 20 MB:

```sql
CREATE BIGFILE TABLESPACE bigtbs_01
  DATAFILE 'bigtbs_f1.dbf'
  SIZE 20M AUTOEXTEND ON;
```

Creating an Undo Tablespace: Example The following example creates a 10 MB undo tablespace undots1:

```sql
CREATE UNDO TABLESPACE undots1
  DATAFILE 'undotbs_1a.dbf'
  SIZE 10M AUTOEXTEND ON
  RETENTION GUARANTEE;
```

Creating a Temporary Tablespace: Example This statement shows how the temporary tablespace that serves as the default temporary tablespace for database users in the sample database was created:

```sql
CREATE TEMPORARY TABLESPACE temp_demo
  TEMPFILE 'temp01.dbf' SIZE 5M AUTOEXTEND ON;
```

Assuming that the default database block size is 2K, and that each bit in the map represents one extent, then each bit maps 2,500 blocks.

The following example sets the default location for data file creation and then creates a tablespace with an Oracle-managed temp file in the default location. The temp file is 100 M and is autoextensible with unlimited maximum size. These are the default values for Oracle Managed Files:

```sql
ALTER SYSTEM SET DB_CREATE_FILE_DEST = '$ORACLE_HOME/rdbms/dbs';

CREATE TEMPORARY TABLESPACE tbs_05;
```
Adding a Temporary Tablespace to a Tablespace Group: Example The following statement creates the tbs_temp_02 temporary tablespace as a member of the tbs_grp_01 tablespace group. If the tablespace group does not already exist, then Oracle Database creates it during execution of this statement:

```
CREATE TEMPORARY TABLESPACE tbs_temp_02
    TEMPFILE 'temp02.dbf' SIZE 5M AUTOEXTEND ON
    TABLESPACE GROUP tbs_grp_01;
```

Creating Basic Tablespaces: Examples This statement creates a tablespace named tbs_01 with one data file:

```
CREATE TABLESPACE tbs_01
    DATAFILE 'tbs_f2.dbf' SIZE 40M
    ONLINE;
```

This statement creates tablespace tbs_03 with one data file and allocates every extent as a multiple of 500K:

```
CREATE TABLESPACE tbs_03
    DATAFILE 'tbs_f03.dbf' SIZE 20M
    LOGGING;
```

Enabling Autoextend for a Tablespace: Example This statement creates a tablespace named tbs_02 with one data file. When more space is required, 500 kilobyte extents will be added up to a maximum size of 100 megabytes:

```
CREATE TABLESPACE tbs_02
    DATAFILE 'diskb:tbs_f5.dbf' SIZE 500K REUSE
    AUTOEXTEND ON NEXT 500K MAXSIZE 100M;
```

Creating a Locally Managed Tablespace: Example The following statement assumes that the database block size is 2K.

```
CREATE TABLESPACE tbs_04 DATAFILE 'file_1.dbf' SIZE 10M
    EXTENT MANAGEMENT LOCAL UNIFORM SIZE 128K;
```

This statement creates a locally managed tablespace in which every extent is 128K and each bit in the bit map describes 64 blocks.

The following statement creates a locally managed tablespace with uniform extents and shows an example of a table stored in that tablespace:

```
CREATE TABLESPACE lmt1 DATAFILE 'lmt_file2.dbf' SIZE 100m REUSE
    EXTENT MANAGEMENT LOCAL UNIFORM SIZE 1M;
```

```
CREATE TABLE lmt_table1 (col1 NUMBER, col2 VARCHAR2(20))
    TABLESPACE lmt1 STORAGE (INITIAL 2m);
```

The initial segment size of the table is 2M.

The following example creates a locally managed tablespace without uniform extents:

```
CREATE TABLESPACE lmt2 DATAFILE 'lmt_file3.dbf' SIZE 100m REUSE
    EXTENT MANAGEMENT LOCAL;
```

```
CREATE TABLE lmt_table2 (col1 NUMBER, col2 VARCHAR2(20))
    TABLESPACE lmt2 STORAGE (INITIAL 2m MAXSIZE 100m);
```

The initial segment size of the table is 2M. Oracle Database determines the size of each extent and the total number of extents allocated to satisfy the initial segment size. The segment's maximum size is limited to 100M.
**Creating an Encrypted Tablespace: Example**  In the following example, the first statement enables encryption for the database by opening the wallet. The second statement creates an encrypted tablespace.

```
ALTER SYSTEM SET ENCRYPTION WALLET OPEN IDENTIFIED BY "wallet_password";

CREATE TABLESPACE encrypt_ts
  DATAFILE '$ORACLE_HOME/dbs/encrypt_df.dbf' SIZE 1M
  ENCRYPTION USING 'AES256'
  DEFAULT STORAGE (ENCRYPT);
```

**Specifying Segment Space Management for a Tablespace: Example**  The following example creates a tablespace with automatic segment-space management:

```
CREATE TABLESPACE auto_seg_ts DATAFILE 'file_2.dbf' SIZE 1M
  EXTENT MANAGEMENT LOCAL
  SEGMENT SPACE MANAGEMENT AUTO;
```

**Creating Oracle Managed Files: Examples**  The following example sets the default location for data file creation and creates a tablespace with a data file in the default location. The data file is 100M and is autoextensible with an unlimited maximum size:

```
ALTER SYSTEM SET DB_CREATE_FILE_DEST = '$ORACLE_HOME/rdbms/dbs';

CREATE TABLESPACE omf_ts1;
```

The following example creates a tablespace with an Oracle-managed data file of 100M that is not autoextensible:

```
CREATE TABLESPACE omf_ts2 DATAFILE AUTOEXTEND OFF;
```
CREATE TRIGGER

Purpose

Triggers are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the CREATE TRIGGER statement to create a database trigger, which is:

- A stored PL/SQL block associated with a table, a schema, or the database or
- An anonymous PL/SQL block or a call to a procedure implemented in PL/SQL or Java

Oracle Database automatically executes a trigger when specified conditions occur.

See Also: ALTER TRIGGER on page 13-2 and DROP TRIGGER on page 18-12

Prerequisites

To create a trigger in your own schema on a table in your own schema or on your own schema (SCHEMA), you must have the CREATE TRIGGER system privilege.

To create a trigger in any schema on a table in any schema, or on another user’s schema (schema.SCHEMA), you must have the CREATE ANY TRIGGER system privilege.

In addition to the preceding privileges, to create a trigger on DATABASE, you must have the ADMINISTER DATABASE TRIGGER system privilege.

To create a trigger on a pluggable database (PDB), the current container must be that PDB and you must have the ADMINISTER DATABASE TRIGGER system privilege. For information about PDBs, see Oracle Database Administrator’s Guide.

In addition to the preceding privileges, to create a crossedition trigger, you must be enabled for editions. For information about enabling editions for a user, see Oracle Database Development Guide.

If the trigger issues SQL statements or calls procedures or functions, then the owner of the trigger must have the privileges necessary to perform these operations. These privileges must be granted directly to the owner rather than acquired through roles.

Syntax

Triggers are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to Oracle Database PL/SQL Language Reference for the PL/SQL syntax, semantics, and examples.

create_trigger ::= 

(create | OR | REPLACE | EDITIONABLE | NONEDITIONABLE | TRIGGER | plsql_trigger_source)

(plsql_trigger_source: See Oracle Database PL/SQL Language Reference.)
Semantics

**OR REPLACE**
Specify `OR REPLACE` to re-create the trigger if it already exists. Use this clause to change the definition of an existing trigger without first dropping it.

**[ EDITIONABLE | NONEDITIONABLE ]**
Use these clauses to specify whether the trigger is an editioned or noneditioned object if editioning is enabled for the schema object type `TRIGGER` in `schema`. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see Oracle Database Development Guide.

**Restriction on NONEDITIONABLE**
You cannot specify `NONEDITIONABLE` for a crossedition trigger.

**plsql_trigger_source**
See Oracle Database PL/SQL Language Reference for the syntax and semantics of the `plsql_trigger_source`. 
SQL Statements: CREATE TYPE to DROP ROLLBACK SEGMENT

This chapter contains the following SQL statements:

- CREATE TYPE
- CREATE TYPE BODY
- CREATE USER
- CREATE VIEW
- DELETE
- DISASSOCIATE STATISTICS
- DROP AUDIT POLICY (Unified Auditing)
- DROP CLUSTER
- DROP CONTEXT
- DROP DATABASE
- DROP DATABASE LINK
- DROP DIMENSION
- DROP DIRECTORY
- DROP DISKGROUP
- DROP EDITION
- DROP FLASHBACK ARCHIVE
- DROP FUNCTION
- DROP INDEX
- DROP INDEXTYPE
- DROP JAVA
- DROP LIBRARY
- DROP MATERIALIZED VIEW
- DROP MATERIALIZED VIEW LOG
- DROP MATERIALIZED ZONEMAP
- DROP OPERATOR
- DROP OUTLINE
• DROP PACKAGE
• DROP PLUGGABLE DATABASE
• DROP PROCEDURE
• DROP PROFILE
• DROP RESTORE POINT
• DROP ROLE
• DROP ROLLBACK SEGMENT
CREATE TYPE

Purpose

Object types are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the CREATE TYPE statement to create the specification of an object type, a SQLJ object type, a named varying array (varray), a nested table type, or an incomplete object type. You create object types with the CREATE TYPE and the CREATE TYPE BODY statements. The CREATE TYPE statement specifies the name of the object type, its attributes, methods, and other properties. The CREATE TYPE BODY statement contains the code for the methods that implement the type.

Notes:

- If you create an object type for which the type specification declares only attributes but no methods, then you need not specify a type body.
- If you create a SQLJ object type, then you cannot specify a type body. The implementation of the type is specified as a Java class.

An incomplete type is a type created by a forward type definition. It is called “incomplete” because it has a name but no attributes or methods. It can be referenced by other types, and so can be used to define types that refer to each other. However, you must fully specify the type before you can use it to create a table or an object column or a column of a nested table type.

See Also:

- CREATE TYPE BODY on page 17-5 for information on creating the member methods of a type
- Oracle Database Object-Relational Developer’s Guide for more information about objects, incomplete types, varrays, and nested tables

Prerequisites

To create a type in your own schema, you must have the CREATE TYPE system privilege. To create a type in another user’s schema, you must have the CREATE ANY TYPE system privilege. You can acquire these privileges explicitly or be granted them through a role.

To create a subtype, you must have the UNDER ANY TYPE system privilege or the UNDER object privilege on the supertype.

The owner of the type must be explicitly granted the EXECUTE object privilege in order to access all other types referenced within the definition of the type, or the type owner must be granted the EXECUTE ANY TYPE system privilege. The owner cannot obtain these privileges through roles.

If the type owner intends to grant other users access to the type, then the owner must be granted the EXECUTE object privilege on the referenced types with the GRANT OPTION or the EXECUTE ANY TYPE system privilege with the ADMIN OPTION. Otherwise, the type owner has insufficient privileges to grant access on the type to other users.
CREATE TYPE

Syntax

Types are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to Oracle Database PL/SQL Language Reference for the PL/SQL syntax, semantics, and examples.

create_type::=

(condition)

(plsql_type_source: See Oracle Database PL/SQL Language Reference.)

Semantics

OR REPLACE

Specify OR REPLACE to re-create the type if it already exists. Use this clause to change the definition of an existing type without first dropping it.

Users previously granted privileges on the re-created object type can use and reference the object type without being granted privileges again.

If any function-based indexes depend on the type, then Oracle Database marks the indexes DISABLED.

[ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the type is an editioned or noneditioned object if editioning is enabled for the schema object type TYPE in schema. The default is EDITIONABLE. For information about editioned and noneditioned objects, see Oracle Database Development Guide.

plsql_type_source

See Oracle Database PL/SQL Language Reference for the syntax and semantics of the plsql_type_source.
CREATE TYPE BODY

Purpose

Type bodies are defined using PL/SQL. Therefore, this section provides some general information but refers to Oracle Database PL/SQL Language Reference for details of syntax and semantics.

Use the `CREATE TYPE BODY` to define or implement the member methods defined in the object type specification. You create object types with the `CREATE TYPE` and the `CREATE TYPE BODY` statements. The `CREATE TYPE` statement specifies the name of the object type, its attributes, methods, and other properties. The `CREATE TYPE BODY` statement contains the code for the methods that implement the type.

For each method specified in an object type specification for which you did not specify the `call_spec`, you must specify a corresponding method body in the object type body.

---

**Note:** If you create a SQLJ object type, then specify it as a Java class.

---

See Also:
- `CREATE TYPE` on page 17-3 for information on creating a type specification
- `ALTER TYPE` on page 13-4 for information on modifying a type specification

Prerequisites

Every member declaration in the `CREATE TYPE` specification for object types must have a corresponding construct in the `CREATE TYPE` or `CREATE TYPE BODY` statement.

To create or replace a type body in your own schema, you must have the `CREATE TYPE` or the `CREATE ANY TYPE` system privilege. To create an object type in another user’s schema, you must have the `CREATE ANY TYPE` system privilege. To replace an object type in another user’s schema, you must have the `DROP ANY TYPE` system privilege.

Syntax

Type bodies are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to Oracle Database PL/SQL Language Reference for the PL/SQL syntax, semantics, and examples.

```
create_type_body ::= CREATE | OR REPLACE TYPE | NONEDITABLE | EDITIONABLE BODY plsql_type_body_source
```

(plsql_type_body_source: See Oracle Database PL/SQL Language Reference.)
Semantics

**OR REPLACE**
Specify **OR REPLACE** to re-create the type body if it already exists. Use this clause to change the definition of an existing type body without first dropping it.

Users previously granted privileges on the re-created object type body can use and reference the object type body without being granted privileges again.

You can use this clause to add new member subprogram definitions to specifications added with the **ALTER TYPE ... REPLACE** statement.

**[ EDITIONABLE | NONEDITIONABLE ]**
If you do not specify this clause, then the type body inherits **EDITIONABLE** or **NONEDITIONABLE** from the type specification. If you do specify this clause, then it must match that of the type specification.

**plsql_type_body_source**
See Oracle Database PL/SQL Language Reference for the syntax and semantics of the **plsql_type_body_source**.
CREATE USER

Purpose

Use the CREATE USER statement to create and configure a database user, which is an account through which you can log in to the database, and to establish the means by which Oracle Database permits access by the user.

You can issue this statement in an Oracle Automatic Storage Management (Oracle ASM) cluster to add a user and password combination to the password file that is local to the Oracle ASM instance of the current node. Each node's Oracle ASM instance can use this statement to update its own password file. The password file itself must have been created by the ORAPWD utility.

You can enable a user to connect to the database through a proxy application or application server. For syntax and discussion, refer to ALTER USER on page 13-6.

Prerequisites

You must have the CREATE USER system privilege. When you create a user with the CREATE USER statement, the user's privilege domain is empty. To log on to Oracle Database, a user must have the CREATE SESSION system privilege. Therefore, after creating a user, you should grant the user at least the CREATE SESSION system privilege. Refer to GRANT on page 18-35 for more information.

Only a user authenticated AS SYSASM can issue this command to modify the Oracle ASM instance password file.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root. To specify CONTAINER = CURRENT, the current container must be a pluggable database (PDB).
Syntax

```
create_user ::= 
```

Semantics

**user**

Specify the name of the user to be created. This name can contain only characters from your database character set and must follow the rules described in the section "Database Object Naming Rules" on page 2-119. Oracle recommends that the user name contain at least one single-byte character regardless of whether the database character set also contains multibyte characters.

In a non-CDB, a user name cannot begin with C## or c##.

In a CDB, the requirements for a user name are as follows:

- In Oracle Database 12c Release 1 (12.1.0.1), the name of a **common user** must begin with C## or c## and the name of a **local user** must not begin with C## or c##.
- Starting with Oracle Database 12c Release 1 (12.1.0.2):
– The name of a **common user** must begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. By default, the prefix is `C##`.

– The name of a **local user** must *not* begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. Regardless of the value of `COMMON_USER_PREFIX`, the name of a local user can never begin with `C##` or `c##`.

---

**Note:** If the value of `COMMON_USER_PREFIX` is an empty string, then there are no requirements for common or local user names with one exception: the name of a local user can never begin with `C##` or `c##`. Oracle recommends against using an empty string value because it might result in conflicts between the names of local and common users when a PDB is plugged into a different CDB, or when opening a PDB that was closed when a common user was created.

---

**Note:** Oracle recommends that user names and passwords be encoded in ASCII or EBCDIC characters only, depending on your platform.

**See Also:** "Creating a Database User: Example" on page 17-13

### IDENTIFIED Clause

The **IDENTIFIED** clause lets you indicate how Oracle Database authenticates the user.

**BY password**

The **BY password** clause lets you creates a **local user** and indicates that the user must specify **password** to log on to the database. Passwords are case sensitive. Any subsequent **CONNECT** string used to connect this user to the database must specify the password using the same case (upper, lower, or mixed) that is used in this **CREATE USER** statement or a subsequent **ALTER USER** statement. Passwords can contain any single-byte, multibyte, or special characters, or any combination of these, from your database character set, with the exception of the double quotation mark ("), and the return character. If a password starts with a non-alphabetic character, or contains a character other than an alphanumeric character, the underscore (_), dollar sign ($), or pound sign (#), then it must be enclosed in double quotation marks. Otherwise, enclosing a password in double quotation marks is optional.

**See Also:** *Oracle Database Security Guide* for more information about case-sensitive passwords, password complexity, and other password guidelines

Passwords must follow the rules described in the section "Database Object Naming Rules" on page 2-119, unless you are using one of the three Oracle Database password complexity verification routines. These routines requires a more complex combination of characters than the normal naming rules permit. You implement these routines with the `UTLPWDMG.SQL` script, which is further described in *Oracle Database Security Guide*. 

---
EXTERNALLY Clause
Specify **EXTERNALLY** to create an **external user**. Such a user must be authenticated by an external service, such as an operating system or a third-party service. In this case, Oracle Database relies on authentication by the operating system or third-party service to ensure that a specific external user has access to a specific database user.

**AS ‘certificate_DN’**  This clause is required for and used for SSL-authenticated external users only. The *certificate_DN* is the distinguished name in the user’s PKI certificate in the user’s wallet. The maximum length of *certificate_DN* is 1024 characters.

**AS ‘kerberos_principal_name’**  This clause is required for and used for Kerberos-authenticated external users only. The maximum length of *kerberos_principal_name* is 1024 characters.

---

**Caution:** Oracle strongly recommends that you do not use **IDENTIFIED EXTERNALLY** with operating systems that have inherently weak login security.

---

**Restrictions on Creating External Users**  The following restrictions apply to creating external users:

- The user **SYS** cannot be an external user.
- Oracle ASM does not support the creation of external users.

See Also:
- *Oracle Database Enterprise User Security Administrator’s Guide* for more information on externally identified users
- "Creating External Database Users: Examples" on page 17-14

**GLOBALLY Clause**
The **GLOBALLY** clause lets you create a **global user**. Such a user must be authorized by the enterprise directory service (Oracle Internet Directory).

The **directory_DN** string can take one of two forms:

- The X.509 name at the enterprise directory service that identifies this user. It should be of the form *CN=username,other_attributes*, where *other_attributes* is the rest of the user’s distinguished name (DN) in the directory. This form creates a **private global schema**.

- A null string (" ") indicating that the enterprise directory service will map authenticated global users to this database schema with the appropriate roles. This form is the same as specifying the **GLOBALLY** keyword alone and creates a **shared global schema**.

---

**Note:** Oracle recommends that user names and passwords be encoded in ASCII or EBCDIC characters only, depending on your platform.

See Also: *Oracle Database Security Guide* to for a detailed discussion of password management and protection
The maximum length of directory_DN is 1024 characters.

You can control the ability of an application server to connect as the specified user and to activate that user's roles using the ALTER USER statement.

**Restriction on Creating Global Users** Oracle ASM does not support the creation of global users.

**See Also:**
- *Oracle Database Security Guide* for more information on global users
- ALTER USER on page 13-6
- "Creating a Global Database User: Example" on page 17-14

**DEFAULT TABLESPACE Clause**
Specify the default tablespace for objects that are created in the user’s schema. If you omit this clause, then the user's objects are stored in the database default tablespace. If no default tablespace has been specified for the database, then the user's objects are stored in the SYSTEM tablespace.

**Restriction on Default Tablespace** You cannot specify a locally managed temporary tablespace, including an undo tablespace, or a dictionary-managed temporary tablespace, as a user's default tablespace.

**See Also:**
- CREATE TABLESPACE on page 16-102 for more information on tablespaces in general and undo tablespaces in particular
- *Oracle Database Security Guide* for more information on assigning default tablespaces to users

**TEMPORARY TABLESPACE Clause**
Specify the tablespace or tablespace group for the user's temporary segments. If you omit this clause, then the user's temporary segments are stored in the database default temporary tablespace or, if none has been specified, in the SYSTEM tablespace.

- Specify `tablespace` to indicate the user's temporary tablespace. If you are connected to a CDB, then you can specify `CDB$DEFAULT` to use the CDB-wide default temporary tablespace.
- Specify `tablespace_group_name` to indicate that the user can save temporary segments in any tablespace in the tablespace group specified by `tablespace_group_name`.

**Restrictions on Temporary Tablespace** This clause is subject to the following restrictions:
- The tablespace must be a temporary tablespace and must have a standard block size.
- The tablespace cannot be an undo tablespace or a tablespace with automatic segment-space management.
See Also:
- *Oracle Database Administrator’s Guide* for information about tablespace groups and *Oracle Database Security Guide* for information on assigning temporary tablespaces to users
- [CREATE TABLESPACE](#) on page 16-102 for more information on undo tablespaces and segment management
- "Assigning a Tablespace Group: Example" on page 13-14

**QUOTA Clause**

Use the `QUOTA` clause to specify the maximum amount of space the user can allocate in the tablespace.

A `CREATE USER` statement can have multiple `QUOTA` clauses for multiple tablespaces. `UNLIMITED` lets the user allocate space in the tablespace without bound. The maximum amount of space that you can specify is 2 terabytes (TB). If you need more space, then specify `UNLIMITED`.

**Restriction on the QUOTA Clause**  You cannot specify this clause for a temporary tablespace.

See Also:  size_clause on page 8-47 for information on that clause and *Oracle Database Security Guide* for more information on assigning tablespace quotas

**PROFILE Clause**

Specify the profile you want to assign to the user. The profile limits the amount of database resources the user can use. If you omit this clause, then Oracle Database assigns the `DEFAULT` profile to the user.

**Note:** Oracle recommends that you use the Database Resource Manager rather SQL profiles to establish database resource limits. The Database Resource Manager offers a more flexible means of managing and tracking resource use. For more information on the Database Resource Manager, refer to *Oracle Database Administrator’s Guide*.

See Also:  [GRANT](#) on page 18-35 and [CREATE PROFILE](#) on page 15-77

**PASSWORD EXPIRE Clause**

Specify `PASSWORD EXPIRE` if you want the user’s password to expire. This setting forces the user or the DBA to change the password before the user can log in to the database.

**ACCOUNT Clause**

Specify `ACCOUNT LOCK` to lock the user’s account and disable access. Specify `ACCOUNT UNLOCK` to unlock the user’s account and enable access to the account. The default is `ACCOUNT UNLOCK`. 
ENABLE EDITIONS

This clause is not reversible. Specify ENABLE EDITIONS to allow the user to create multiple versions of editionable objects in this schema using editions. Editionable objects in schemas that are not editions-enabled cannot be editioned.

Restriction on Enabling Editions  You cannot enable editions for any schemas supplied by Oracle except for the sample schemas in the seed database.

CONTAINER Clause

The CONTAINER clause applies when you are connected to a CDB. However, it is not necessary to specify the CONTAINER clause because its default values are the only allowed values.

- To create a common user, you must be connected to the root. You can optionally specify CONTAINER = ALL, which is the default when you are connected to the root.
- To create a local user, you must be connected to a PDB. You can optionally specify CONTAINER = CURRENT, which is the default when you are connected to a PDB.

While creating a common user, any default tablespace, temporary tablespace, or profile specified using the following clauses must exist in all the containers belonging to the CDB:

- DEFAULT TABLESPACE
- TEMPORARY TABLESPACE
- QUOTA
- PROFILE

If these objects do not exist in all the containers, the CREATE USER statement fails.

Examples

All of the following examples use the example tablespace, which exists in the seed database and is accessible to the sample schemas.

Creating a Database User: Example  If you create a new user with PASSWORD EXPIRE, then the user's password must be changed before the user attempts to log in to the database. You can create the user sidney by issuing the following statement:

```sql
CREATE USER sidney
  IDENTIFIED BY out_standing1
  DEFAULT TABLESPACE example
  QUOTA 10M ON example
  TEMPORARY TABLESPACE temp
  QUOTA 5M ON system
  PROFILE app_user
  PASSWORD EXPIRE;
```

The user sidney has the following characteristics:

- The password out_standing1
- Default tablespace example, with a quota of 10 megabytes
- Temporary tablespace temp
- Access to the tablespace SYSTEM, with a quota of 5 megabytes
- Limits on database resources defined by the profile app_user (which was created in "Creating a Profile: Example" on page 15-82)
An expired password, which must be changed before sidney can log in to the database

Creating External Database Users: Examples  The following example creates an external user, who must be identified by an external source before accessing the database:

```
CREATE USER app_user1
IDENTIFIED EXTERNALLY
DEFAULT TABLESPACE example
QUOTA 5M ON example
PROFILE app_user;
```

The user app_user1 has the following additional characteristics:
- Default tablespace example
- Default temporary tablespace example
- 5M of space on the tablespace example and unlimited quota on the temporary tablespace of the database
- Limits on database resources defined by the app_user profile

To create another user accessible only by an operating system account, prefix the user name with the value of the initialization parameter OS_AUTHENT_PREFIX. For example, if this value is "ops$", then you can create the externally identified user external_user with the following statement:

```
CREATE USER ops$external_user
IDENTIFIED EXTERNALLY
DEFAULT TABLESPACE example
QUOTA 5M ON example
PROFILE app_user;
```

Creating a Global Database User: Example  The following example creates a global user. When you create a global user, you can specify the X.509 name that identifies this user at the enterprise directory server:

```
CREATE USER global_user
IDENTIFIED GLOBALLY AS 'CN=analyst, OU=division1, O=oracle, C=US'
DEFAULT TABLESPACE example
QUOTA 5M ON example;
```

Creating a Common User in a CDB  The following example creates a common user called c##comm_user in a CDB. Before you run this CREATE USER statement, ensure that the tablespaces example and temp_tbs exist in all of the containers in the CDB.

```
CREATE USER c##comm_user
IDENTIFIED BY comm_pwd
DEFAULT TABLESPACE example
QUOTA 20M ON example
TEMPORARY TABLESPACE temp_tbs;
```

The user comm_user has the following additional characteristics:
- The password comm_pwd
- Default tablespace example, with a quota of 20 megabytes
- Temporary tablespace temp_tbs
CREATE VIEW

Purpose

Use the CREATE VIEW statement to define a view, which is a logical table based on one or more tables or views. A view contains no data itself. The tables upon which a view is based are called base tables.

You can also create an object view or a relational view that supports LOBs, object types, REF data types, nested table, or varray types on top of the existing view mechanism. An object view is a view of a user-defined type, where each row contains objects, each object with a unique object identifier.

You can also create XMLType views, which are similar to object views but display data from XMLSchema-based tables of XMLType.

See Also:
- Oracle Database Concepts, Oracle Database Development Guide, and Oracle Database Administrator’s Guide for information on various types of views and their uses
- Oracle XML DB Developer’s Guide for information on XMLType views
- ALTER VIEW on page 13-16 and DROP VIEW on page 18-18 for information on modifying a view and removing a view from the database

Prerequisites

To create a view in your own schema, you must have the CREATE VIEW system privilege. To create a view in another user’s schema, you must have the CREATE ANY VIEW system privilege.

To create a subview, you must have the UNDER ANY VIEW system privilege or the UNDER object privilege on the superview.

The owner of the schema containing the view must have the privileges necessary to either select (READ or SELECT privilege), insert, update, or delete rows from all the tables or views on which the view is based. The owner must be granted these privileges directly, rather than through a role.

To use the basic constructor method of an object type when creating an object view, one of the following must be true:

- The object type must belong to the same schema as the view to be created.
- You must have the EXECUTE ANY TYPE system privileges.
- You must have the EXECUTE object privilege on that object type.

See Also: SELECT on page 19-4, INSERT on page 18-62, UPDATE on page 19-93, and DELETE on page 17-28 for information on the privileges required by the owner of a view on the base tables or views of the view being created.
Syntax

create_view::=

(inline_constraint::= on page 8-5 and out_of_line_constraint::= on page 8-5, object_view_clause::= on page 17-16, XMLType_view_clause::= on page 17-17, subquery::= on page 19-5—part of SELECT, subquery_restriction_clause::= on page 17-17)

object_view_clause::=

(inline_constraint::= on page 8-5 and out_of_line_constraint::= on page 8-5)
XMLType_view_clause ::=  

XMLSchema_spec ::=  

subquery_restriction_clause ::=  

Semantics  

OR REPLACE  
Specify OR REPLACE to re-create the view if it already exists. You can use this clause to change the definition of an existing view without dropping, re-creating, and regranting object privileges previously granted on it.  

INSTEAD OF triggers defined on a conventional view are dropped when the view is re-created. DML triggers defined on an editioning view are retained when an editioning view is re-created. However, such triggers can be rendered permanently invalid if the editioning view has changed so that it can no longer be compiled—for example if an editioning view column referenced in the trigger definition has been dropped.  

If any materialized views are dependent on view, then those materialized views will be marked UNUSABLE and will require a full refresh to restore them to a usable state. Invalid materialized views cannot be used by query rewrite and cannot be refreshed until they are recompiled.  

You cannot replace a conventional view with an editioning view or an editioning view with a conventional view. See Oracle Database Development Guide for more information on editioning views.
See Also:

- **ALTER MATERIALIZED VIEW** on page 11-3 for information on refreshing invalid materialized views
- *Oracle Database Concepts* for information on materialized views in general
- **CREATE TRIGGER** on page 16-118 for more information about the INSTEAD OF clause

**FORCE**

Specify **FORCE** if you want to create the view regardless of whether the base tables of the view or the referenced object types exist or the owner of the schema containing the view has privileges on them. These conditions must be true before any SELECT, INSERT, UPDATE, or DELETE statements can be issued against the view.

If the view definition contains any constraints, **CREATE VIEW ... FORCE** fails if the base table does not exist or the referenced object type does not exist. **CREATE VIEW ... FORCE** also fails if the view definition names a constraint that does not exist.

**NO FORCE**

Specify **NOFORCE** if you want to create the view only if the base tables exist and the owner of the schema containing the view has privileges on them. This is the default.

**EDITIONING**

Use this clause to create an **editioning view**. An editioning view is a single-table view that selects all rows from the base table and displays a subset of the base table columns. You can use an editioning view to isolate an application from DDL changes to the base table during administrative operations such as upgrades. You can obtain information about the relationship of existing editioning view to their base tables by querying the **USER_**, **ALL_**, and **DBA_EDITIONING_VIEW** data dictionary views.

The owner of an editioning view must be editions-enabled. Refer to **ENABLE EDITIONS** on page 13-10 for more information.

**Notes on Editioning Views**  Editioning views differ from conventional views in several important ways:

- Editioning views are intended only to select and provide aliases for a subset of columns in a table. Therefore, the syntax for creating an editioning view is more limited than the syntax for creating a conventional view. Any violation of the restrictions that follow causes the creation of the view to fail, even if you specify **FORCE**.

- You can create DML triggers on editioning views. In this case, the database considers the editioning view to be the base object of the trigger. Such triggers fire when a DML operation target the editioning view itself. They do not fire if the DML operation targets the base table.

- You cannot create **INSTEAD OF** triggers on editioning views.

**Restrictions on Editioning Views**  Editioning views are subject to the following restrictions:

- Within any edition, you can create only one editioning view for any single table.

- You cannot specify the **object_view_clause**, **XMLType_view_clause**, or **BEQUEATH** clause.
CREATE VIEW

- You cannot define a constraint WITH CHECK OPTION on an editioning view.

- In the select list of the defining subquery, you can specify only simple references to the columns of the base table, and you can specify each column of the base table only once in the select list. The asterisk wildcard symbol * and t_alias.* are supported to designate all columns of a base table.

- The FROM clause of the defining subquery of the view can reference only a single existing database table. Joins are not permitted. The base table must be in the same schema as the view being created. You cannot use a synonym to identify the table, but you can specify a table alias.

- The following clauses of the defining subquery are not valid for editioning views: subquery_factoring_clause, DISTINCT or UNIQUE, where_clause, hierarchical_query_clause, group_by_clause, HAVING condition, model_clause, or the set operators (UNION, INTERSECT, or MINUS)

**See Also:**
- Oracle Database Development Guide for detailed information about editioning views
- CREATE EDITION on page 14-64 for information about editions, including an example of an editioning view

**EDITIONABLE | NONEDITIONABLE**

Use these clauses to specify whether the view becomes an editioned or noneditioned object if editioning is enabled for the schema object type VIEW in schema. The default is EDITIONABLE. For information about editioned and noneditioned objects, see Oracle Database Development Guide.

**schema**

Specify the schema to contain the view. If you omit schema, then Oracle Database creates the view in your own schema.

**view**

Specify the name of the view or the object view. The name must satisfy the requirements listed in "Database Object Naming Rules" on page 2-119.

**Restriction on Views** If a view has INSTEAD OF triggers, then any views created on it must have INSTEAD OF triggers, even if the views are inherently updatable.

**See Also:** "Creating a View: Example" on page 17-24

**alias**

Specify names for the expressions selected by the defining query of the view. The number of aliases must match the number of expressions selected by the view. Aliases must follow the rules for naming Oracle Database schema objects. Aliases must be unique within the view.

If you omit the aliases, then the database derives them from the columns or column aliases in the query. For this reason, you must use aliases if the query contains expressions rather than only column names. Also, you must specify aliases if the view definition includes constraints.

**Restriction on View Aliases** You cannot specify an alias when creating an object view.

**VISIBLE | INVISIBLE**

Use this clause to specify whether a view column is **VISIBLE** or **INVISIBLE**. By default, view columns are **VISIBLE** regardless of their visibility in the base tables, unless you specify **INVISIBLE**. This applies to conventional views and editioning views. For complete information on these clauses, refer to “VISIBLE | INVISIBLE” on page 16-33 in the documentation on CREATE TABLE.

**inline_constraint and out_of_line_constraint**

You can specify constraints on views and object views. You define the constraint at the view level using the **out_of_line_constraint** clause. You define the constraint as part of column or attribute specification using the **inline_constraint** clause after the appropriate alias.

Oracle Database does not enforce view constraints. For a full discussion of view constraints, including restrictions, refer to “View Constraints” on page 8-19.

**See Also:** “Creating a View with Constraints: Example” on page 17-25

**object_view_clause**

The **object_view_clause** lets you define a view on an object type.

**See Also:** ”Creating an Object View: Example” on page 17-26

**OF type_name Clause**

Use this clause to explicitly create an **object view** of type **type_name**. The columns of an object view correspond to the top-level attributes of type **type_name**. Each row will contain an object instance and each instance will be associated with an object identifier as specified in the **WITH OBJECT IDENTIFIER** clause. If you omit **schema**, then the database creates the object view in your own schema.

Object tables, as well as **XMLType** tables, object views, and **XMLType** views, do not have any column names specified for them. Therefore, Oracle Database defines a system-generated pseudocolumn **OBJECT_ID**. You can use this column name in queries and to create object views with the **WITH OBJECT IDENTIFIER** clause.

**WITH OBJECT IDENTIFIER Clause**

Use the **WITH OBJECT IDENTIFIER** clause to specify a top-level (root) object view. This clause lets you specify the attributes of the object type that will be used as a key to identify each row in the object view. In most cases these attributes correspond to the primary key columns of the base table. You must ensure that the attribute list is unique and identifies exactly one row in the view. The **WITH OBJECT IDENTIFIER** and **WITH OBJECT ID** clauses can be used interchangeably and are provided for semantic clarity.

**Restrictions on Object Views**

Object views are subject to the following restrictions:

- If you try to dereference or pin a primary key **REF** that resolves to more than one instance in the object view, then the database returns an error.
- You cannot specify this clause if you are creating a subview, because subviews inherit object identifiers from superviews.
If the object view is defined on an object table or an object view, then you can omit this clause or specify `DEFAULT`.

**DEFAULT** Specify `DEFAULT` if you want the database to use the intrinsic object identifier of the underlying object table or object view to uniquely identify each row.

**attribute** For `attribute`, specify an attribute of the object type from which the database should create the object identifier for the object view.

**UNDER Clause**
Use the `UNDER` clause to specify a subview based on an object superview.

**Restrictions on Subviews**
Subviews are subject to the following restrictions:
- You must create a subview in the same schema as the superview.
- The object type `type_name` must be the immediate subtype of `superview`.
- You can create only one subview of a particular type under the same superview.

**See Also:**
- `CREATE TYPE` on page 17-3 for information about creating objects
- Oracle Database Reference for information on data dictionary views

**XMLType_view_clause**
Use this clause to create an XMLType view, which displays data from an XMLSchema-based table of type XMLType. The `XMLSchema_spec` indicates the XMLSchema to be used to map the XML data to its object-relational equivalents. The XMLSchema must already have been created before you can create an XMLType view.

The `WITH OBJECT IDENTIFIER` and `WITH OBJECT ID` clauses can be used interchangeably and are provided for semantic clarity.

Object tables, as well as XMLType tables, object views, and XMLType views, do not have any column names specified for them. Therefore, Oracle Database defines a system-generated pseudocolumn `OBJECT_ID`. You can use this column name in queries and to create object views with the `WITH OBJECT IDENTIFIER` clause.

**See Also:**
- Oracle XML DB Developer’s Guide for information on XMLType views and XMLSchemas
- "Creating an XMLType View: Example" on page 17-27 and "Creating a View on an XMLType Table: Example" on page 17-27

**BEQUEATH**
Use the `BEQUEATH` clause to specify whether functions referenced in the view are executed using the view invoker’s rights or the view definer’s rights.

**CURRENT_USER**
If you specify `BEQUEATH CURRENT_USER`, then functions referenced by the view are executed using the view invoker’s rights as long as one of the following conditions is met:
- The view owner has the `INHERIT PRIVILEGES` object privilege on the invoking user.
- The view owner has the `INHERIT ANY PRIVILEGES` system privilege.
If a query of the view invokes an identity- or privilege-sensitive SQL function, or an invoker’s rights PL/SQL or Java function, then the current schema, current user, and currently enabled roles within the operation’s execution are inherited from the querying user’s environment, rather than from the owner of the view.

This clause does not turn the view itself into an invoker’s rights object. Name resolution within the view is still handled using the view owner’s schema, and privilege checking for the view is done using the view owner's privileges.

**DEFINER** If you specify `BEQUEATH DEFINER`, then functions referenced by the view are executed using the view definer’s rights. If a query on the view invokes an identity- or privilege-sensitive SQL function, or an invoker’s rights PL/SQL or Java function, then the current schema, current user, and currently enabled roles within the operation’s execution are inherited from the owner of the view.

Name resolution within the view is handled using the view owner’s schema, and privilege checking for the view is done using the view owner's privileges.

This is the default.

**Restriction on the BEQUEATH Clause** You cannot specify this clause with the EDITIONING clause.

**See Also:** Oracle Database Security Guide for more information on controlling invoker’s rights and definer’s rights in views

**AS subquery**

Specify a subquery that identifies columns and rows of the table(s) that the view is based on. The select list of the subquery can contain up to 1000 expressions.

If you create views that refer to remote tables and views, then the database links you specify must have been created using the `CONNECT TO` clause of the `CREATE DATABASE LINK` statement, and you must qualify them with a schema name in the view subquery.

If you create a view with the `flashback_query_clause` in the defining query, then the database does not interpret the `AS OF` expression at create time but rather each time a user subsequently queries the view.

**See Also:** "Creating a Join View: Example" on page 17-25 and Oracle Database Development Guide for more information on Oracle Flashback Query

**Restrictions on the Defining Query of a View** The view query is subject to the following restrictions:

- The subquery cannot select the `CURRVAL` or `NEXTVAL` pseudocolumns.
- If the subquery selects the `ROWID`, `ROWNUM`, or `LEVEL` pseudocolumns, then those columns must have aliases in the view subquery.
- If the subquery uses an asterisk (*) to select all columns of a table, and you later add new columns to the table, then the view will not contain those columns until you re-create the view by issuing a `CREATE OR REPLACE VIEW` statement.
- For object views, the number of elements in the subquery select list must be the same as the number of top-level attributes for the object type. The data type of each of the selecting elements must be the same as the corresponding top-level attribute.
- You cannot specify the `SAMPLE` clause.
The preceding restrictions apply to materialized views as well.

**Notes on Updatable Views**  The following notes apply to updatable views:

An updatable view is one you can use to insert, update, or delete base table rows. You can create a view to be inherently updatable, or you can create an INSTEAD OF trigger on any view to make it updatable.

To learn whether and in what ways the columns of an inherently updatable view can be modified, query the USER_UPDATABLE_COLUMNS data dictionary view. The information displayed by this view is meaningful only for inherently updatable views. For a view to be inherently updatable, the following conditions must be met:

- Each column in the view must map to a column of a single table. For example, if a view column maps to the output of a TABLE clause (an unnested collection), then the view is not inherently updatable.

- The view must not contain any of the following constructs:
  - A set operator
  - A DISTINCT operator
  - An aggregate or analytic function
  - A GROUP BY, ORDER BY, MODEL, CONNECT BY, or START WITH clause
  - A collection expression in a SELECT list
  - A subquery in a SELECT list
  - A subquery designated WITH READ ONLY
  - Joins, with some exceptions, as documented in Oracle Database Administrator’s Guide

- In addition, if an inherently updatable view contains pseudocolumns or expressions, then you cannot update base table rows with an UPDATE statement that refers to any of these pseudocolumns or expressions.

- If you want a join view to be updatable, then all of the following conditions must be true:
  - The DML statement must affect only one table underlying the join.
  - For an INSERT statement, the view must not be created WITH CHECK OPTION, and all columns into which values are inserted must come from a key-preserved table. A key-preserved table is one for which every primary key or unique key value in the base table is also unique in the join view.
  - For an UPDATE statement, the view must not be created WITH CHECK OPTION, and all columns updated must be extracted from a key-preserved table.
  - For a DELETE statement, if the join results in more than one key-preserved table, then Oracle Database deletes from the first table named in the FROM clause, whether or not the view was created WITH CHECK OPTION.

**See Also:**

- Oracle Database Administrator’s Guide for more information on updatable views
- "Creating an Updatable View: Example" on page 17-25, "Creating a Join View: Example" on page 17-25 for an example of updatable join views and key-preserved tables, and Oracle Database PL/SQL Language Reference for an example of an INSTEAD OF trigger on a view that is not inherently updatable
subquery_restriction_clause

Use the subquery_restriction_clause to restrict the defining query of the view in one of the following ways:

WITH READ ONLY Specify WITH READ ONLY to indicate that the table or view cannot be updated.

WITH CHECK OPTION Specify WITH CHECK OPTION to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the FROM clause but not in subquery in the WHERE clause.

CONSTRAINT constraint Specify the name of the READ ONLY or CHECK OPTION constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form SYS_Cn, where n is an integer that makes the constraint name unique within the database.

Note: For tables, WITH CHECK OPTION guarantees that inserts and updates result in tables that the defining table subquery can select. For views, WITH CHECK OPTION cannot make this guarantee if:

- There is a subquery within the defining query of this view or any view on which this view is based or
- INSERT, UPDATE, or DELETE operations are performed using INSTEAD OF triggers.

Restriction on the subquery_restriction_clause You cannot specify this clause if you specify an ORDER BY clause.

See Also: "Creating a Read-Only View: Example" on page 17-26

Examples

Creating a View: Example The following statement creates a view of the sample table employees named emp_view. The view shows the employees in department 20 and their annual salary:

```
CREATE VIEW emp_view AS
  SELECT last_name, salary*12 AS annual_salary
  FROM employees
  WHERE department_id = 20;
```

The view declaration need not define a name for the column based on the expression salary*12, because the subquery uses a column alias (annual_salary) for this expression.

Creating an Editioning View: Example The following statement creates an editioning view of the orders table:

```
CREATE EDITIONING VIEW ed_orders_view (o_id, o_date, o_status)
  AS SELECT order_id, order_date, order_status
  FROM orders
  WITH READ ONLY;
```
CREATE VIEW

You can use this view to isolate an application from DDL changes to the \texttt{orders} table during an administrative operation such as an upgrade. You can create a DML trigger on this view, so that the trigger fires when a DML operation targets the view itself, but does not fire if the DML operation targets the \texttt{orders} table.

**Creating a View with Constraints: Example**  
The following statement creates a restricted view of the sample table hr.\texttt{employees} and defines a unique constraint on the \texttt{email} view column and a primary key constraint for the view on the \texttt{emp_id} view column:

```sql
CREATE VIEW emp_sal (emp_id, last_name, email UNIQUE RELY DISABLE NOVALIDATE,
CONSTRAINT id_pk PRIMARY KEY (emp_id) RELY DISABLE NOVALIDATE)
AS SELECT employee_id, last_name, email FROM employees;
```

**Creating an Updatable View: Example**  
The following statement creates an updatable view named \texttt{clerk} of all clerks in the \texttt{employees} table. Only the employees' IDs, last names, department numbers, and jobs are visible in this view, and these columns can be updated only in rows where the employee is a kind of clerk:

```sql
CREATE VIEW clerk AS
 SELECT employee_id, last_name, department_id, job_id
 FROM employees
 WHERE job_id = 'PU_CLERK'
 or job_id = 'SH_CLERK'
 or job_id = 'ST_CLERK';
```

This view lets you change the \texttt{job_id} of a purchasing clerk to purchasing manager (\texttt{PU\_MAN}):  

```sql
UPDATE clerk SET job_id = 'PU\_MAN' WHERE employee_id = 118;
```

The next example creates the same view \texttt{WITH CHECK OPTION}. You cannot subsequently insert a new row into \texttt{clerk} if the new employee is not a clerk. You can update an employee's \texttt{job_id} from one type of clerk to another type of clerk, but the update in the preceding statement would fail, because the view cannot access employees with non-clerk \texttt{job_id}.

```sql
CREATE VIEW clerk AS
 SELECT employee_id, last_name, department_id, job_id
 FROM employees
 WHERE job_id = 'PU_CLERK'
 or job_id = 'SH_CLERK'
 or job_id = 'ST_CLERK'
 WITH CHECK OPTION;
```

**Creating a Join View: Example**  
A join view is one whose view subquery contains a join. If at least one column in the join has a unique index, then it may be possible to modify one base table in a join view. You can query \texttt{USER\_UPDATABLE\_COLUMNS} to see whether the columns in a join view are updatable. For example:

```sql
CREATE VIEW locations_view AS
SELECT d.department_id, d.department_name, l.location_id, l.city
FROM departments d, locations l
WHERE d.location_id = l.location_id;
```

```sql
SELECT column_name, updatable
FROM user_updatable_columns
WHERE table_name = 'LOCATIONS\_VIEW'
ORDER BY column_name, updatable;
```
CREATE VIEW

<table>
<thead>
<tr>
<th>COLUMN_NAME</th>
<th>UPD</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEPARTMENT_ID</td>
<td>YES</td>
</tr>
<tr>
<td>DEPARTMENT_NAME</td>
<td>YES</td>
</tr>
<tr>
<td>LOCATION_ID</td>
<td>NO</td>
</tr>
<tr>
<td>CITY</td>
<td>NO</td>
</tr>
</tbody>
</table>

In the preceding example, the primary key index on the location_id column of the locations table is not unique in the locations_view view. Therefore, locations is not a key-preserved table and columns from that base table are not updatable.

```
INSERT INTO locations_view VALUES
    (999, 'Entertainment', 87, 'Roma');
ERROR at line 1:
ORA-01776: cannot modify more than one base table through a join view
```

You can insert, update, or delete a row from the departments base table, because all the columns in the view mapping to the departments table are marked as updatable and because the primary key of departments is retained in the view.

```
INSERT INTO locations_view (department_id, department_name)
VALUES (999, 'Entertainment');
```

1 row created.

---

**Note:** For you to insert into the table using the view, the view must contain all NOT NULL columns of all tables in the join, unless you have specified DEFAULT values for the NOT NULL columns.

---

**See Also:** Oracle Database Administrator’s Guide for more information on updating join views

**Creating a Read-Only View: Example** The following statement creates a read-only view named customer_ro of the oe.customers table. Only the customers' last names, language, and credit limit are visible in this view:

```
CREATE VIEW customer_ro (name, language, credit) AS
    SELECT cust_last_name, nls_language, credit_limit
    FROM customers
    WITH READ ONLY;
```

**Creating an Object View: Example** The following example shows the creation of the type inventory_typ in the oc schema, and the oc_inventories view that is based on that type:

```
CREATE TYPE inventory_typ
    OID '824A4A46A4CD4656DE034080020D0E3D'
    AS OBJECT
    ( product_id          NUMBER(6)
    , warehouse           warehouse_typ
    , quantity_on_hand    NUMBER(8)
    );
/
CREATE OR REPLACE VIEW oc_inventories OF inventory_typ
    WITH OBJECT OID (product_id)
    AS SELECT i.product_id,
CREATE VIEW

warehouse_typ(w.warehouse_id, w.warehouse_name, w.location_id),
i.quantity_on_hand
FROM inventories i, warehouses w
WHERE i.warehouse_id=w.warehouse_id;

Creating a View on an XMLType Table: Example  The following example builds a
regular view on the XMLType table xwarehouses, which was created in "Examples" on
page 16-89:

CREATE VIEW warehouse_view AS
  SELECT VALUE(p) AS warehouse_xml
  FROM xwarehouses p;

You select from such a view as follows:

SELECT e.warehouse_xml.getclobval()
  FROM warehouse_view e
  WHERE EXISTSNODE(warehouse_xml, ' //Docks') =1;

Creating an XMLType View: Example  In some cases you may have an
object-relational table upon which you would like to build an XMLType view. The
following example creates an object-relational table resembling the XMLType column
warehouse_spec in the sample table oe.warehouses, and then creates an XMLType view
of that table:

CREATE TABLE warehouse_table
{
  WarehouseID       NUMBER,
  Area              NUMBER,
  Docks             NUMBER,
  DockType          VARCHAR2(100),
  WaterAccess       VARCHAR2(10),
  RailAccess        VARCHAR2(10),
  Parking           VARCHAR2(20),
  VClearance        NUMBER
};

INSERT INTO warehouse_table
  VALUES(5, 103000,3,'Side Load','false','true','Lot',15);

CREATE VIEW warehouse_view OF XMLTYPE
XMLSCHEMA 'http://www.example.com/xwarehouses.xsd'
ELEMENT 'Warehouse'
WITH OBJECT ID
(extract(OBJECT_VALUE, '//Warehouse/Area/text()').getnumberval())
AS SELECT XMLELEMENT("Warehouse",
   XMLFOREST(WarehouseID as "Building",
     area as "Area",
     docks as "Docks",
     docktype as "DockType",
     wateraccess as "WaterAccess",
     railaccess as "RailAccess",
     parking as "Parking",
     VClearance as "VClearance")
FROM warehouse_table;

You query this view as follows:

SELECT VALUE(e) FROM warehouse_view e;
DELETE

Purpose

Use the DELETE statement to remove rows from:

- An unpartitioned or partitioned table
- The unpartitioned or partitioned base table of a view
- The unpartitioned or partitioned container table of a writable materialized view
- The unpartitioned or partitioned master table of an updatable materialized view

Prerequisites

For you to delete rows from a table, the table must be in your own schema or you must have the DELETE object privilege on the table.

For you to delete rows from an updatable materialized view, the materialized view must be in your own schema or you must have the DELETE object privilege on the materialized view.

For you to delete rows from the base table of a view, the owner of the schema containing the view must have the DELETE object privilege on the base table. Also, if the view is in a schema other than your own, then you must have the DELETE object privilege on the view.

The DELETE ANY TABLE system privilege also allows you to delete rows from any table or table partition or from the base table of any view.

To delete rows from an object on a remote database, you must also have the READ or SELECT object privilege on the object.

If the SQL92_SECURITY initialization parameter is set to TRUE and the DELETE operation references table columns, such as the columns in a where clause, then you must also have the SELECT object privilege on the object from which you want to delete rows.

You cannot delete rows from a table if a function-based index on the table has become invalid. You must first validate the function-based index.

Syntax

\[
delete ::= \\
\text{DELETE hint \{FROM dml\_table\_expression\_clause (\text{only} \{dml\_table\_expression\_clause\})\} t\_alias \text{where\_clause returning\_clause error\_logging\_clause}}
\]

(DML_table_expression_clause::= on page 17-29, where_clause::= on page 17-29, returning_clause::= on page 17-29, error_logging_clause::= on page 17-30)
DML_table_expression_clause ::= 

\[\text{partition_extension_clause} \]

\[\text{partition_extension_clause} \]

\[\text{subquery} \]

\[\text{table_collection_expression} \]

\(\text{partition_extension_clause}::=\) on page 17-29, \(\text{subquery}::=\) on page 19-5, \(\text{subquery_restriction_clause}::=\) on page 17-29, \(\text{table_collection_expression}::=\) on page 17-29

partition_extension_clause ::= 

\(\text{PARTITION} \)\(\text{partition} \)

\(\text{FOR} \)\(\text{partition_key_value} \)

\(\text{SUBPARTITION} \)\(\text{subpartition} \)

\(\text{FOR} \)\(\text{subpartition_key_value} \)

subquery_restriction_clause ::= 

\(\text{WITH} \)\(\text{READ ONLY} \)

\(\text{CONRAINT} \)\(\text{constraint} \)

table_collection_expression ::= 

\(\text{TABLE} \)\(\text{collection_expression} \)

where_clause ::= 

\(\text{WHERE} \)\(\text{condition} \)

returning_clause ::= 

\(\text{RETURN} \)\(\text{expr} \)

\(\text{INTO} \)\(\text{data_item} \)
**error_logging_clause**::=

```
LOG ERRORS INTO schema.table (simple_expression)
REJECT LIMIT integer UNLIMITED
```

**Semantics**

**hint**
Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

*See Also:* "Hints" on page 2-77 for the syntax and description of hints

**from_clause**
Use the FROM clause to specify the database objects from which you are deleting rows.

The ONLY syntax is relevant only for views. Use the ONLY clause if the view in the FROM clause belongs to a view hierarchy and you do not want to delete rows from any of its subviews.

**DML_table_expression_clause**
Use this clause to specify the objects from which data is being deleted.

**schema**
Specify the schema containing the table or view. If you omit schema, then Oracle Database assumes the table or view is in your own schema.

**table | view | materialized view | subquery**
Specify the name of a table, view, materialized view, or the column or columns resulting from a subquery, from which the rows are to be deleted.

When you delete rows from an updatable view, Oracle Database deletes rows from the base table.

You cannot delete rows from a read-only materialized view. If you delete rows from a writable materialized view, then the database removes the rows from the underlying container table. However, the deletions are overwritten at the next refresh operation. If you delete rows from an updatable materialized view that is part of a materialized view group, then the database also removes the corresponding rows from the master table.

If table or the base table of view or the master table of materialized_view contains one or more domain index columns, then this statement executes the appropriate indextype delete routine.

*See Also:* Oracle Database Data Cartridge Developer’s Guide for more information on these routines
Issuing a `DELETE` statement against a table fires any `DELETE` triggers defined on the table.

All table or index space released by the deleted rows is retained by the table and index.

**partition_extension_clause**
Specify the name or partition key value of the partition or subpartition targeted for deletes within the object.

You need not specify the partition name when deleting values from a partitioned object. However, in some cases, specifying the partition name is more efficient than a complicated `where_clause`.

**See Also:** "References to Partitioned Tables and Indexes" on page 2-128 and "Deleting Rows from a Partition: Example" on page 17-34

**dblink**
Specify the complete or partial name of a database link to a remote database where the object is located. You can delete rows from a remote object only if you are using Oracle Database distributed functionality.

**See Also:** "References to Objects in Remote Databases" on page 2-126 for information on referring to database links and "Deleting Rows from a Remote Database: Example" on page 17-34

If you omit `dblink`, then the database assumes that the object is located on the local database.

**subquery_restriction_clause**
The `subquery_restriction_clause` lets you restrict the subquery in one of the following ways:

**WITH READ ONLY** Specify `WITH READ ONLY` to indicate that the table or view cannot be updated.

**WITH CHECK OPTION** Specify `WITH CHECK OPTION` to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the `FROM` clause but not in subquery in the `WHERE` clause.

**CONSTRAINT constraint** Specify the name of the `CHECK OPTION` constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form `SYS_Cn`, where n is an integer that makes the constraint name unique within the database.

**See Also:** "Using the WITH CHECK OPTION Clause: Example" on page 19-66

**table_collection_expression**
The `table_collection_expression` lets you inform Oracle that the value of `collection_expression` should be treated as a table for purposes of query and DML operations. The `collection_expression` can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is,
a value whose type is nested table or varray. This process of extracting the elements of a collection is called **collection unnesting**.

The optional plus (+) is relevant if you are joining the `TABLE` collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

---

**Note:** In earlier releases of Oracle, when `collection_expression` was a subquery, `table_collection_expression` was expressed as THE subquery. That usage is now deprecated.

---

You can use a `table_collection_expression` in a correlated subquery to delete rows with values that also exist in another table.

**See Also:** "Table Collections: Examples" on page 19-73

**collection_expression** Specify a subquery that selects a nested table column from the object from which you are deleting.

**Restrictions on the dml_table_expression_clause Clause** This clause is subject to the following restrictions:

- You cannot execute this statement if `table` or the base or master table of `view` or `materialized_view` contains any domain indexes marked `IN_PROGRESS` or `FAILED`.
- You cannot insert into a partition if any affected index partitions are marked `UNUSABLE`.
- You cannot specify the `ORDER BY` clause in the subquery of the `DML_table_expression_clause`.
- You cannot delete from a view except through `INSTEAD OF` triggers if the defining query of the view contains one of the following constructs:
  - A set operator
  - A `DISTINCT` operator
  - An aggregate or analytic function
  - A `GROUP BY`, `ORDER BY`, `MODEL`, `CONNECT BY`, or `START WITH` clause
  - A collection expression in a `SELECT` list
  - A subquery in a `SELECT` list
  - A subquery designated `WITH READ ONLY` Joins, with some exceptions, as documented in Oracle Database Administrator’s Guide

If you specify an index, index partition, or index subpartition that has been marked `UNUSABLE`, then the `DELETE` statement will fail unless the `SKIP_UNUSABLE_INDEXES` initialization parameter has been set to `true`.

**See Also:** ALTER SESSION on page 11-65

**where_clause**

Use the `where_clause` to delete only rows that satisfy the condition. The condition can reference the object from which you are deleting and can contain a subquery. You can delete rows from a remote object only if you are using Oracle Database distributed functionality. Refer to Chapter 6, "Conditions" for the syntax of `condition`.

If this clause contains a subquery that refers to remote objects, then the `DELETE` operation can run in parallel as long as the reference does not loop back to an object on
the local database. However, if the subquery in the DML_table_expression_clause refers to any remote objects, then the DELETE operation will run serially without notification. Refer to the parallel_clause on page 16-81 in the CREATE TABLE documentation for additional information.

If you omit dblink, then the database assumes that the table or view is located on the local database.

If you omit the where_clause, then the database deletes all rows of the object.

t_alias Provide a correlation name for the table, view, materialized view, subquery, or collection value to be referenced elsewhere in the statement. This alias is required if the DML_table_expression_clause references any object type attributes or object type methods. Table aliases are generally used in DELETE statements with correlated queries.

returning_clause
This clause lets you return values from deleted columns, and thereby eliminate the need to issue a SELECT statement following the DELETE statement.

The returning clause retrieves the rows affected by a DML statement. You can specify this clause for tables and materialized views and for views with a single base table.

When operating on a single row, a DML statement with a returning_clause can retrieve column expressions using the affected row, rowid, and REFs to the affected row and store them in host variables or PL/SQL variables.

When operating on multiple rows, a DML statement with the returning_clause stores values from expressions, rowids, and REFs involving the affected rows in bind arrays.

eexpr Each item in the expr list must be a valid expression syntax.

INTO The INTO clause indicates that the values of the changed rows are to be stored in the variable(s) specified in data_item list.

data_item Each data_item is a host variable or PL/SQL variable that stores the retrieved expr value.

For each expression in the RETURNING list, you must specify a corresponding type-compatible PL/SQL variable or host variable in the INTO list.

Restrictions The following restrictions apply to the RETURNING clause:

- The expr is restricted as follows:
  - For UPDATE and DELETE statements each expr must be a simple expression or a single-set aggregate function expression. You cannot combine simple expressions and single-set aggregate function expressions in the same returning_clause. For INSERT statements, each expr must be a simple expression. Aggregate functions are not supported in an INSERT statement RETURNING clause.
  - Single-set aggregate function expressions cannot include the DISTINCT keyword.
- If the expr list contains a primary key column or other NOT NULL column, then the update statement fails if the table has a BEFORE UPDATE trigger defined on it.
- You cannot specify the returning_clause for a multitable insert.
- You cannot use this clause with parallel DML or with remote objects.
You cannot retrieve LONG types with this clause.

You cannot specify this clause for a view on which an INSTEAD OF trigger has been defined.

See Also:
- Oracle Database PL/SQL Language Reference for information on using the BULK COLLECT clause to return multiple values to collection variables
- "Using the RETURNING Clause: Example" on page 17-34

error_logging_clause
The error_logging_clause has the same behavior in DELETE statement as it does in an INSERT statement. Refer to the INSERT statement error_logging_clause on page 18-73 for more information.

See Also: "Inserting Into a Table with Error Logging: Example" on page 18-74

Examples

Deleting Rows: Examples The following statement deletes all rows from the sample table oe.product_descriptions where the value of the language_id column is AR:

```
DELETE FROM product_descriptions
  WHERE language_id = 'AR';
```

The following statement deletes from the sample table hr.employees purchasing clerks whose commission rate is less than 10%:

```
DELETE FROM employees
  WHERE job_id = 'SA_REP'
    AND commission_pct < .2;
```

The following statement has the same effect as the preceding example, but uses a subquery:

```
DELETE FROM (SELECT * FROM employees)
  WHERE job_id = 'SA_REP'
    AND commission_pct < .2;
```

Deleting Rows from a Remote Database: Example The following statement deletes specified rows from the locations table owned by the user hr on a database accessible by the database link remote:

```
DELETE FROM hr.locations@remote
  WHERE location_id > 3000;
```

Deleting Nested Table Rows: Example For an example that deletes nested table rows, refer to "Table Collections: Examples" on page 19-73.

Deleting Rows from a Partition: Example The following example removes rows from partition sales_q1_1998 of the sh.sales table:

```
DELETE FROM sales PARTITION (sales_q1_1998)
  WHERE amount_sold > 1000;
```

Using the RETURNING Clause: Example
The following example returns column `salary` from the deleted rows and stores the result in bind variable `:bnd1`. The bind variable must already have been declared.

```
DELETE FROM employees
WHERE job_id = 'SA_REP'
AND hire_date + TO_YMINTERVAL('01-00') < SYSDATE
RETURNING salary INTO :bnd1;
```
DISASSOCIATE STATISTICS

Purpose

Use the DISASSOCIATE STATISTICS statement to disassociate default statistics or a statistics type from columns, standalone functions, packages, types, domain indexes, or indextypes.

See Also: ASSOCIATE STATISTICS on page 13-27 for more information on statistics type associations

Prerequisites

To issue this statement, you must have the appropriate privileges to alter the underlying table, function, package, type, domain index, or indextype.

Syntax

\[
\text{disassociate} \_{\text{statistics}}::= \\
\text{DISASSOCIATE_ STATISTICS_ FROM} \\
\text{COLUMNS}_ \text{schema}_ \text{.table}_ \text{.column} \\
\text{FUNCTIONS}_ \text{schema}_ \text{.function} \\
\text{PACKAGES}_ \text{schema}_ \text{.package} \\
\text{TYPES}_ \text{schema}_ \text{.type} \\
\text{INDEXES}_ \text{schema}_ \text{.index} \\
\text{INDEXTYPES}_ \text{schema}_ \text{.indextype} \\
\text{FORCE}_ \text{.}
\]
DISASSOCIATE STATISTICS

Semantics

FROM COLUMNS | FUNCTIONS | PACKAGES | TYPES | INDEXES | INDEXTYPES
Specify one or more columns, standalone functions, packages, types, domain indexes, or indextypes from which you are disassociating statistics.

If you do not specify schema, then Oracle Database assumes the object is in your own schema.

If you have collected user-defined statistics on the object, then the statement fails unless you specify FORCE.

FORCE
Specify FORCE to remove the association regardless of whether any statistics exist for the object using the statistics type. If statistics do exist, then the statistics are deleted before the association is deleted.

Note: When you drop an object with which a statistics type has been associated, Oracle Database automatically disassociates the statistics type with the FORCE option and drops all statistics that have been collected with the statistics type.

Examples

Disassociating Statistics: Example  This statement disassociates statistics from the emp_mgmt package. See Oracle Database PL/SQL Language Reference for the example that creates this package in the hr schema.

DISASSOCIATE STATISTICS FROM PACKAGES hr.emp_mgmt;
This section describes the `DROP AUDIT POLICY` statement for unified auditing. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to Oracle Database Security Guide for more information on unified auditing.

### Purpose

Use the `DROP AUDIT POLICY` statement to remove a unified audit policy from the database.

**See Also:**
- CREATE AUDIT POLICY (Unified Auditing) on page 14-2
- ALTER AUDIT POLICY (Unified Auditing) on page 10-24
- AUDIT (Unified Auditing) on page 13-45
- NOAUDIT (Unified Auditing) on page 18-92

### Prerequisites

You must have the `AUDIT SYSTEM` system privilege or the `AUDIT_ADMIN` role.

To drop a common unified audit policy, the current container must be the root and you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role. To drop a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role, or you must have the locally granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` local role in the container.

### Syntax

```
drop_audit_policy ::= 
  DROP AUDIT POLICY policy
```

### Semantics

**policy**

Specify the name of the unified audit policy you want to drop. The policy must have been created using the `CREATE AUDIT POLICY` statement.

You can find the names of all unified audit policies by querying the `AUDIT_UNIFIED_POLICIES` view and the names of all enabled unified audit policies by querying the `AUDIT_UNIFIED_ENABLED_POLICIES` view.

**Restriction on Dropping Unified Audit Policies**

You cannot drop an enabled unified audit policy. You must first disable the policy using the `NOAUDIT` statement.
Examples

**Dropping a Unified Audit Policy: Example**  The following statement drops unified audit policy `table_pol`:

```sql
DROP AUDIT POLICY table_pol;
```
DROP CLUSTER

Purpose

Use the DROP CLUSTER clause to remove a cluster from the database.

---

**Caution:** When you drop a cluster, any tables in the recycle bin that were once part of that cluster are purged from the recycle bin and can no longer be recovered with a FLASHBACK TABLE operation.

---

You cannot uncluster an individual table. Instead you must perform these steps:

1. Create a new table with the same structure and contents as the old one, but with no CLUSTER clause.
2. Drop the old table.
3. Use the RENAME statement to give the new table the name of the old one.

**See Also:** CREATE TABLE on page 16-6, DROP TABLE on page 18-5, RENAME on page 18-98, GRANT on page 18-35 for information on these steps

Prerequisites

The cluster must be in your own schema or you must have the DROP ANY CLUSTER system privilege.

Syntax

```
drop_cluster ::= 
```

Semantics

**schema**

Specify the schema containing the cluster. If you omit `schema`, then the database assumes the cluster is in your own schema.

**cluster**

Specify the name of the cluster to be dropped. Dropping a cluster also drops the cluster index and returns all cluster space, including data blocks for the index, to the appropriate tablespace(s).

**INCLUDING TABLES**

Specify `INCLUDING TABLES` to drop all tables that belong to the cluster.
CASCADe CONSTRAINTs

Specify CASCADE CONSTRAINTS to drop all referential integrity constraints from tables outside the cluster that refer to primary and unique keys in tables of the cluster. If you omit this clause and such referential integrity constraints exist, then the database returns an error and does not drop the cluster.

Examples

Dropping a Cluster: Examples  The following examples drop the clusters created in the “Examples” section of CREATE CLUSTER on page 14-17.

The following statements drops the language cluster:

DROP CLUSTER language;

The following statement drops the personnel cluster as well as tables dept_10 and dept_20 and any referential integrity constraints that refer to primary or unique keys in those tables:

DROP CLUSTER personnel
  INCLUDING TABLES
  CASCADE CONSTRAINTS;
Purpose

Use the DROP CONTEXT statement to remove a context namespace from the database. Removing a context namespace does not invalidate any context under that namespace that has been set for a user session. However, the context will be invalid when the user next attempts to set that context.

See Also: CREATE CONTEXT on page 14-19 and Oracle Database Security Guide for more information on contexts

Prerequisites

You must have the DROP ANY CONTEXT system privilege.

Syntax

\[
drop\_context::=\text{DROP CONTEXT }\text{name}\text{space}\]

Semantics

\text{name}\text{space}

Specify the name of the context namespace to drop. You cannot drop the built-in namespace USERENV.

See Also: SYS_CONTEXT on page 7-334 for information on the USERENV namespace

Examples

**Dropping an Application Context: Example**  The following statement drops the context created in CREATE CONTEXT on page 14-19:

\[
\text{DROP CONTEXT } hr\_context;\]
DROP DATABASE

Purpose

Caution: You cannot roll back a DROP DATABASE statement.

Use the DROP DATABASE statement to drop the database. This statement is useful when you want to drop a test database or drop an old database after successful migration to a new host.

See Also: Oracle Database Backup and Recovery User's Guide for more information on dropping the database

Prerequisites

You must have the SYSDBA system privilege to issue this statement. The database must be mounted in exclusive and restricted mode, and it must be closed.

Syntax

`drop_database::=`

Semantics

When you issue this statement, Oracle Database drops the database and deletes all control files and data files listed in the control file. If the database used a server parameter file (spfile), then the spfile is also deleted.

Archived logs and backups are not removed, but you can use Recovery Manager (RMAN) to remove them. If the database is on raw disks, then this statement does not delete the actual raw disk special files.
DROP DATABASE LINK

Purpose

Use the DROP DATABASE LINK statement to remove a database link from the database.

See Also: CREATE DATABASE LINK on page 14-44 for information on creating database links

Prerequisites

A private database link must be in your own schema. To drop a PUBLIC database link, you must have the DROP PUBLIC DATABASE LINK system privilege.

Syntax

drop_database_link ::= 

Semantics

PUBLIC

You must specify PUBLIC to drop a PUBLIC database link.

dblink

Specify the name of the database link to be dropped.

Restriction on Dropping Database Links

You cannot drop a database link in another user's schema, and you cannot qualify dblink with the name of a schema, because periods are permitted in names of database links. Therefore, Oracle Database interprets the entire name, such as ralph.linktosales, as the name of a database link in your schema rather than as a database link named linktosales in the schema ralph.

Examples

Dropping a Database Link: Example

The following statement drops the public database link named remote, which was created in "Defining a Public Database Link: Example" on page 14-47:

DROP PUBLIC DATABASE LINK remote;
DROP DIMENSION

Purpose

Use the DROP DIMENSION statement to remove the named dimension. This statement does not invalidate materialized views that use relationships specified in dimensions. However, requests that have been rewritten by query rewrite may be invalidated, and subsequent operations on such views may execute more slowly.

See Also:
- CREATE DIMENSION on page 14-49 and ALTER DIMENSION on page 10-75 for information on creating and modifying a dimension
- Oracle Database Concepts for general information about dimensions

Prerequisites

The dimension must be in your own schema or you must have the DROP ANY DIMENSION system privilege to use this statement.

Syntax

\[ \text{drop\_dimension} ::= \]

\[ \text{DROP DIMENSION} \quad \text{schema} \quad \text{dimension} \]

Semantics

\text{schema}

Specify the name of the schema in which the dimension is located. If you omit \text{schema}, then Oracle Database assumes the dimension is in your own schema.

\text{dimension}

Specify the name of the dimension you want to drop. The dimension must already exist.

Examples

**Dropping a Dimension: Example**  
This example drops the \text{sh.customers\_dim} dimension:

\[ \text{DROP DIMENSION customers\_dim;} \]

See Also:  
"Creating a Dimension: Examples" on page 14-52 and "Modifying a Dimension: Examples" on page 10-77 for examples of creating and modifying this dimension
DROP DIRECTORY

Purpose

Use the DROP DIRECTORY statement to remove a directory object from the database.

See Also: CREATE DIRECTORY on page 14-54 for information on creating a directory

Prerequisites

To drop a directory, you must have the DROP ANY DIRECTORY system privilege.

Caution: Do not drop a directory when files in the associated file system are being accessed by PL/SQL or OCI programs.

Syntax

drop_directory ::= 

Semantics

directory_name

Specify the name of the directory database object to be dropped.

Oracle Database removes the directory object but does not delete the associated operating system directory on the server file system.

Examples

Dropping a Directory: Example

The following statement drops the directory object bfile_dir:

DROP DIRECTORY bfile_dir;

See Also: "Creating a Directory: Examples" on page 14-55
**DROP DISKGROUP**

**Purpose**

The **DROP DISKGROUP** statement lets you drop an Oracle ASM disk group along with all the files in the disk group. Oracle ASM first ensures that no files in the disk group are open. It then drops the disk group and all its member disks and clears the disk header.

See Also:

- **CREATE DISKGROUP** on page 14-56 and **ALTER DISKGROUP** on page 10-78 for information on creating and modifying disk groups
- Oracle Automatic Storage Management Administrator’s Guide for information on Oracle ASM and using disks groups to simplify database administration

**Prerequisites**

You must have the **SYSASM** system privilege and you must have an Oracle ASM instance started, from which you issue this statement. The disk group to be dropped must be mounted.

**Syntax**

```
drop_diskgroup::=  
```

```
DROP DISKGROUP diskgroup_name  
```

**Semantics**

**diskgroup_name**

Specify the name of the disk group you want to drop.

**INCLUDING CONTENTS**

Specify **INCLUDING CONTENTS** to confirm that Oracle ASM should drop all the files in the disk group. You must specify this clause if the disk group contains any files.

---

**Note:** This SQL statement is valid only if you are using Oracle ASM and you have started an Oracle ASM instance. You must issue this statement from within the Oracle ASM instance, not from a normal database instance. For information on starting an Oracle ASM instance, refer to *Oracle Automatic Storage Management Administrator’s Guide*.
**EXCLUDING CONTENTS**

Specify **EXCLUDING CONTENTS** to ensure that Oracle ASM drops the disk group only when the disk group is empty. This is the default. If the disk group is not empty, then an error will be returned.

**FORCE**

This clause clears the headers on the disk belonging to a disk group that cannot be mounted by the Oracle ASM instance. The disk group cannot be mounted by any instance of the database.

The Oracle ASM instance first determines whether the disk group is being used by any other Oracle ASM instance using the same storage subsystem. If it is being used, and if the disk group is in the same cluster, or on the same node, then the statement fails. If the disk group is in a different cluster, then the system further checks to determine whether the disk group is mounted by any instance in the other cluster. If it is mounted elsewhere, then the statement fails. However, this latter check is not as definitive as the checks for disk groups in the same cluster. Therefore, use this clause with caution.

**Examples**

**Dropping a Diskgroup: Example**  The following statement drops the Oracle ASM disk group `dgroup_01`, which was created in 'Creating a Diskgroup: Example' on page 14-63, and all of the files in the disk group:

```
DROP DISKGROUP dgroup_01 INCLUDING CONTENTS;
```
DROP EDITION

Purpose

Use the `DROP EDITION` statement to drop an edition, along with all actual editionable objects it contains. An actual editionable object is an editionable object that has been created or modified in an edition.

See Also: `CREATE EDITION` on page 14-64 for a listing of editionable object types

Prerequisites

You must have the `DROP ANY EDITION` system privilege, granted either directly or through a role.

Syntax

```
drop_edition ::= drop EDITION edition CASCADE
```

Semantics

When successful, this statement drops the specified edition, including versions of any objects associated with that edition. Versions of the same objects in other editions are not dropped. Objects that are not editionable, or that are editionable but have not been actualized in the current edition, are not dropped.

You must specify `CASCADE` if the specified edition contains any actual editionable objects.

This statement is subject to the following conditions and restrictions:

- The specified edition cannot have both a parent edition and a child edition.
- The specified edition cannot contain any actual editionable objects that are inherited by a child edition, even if you specify `CASCADE`.
- `DROP EDITION` will fail if you attempt to drop the default edition.
- `DROP EDITION` will fail if you attempt to drop the root edition and the recycle bin contains at least one object that used to be in that edition before it was dropped. Under these circumstances, even `DROP EDITION CASCADE` will fail. In this case, you can purge all objects from the recycle bin with the `PURGE DBA_RECYCLEBIN` statement and then drop the edition. Refer to `PURGE` on page 18-96 for more information.
- `DROP EDITION` will also fail if you attempt to drop the leaf edition and the recycle bin contains at least one object that used to be in that edition before it was dropped. However, under these circumstances, `DROP EDITION CASCADE` will succeed.

The only type of editioned object that might be in the recycle bin is a trigger.
Examples

For examples that use this statement, refer to CREATE EDITION on page 14-64.
DROP FLASHBACK ARCHIVE

Purpose

Use the DROP FLASHBACK ARCHIVE clause to remove a flashback data archive from the system. This statement removes the flashback data archive and all the historical data in it, but does not drop the tablespaces that were used by the flashback data archive.

Prerequisites

You must have the FLASHBACK ARCHIVE ADMINISTER system privilege to drop a flashback data archive.

Syntax

```sql
drop_flashback_archive ::= 

DROP FLASHBACK ARCHIVE flashback_archive
```

Semantics

**flashback_archive**

Specify the name of the flashback data archive you want to drop.

See Also: CREATE FLASHBACK ARCHIVE on page 14-68 for information on creating flashback data archives and for some simple examples of using flashback data archives
DROP FUNCTION

Purpose

Functions are defined using PL/SQL. Refer to Oracle Database PL/SQL Language Reference for complete information on creating, altering, and dropping functions.

Use the DROP FUNCTION statement to remove a standalone stored function from the database.

Note: Do not use this statement to remove a function that is part of a package. Instead, either drop the entire package using the DROP PACKAGE statement or redefine the package without the function using the CREATE PACKAGE statement with the OR REPLACE clause.

Prerequisites

The function must be in your own schema or you must have the DROP ANY PROCEDURE system privilege.

Syntax

drop_function::=

DROP FUNCTION schema function_name;

Semantics

schema

Specify the schema containing the function. If you omit schema, then Oracle Database assumes the function is in your own schema.

function_name

Specify the name of the function to be dropped.

Oracle Database invalidates any local objects that depend on, or call, the dropped function. If you subsequently reference one of these objects, then the database tries to recompile the object and returns an error if you have not re-created the dropped function.

If any statistics types are associated with the function, then the database disassociates the statistics types with the FORCE option and drops any user-defined statistics collected with the statistics type.

See Also:

- Oracle Database Concepts for more information on how Oracle Database maintains dependencies among schema objects, including remote objects
- ASSOCIATE STATISTICS on page 13-27 and DISASSOCIATE STATISTICS on page 17-36 for more information on statistics type associations
Examples

**Dropping a Function: Example**  The following statement drops the function SecondMax in the sample schema oe and invalidates all objects that depend upon SecondMax:

```
DROP FUNCTION oe.SecondMax;
```

**See Also:**  *Oracle Database PL/SQL Language Reference* for the example that creates the SecondMax function
DROP INDEX

Purpose

Use the DROP INDEX statement to remove an index or domain index from the database.

When you drop a global partitioned index, a range-partitioned index, or a hash-partitioned index, all the index partitions are also dropped. If you drop a composite-partitioned index, then all the index partitions and subpartitions are also dropped.

In addition, when you drop a domain index:

- Oracle Database invokes the appropriate routine.
- If any statistics are associated with the domain index, then Oracle Database disassociates the statistics types with the FORCE clause and removes the user-defined statistics collected with the statistics type.

See Also:
- Oracle Database Data Cartridge Developer’s Guide for information on the routines
- CREATE INDEX on page 14-73 and ALTER INDEX on page 10-107 for information on creating and modifying an index
- The domain_index_clause of CREATE INDEX on page 14-73 for more information on domain indexes
- ASSOCIATE STATISTICS on page 13-27 and DISASSOCIATE STATISTICS on page 17-36 for more information on statistics type associations

Prerequisites

The index must be in your own schema or you must have the DROP ANY INDEX system privilege.

Syntax

\[\text{drop\_index::=}\]

\[\text{DROP INDEX schema index ONLINE FORCE}\]

Semantics

\textit{schema}

Specify the schema containing the index. If you omit \textit{schema}, then Oracle Database assumes the index is in your own schema.

\textit{index}

Specify the name of the index to be dropped. When the index is dropped, all data blocks allocated to the index are returned to the tablespace that contained the index.
ONLINE
Specify ONLINE to indicate that DML operations on the table or partition will be allowed while dropping the index.

FORCE
FORCE applies only to domain indexes. This clause drops the domain index even if the indextype routine invocation returns an error or the index is marked IN_PROGRESS. Without FORCE, you cannot drop a domain index if its indextype routine invocation returns an error or the index is marked IN_PROGRESS.

Restrictions on Dropping Indexes  The following restrictions apply to dropping indexes:

- You cannot drop a domain index if the index or any of its index partitions is marked IN_PROGRESS.
- You cannot specify the ONLINE clause when dropping a domain index, a cluster index, or an index on a queue table.

Examples

Dropping an Index: Example  This statement drops an index named ord_customer_ix_demo, which was created in "Compressing an Index: Example" on page 14-97:

DROP INDEX ord_customer_ix_demo;
DROP INDEXTYPE

Purpose

Use the DROP INDEXTYPE statement to drop an indextype as well as any association with a statistics type.

See Also: CREATE INDEXTYPE on page 14-103 for more information on indextypes

Prerequisites

The indextype must be in your own schema or you must have the DROP ANY INDEXTYPE system privilege.

Syntax

drop_indextype::=

Semantics

schema
Specify the schema containing the indextype. If you omit schema, then Oracle Database assumes the indextype is in your own schema.

indextype
Specify the name of the indextype to be dropped.

If any statistics types have been associated with indextype, then the database disassociates the statistics type from the indextype and drops any statistics that have been collected using the statistics type.

See Also: ASSOCIATE STATISTICS on page 13-27 and DISASSOCIATE STATISTICS on page 17-36 for more information on statistics associations

FORCE
Specify FORCE to drop the indextype even if the indextype is currently being referenced by one or more domain indexes. Oracle Database marks those domain indexes INVALID. Without FORCE, you cannot drop an indextype if any domain indexes reference the indextype.

Examples

Dropping an Indextype: Example

The following statement drops the indextype position_indextype, created in "Using Extensible Indexing" on page F-1, and marks INVALID any domain indexes defined on this indextype:

DROP INDEXTYPE position_indextype FORCE;
DROP JAVA

Purpose
Use the DROP JAVA statement to drop a Java source, class, or resource schema object.

See Also:
- CREATE JAVA on page 14-107 for information on creating Java objects
- Oracle Database Java Developer’s Guide for more information on resolving Java sources, classes, and resources

Prerequisites
The Java source, class, or resource must be in your own schema or you must have the DROP ANY PROCEDURE system privilege. You also must have the EXECUTE object privilege on Java classes to use this command.

Syntax

\[
\text{drop java}::=\]

\[
\text{DROP JAVA SOURCE schema object_name ;}
\]

\[
\text{DROP JAVA CLASS schema object_name ;}
\]

\[
\text{DROP JAVA RESOURCE schema object_name ;}
\]

Semantics

JAVA SOURCE
Specify SOURCE to drop a Java source schema object and all Java class schema objects derived from it.

JAVA CLASS
Specify CLASS to drop a Java class schema object.

JAVA RESOURCE
Specify RESOURCE to drop a Java resource schema object.

\text{object_name}
Specify the name of an existing Java class, source, or resource schema object. Enclose the \text{object_name} in double quotation marks to preserve lower- or mixed-case names.

Examples

Dropping a Java Class Object: Example  The following statement drops the Java class Agent, created in "Creating a Java Class Object: Example" on page 14-111:

\[
\text{DROP JAVA CLASS 'Agent';}
\]
DROP LIBRARY

Purpose

Use the DROP LIBRARY statement to remove an external procedure library from the database.

See Also: CREATE LIBRARY on page 15-2 for information on creating a library

Prerequisites

You must have the DROP ANY LIBRARY system privilege.

Syntax

\[ \text{drop_library ::=} \]

\[
\{ \text{DROP LIBRARY} (\text{library_name}) \}
\]

Semantics

\text{library_name}

Specify the name of the external procedure library being dropped.

Examples

\textbf{Dropping a Library: Example} The following statement drops the \textit{ext_lib} library:

\[
\text{DROP LIBRARY ext_lib;}
\]
DROP MATERIALIZED VIEW

Purpose

Use the DROP MATERIALIZED VIEW statement to remove an existing materialized view from the database.

When you drop a materialized view, Oracle Database does not place it in the recycle bin. Therefore, you cannot subsequently either purge or undrop the materialized view.

Note: The keyword SNAPSHOT is supported in place of MATERIALIZED VIEW for backward compatibility.

See Also:
- CREATE MATERIALIZED VIEW on page 15-4 for more information on the various types of materialized views
- ALTER MATERIALIZED VIEW on page 11-3 for information on modifying a materialized view
- Oracle Database Advanced Replication for information on materialized views in a replication environment
- Oracle Database Data Warehousing Guide for information on materialized views in a data warehousing environment

Prerequisites

The materialized view must be in your own schema or you must have the DROP ANY MATERIALIZED VIEW system privilege. You must also have the privileges to drop the internal table, views, and index that the database uses to maintain the materialized view data.

See Also: DROP TABLE on page 18-5, DROP VIEW on page 18-18, and DROP INDEX on page 17-54 for information on privileges required to drop objects that the database uses to maintain the materialized view

Syntax

\[
\text{drop\_materialized\_view}::= \\
\text{DROP} \hspace{0.5cm} \text{MATERIALIZED} \hspace{0.5cm} \text{VIEW} \hspace{0.5cm} \text{schema} \hspace{0.5cm} \text{materialized\_view} \hspace{0.5cm} \text{PRESERVE} \hspace{0.5cm} \text{TABLE}
\]

Semantics

- **schema**
  Specify the schema containing the materialized view. If you omit schema, then Oracle Database assumes the materialized view is in your own schema.

- **materialized\_view**
  Specify the name of the existing materialized view to be dropped.
If you drop a simple materialized view that is the least recently refreshed materialized view of a master table, then the database automatically purges from the master table materialized view log only the rows needed to refresh the dropped materialized view.

If you drop a materialized view that was created on a prebuilt table, then the database drops the materialized view, and the prebuilt table reverts to its identity as a table.

When you drop a master table, the database does not automatically drop materialized views based on the table. However, the database returns an error when it tries to refresh a materialized view based on a master table that has been dropped.

If you drop a materialized view, then any compiled requests that were rewritten to use the materialized view will be invalidated and recompiled automatically. If the materialized view was prebuilt on a table, then the table is not dropped, but it can no longer be maintained by the materialized view refresh mechanism.

**PRESERVE TABLE Clause**
This clause lets you retain the materialized view container table and its contents after the materialized view object is dropped. The resulting table has the same name as the dropped materialized view.

Oracle Database removes all metadata associated with the materialized view. However, indexes created on the container table automatically during creation of the materialized view are preserved, with one exception: the index created during the creation of a rowid materialized view is dropped. Also, if the materialized view has any nested table columns, then the storage tables for those columns are preserved, along with their metadata.

**Restriction on the PRESERVE TABLE Clause** This clause is not valid for materialized views that have been imported from releases earlier than Oracle9i, when these objects were called "snapshots".

**Examples**

**Dropping a Materialized View: Examples** The following statement drops the materialized view `emp_data` in the sample schema `hr`:

```sql
DROP MATERIALIZED VIEW emp_data;
```

The following statement drops the `sales_by_month_by_state` materialized view and the underlying table of the materialized view, unless the underlying table was registered in the `CREATE MATERIALIZED VIEW` statement with the `ON PREBUILT TABLE` clause:

```sql
DROP MATERIALIZED VIEW sales_by_month_by_state;
```
DROP MATERIALIZED VIEW LOG

Purpose

Use the DROP MATERIALIZED VIEW LOG statement to remove a materialized view log from the database.

Note: The keyword SNAPSHOT is supported in place of MATERIALIZED VIEW for backward compatibility.

See Also:
- CREATE MATERIALIZED VIEW on page 15-4 and ALTER MATERIALIZED VIEW on page 11-3 for more information on materialized views
- CREATE MATERIALIZED VIEW LOG on page 15-31 for information on materialized view logs
- Oracle Database Advanced Replication for information on materialized views in a replication environment
- Oracle Database Data Warehousing Guide for information on materialized views in a data warehousing environment

Prerequisites

To drop a materialized view log, you must have the privileges needed to drop a table.

See Also: DROP TABLE on page 18-5

Syntax

\[ \text{drop\_materialized\_view\_log::=} \]

\[ \text{DROP MATERIALIZED VIEW LOG ON} \text{schema}\text{table} \]

Semantics

**schema**

Specify the schema containing the materialized view log and its master table. If you omit schema, then Oracle Database assumes the materialized view log and master table are in your own schema.

**table**

Specify the name of the master table associated with the materialized view log to be dropped.

After you drop a materialized view log that was created FOR FAST REFRESH, some materialized views based on the materialized view log master table can no longer be fast refreshed. These materialized views include rowid materialized views, primary key materialized views, and subquery materialized views.
After you drop a materialized view log that was created FOR SYNONymous REFRESH (a staging log), the materialized views based on the staging log master table can no longer be synchronous refreshed.

Examples

**Dropping a Materialized View Log: Example**  The following statement drops the materialized view log on the oe.customers master table:

```sql
DROP MATERIALIZED VIEW LOG ON customers;
```
DROP MATERIALIZED ZONEMAP

Note: The DROP MATERIALIZED ZONEMAP statement is available starting with Oracle Database 12c Release 1 (12.1.0.2).

Purpose
Use the DROP MATERIALIZED ZONEMAP statement to remove an existing zone map from the database.

Prerequisites
The zone map must be in your own schema or you must have the DROP ANY MATERIALIZED VIEW system privilege. You must also have the privileges to drop the internal table and indexes that the database uses to maintain the zone map data.

See Also: DROP TABLE on page 18-5 and DROP INDEX on page 17-54 for information on privileges required to drop objects that the database uses to maintain the zone map.

Syntax

```
drop_materialized_zonemap ::=<br>  DROP  MATERIALIZED  ZONEMAP  (schema  zonemap_name)<br>
```

Semantics

**schema**
Specify the schema containing the zone map. If you omit `schema`, then Oracle Database assumes the zone map is in your own schema.

**zonemap_name**
Specify the name of the existing zone map to be dropped.

Example

**Dropping a Zone Map: Examples**
The following statement drops the zone map `sales_zmap`:

```
DROP MATERIALIZED ZONEMAP sales_zmap;
```
DROP OPERATOR

Purpose

Use the DROP OPERATOR statement to drop a user-defined operator.

See Also:

- CREATE OPERATOR on page 15-49 and ALTER OPERATOR on page 11-31 for information on creating and modifying operators
- "User-Defined Operators" on page 4-8 and Oracle Database Data Cartridge Developer’s Guide for more information on operators in general
- ALTER INDEXTYPE on page 10-127 for information on dropping an operator of a user-defined indextype

Prerequisites

The operator must be in your schema or you must have the DROP ANY OPERATOR system privilege.

Syntax

\[
drop\_\text{operator}::=\]

\[
\text{DROP} \rightarrow \text{OPERATOR} \rightarrow \text{schema} \rightarrow \text{operator} \rightarrow \text{FORCE} \rightarrow \cdot
\]

Semantics

\text{schema}

Specify the schema containing the operator. If you omit schema, then Oracle Database assumes the operator is in your own schema.

\text{operator}

Specify the name of the operator to be dropped.

\text{FORCE}

Specify FORCE to drop the operator even if it is currently being referenced by one or more schema objects, such as indextypes, packages, functions, procedures, and so on. The database marks any such dependent objects INVALID. Without FORCE, you cannot drop an operator if any schema objects reference it.

Examples

Dropping a User-Defined Operator: Example

The following statement drops the operator eq_op:

\[
\text{DROP OPERATOR eq_op;}
\]

Because the FORCE clause is not specified, this operation will fail if any of the bindings of this operator are referenced by an indextype.
DROP OUTLINE

Purpose

Note: Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. SQL plan management creates SQL plan baselines, which offer superior SQL performance stability compared with stored outlines.

You can migrate existing stored outlines to SQL plan baselines by using the MIGRATE_STORED_OUTLINE function of the DBMS_SPM package or Enterprise Manager Cloud Control. When the migration is complete, the stored outlines are marked as migrated and can be removed. You can drop all migrated stored outlines on your system by using the DROP_MIGRATED_STORED_OUTLINE function of the DBMS_SPM package.

See Also: Oracle Database SQL Tuning Guide for more information about SQL plan management and Oracle Database PL/SQL Packages and Types Reference for information about the DBMS_SPM package.

Use the DROP OUTLINE statement to drop a stored outline.

See Also: CREATE OUTLINE on page 15-52 for information on creating an outline.

Prerequisites

To drop an outline, you must have the DROP ANY OUTLINE system privilege.

Syntax

drop_outline::=

    DROP OUTLINE outline

Semantics

outline

Specify the name of the outline to be dropped.

After the outline is dropped, if the SQL statement for which the stored outline was created is compiled, then the optimizer generates a new execution plan without the influence of the outline.

Examples

Dropping an Outline: Example The following statement drops the stored outline called salaries.

    DROP OUTLINE salaries;
DROP PACKAGE

Purpose

Packages are defined using PL/SQL. Refer to Oracle Database PL/SQL Language Reference for complete information on creating, altering, and dropping packages.

Use the DROP PACKAGE statement to remove a stored package from the database. This statement drops the body and specification of a package.

**Note:** Do not use this statement to remove a single object from a package. Instead, re-create the package without the object using the CREATE PACKAGE and CREATE PACKAGE BODY statements with the OR REPLACE clause.

Prerequisites

The package must be in your own schema or you must have the DROP ANY PROCEDURE system privilege.

Syntax

drop_package ::= 

```
DROP PACKAGE schema/package ;
```

Semantics

**BODY**

Specify BODY to drop only the body of the package. If you omit this clause, then Oracle Database drops both the body and specification of the package.

When you drop only the body of a package but not its specification, the database does not invalidate dependent objects. However, you cannot call one of the procedures or stored functions declared in the package specification until you re-create the package body.

**schema**

Specify the schema containing the package. If you omit schema, then the database assumes the package is in your own schema.

**package**

Specify the name of the package to be dropped.

Oracle Database invalidates any local objects that depend on the package specification. If you subsequently reference one of these objects, then the database tries to recompile the object and returns an error if you have not re-created the dropped package.

If any statistics types are associated with the package, then the database disassociates the statistics types with the FORCE clause and drops any user-defined statistics collected with the statistics types.
Examples

Dropping a Package: Example  The following statement drops the specification and body of the emp_mgmt package, invalidating all objects that depend on the specification. See Oracle Database PL/SQL Language Reference for the example that creates this package.

DROP PACKAGE emp_mgmt;
**DROP PLUGGABLE DATABASE**

**Purpose**

Use the `DROP PLUGGABLE DATABASE` statement to drop a pluggable database (PDB).

When you drop a PDB, the control file of the multitenant container database (CDB) is modified to remove all references to the dropped PDB and its data files. Archived logs and backups associated with the dropped PDB are not deleted. You can delete them using Oracle Recovery Manager (RMAN), or you can retain them in case you subsequently want to perform point-in-time recovery of the PDB.

---

**Caution:** You cannot roll back a `DROP PLUGGABLE DATABASE` statement.

---

**Prerequisites**

You must be connected to a CDB.

The current container must be the root, you must be authenticated `AS SYSDBA` or `AS SYSOPER`, and the `SYSDBA` or `SYSOPER` privilege must be either granted to you commonly, or granted to you locally in the root and locally in PDB you want to drop.

To specify `KEEP DATAFILES` (the default), the PDB you want to drop must be unplugged.

To specify `INCLUDING DATAFILES`, the PDB you want to drop must be in mounted mode or it must be unplugged.

**Syntax**

```
drop_pluggable_database::=  
```

---

**Semantics**

`pdb_name`

Specify the name of the PDB you want to drop. You cannot drop the seed (`PDB$SEED`).

**KEEP DATAFILES**

Specify `KEEP DATAFILES` to retain the data files associated with the PDB after the PDB is dropped. The temp file for the PDB is deleted because it is no longer needed. This is the default.

Keeping data files may be useful in scenarios where a PDB that is unplugged from one CDB is plugged into another CDB, with both CDBs sharing storage devices.

**INCLUDING DATAFILES**

Specify `INCLUDING DATAFILES` to delete the data files associated with the PDB being dropped. The temp file for the PDB is also deleted.
Restriction on Dropping SNAPSHOT COPY PDBs  If a PDB was created with the SNAPSHOT COPY clause, then you must specify INCLUDING DATAFILES when you drop the PDB.

Examples

Dropping a PDB: Example  The following statement drops the PDB pdb1 and its associated data files:

```
DROP PLUGGABLE DATABASE pdb1
  INCLUDING DATAFILES;
```
DROP PROCEDURE

Purpose

Procedures are defined using PL/SQL. Refer to Oracle Database PL/SQL Language Reference for complete information on creating, altering, and dropping procedures.

Use the DROP PROCEDURE statement to remove a standalone stored procedure from the database. Do not use this statement to remove a procedure that is part of a package. Instead, either drop the entire package using the DROP PACKAGE statement, or redefine the package without the procedure using the CREATE PACKAGE statement with the OR REPLACE clause.

Prerequisites

The procedure must be in your own schema or you must have the DROP ANY PROCEDURE system privilege.

Syntax

\[
drop\_procedure::=\\
\]

Semantics

\[
schema\\n\]

Specify the schema containing the procedure. If you omit \textit{schema}, then Oracle Database assumes the procedure is in your own schema.

\[
procedure\\n\]

Specify the name of the procedure to be dropped.

When you drop a procedure, Oracle Database invalidates any local objects that depend upon the dropped procedure. If you subsequently reference one of these objects, then the database tries to recompile the object and returns an error message if you have not re-created the dropped procedure.

Examples

\textbf{Dropping a Procedure: Example} The following statement drops the procedure \texttt{remove\_emp} owned by the user \texttt{hr} and invalidates all objects that depend upon \texttt{remove\_emp}:

\begin{verbatim}
DROP PROCEDURE hr.remove_emp;
\end{verbatim}
DROP PROFILE

Purpose

Use the DROP PROFILE statement to remove a profile from the database. You can drop any profile except the DEFAULT profile.

See Also: CREATE PROFILE on page 15-77 and ALTER PROFILE on page 11-52 on creating and modifying a profile

Prerequisites

You must have the DROP PROFILE system privilege.

Syntax

drop_profile::=

Semantics

profile
Specify the name of the profile to be dropped.

CASCADE
Specify CASCADE to deassign the profile from any users to whom it is assigned. Oracle Database automatically assigns the DEFAULT profile to such users. You must specify this clause to drop a profile that is currently assigned to users.

Examples

Dropping a Profile: Example The following statement drops the profile app_user, which was created in "Creating a Profile: Example" on page 15-82. Oracle Database drops the profile app_user and assigns the DEFAULT profile to any users currently assigned the app_user profile:

DROP PROFILE app_user CASCADE;
DROP RESTORE POINT

Purpose

Use the DROP RESTORE POINT statement to remove a normal restore point or a guaranteed restore point from the database.

- You need not drop normal restore points. The database automatically drops the oldest restore points when necessary, as described in the semantics for `restore_point` on page 15-85. However, you can drop a normal restore point if you want to reuse the name.
- Guaranteed restore points are not dropped automatically. Therefore, if you want to remove a guaranteed restore point from the database, then you must do so explicitly using this statement.

See Also: CREATE RESTORE POINT on page 15-84, FLASHBACK DATABASE on page 18-26, and FLASHBACK TABLE on page 18-29 for information on creating and using restore points

Prerequisites

To drop a normal restore point, you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSBACKUP, or SYSDG system privilege. To drop a guaranteed restore point, you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege.

Syntax

```
drop_restore_point ::= 
```

Semantics

`restore_point` Specify the name of the restore point you want to drop.

Examples

**Dropping a Restore Point: Example** The following example drops the `good_data` restore point, which was created in "Creating and Using a Restore Point: Example" on page 15-85:

```
DROP RESTORE POINT good_data;
```
DROP ROLE

Purpose
Use the DROP ROLE statement to remove a role from the database. When you drop a role, Oracle Database revokes it from all users and roles to whom it has been granted and removes it from the database. User sessions in which the role is already enabled are not affected. However, no new user session can enable the role after it is dropped.

See Also:
- CREATE ROLE on page 15-87 and ALTER ROLE on page 11-58 for information on creating roles and changing the authorization needed to enable a role
- SET ROLE on page 19-81 for information on disabling roles for the current session

Prerequisites
You must have been granted the role with the ADMIN OPTION or you must have the DROP ANY ROLE system privilege.

Syntax

```sql
drop_role ::= 
```

Semantics

```sql
role
```
Specify the name of the role to be dropped.

Examples

**Dropping a Role: Example** To drop the role `dw_manager`, which was created in "Creating a Role: Example" on page 15-89, issue the following statement:

```sql
DROP ROLE dw_manager;
```
DROP ROLLBACK SEGMENT

Purpose

Use the DROP ROLLBACK SEGMENT to remove a rollback segment from the database. When you drop a rollback segment, all space allocated to the rollback segment returns to the tablespace.

Note: If your database is running in automatic undo mode, then this is the only valid operation on rollback segments. In that mode, you cannot create or alter a rollback segment.

Prerequisites

You must have the DROP ROLLBACK SEGMENT system privilege, and the rollback segment must be offline.

Syntax

drop_rollback_segment ::= \

DROP ROLLBACK SEGMENT (rollback_segment) ;

Semantics

rollback_segment

Specify the name the rollback segment to be dropped.

Restrictions on Dropping Rollback Segments

This statement is subject to the following restrictions:

- You can drop a rollback segment only if it is offline. To determine whether a rollback segment is offline, query the data dictionary view DBA_ROLLBACK_SEGS. Offline rollback segments have the value AVAILABLE in the STATUS column. You can take a rollback segment offline with the OFFLINE clause of the ALTER ROLLBACK SEGMENT statement.
- You cannot drop the SYSTEM rollback segment.

Examples

Dropping a Rollback Segment: Example

The following syntax drops the rollback segment created in "Creating a Rollback Segment: Example" on page 15-93:

DROP ROLLBACK SEGMENT rbs_one;
This chapter contains the following SQL statements:

- DROP SEQUENCE
- DROP SYNONYM
- DROP TABLE
- DROP TABLESPACE
- DROP TRIGGER
- DROP TYPE
- DROP TYPE BODY
- DROP USER
- DROP VIEW
- EXPLAIN PLAN
- EXPLAIN WORK
- FLASHBACK DATABASE
- FLASHBACK TABLE
- GRANT
- INSERT
- LOCK TABLE
- MERGE
- NOAUDIT (Traditional Auditing)
- NOAUDIT (Unified Auditing)
- PURGE
- RENAME
- REVOKE
- ROLLBACK
DROP SEQUENCE

Purpose

Use the DROP SEQUENCE statement to remove a sequence from the database.

You can also use this statement to restart a sequence by dropping and then re-creating it. For example, if you have a sequence with a current value of 150 and you would like to restart the sequence with a value of 27, then you can drop the sequence and then re-create it with the same name and a START WITH value of 27.

See Also: CREATE SEQUENCE on page 15-96 and ALTER SEQUENCE on page 11-63 for more information on creating and modifying a sequence.

Prerequisites

The sequence must be in your own schema or you must have the DROP ANY SEQUENCE system privilege.

Syntax

\[
drop\_sequence::=\]

\[
\text{DROP SEQUENCE } \text{schema} (,) \text{sequence_name}\]

Semantics

\text{schema}

Specify the schema containing the sequence. If you omit \text{schema}, then Oracle Database assumes the sequence is in your own schema.

\text{sequence_name}

Specify the name of the sequence to be dropped.

Examples

\textbf{Dropping a Sequence: Example}  
The following statement drops the sequence customers_seq owned by the user oe, which was created in "Creating a Sequence: Example" on page 15-100. To issue this statement, you must either be connected as user oe or have the DROP ANY SEQUENCE system privilege:

\text{DROP SEQUENCE oe.customers_seq;}

DROP SYNONYM

Purpose

Use the DROP SYNONYM statement to remove a synonym from the database or to change the definition of a synonym by dropping and re-creating it.

See Also: CREATE SYNONYM on page 16-2 for more information on synonyms

Prerequisites

To drop a private synonym, either the synonym must be in your own schema or you must have the DROP ANY SYNONYM system privilege.

To drop a PUBLIC synonym, you must have the DROP PUBLIC SYNONYM system privilege.

Syntax

\( \text{drop_synonym} := \)

\[
\text{DROP PUBLIC SYNONYM <schema> synonym FORCE}
\]

Semantics

\( \text{PUBLIC} \)

You must specify PUBLIC to drop a public synonym. You cannot specify \( \text{schema} \) if you have specified PUBLIC.

\( \text{schema} \)

Specify the schema containing the synonym. If you omit \( \text{schema} \), then Oracle Database assumes the synonym is in your own schema.

\( \text{synonym} \)

Specify the name of the synonym to be dropped.

If you drop a synonym for the master table of a materialized view, and if the defining query of the materialized view specified the synonym rather than the actual table name, then Oracle Database marks the materialized view unusable.

If an object type synonym has any dependent tables or user-defined types, then you cannot drop the synonym unless you also specify \( \text{FORCE} \).

\( \text{FORCE} \)

Specify \( \text{FORCE} \) to drop the synonym even if it has dependent tables or user-defined types.
Caution: Oracle does not recommend that you specify \texttt{FORCE} to drop object type synonyms with dependencies. This operation can result in invalidation of other user-defined types or marking \texttt{UNUSED} the table columns that depend on the synonym. For information about type dependencies, see \textit{Oracle Database Object-Relational Developer's Guide}.

Examples

**Dropping a Synonym: Example**  
To drop the public synonym named \texttt{customers}, which was created in "\textit{Oracle Database Resolution of Synonyms: Example}" on page 16-5, issue the following statement:

\begin{verbatim}
DROP PUBLIC SYNONYM customers;
\end{verbatim}
DROP TABLE

Purpose

Use the DROP TABLE statement to move a table or object table to the recycle bin or to remove the table and all its data from the database entirely.

---

**Caution:** Unless you specify the PURGE clause, the DROP TABLE statement does not result in space being released back to the tablespace for use by other objects, and the space continues to count toward the user’s space quota.

---

For an external table, this statement removes only the table metadata in the database. It has no affect on the actual data, which resides outside of the database.

When you drop a table that is part of a cluster, the table is moved to the recycle bin. However, if you subsequently drop the cluster, then the table is purged from the recycle bin and can no longer be recovered with a FLASHBACK TABLE operation.

Dropping a table invalidates dependent objects and removes object privileges on the table. If you want to re-create the table, then you must regrant object privileges on the table, re-create the indexes, integrity constraints, and triggers for the table, and re-specify its storage parameters. Truncating has none of these effects. Therefore, removing rows with the TRUNCATE statement can be more efficient than dropping and re-creating a table.

See Also:

- CREATE TABLE on page 16-6 and ALTER TABLE on page 12-2 for information on creating and modifying tables
- TRUNCATE TABLE on page 19-89 and DELETE on page 17-28 for information on removing data from a table
- FLASHBACK TABLE on page 18-29 for information on retrieving a dropped table from the recycle bin

Prerequisites

The table must be in your own schema or you must have the DROP ANY TABLE system privilege.

You can perform DDL operations (such as ALTER TABLE, DROP TABLE, CREATE INDEX) on a temporary table only when no session is bound to it. A session becomes bound to a temporary table by performing an INSERT operation on the table. A session becomes unbound to the temporary table by issuing a TRUNCATE statement or at session termination, or, for a transaction-specific temporary table, by issuing a COMMIT or ROLLBACK statement.

Syntax

```
drop_table::=  DROP TABLE [ schema ] [ table ] [ CASCADE [ CONSTRAINTS ] ] [ PURGE ]
```
Semantics

**schema**
Specify the schema containing the table. If you omit `schema`, then Oracle Database assumes the table is in your own schema.

**table**
Specify the name of the table to be dropped. Oracle Database automatically performs the following operations:

- All rows from the table are dropped.
- All table indexes and domain indexes are dropped, as well as any triggers defined on the table, regardless of who created them or whose schema contains them. If `table` is partitioned, then any corresponding local index partitions are also dropped.
- All the storage tables of nested tables and LOBs of `table` are dropped.
- When you drop a range-, hash-, or list-partitioned table, then the database drops all the table partitions. If you drop a composite-partitioned table, then all the partitions and subpartitions are also dropped.
- When you drop a partitioned table with the **PURGE** keyword, the statement executes as a series of subtransactions, each of which drops a subset of partitions or subpartitions and their metadata. This division of the drop operation into subtransactions optimizes the processing of internal system resource consumption (for example, the library cache), especially for the dropping of very large partitioned tables. As soon as the first subtransaction commits, the table is marked **UNUSABLE**. If any of the subtransactions fails, then the only operation allowed on the table is another **DROP TABLE** ... **PURGE** statement. Such a statement will resume work from where the previous **DROP TABLE** statement failed, assuming that you have corrected any errors that the previous operation encountered.

You can list the tables marked **UNUSABLE** by such a drop operation by querying the `status` column of the `*_TABLES, _PART_TABLES, _ALL_TABLES, or _OBJECT_TABLES` data dictionary views, as appropriate.

See Also: Oracle Database VLDB and Partitioning Guide for more information on dropping partitioned tables.

- For an index-organized table, any mapping tables defined on the index-organized table are dropped.
- For a domain index, the appropriate drop routines are invoked. Refer to Oracle Database Data Cartridge Developer’s Guide for more information on these routines.
- If any statistics types are associated with the table, then the database disassociates the statistics types with the **FORCE** clause and removes any user-defined statistics collected with the statistics type.

See Also: ASSOCIATE STATISTICS on page 13-27 and DISASSOCIATE STATISTICS on page 17-36 for more information on statistics type associations

- If the table is not part of a cluster, then the database returns all data blocks allocated to the table and its indexes to the tablespaces containing the table and its indexes.
To drop a cluster and all its the tables, use the DROP CLUSTER statement with the INCLUDING TABLES clause to avoid dropping each table individually. See DROP CLUSTER on page 17-40.

- If the table is a base table for a view, a container or master table of a materialized view, or if it is referenced in a stored procedure, function, or package, then the database invalidates these dependent objects but does not drop them. You cannot use these objects unless you re-create the table or drop and re-create the objects so that they no longer depend on the table.

If you choose to re-create the table, then it must contain all the columns selected by the subqueries originally used to define the materialized views and all the columns referenced in the stored procedures, functions, or packages. Any users previously granted object privileges on the views, stored procedures, functions, or packages need not be regranted these privileges.

If the table is a master table for a materialized view, then the materialized view can still be queried, but it cannot be refreshed unless the table is re-created so that it contains all the columns selected by the defining query of the materialized view.

If the table has a materialized view log, then the database drops this log and any other direct-path INSERT refresh information associated with the table.

Restrictions on Dropping Tables

- You cannot directly drop the storage table of a nested table. Instead, you must drop the nested table column using the ALTER TABLE ... DROP COLUMN clause.

- You cannot drop the parent table of a reference-partitioned table. You must first drop all reference-partitioned child tables.

- You cannot drop a table that uses a flashback data archive for historical tracking. You must first disable the table’s use of the flashback data archive.

CASCADE CONSTRAINTS

Specify CASCADE CONSTRAINTS to drop all referential integrity constraints that refer to primary and unique keys in the dropped table. If you omit this clause, and such referential integrity constraints exist, then the database returns an error and does not drop the table.

PURGE

Specify PURGE if you want to drop the table and release the space associated with it in a single step. If you specify PURGE, then the database does not place the table and its dependent objects into the recycle bin.

Caution: You cannot roll back a DROP TABLE statement with the PURGE clause, nor can you recover the table if you have dropped it with the PURGE clause.

Using this clause is equivalent to first dropping the table and then purging it from the recycle bin. This clause lets you save one step in the process. It also provides enhanced security if you want to prevent sensitive material from appearing in the recycle bin.

See Also: Oracle Database Administrator’s Guide for information on the recycle bin and naming conventions for objects in the recycle bin.
Examples

Dropping a Table: Example  The following statement drops the oe.list_customers table created in "List Partitioning Example" on page 16-97.

DROP TABLE list_customers PURGE;
DROP TABLESPACE

Purpose

Use the DROP TABLESPACE statement to remove a tablespace from the database.

When you drop a tablespace, Oracle Database does not place it in the recycle bin. Therefore, you cannot subsequently either purge or undrop the tablespace.

See Also: CREATE TABLESPACE on page 16-102 and ALTER TABLESPACE on page 12-114 for information on creating and modifying a tablespace

Prerequisites

You must have the DROP TABLESPACE system privilege. You cannot drop a tablespace if it contains any rollback segments holding active transactions.

Syntax

\[
\text{drop_tablespace::=}
\]

Semantics

tablespace

Specify the name of the tablespace to be dropped.

You can drop a tablespace regardless of whether it is online or offline. Oracle recommends that you take the tablespace offline before dropping it to ensure that no SQL statements in currently running transactions access any of the objects in the tablespace.

You cannot drop the SYSTEM tablespace. You can drop the SYSAUX tablespace only if you have the SYSDBA system privilege and you have started the database in UPGRADE mode.

You may want to alert any users who have been assigned the tablespace as either a default or temporary tablespace. After the tablespace has been dropped, these users cannot allocate space for objects or sort areas in the tablespace. You can reassign users new default and temporary tablespaces with the ALTER USER statement.

Any objects that were previously dropped from the tablespace and moved to the recycle bin are purged from the recycle bin. Oracle Database removes from the data dictionary all metadata about the tablespace and all data files and temp files in the tablespace. The database also automatically drops from the operating system any
Oracle-managed data files and temp files in the tablespace. Other data files and temp files are not removed from the operating system unless you specify \texttt{INCLUDING CONTENTS AND DATAFILES}.

You cannot use this statement to drop a tablespace group. However, if \textit{tablespace} is the only tablespace in a tablespace group, then Oracle Database removes the tablespace group from the data dictionary as well.

\textbf{Restrictions on Dropping Tablespaces} Dropping tablespaces is subject to the following restrictions:

- You cannot drop a tablespace that contains a domain index or any objects created by a domain index.
- You cannot drop an undo tablespace if it is being used by any instance or if it contains any undo data needed to roll back uncommitted transactions.
- You cannot drop a tablespace that has been designated as the default tablespace for the database. You must first reassign another tablespace as the default tablespace and then drop the old default tablespace.
- You cannot drop a temporary tablespace if it is part of the database default temporary tablespace group. You must first remove the tablespace from the database default temporary tablespace group and then drop it.
- You cannot drop a temporary tablespace if it contains segments that are in use by existing sessions. In this case, no error is raised. The database waits until there are no segments in use by existing sessions and then drops the tablespace.
- You cannot drop a tablespace, even with the \texttt{INCLUDING CONTENTS} and \texttt{CASCADE CONSTRAINTS} clauses, if doing so would disable a primary key or unique constraint in another tablespace. For example, if the tablespace being dropped contains a primary key index, but the primary key column itself is in a different tablespace, then you cannot drop the tablespace until you have manually disabled the primary key constraint in the other tablespace.

\textbf{See Also:} \textit{Oracle Database Data Cartridge Developer’s Guide} and \textit{Oracle Database Concepts} for more information on domain indexes

\texttt{\{DROP | KEEP\} QUOTA}

Specify \texttt{DROP QUOTA} to drop all user quotas for the tablespace. Specify \texttt{KEEP QUOTA} to retain all user quotas for the tablespace. The default is \texttt{KEEP QUOTA}.

You can view all user quotas for a tablespace by querying the \texttt{DBA_TS_QUOTAS} data dictionary view.

\texttt{INCLUDING CONTENTS}

Specify \texttt{INCLUDING CONTENTS} to drop all the contents of the tablespace. You must specify this clause to drop a tablespace that contains any database objects. If you omit this clause, and the tablespace is not empty, then the database returns an error and does not drop the tablespace.

\texttt{DROP TABLESPACE} fails, even if you specify \texttt{INCLUDING CONTENTS}, if the tablespace contains some, but not all, of the partitions or subpartitions of a single table. If all the partitions or subpartitions of a partitioned table reside in \texttt{tablespace}, then \texttt{DROP TABLESPACE ... INCLUDING CONTENTS} drops \texttt{tablespace}, as well as any associated index segments, LOB data and index segments, and nested table data and index segments of \texttt{table} in other tablespace(s).
For a partitioned index-organized table, if all the primary key index segments are in this tablespace, then this clause will also drop any overflow segments that exist in other tablespaces, as well as any associated mapping table in other tablespaces. If some of the primary key index segments are not in this tablespace, then the statement will fail. In that case, before you can drop the tablespace, you must use ALTER TABLE ... MOVE PARTITION to move those primary key index segments into this tablespace, drop the partitions whose overflow data segments are not in this tablespace, and drop the partitioned index-organized table.

If the tablespace contains a master table of a materialized view, then the database invalidates the materialized view.

If the tablespace contains a materialized view log, then the database drops the log and any other direct-path INSERT refresh information associated with the table.

**AND DATAFILES**

When you specify INCLUDING CONTENTS, the AND DATAFILES clause lets you instruct the database to delete the associated operating system files as well. Oracle Database writes a message to the alert log for each operating system file deleted. This clause is not needed for Oracle Managed Files, because they are removed from the system even if you do not specify AND DATAFILES.

**KEEP DATAFILES**

When you specify INCLUDING CONTENTS, the KEEP DATAFILES clause lets you instruct the database to leave untouched the associated operating system files, including Oracle Managed Files. You must specify this clause if you are using Oracle Managed Files and you do not want the associated operating system files removed by the INCLUDING CONTENTS clause.

**CASCADE CONSTRAINTS**

Specify CASCADE CONSTRAINTS to drop all referential integrity constraints from tables outside tablespace that refer to primary and unique keys of tables inside tablespace. If you omit this clause and such referential integrity constraints exist, then Oracle Database returns an error and does not drop the tablespace.

### Examples

**Dropping a Tablespace: Example**  The following statement drops the tbs_01 tablespace and drops all referential integrity constraints that refer to primary and unique keys inside tbs_01:

```sql
DROP TABLESPACE tbs_01
    INCLUDING CONTENTS
    CASCADE CONSTRAINTS;
```

**Deleting Operating System Files: Example**  The following example drops the tbs_02 tablespace and deletes all associated operating system data files:

```sql
DROP TABLESPACE tbs_02
    INCLUDING CONTENTS AND DATAFILES;
```
DROP TRIGGER

Purpose  
Triggers are defined using PL/SQL. Refer to Oracle Database PL/SQL Language Reference for complete information on creating, altering, and dropping triggers.

Use the DROP TRIGGER statement to remove a database trigger from the database.

See Also: CREATE TRIGGER on page 16-118 and ALTER TRIGGER on page 13-2

Prerequisites  
The trigger must be in your own schema or you must have the DROP ANY TRIGGER system privilege. To drop a trigger on DATABASE in another user’s schema, you must also have the ADMINISTER DATABASE TRIGGER system privilege.

Syntax  

\[
\text{drop\_trigger::=}
\]

\[
\text{DROP TRIGGER \text{schema}\rightarrow \text{trigger}\rightarrow 0}
\]

Semantics  

\text{schema}  
Specify the schema containing the trigger. If you omit schema, then Oracle Database assumes the trigger is in your own schema.

\text{trigger}  
Specify the name of the trigger to be dropped. Oracle Database removes it from the database and does not fire it again.

Examples  

Dropping a Trigger: Example  
The following statement drops the salary_check trigger in the schema hr:

```
DROP TRIGGER hr.salary_check;
```
DROP TYPE

Purpose

Object types are defined using PL/SQL. Refer to Oracle Database PL/SQL Language Reference for complete information on creating, altering, and dropping object types.

Use the DROP TYPE statement to drop the specification and body of an object type, a varray, or a nested table type.

Prerequisites

The object type, varray, or nested table type must be in your own schema or you must have the DROP ANY TYPE system privilege.

Syntax

drop_type::=

Semantics

schema
Specify the schema containing the type. If you omit schema, then Oracle Database assumes the type is in your own schema.

type_name
Specify the name of the object, varray, or nested table type to be dropped. You can drop only types with no type or table dependencies.

If type_name is a supertype, then this statement will fail unless you also specify FORCE. If you specify FORCE, then the database invalidates all subtypes depending on this supertype.

If type_name is a statistics type, then this statement will fail unless you also specify FORCE. If you specify FORCE, then the database first disassociates all objects that are associated with type_name and then drops type_name.

See Also: ASSOCIATE STATISTICS on page 13-27 and DISASSOCIATE STATISTICS on page 17-36 for more information on statistics types.

If type_name is an object type that has been associated with a statistics type, then the database first attempts to disassociate type_name from the statistics type and then drops type_name. However, if statistics have been collected using the statistics type, then the database will be unable to disassociate type_name from the statistics type, and this statement will fail.

If type_name is an implementation type for an indextype, then the indextype will be marked INVALID.
If \textit{type\_name} has a public synonym defined on it, then the database will also drop the synonym.

Unless you specify \texttt{FORCE}, you can drop only object types, nested tables, or varray types that are standalone schema objects with no dependencies. This is the default behavior.

\textbf{See Also:} \texttt{CREATE INDEXTYPE} on page 14-103

\textbf{FORCE}

Specify \texttt{FORCE} to drop the type even if it has dependent database objects. Oracle Database marks \texttt{UNUSED} all columns dependent on the type to be dropped, and those columns become inaccessible.

\textbf{Caution:} Oracle does not recommend that you specify \texttt{FORCE} to drop object types with dependencies. This operation is not recoverable and could cause the data in the dependent tables or columns to become inaccessible.

\textbf{VALIDATE}

If you specify \texttt{VALIDATE} when dropping a type, then Oracle Database checks for stored instances of this type within substitutable columns of any of its supertypes. If no such instances are found, then the database completes the drop operation.

This clause is meaningful only for subtypes. Oracle recommends the use of this option to safely drop subtypes that do not have any explicit type or table dependencies.

\textbf{Examples}

\textbf{Dropping an Object Type: Example} The following statement removes object type \texttt{person\_t}. See \textit{Oracle Database PL/SQL Language Reference} for the example that creates this object type. Any columns that are dependent on \texttt{person\_t} are marked \texttt{UNUSED} and become inaccessible.

\begin{verbatim}
DROP TYPE person\_t FORCE;
\end{verbatim}
DROP TYPE BODY

Purpose

Object types are defined using PL/SQL. Refer to Oracle Database PL/SQL Language Reference for complete information on creating, altering, and dropping object types.

Use the DROP TYPE BODY statement to drop the body of an object type, varray, or nested table type. When you drop a type body, the object type specification still exists, and you can re-create the type body. Prior to re-creating the body, you can still use the object type, although you cannot call the member functions.

Prerequisites

The object type body must be in your own schema or you must have the DROP ANY TYPE system privilege.

Syntax

\[\text{drop-type-body}::=\]

\[\text{DROP TYPE BODY schema.type-name} ;\]

Semantics

\textit{schema}
Specify the schema containing the object type. If you omit \textit{schema}, then Oracle Database assumes the object type is in your own schema.

\textit{type-name}
Specify the name of the object type body to be dropped.

\textbf{Restriction on Dropping Type Bodies} You can drop a type body only if it has no type or table dependencies.

Examples

\textbf{Dropping an Object Type Body: Example} The following statement removes object type body \textit{data_typ1}. See Oracle Database PL/SQL Language Reference for the example that creates this object type.

\[\text{DROP TYPE BODY data_typ1;}\]
DROP USER

Purpose

Use the DROP USER statement to remove a database user and optionally remove the user's objects.

In an Oracle Automatic Storage Management (Oracle ASM) cluster, a user authenticated as SYSASM can use this clause to remove a user from the password file that is local to the Oracle ASM instance of the current node.

When you drop a user, Oracle Database also purges all of that user's schema objects from the recycle bin.

**Caution:** Do not attempt to drop the users SYS or SYSTEM. Doing so will corrupt your database.

**See Also:** CREATE USER on page 17-7 and ALTER USER on page 13-6 for information on creating and modifying a user

Prerequisites

You must have the DROP USER system privilege. In an Oracle ASM cluster, you must be authenticated AS SYSASM.

Syntax

```
drop_user ::= DROP USER user [ CASCADE ]
```

Semantics

**user**

Specify the user to be dropped. Oracle Database does not drop users whose schemas contain objects unless you specify CASCADE or unless you first explicitly drop the user's objects.

**Restriction on Dropping Users** You cannot drop a user whose schema contains a table that uses a flashback data archive for historical tracking. You must first disable the table's use of the flashback data archive.

**CASCADE**

Specify CASCADE to drop all objects in the user's schema before dropping the user. You must specify this clause to drop a user whose schema contains any objects.

- If the user's schema contains tables, then Oracle Database drops the tables and automatically drops any referential integrity constraints on tables in other schemas that refer to primary and unique keys on these tables.
- If this clause results in tables being dropped, then the database also drops all domain indexes created on columns of those tables and invokes appropriate drop routines.

  **See Also:** *Oracle Database Data Cartridge Developer’s Guide* for more information on these routines

- Oracle Database invalidates, but does not drop, the following objects in other schemas:
  - Views or synonyms for objects in the dropped user’s schema
  - Stored procedures, functions, or packages that query objects in the dropped user’s schema

- Oracle Database does not drop materialized views in other schemas that are based on tables in the dropped user’s schema. However, because the base tables no longer exist, the materialized views in the other schemas can no longer be refreshed.

- Oracle Database drops all triggers in the user’s schema.

- Oracle Database does not drop roles created by the user.

  **Caution:** Oracle Database also drops with **FORCE** all types owned by the user. See the **FORCE** keyword of **DROP TYPE** on page 18-14.

**Restriction on Dropping Users** You cannot drop a user whose schema contains a table that uses a flashback data archive. You must first disable use of the flashback data archive.

**Examples**

**Dropping a Database User: Example** If user Sidney’s schema contains no objects, then you can drop *sidney* by issuing the statement:

```
DROP USER sidney;
```

If Sidney’s schema contains objects, then you must use the **CASCADE** clause to drop *sidney* and the objects:

```
DROP USER sidney CASCADE;
```
DROP VIEW

Purpose

Use the DROP VIEW statement to remove a view or an object view from the database. You can change the definition of a view by dropping and re-creating it.

See Also: CREATE VIEW on page 17-15 and ALTER VIEW on page 13-16 for information on creating and modifying a view

Prerequisites

The view must be in your own schema or you must have the DROP ANY VIEW system privilege.

Syntax

drop_view::=

\[
\text{DROP VIEW schema view [CASCADE CONSTRAINTS]}
\]

Semantics

\textit{schema}

Specify the schema containing the view. If you omit \textit{schema}, then Oracle Database assumes the view is in your own schema.

\textit{view}

Specify the name of the view to be dropped.

Oracle Database does not drop views, materialized views, and synonyms that are dependent on the view but marks them INVALID. You can drop them or redefine views and synonyms, or you can define other views in such a way that the invalid views and synonyms become valid again.

If any subviews have been defined on \textit{view}, then the database invalidates the subviews as well. To determine whether the view has any subviews, query the \textit{SUPERVIEW_NAME} column of the \textit{USER_}, \textit{ALL_}, or \textit{DBA_VIEWS} data dictionary views.

See Also:

- CREATE TABLE on page 16-6 and CREATE SYNONYM on page 16-2
- ALTER MATERIALIZED VIEW on page 11-3 for information on revalidating invalid materialized views

CASCADE CONSTRAINTS

Specify CASCADE CONSTRAINTS to drop all referential integrity constraints that refer to primary and unique keys in the view to be dropped. If you omit this clause, and such constraints exist, then the DROP statement fails.
Examples

**Dropping a View: Example**  The following statement drops the `emp_view` view, which was created in "Creating a View: Example" on page 17-24:

```sql
DROP VIEW emp_view;
```
EXPLAIN PLAN

Purpose

Use the EXPLAIN PLAN statement to determine the execution plan Oracle Database follows to execute a specified SQL statement. This statement inserts a row describing each step of the execution plan into a specified table. You can also issue the EXPLAIN PLAN statement as part of the SQL trace facility.

This statement also determines the cost of executing the statement. If any domain indexes are defined on the table, then user-defined CPU and I/O costs will also be inserted.

The definition of a sample output table PLAN_TABLE is available in a SQL script on your distribution media. Your output table must have the same column names and data types as this table. The common name of this script is UTLXPLAN.SQL. The exact name and location depend on your operating system.

Oracle Database provides information on cached cursors through several dynamic performance views:

- For information on the work areas used by SQL cursors, query V$SQL_WORKAREA.
- For information on the execution plan for a cached cursor, query V$SQL_PLAN.
- For execution statistics at each step or operation of an execution plan of cached cursors (for example, number of produced rows, number of blocks read), query V$SQL_PLAN_STATISTICS.
- For a selective precomputed join of the preceding three views, query V$SQL_PLAN_STATISTICS_ALL.
- Execution statistics at each step or operation of an execution plan of cached cursors are displayed in V$SQL_PLAN_MONITOR if the statement execution is monitored. You can force monitoring using the MONITOR hint.

See Also:

- Oracle Database SQL Tuning Guide for information on the output of EXPLAIN PLAN, how to use the SQL trace facility, and how to generate and interpret execution plans
- Oracle Database Reference for information on dynamic performance views

Prerequisites

To issue an EXPLAIN PLAN statement, you must have the privileges necessary to insert rows into an existing output table that you specify to hold the execution plan.

You must also have the privileges necessary to execute the SQL statement for which you are determining the execution plan. If the SQL statement accesses a view, then you must have privileges to access any tables and views on which the view is based. If the view is based on another view that is based on a table, then you must have privileges to access both the other view and its underlying table.

To examine the execution plan produced by an EXPLAIN PLAN statement, you must have the privileges necessary to query the output table.

The EXPLAIN PLAN statement is a data manipulation language (DML) statement, rather than a data definition language (DDL) statement. Therefore, Oracle Database does not
EXPLAIN PLAN

implicitly commit the changes made by an EXPLAIN PLAN statement. If you want to keep the rows generated by an EXPLAIN PLAN statement in the output table, then you must commit the transaction containing the statement.

See Also: INSERT on page 18-62 and SELECT on page 19-4 for information on the privileges you need to populate and query the plan table

Syntax

explain_plan ::= 

```
EXPLAIN PLAN SET STATEMENT_ID = string
INTO schema.table @dblink FOR statement
```

Semantics

SET STATEMENT_ID Clause
Specify a value for the STATEMENT_ID column for the rows of the execution plan in the output table. You can then use this value to identify these rows among others in the output table. Be sure to specify a STATEMENT_ID value if your output table contains rows from many execution plans. If you omit this clause, then the STATEMENT_ID value defaults to null.

INTO table Clause
Specify the name of the output table, and optionally its schema and database. This table must exist before you use the EXPLAIN PLAN statement.

If you omit `schema`, then the database assumes the table is in your own schema.

The `dblink` can be a complete or partial name of a database link to a remote Oracle Database where the output table is located. You can specify a remote output table only if you are using Oracle Database distributed functionality. If you omit `dblink`, then the database assumes the table is on your local database. See "References to Objects in Remote Databases" on page 2-126 for information on referring to database links.

If you omit `INTO` altogether, then the database assumes an output table named `PLAN_TABLE` in your own schema on your local database.

FOR statement Clause
Specify a SELECT, INSERT, UPDATE, DELETE, MERGE, CREATE TABLE, CREATE INDEX, or ALTER INDEX ... REBUILD statement for which the execution plan is generated.

Notes on EXPLAIN PLAN
The following notes apply to EXPLAIN PLAN:

- If `statement` includes the `parallel_clause`, then the resulting execution plan will indicate parallel execution. However, EXPLAIN PLAN actually inserts the statement into the plan table, so that the parallel DML statement you submit is no longer the first DML statement in the transaction. This violates the Oracle Database restriction of one parallel DML statement in a single transaction, and the statement...
EXPLAIN PLAN

will be executed serially. To maintain parallel execution of the statements, you must commit or roll back the EXPLAIN PLAN statement, and then submit the parallel DML statement.

- To determine the execution plan for an operation on a temporary table, EXPLAIN PLAN must be run from the same session, because the data in temporary tables is session specific.

Examples

EXPLAIN PLAN Examples  The following statement determines the execution plan and cost for an UPDATE statement and inserts rows describing the execution plan into the specified plan_table table with the statement_id value of 'Raise in Tokyo':

EXPLAIN PLAN
SET STATEMENT_ID = 'Raise in Tokyo'
INTO plan_table
FOR UPDATE employees
SET salary = salary * 1.10
WHERE department_id =
(SELECT department_id FROM departments
WHERE location_id = 1700);

The following SELECT statement queries the plan_table table and returns the execution plan and the cost:

SELECT id, LPAD(' ',2*(LEVEL-1))||operation operation, options,
object_name, object_alias, position
FROM plan_table
START WITH id = 0 AND statement_id = 'Raise in Tokyo'
CONNECT BY PRIOR id = parent_id AND statement_id = 'Raise in Tokyo'
ORDER BY id;

The query returns this execution plan:

<table>
<thead>
<tr>
<th>ID</th>
<th>OPERATION</th>
<th>OPTIONS</th>
<th>OBJECT_NAME</th>
<th>OBJECT_ALIAS</th>
<th>POSITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>UPDATE STATEMENT</td>
<td></td>
<td></td>
<td></td>
<td>4</td>
</tr>
<tr>
<td>1</td>
<td>UPDATE</td>
<td></td>
<td>EMPLOYEES</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>INDEX</td>
<td>RANGE SCAN</td>
<td>EMP_DEPARTMENT_IX</td>
<td>EMPLOYEES#UPD$1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>TABLE ACCESS</td>
<td>BY INDEX ROWID</td>
<td>DEPARTMENTS</td>
<td>DEPARTMENTS#SEL$1</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>INDEX</td>
<td>RANGE SCAN</td>
<td>DEPT_LOCATION_IX</td>
<td>DEPARTMENTS#SEL$1</td>
<td>1</td>
</tr>
</tbody>
</table>

The value in the POSITION column of the first row shows that the statement has a cost of 4.

EXPLAIN PLAN: Partitioned Example  The sample table sh.sales is partitioned on the time_id column. Partition sales_q3_2000 contains time values less than Oct. 1, 2000, and there is a local index sales_time_bix on the time_id column.

Consider the query:

EXPLAIN PLAN FOR
SELECT * FROM sales
WHERE time_id BETWEEN :h AND '01-OCT-2000';

where :h represents an already declared bind variable. EXPLAIN PLAN executes this query with PLAN_TABLE as the output table. The basic execution plan, including partitioning information, is obtained with the following query:

SELECT operation, options, partition_start, partition_stop,
partition_id
FROM plan_table;
EXPLAIN WORK

Purpose
Use the EXPLAIN WORK statement to obtain an estimate of the work involved in an Oracle Automatic Storage Management (Oracle ASM) disk group rebalance operation.

This statement inserts one row into the V$ASM_ESTIMATE dynamic performance view. The row contains a NUMBER value, EST_WORK, which represents the estimated number of allocation units that must be moved by the rebalance operation.

See Also:
- Oracle Automatic Storage Management Administrator’s Guide for more information on disk group rebalance operations
- Oracle Database Reference for information on the V$ASM_ESTIMATE dynamic performance view

Prerequisites
To issue an EXPLAIN WORK statement, you must have the privileges necessary to insert rows into the V$ASM_ESTIMATE dynamic performance view.

You must also have the privileges necessary to execute the ALTER DISKGROUP statement for which you are obtaining a work estimate.

To view the work estimate produced by an EXPLAIN WORK statement, you must have the privileges necessary to query the V$ASM_ESTIMATE dynamic performance view.

The EXPLAIN WORK statement is a data manipulation language (DML) statement, rather than a data definition language (DDL) statement. Therefore, Oracle Database does not implicitly commit the changes made by an EXPLAIN WORK statement. If you want to keep the row generated by an EXPLAIN WORK statement in the V$ASM_ESTIMATE view, then you must commit the transaction containing the statement.

Syntax
explain_work::=  

EXPLAIN WORK SET STATEMENT_ID = string FOR statement ;

Semantics

SET STATEMENT_ID Clause
Specify a value for the STATEMENT_ID column for the row created by this statement in the V$ASM_ESTIMATE view. You can then use this value to identify this row among others in the view. Be sure to specify a STATEMENT_ID value if the view contains rows from many work estimates. If you omit this clause, then the STATEMENT_ID value defaults to null.
FOR statement Clause

Specify the SQL statement for which you want a work estimate. You can specify an ALTER DISKGROUP statement that contains any of the following clauses:

- add_disk_clause (adds one or more disks to a disk group)
- disk_online_clause (brings one or more disks online)
- drop_disk_clause (drops one or more disks from a disk group)
- rebalance_diskgroup_clause (rebalances a disk group)
- replace_disk_clause (replaces one or more disks in a disk group)
- resize_disk_clause (resizes the disks in a disk group)
- undrop_disk_clause (cancels the drop of disks from a disk group)

The EXPLAIN WORK statement estimates the number of allocation units that must be moved during the explicit disk group rebalance that occurs when you issue the rebalance_diskgroup_clause, or the automatic disk group rebalance that occurs when you issue any of the other clauses.

See Also: ALTER DISKGROUP on page 10-78 for full information on these clauses

Examples

The following statement estimates the amount of work required to explicitly rebalance disk group dg1. The resulting estimate is inserted into the V$ASM_ESTIMATE view.

```
EXPLAIN WORK
  FOR ALTER DISKGROUP dg1 REBALANCE;
SELECT est_work FROM V$ASM_ESTIMATE;
```

```
EST_WORK
--------
5680
```

The following statement estimates the amount of work required to automatically rebalance disk group dg2 after dropping a disk. The statement specifies a STATEMENT_ID, which enables you to query the appropriate work estimate in the V$ASM_ESTIMATE view.

```
EXPLAIN WORK SET STATEMENT_ID='drop d0'
  FOR ALTER DISKGROUP dg2 DROP DISK d0;
Explained.
SELECT est_work FROM V$ASM_ESTIMATE
  WHERE STATEMENT_ID='drop d0';
```

```
EST_WORK
--------
  426
```
FLASHBACK DATABASE

Purpose

Use the FLASHBACK DATABASE statement to return the database to a past time or system change number (SCN). This statement provides a fast alternative to performing incomplete database recovery.

Following a FLASHBACK DATABASE operation, in order to have write access to the flashed back database, you must reopen it with an ALTER DATABASE OPEN RESETLOGS statement.

See Also: Oracle Database Backup and Recovery User’s Guide for more information on FLASHBACK DATABASE

Prerequisites

You must have the SYSDBA, SYSBACKUP, or SYSDG system privilege. A fast recovery area must have been prepared for the database. The database must have been put in FLASHBACK mode with an ALTER DATABASE FLASHBACK ON statement unless you are flashing the database back to a guaranteed restore point. The database must be mounted but not open. In addition:

- The database must run in ARCHIVELOG mode.
- The database must be mounted, but not open, with a current control file. The control file cannot be a backup or re-created. When the database control file is restored from backup or re-created, all existing flashback log information is discarded.
- The database must contain no online tablespaces for which flashback functionality was disabled with the SQL statement ALTER TABLESPACE ... FLASHBACK OFF.

See Also: Oracle Database Backup and Recovery User’s Guide and the ALTER DATABASE ... flashback_mode_clause on page 10-68 for information on putting the database in FLASHBACK mode

- CREATE RESTORE POINT on page 15-84 for information on restore points and guaranteed restore points

Syntax

\[
\text{flashback\_database::=} \\
\text{FLASHBACK \hspace{1em} STANDBY \hspace{1em} DATABASE \hspace{1em} TO \hspace{1em} SCN \hspace{1em} TIMESTAMP \hspace{1em} expr \hspace{1em} RESTORE \hspace{1em} POINT \hspace{1em} restore\_point \hspace{1em} TO \hspace{1em} BEFORE \hspace{1em} SCN \hspace{1em} TIMESTAMP \hspace{1em} expr \hspace{1em} RESETLOGS}
\]
Semantics

When you issue a `FLASHBACK DATABASE` statement, Oracle Database first verifies that all required archived and online redo logs are available. If they are available, then it reverts all currently online data files in the database to the SCN or time specified in this statement.

- The amount of Flashback data retained in the database is controlled by the `DB_FLASHBACK_RETENTION_TARGET` initialization parameter and the size of the fast recovery area. You can determine how far back you can flash back the database by querying the `V$FLASHBACK_DATABASE_LOG` view.
- If insufficient data remains in the database to perform the flashback, then you can use standard recovery procedures to recover the database to a past point in time.
- If insufficient data remains for a set of data files, then the database returns an error. In this case, you can take those data files offline and reissue the statement to revert the remainder of the database. You can then attempt to recover the offline data files using standard recovery procedures.

**See Also:** *Oracle Database Backup and Recovery User’s Guide* for more information on recovering data files

**STANDBY**

Specify `STANDBY` to revert the standby database to an earlier SCN or time. If the database is not a standby database, then the database returns an error. If you omit this clause, then `database` can be either a primary or a standby database.

**See Also:** *Oracle Data Guard Concepts and Administration* for information on how you can use `FLASHBACK DATABASE` on a standby database to achieve different delays

**TO SCN Clause**

Specify a system change number (SCN):

- `TO SCN` reverts the database back to its state at the specified SCN.
- `TO BEFORE SCN` reverts the database back to its state at the system change number just preceding the specified SCN.

You can determine the current SCN by querying the `CURRENT_SCN` column of the `V$DATABASE` view. This in turn lets you save the SCN to a spool file, for example, before running a high-risk batch job.

**TO TIMESTAMP Clause**

Specify a valid datetime expression.

- `TO TIMESTAMP` reverts the database back to its state at the specified timestamp.
- `TO BEFORE TIMESTAMP` reverts the database back to its state one second before the specified timestamp.

You can represent the timestamp as an offset from a determinate value, such as `SYSDATE`, or as an absolute system timestamp.

**TO RESTORE POINT Clause**

Specify this clause to flash back the database to the specified restore point. If you have not enabled flashback database, then this is the only clause you can specify in this `FLASHBACK DATABASE` statement. If the database is not in `FLASHBACK` mode, as described
in the "Prerequisites" section above, then this is the only clause you can specify for this statement.

**RESETLOGS**

Specify `TO BEFORE RESETLOGS` to flash the database back to just before the last resetlogs operation (`ALTER DATABASE OPEN RESETLOGS`).

*See Also:* Oracle Database Backup and Recovery User’s Guide for more information about this clause

**Examples**

Assuming that you have prepared a fast recovery area for the database and enabled media recovery, enable database FLASHBACK mode and open the database with the following statements:

```
STARTUP MOUNT
ALTER DATABASE FLASHBACK ON;
ALTER DATABASE OPEN;
```

With your database open for at least a day, you can flash back the database one day with the following statements:

```
SHUTDOWN DATABASE
STARTUP MOUNT
FLASHBACK DATABASE TO TIMESTAMP SYSDATE-1;
```
FLASHBACK TABLE

Purpose

Use the FLASHBACK TABLE statement to restore an earlier state of a table in the event of human or application error. The time in the past to which the table can be flashed back is dependent on the amount of undo data in the system. Also, Oracle Database cannot restore a table to an earlier state across any DDL operations that change the structure of the table.

You cannot roll back a FLASHBACK TABLE statement. However, you can issue another FLASHBACK TABLE statement and specify a time just prior to the current time. Therefore, it is advisable to record the current SCN before issuing a FLASHBACK TABLE clause.

Prerequisites

To flash back a table to an earlier SCN or timestamp, you must have either the FLASHBACK object privilege on the table or the FLASHBACK ANY TABLE system privilege. In addition, you must have the READ or SELECT object privilege on the table, and you must have the INSERT, DELETE, and ALTER object privileges on the table.

Row movement must be enabled for all tables in the Flashback list unless you are flashing back the table TO BEFORE DROP. That operation is called a flashback drop operation, and it uses dropped data in the recycle bin rather than undo data. Refer to row_movement_clause on page 10-68 for information on enabling row movement.

To flash back a table to a restore point, you must have the SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege or the SELECT_CATALOG_ROLE role.

To flash back a table to before a DROP TABLE operation, you need only the privileges necessary to drop the table.

Note: Oracle strongly recommends that you run your database in automatic undo mode by leaving the UNDO_MANAGEMENT initialization parameter set to AUTO, which is the default. In addition, set the UNDO_RETENTION initialization parameter to an interval large enough to include the oldest data you anticipate needing. For more information refer to the documentation on the UNDO_MANAGEMENT and UNDO_RETENTION initialization parameters.

| ■ FLASHBACK DATABASE on page 18-26 for information on reverting the entire database to an earlier version |
| ■ the flashback_query_clause of SELECT on page 19-22 for information on retrieving past data from a table |
| ■ Oracle Database Backup and Recovery User's Guide for additional information on using the FLASHBACK TABLE statement |

SQL Statements: DROP SEQUENCE to ROLLBACK 18-29
Syntax

```
flashback_table ::= ...
```

Semantics

During an Oracle Flashback Table operation, Oracle Database acquires exclusive DML locks on all the tables specified in the Flashback list. These locks prevent any operations on the tables while they are reverting to their earlier state.

The Flashback Table operation is executed in a single transaction, regardless of the number of tables specified in the Flashback list. Either all of the tables revert to the earlier state or none of them do. If the Flashback Table operation fails on any table, then the entire statement fails.

At the completion of the Flashback Table operation, the data in `table` is consistent with `table` at the earlier time. However, `FLASHBACK TABLE TO SCN` or `TIMESTAMP` does not preserve rowids, and `FLASHBACK TABLE TO BEFORE DROP` does not recover referential constraints.

Oracle Database does not revert statistics associated with `table` to their earlier form. Indexes on `table` that exist currently are reverted and reflect the state of the table at the Flashback point. If the index exists now but did not yet exist at the Flashback point, then the database updates the index to reflect the state of the table at the Flashback point. However, indexes that were dropped during the interval between the Flashback point and the current time are not restored.

`schema`

Specify the schema containing the table. If you omit `schema`, then the database assumes the table is in your own schema.

`table`

Specify the name of one or more tables containing data you want to revert to an earlier version.

Restrictions on Flashing Back Tables

This statement is subject to the following restrictions:

- Flashback Table operations are not valid for the following type objects: tables that are part of a cluster, materialized views, Advanced Queuing (AQ) tables, static data dictionary tables, system tables, remote tables, object tables, nested tables, or individual table partitions or subpartitions.
The following DDL operations change the structure of a table, so that you cannot subsequently use the TO SCN or TO TIMESTAMP clause to flash the table back to a time preceding the operation: upgrading, moving, or truncating a table; adding a constraint to a table, adding a table to a cluster; modifying or dropping a column; changing a column encryption key; adding, dropping, merging, splitting, coalescing, or truncating a partition or subpartition (with the exception of adding a range partition).

**TO SCN Clause**
Specify the system change number (SCN) corresponding to the point in time to which you want to return the table. The `expr` must evaluate to a number representing a valid SCN.

**TO TIMESTAMP Clause**
Specify a timestamp value corresponding to the point in time to which you want to return the table. The `expr` must evaluate to a valid timestamp in the past. The table will be flashed back to a time within approximately 3 seconds of the specified timestamp.

**TO RESTORE POINT Clause**
Specify a restore point to which you want to flash back the table. The restore point must already have been created.

See Also: [CREATE RESTORE POINT](#) on page 15-84 for information on creating restore points

**ENABLE | DISABLE TRIGGERS**
By default, Oracle Database disables all enabled triggers defined on `table` during the Flashback Table operation and then reenables them after the Flashback Table operation is complete. Specify `ENABLE TRIGGERS` if you want to override this default behavior and keep the triggers enabled during the Flashback process.

This clause affects only those database triggers defined on `table` that are already enabled. To enable currently disabled triggers selectively, use the `ALTER TABLE ... enable_disable_clause` before you issue the `FLASHBACK TABLE` statement with the ENABLE TRIGGERS clause.

**TO BEFORE DROP Clause**
Use this clause to retrieve from the recycle bin a table that has been dropped, along with all possible dependent objects. The table must have resided in a locally managed tablespace other than the `SYSTEM` tablespace.

See Also:
- Oracle Database Administrator’s Guide for information on the recycle bin and naming conventions for objects in the recycle bin
- [PURGE](#) on page 18-96 for information on removing objects permanently from the recycle bin

You can specify either the original user-specified name of the table or the system-generated name Oracle Database assigned to the object when it was dropped.

- System-generated recycle bin object names are unique. Therefore, if you specify the system-generated name, then the database retrieves that specified object.
To see the contents of your recycle bin, query the `USER_RECYCLEBIN` data dictionary view. You can use the `RECYCLEBIN` synonym instead. The following two statements return the same rows:

```
SELECT * FROM RECYCLEBIN;
SELECT * FROM USER_RECYCLEBIN;
```

- If you specify the user-specified name, and if the recycle bin contains more than one object of that name, then the database retrieves the object that was moved to the recycle bin most recently. If you want to retrieve an older version of the table, then do one of these things:
  - Specify the system-generated recycle bin name of the table you want to retrieve.
  - Issue additional `FLASHBACK TABLE ... TO BEFORE DROP` statements until you retrieve the table you want.

Oracle Database attempts to preserve the original table name. If a new table of the same name has been created in the same schema since the original table was dropped, then the database returns an error unless you also specify the `RENAME TO` clause.

**RENAME TO Clause**  Use this clause to specify a new name for the table being retrieved from the recycle bin.

**Notes on Flashing Back Dropped Tables**  The following notes apply to flashing back dropped tables:

- Oracle Database retrieves all indexes defined on the table retrieved from the recycle bin except for bitmap join indexes and domain indexes. (Bitmap join indexes and domain indexes are not put in the recycle bin during a `DROP TABLE` operation, so cannot be retrieved.)
- The database also retrieves all triggers and constraints defined on the table except for referential integrity constraints that reference other tables.

The retrieved indexes, triggers, and constraints have recycle bin names. Therefore it is advisable to query the `USER_RECYCLEBIN` view before issuing a `FLASHBACK TABLE ... TO BEFORE DROP` statement so that you can rename the retrieved triggers and constraints to more usable names.

- When you drop a table, all materialized view logs defined on the table are also dropped but are not placed in the recycle bin. Therefore, the materialized view logs cannot be flashed back along with the table.
- When you drop a table, any indexes on the table are dropped and put into the recycle bin along with the table. If subsequent space pressures arise, then the database reclaims space from the recycle bin by first purging indexes. In this case, when you flash back the table, you may not get back all of the indexes that were defined on the table.
- You cannot flash back a table if it has been purged, either by a user or by Oracle Database as a result of some space reclamation operation.

**Examples**

**Restoring a Table to an Earlier State: Examples**  The examples below create a new table, `employees_test`, with row movement enabled, update values within the new table, and issue the `FLASHBACK TABLE` statement.
Create table employees_test, with row movement enabled, from table employees of the sample hr schema:

```
CREATE TABLE employees_test
    AS SELECT * FROM employees;
```

As a benchmark, list those salaries less than 2500:

```
SELECT salary
FROM employees_test
WHERE salary < 2500;
```

```
SALARY
--------
2400
2200
2100
2400
2200
```

---

**Note:** To allow time for the SCN to propagate to the mapping table used by the FLASHBACK TABLE statement, wait a minimum of 5 minutes prior to issuing the following statement. This wait would not be necessary if a previously existing table were being used in this example.

---

Enable row movement for the table:

```
ALTER TABLE employees_test
    ENABLE ROW MOVEMENT;
```

Issue a 10% salary increase to those employees earning less than 2500:

```
UPDATE employees_test
    SET salary = salary * 1.1
    WHERE salary < 2500;
```

5 rows updated.

```
COMMIT;
```

As a second benchmark, list those salaries that remain less than 2500 following the 10% increase:

```
SELECT salary
FROM employees_test
WHERE salary < 2500;
```

```
SALARY
--------
2420
2310
2420
```

Restore the table employees_test to its state prior to the current system time. The unrealistic duration of 1 minute is used so that you can test this series of examples quickly. Under normal circumstances a much greater interval would have elapsed.

```
FLASHBACK TABLE employees_test
    TO TIMESTAMP (SYSTIMESTAMP - INTERVAL '1' minute);
```
List those salaries less than 2500. After the FLASHBACK TABLE statement issued above, this list should match the list in the first benchmark.

```
SELECT salary
FROM employees_test
WHERE salary < 2500;
```

<table>
<thead>
<tr>
<th>SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>2400</td>
</tr>
<tr>
<td>2200</td>
</tr>
<tr>
<td>2100</td>
</tr>
<tr>

**Retrieving a Dropped Table: Example**  If you accidentally drop the `pm.print_media` table and want to retrieve it, then issue the following statement:

```
FLASHBACK TABLE print_media TO BEFORE DROP;
```

If another `print_media` table has been created in the `pm` schema, then use the `RENAME TO` clause to rename the retrieved table:

```
FLASHBACK TABLE print_media TO BEFORE DROP RENAME TO print_media_old;
```

If you know that the employees table has been dropped multiple times, and you want to retrieve the oldest version, then query the `USER_RECYCLEBIN` table to determine the system-generated name, and then use that name in the FLASHBACK TABLE statement.  (System-generated names in your database will differ from those shown here.)

```
SELECT object_name, droptime
FROM user_recyclebin
WHERE original_name = 'PRINT_MEDIA';
```

GRANT

Purpose

Use the `GRANT` statement to grant:

- System privileges to users and roles. Table 18–1 lists the system privileges (organized by the database object operated upon).

- Roles to users, roles, and program units. The granted roles can be either user-defined (local or external) or predefined. For a list of predefined roles, refer to Oracle Database Security Guide.

- Object privileges for a particular object to users and roles. Table 18–2 lists the object privileges (organized by the database object operated upon).

Note: Global roles (created with `IDENTIFIED GLOBALLY`) are granted through enterprise roles and cannot be granted using the `GRANT` statement.

Notes on Authorizing Database Users You can authorize database users through means other than the database and the `GRANT` statement.

- Many Oracle Database privileges are granted through supplied PL/SQL and Java packages. For information on those privileges, refer to the documentation for the appropriate package.

- Some operating systems have facilities that let you grant roles to Oracle Database users with the initialization parameter `OS_ROLES`. If you choose to grant roles to users through operating system facilities, then you cannot also grant roles to users with the `GRANT` statement, although you can use the `GRANT` statement to grant system privileges to users and system privileges and roles to other roles.

Note on Oracle Automatic Storage Management A user authenticated AS `SYSASM` can use this statement to grant the system privileges `SYSASM`, `SYSOPER`, and `SYSDBA` to a user in the Oracle ASM password file of the current node.

Note on Editionable Objects A `GRANT` operation to grant object privileges on an editionable object actualizes the object in the current edition. See Oracle Database Development Guide for more information about editions and editionable objects.

See Also:

- `CREATE USER` on page 17-7 and `CREATE ROLE` on page 15-87 for definitions of local, global, and external privileges
- Oracle Database Security Guide for information about other authorization methods and for information about privileges
- `REVOKE` on page 18-100 for information on revoking grants

Prerequisites

To grant a **system privilege**, one of the following conditions must be met:

- You must have been granted the `GRANT ANY PRIVILEGE` system privilege. In this case, if you grant the system privilege to a role, then a user to whom the role has
been granted does not have the privilege unless the role is enabled in user’s session.

- You must have been granted the system privilege with the ADMIN OPTION. In this case, if you grant the system privilege to a role, then a user to whom the role has been granted has the privilege regardless whether the role is enabled in the user’s session.

To grant a role to a user or another role, you must have been directly granted the role with the ADMIN OPTION, or you must have been granted the GRANT ANY ROLE system privilege, or you must have created the role.

To grant a role to a program unit in your own schema:

- For Oracle Database 12c Release 1 (12.1.0.1), you must have been directly granted the role, or you must have created the role.
- Starting with Oracle Database 12c Release 1 (12.1.0.2), you must have been directly granted the role with either the ADMIN OPTION or the DELEGATE OPTION, or you must have been granted the GRANT ANY ROLE system privilege, or you must have created the role.

To grant a role to a program unit in another user’s schema, you must be the user SYS and the role must have been created by the schema owner or directly granted to the schema owner.

To grant an object privilege on a user, by specifying the ON USER clause of the on_object_clause, you must be the user on whom the privilege is granted, or you must have been granted the object privilege on that user with the WITH GRANT OPTION, or you must have been granted the GRANT ANY OBJECT PRIVILEGE system privilege. If you can grant an object privilege on a user only because you have the GRANT ANY OBJECT PRIVILEGE, then the GRANTOR column of the *_TAB_PRIVS views displays the user on whom the privilege is granted rather than the user who issued the GRANT statement.

To grant an object privilege on all other types of objects, you must own the object, or the owner of the object must have granted you the object privileges with the WITH GRANT OPTION, or you must have been granted the GRANT ANY OBJECT PRIVILEGE system privilege. If you have the GRANT ANY OBJECT PRIVILEGE, then you can grant the object privilege only if the object owner could have granted the same object privilege. In this case, the GRANTOR column of the *_TAB_PRIVS views displays the object owner rather than the user who issued the GRANT statement.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root.

Syntax

Semantics

grant_system_privileges
Use these clauses to grant system privileges.

system_privilege
Specify the system privilege you want to grant. Table 18–1 lists the system privileges, organized by the database object operated upon.

- If you grant a privilege to a user, then the database adds the privilege to the user's privilege domain. The user can immediately exercise the privilege. Oracle recommends that you only grant the ANY privileges to trusted users.

- If you grant a privilege to a role, then the database adds the privilege to the privilege domain of the role. Users who have been granted and have enabled the role can immediately exercise the privilege. Other users who have been granted the role can enable the role and exercise the privilege.
See Also: Granting a System Privilege to a User: Example on page 18-59 and "Granting System Privileges to a Role: Example" on page 18-59

If you grant a privilege to PUBLIC, then the database adds the privilege to the privilege domains of each user. All users can immediately perform operations authorized by the privilege. Oracle recommends against granting system privileges to PUBLIC.

role
Specify the role you want to grant. You can grant an Oracle Database predefined role or a user-defined role.

If you grant a role to a user, then the database makes the role available to the user. The user can immediately enable the role and exercise the privileges in the privilege domain of the role.

In the case of a secure application role, you need not grant such a role directly to the user. You can let the associated PL/SQL package do this, assuming the user passes appropriate security policies. For more information, see the CREATE ROLE semantics for USING package on page 15-89 and Oracle Database Security Guide

If you grant a role to another role, then the database adds the privilege domain of the granted role to the privilege domain of the grantee role. Users who have been granted the grantee role can enable it and exercise the privileges in the granted role's privilege domain.

If you grant a role to PUBLIC, then the database makes the role available to all users. All users can immediately enable the role and exercise the privileges in the privilege domain of the role.

ALL PRIVILEGES
Specify ALL PRIVILEGES to grant all of the system privileges listed in Table 18–1 on page 18-44, except the SELECT ANY DICTIONARY, ALTER DATABASE LINK, and ALTER PUBLIC DATABASE LINK privileges.

See Also:

Oracle Database Security Guide for information on the Oracle predefined roles

"Granting a Role to a Role: Example" on page 18-60

CREATE ROLE on page 15-87 for information on creating a user-defined role

grantee_clause
Use the grantee_clause to specify the users or roles to which the system privilege, role, or object privilege is granted.

PUBLIC Specify PUBLIC to grant the privileges to all users. Oracle recommends against granting system privileges to PUBLIC.

Restriction on Grantees A user, role, or PUBLIC cannot appear more than once in the grantee_clause.
The `grantee_identified_by` clause lets you assign passwords to users when granting them system privileges and roles. You must specify an equal number of users and passwords. The first password is assigned to the first user, the second password is assigned to the second user, and so on. If a specified user exists, then the database resets the user's password. If a specified user does not exist, then the database creates the user with the password.

**See Also:** [CREATE USER](#) on page 17-7 for restrictions on usernames and passwords and "Assigning User Passwords When Granting a System Privilege: Example" on page 18-59

**WITH ADMIN OPTION**

Specify `WITH ADMIN OPTION` to enable the grantee to:

- Grant the privilege or role to another user or role, unless the role is a [GLOBAL role](#).
- Revoke the privilege or role from another user or role
- Alter the privilege or role to change the authorization needed to access it
- Drop the privilege or role
- Grant the role to a program unit in the grantee's schema.
- Revoke the role from a program unit in the grantee's schema.

If you grant a system privilege or role to a user without specifying `WITH ADMIN OPTION`, and then subsequently grant the privilege or role to the user `WITH ADMIN OPTION`, then the user has the `ADMIN OPTION` on the privilege or role.

To revoke the `ADMIN OPTION` on a system privilege or role from a user, you must revoke the privilege or role from the user altogether and then grant the privilege or role to the user without the `ADMIN OPTION`.

**See Also:** "Granting a Role with the ADMIN OPTION: Example" on page 18-60

**WITH DELEGATE OPTION**

You can specify this clause only when granting a role to a user.

Specify `WITH DELEGATE OPTION` to enable the grantee to:

- Grant the role to a program unit in the grantee's schema
- Revoke the role from a program unit in the grantee's schema

If you grant a role to a user without specifying `WITH DELEGATE OPTION`, and then subsequently grant the role to the user `WITH DELEGATE OPTION`, then the user has the `DELEGATE OPTION` on the role.

To revoke the `DELEGATE OPTION` on a role from a user, you must revoke the role from the user altogether and then grant the role to the user without the `DELEGATE OPTION`.

---

**Note:** The `WITH DELEGATE OPTION` clause is available starting with Oracle Database 12c Release 1 (12.1.0.2).
Restrictions on Granting System Privileges and Roles

Privileges and roles are subject to the following restrictions:

- A privilege or role cannot appear more than once in the list of privileges and roles to be granted.
- You cannot grant a role to itself.
- You cannot grant a role IDENTIFIED GLOBALLY to anything.
- You cannot grant a role IDENTIFIED EXTERNALLY to a global user or global role.
- You cannot grant roles circularly. For example, if you grant the role banker to the role teller, then you cannot subsequently grant teller to banker.
- You cannot grant an IDENTIFIED BY role, IDENTIFIED USING role, or IDENTIFIED EXTERNALLY role to another role.

grant_object_privileges

Use these clauses to grant object privileges.

object_privilege

Specify the object privilege you want to grant. Table 18–2 lists the object privileges, organized by the type of object on which they can be granted. When you grant an object privilege on an editionable object, either to a user or to a role, the object is actualized in the edition in which the grant is made. Refer to CREATE EDITION on page 14-64 for information on editionable object types and editions.

Note: To grant SELECT on a view to another user, either you must own all of the objects underlying the view or you must have been granted the SELECT object privilege WITH GRANT OPTION on all of those underlying objects. This is true even if the grantee already has SELECT privileges on those underlying objects.

To grant READ on a view to another user, either you must own all of the objects underlying the view or you must have been granted the READ or SELECT object privilege WITH GRANT OPTION on all of those underlying objects. This is true even if the grantee already has the READ or SELECT privilege on those underlying objects.

Restriction on Object Privileges

A privilege cannot appear more than once in the list of privileges to be granted.

ALL [PRIVILEGES]

Specify ALL to grant all the privileges for the object that you have been granted with the GRANT OPTION. The user who owns the schema containing an object automatically has all privileges on the object with the GRANT OPTION. The keyword PRIVILEGES is provided for semantic clarity and is optional.
**column**

Specify the table or view column on which privileges are to be granted. You can specify columns only when granting the `INSERT`, `REFERENCES`, or `UPDATE` privilege. If you do not list columns, then the grantee has the specified privilege on all columns in the table or view.

For information on existing column object grants, query the `USER_`, `ALL_`, or `DBA_COL_PRIVS` data dictionary view.

**See Also:** *Oracle Database Reference* for information on the data dictionary views and "Granting Multiple Object Privileges on Individual Columns: Example" on page 18-61

**on_object_clause**

The `on_object_clause` identifies the object on which the privileges are granted. Users, directory schema objects, editions, data mining models, Java source and resource schema objects, and SQL translation profiles are identified separately because they reside in separate namespaces.

**See Also:** "Granting Object Privileges to a Role: Example" on page 18-60

**object** Specify the schema object on which the privileges are to be granted. If you do not qualify `object` with `schema`, then the database assumes the object is in your own schema. The object can be one of the following types:

- Table, view, or materialized view
- Sequence
- Procedure, function, or package
- User-defined type
- Synonym for any of the preceding items
- Directory, library, operator, or indextype
- Java source, class, or resource

You cannot grant privileges directly to a single partition of a partitioned table.

**See Also:** "Granting Object Privileges on a Table to a User: Example" on page 18-61, "Granting Object Privileges on a View: Example" on page 18-61, and "Granting Object Privileges to a Sequence in Another Schema: Example" on page 18-61

**ON USER** Specify one or more database users on whom privileges are to be granted.

**Restriction on Granting Privileges on Users** You cannot grant privileges on user `PUBLIC`.

**See Also:** "Granting an Object Privilege on a User: Example" on page 18-60

**ON DIRECTORY** Specify the name of the directory schema object on which privileges are to be granted. You cannot qualify `directory_name` with a schema name.

**See Also:** `CREATE DIRECTORY` on page 14-54 and "Granting an Object Privilege on a Directory: Example" on page 18-60
ON EDITION Specify the name of the edition on which the USE object privilege is to be granted. You cannot qualify edition_name with a schema name.

ON MINING MODEL Specify the name of the mining model on which privileges are to be granted. If you do not qualify mining_model_name with schema, then the database assumes that the mining model is in your own schema.

ON JAVA SOURCE | RESOURCE Specify the name of the Java source or resource schema object on which privileges are to be granted. If you do not qualify object with schema, then the database assumes that the object is in your own schema.

See Also: CREATE JAVA on page 14-107

ON SQL TRANSLATION PROFILE Specify the name of the SQL translation profile on which privileges are to be granted. If you do not qualify profile with schema, then the database assumes that the profile is in your own schema.

WITH HIERARCHY OPTION
Specify WITH HIERARCHY OPTION to grant the specified object privilege on all subobjects of object, such as subviews created under a view, including subobjects created subsequent to this statement.

This clause is meaningful only in combination with the READ or SELECT object privilege.

WITH GRANT OPTION
Specify WITH GRANT OPTION to enable the grantee to grant the object privileges to other users and roles.

If you grant an object privilege to a user without specifying WITH GRANT OPTION, and then subsequently grant the privilege to the user WITH GRANT OPTION, then the user has the GRANT OPTION on the privilege.

To revoke the GRANT OPTION on an object privilege from a user, you must revoke the privilege from the user altogether and then grant the privilege to the user without the GRANT OPTION.

Restriction on Granting WITH GRANT OPTION You can specify WITH GRANT OPTION only when granting to a user or to PUBLIC, not when granting to a role.

grant_roles_to_programs
Use this clause to grant roles to program units. Such roles are called code based access control (CBAC) roles.

role
Specify the role you want to grant. You can grant an Oracle Database predefined role or a user-defined role. The role must have been created by or directly granted to the schema owner of the program unit.

program_unit
Specify the program unit to which the role is to be granted. You can specify a PL/SQL function, procedure, or package. If you do not specify schema, then Oracle Database assumes the function, procedure, or package is in your own schema.

See Also: Oracle Database Security Guide for more information on granting code based access control roles to program units
CONTAINER Clause

If the current container is a pluggable database (PDB):

- Specify `CONTAINER = CURRENT` to locally grant a system privilege, object privilege, or role to a user or role. The privilege or role is granted to the user or role only in the current PDB.

If the current container is the root:

- Specify `CONTAINER = CURRENT` to locally grant a system privilege, object privilege, or role to a common user or common role. The privilege or role is granted to the user or role only in the root.
- Specify `CONTAINER = ALL` to commonly grant a system privilege, object privilege on a common object, or role, to a common user or common role.

If you omit this clause, then `CONTAINER = CURRENT` is the default.

---

**Note:** If you specify the `CONTAINER` clause when granting a privilege or role, then the current container must be the same container and you must specify the same `CONTAINER` clause when you revoke the privilege or role. Refer to the `CONTAINER Clause` of the `REVOKE` statement on page 18-106 for more information.

---

Listings of System and Object Privileges

**Note:** When you grant a privilege on *ANY* object, such as `CREATE ANY CLUSTER`, the result is determined by the value of the `O7_DICTIONARY_ACCESSIBILITY` initialization parameter. By default, this parameter is set to `FALSE`, so that *ANY* privileges give the grantee access to that type of object in all schemas except the `SYS` schema. If you set `O7_DICTIONARY_ACCESSIBILITY` to `TRUE`, then the *ANY* privileges also give the grantee access, in the `SYS` schema, to all objects except Oracle Scheduler objects. For security reasons, Oracle recommends that you use this setting only with great caution.

<td>Create public synonyms.</td>
</tr>
<tr>
<td>DROP ANY SYNONYM</td>
<td>Drop private synonyms in any schema except SYS.</td>
</tr>
</tbody>
</table>

**Caution:** CREATE PUBLIC SYNONYM and DROP PUBLIC SYNONYM are extremely powerful privileges that should be granted only to trusted users. Refer to Oracle Database Security Guide before granting these privileges.
DROP PUBLIC SYNONYM

DROP TABLES:

Note: For external tables, the only valid privileges are CREATE ANY TABLE, ALTER ANY TABLE, DROP ANY TABLE, READ ANY TABLE, and SELECT ANY TABLE.

CREATE TABLE
Create tables in the grantee’s schema.

CREATE ANY TABLE
Create tables in any schema except SYS. The owner of the schema containing the table must have space quota on the tablespace to contain the table.

ALTER ANY TABLE
Alter a table or view in any schema except SYS.

BACKUP ANY TABLE
Use the Export utility to incrementally export objects from the schema of other users except SYS.

DELETE ANY TABLE
Delete rows from tables, table partitions, or views in any schema except SYS.

DROP ANY TABLE
Drop or truncate tables or table partitions in any schema except SYS.

INSERT ANY TABLE
Insert rows into tables and views in any schema except SYS.

LOCK ANY TABLE
Lock tables and views in any schema except SYS.

READ ANY TABLE
Query tables, views, or materialized views in any schema except SYS.

Note: This privilege is available starting with Oracle Database 12c Release 1 (12.1.0.2).

SELECT ANY TABLE
Query tables, views, or materialized views in any schema except SYS. Obtain row locks using a SELECT ... FOR UPDATE.

FLASHBACK ANY TABLE
Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.

UPDATE ANY TABLE
Update rows in tables and views in any schema except SYS.

TABLESPACES:

—

CREATE TABLESPACE
Create tablespaces.

ALTER TABLESPACE
Alter tablespaces.

DROP TABLESPACE
Drop tablespaces.

MANAGE TABLESPACE
Take tablespaces offline and online and begin and end tablespace backups.

UNLIMITED TABLESPACE
Use an unlimited amount of any tablespace. This privilege overrides any specific quotas assigned. If you revoke this privilege from a user, then the user’s schema objects remain but further tablespace allocation is denied unless authorized by specific tablespace quotas. You cannot grant this system privilege to roles.

TRIGGERS:

—

CREATE TRIGGER
Create database triggers in the grantee’s schema.

CREATE ANY TRIGGER
Create database triggers in any schema except SYS.

ALTER ANY TRIGGER
Enable, disable, or compile database triggers in any schema except SYS.

DROP ANY TRIGGER
Drop database triggers in any schema except SYS.
**Table 18–1 (Cont.) System Privileges (Organized by the Database Object Operated Upon)**

<table>
<thead>
<tr>
<th>System Privilege Name</th>
<th>Operations Authorized</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ADMINISTER DATABASE TRIGGER</strong></td>
<td>Create a trigger on DATABASE. You must also have the CREATE TRIGGER or CREATE ANY TRIGGER system privilege.</td>
</tr>
<tr>
<td><strong>TYPES:</strong></td>
<td></td>
</tr>
<tr>
<td>CREATE TYPE</td>
<td>Create object types and object type bodies in the grantee's schema.</td>
</tr>
<tr>
<td>CREATE ANY TYPE</td>
<td>Create object types and object type bodies in any schema except SYS.</td>
</tr>
<tr>
<td>ALTER ANY TYPE</td>
<td>Alter object types in any schema except SYS.</td>
</tr>
<tr>
<td>DROP ANY TYPE</td>
<td>Drop object types and object type bodies in any schema except SYS.</td>
</tr>
<tr>
<td>EXECUTE ANY TYPE</td>
<td>Use and reference object types and collection types in any schema, except SYS, and invoke methods of an object type in any schema, except SYS, if you make the grant to a specific user. If you grant EXECUTE ANY TYPE to a role, then users holding the enabled role will not be able to invoke methods of an object type in any schema.</td>
</tr>
<tr>
<td>UNDER ANY TYPE</td>
<td>Create subtypes under any nonfinal object types.</td>
</tr>
<tr>
<td><strong>USERS:</strong></td>
<td></td>
</tr>
<tr>
<td>CREATE USER</td>
<td>Create users. This privilege also allows the creator to:</td>
</tr>
<tr>
<td></td>
<td>■ Assign quotas on any tablespace.</td>
</tr>
<tr>
<td></td>
<td>■ Set default and temporary tablespaces.</td>
</tr>
<tr>
<td></td>
<td>■ Assign a profile as part of a CREATE USER statement.</td>
</tr>
<tr>
<td>ALTER USER</td>
<td>Alter any user. This privilege authorizes the grantee to:</td>
</tr>
<tr>
<td></td>
<td>■ Change another user's password or authentication method.</td>
</tr>
<tr>
<td></td>
<td>■ Assign quotas on any tablespace.</td>
</tr>
<tr>
<td></td>
<td>■ Set default and temporary tablespaces.</td>
</tr>
<tr>
<td></td>
<td>■ Assign a profile and default roles.</td>
</tr>
<tr>
<td>DROP USER</td>
<td>Drop users</td>
</tr>
<tr>
<td><strong>VIEWS:</strong></td>
<td></td>
</tr>
<tr>
<td>CREATE VIEW</td>
<td>Create views in the grantee's schema.</td>
</tr>
<tr>
<td>CREATE ANY VIEW</td>
<td>Create views in any schema except SYS.</td>
</tr>
<tr>
<td>DROP ANY VIEW</td>
<td>Drop views in any schema except SYS.</td>
</tr>
<tr>
<td>UNDER ANY VIEW</td>
<td>Create subviews under any object views.</td>
</tr>
<tr>
<td>FLASHBACK ANY TABLE</td>
<td>Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.</td>
</tr>
<tr>
<td>MERGE ANY VIEW</td>
<td>If a user has been granted the MERGE ANY VIEW privilege, then for any query issued by that user, the optimizer can use view merging to improve query performance without performing the checks that would otherwise be performed to ensure that view merging does not violate any security intentions of the view creator. See also Oracle Database Reference for information on the OPTIMIZER_SECURE_VIEW_MERGING parameter and Oracle Database SQL Tuning Guide for information on view merging.</td>
</tr>
<tr>
<td><strong>MISCELLANEOUS:</strong></td>
<td></td>
</tr>
<tr>
<td>ANALYZE ANY</td>
<td>Analyze a table, cluster, or index in any schema except SYS.</td>
</tr>
</tbody>
</table>
### Table 18–1 (Cont.) System Privileges (Organized by the Database Object Operated Upon)

<table>
<thead>
<tr>
<th>System Privilege Name</th>
<th>Operations Authorized</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUDIT ANY</td>
<td>Audit an object in any schema, except SYS, using AUDIT schema_objects statements.</td>
</tr>
<tr>
<td>BECOME USER</td>
<td>Allow users of the Data Pump Import utility (impdp) and the original Import utility (imp) to assume the identity of another user in order to perform operations that cannot be directly performed by a third party (for example, loading objects such as object privilege grants). Allow Streams administrators to create or alter capture users and apply users in a Streams environment. By default this privilege is part of the DBA role. Database Vault removes this privileges from the DBA role. Therefore, this privilege is needed by Streams only in an environment where Database Vault is installed.</td>
</tr>
<tr>
<td>CHANGE NOTIFICATION</td>
<td>Create a registration on queries and receive database change notifications in response to DML or DDL changes to the objects associated with the registered queries. Refer to Oracle Database Development Guide for more information on database change notification.</td>
</tr>
<tr>
<td>COMMENT ANY TABLE</td>
<td>Comment on a table, view, or column in any schema except SYS.</td>
</tr>
<tr>
<td>EXEMPT ACCESS POLICY</td>
<td>Bypass fine-grained access control. <strong>Caution:</strong> This is a very powerful system privilege, as it lets the grantee bypass application-driven security policies. Database administrators should use caution when granting this privilege.</td>
</tr>
<tr>
<td>FORCE ANY TRANSACTION</td>
<td>Force the commit or rollback of any in-doubt distributed transaction in the local database. Induce the failure of a distributed transaction.</td>
</tr>
<tr>
<td>FORCE TRANSACTION</td>
<td>Force the commit or rollback of the grantee's in-doubt distributed transactions in the local database.</td>
</tr>
<tr>
<td>GRANT ANY OBJECT PRIVILEGE</td>
<td>Grant any object privilege that the object owner is permitted to grant. Revoke any object privilege that was granted by the object owner or by some other user with the GRANT ANY OBJECT PRIVILEGE privilege.</td>
</tr>
<tr>
<td>GRANT ANY PRIVILEGE</td>
<td>Grant any system privilege.</td>
</tr>
<tr>
<td>INHERIT ANY PRIVILEGES</td>
<td>Execute invoker's rights procedures owned by the grantee with the privileges of the invoker.</td>
</tr>
<tr>
<td>KEEP DATE TIME</td>
<td>The SYSDATE and SYSTIMESTAMP functions return their original values during replay for Application Continuity when the grantee is running the application. This privilege is useful for providing bind variable consistency after recoverable errors. <strong>Note:</strong> If this privilege is granted or revoked between runtime and failover of a request, then the original values are not returned during replay for Application Continuity for that request.</td>
</tr>
<tr>
<td>KEEP SYSGUID</td>
<td>The SYS_GUID function returns its original value during replay for Application Continuity when the grantee is running the application. This privilege is useful for providing bind variable consistency after recoverable errors. <strong>Note:</strong> If this privilege is granted or revoked between runtime and failover of a request, then the original value is not returned during replay for Application Continuity for that request.</td>
</tr>
<tr>
<td>PURGE DBA_RECYCLEBIN</td>
<td>Remove all objects from the system-wide recycle bin.</td>
</tr>
</tbody>
</table>
### Table 18–1  (Cont.) System Privileges (Organized by the Database Object Operated Upon)

<table>
<thead>
<tr>
<th>System Privilege Name</th>
<th>Operations Authorized</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESUMABLE</td>
<td>Enable resumable space allocation.</td>
</tr>
<tr>
<td>SELECT ANY DICTIONARY</td>
<td>Query any data dictionary object in the SYS schema, with the exception of the following objects: DEFAULT_PWD$, ENC$, LINK$, USER$, USER_HISTORY$, and X$VERIFIERS. This privilege lets you selectively override the default FALSE setting of the O7_DICTIONARY_ACCESSIBILITY initialization parameter.</td>
</tr>
<tr>
<td>SELECT ANY TRANSACTION</td>
<td>Query the contents of the FLASHBACK_TRANSACTION_QUERY view. <strong>Caution:</strong> This is a very powerful system privilege, as it lets the grantee view all data in the database, including past data. This privilege should be granted only to users who need to use the Oracle Flashback Transaction Query feature.</td>
</tr>
<tr>
<td>SYSBACKUP</td>
<td>Perform the following backup and recovery operations: STARTUP and SHUTDOWN. CREATE CONTROLFILE. CREATE PFILE and CREATE SPFILE. FLASHBACK DATABASE. Create, use, view, and drop restore points (including guaranteed restore points). Execute procedures in the DBMS_DATAPUMP, DBMS_PIPE, DBMS_TDB, and DBMS_TTS packages. SELECT on X$ tables, V$ views, and GV$ views. Includes the ALTER DATABASE, ALTER SESSION, ALTER SYSTEM, ALTER TABLESPACE, CREATE ANY CLUSTER, CREATE ANY DIRECTORY, CREATE ANY TABLE, CREATE SESSION, DROP DATABASE, DROP TABLESPACE, RESUMABLE, SELECT ANY DICTIONARY, SELECT ANY TRANSACTION, UNLIMITED TABLESPACE privileges and the SELECT_CATALOG_ROLE role.</td>
</tr>
<tr>
<td>SYSDBA</td>
<td>STARTUP and SHUTDOWN. ALTER DATABASE: open, mount, back up, or change character set. CREATE DATABASE. DROP DATABASE. ARCHIVELOG and RECOVERY. CREATE SPFILE. Includes the RESTRICTED SESSION privilege.</td>
</tr>
</tbody>
</table>
Perform the following Oracle Data Guard operations:
- `STARTUP` and `SHUTDOWN`.
- `FLASHBACK DATABASE`.
- Create, use, view, and drop restore points (including guaranteed restore points).
- `SELECT` on `X$` tables, `V$` views, and `GV$` views.
- Includes the `ALTER DATABASE`, `ALTER SESSION`, `ALTER SYSTEM`, `CREATE SESSION`, and `SELECT ANY DICTIONARY` privileges.

Perform the following encryption key management operations:
- Connect to the database even if the database is not open.
- `SELECT` on the following views when the database is open:
  - `V$CLIENT_SECRET`, `V$ENCRYPTED_TABLESPACES`, `V$ENCRYPTION KEYS`, `V$ENCRYPTION_WALLET` and `V$WALLET`.
- Includes the `ADMINISTER KEY MANAGEMENT` and `CREATE SESSION` privileges.

STARTUP and SHUTDOWN operations.
- `ALTER DATABASE`: open, mount, or back up.
- `ARCHIVELOG` and `RECOVERY`.
- `CREATE SPFILE`.
- Includes the `RESTRICTED SESSION` privilege.

The following directory privileges provide secured access to the files stored in the operating system directory to which the directory object serves as a pointer. The directory object contains the full path name of the operating system directory where the files reside. Because the files are actually stored outside the database, Oracle Database server processes also need to have appropriate file permissions on the file system server. Granting object privileges on the directory database object to individual database users, rather than on the operating system, allows the database to enforce security during file operations.

**Restriction:** This privilege does not allow the grantee to write to a `BFILE`.

The following edition privilege authorizes the use of an edition.

Use an edition.

The following indextype privilege authorizes operations on indextypes.

Reference an indextype.
<table>
<thead>
<tr>
<th>Object Privilege Name</th>
<th>Operations Authorized</th>

<tr>
<td><strong>LIBRARY PRIVILEGE</strong></td>
<td>The following <strong>library privilege</strong> authorizes operations on a library.</td>
</tr>
<tr>
<td><strong>EXECUTE</strong></td>
<td>Use and reference the specified object and invoke its methods. <strong>Caution:</strong> This extremely powerful privilege should be granted only to trusted users. Refer to Oracle Database Security Guide before granting this privilege.</td>
</tr>
<tr>
<td><strong>MATERIALIZED VIEW PRIVILEGES</strong></td>
<td>The following <strong>materialized view privileges</strong> authorize operations on a materialized view. The DELETE, INSERT, and UPDATE privileges can be granted only to updatable materialized views.</td>
</tr>
<tr>
<td><strong>ON COMMIT REFRESH</strong></td>
<td>Create a refresh-on-commit materialized view on the specified table.</td>
</tr>
<tr>
<td><strong>QUERY REWRITE</strong></td>
<td>Create a materialized view for query rewrite using the specified table.</td>
</tr>
<tr>
<td><strong>READ</strong></td>
<td>Query the materialized view. <strong>Note:</strong> This privilege is available starting with Oracle Database 12c Release 1 (12.1.0.2).</td>
</tr>
<tr>
<td><strong>SELECT</strong></td>
<td>Query the materialized view. Obtain row locks with the SELECT ... FOR UPDATE or LOCK TABLE statement.</td>
</tr>
<tr>
<td><strong>MINING MODEL PRIVILEGES</strong></td>
<td>The following mining model privileges authorize operations on a mining model. These privileges are not required for models within the users own schema.</td>
</tr>
<tr>
<td><strong>ALTER</strong></td>
<td>Change the mining model name or the associated cost matrix using the applicable DBMS_DATA_MINING procedures.</td>
</tr>
<tr>
<td><strong>SELECT</strong></td>
<td>Score or view the mining model. Scoring is done with the PREDICTION family of SQL functions or with the DBMS_DATA_MINING.APPLY procedure. Viewing the model is done with the DBMS_DATA_MINING.GET_MODEL_DETAILS_* procedures.</td>
</tr>
<tr>
<td><strong>OBJECT TYPE PRIVILEGES</strong></td>
<td>The following <strong>object type privileges</strong> authorize operations on a database object type.</td>
</tr>
<tr>
<td><strong>DEBUG</strong></td>
<td>Access, through a debugger, all public and nonpublic variables, methods, and types defined on the object type. Place a breakpoint or stop at a line or instruction boundary within the type body.</td>
</tr>
<tr>
<td><strong>EXECUTE</strong></td>
<td>Use and reference the specified object and invoke its methods. Access, through a debugger, public variables, types, and methods defined on the object type.</td>
</tr>
<tr>
<td><strong>UNDER</strong></td>
<td>Create a subtype under this type. You can grant this object privilege only if you have the UNDER ANY TYPE privilege only if you have the UNDER ANY TYPE privilege WITH GRANT OPTION on the immediate supertype of this type.</td>
</tr>
<tr>
<td><strong>OLAP PRIVILEGES</strong></td>
<td>The following object privileges are valid if you are using Oracle Database with the OLAP option.</td>

</tr>
<tr>
<td><strong>EXECUTE</strong></td>
<td>Reference an operator.</td>
</tr>
<tr>
<td><strong>PROCEDURE, FUNCTION, PACKAGE PRIVILEGES</strong></td>
<td>The following procedure, function, and package privileges authorize operations on procedures, functions, and packages. These privileges also apply to Java sources, classes, and resources, which Oracle Database treats as though they were procedures for purposes of granting object privileges.</td>
</tr>
<tr>
<td><strong>DEBUG</strong></td>
<td>Access, through a debugger, all public and nonpublic variables, methods, and types defined on the object. Place a breakpoint or stop at a line or instruction boundary within the procedure, function, or package. This privilege grants access to the declarations in the method or package specification and body.</td>
</tr>
<tr>
<td><strong>EXECUTE</strong></td>
<td>Execute the procedure or function directly, or access any program object declared in the specification of a package, or compile the object implicitly during a call to a currently invalid or uncompiled function or procedure. This privilege does not allow the grantee to explicitly compile using ALTER PROCEDURE or ALTER FUNCTION. For explicit compilation you need the appropriate ALTER system privilege. Access, through a debugger, public variables, types, and methods defined on the procedure, function, or package. This privilege grants access to the declarations in the method or package specification only. Job scheduler objects are created using the DBMS_SCHEDULER package. After these objects are created, you can grant the EXECUTE object privilege on job scheduler classes and programs. You can also grant ALTER privilege on job scheduler jobs, programs, and schedules. <strong>Note:</strong> Users do not need this privilege to execute a procedure, function, or package indirectly.</td>
</tr>
<tr>
<td><strong>SCHEDULER PRIVILEGES</strong></td>
<td>Job scheduler objects are created using the DBMS_SCHEDULER package. After these objects are created, you can grant the following privileges. Operations on job classes, programs, chains, and credentials. Modifications to jobs, programs, chains, credentials, and schedules.</td>
</tr>
<tr>
<td><strong>SEQUENCE PRIVILEGES</strong></td>
<td>The following sequence privileges authorize operations on a sequence. Change the sequence definition with the ALTER SEQUENCE statement.</td>
</tr>
<tr>
<td><strong>KEEP SEQUENCE</strong></td>
<td>The sequence pseudocolumn NEXTVAL retains its original value during replay for Application Continuity when the grantee is running the application. This privilege is useful for providing bind variable consistency when replaying after recoverable errors. If this privilege is granted or revoked between runtime and failover of a request, then the original value of NEXTVAL is not retained during replay for Application Continuity for that request. <strong>Note:</strong> This privilege is not granted by the GRANT ALL PRIVILEGES ON sequence statement. You must explicitly grant this privilege. <strong>Note:</strong> This privilege is part of the DBA role.</td>
</tr>
<tr>
<td><strong>SELECT</strong></td>
<td>Examine and increment values of the sequence with the CURRVAL and NEXTVAL pseudocolumns.</td>
</tr>
<tr>
<td><strong>SQL TRANSLATION PROFILE PRIVILEGES</strong></td>
<td>The following SQL translation profile privileges authorize operations on a SQL translation profile.</td>

<tr>
<td>SELECT</td>
<td>Query the table with the SELECT statement, including SELECT ... FOR UPDATE.</td>
</tr>
<tr>
<td>UPDATE</td>
<td>Change data in the table with the UPDATE statement.&lt;br&gt;<strong>Note:</strong> You must grant the SELECT privilege on the table along with the UPDATE privilege if the table is on a remote database.</td>
</tr>
<tr>
<td>USER PRIVILEGES</td>
<td>The following privileges authorize operations on a user.</td>
</tr>
<tr>
<td>INHERIT PRIVILEGES</td>
<td>Execute invoker’s rights procedures owned by the grantee with the privileges of the invoker when the invoker is the user on whom this privilege is granted.</td>
</tr>
<tr>
<td>TRANSLATE SQL</td>
<td>Translate SQL through the grantee’s SQL translation profile for the user on whom this privilege is granted.</td>
</tr>
<tr>
<td>VIEW PRIVILEGES</td>
<td>The following view privileges authorize operations on a view. Any one of the following object privileges, except the READ privilege, allows the grantee to lock the view in any lock mode with the LOCK TABLE statement. &lt;br&gt;To grant a privilege on a view, you must have that privilege with the GRANT OPTION on all of the base tables of the view.</td>
</tr>
</tbody>
</table>
Granting a System Privilege to a User: Example  To grant the CREATE SESSION system privilege to the sample user hr, allowing hr to log on to Oracle Database, issue the following statement:

```
GRANT CREATE SESSION TO hr;
```

Assigning User Passwords When Granting a System Privilege: Example  Assume that user hr exists and user newuser does not exist. The following statement resets the user hr password to password1, creates user newuser with password2, and grants both users the CREATE SESSION system privilege:

```
GRANT CREATE SESSION
  TO hr,
newuser IDENTIFIED BY password1, password2;
```

Granting System Privileges to a Role: Example  The following statement grants appropriate system privileges to a data warehouse manager role, which was created in the "Creating a Role: Example" on page 15-89:

```
GRANT
  CREATE ANY MATERIALIZED VIEW,
  ALTER ANY MATERIALIZED VIEW,
  DROP ANY MATERIALIZED VIEW,
  QUERY REWRITE,
  GLOBAL QUERY REWRITE
TO the_data_warehouse_manager_role;
```
TO dw_manager
   WITH ADMIN OPTION;

The dw_manager privilege domain now contains the system privileges related to materialized views.

Granting a Role with the ADMIN OPTION: Example  To grant the dw_manager role with the ADMIN OPTION to the sample user sh, issue the following statement:

```
GRANT dw_manager
   TO sh
   WITH ADMIN OPTION;
```

User sh can now perform the following operations with the dw_manager role:

- Enable the role and exercise any privileges in the privilege domain of the role, including the CREATE MATERIALIZED VIEW system privilege
- Grant and revoke the role to and from other users
- Drop the role
- Grant and revoke the dw_manager role to and from program units in the sh schema

Granting a Role with the DELEGATE OPTION: Example  To grant the dw_manager role with the DELEGATE OPTION to the sample user sh, issue the following statement:

```
GRANT dw_manager
   TO sh
   WITH DELEGATE OPTION;
```

User sh can now grant and revoke the dw_manager role to and from program units in the sh schema.

Granting Object Privileges to a Role: Example  The following example grants the SELECT object privileges to a data warehouse user role, which was created in the "Creating a Role: Example" on page 15-89:

```
GRANT SELECT ON sh.sales TO warehouse_user;
```

Granting a Role to a Role: Example  The following statement grants the warehouse_user role to the dw_manager role. Both roles were created in the "Creating a Role: Example" on page 15-89:

```
GRANT warehouse_user TO dw_manager;
```

The dw_manager role now contains all of the privileges in the domain of the warehouse_user role.

Granting an Object Privilege on a User: Example  To grant the INHERIT PRIVILEGES object privilege on user sh to user hr, issue the following statement:

```
GRANT INHERIT PRIVILEGES ON USER sh TO hr;
```

Granting an Object Privilege on a Directory: Example  To grant READ on directory bfile_dir to user hr, with the GRANT OPTION, issue the following statement:

```
GRANT READ ON DIRECTORY bfile_dir TO hr
   WITH GRANT OPTION;
```
Granting Object Privileges on a Table to a User: Example  To grant all privileges on the table oe.bonuses, which was created in "Merging into a Table: Example" on page 18-85, to the user hr with the GRANT OPTION, issue the following statement:

```sql
GRANT ALL ON bonuses TO hr
    WITH GRANT OPTION;
```

The user hr can subsequently perform the following operations:
- Exercise any privilege on the bonuses table
- Grant any privilege on the bonuses table to another user or role

Granting Object Privileges on a View: Example  To grant SELECT and UPDATE privileges on the view emp_view, which was created in "Creating a View: Example" on page 17-24, to all users, issue the following statement:

```sql
GRANT SELECT, UPDATE
    ON emp_view TO PUBLIC;
```

All users can subsequently query and update the view of employee details.

Granting Object Privileges to a Sequence in Another Schema: Example  To grant SELECT privilege on the customers_seq sequence in the schema oe to the user hr, issue the following statement:

```sql
GRANT SELECT
    ON oe.customers_seq TO hr;
```

The user hr can subsequently generate the next value of the sequence with the following statement:

```sql
SELECT oe.customers_seq.NEXTVAL
    FROM DUAL;
```

Granting Multiple Object Privileges on Individual Columns: Example  To grant to user oe the REFERENCES privilege on the employee_id column and the UPDATE privilege on the employee_id, salary, and commission_pct columns of the employees table in the schema hr, issue the following statement:

```sql
GRANT REFERENCES (employee_id),
    UPDATE (employee_id, salary, commission_pct)
    ON hr.employees
    TO oe;
```

The user oe can subsequently update values of the employee_id, salary, and commission_pct columns. User oe can also define referential integrity constraints that refer to the employee_id column. However, because the GRANT statement lists only these columns, oe cannot perform operations on any of the other columns of the employees table.

For example, oe can create a table with a constraint:

```sql
CREATE TABLE dependent
    (dependno   NUMBER,
     dependname VARCHAR2(10),
     employee   NUMBER
     CONSTRAINT in_emp REFERENCES hr.employees(employee_id) );
```

The constraint in_emp ensures that all dependents in the dependent table correspond to an employee in the employees table in the schema hr.
**INSERT**

**Purpose**

Use the `INSERT` statement to add rows to a table, the base table of a view, a partition of a partitioned table or a subpartition of a composite-partitioned table, or an object table or the base table of an object view.

**Prerequisites**

For you to insert rows into a table, the table must be in your own schema or you must have the `INSERT` object privilege on the table.

For you to insert rows into the base table of a view, the owner of the schema containing the view must have the `INSERT` object privilege on the base table. Also, if the view is in a schema other than your own, then you must have the `INSERT` object privilege on the view.

If you have the `INSERT ANY TABLE` system privilege, then you can also insert rows into any table or the base table of any view.

You must also have the `READ` or `SELECT` object privilege on the table into which you want to insert rows if the table is on a remote database.

**Conventional and Direct-Path INSERT**

You can use the `INSERT` statement to insert data into a table, partition, or view in two ways: conventional `INSERT` and direct-path `INSERT`. When you issue a conventional `INSERT` statement, Oracle Database reuses free space in the table into which you are inserting and maintains referential integrity constraints. With direct-path `INSERT`, the database appends the inserted data after existing data in the table. Data is written directly into data files, bypassing the buffer cache. Free space in the existing data is not reused. This alternative enhances performance during insert operations and is similar to the functionality of the Oracle direct-path loader utility, SQL*Loader. When you insert into a table that has been created in parallel mode, direct-path `INSERT` is the default.

The manner in which the database generates redo and undo data depends in part on whether you are using conventional or direct-path `INSERT`:

- Conventional `INSERT` always generates maximal redo and undo for changes to both data and metadata, regardless of the logging setting of the table and the archivelog and force logging settings of the database.

- Direct-path `INSERT` generates both redo and undo for metadata changes, because these are needed for operation recovery. For data changes, undo and redo are generated as follows:
  - Direct-path `INSERT` always bypasses undo generation for data changes.
  - If the database is not in `ARCHIVELOG` or `FORCE LOGGING` mode, then no redo is generated for data changes, regardless of the logging setting of the table.
  - If the database is in `ARCHIVELOG` mode (but not in `FORCE LOGGING` mode), then direct-path `INSERT` generates data redo for `LOGGING` tables but not for `NOLOGGING` tables.
  - If the database is in `ARCHIVELOG` and `FORCE LOGGING` mode, then direct-path SQL generate data redo for both `LOGGING` and `NOLOGGING` tables.
Direct-path `INSERT` is subject to a number of restrictions. If any of these restrictions is violated, then Oracle Database executes conventional `INSERT` serially without returning any message, unless otherwise noted:

- You can have multiple direct-path `INSERT` statements in a single transaction, with or without other DML statements. However, after one DML statement alters a particular table, partition, or index, no other DML statement in the transaction can access that table, partition, or index.

- Queries that access the same table, partition, or index are allowed before the direct-path `INSERT` statement, but not after it.

- If any serial or parallel statement attempts to access a table that has already been modified by a direct-path `INSERT` in the same transaction, then the database returns an error and rejects the statement.

- The target table cannot be of a cluster.

- The target table cannot contain object type columns.

- Direct-path `INSERT` is not supported for an index-organized table (IOT) if it has a mapping table, or if it is reference by a materialized view.

- Direct-path `INSERT` into a single partition of an index-organized table (IOT), into a partitioned IOT with only one partition, or into an IOT that is not partitioned, will be done serially, even if the IOT was created in parallel mode or you specify the `APPEND` or `APPEND_VALUES` hint. However, direct-path `INSERT` operations into a partitioned IOT will honor parallel mode as long as the partition-extended name is not used and the IOT has more than one partition.

- The target table cannot have any triggers or referential integrity constraints defined on it.

- The target table cannot be replicated.

- A transaction containing a direct-path `INSERT` statement cannot be or become distributed.

You cannot query or modify direct-path inserted data immediately after the insert is complete. If you attempt to do so, an `ORA-12838` error is generated. You must first issue a `COMMIT` statement before attempting to read or modify the newly-inserted data.

\end{tikzpicture}
Semantics

**hint**
Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

For a multitable insert, if you specify the `PARALLEL` hint for any target table, then the entire multitable insert statement is parallelized even if the target tables have not been created or altered with `PARALLEL` specified. If you do not specify the `PARALLEL` hint, then the insert operation will not be parallelized unless all target tables were created or altered with `PARALLEL` specified.

**See Also:**
- "Hints" on page 2-77 for the syntax and description of hints
- "Restrictions on Multitable Inserts" on page 18-71

**single_table_insert**
In a single-table insert, you insert values into one row of a table, view, or materialized view by specifying values explicitly or by retrieving the values through a subquery.

You can use the `flashback_query_clause` in subquery to insert past data into table. Refer to the `flashback_query_clause` of `SELECT` on page 19-22 for more information on this clause.

**Restriction on Single-table Inserts**  If you retrieve values through a subquery, then the select list of the subquery must have the same number of columns as the column list of the `INSERT` statement. If you omit the column list, then the subquery must provide values for every column in the table.

**See Also:**  "Inserting Values into Tables: Examples" on page 18-74

**insert_into_clause**
Use the `INSERT INTO` clause to specify the target object or objects into which the database is to insert data.

**DML_table_expression_clause**
Use the `INTO DML_table_expression_clause` to specify the objects into which data is being inserted.

**schema**  Specify the schema containing the table, view, or materialized view. If you omit `schema`, then the database assumes the object is in your own schema.

**table | view | materialized_view | subquery**  Specify the name of the table or object table, view or object view, materialized view, or the column or columns returned by a subquery, into which rows are to be inserted. If you specify a view or object view, then the database inserts rows into the base table of the view.

You cannot insert rows into a read-only materialized view. If you insert rows into a writable materialized view, then the database inserts the rows into the underlying container table. However, the insertions are overwritten at the next refresh operation. If you insert rows into an updatable materialized view that is part of a materialized view group, then the database also inserts the corresponding rows into the master table.
If any value to be inserted is a REF to an object table, and if the object table has a primary key object identifier, then the column into which you insert the REF must be a REF column with a referential integrity or SCOPE constraint to the object table.

If table, or the base table of view, contains one or more domain index columns, then this statement executes the appropriate indextype insert routine.

Issuing an INSERT statement against a table fires any INSERT triggers defined on the table.

See Also: Oracle Database Data Cartridge Developer’s Guide for more information on these routines

Restrictions on the DML_table_expression_clause This clause is subject to the following restrictions:

■ You cannot execute this statement if table or the base table of view contains any domain indexes marked IN_PROGRESS or FAILED.

■ You cannot insert into a partition if any affected index partitions are marked UNUSABLE.

■ With regard to the ORDER BY clause of the subquery in the DML_table_expression_clause, ordering is guaranteed only for the rows being inserted, and only within each extent of the table. Ordering of new rows with respect to existing rows is not guaranteed.

■ If a view was created using the WITH CHECK OPTION, then you can insert into the view only rows that satisfy the defining query of the view.

■ If a view was created using a single base table, then you can insert rows into the view and then retrieve those values using the returning_clause.

■ You cannot insert rows into a view except with INSTEAD OF triggers if the defining query of the view contains one of the following constructs:

  - A set operator
  - A DISTINCT operator
  - An aggregate or analytic function
  - A GROUP BY, ORDER BY, MODEL, CONNECT BY, or START WITH clause
  - A collection expression in a SELECT list
  - A subquery in a SELECT list
  - A subquery designated WITH READ ONLY

Joins, with some exceptions, as documented in Oracle Database Administrator’s Guide

■ If you specify an index, index partition, or index subpartition that has been marked UNUSABLE, then the INSERT statement will fail unless the SKIP_UNUSABLE_INDEXES session parameter has been set to TRUE. Refer to ALTER SESSION on page 11-65 for information on the SKIP_UNUSABLE_INDEXES session parameter.

partition_extension_clause Specify the name or partition key value of the partition or subpartition within table, or the base table of view, targeted for inserts.

If a row to be inserted does not map into a specified partition or subpartition, then the database returns an error.

Restriction on Target Partitions and Subpartitions This clause is not valid for object tables or object views.
See Also: "References to Partitioned Tables and Indexes" on page 2-128

dblink Specify a complete or partial name of a database link to a remote database where the table or view is located. You can insert rows into a remote table or view only if you are using Oracle Database distributed functionality.

If you omit dblink, then Oracle Database assumes that the table or view is on the local database.

See Also:
- "Syntax for Schema Objects and Parts in SQL Statements" on page 2-124 and "References to Objects in Remote Databases" on page 2-126 for information on referring to database links
- "Inserting into a Remote Database: Example" on page 18-75

subquery_restriction_clause Use the subquery_restriction_clause to restrict the subquery in one of the following ways:

WITH READ ONLY Specify WITH READ ONLY to indicate that the table or view cannot be updated.

WITH CHECK OPTION Specify WITH CHECK OPTION to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the FROM clause but not in subquery in the WHERE clause.

CONSTRANIT constraint Specify the name of the CHECK OPTION constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form SYS_Cn, where n is an integer that makes the constraint name unique within the database.

See Also: "Using the WITH CHECK OPTION Clause: Example" on page 19-66

table_collection_expression The table_collection_expression lets you inform Oracle that the value of collection_expression should be treated as a table for purposes of query and DML operations. The collection_expression can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray.

This process of extracting the elements of a collection is called collection unnesting.

The optional plus (+) is relevant if you are joining the TABLE collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

Note: In earlier releases of Oracle, when collection_expression was a subquery, table_collection_expression was expressed as THE subquery. That usage is now deprecated.

See Also: "Table Collections: Examples" on page 19-73
**t_alias**

Specify a correlation name, which is an alias for the table, view, materialized view, or subquery to be referenced elsewhere in the statement.

**Restriction on Table Aliases** You cannot specify **t_alias** during a multitable insert.

**column**

Specify a column of the table, view, or materialized view. In the inserted row, each column in this list is assigned a value from the **values_clause** or the subquery. If you want to assign a value to an **INVISIBLE** column, then you must include the column in this list.

If you omit one or more of the table’s columns from this list, then the column value of that column for the inserted row is the column default value as specified when the table was created or last altered. If any omitted column has a **NOT NULL** constraint and no default value, then the database returns an error indicating that the constraint has been violated and rolls back the **INSERT** statement. Refer to **CREATE TABLE** on page 16-6 for more information on default column values.

If you omit the column list altogether, then the **values_clause** or query must specify values for all columns in the table.

**values_clause**

For a **single-table insert** operation, specify a row of values to be inserted into the table or view. You must specify a value in the **values_clause** for each column in the column list. If you omit the column list, then the **values_clause** must provide values for every column in the table.

For a **multitable insert** operation, each expression in the **values_clause** must refer to columns returned by the select list of the subquery. If you omit the **values_clause**, then the select list of the subquery determines the values to be inserted, so it must have the same number of columns as the column list of the corresponding **insert_into_clause**. If you do not specify a column list in the **insert_into_clause**, then the computed row must provide values for all columns in the target table.

For both types of insert operations, if you specify a column list in the **insert_into_clause**, then the database assigns to each column in the list a corresponding value from the values clause or the subquery. You can specify **DEFAULT** for any value in the **values_clause**. If you have specified a default value for the corresponding column of the table or view, then that value is inserted. If no default value for the corresponding column has been specified, then the database inserts null. Refer to "About SQL Expressions" on page 5-1 and **SELECT** on page 19-4 for syntax of valid expressions.

**Restrictions on Inserted Values** The value are subject to the following restrictions:

- You cannot insert a **BFILE** value until you have initialized the **BFILE** locator to null or to a directory name and filename.

**See Also:**

- **BFILENAME** on page 7-31 for information on initializing **BFILE** values and for an example of inserting into a **BFILE**
- **Oracle Database SecureFiles and Large Objects Developer’s Guide** for information on initializing **BFILE** locators
When inserting into a list-partitioned table, you cannot insert a value into the partitioning key column that does not already exist in the `partition_key_value` list of one of the partitions.

You cannot specify `DEFAULT` when inserting into a view.

If you insert string literals into a `RAW` column, then during subsequent queries Oracle Database will perform a full table scan rather than using any index that might exist on the `RAW` column.

**See Also:**

- "Using XML in SQL Statements" on page F-8 for information on inserting values into an XMLType table
- "Inserting into a Substitutable Tables and Columns: Examples" on page 18-75, "Inserting Using the TO_LOB Function: Example" on page 18-75, "Inserting Sequence Values: Example" on page 18-75, and "Inserting Using Bind Variables: Example" on page 18-75

**returning_clause**

The returning clause retrieves the rows affected by a DML statement. You can specify this clause for tables and materialized views and for views with a single base table.

When operating on a single row, a DML statement with a `returning_clause` can retrieve column expressions using the affected row, rowid, and `REFs` to the affected row and store them in host variables or PL/SQL variables.

When operating on multiple rows, a DML statement with the `returning_clause` stores values from expressions, rowids, and `REFs` involving the affected rows in bind arrays.

**expr** Each item in the `expr` list must be a valid expression syntax.

**INTO** The `INTO` clause indicates that the values of the changed rows are to be stored in the variable(s) specified in `data_item` list.

**data_item** Each `data_item` is a host variable or PL/SQL variable that stores the retrieved `expr` value.

For each expression in the `RETURNING` list, you must specify a corresponding type-compatible PL/SQL variable or host variable in the `INTO` list.

**Restrictions** The following restrictions apply to the `RETURNING` clause:

- The `expr` is restricted as follows:
  - For `UPDATE` and `DELETE` statements each `expr` must be a simple expression or a single-set aggregate function expression. You cannot combine simple expressions and single-set aggregate function expressions in the same `returning_clause`. For `INSERT` statements, each `expr` must be a simple expression. Aggregate functions are not supported in an `INSERT` statement `returning_clause`.
  - Single-set aggregate function expressions cannot include the `DISTINCT` keyword.
- If the `expr` list contains a primary key column or other `NOT NULL` column, then the update statement fails if the table has a `BEFORE UPDATE` trigger defined on it.
- You cannot specify the `returning_clause` for a multitable insert.
- You cannot use this clause with parallel DML or with remote objects.
You cannot retrieve LONG types with this clause.

You cannot specify this clause for a view on which an INSTEAD OF trigger has been defined.

**See Also:** Oracle Database PL/SQL Language Reference for information on using the BULK COLLECT clause to return multiple values to collection variables

**multi_table_insert**

In a multitable insert, you insert computed rows derived from the rows returned from the evaluation of a subquery into one or more tables.

Table aliases are not defined by the select list of the subquery. Therefore, they are not visible in the clauses dependent on the select list. For example, this can happen when trying to refer to an object column in an expression. To use an expression with a table alias, you must put the expression into the select list with a column alias, and then refer to the column alias in the VALUES clause or WHEN condition of the multitable insert.

**ALL into_clause**

Specify ALL followed by multiple insert_into_clauses to perform an unconditional multitable insert. Oracle Database executes each insert_into_clause once for each row returned by the subquery.

**conditional_insert_clause**

Specify the conditional_insert_clause to perform a conditional multitable insert. Oracle Database filters each insert_into_clause through the corresponding WHEN condition, which determines whether that insert_into_clause is executed. Each expression in the WHEN condition must refer to columns returned by the select list of the subquery. A single multitable insert statement can contain up to 127 WHEN clauses.

**ALL** If you specify ALL, the default value, then the database evaluates each WHEN clause regardless of the results of the evaluation of any other WHEN clause. For each WHEN clause whose condition evaluates to true, the database executes the corresponding INTO clause list.

**FIRST** If you specify FIRST, then the database evaluates each WHEN clause in the order in which it appears in the statement. For the first WHEN clause that evaluates to true, the database executes the corresponding INTO clause and skips subsequent WHEN clauses for the given row.

**ELSE clause** For a given row, if no WHEN clause evaluates to true, then:

- If you have specified an ELSE clause, then the database executes the INTO clause list associated with the ELSE clause.
- If you did not specify an else clause, then the database takes no action for that row.

**Restrictions on Multitable Inserts** Multitable inserts are subject to the following restrictions:

- You can perform multitable inserts only on tables, not on views or materialized views.
- You cannot perform a multitable insert into a remote table.

**See Also:** "Multitable Inserts: Examples" on page 18-76
You cannot specify a TABLE collection expression when performing a multitable insert.

Multitable inserts are not parallelized if any target table is index organized or if any target table has a bitmap index defined on it.

Plan stability is not supported for multitable insert statements.

You cannot specify a sequence in any part of a multitable insert statement. A multitable insert is considered a single SQL statement. Therefore, the first reference to NEXTVAL generates the next number, and all subsequent references in the statement return the same number.

**subquery**

Specify a subquery that returns rows that are inserted into the table. The subquery can refer to any table, view, or materialized view, including the target tables of the INSERT statement. If the subquery selects no rows, then the database inserts no rows into the table.

You can use subquery in combination with the TO_LOB function to convert the values in a LONG column to LOB values in another column in the same or another table.

To migrate LONG values to LOB values in another column in a view, you must perform the migration on the base table and then add the LOB column to the view.

To migrate LONG values on a remote table to LOB values in a local table, you must perform the migration on the remote table using the TO_LOB function, and then perform an INSERT ... subquery operation to copy the LOB values from the remote table into the local table.

**Notes on Inserting with a Subquery**

The following notes apply when inserting with a subquery:

- If subquery returns the partial or total equivalent of a materialized view, then the database may use the materialized view for query rewrite in place of one or more tables specified in subquery.

  See Also: Oracle Database Data Warehousing Guide for more information on materialized views and query rewrite

- If subquery refers to remote objects, then the INSERT operation can run in parallel as long as the reference does not loop back to an object on the local database. However, if the subquery in the DML_table_expression_clause refers to any remote objects, then the INSERT operation will run serially without notification. See parallel_clause on page 16-81 for more information.

- If subquery includes an ORDER BY clause, then it will override row ordering specified using attribute clustering table properties.

  See Also:

  - "Inserting Values with a Subquery: Example" on page 18-74
  - BFILENAME on page 7-31 for an example of inserting into a BFILE
  - Oracle Database SecureFiles and Large Objects Developer’s Guide for information on initializing BFILES
  - "About SQL Expressions" on page 5-1 and SELECT on page 19-4 for syntax of valid expressions
**error_logging_clause**

The `error_logging_clause` lets you capture DML errors and the log column values of the affected rows and save them in an error logging table.

**INTO table** Specify the name of the error logging table. If you omit this clause, then the database assigns the default name generated by the `DBMS_ERRLOG` package. The default error log table name is `ERR$` followed by the first 25 characters of the name of the table upon which the DML operation is being executed.

**simple_expression** Specify the value to be used as a statement tag, so that you can identify the errors from this statement in the error logging table. The expression can be either a text literal, a number literal, or a general SQL expression such as a bind variable. You can also use a function expression if you convert it to a text literal — for example, `TO_CHAR(SYSDATE)`.

**REJECT LIMIT** This clause lets you specify an integer as an upper limit for the number of errors to be logged before the statement terminates and rolls back any changes made by the statement. The default rejection limit is zero. For parallel DML operations, the reject limit is applied to each parallel server.

**Restrictions on DML Error Logging**

- The following conditions cause the statement to fail and roll back without invoking the error logging capability:
  - Violated deferred constraints.
  - Any direct-path `INSERT` or `MERGE` operation that raises a unique constraint or index violation.
  - Any update operation `UPDATE` or `MERGE` that raises a unique constraint or index violation.
- You cannot track errors in the error logging table for `LONG`, `LOB`, or object type columns. However, the table that is the target of the DML operation can contain these types of columns.
  - If you create or modify the corresponding error logging table so that it contains a column of an unsupported type, and if the name of that column corresponds to an unsupported column in the target DML table, then the DML statement fails at parse time.
  - If the error logging table does not contain any unsupported column types, then all DML errors are logged until the reject limit of errors is reached. For rows on which errors occur, column values with corresponding columns in the error logging table are logged along with the control information.

**See Also:**

- **Oracle Database PL/SQL Packages and Types Reference** for information on using the `create_error_log` procedure of the `DBMS_ERRLOG` package and **Oracle Database Administrator’s Guide** for general information on DML error logging.
- "Inserting Into a Table with Error Logging: Example" on page 18-74
Examples

Inserting Values into Tables: Examples  The following statement inserts a row into the sample table departments:

```
INSERT INTO departments
VALUES (280, 'Recreation', 121, 1700);
```

If the departments table had been created with a default value of 121 for the manager_id column, then you could issue the same statement as follows:

```
INSERT INTO departments
VALUES (280, 'Recreation', DEFAULT, 1700);
```

The following statement inserts a row with six columns into the employees table. One of these columns is assigned NULL and another is assigned a number in scientific notation:

```
INSERT INTO employees (employee_id, last_name, email, hire_date, job_id, salary, commission_pct)
VALUES (207, 'Gregory', 'pgregory@example.com', sysdate, 'PU_CLERK', 1.2E3, NULL);
```

The following statement has the same effect as the preceding example, but uses a subquery in the DML_table_expression_clause:

```
INSERT INTO
(SELECT employee_id, last_name, email, hire_date, job_id, salary, commission_pct FROM employees)
VALUES (207, 'Gregory', 'pgregory@example.com', sysdate, 'PU_CLERK', 1.2E3, NULL);
```

Inserting Values with a Subquery: Example  The following statement copies employees whose commission exceeds 25% of their salary into the bonuses table, which was created in "Merging into a Table: Example" on page 18-85:

```
INSERT INTO bonuses
SELECT employee_id, salary*1.1
FROM employees
WHERE commission_pct > .25;
```

Inserting Into a Table with Error Logging: Example  The following statements create a raises table in the sample schema hr, create an error logging table using the DBMS_ERRLOG package, and populate the raises table with data from the employees table. One of the inserts violates the check constraint on raises, and that row can be seen in errlog. If more than ten errors had occurred, then the statement would have aborted, rolling back any insertions made:

```
CREATE TABLE raises (emp_id NUMBER, sal NUMBER
CONSTRAINT check_sal CHECK(sal > 8000));

EXECUTE DBMS_ERRLOG.CREATE_ERROR_LOG('raises', 'errlog');

INSERT INTO raises
SELECT employee_id, salary*1.1 FROM employees
WHERE commission_pct > .2
LOG ERRORS INTO errlog ('my_bad') REJECT LIMIT 10;

SELECT ORA_ERR_MESG$, ORA_ERR_TAG$, emp_id, sal FROM errlog;
ORA_ERR_MESG$ ORA_ERR_TAG$ EMP_ID SAL
Inserting into a Remote Database: Example The following statement inserts a row into the employees table owned by the user hr on the database accessible by the database link remote:

```sql
INSERT INTO employees@remote
VALUES (8002, 'Juan', 'Fernandez', 'juanf@example.com', NULL,
TO_DATE('04-OCT-1992', 'DD-MON-YYYY'), 'SH_CLERK', 3000,
NULL, 121, 20);
```

Inserting Sequence Values: Example The following statement inserts a new row containing the next value of the departments_seq sequence into the departments table:

```sql
INSERT INTO departments
VALUES (departments_seq.nextval, 'Entertainment', 162, 1400);
```

Inserting Using Bind Variables: Example The following example returns the values of the inserted rows into output bind variables :bnd1 and :bnd2. The bind variables must first be declared.

```sql
INSERT INTO employees
(employee_id, last_name, email, hire_date, job_id, salary)
VALUES (employees_seq.nextval, 'Doe', 'john.doe@example.com',
SYSDATE, 'SH_CLERK', 2400)
RETURNING salary*12, job_id INTO :bnd1, :bnd2;
```

Inserting into a Substitutable Tables and Columns: Examples The following example inserts into the persons table, which is created in “Substitutable Table and Column Examples” on page 16-91. The first statement uses the root type person_t. The second insert uses the employee_t subtype of person_t, and the third insert uses the part_time_emp_t subtype of employee_t:

```sql
INSERT INTO persons VALUES (person_t('Bob', 1234));
INSERT INTO persons VALUES (employee_t('Joe', 32456, 12, 100000));
INSERT INTO persons VALUES (part_time_emp_t('Tim', 5678, 13, 1000, 20));
```

You can extract data from substitutable tables and columns using built-in functions and conditions. For examples, see the functions TREAT on page 7-385 and SYS_TYPEID on page 7-346, and “IS OF type Condition” on page 6-34.

Inserting Using the TO_LOB Function: Example The following example copies LONG data to a LOB column in the following long_tab table:

```sql
```

ORA-02290: check constraint my_bad (HR.SYS_C004266) violated
CREATE TABLE long_tab (pic_id NUMBER, long_pics LONG RAW);

First you must create a table with a LOB.

CREATE TABLE lob_tab (pic_id NUMBER, lob_pics BLOB);

Next, use an INSERT ... SELECT statement to copy the data in all rows for the LONG column into the newly created LOB column:

INSERT INTO lob_tab 
SELECT pic_id, TO_LOB(long_pics) FROM long_tab;

When you are confident that the migration has been successful, you can drop the long_pics table. Alternatively, if the table contains other columns, then you can simply drop the LONG column from the table as follows:

ALTER TABLE long_tab DROP COLUMN long_pics;

Multitable Inserts: Examples  The following example uses the multitable insert syntax to insert into the sample table sh.sales some data from an input table with a different structure.

The input table looks like this:

<table>
<thead>
<tr>
<th>PRODUCT_ID</th>
<th>CUSTOMER_ID</th>
<th>WEEKLY_ST</th>
<th>SALES_SUN</th>
<th>SALES_MON</th>
<th>SALES_TUE</th>
<th>SALES_WED</th>
<th>SALES_THU</th>
<th>SALES_FRI</th>
<th>SALES_SAT</th>
</tr>
</thead>
<tbody>
<tr>
<td>111</td>
<td>222</td>
<td>01-OCT-00</td>
<td>100</td>
<td>200</td>
<td>300</td>
<td>400</td>
<td>500</td>
<td>600</td>
<td>700</td>
</tr>
<tr>
<td>222</td>
<td>333</td>
<td>08-OCT-00</td>
<td>200</td>
<td>300</td>
<td>400</td>
<td>500</td>
<td>600</td>
<td>700</td>
<td>800</td>
</tr>
<tr>
<td>333</td>
<td>444</td>
<td>15-OCT-00</td>
<td>300</td>
<td>400</td>
<td>500</td>
<td>600</td>
<td>700</td>
<td>800</td>
<td>900</td>
</tr>
</tbody>
</table>

The multitable insert statement looks like this:

INSERT ALL 
INTO sales (prod_id, cust_id, time_id, amount) 
VALUES (product_id, customer_id, weekly_start_date, sales_sun) 
INTO sales (prod_id, cust_id, time_id, amount) 
VALUES (product_id, customer_id, weekly_start_date+1, sales_mon) 
INTO sales (prod_id, cust_id, time_id, amount) 
VALUES (product_id, customer_id, weekly_start_date+2, sales_tue) 
INTO sales (prod_id, cust_id, time_id, amount) 
VALUES (product_id, customer_id, weekly_start_date+3, sales_wed) 
INTO sales (prod_id, cust_id, time_id, amount) 
VALUES (product_id, customer_id, weekly_start_date+4, sales_thu) 
INTO sales (prod_id, cust_id, time_id, amount) 
VALUES (product_id, customer_id, weekly_start_date+5, sales_fri) 
INTO sales (prod_id, cust_id, time_id, amount) 
VALUES (product_id, customer_id, weekly_start_date+6, sales_sat) 
SELECT product_id, customer_id, weekly_start_date, sales_sun, 
    sales_mon, sales_tue, sales_wed, sales_thu, sales_fri, sales_sat 
FROM sales_input_table;

Assuming these are the only rows in the sales table, the contents now look like this:

SELECT * FROM sales
```sql
ORDER BY prod_id, cust_id, time_id;

<table>
<thead>
<tr>
<th>PROD_ID</th>
<th>CUST_ID</th>
<th>TIME_ID</th>
<th>C</th>
<th>PROMO_ID</th>
<th>QUANTITY_SOLD</th>
<th>AMOUNT</th>
<th>COST</th>
</tr>
</thead>
<tbody>
<tr>
<td>111</td>
<td>222</td>
<td>01-OCT-00</td>
<td></td>
<td></td>
<td>100</td>
<td></td>
<td></td>
</tr>
<tr>
<td>111</td>
<td>222</td>
<td>02-OCT-00</td>
<td></td>
<td></td>
<td>200</td>
<td></td>
<td></td>
</tr>
<tr>
<td>111</td>
<td>222</td>
<td>03-OCT-00</td>
<td></td>
<td></td>
<td>300</td>
<td></td>
<td></td>
</tr>
<tr>
<td>111</td>
<td>222</td>
<td>04-OCT-00</td>
<td></td>
<td></td>
<td>400</td>
<td></td>
<td></td>
</tr>
<tr>
<td>111</td>
<td>222</td>
<td>05-OCT-00</td>
<td></td>
<td></td>
<td>500</td>
<td></td>
<td></td>
</tr>
<tr>
<td>111</td>
<td>222</td>
<td>06-OCT-00</td>
<td></td>
<td></td>
<td>600</td>
<td></td>
<td></td>
</tr>
<tr>
<td>111</td>
<td>222</td>
<td>07-OCT-00</td>
<td></td>
<td></td>
<td>700</td>
<td></td>
<td></td>
</tr>
<tr>
<td>222</td>
<td>333</td>
<td>08-OCT-00</td>
<td></td>
<td></td>
<td>200</td>
<td></td>
<td></td>
</tr>
<tr>
<td>222</td>
<td>333</td>
<td>09-OCT-00</td>
<td></td>
<td></td>
<td>300</td>
<td></td>
<td></td>
</tr>
<tr>
<td>222</td>
<td>333</td>
<td>10-OCT-00</td>
<td></td>
<td></td>
<td>400</td>
<td></td>
<td></td>
</tr>
<tr>
<td>222</td>
<td>333</td>
<td>11-OCT-00</td>
<td></td>
<td></td>
<td>500</td>
<td></td>
<td></td>
</tr>
<tr>
<td>222</td>
<td>333</td>
<td>12-OCT-00</td>
<td></td>
<td></td>
<td>600</td>
<td></td>
<td></td>
</tr>
<tr>
<td>222</td>
<td>333</td>
<td>13-OCT-00</td>
<td></td>
<td></td>
<td>700</td>
<td></td>
<td></td>
</tr>
<tr>
<td>222</td>
<td>333</td>
<td>14-OCT-00</td>
<td></td>
<td></td>
<td>800</td>
<td></td>
<td></td>
</tr>
<tr>
<td>333</td>
<td>444</td>
<td>15-OCT-00</td>
<td></td>
<td></td>
<td>300</td>
<td></td>
<td></td>
</tr>
<tr>
<td>333</td>
<td>444</td>
<td>16-OCT-00</td>
<td></td>
<td></td>
<td>400</td>
<td></td>
<td></td>
</tr>
<tr>
<td>333</td>
<td>444</td>
<td>17-OCT-00</td>
<td></td>
<td></td>
<td>500</td>
<td></td>
<td></td>
</tr>
<tr>
<td>333</td>
<td>444</td>
<td>18-OCT-00</td>
<td></td>
<td></td>
<td>600</td>
<td></td>
<td></td>
</tr>
<tr>
<td>333</td>
<td>444</td>
<td>19-OCT-00</td>
<td></td>
<td></td>
<td>700</td>
<td></td>
<td></td>
</tr>
<tr>
<td>333</td>
<td>444</td>
<td>20-OCT-00</td>
<td></td>
<td></td>
<td>800</td>
<td></td>
<td></td>
</tr>
<tr>
<td>333</td>
<td>444</td>
<td>21-OCT-00</td>
<td></td>
<td></td>
<td>900</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The next examples insert into multiple tables. Suppose you want to provide to sales representatives some information on orders of various sizes. The following example creates tables for small, medium, large, and special orders and populates those tables with data from the sample table `oe.orders`:

```
CREATE TABLE small_orders
    (order_id       NUMBER(12)   NOT NULL,
    customer_id    NUMBER(6)    NOT NULL,
    order_total    NUMBER(8,2),
    sales_rep_id   NUMBER(6));

CREATE TABLE medium_orders AS SELECT * FROM small_orders;

CREATE TABLE large_orders AS SELECT * FROM small_orders;

CREATE TABLE special_orders
    (order_id       NUMBER(12)    NOT NULL,
    customer_id    NUMBER(6)     NOT NULL,
    order_total    NUMBER(8,2),
    sales_rep_id   NUMBER(6),
    credit_limit   NUMBER(9,2),
    cust_email     VARCHAR2(40));

The first multitable insert populates only the tables for small, medium, and large orders:

```

```sql
INSERT ALL
    WHEN order_total <= 100000 THEN
        INTO small_orders
    WHEN order_total > 100000 AND order_total <= 200000 THEN
        INTO medium_orders
    WHEN order_total > 200000 THEN
        INTO large_orders
```
SELECT order_id, order_total, sales_rep_id, customer_id
FROM orders;

You can accomplish the same thing using the ELSE clause in place of the insert into the large_orders table:

INSERT ALL
WHEN order_total <= 100000 THEN
  INTO small_orders
WHEN order_total > 100000 AND order_total <= 200000 THEN
  INTO medium_orders
ELSE
  INTO large_orders
SELECT order_id, order_total, sales_rep_id, customer_id
FROM orders;

The next example inserts into the small, medium, and large tables, as in the preceding example, and also puts orders greater than 290,000 into the special_orders table. This table also shows how to use column aliases to simplify the statement:

INSERT ALL
WHEN ottl <= 100000 THEN
  INTO small_orders
VALUES(oid, ottl, sid, cid)
WHEN ottl > 100000 and ottl <= 200000 THEN
  INTO medium_orders
VALUES(oid, ottl, sid, cid)
WHEN ottl > 200000 THEN
  INTO large_orders
VALUES(oid, ottl, sid, cid)
WHEN ottl > 290000 THEN
  INTO special_orders
SELECT o.order_id oid, o.customer_id cid, o.order_total ottl,
  o.sales_rep_id sid, c.credit_limit cl, c.cust_email cem
FROM orders o, customers c
WHERE o.customer_id = c.customer_id;

Finally, the next example uses the FIRST clause to put orders greater than 290,000 into the special_orders table and exclude those orders from the large_orders table:

INSERT FIRST
WHEN ottl <= 100000 THEN
  INTO small_orders
VALUES(oid, ottl, sid, cid)
WHEN ottl > 100000 and ottl <= 200000 THEN
  INTO medium_orders
VALUES(oid, ottl, sid, cid)
WHEN ottl > 200000 THEN
  INTO large_orders
VALUES(oid, ottl, sid, cid)
WHEN ottl > 290000 THEN
  INTO special_orders
SELECT o.order_id oid, o.customer_id cid, o.order_total ottl,
  o.sales_rep_id sid, c.credit_limit cl, c.cust_email cem
FROM orders o, customers c
WHERE o.customer_id = c.customer_id;
LOCK TABLE

Purpose

Use the LOCK TABLE statement to lock one or more tables, table partitions, or table subpartitions in a specified mode. This lock manually overrides automatic locking and permits or denies access to a table or view by other users for the duration of your operation.

Some forms of locks can be placed on the same table at the same time. Other locks allow only one lock for a table.

A locked table remains locked until you either commit your transaction or roll it back, either entirely or to a savepoint before you locked the table.

A lock never prevents other users from querying the table. A query never places a lock on a table. Readers never block writers and writers never block readers.

See Also:

- Oracle Database Concepts for a complete description of the interaction of lock modes
- COMMIT on page 13-57
- ROLLBACK on page 18-110
- SAVEPOINT on page 19-2

Prerequisites

The table or view must be in your own schema, or you must have the LOCK ANY TABLE system privilege, or you must have any object privilege (except the READ object privilege) on the table or view.

Syntax

```
lock_table ::=  
```

```
LOCK TABLE schema [table [view] [partition_extension_clause] @dblink ] MODE lockmode IN [NOWAIT | WAIT integer ];
```

SQL Statements: DROP SEQUENCE to ROLLBACK  18-79
**partition_extension_clause::=**

- **PARTITION**
  - **partition**
  - **FOR**
    - **partition_key_value**

- **SUBPARTITION**
  - **subpartition**
  - **FOR**
    - **subpartition_key_value**

### Semantics

**schema**
Specify the schema containing the table or view. If you omit `schema`, then Oracle Database assumes the table or view is in your own schema.

**table / view**
Specify the name of the table or view to be locked.

If you specify `view`, then Oracle Database locks the base tables of the view.

If you specify the `partition_extension_clause`, then Oracle Database first acquires an implicit lock on the table. The table lock is the same as the lock you specify for the partition or subpartition, with two exceptions:

- If you specify a `SHARE` lock for the subpartition, then the database acquires an implicit `ROW SHARE` lock on the table.
- If you specify an `EXCLUSIVE` lock for the subpartition, then the database acquires an implicit `ROW EXCLUSIVE` lock on the table.

If you specify `PARTITION` and `table` is composite-partitioned, then the database acquires locks on all the subpartitions of the partition.

**Restriction on Locking Tables** If `view` is part of a hierarchy, then it must be the root of the hierarchy.

**dblink**
Specify a database link to a remote Oracle Database where the table or view is located. You can lock tables and views on a remote database only if you are using Oracle distributed functionality. All tables locked by a `LOCK TABLE` statement must be on the same database.

If you omit `dblink`, then Oracle Database assumes the table or view is on the local database.

See Also: "References to Objects in Remote Databases" on page 2-126 for information on specifying database links

**lockmode Clause**
Specify one of the following modes:

- **ROW SHARE**  ROW SHARE permits concurrent access to the locked table but prohibits users from locking the entire table for exclusive access. **ROW SHARE** is synonymous with
SHARE UPDATE, which is included for compatibility with earlier versions of Oracle Database.

**ROW EXCLUSIVE** ROW EXCLUSIVE is the same as ROW SHARE, but it also prohibits locking in SHARE mode. ROW EXCLUSIVE locks are automatically obtained when updating, inserting, or deleting.

**SHARE UPDATE** See ROW SHARE on page 18-80.

**SHARE** SHARE permits concurrent queries but prohibits updates to the locked table.

**SHARE ROW EXCLUSIVE** SHARE ROW EXCLUSIVE is used to look at a whole table and to allow others to look at rows in the table but to prohibit others from locking the table in SHARE mode or from updating rows.

**EXCLUSIVE** EXCLUSIVE permits queries on the locked table but prohibits any other activity on it.

**NOWAIT**
Specify NOWAIT if you want the database to return control to you immediately if the specified table, partition, or table subpartition is already locked by another user. In this case, the database returns a message indicating that the table, partition, or subpartition is already locked by another user.

**WAIT**
Use the WAIT clause to indicate that the LOCK TABLE statement should wait up to the specified number of seconds to acquire a DML lock. There is no limit on the value of integer.

If you specify neither NOWAIT nor WAIT, then the database waits indefinitely until the table is available, locks it, and returns control to you. When the database is executing DDL statements concurrently with DML statements, a timeout or deadlock can sometimes result. The database detects such timeouts and deadlocks and returns an error.

**See Also:** Oracle Database Administrator's Guide for more information about locking tables

**Examples**

**Locking a Table: Example** The following statement locks the employees table in exclusive mode but does not wait if another user already has locked the table:

```sql
LOCK TABLE employees
    IN EXCLUSIVE MODE
    NOWAIT;
```

The following statement locks the remote employees table that is accessible through the database link remote:

```sql
LOCK TABLE employees@remote
    IN SHARE MODE;
```
Use the `MERGE` statement to select rows from one or more sources for update or insertion into a table or view. You can specify conditions to determine whether to update or insert into the target table or view.

This statement is a convenient way to combine multiple operations. It lets you avoid multiple `INSERT`, `UPDATE`, and `DELETE` DML statements.

`MERGE` is a deterministic statement. You cannot update the same row of the target table multiple times in the same `MERGE` statement.

**Prerequisites**

You must have the `INSERT` and `UPDATE` object privileges on the target table and the `READ` or `SELECT` object privilege on the source table. To specify the `DELETE` clause of the `merge_update_clause`, you must also have the `DELETE` object privilege on the target table.

**Syntax**

```
merge::=
```

In previous releases of Oracle Database, when you created an Oracle Virtual Private Database policy on an application that included the `MERGE INTO` statement, the `MERGE INTO` statement would be prevented with an `ORA-28132: Merge into syntax does not support security policies` error, due to the presence of the Virtual Private Database policy. Beginning with Oracle Database 11g Release 2 (11.2.0.2), you can create policies on applications that include `MERGE INTO` operations. To do so, in the `DBMS_RLS.ADD_POLICY statement_types` parameter, include the `INSERT`, `UPDATE`, and `DELETE` statements, or just omit the `statement_types` parameter altogether. Refer to Oracle Database Security Guide for more information on enforcing policies on specific SQL statement types.
Note: You must specify at least one of the clauses `merge_update_clause` or `merge_insert_clause`.

```
merge_update_clause ::= 
  WHEN MATCHED THEN UPDATE SET column = expr DEFAULT 
  where_clause 
  DELETE where_clause

merge_insert_clause ::= 
  WHEN NOT MATCHED THEN INSERT (column) VALUES (expr DEFAULT, ... ) where_clause

where_clause ::= 
  WHERE condition

error_logging_clause ::= 
  LOG ERRORS INTO schema.table (simple_expression) 
  REJECT LIMIT integer UNLIMITED
```

Semantics

**INTO Clause**
Use the `INTO` clause to specify the target table or view you are updating or inserting into. In order to merge data into a view, the view must be updatable. Refer to "Notes on Updatable Views" on page 17-23 for more information.
Restriction on Target Views  You cannot specify a target view on which an INSTEAD OF trigger has been defined.

USING Clause
Use the USING clause to specify the source of the data to be updated or inserted. The source can be a table, view, or the result of a subquery.

ON Clause
Use the ON clause to specify the condition upon which the MERGE operation either updates or inserts. For each row in the target table for which the search condition is true, Oracle Database updates the row with corresponding data from the source table. If the condition is not true for any rows, then the database inserts into the target table based on the corresponding source table row.

Restrictions on the ON Clause  In previous releases of Oracle Database, when you created an Oracle Virtual Private Database policy on an application that included the MERGE INTO statement, the MERGE INTO statement would be prevented with an ORA-28132: Merge into syntax does not support security policies error, due to the presence of the Virtual Private Database policy. Beginning with Oracle Database 11g Release 2 (11.2.0.2), you can create policies on applications that include MERGE INTO operations. To do so, in the DBMS_RLS.ADD_POLICY statement_types parameter, include the INSERT, UPDATE, and DELETE statements, or just omit the statement_types parameter altogether. Refer to Oracle Database Security Guide for more information on enforcing policies on specific SQL statement types.

merge_update_clause
The merge_update_clause specifies the new column values of the target table. Oracle performs this update if the condition of the ON clause is true. If the update clause is executed, then all update triggers defined on the target table are activated.

Specify the WHERE clause if you want the database to execute the update operation only if the specified condition is true. The condition can refer to either the data source or the target table. If the condition is not true, then the database skips the update operation when merging the row into the table.

Specify the DELETE WHERE clause to clean up data in a table while populating or updating it. The only rows affected by this clause are those rows in the destination table that are updated by the merge operation. The DELETE WHERE condition evaluates the updated value, not the original value that was evaluated by the UPDATE SET ...
WHERE condition. If a row of the destination table meets the DELETE condition but is not included in the join defined by the ON clause, then it is not deleted. Any delete triggers defined on the target table will be activated for each row deletion.

You can specify this clause by itself or with the merge_insert_clause. If you specify both, then they can be in either order.

Restrictions on the merge_update_clause  This clause is subject to the following restrictions:
- You cannot update a column that is referenced in the ON condition clause.
- You cannot specify DEFAULT when updating a view.

merge_insert_clause
The merge_insert_clause specifies values to insert into the column of the target table if the condition of the ON clause is false. If the insert clause is executed, then all insert
triggers defined on the target table are activated. If you omit the column list after the 
`INSERT` keyword, then the number of columns in the target table must match the 
number of values in the `VALUES` clause.

To insert all of the source rows into the table, you can use a constant filter predicate 
in the `ON` clause condition. An example of a constant filter predicate is `ON (0=1)`. Oracle 
Database recognizes such a predicate and makes an unconditional insert of all source 
rows into the table. This approach is different from omitting the `merge_update_clause`. 
In that case, the database still must perform a join. With constant filter predicate, no 
join is performed.

Specify the `where_clause` if you want Oracle Database to execute the insert operation 
only if the specified condition is true. The condition can refer only to the data source 
table. Oracle Database skips the insert operation for all rows for which the condition is 
not true.

You can specify this clause by itself or with the `merge_update_clause`. If you specify 
both, then they can be in either order.

**Restriction on the merge_insert_clause**  You cannot specify `DEFAULT` when inserting 
into a view.

**error_logging_clause**

The `error_logging_clause` has the same behavior in a `MERGE` statement as in an `INSERT` 
statement. Refer to the `INSERT` statement `error_logging_clause` on page 18-73 for more 
information.

**Examples**

**Merging into a Table: Example**  The following example uses the `bonuses` table in the 
sample schema `oe` with a default bonus of 100. It then inserts into the `bonuses` table all 
employees who made sales, based on the `sales_rep_id` column of the `oe.orders` 
table. Finally, the human resources manager decides that employees with a salary of 
$8000 or less should receive a bonus. Those who have not made sales get a bonus of 
1% of their salary. Those who already made sales get an increase in their bonus equal 
to 1% of their salary. The `MERGE` statement implements these changes in one step:

```sql
CREATE TABLE bonuses (employee_id NUMBER, bonus NUMBER DEFAULT 100);

INSERT INTO bonuses(employee_id)
VALUES (SELECT e.employee_id FROM employees e, orders o
WHERE e.employee_id = o.sales_rep_id
GROUP BY e.employee_id);

SELECT * FROM bonuses ORDER BY employee_id;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>BONUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>153</td>
<td>100</td>
</tr>
<tr>
<td>154</td>
<td>100</td>
</tr>
<tr>
<td>155</td>
<td>100</td>
</tr>
<tr>
<td>156</td>
<td>100</td>
</tr>
<tr>
<td>158</td>
<td>100</td>
</tr>
<tr>
<td>159</td>
<td>100</td>
</tr>
<tr>
<td>160</td>
<td>100</td>
</tr>
</tbody>
</table>

**See Also:**  "Inserting Into a Table with Error Logging: Example" on page 18-74
MERGE INTO bonuses D
USING (SELECT employee_id, salary, department_id FROM employees
WHERE department_id = 80) S
ON (D.employee_id = S.employee_id)
WHEN MATCHED THEN UPDATE SET D.bonus = D.bonus + S.salary*.01
DELETE WHERE (S.salary > 8000)
WHEN NOT MATCHED THEN INSERT (D.employee_id, D.bonus)
VALUES (S.employee_id, S.salary*.01)
WHERE (S.salary <= 8000);

SELECT * FROM bonuses ORDER BY employee_id;

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>BONUS</th>
</tr>

NOAUDIT (Traditional Auditing)

This section describes the NOAUDIT statement for traditional auditing, which is the same auditing functionality used in releases earlier than Oracle Database 12c.

Beginning with Oracle Database 12c, Oracle introduces unified auditing, which provides a full set of enhanced auditing features. For backward compatibility, traditional auditing is still supported. However, Oracle recommends that you plan the migration of your existing audit settings to the new unified audit policy syntax. For new audit requirements, Oracle recommends that you use the new unified auditing. Traditional auditing may be desupported in a future major release.

See Also: NOAUDIT (Unified Auditing) on page 18-92 for a description of the NOAUDIT statement for unified auditing

Purpose

Use the NOAUDIT statement to stop auditing operations previously enabled by the AUDIT statement.

The NOAUDIT statement must have the same syntax as the previous AUDIT statement. Further, it reverses the effects only of that particular statement. For example, suppose one AUDIT statement A enables auditing for a specific user. A second statement B enables auditing for all users. A NOAUDIT statement C to disable auditing for all users reverses statement B. However, statement C leaves statement A in effect and continues to audit the user that statement A specified.

See Also: AUDIT (Traditional Auditing) on page 13-31

Prerequisites

To stop auditing of SQL statements, you must have the AUDIT SYSTEM system privilege.

To stop auditing of schema objects, you must be the owner of the object on which you stop auditing or you must have the AUDIT ANY system privilege. In addition, if the object you chose for auditing is a directory, then even if you created it, you must have the AUDIT ANY system privilege.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root and you must have the commonly granted AUDIT SYSTEM privilege in order to stop auditing for the issuances of a SQL statement, or the commonly granted AUDIT ANY privilege in order to stop auditing for the operations on a schema object. To specify CONTAINER = CURRENT, the current container must be a pluggable database (PDB) and you must have the locally granted AUDIT SYSTEM privilege in order to stop auditing the issuances of a SQL statement, or the locally granted AUDIT ANY privilege in order to stop auditing operations on a schema object.
Syntax

```plaintext
noaudit::=

audit_operation_clause

auditing_by_clause

audit_schema_object_clause

WHENEVER NOT SUCCESSFUL

CONTAINER = CURRENT ALL
```

(audit_operation_clause::= on page 18-88, auditing_by_clause::= on page 18-88, audit_schema_object_clause::= on page 18-88)

```plaintext
audit_operation_clause::=

sql_statement_shortcut

ALL

ALL STATEMENTS

system_privilege

ALL PRIVILEGES
```

```plaintext
auditing_by_clause::=

BY user
```

```plaintext
audit_schema_object_clause::=

sql_operation

ALL auditing_on_clause
```
**NOAUDIT (Traditional Auditing)**

**auditing_on_clause::=**

```
+----------------+-----------------+
| schema          |
| object          |
| directory_name  |
| model           |
| schema          |
| model           |
+----------------+-----------------+
```

**Semantics**

**audit_operation_clause**

Use the audit_operation_clause to stop auditing of a particular SQL statement.

**statement_option** For sql_statement_shortcut, specify the shortcut for the SQL statements for which auditing is to be stopped. Refer to Table 13–1 on page 13-38 and Table 13–2 on page 13-40 for a list of the SQL statement shortcuts and the SQL statements they audit.

**ALL** Specify ALL to stop auditing of all statement options currently being audited because of an earlier AUDIT ALL ... statement. You cannot use this clause to reverse an earlier AUDIT ALL STATEMENTS ... statement.

**ALL STATEMENTS** Specify ALL STATEMENTS to reverse an earlier AUDIT ALL STATEMENTS ... statement. You cannot use this clause to reverse an earlier AUDIT ALL ... statement.

**system_privilege** For system privilege, specify the system privilege for which auditing is to be stopped. Refer to Table 18–1 on page 18-44 for a list of the system privileges and the statements they authorize.

**ALL PRIVILEGES** Specify ALL PRIVILEGES to stop auditing of all system privileges currently being audited.

**auditing_byClause**

Use the auditing_by_clause to stop auditing only for SQL statements issued by the specified users in their subsequent sessions. If you omit this clause, then Oracle Database stops auditing for all users’ statements, except for the situation described for WHENEVER SUCCESSFUL.

**audit_schema_object_clause**

Use the audit_schema_object_clause to stop auditing of a particular database object.

**sql_operation** For sql_operation, specify the type of operation for which auditing is to be stopped on the object specified in the ON clause. Refer to Table 13–3 on page 13-41 for a list of these options.

**ALL** Specify ALL as a shortcut equivalent to specifying all SQL operations applicable for the type of object.
**auditing_on_clause**  The *auditing_on_clause* lets you specify the particular schema object for which auditing is to be stopped.

- For object, specify the object name of a table, view, sequence, stored procedure, function, or package, materialized view, or library. If you do not qualify `object` with `schema`, then Oracle Database assumes the object is in your own schema. Refer to **AUDIT (Traditional Auditing)** on page 13-31 for information on auditing specific schema objects.

- The `DIRECTORY` clause lets you specify the name of the directory on which auditing is to be stopped.

- The `SQL TRANSLATION PROFILE` clause lets you specify the SQL translation profile on which auditing is to be stopped.

- Specify `DEFAULT` to remove the specified object options as default object options for subsequently created objects.

**NETWORK**  Use this clause to discontinue auditing of database link usage and logins.

**DIRECT_PATH LOAD**  Use this clause to discontinue auditing of SQL*Loader direct path loads.

**WHENEVER [NOT] SUCCESSFUL**
Specify `WHENEVER SUCCESSFUL` to stop auditing only for SQL statements and operations on schema objects that complete successfully.

Specify `WHENEVER NOT SUCCESSFUL` to stop auditing only for SQL statements and operations that result in Oracle Database errors.

If you omit this clause, then the database stops auditing for all statements or operations, regardless of success or failure.

**CONTAINER Clause**
Use the `CONTAINER` clause to specify the scope of the `NOAUDIT` command.

- Specify `CONTAINER = CURRENT` to stop auditing in the PDB to which you are connected. If you specify the `auditing_by_clause`, then `user` must be a common user or local user in the current PDB. If you specify the `auditing_on_clause`, then the objects must be local objects in the current PDB.

- Specify `CONTAINER = ALL` to stop auditing across the entire CDB. If you specify the `auditing_by_clause`, then `user` must be a common user. If you do not specify the `auditing_by_clause`, then auditing is stopped for all common users and all local users in each PDB. If you specify the `auditing_on_clause`, then the objects must be common objects.

If you omit this clause, then `CONTAINER = CURRENT` is the default.

**Examples**

**Stop Auditing of SQL Statements Related to Roles: Example**  If you have chosen auditing for every SQL statement that creates or drops a role, then you can stop auditing of such statements by issuing the following statement:

```
NOAUDIT ROLE;
```
Stop Auditing of Updates or Queries on Objects Owned by a Particular User:
Example If you have chosen auditing for any statement that queries or updates any table issued by the users hr and oe, then you can stop auditing for queries by hr by issuing the following statement:

NOAUDIT SELECT TABLE BY hr;

The preceding statement stops auditing only queries by hr, so the database continues to audit queries and updates by oe as well as updates by hr.

Stop Auditing of Statements Authorized by a Particular Object Privilege: Example
To stop auditing on all statements that are authorized by DELETE ANY TABLE system privilege, issue the following statement:

NOAUDIT DELETE ANY TABLE;

Stop Auditing of Queries on a Particular Object: Example If you have chosen auditing for every SQL statement that queries the employees table in the schema hr, then you can stop auditing for such queries by issuing the following statement:

NOAUDIT SELECT
   ON hr.employees;

Stop Auditing of Queries that Complete Successfully: Example You can stop auditing for queries that complete successfully by issuing the following statement:

NOAUDIT SELECT
   ON hr.employees
   WHENEVER SUCCESSFUL;

This statement stops auditing only for successful queries. Oracle Database continues to audit queries resulting in Oracle Database errors.
This section describes the NOAUDIT statement for unified auditing. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to Oracle Database Security Guide for more information on unified auditing.

Purpose

Use the NOAUDIT statement to:

- Disable a unified audit policy for all users or for specified users
- Exclude the values of context attributes from audit records

Operations performed with this statement take effect in subsequent user sessions, not in the current session.

See Also:

- AUDIT (Unified Auditing) on page 13-45
- CREATE AUDIT POLICY (Unified Auditing) on page 14-2
- ALTER AUDIT POLICY (Unified Auditing) on page 10-24
- DROP AUDIT POLICY (Unified Auditing) on page 17-38

Prerequisites

You must have the AUDIT SYSTEM system privilege or the AUDIT_ADMIN role.

If you are connected to a multitenant container database (CDB), then to disable a common unified audit policy, the current container must be the root and you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role. To disable a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT_ADMIN local role in the container.

To specify the NOAUDIT CONTEXT ... statement when connected to a CDB, you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT_ADMIN local role in the current session’s container.

Syntax

unified_noaudit::=

```sql
NOAUDIT
```
**Semantics**

*policy*

Specify the name of the unified audit policy you want to disable.

You can find descriptions of all unified audit policies by querying the `AUDIT_UNIFIED_POLICIES` view and descriptions of all enabled unified audit policies by querying the `AUDIT_UNIFIED_ENABLED_POLICIES` view.

**See Also:** Oracle Database Reference for more information on the `AUDIT_UNIFIED_POLICIES` and `AUDIT_UNIFIED_ENABLED_POLICIES` views

**CONTEXT Clause**

Specify the `CONTEXT` clause to exclude the values of context attributes in audit records.

- For *namespace*, specify the context namespace.
- For *attribute*, specify one or more context attributes whose values you want to exclude from audit records.

If you specify the `CONTEXT` clause when the current container is the root of a CDB, then the values of context attributes will be included in audit records only for events executed in the root. If you specify the optional `BY` clause, then *user* must be a common user.

If you specify the `CONTEXT` clause when the current container is a pluggable database (PDB), then the values of context attributes will be included in audit records only for events executed in that PDB. If you specify the optional `BY` clause, then *user* must be a common user or a local user in that PDB.

You can find the application context attributes that are configured to be captured in the audit trail by querying the `AUDIT_UNIFIED_CONTEXTS` view.

**See Also:** Oracle Database Reference for more information on the `AUDIT_UNIFIED_CONTEXTS` view

**BY**

You can specify the `BY` clause for the `NOAUDIT POLICY` and `NOAUDIT CONTEXT` statements.

**NOAUDIT POLICY ... BY**  The behavior of the `BY` clause depends on whether *policy* is enabled for all users or specific users.

- If *policy* is enabled for all users, then you can disable *policy* for all users by omitting the `BY` clause. If you specify the `BY` clause, then the `NOAUDIT POLICY` statement will have no effect.

- If *policy* is enabled for one or more users (using the `AUDIT POLICY ... BY ...` statement), then you can:
  - Disable *policy* for one or more of those users by specifying the `BY` clause followed by the users for whom you want *policy* disabled
  - Completely disable *policy* by specifying the `BY` clause followed by all of the users for whom *policy* is enabled

If you do not specify the `BY` clause, then the `NOAUDIT POLICY` statement will have no effect.
If policy is enabled for all users except specific users (using the AUDIT POLICY ... EXCEPT ... statement), then you can disable policy for all users by omitting the BY clause. If you specify the BY clause, then the NOAUDIT POLICY statement will have no effect.

If policy is a common unified audit policy, then user must be a common user. If policy is a local unified audit policy, then user must be a common user or a local user in the container to which you are connected.

NOAUDIT CONTEXT ... BY The behavior of the BY clause depends on whether attribute is configured to be included in audit records for all users or specific users.

If attribute is configured to be included in audit records for all users, then you can exclude attribute from audit records for all users by omitting the BY clause. If you specify the BY clause, then the NOAUDIT CONTEXT statement will have no effect.

If attribute is configured to be included in audit records for specific users, then you can exclude attribute for one or more of those users by specifying the BY clause followed by the users for whom you want attribute excluded. If you do not specify the BY clause, then the NOAUDIT CONTEXT statement will have no effect.

Examples

The following examples disable unified audit policies that were created in the CREATE AUDIT POLICY "Examples" on page 14-8 and enabled in the AUDIT "Examples" on page 13-48.

Disabling a Unified Audit Policy for All Users: Example Assume that unified audit policy table_pol is enabled for all users. The following statement disables table_pol for all users:

NOAUDIT POLICY table_pol;

The following statement returns no rows, which verifies that table_pol is disabled for all users:

SELECT *
FROM audit_unified_enabled_policies
WHERE policy_name = 'TABLE_POL';

Disabling a Unified Audit Policy for Specific Users: Example Assume that unified audit policy dml_pol is enabled for users hr and sh, as shown by the following query:

SELECT policy_name, enabled_opt, user_name
FROM audit_unified_enabled_policies
WHERE policy_name = 'DML_POL'
ORDER BY user_name;

<table>
<thead>
<tr>
<th>POLICY_NAME</th>
<th>ENABLED_OPT</th>
<th>USER_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>DML_POL</td>
<td>BY</td>
<td>HR</td>
</tr>
<tr>
<td>DML_POL</td>
<td>BY</td>
<td>SH</td>
</tr>
</tbody>
</table>

The following statement disables dml_pol for user hr:

NOAUDIT POLICY dml_pol BY hr;

The following statement verifies that dml_pol is now enabled for only user sh:

SELECT policy_name, enabled_opt, user_name
FROM audit_unified_enabled_policies
WHERE policy_name = 'DML_POL';

<table>
<thead>
<tr>
<th>POLICY_NAME</th>
<th>ENABLED_OPT</th>
<th>USER_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>DML_POL</td>
<td>BY</td>
<td>SH</td>
</tr>
</tbody>
</table>

The following statement disables dml_pol for user sh:

NOAUDIT POLICY dml_pol BY sh;

The following statement returns no rows, which verifies that dml_pol is disabled for all users:

SELECT *
    FROM audit_unified_enabled_policies
    WHERE policy_name = 'DML_POL';

Excluding Values of Context Attributes in Audit Records: Example

The following statement instructs the database to exclude the values of namespace USERENV attributes CURRENT_USER and DB_NAME from all audit records for user hr:

NOAUDIT CONTEXT NAMESPACE userenv
    ATTRIBUTES current_user, db_name
    BY hr;
PURGE

Purpose

Use the PURGE statement to remove a table or index from your recycle bin and release all of the space associated with the object, or to remove the entire recycle bin, or to remove part of all of a dropped tablespace from the recycle bin.

Caution: You cannot roll back a PURGE statement, nor can you recover an object after it is purged.

To see the contents of your recycle bin, query the USER_RECYCLEBIN data dictionary view. You can use the RECYCLEBIN synonym instead. The following two statements return the same rows:

```sql
SELECT * FROM RECYCLEBIN;
SELECT * FROM USER_RECYCLEBIN;
```

See Also:

- Oracle Database Administrator’s Guide for information on the recycle bin and naming conventions for objects in the recycle bin
- FLASHBACK TABLE on page 18-29 for information on retrieving dropped tables from the recycle bin
- Oracle Database Reference for information on using the RECYCLEBIN initialization parameter to control whether dropped tables go into the recycle bin

Prerequisites

The database object must reside in your own schema or you must have the DROP ANY ... system privilege for the type of object to be purged, or you must have the SYSDBA system privilege. To perform the PURGE DBA_RECYCLEBIN operation, you must have the SYSDBA or PURGE DBA_RECYCLEBIN system privilege.

Syntax

```
purge::=
```

![Diagram](image.png)
Semantics

TABLE or INDEX
Specify the name of the table or index in the recycle bin that you want to purge. You can specify either the original user-specified name or the system-generated name Oracle Database assigned to the object when it was dropped.

- If you specify the user-specified name, and if the recycle bin contains more than one object of that name, then the database purges the object that has been in the recycle bin the longest.
- System-generated recycle bin object names are unique. Therefore, if you specify the system-generated name, then the database purges that specified object.

When the database purges a table, all table partitions, LOBs and LOB partitions, indexes, and other dependent objects of that table are also purged.

RECYCLEBIN
Use this clause to purge the current user's recycle bin. Oracle Database will remove all objects from the user's recycle bin and release all space associated with objects in the recycle bin.

DBA_RECYCLEBIN
This clause is valid only if you have the SYSDBA or PURGE DBA_RECYCLEBIN system privilege. It lets you remove all objects from the system-wide recycle bin, and is equivalent to purging the recycle bin of every user. This operation is useful, for example, before backward migration.

TABLESPACE tablespace
Use this clause to purge all the objects residing in the specified tablespace from the recycle bin.

USER user
Use this clause to reclaim space in a tablespace for a specified user. This operation is useful when a particular user is running low on disk quota for the specified tablespace.

Examples

Remove a File From Your Recycle Bin: Example
The following statement removes the table test from the recycle bin. If more than one version of test resides in the recycle bin, then Oracle Database removes the version that has been there the longest:

```
PURGE TABLE test;
```

To determine system-generated name of the table you want removed from your recycle bin, issue a SELECT statement on your recycle bin. Using that object name, you can remove the table by issuing a statement similar to the following statement. (The system-generated name will differ from the one shown in the example.)

```
PURGE TABLE RB$33750$TABLE$0;
```

Remove the Contents of Your Recycle Bin: Example
To remove the entire contents of your recycle bin, issue the following statement:

```
PURGE RECYCLEBIN;
```
RENAME

Purpose

Caution: You cannot roll back a RENAME statement.

Use the RENAME statement to rename a table, view, sequence, or private synonym.

- Oracle Database automatically transfers integrity constraints, indexes, and grants on the old object to the new object.
- Oracle Database invalidates all objects that depend on the renamed object, such as views, synonyms, and stored procedures and functions that refer to a renamed table.

See Also: CREATE SYNONYM on page 16-2 and DROP SYNONYM on page 18-3

Prerequisites

The object must be in your own schema.

Syntax

\[
\text{rename ::= RENAME (old_name) TO new_name ;}
\]

Semantics

old_name
Specify the name of an existing table, view, sequence, or private synonym.

new_name
Specify the new name to be given to the existing object. The new name must not already be used by another schema object in the same namespace and must follow the rules for naming schema objects.

Restrictions on Renaming Objects
Renaming objects is subject to the following restrictions:

- You cannot rename a public synonym. Instead, drop the public synonym and then re-create the public synonym with the new name.
- You cannot rename a type synonym that has any dependent tables or dependent valid user-defined object types.

See Also: "Database Object Naming Rules" on page 2-119
Examples

**Renaming a Database Object: Example**  The following example uses a copy of the sample table `hr.departments`. To change the name of table `departments_new` to `emp_departments`, issue the following statement:

```
RENAME departments_new TO emp_departments;
```

You cannot use this statement directly to rename columns. However, you can rename a column using the `ALTER TABLE ... rename_column_clause`.

**See Also:** `rename_column_clause` on page 12-68

Another way to rename a column is to use the `RENAME` statement together with the `CREATE TABLE` statement with `AS subquery`. This method is useful if you are changing the structure of a table rather than only renaming a column. The following statements re-create the sample table `hr.job_history`, renaming a column from `department_id` to `dept_id`:

```
CREATE TABLE temporary
  (employee_id, start_date, end_date, job_id, dept_id)
AS SELECT
  employee_id, start_date, end_date, job_id, department_id
FROM job_history;

DROP TABLE job_history;

RENAME temporary TO job_history;
```

Any integrity constraints defined on table `job_history` will be lost in the preceding example. You will have to redefine them on the new `job_history` table using an `ALTER TABLE` statement.
REVOKE

Purpose

Use the REVOKE statement to:

- Revoke system privileges from users and roles
- Revoke roles from users, roles, and program units.
- Revoke object privileges for a particular object from users and roles

**Note on Oracle Automatic Storage Management**  A user authenticated as SYSASM can use this statement to revoke the system privileges SYSASM, SYSOPER, and SYSDBA from a user in the Oracle ASM password file of the current node.

**Note on Editionable Objects**  A REVOKE operation to revoke object privileges on an editionable object actualizes the object in the current edition. See *Oracle Database Development Guide* for more information about editions and editionable objects.

See Also:

- GRANT on page 18-35 for information on granting system privileges and roles
- Table 18–2 on page 18-55 for a listing of the object privileges for each type of object

Prerequisites

To revoke a **system privilege**, you must have been granted the privilege with the **ADMIN OPTION**. You can revoke any privilege if you have the **GRANT ANY PRIVILEGE** system privilege.

To revoke a **role from a user or another role**, you must have been directly granted the role with the **ADMIN OPTION** or you must have created the role. You can revoke any role if you have the **GRANT ANY ROLE** system privilege.

To revoke a **role from a program unit**, you must be the user **SYS** or you must be the schema owner of the program unit.

To revoke an **object privilege**, one of the following conditions must be met:

- You must previously have granted the object privilege to the user or role.
- You must have the **GRANT ANY OBJECT PRIVILEGE** system privilege. In this case, you can revoke any object privilege that was granted by the object owner or on behalf of the owner by a user with the **GRANT ANY OBJECT PRIVILEGE**. However, you cannot revoke an object privilege that was granted by way of a **WITH GRANT OPTION** grant.

See Also:  "Revoke Operations that Use GRANT ANY OBJECT PRIVILEGE: Example" on page 18-109

The REVOKE statement can revoke only privileges and roles that were previously granted directly with a **GRANT** statement. You cannot use this statement to revoke:

- Privileges or roles not granted to the revokee
- Roles or object privileges granted through the operating system
Privileges or roles granted to the revokee through roles

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root.

**Syntax**

`revoke ::=`

```plaintext
revoke_system_privileges ::= (revokee_clause::= on page 18-101, revoke_object_privileges ::= on page 18-101, revoke_roles_from_programs ::= on page 18-102)
```

`revoke_object_privileges ::=`

```plaintext
object_privilege ::= (on_object_clause::= on page 18-102, revokee_clause::= on page 18-101)  
```

`revokee_clause ::=`

```plaintext
user role PUBLIC
```

(revokee_clause ::= on page 18-101)
on_object_clause::=

revoke_roles_from_programs::=

program_unit::=

Semantics

revoke_system_privileges
Use these clauses to revoke system privileges.

system_privilege
Specify the system privilege to be revoked. Refer to Table 18–1 on page 18-44 for a list of the system privileges.

If you revoke a system privilege from a user, then the database removes the privilege from the user's privilege domain. Effective immediately, the user cannot exercise the privilege.

If you revoke a system privilege from a role, then the database removes the privilege from the privilege domain of the role. Effective immediately, users with the role enabled cannot exercise the privilege. Also, other users who have been granted the role and subsequently enable the role cannot exercise the privilege.
If you revoke a system privilege from **PUBLIC**, then the database removes the privilege from the privilege domain of each user who has been granted the privilege through **PUBLIC**. Effective immediately, such users can no longer exercise the privilege. However, the privilege is not revoked from users who have been granted the privilege directly or through roles.

Oracle Database provides a shortcut for specifying all system privileges at once: Specify **ALL PRIVILEGES** to revoke all the system privileges listed in Table 18–1 on page 18-44.

**Restriction on Revoking System Privileges**  A system privilege cannot appear more than once in the list of privileges to be revoked.

**role**  Specify the role to be revoked.

If you revoke a role from a **user**, then the database makes the role unavailable to the user. If the role is currently enabled for the user, then the user can continue to exercise the privileges in the role’s privilege domain as long as it remains enabled. However, the user cannot subsequently enable the role.

If you revoke a role from another **role**, then the database removes the privilege domain of the revoked role from the privilege domain of the revokee role. Users who have been granted and have enabled the revokee role can continue to exercise the privileges in the privilege domain of the revoked role as long as the revokee role remains enabled. However, other users who have been granted the revokee role and subsequently enable it cannot exercise the privileges in the privilege domain of the revoked role.

See Also:  "Revoking a Role from a User: Example" on page 18-107 and "Revoking a Role from a Role: Example" on page 18-107

If you revoke a role from **PUBLIC**, then the database makes the role unavailable to all users who have been granted the role through **PUBLIC**. Any user who has enabled the role can continue to exercise the privileges in its privilege domain as long as it remains enabled. However, users cannot subsequently enable the role. The role is not revoked from users who have been granted the role directly or through other roles.

**Restriction on Revoking System Roles**  A system role cannot appear more than once in the list of roles to be revoked. For information on the predefined roles, refer to *Oracle Database Security Guide*.

**revokee_clause**  Use the **revokee_clause** to specify the users or roles from which the system privilege, role, or object privilege is to be revoked.

**PUBLIC**  Specify **PUBLIC** to revoke the privileges or roles from all users.

**revoke_object_privileges**  Use these clauses to revoke object privileges.
**object_privilege**
 Specify the object privilege to be revoked. The object privileges, categorized by the type of object to which they apply, are described in Table 18–2.

---

**Note:** Each privilege authorizes some operation. By revoking a privilege, you prevent the revokee from performing that operation. However, multiple users may grant the same privilege to the same user, role, or PUBLIC. To remove the privilege from the grantee’s privilege domain, all grantors must revoke the privilege. If even one grantor does not revoke the privilege, then the grantee can still exercise the privilege by virtue of that grant.

---

If you revoke an object privilege from a **user**, then the database removes the privilege from the user’s privilege domain. Effective immediately, the user cannot exercise the privilege.

- If that user has granted that privilege to other users or roles, then the database also revokes the privilege from those other users or roles.
- If that user’s schema contains a procedure, function, or package that contains SQL statements that exercise the privilege, then the procedure, function, or package can no longer be executed.
- If that user’s schema contains a view on that object, then the database invalidates the view.
- If you revoke the **REFERENCES** object privilege from a user who has exercised the privilege to define referential integrity constraints, then you must specify the **CASCADE CONSTRAINTS** clause.

If you revoke an object privilege from a **role**, then the database removes the privilege from the privilege domain of the role. Effective immediately, users with the role enabled cannot exercise the privilege. Other users who have been granted the role cannot exercise the privilege after enabling the role.

If you revoke an object privilege from **PUBLIC**, then the database removes the privilege from the privilege domain of each user who has been granted the privilege through PUBLIC. Effective immediately, all such users are restricted from exercising the privilege. However, the privilege is not revoked from users who have been granted the privilege directly or through roles.

**ALL [PRIVILEGES]**
 Specify **ALL** to revoke all object privileges that you have granted to the revokee. (The keyword **PRIVILEGES** is provided for semantic clarity and is optional.)

If no privileges have been granted on the object, then the database takes no action and does not return an error.

**Restriction on Revoking Object Privileges** A privilege cannot appear more than once in the list of privileges to be revoked. A user, a role, or PUBLIC cannot appear more than once in the **FROM** clause.

**See Also:** "Revoking an Object Privilege from a User: Example" on page 18-107, "Revoking Object Privileges from PUBLIC: Example" on page 18-107, and "Revoking All Object Privileges from a User: Example" on page 18-107

---

18-104  Oracle Database SQL Language Reference
CASCADE CONSTRAINTS
This clause is relevant only if you revoke the REFERENCES privilege or ALL [PRIVILEGES]. It drops any referential integrity constraints that the revokee has defined using the REFERENCES privilege, which might have been granted either explicitly or implicitly through a grant of ALL [PRIVILEGES].

See Also: "Revoking an Object Privilege with CASCADE CONSTRAINTS: Example" on page 18-108

FORCE
Specify FORCE to revoke the EXECUTE object privilege on user-defined type objects with table or type dependencies. You must use FORCE to revoke the EXECUTE object privilege on user-defined type objects with table dependencies.

If you specify FORCE, then all privileges are revoked, all dependent objects are marked INVALID, data in dependent tables becomes inaccessible, and all dependent function-based indexes are marked UNUSABLE. Regranting the necessary type privilege will revalidate the table.

See Also: Oracle Database Concepts for detailed information about type dependencies and user-defined object privileges

on_object_clause
The on_object_clause identifies the objects on which privileges are to be revoked.

object Specify the object on which the object privileges are to be revoked. This object can be:
- A table, view, sequence, procedure, stored function, package, or materialized view
- A synonym for a table, view, sequence, procedure, stored function, package, materialized view, or user-defined type
- A library, indextype, or user-defined operator

If you do not qualify object with schema, then the database assumes the object is in your own schema.

See Also: "Revoking an Object Privilege on a Sequence from a User: Example" on page 18-108

If you revoke the READ or SELECT object privilege on the containing table or materialized view of a materialized view, whether the privilege was granted with or without the GRANT OPTION, then the database invalidates the materialized view.

If you revoke the READ or SELECT object privilege on any of the master tables of a materialized view, whether the privilege was granted with or without the GRANT OPTION, then the database invalidates both the materialized view and its containing table or materialized view.

ON USER Specify one or more database users on whom privileges are to be revoked.

See Also: "Revoking an Object Privilege on a User from a User: Example" on page 18-108

ON DIRECTORY Specify the name of the directory object on which privileges are to be revoked. You cannot qualify directory_name with a schema name.
See Also:  CREATE DIRECTORY on page 14-54 and "Revoking an Object Privilege on a Directory from a User: Example" on page 18-109

ON EDITION Specify the name of the edition on which the USE object privilege is to be revoked. You cannot qualify edition_name with a schema name.

ON MINING MODEL Specify the name of the mining model on which privileges are to be revoked. If you do not qualify mining_model_name with schema, then the database assumes that the mining model is in your own schema.

ON JAVA SOURCE | RESOURCE Specify the name of the Java source or resource schema object on which privileges are to be revoked. If you do not qualify object with schema, then the database assumes that the object is in your own schema.

ON SQL TRANSLATION PROFILE Specify the name of the SQL translation profile on which privileges are to be revoked. If you do not qualify profile with schema, then the database assumes the profile is in your own schema.

revoke_roles_from_programs
Use this clause to revoke code based access control (CBAC) roles from program units.

role
Specify the role you want to revoke.

ALL
Specify ALL to revoke all roles that are granted to the program unit.

program_unit
Specify the program unit from which the role is to be revoked. You can specify a PL/SQL function, procedure, or package. If you do not specify schema, then Oracle Database assumes the function, procedure, or package is in your own schema.

CONTAINER Clause
If the current container is a pluggable database (PDB):

■ Specify CONTAINER = CURRENT to revoke a locally granted system privilege, object privilege, or role from a local user, common user, local role, or common role. The privilege or role is revoked from the user or role only in the current PDB. This clause does not revoke privileges granted with CONTAINER = ALL.

If the current container is the root:

■ Specify CONTAINER = CURRENT to revoke a locally granted system privilege, object privilege, or role from a common user or common role. The privilege or role is revoked from the user or role only in the root. This clause does not revoke privileges granted with CONTAINER = ALL.

■ Specify CONTAINER = ALL to revoke a commonly granted system privilege, object privilege on a common object, or role from a common user or common role. The privilege or role is revoked from the user or role across the entire CDB. This clause can revoke only a privilege or role granted with CONTAINER = ALL from the specified common user or common role. This clause does not revoke privileges
REVOKE

granted locally with CONTAINER = CURRENT. However, any locally granted privileges that depend on the commonly granted privilege being revoked are also revoked.

If you omit this clause, then CONTAINER = CURRENT is the default.

Examples

Revoking a System Privilege from a User: Example  The following statement revokes the DROP ANY TABLE system privilege from the users hr and oe:

```
REVOKE DROP ANY TABLE
    FROM hr, oe;
```

The users hr and oe can no longer drop tables in schemas other than their own.

Revoking a Role from a User: Example  The following statement revokes the role dw_manager from the user sh:

```
REVOKE dw_manager
    FROM sh;
```

The user sh can no longer enable the dw_manager role.

Revoking a System Privilege from a Role: Example  The following statement revokes the CREATE TABLESPACE system privilege from the dw_manager role:

```
REVOKE CREATE TABLESPACE
    FROM dw_manager;
```

Enabling the dw_manager role no longer allows users to create tablespaces.

Revoking a Role from a Role: Example  To revoke the role dw_user from the role dw_manager, issue the following statement:

```
REVOKE dw_user
    FROM dw_manager;
```

The dw_user role privileges are no longer granted to dw_manager.

Revoking an Object Privilege from a User: Example  You can grant DELETE, INSERT, READ, SELECT, and UPDATE privileges on the table orders to the user hr with the following statement:

```
GRANT ALL
    ON orders TO hr;
```

To revoke the DELETE privilege on orders from hr, issue the following statement:

```
REVOKE DELETE
    ON orders FROM hr;
```

Revoking All Object Privileges from a User: Example  To revoke the remaining privileges on orders that you granted to hr, issue the following statement:

```
REVOKE ALL
    ON orders FROM hr;
```

Revoking Object Privileges from PUBLIC: Example  You can grant SELECT and UPDATE privileges on the view emp_details_view to all users by granting the privileges to the role PUBLIC:
GRANT SELECT, UPDATE
   ON emp_details_view TO public;

The following statement revokes UPDATE privilege on emp_details_view from all users:
REVOKE UPDATE
   ON emp_details_view FROM public;

Users can no longer update the emp_details_view view, although users can still query it. However, if you have also granted the UPDATE privilege on emp_details_view to any users, either directly or through roles, then these users retain the privilege.

Revoking an Object Privilege on a User from a User: Example  You can grant the user hr the INHERIT PRIVILEGES privilege on user sh with the following statement:
GRANT INHERIT PRIVILEGES ON USER sh TO hr;

To revoke the INHERIT PRIVILEGES privilege on user sh from user hr, issue the following statement:
REVOKE INHERIT PRIVILEGES ON USER sh FROM hr;

Revoking an Object Privilege on a Sequence from a User: Example  You can grant the user oe the SELECT privilege on the departments_seq sequence in the schema hr with the following statement:
GRANT SELECT
   ON hr.departments_seq TO oe;

To revoke the SELECT privilege on departments_seq from oe, issue the following statement:
REVOKE SELECT
   ON hr.departments_seq FROM oe;

However, if the user hr has also granted SELECT privilege on departments to sh, then sh can still use departments by virtue of hr's grant.

Revoking an Object Privilege with CASCADE CONSTRAINTS: Example  You can grant to oe the privileges REFERENCES and UPDATE on the employees table in the schema hr with the following statement:
GRANT REFERENCES, UPDATE
   ON hr.employees TO oe;

The user oe can exercise the REFERENCES privilege to define a constraint in his or her own dependent table that refers to the employees table in the schema hr:
CREATE TABLE dependent
  (dependno   NUMBER,
   dependname VARCHAR2(10),
   employee NUMBER
  CONSTRAINT in_emp REFERENCES hr.employees(employee_id) );

You can revoke the REFERENCES privilege on hr.employees from oe by issuing the following statement that contains the CASCADE CONSTRAINTS clause:
REVOKE REFERENCES
   ON hr.employees
   FROM oe
   CASCADE CONSTRAINTS;
Revoking oe’s REFERENCES privilege on hr.employees causes Oracle Database to drop the in_emp constraint, because oe required the privilege to define the constraint.

However, if oe has also been granted the REFERENCES privilege on hr.employees by a user other than you, then the database does not drop the constraint. oe still has the privilege necessary for the constraint by virtue of the other user’s grant.

**Revoking an Object Privilege on a Directory from a User: Example**  You can revoke the READ object privilege on directory bfile_dir from hr by issuing the following statement:

```sql
REVOKE READ ON DIRECTORY bfile_dir FROM hr;
```

**Revoke Operations that Use GRANT ANY OBJECT PRIVILEGE: Example**  Suppose that the database administrator has granted GRANT ANY OBJECT PRIVILEGE to user sh. Now suppose that user hr grants the update privilege on the employees table to oe:

```sql
CONNECT hr
GRANT UPDATE ON employees TO oe WITH GRANT OPTION;
```

This grant gives user oe the right to pass the object privilege along to another user:

```sql
CONNECT oe
GRANT UPDATE ON hr.employees TO pm;
```

User sh, who has the GRANT ANY OBJECT PRIVILEGE, can now act on behalf of user hr and revoke the update privilege from user oe, because oe was granted the privilege by hr:

```sql
CONNECT sh
REVOKE UPDATE ON hr.employees FROM oe;
```

User sh cannot revoke the update privilege from user pm explicitly, because pm received the grant neither from the object owner (hr), nor from sh, nor from another user with GRANT ANY OBJECT PRIVILEGE, but from user oe. However, the preceding statement cascades, removing all privileges that depend on the one revoked. Therefore the object privilege is implicitly revoked from pm as well.
ROLLBACK

Purpose

Use the ROLLBACK statement to undo work done in the current transaction or to manually undo the work done by an in-doubt distributed transaction.

Note: Oracle recommends that you explicitly end transactions in application programs using either a COMMIT or ROLLBACK statement. If you do not explicitly commit the transaction and the program terminates abnormally, then Oracle Database rolls back the last uncommitted transaction.

See Also:
- Oracle Database Concepts for information on transactions
- Oracle Database Heterogeneous Connectivity User’s Guide for information on distributed transactions
- SET TRANSACTION on page 19-84 for information on setting characteristics of the current transaction
- COMMIT on page 13-57 and SAVEPOINT on page 19-2

Prerequisites

To roll back your current transaction, no privileges are necessary.

To manually roll back an in-doubt distributed transaction that you originally committed, you must have the FORCE TRANSACTION system privilege. To manually roll back an in-doubt distributed transaction originally committed by another user, you must have the FORCE ANY TRANSACTION system privilege.

Syntax

rollback::=

Semantics

WORK
The keyword WORK is optional and is provided for SQL standard compatibility.

TO SAVEPOINT Clause
Specify the savepoint to which you want to roll back the current transaction. If you omit this clause, then the ROLLBACK statement rolls back the entire transaction.

Using ROLLBACK without the TO SAVEPOINT clause performs the following operations:
ROLLBACK

- Ends the transaction
- Undoes all changes in the current transaction
- Erases all savepoints in the transaction
- Releases any transaction locks

See Also: SAVEPOINT on page 19-2

Using ROLLBACK with the TO SAVEPOINT clause performs the following operations:

- Rolls back just the portion of the transaction after the savepoint. It does not end the transaction.
- Erases all savepoints created after that savepoint. The named savepoint is retained, so you can roll back to the same savepoint multiple times. Prior savepoints are also retained.
- Releases all table and row locks acquired since the savepoint. Other transactions that have requested access to rows locked after the savepoint must continue to wait until the transaction is committed or rolled back. Other transactions that have not already requested the rows can request and access the rows immediately.

Restriction on In-doubt Transactions You cannot manually roll back an in-doubt transaction to a savepoint.

FORCE Clause

Specify FORCE to manually roll back an in-doubt distributed transaction. The transaction is identified by the string containing its local or global transaction ID. To find the IDs of such transactions, query the data dictionary view DBA_2PC_PENDING.

A ROLLBACK statement with a FORCE clause rolls back only the specified transaction. Such a statement does not affect your current transaction.

See Also: Oracle Database Administrator’s Guide for more information on distributed transactions and rolling back in-doubt transactions

Examples

Rolling Back Transactions: Examples The following statement rolls back your entire current transaction:

ROLLBACK;

The following statement rolls back your current transaction to savepoint banda_sal:

ROLLBACK TO SAVEPOINT banda_sal;

See "Creating Savepoints: Example" on page 19-2 for a full version of the preceding example.

The following statement manually rolls back an in-doubt distributed transaction:

ROLLBACK WORK
    FORCE '25.32.87';
This chapter contains the following SQL statements:

- **SAVEPOINT**
- **SELECT**
- **SET CONSTRAINT[S]**
- **SET ROLE**
- **SET TRANSACTION**
- **TRUNCATE CLUSTER**
- **TRUNCATE TABLE**
- **UPDATE**
SAVEPOINT

Purpose
Use the SAVEPOINT statement to create a name for a system change number (SCN), to which you can later roll back.

See Also:
- Oracle Database Concepts for information on savepoints.
- ROLLBACK on page 18-110 for information on rolling back transactions
- SET TRANSACTION on page 19-84 for information on setting characteristics of the current transaction

Prerequisites
None.

Syntax
savepoint::=

Semantics

savepoint
Specify the name of the savepoint to be created.

Savepoint names must be distinct within a given transaction. If you create a second savepoint with the same identifier as an earlier savepoint, then the earlier savepoint is erased. After a savepoint has been created, you can either continue processing, commit your work, roll back the entire transaction, or roll back to the savepoint.

Examples

Creating Savepoints: Example To update the salary for Banda and Greene in the sample table hr.employees, check that the total department salary does not exceed 314,000, then reenter the salary for Greene:

UPDATE employees
SET salary = 7000
WHERE last_name = 'Banda';
SAVEPOINT banda_sal;

UPDATE employees
SET salary = 12000
WHERE last_name = 'Greene';
SAVEPOINT greene_sal;

SELECT SUM(salary) FROM employees;

ROLLBACK TO SAVEPOINT banda_sal;
UPDATE employees
    SET salary = 11000
    WHERE last_name = 'Greene';

COMMIT;
SELECT

Purpose

Use a SELECT statement or subquery to retrieve data from one or more tables, object tables, views, object views, or materialized views.

If part or all of the result of a SELECT statement is equivalent to an existing materialized view, then Oracle Database may use the materialized view in place of one or more tables specified in the SELECT statement. This substitution is called query rewrite. It takes place only if cost optimization is enabled and the QUERY_REWRITE_ENABLED parameter is set to TRUE. To determine whether query rewrite has occurred, use the EXPLAIN PLAN statement.

See Also:

- Chapter 9, "SQL Queries and Subqueries" for general information on queries and subqueries
- Oracle Database Data Warehousing Guide for more information on materialized views and query rewrite
- EXPLAIN PLAN on page 18-20

Prerequisites

For you to select data from a table or materialized view, the table or materialized view must be in your own schema or you must have the READ or SELECT privilege on the table or materialized view.

For you to select rows from the base tables of a view:

- The view must be in your own schema or you must have the READ or SELECT privilege on the view, and
- Whoever owns the schema containing the view must have the READ or SELECT privilege on the base tables.

The READ ANY TABLE or SELECT ANY TABLE system privilege also allows you to select data from any table or any materialized view or the base table of any view.

To specify the FOR UPDATE clause, the preceding prerequisites apply with the following exception: The READ and READ ANY TABLE privileges, where mentioned, do not allow you to specify the FOR UPDATE clause.

To issue an Oracle Flashback Query using the flashback_query_clause, you must have the READ or SELECT privilege on the objects in the select list. In addition, either you must have FLASHBACK object privilege on the objects in the select list, or you must have FLASHBACK ANY TABLE system privilege.

Syntax

```
select ::= 

subquery for_update_clause ;
```

(subquery ::= on page 19-5, for_update_clause ::= on page 19-13)
### SQL Statements: SAVEPOINT to UPDATE

**subquery ::=**

Semantics

with_clause
Use the with_clause to define the following:

■ PL/SQL procedures and functions (using the plsql_declarations clause)
■ Subquery blocks (using the subquery_factoring_clause)

plsql_declarations
The plsql_declarations clause lets you declare and define PL/SQL functions and procedures. You can then reference the PL/SQL functions in the query in which you specify this clause, as well as its subqueries, if any. For the purposes of name resolution, these function names have precedence over schema-level stored functions.

If the query in which you specify this clause is not a top-level SELECT statement, then the following rules apply to the top-level SQL statement that contains the query:

■ If the top-level statement is a SELECT statement, then it must have either a WITH plsql_declarations clause or the WITH_PLSQL hint.
■ If the top-level statement is a DELETE, MERGE, INSERT, or UPDATE statement, then it must have the WITH_PLSQL hint.

The WITH_PLSQL hint only enables you to specify the WITH plsql_declarations clause within the statement. It is not an optimizer hint.

See Also:

■ Oracle Database PL/SQL Language Reference for syntax and restrictions for function_declaration and procedure_declaration.
■ "Using a PL/SQL Function in the WITH Clause: Examples" on page 19-53
subquery_factoring_clause

The subquery_factoring_clause lets you assign a name (query_name) to a subquery block. You can then reference the subquery block multiple places in the query by specifying query_name. Oracle Database optimizes the query by treating the query_name as either an inline view or as a temporary table. The query_name is subject to the same naming conventions and restrictions as database schema objects. Refer to "Database Object Naming Rules" on page 2-119 for information on database object names.

The column aliases following the query_name and the set operators separating multiple subqueries in the AS clause are valid and required for recursive subquery factoring. The search_clause and cycle_clause are valid only for recursive subquery factoring but are not required. See "Recursive Subquery Factoring" on page 19-18.

You can specify this clause in any top-level SELECT statement and in most types of subqueries. The query name is visible to the main query and to all subsequent subqueries. For recursive subquery factoring, the query name is even visible to the subquery that defines the query name itself.

Recursive Subquery Factoring If a subquery_factoring_clause refers to its own query_name in the subquery that defines it, then the subquery_factoring_clause is said to be recursive. A recursive subquery_factoring_clause must contain two query blocks: the first is the anchor member and the second is the recursive member. The anchor member must appear before the recursive member, and it cannot reference query_name. The anchor member can be composed of one or more query blocks combined by the set operators: UNION ALL, UNION, INTERSECT or MINUS. The recursive member must follow the anchor member and must reference query_name exactly once. You must combine the recursive member with the anchor member using the UNION ALL set operator.

The number of column aliases following WITH query_name and the number of columns in the SELECT lists of the anchor and recursive query blocks must be the same.

The recursive member cannot contain any of the following elements:

- The DISTINCT keyword or a GROUP BY clause
- The model_clause
- An aggregate function. However, analytic functions are permitted in the select list.
- Subqueries that refer to query_name.
- Outer joins that refer to query_name as the right table.

search_clause Use the SEARCH clause to specify an ordering for the rows.

- Specify BREADTH FIRST BY if you want sibling rows returned before any child rows are returned.
- Specify DEPTH FIRST BY if you want child rows returned before any siblings rows are returned.
- Sibling rows are ordered by the columns listed after the BY keyword.
- The c_alias list following the SEARCH keyword must contain column names from the column alias list for query_name.
- The ordering_column is automatically added to the column list for the query name. The query that selects from query_name can include an ORDER BY on ordering_column to return the rows in the order that was specified by the SEARCH clause.
**cycle_clause**  Use the **CYCLE** clause to mark cycles in the recursion.

- The `c_alias` list following the **CYCLE** keyword must contain column names from the column alias list for `query_name`. Oracle Database uses these columns to detect a cycle.
- `cycle_value` and `no_cycle_value` should be character strings of length 1.
- If a cycle is detected, then the cycle mark column specified by `cycle_mark_c_alias` for the row causing the cycle is set to the value specified for `cycle_value`. The recursion will then stop for this row. That is, it will not look for child rows for the offending row, but it will continue for other noncyclic rows.
- If no cycles are found, then the cycle mark column is set to the default value specified for `no_cycle_value`.
- The cycle mark column is automatically added to the column list for the `query_name`.
- A row is considered to form a cycle if one of its ancestor rows has the same values for the cycle columns.

If you omit the **CYCLE** clause, then the recursive **WITH** clause returns an error if cycles are discovered. In this case, a row forms a cycle if one of its ancestor rows has the same values for all the columns in the column alias list for `query_name` that are referenced in the **WHERE** clause of the recursive member.

**Restrictions on Subquery Factoring**  This clause is subject to the following restrictions:

- You can specify only one `subquery_factoring_clause` in a single SQL statement. Any `query_name` defined in the `subquery_factoring_clause` can be used in any subsequent named query block in the `subquery_factoring_clause`.
- In a compound query with set operators, you cannot use the `query_name` for any of the component queries, but you can use the `query_name` in the **FROM** clause of any of the component queries.
- You cannot specify duplicate names in the column alias list for `query_name`.
- The name used for the `ordering_column` has to be different from the name used for `cycle_mark_c_alias`.
- The `ordering_column` and cycle mark column names cannot already be in the column alias list for `query_name`.

**See Also:**

- *Oracle Database Concepts* for information about inline views
- "Subquery Factoring: Example" on page 19-54
- "Recursive Subquery Factoring: Examples" on page 19-54

**hint**

Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

**See Also:**  "Hints" on page 2-77 for the syntax and description of hints
DISTINCT | UNIQUE
Specify DISTINCT or UNIQUE if you want the database to return only one copy of each set of duplicate rows selected. These two keywords are synonymous. Duplicate rows are those with matching values for each expression in the select list.

Restrictions on DISTINCT and UNIQUE Queries
These types of queries are subject to the following restrictions:

- When you specify DISTINCT or UNIQUE, the total number of bytes in all select list expressions is limited to the size of a data block minus some overhead. This size is specified by the initialization parameter DB_BLOCK_SIZE.
- You cannot specify DISTINCT if the select_list contains LOB columns.

ALL
Specify ALL if you want the database to return all rows selected, including all copies of duplicates. The default is ALL.

select_list
The select_list lets you specify the columns you want to retrieve from the database.

* (all-column wildcard)
Specify the all-column wildcard (asterisk) to select all columns, excluding pseudocolumns and INVISIBLE columns, from all tables, views, or materialized views listed in the FROM clause. The columns are returned in the order indicated by the COLUMN_ID column of the *_TAB_COLUMNS data dictionary view for the table, view, or materialized view.

If you are selecting from a table rather than from a view or a materialized view, then columns that have been marked as UNUSED by the ALTER TABLE SET UNUSED statement are not selected.

See Also: ALTER TABLE on page 12-2, "Simple Query Examples" on page 19-58, and "Selecting from the DUAL Table: Example" on page 19-77

query_name.*
Specify query_name followed by a period and the asterisk to select all columns from the specified subquery block. For query_name, specify a subquery block name already specified in the subquery_factoring_clause. You must have specified the subquery_factoring_clause in order to specify query_name in the select_list. If you specify query_name in the select_list, then you also must specify query_name in the query_table_expression (FROM clause).

table.* | view.* | materialized view.*
Specify the object name followed by a period and the asterisk to select all columns from the specified table, view, or materialized view. Oracle Database returns a set of columns in the order in which the columns were specified when the object was created. A query that selects rows from two or more tables, views, or materialized views is a join.

You can use the schema qualifier to select from a table, view, or materialized view in a schema other than your own. If you omit schema, then the database assumes the table, view, or materialized view is in your own schema.
**t_alias.***
Specify a correlation name (alias) followed by a period and the asterisk to select all columns from the object with that correlation name specified in the `FROM` clause of the same subquery. The object can be a table, view, materialized view, or subquery. Oracle Database returns a set of columns in the order in which the columns were specified when the object was created. A query that selects rows from two or more objects is a join.

**expr**
Specify an expression representing the information you want to select. A column name in this list can be qualified with `schema` only if the table, view, or materialized view containing the column is qualified with `schema` in the `FROM` clause. If you specify a member method of an object type, then you must follow the method name with parentheses even if the method takes no arguments.

**c_alias** Specify an alias for the column expression. Oracle Database will use this alias in the column heading of the result set. The `AS` keyword is optional. The alias effectively renames the select list item for the duration of the query. The alias can be used in the `order_by_clause` but not other clauses in the query.

**Restrictions on the Select List**
The select list is subject to the following restrictions:

- You can select a `rowid` from a join view only if the join has one and only one key-preserved table. The `rowid` of that table becomes the `rowid` of the view.

**See Also:**
- Oracle Database Administrator’s Guide for information on key-preserved tables
- Oracle Database Data Warehousing Guide for information on using the `expr AS c_alias` syntax with the `UNION ALL` operator in queries of multiple materialized views
- "About SQL Expressions" on page 5-1 for the syntax of `expr`
If two or more tables have some column names in common, and if you are specifying a join in the FROM clause, then you must qualify column names with names of tables or table aliases.

FROM Clause
The FROM clause lets you specify the objects from which data is selected.

query_table_expression
Use the query_table_expression clause to identify a subquery block, table, view, materialized view, partition, or subpartition, or to specify a subquery that identifies the objects. In order to specify a subquery block, you must have specified the subquery block name (query_name) in the subquery_factoring_clause.

See Also: "Using Subqueries: Examples" on page 19-68

ONLY The ONLY clause applies only to views. Specify ONLY if the view in the FROM clause is a view belonging to a hierarchy and you do not want to include rows from any of its subviews.

LATERAL Specify LATERAL to designate subquery as a lateral inline view. Within a lateral inline view, you can specify tables that appear to the left of the lateral inline view in the FROM clause of a query. You can specify this left correlation anywhere within subquery (such as the SELECT, FROM, and WHERE clauses) and at any nesting level.

Restrictions on LATERAL: Lateral inline views are subject to the following restrictions:

- If you specify LATERAL, then you cannot specify the pivot_clause, the unpivot_clause, or a pattern in the table_reference clause.
- If a lateral inline view contains the query_partition_clause, and it is the right side of a join clause, then it cannot contain a left correlation to the left table in the join clause. However, it can contain a left correlation to a table to its left in the FROM clause that is not the left table.
- A lateral inline view cannot contain a left correlation to the first table in a right outer join or full outer join.

See Also: "Using Lateral Inline Views: Example" on page 19-73

flashback_query_clause
Use the flashback_query_clause to retrieve data from a table, view, or materialized view based on time dimensions associated with the data.

This clause implements SQL-driven Flashback, which lets you specify the following:

- A different system change number or timestamp for each object in the select list, using the clauses VERSIONS BETWEEN (SCN | TIMESTAMP) or VERSIONS AS OF (SCN | TIMESTAMP). You can also implement session-level Flashback using the DBMS_FLASHBACK package.
- A valid time period for each object in the select list, using the clauses VERSIONS PERIOD FOR or AS OF PERIOD FOR. You can also implement valid-time session-level Flashback using the DBMS_FLASHBACK_ARCHIVE package.

A Flashback Query lets you retrieve a history of changes made to a row. You can retrieve the corresponding identifier of the transaction that made the change using the VERSIONS_XID pseudocolumn. You can also retrieve information about the transaction
that resulted in a particular row version by issuing an Oracle Flashback Transaction Query. You do this by querying the FLASHBACK_TRANSACTION_QUERY data dictionary view for a particular transaction ID.

**VERSIONS BETWEEN { SCN | TIMESTAMP }** Specify VERSIONS BETWEEN to retrieve multiple versions of the rows returned by the query. Oracle Database returns all committed versions of the rows that existed between two SCNs or between two timestamp values. The first specified SCN or timestamp must be earlier than the second specified SCN or timestamp. The rows returned include deleted and subsequently reinserted versions of the rows.

- Specify VERSIONS BETWEEN SCN ... to retrieve the versions of the row that existed between two SCNs. Both expressions must evaluate to a number and cannot evaluate to NULL. MINVALUE and MAXVALUE resolve to the SCN of the oldest and most recent data available, respectively.

- Specify VERSIONS BETWEEN TIMESTAMP ... to retrieve the versions of the row that existed between two timestamps. Both expressions must evaluate to a timestamp value and cannot evaluate to NULL. MINVALUE and MAXVALUE resolve to the timestamp of the oldest and most recent data available, respectively.

**AS OF { SCN | TIMESTAMP }** Specify AS OF to retrieve the single version of the rows returned by the query at a particular change number (SCN) or timestamp. If you specify SCN, then expr must evaluate to a number. If you specify TIMESTAMP, then expr must evaluate to a timestamp value. In either case, expr cannot evaluate to NULL. Oracle Database returns rows as they existed at the specified system change number or time.

Oracle Database provides a group of version query pseudocolumns that let you retrieve additional information about the various row versions. Refer to "Version Query Pseudocolumns" on page 3-5 for more information.

When both clauses are used together, the AS OF clause determines the SCN or moment in time from which the database issues the query. The VERSIONS clause determines the versions of the rows as seen from the AS OF point. The database returns null for a row version if the transaction started before the first BETWEEN value or ended after the AS OF point.

**VERSIONS PERIOD FOR** Specify VERSIONS PERIOD FOR to retrieve rows from table based on whether they are considered valid during the specified time period. In order to use this clause, table must support Temporal Validity.

- For valid_time_column, specify the name of the valid time dimension column for table.

- Use the BETWEEN clause to specify the time period during which rows are considered valid. Both expressions must evaluate to a timestamp value and cannot evaluate to NULL. MINVALUE resolves to the earliest date or timestamp in the start time column of table. MAXVALUE resolves to latest date or timestamp in the end time column of table.

**AS OF PERIOD FOR** Specify AS OF PERIOD FOR to retrieve rows from table based on whether they are considered valid as of the specified time. In order to use this clause, table must support Temporal Validity.

- For valid_time_column, specify the name of the valid time dimension column for table.
Use `expr` to specify the time as of which rows are considered valid. The expression must evaluate to a timestamp value and cannot evaluate to NULL.

**See Also:**
- *Oracle Database Development Guide* for more information on Temporal Validity
- `CREATE TABLE period_definition` on page 16-40 to learn how to configure a table to support Temporal Validity and for information about the `valid_time_column`, start time column, and end time column

**Note on Flashback Queries** When performing a flashback query, Oracle Database might not use query optimizations that it would use for other types of queries, which could have a negative impact on performance. In particular, this occurs when you specify multiple flashback queries in a hierarchical query.

**Restrictions on Flashback Queries** These queries are subject to the following restrictions:
- You cannot specify a column expression or a subquery in the expression of the `AS OF` clause.
- You cannot specify the `AS OF` clause if you have specified the `for_update_clause`.
- You cannot use the `AS OF` clause in the defining query of a materialized view.
- You cannot use the `VERSIONS` clause in flashback queries to temporary or external tables, or tables that are part of a cluster.
- You cannot use the `VERSIONS` clause in flashback queries to views. However, you can use the `VERSIONS` syntax in the defining query of a view.
- You cannot specify the `flashback_query_clause` if you have specified `query_name` in the `query_table_expression`.

**See Also:**
- *Oracle Database Development Guide* for more information on Oracle Flashback Query
- “Using Flashback Queries: Example” on page 19-59
- *Oracle Database Development Guide* and *Oracle Database PL/SQL Packages and Types Reference* for information about session-level Flashback using the `DBMS_FLASHBACK` package
- *Oracle Database Administrator’s Guide* and to the description of `FLASHBACK_TRANSACTION_QUERY` in the *Oracle Database Reference* for more information about transaction history

**partition_extension_clause** For `PARTITION` or `SUBPARTITION`, specify the name or key value of the partition or subpartition within `table` from which you want to retrieve data.

For range- and list-partitioned data, as an alternative to this clause, you can specify a condition in the `WHERE` clause that restricts the retrieval to one or more partitions of `table`. Oracle Database will interpret the condition and fetch data from only those partitions. It is not possible to formulate such a `WHERE` condition for hash-partitioned data.
dblink  For dblink, specify the complete or partial name for a database link to a remote database where the table, view, or materialized view is located. This database need not be an Oracle Database.

Restrictions on Database Links  Database links are subject to the following restrictions:

- You cannot query a user-defined type or an object REF on a remote table.
- You cannot query columns of type ANYTYPE, ANYDATA, or ANYDATASET from remote tables.

Specify the name of a table, view, or materialized view from which data is selected.

sample_clause  The sample_clause lets you instruct the database to select from a random sample of data from the table, rather than from the entire table.

Caution:  The use of statistically incorrect assumptions when using this feature can lead to incorrect or undesirable results.

SEED seed_value  Specify this clause to instruct the database to attempt to return the same sample from one execution to the next. The seed_value must be an integer.
between 0 and 4294967295. If you omit this clause, then the resulting sample will change from one execution to the next.

**Restrictions on `sample_clause`** The following restrictions apply to the `SAMPLE` clause:

- You cannot specify the `SAMPLE` clause in a subquery in a DML statement.
- You can specify the `SAMPLE` clause in a query on a base table, a container table of a materialized view, or a view that is key preserving. You cannot specify this clause on a view that is not key preserving.

**subquery_restriction_clause** The `subquery_restriction_clause` lets you restrict the subquery in one of the following ways:

**WITH READ ONLY** Specify `WITH READ ONLY` to indicate that the table or view cannot be updated.

**WITH CHECK OPTION** Specify `WITH CHECK OPTION` to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the `FROM` clause but not in subquery in the `WHERE` clause.

**CONSTRAINT constraint** Specify the name of the `CHECK OPTION` constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form `SYS_Cn`, where `n` is an integer that makes the constraint name unique within the database.

**See Also:** "Using the WITH CHECK OPTION Clause: Example" on page 19-66

---

**table_collection_expression**

The `table_collection_expression` lets you inform Oracle that the value of `collection_expression` should be treated as a table for purposes of query and DML operations. The `collection_expression` can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called **collection unnesting**.

The optional plus (+) is relevant if you are joining the `TABLE` collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

**Note:** In earlier releases of Oracle, when `collection_expression` was a subquery, `table_collection_expression` was expressed as `THE subquery`. That usage is now deprecated.

---

The `collection_expression` can reference columns of tables defined to its left in the `FROM` clause. This is called **left correlation**. Left correlation can occur only in `table_collection_expression`. Other subqueries cannot contains references to columns defined outside the subquery.

The optional (+) lets you specify that `table_collection_expression` should return a row with all fields set to null if the collection is null or empty. The (+) is valid only if `collection_expression` uses left correlation. The result is similar to that of an outer join.
When you use the (+) syntax in the WHERE clause of a subquery in an UPDATE or DELETE operation, you must specify two tables in the FROM clause of the subquery. Oracle Database ignores the outer join syntax unless there is a join in the subquery itself.

See Also:
- "Outer Joins" on page 9-12
- "Table Collections: Examples" on page 19-73 and "Collection Unnesting: Examples" on page 19-74

**t_alias**

Specify a correlation name, which is an alias for the table, view, materialized view, or subquery for evaluating the query. This alias is required if the select list references any object type attributes or object type methods. Correlation names are most often used in a correlated query. Other references to the table, view, or materialized view throughout the query must refer to this alias.

See Also: "Using Correlated Subqueries: Examples" on page 19-76

**pivot_clause**

The pivot_clause lets you write cross-tabulation queries that rotate rows into columns, aggregating data in the process of the rotation. The output of a pivot operation typically includes more columns and fewer rows than the starting data set. The pivot_clause performs the following steps:

1. The pivot_clause computes the aggregation functions specified at the beginning of the clause. Aggregation functions must specify a GROUP BY clause to return multiple values, yet the pivot_clause does not contain an explicit GROUP BY clause. Instead, the pivot_clause performs an implicit GROUP BY. The implicit grouping is based on all the columns not referred to in the pivot_clause, along with the set of values specified in the pivot_in_clause. If you specify more than one aggregation function, then you must provide aliases for at least all but one of the aggregation functions.

2. The grouping columns and aggregated values calculated in Step 1 are configured to produce the following cross-tabular output:
   - All the implicit grouping columns not referred to in the pivot_clause, followed by
   - New columns corresponding to values in the pivot_in_clause. Each aggregated value is transposed to the appropriate new column in the cross-tabulation. If you specify the XML keyword, then the result is a single new column that expresses the data as an XML string. The database generates a name for each new column. If you do not provide an alias for an aggregation function, then the database uses each pivot column value as the name for each new column to which that aggregated value is transposed. If you provide an alias for an aggregation function, then the database generates a name for each new column to which that aggregated value is transposed by concatenating the pivot column name, the underscore character (_), and the aggregation function alias. If a generated column name exceeds the maximum length of a column name, then an ORA-00918 error is returned. To avoid this issue, specify a shorter alias for the pivot column heading, the aggregation function, or both.

The subclauses of the pivot_clause have the following semantics:
XML  The optional XML keyword generates XML output for the query. The XML keyword permits the `pivot_in_clause` to contain either a subquery or the wildcard keyword `ANY`. Subqueries and `ANY` wildcards are useful when the `pivot_in_clause` values are not known in advance. With XML output, the values of the pivot column are evaluated at execution time. You cannot specify XML when you specify explicit pivot values using expressions in the `pivot_in_clause`.

When XML output is generated, the aggregate function is applied to each distinct pivot value, and the database returns a column of `XMLType` containing an XML string for all value and measure pairs.

`expr`  For `expr`, specify an expression that evaluates to a constant value of a pivot column. You can optionally provide an alias for each pivot column value. If there is no alias, the column heading becomes a quoted identifier.

`subquery`  A subquery is used only in conjunction with the XML keyword. When you specify a subquery, all values found by the subquery are used for pivoting. The output is not the same cross-tabular format returned by non-XML pivot queries. Instead of multiple columns specified in the `pivot_in_clause`, the subquery produces a single XML string column. The XML string for each row holds aggregated data corresponding to the implicit `GROUP BY` value of that row. The XML string for each output row includes all pivot values found by the subquery, even if there are no corresponding rows in the input data.

The subquery must return a list of unique values at the execution time of the pivot query. If the subquery does not return a unique value, then Oracle Database raises a run-time error. Use the `DISTINCT` keyword in the subquery if you are not sure the query will return unique values.

`ANY`  The `ANY` keyword is used only in conjunction with the XML keyword. The `ANY` keyword acts as a wildcard and is similar in effect to `subquery`. The output is not the same cross-tabular format returned by non-XML pivot queries. Instead of multiple columns specified in the `pivot_in_clause`, the `ANY` keyword produces a single XML string column. The XML string for each row holds aggregated data corresponding to the implicit `GROUP BY` value of that row. However, in contrast to the behavior when you specify `subquery`, the `ANY` wildcard produces an XML string for each output row that includes only the pivot values found in the input data corresponding to that row.

See Also:  *Oracle Database Data Warehousing Guide* for more information about `PIVOT` and `UNPIVOT` and "Using PIVOT and UNPIVOT: Examples" on page 19-67

`unpivot_clause`  The `unpivot_clause` rotates columns into rows.

- The `INCLUDE | EXCLUDE NULLS` clause gives you the option of including or excluding null-valued rows. `INCLUDE NULLS` causes the unpivot operation to include null-valued rows; `EXCLUDE NULLS` eliminates null-values rows from the return set. If you omit this clause, then the unpivot operation excludes nulls.

- For `column`, specify a name for each output column that will hold measure values, such as `sales_quantity`.

- In the `pivot_for_clause`, specify a name for each output column that will hold descriptor values, such as quarter or product.

- In the `unpivot_in_clause`, specify the input data columns whose names will become values in the output columns of the `pivot_for_clause`. These input data
columns have names specifying a category value, such as Q1, Q2, Q3, Q4. The optional AS clause lets you map the input data column names to the specified literal values in the output columns.

The unpivot operation turns a set of value columns into one column. Therefore, the data types of all the value columns must be in the same data type group, such as numeric or character.

- If all the value columns are CHAR, then the unpivoted column is CHAR. If any value column is VARCHAR2, then the unpivoted column is VARCHAR2.
- If all the value columns are NUMBER, then the unpivoted column is NUMBER. If any value column is BINARY_DOUBLE, then the unpivoted column is BINARY_DOUBLE. If no value column is BINARY_DOUBLE but any value column is BINARY_FLOAT, then the unpivoted column is BINARY_FLOAT.

containers_clause
The CONTAINERS clause is useful in a multitenant container database (CDB). This clause lets you query data in the specified table or view across all containers in a CDB.

In order to issue this clause, you must be a common user connected to the root, the table or view must exist in the root and in all PDBs, and the table or view must be in your own schema. It is not necessary to specify schema, but if you do then you must specify your own schema.

The query returns all rows from the table or view in the root and in all open PDBs, except PDBs that are open in RESTRICTED mode. If the queried table or view does not already contain a CON_ID column, then the query adds a CON_ID column to the query result, which identifies the container whose data a given row represents.

See Also: Oracle Database Administrator’s Guide for more information on the CONTAINERS clause

join_clause
Use the appropriate join_clause syntax to identify tables that are part of a join from which to select data. The inner_cross_join_clause lets you specify an inner or cross join. The outer_join_clause lets you specify an outer join. The cross_outer_apply_clause lets you specify a variation of an ANSI CROSS JOIN or an ANSI LEFT OUTER JOIN with left correlation support.

When you join more than two row sources, you can use parentheses to override default precedence. For example, the following syntax:

```
SELECT ... FROM a JOIN (b JOIN c) ...
```

results in a join of b and c, and then a join of that result set with a.

inner_cross_join_clause
Inner joins return only those rows that satisfy the join condition.

INNER Specify INNER to explicitly specify an inner join.
JOIN  The JOIN keyword explicitly states that a join is being performed. You can use this syntax to replace the comma-delimited table expressions used in WHERE clause joins with FROM clause join syntax.

ON condition  Use the ON clause to specify a join condition. Doing so lets you specify join conditions separate from any search or filter conditions in the WHERE clause.

USING (column)  When you are specifying an equijoin of columns that have the same name in both tables, the USING column clause indicates the columns to be used. You can use this clause only if the join columns in both tables have the same name. Within this clause, do not qualify the column name with a table name or table alias.

CROSS  The CROSS keyword indicates that a cross join is being performed. A cross join produces the cross-product of two relations and is essentially the same as the comma-delimited Oracle Database notation.

NATURAL  The NATURAL keyword indicates that a natural join is being performed. Refer to NATURAL on page 19-31 for the full semantics of this clause.

outer_join_clause
Outer joins return all rows that satisfy the join condition and also return some or all of those rows from one table for which no rows from the other satisfy the join condition. You can specify two types of outer joins: a conventional outer join using the table_reference syntax on both sides of the join, or a partitioned outer join using the query_partition_clause on one side or the other. A partitioned outer join is similar to a conventional outer join except that the join takes place between the outer table and each partition of the inner table. This type of join lets you selectively make sparse data more dense along the dimensions of interest. This process is called data densification.

query_partition_clause  The query_partition_clause lets you define a partitioned outer join. Such a join extends the conventional outer join syntax by applying the outer join to partitions returned by the query. Oracle Database creates a partition of rows for each expression you specify in the PARTITION BY clause. The rows in each query partition have same value for the PARTITION BY expression. The query_partition_clause can be on either side of the outer join. The result of a partitioned outer join is a UNION of the outer joins of each of the partitions in the partitioned result set and the table on the other side of the join. This type of result is useful for filling gaps in sparse data, which simplifies analytic calculations.

If you omit this clause, then the database treats the entire table expression—everything specified in table_reference—as a single partition, resulting in a conventional outer join.

To use the query_partition_clause in an analytic function, use the upper branch of the syntax (without parentheses). To use this clause in a model query (in the model_column_clauses) or a partitioned outer join (in the outer_join_clause), use the lower branch of the syntax (with parentheses).

Restrictions on Partitioned Outer Joins  Partitioned outer joins are subject to the following restrictions:
- You can specify the query_partition_clause on either the right or left side of the join, but not both.
- You cannot specify a FULL partitioned outer join.
If you specify the `query_partition_clause` in an outer join with an `ON` clause, then you cannot specify a subquery in the `ON` condition.

**See Also:** "Using Partitioned Outer Joins: Examples" on page 19-71

**NATURAL** The NATURAL keyword indicates that a natural join is being performed. A natural join is based on all columns in the two tables that have the same name. It selects rows from the two tables that have equal values in the relevant columns. If two columns with the same name do not have compatible data types, then an error is raised. When specifying columns that are involved in the natural join, do not qualify the column name with a table name or table alias.

On occasion, the table pairings in natural or cross joins may be ambiguous. For example, consider the following join syntax:

```
a NATURAL LEFT JOIN b LEFT JOIN c ON b.c1 = c.c1
```

This example can be interpreted in either of the following ways:

```
(a NATURAL LEFT JOIN (b LEFT JOIN c ON b.c1 = c.c1))
(a NATURAL LEFT JOIN b) LEFT JOIN c ON b.c1 = c.c1
```

To avoid this ambiguity, you can use parentheses to specify the pairings of joined tables. In the absence of such parentheses, the database uses left associativity, pairing the tables from left to right.

**Restriction on Natural Joins** You cannot specify a LOB column, columns of `ANYTYPE`, `ANYDATA`, or `ANYDATASET`, or a collection column as part of a natural join.

**outer_join_type** The `outer_join_type` indicates the kind of outer join being performed:

- Specify `RIGHT` to indicate a right outer join.
- Specify `LEFT` to indicate a left outer join.
- Specify `FULL` to indicate a full or two-sided outer join. In addition to the inner join, rows from both tables that have not been returned in the result of the inner join will be preserved and extended with nulls.
- You can specify the optional `OUTER` keyword following `RIGHT`, `LEFT`, or `FULL` to explicitly clarify that an outer join is being performed.

**ON condition** Use the `ON` clause to specify a join condition. Doing so lets you specify join conditions separate from any search or filter conditions in the `WHERE` clause.

**Restriction on the ON condition Clause** You cannot specify this clause with a NATURAL outer join.

**USING column** In an outer join with the `USING` clause, the query returns a single column which is a coalesce of the two matching columns in the join. The coalesce functions as follows:

\[
\text{COALESCE} (a, b) = a \text{ if } a \text{ NOT NULL, else } b.
\]

Therefore:

- A left outer join returns all the common column values from the left table in the `FROM` clause.
A right outer join returns all the common column values from the right table in the FROM clause.

A full outer join returns all the common column values from both joined tables.

Restriction on the USING column Clause  The USING column clause is subject to the following restrictions:

- Within this clause, do not qualify the column name with a table name or table alias.
- You cannot specify a LOB column or a collection column in the USING column clause.
- You cannot specify this clause with a NATURAL outer join.

See Also:
- "Outer Joins" on page 9-12 for additional rules and restrictions pertaining to outer joins
- Oracle Database Data Warehousing Guide for a complete discussion of partitioned outer joins and data densification
- "Using Outer Joins: Examples" on page 19-69

cross_outer_apply_clause  This clause allows you to perform a variation of an ANSI CROSS JOIN or an ANSI LEFT OUTER JOIN with left correlation support. You can specify a table_reference or collection_expression to the right of the APPLY keyword. The table_reference can be a table, inline view, or TABLE collection expression. The collection_expression can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. The table_reference or collection_expression can reference columns of tables defined in the FROM clause to the left of the APPLY keyword. This is called left correlation.

- Specify CROSS APPLY to perform a variation of an ANSI CROSS JOIN. Only rows from the table on the left side of the join that produce a result set from table_reference or collection_expression are returned.

- Specify OUTER APPLY to perform a variation of an ANSI LEFT OUTER JOIN. All rows from the table on the left side of the join are returned. Rows that do not produce a result set from table_reference or collection_expression have the NULL value in the corresponding column(s).

Restriction on the cross_outer_apply_clause  The table_reference cannot be a lateral inline view.

See Also:  Using CROSS APPLY and OUTER APPLY Joins: Examples on page 19-72

where_clause  The WHERE condition lets you restrict the rows selected to those that satisfy one or more conditions. For condition, specify any valid SQL condition.

If you omit this clause, then the database returns all rows from the tables, views, or materialized views in the FROM clause.
**Note:** If this clause refers to a DATE column of a partitioned table or index, then the database performs partition pruning only if:

- You created the table or index partitions by fully specifying the year using the TO_DATE function with a 4-digit format mask, and
- You specify the date in the where_clause of the query using the TO_DATE function and either a 2- or 4-digit format mask.

---

**See Also:**
- Chapter 6, "Conditions" for the syntax description of condition
- "Selecting from a Partition: Example" on page 19-58

**hierarchical_query_clause**

The hierarchical_query_clause lets you select rows in a hierarchical order.

SELECT statements that contain hierarchical queries can contain the LEVEL pseudocolumn in the select list. LEVEL returns the value 1 for a root node, 2 for a child node of a root node, 3 for a grandchild, and so on. The number of levels returned by a hierarchical query may be limited by available user memory.

Oracle processes hierarchical queries as follows:

- A join, if present, is evaluated first, whether the join is specified in the FROM clause or with WHERE clause predicates.
- The CONNECT BY condition is evaluated.
- Any remaining WHERE clause predicates are evaluated.

If you specify this clause, then do not specify either ORDER BY or GROUP BY, because they will destroy the hierarchical order of the CONNECT BY results. If you want to order rows of siblings of the same parent, then use the ORDER SIBLINGS BY clause.

**See Also:** "Hierarchical Queries" on page 9-3 for a discussion of hierarchical queries and "Using the LEVEL Pseudocolumn: Examples" on page 19-74

**START WITH Clause**

Specify a condition that identifies the row(s) to be used as the root(s) of a hierarchical query. The condition can be any condition as described in Chapter 6, "Conditions". Oracle Database uses as root(s) all rows that satisfy this condition. If you omit this clause, then the database uses all rows in the table as root rows.

**CONNECT BY Clause**

Specify a condition that identifies the relationship between parent rows and child rows of the hierarchy. The condition can be any condition as described in Chapter 6, "Conditions". However, it must use the PRIOR operator to refer to the parent row.
group_by_clause

Specify the GROUP BY clause if you want the database to group the selected rows based on the value of expr(s) for each row and return a single row of summary information for each group. If this clause contains CUBE or ROLLUP extensions, then the database produces superaggregate groupings in addition to the regular groupings.

Expressions in the GROUP BY clause can contain any columns of the tables, views, or materialized views in the FROM clause, regardless of whether the columns appear in the select list.

The GROUP BY clause groups rows but does not guarantee the order of the result set. To order the groupings, use the ORDER BY clause.

If the NLS_SORT parameter has a setting other than BINARY and the NLS_COMP parameter is set to LINGUISTIC, then expression values are compared linguistically according to the linguistic definition specified in NLS_SORT to decide if they are equal and therefore belong to the same group. When character values are compared linguistically for GROUP BY, they are first transformed to collation keys and then compared like RAW values. The collation keys are the same values that are returned by the function NLSSORT and are subject to the same restrictions that are described in "NLSSORT" on page 7-208. As a result of these restrictions, two values may compare as linguistically equal and be grouped together if they do not differ in the prefix that was used to produce the collation key, even if they differ in the rest of the value.

- Oracle Database Data Warehousing Guide for an expanded discussion and examples of using SQL grouping syntax for data aggregation
- the GROUP_ID, GROUPING, and GROUPING_ID functions on page 7-130 for examples
- "Using the GROUP BY Clause: Examples" on page 19-60

ROLLUP

The ROLLUP operation in the simple_grouping_clause groups the selected rows based on the values of the first n, n-1, n-2, ... 0 expressions in the GROUP BY specification, and returns a single row of summary for each group. You can use the ROLLUP operation to produce subtotal values by using it with the SUM function. When used with SUM, ROLLUP generates subtotals from the most detailed level to the grand total. Aggregate functions such as COUNT can be used to produce other kinds of superaggregates.

For example, given three expressions (n=3) in the ROLLUP clause of the simple_grouping_clause, the operation results in n+1 = 3+1 = 4 groupings.

Rows grouped on the values of the first n expressions are called regular rows, and the others are called superaggregate rows.

See Also: Oracle Database Data Warehousing Guide for information on using ROLLUP with materialized views
**CUBE**  The CUBE operation in the `simple_grouping_clause` groups the selected rows based on the values of all possible combinations of expressions in the specification. It returns a single row of summary information for each group. You can use the CUBE operation to produce cross-tabulation values.

For example, given three expressions \((n=3)\) in the CUBE clause of the `simple_grouping_clause`, the operation results in \(2^n = 2^3 = 8\) groupings. Rows grouped on the values of \(n\) expressions are called regular rows, and the rest are called superaggregate rows.

**GROUPING SETS**  GROUPING SETS are a further extension of the GROUP BY clause that let you specify multiple groupings of data. Doing so facilitates efficient aggregation by pruning the aggregates you do not need. You specify just the desired groups, and the database does not need to perform the full set of aggregations generated by CUBE or ROLLUP. Oracle Database computes all groupings specified in the GROUPING SETS clause and combines the results of individual groupings with a UNION ALL operation. The UNION ALL means that the result set can include duplicate rows.

Within the GROUP BY clause, you can combine expressions in various ways:

- To specify composite columns, group columns within parentheses so that the database treats them as a unit while computing ROLLUP or CUBE operations.
- To specify concatenated grouping sets, separate multiple grouping sets, ROLLUP, and CUBE operations with commas so that the database combines them into a single GROUP BY clause. The result is a cross-product of groupings from each grouping set.

**HAVING Clause**

Use the HAVING clause to restrict the groups of returned rows to those groups for which the specified condition is TRUE. If you omit this clause, then the database returns summary rows for all groups.

Specify GROUP BY and HAVING after the `where_clause` and `hierarchical_query_clause`. If you specify both GROUP BY and HAVING, then they can appear in either order.

**Restrictions on the GROUP BY Clause:** This clause is subject to the following restrictions:

- You cannot specify LOB columns, nested tables, or varrays as part of `expr`.
- The expressions can be of any form except scalar subquery expressions.
- If the `group_by_clause` references any object type columns, then the query will not be parallelized.

**model_clause**

The `model_clause` lets you view selected rows as a multidimensional array and randomly access cells within that array. Using the `model_clause`, you can specify a
series of cell assignments, referred to as rules, that invoke calculations on individual cells and ranges of cells. These rules operate on the results of a query and do not update any database tables.

When using the model_clause in a query, the SELECT and ORDER BY clauses must refer only to those columns defined in the model_column_clauses.

See Also:
- The syntax description of expr in "About SQL Expressions" on page 5-1 and the syntax description of condition in Chapter 6, "Conditions"
- Oracle Database Data Warehousing Guide for an expanded discussion and examples
- "The MODEL clause: Examples" on page 19-63

**main_model**
The main_model clause defines how the selected rows will be viewed in a multidimensional array and what rules will operate on which cells in that array.

**model_column_clauses**
The model_column_clauses define and classify the columns of a query into three groups: partition columns, dimension columns, and measure columns. For expr, you can specify a column, constant, host variable, single-row function, aggregate function, or any expression involving them. If expr is a column, then the column alias (c_alias) is optional. If expr is not a column, then the column alias is required. If you specify a column alias, then you must use the alias to refer to the column in the model_rules_clause, SELECT list, and the query ORDER BY clauses.

**PARTITION BY** The PARTITION BY clause specifies the columns that will be used to divide the selected rows into partitions based on the values of the specified columns.

**DIMENSION BY** The DIMENSION BY clause specifies the columns that will identify a row within a partition. The values of the dimension columns, along with those of the partition columns, serve as array indexes to the measure columns within a row.

**MEASURES** The MEASURES clause identifies the columns on which the calculations can be performed. Measure columns in individual rows are treated like cells that you can reference, by specifying the values for the partition and dimension columns, and update.

**cell_reference_options**
Use the cell_reference_options clause to specify how null and absent values are treated in rules and how column uniqueness is constrained.

**IGNORE NAV** When you specify IGNORE NAV, the database returns the following values for the null and absent values of the data type specified:
- Zero for numeric data types
- 01-JAN-2000 for datetime data types
- An empty string for character data types
- Null for all other data types
**KEEP NAV**  When you specify **KEEP NAV**, the database returns null for both null and absent cell values. **KEEP NAV** is the default.

**UNIQUE SINGLE REFERENCE**  When you specify **UNIQUE SINGLE REFERENCE**, the database checks only single-cell references on the right-hand side of the rule for uniqueness, not the entire query result set.

**UNIQUE DIMENSION**  When you specify **UNIQUE DIMENSION**, the database checks that the **PARTITION BY** and **DIMENSION BY** columns form a unique key to the query. **UNIQUE DIMENSION** is the default.

**model_rules_clause**

Use the **model_rules_clause** to specify the cells to be updated, the rules for updating those cells, and optionally, how the rules are to be applied and processed.

Each rule represents an assignment and consists of a left-hand side and right-hand side. The left-hand side of the rule identifies the cells to be updated by the right-hand side of the rule. The right-hand side of the rule evaluates to the values to be assigned to the cells specified on the left-hand side of the rule.

**UPSERT ALL**  **UPSERT ALL** allows **UPSERT** behavior for a rule with both positional and symbolic references on the left-hand side of the rule. When evaluating an **UPSERT ALL** rule, Oracle performs the following steps to create a list of cell references to be upserted:

1. Find the existing cells that satisfy all the symbolic predicates of the cell reference.
2. Using just the dimensions that have symbolic references, find the distinct dimension value combinations of these cells.
3. Perform a cross product of these value combinations with the dimension values specified by way of positional references.

Refer to **Oracle Database Data Warehousing Guide** for more information on the semantics of **UPSERT ALL**.

**UPSERT**  When you specify **UPSERT**, the database applies the rules to those cells referenced on the left-hand side of the rule that exist in the multidimensional array, and inserts new rows for those that do not exist. **UPSERT** behavior applies only when positional referencing is used on the left-hand side and a single cell is referenced. **UPSERT** is the default. Refer to **cell_assignment** on page 19-38 for more information on positional referencing and single-cell references.

**UPDATE and UPSERT** can be specified for individual rules as well. When either **UPDATE** or **UPSERT** is specified for a specific rule, it takes precedence over the option specified in the **RULES** clause.

---

**Notes on UPSERT [ALL] and UPDATE:**  If an **UPSERT ALL**, **UPSERT**, or **UPDATE** rule does not contain the appropriate predicates, then the database may implicitly convert it to a different type of rule:

- If an **UPSERT** rule contains an existential predicate, then the rule is treated as an **UPDATE** rule.
- An **UPSERT ALL** rule must have at least one existential predicate and one qualified predicate on its left side. If it has no existential predicate, then it is treated as an **UPSERT** rule. If it has no qualified predicate, then it is treated as an **UPDATE** rule.
**UPDATE**  When you specify `UPDATE`, the database applies the rules to those cells referenced on the left-hand side of the rule that exist in the multidimensional array. If the cells do not exist, then the assignment is ignored.

**AUTOMATIC ORDER**  When you specify `AUTOMATIC ORDER`, the database evaluates the rules based on their dependency order. In this case, a cell can be assigned a value once only.

**SEQUENTIAL ORDER**  When you specify `SEQUENTIAL ORDER`, the database evaluates the rules in the order they appear. In this case, a cell can be assigned a value more than once. `SEQUENTIAL ORDER` is the default.

**ITERATE ... [UNTIL]**  Use `ITERATE ... [UNTIL]` to specify the number of times to cycle through the rules and, optionally, an early termination condition. The parentheses around the `UNTIL` condition are optional.

When you specify `ITERATE ... [UNTIL]`, rules are evaluated in the order in which they appear. Oracle Database returns an error if both `AUTOMATIC ORDER` and `ITERATE ... [UNTIL]` are specified in the `model_rules_clause`.

**cell_assignment**
The `cell_assignment` clause, which is the left-hand side of the rule, specifies one or more cells to be updated. When a `cell_assignment` references a single cell, it is called a **single-cell reference**. When more than one cell is referenced, it is called a **multiple-cell reference**.

All dimension columns defined in the `model_clause` must be qualified in the `cell_assignment` clause. A dimension can be qualified using either symbolic or positional referencing.

A **symbolic reference** qualifies a single dimension column using a Boolean condition like `dimension_column=constant`. A **positional reference** is one where the dimension column is implied by its position in the `DIMENSION BY` clause. The only difference between symbolic references and positional references is in the treatment of nulls.

Using a single-cell symbolic reference such as `a[x=null,y=2000]`, no cells qualify because `x=null` evaluates to `FALSE`. However, using a single-cell positional reference such as `a[null,2000]`, a cell where `x` is null and `y` is 2000 qualifies because `null = null` evaluates to `TRUE`. With single-cell positional referencing, you can reference, update, and insert cells where dimension columns are null.

You can specify a condition or an expression representing a dimension column value using either symbolic or positional referencing. `condition` cannot contain aggregate functions or the `CV` function, and `condition` must reference a single dimension column. `expr` cannot contain a subquery. Refer to "Model Expressions" on page 5-13 for information on model expressions.

**single_column_for_loop**
The `single_column_for_loop` clause lets you specify a range of cells to be updated within a single dimension column.

The `IN` clause lets you specify the values of the dimension column as either a list of values or as a subquery. When using `subquery`, it cannot:

- Be a correlated query
- Return more than 10,000 rows
- Be a query defined in the `WITH` clause
The **FROM** clause lets you specify a range of values for a dimension column with discrete increments within the range. The **FROM** clause can only be used for those columns with a data type for which addition and subtraction is supported. The **INCREMENT** and **DECREMENT** values must be positive.

Optionally, you can specify the **LIKE** clause within the **FROM** clause. In the **LIKE** clause, **pattern** is a character string containing a single pattern-matching character `%`. This character is replaced during execution with the current incremented or decremented value in the **FROM** clause.

If all dimensions other than those used by a **FOR** loop involve a single-cell reference, then the expressions can insert new rows. The number of dimension value combinations generated by **FOR** loops is counted as part of the 10,000 row limit of the **MODEL** clause.

**multi_column_for_loop**

The **multi_column_for_loop** clause lets you specify a range of cells to be updated across multiple dimension columns. The **IN** clause lets you specify the values of the dimension columns as either multiple lists of values or as a subquery. When using **subquery**, it cannot:

- Be a correlated query
- Return more than 10,000 rows
- Be a query defined in the **WITH** clause

If all dimensions other than those used by a **FOR** loop involve a single-cell reference, then the expressions can insert new rows. The number of dimension value combinations generated by **FOR** loops is counted as part of the 10,000 row limit of the **MODEL** clause.

**See Also:** *Oracle Database Data Warehousing Guide* for more information about using **FOR** loops in the **MODEL** clause

**order_by_clause**

Use the **ORDER BY** clause to specify the order in which cells on the left-hand side of the rule are to be evaluated. The **expr** must resolve to a dimension or measure column. If the **ORDER BY** clause is not specified, then the order defaults to the order of the columns as specified in the **DIMENSION BY** clause. See **order_by_clause** on page 19-40 for more information.

**Restrictions on the order_by_clause** Use of the **ORDER BY** clause in the model rule is subject to the following restrictions:

- You cannot specify **SIBLINGS**, **position**, or **c_alias** in the **order_by_clause** of the **model_clause**.
- You cannot specify this clause on the left-hand side of the model rule and also specify a **FOR** loop on the right-hand side of the rule.

**expr**

Specify an expression representing the value or values of the cell or cells specified on the right-hand side of the rule. **expr** cannot contain a subquery. Refer to "Model Expressions" on page 5-13 for information on model expressions.
**return_rows_clause**

The `return_rows_clause` lets you specify whether to return all rows selected or only those rows updated by the model rules. `ALL` is the default.

**reference_model**

Use the `reference_model` clause when you need to access multiple arrays from inside the `model_clause`. This clause defines a read-only multidimensional array based on the results of a query.

The subclauses of the `reference_model` clause have the same semantics as for the `main_model` clause. Refer to `model_column_clauses` on page 19-36 and `cell_reference_options` on page 19-36.

**Restrictions on the reference_model clause** This clause is subject to the following restrictions:

- PARTITION BY columns cannot be specified for reference models.
- The subquery of the reference model cannot refer to columns in an outer subquery.

**Set Operators: UNION, UNION ALL, INTERSECT, MINUS**

The set operators combine the rows returned by two `SELECT` statements into a single result. The number and data types of the columns selected by each component query must be the same, but the column lengths can be different. The names of the columns in the result set are the names of the expressions in the select list preceding the set operator.

If you combine more than two queries with set operators, then the database evaluates adjacent queries from left to right. The parentheses around the subquery are optional. You can use them to specify a different order of evaluation.

Refer to "The UNION [ALL], INTERSECT, MINUS Operators" on page 9-8 for information on these operators, including restrictions on their use.

**order_by_clause**

Use the `ORDER BY` clause to order rows returned by the statement. Without an `order_by_clause`, no guarantee exists that the same query executed more than once will retrieve rows in the same order.

**SIBLINGS** The `SIBLINGS` keyword is valid only if you also specify the `hierarchical_query_clause` (`CONNECT BY`). ORDER SIBLINGS BY preserves any ordering specified in the hierarchical query clause and then applies the `order_by_clause` to the siblings of the hierarchy.

`expr expr` orders rows based on their value for `expr`. The expression is based on columns in the select list or columns in the tables, views, or materialized views in the `FROM` clause.

`position position` Specify `position` to order rows based on their value for the expression in this position of the select list. The `position` value must be an integer.

You can specify multiple expressions in the `order_by_clause`. Oracle Database first sorts rows based on their values for the first expression. Rows with the same value for the first expression are then sorted based on their values for the second expression, and so on. The database sorts nulls following all others in ascending order and preceding all others in descending order. Refer to "Sorting Query Results" on page 9-10 for a discussion of ordering query results.
ASC I DESC  Specify whether the ordering sequence is ascending or descending. ASC is the default.

NULLS FIRST | NULLS LAST  Specify whether returned rows containing null values should appear first or last in the ordering sequence.

NULLS LAST is the default for ascending order, and NULLS FIRST is the default for descending order.

Restrictions on the ORDER BY Clause  The following restrictions apply to the ORDER BY clause:

- If you have specified the DISTINCT operator in this statement, then this clause cannot refer to columns unless they appear in the select list.
- An order_by_clause can contain no more than 255 expressions.
- You cannot order by a LOB, LONG, or LONG RAW column, nested table, or varray.
- If you specify a group_by_clause in the same statement, then this order_by_clause is restricted to the following expressions:
  - Constants
  - Aggregate functions
  - Analytic functions
  - The functions USER, UID, and SYSDATE
  - Expressions identical to those in the group_by_clause
  - Expressions comprising the preceding expressions that evaluate to the same value for all rows in a group

See Also:  "Using the ORDER BY Clause: Examples" on page 19-62

row_limiting_clause

The row_limiting_clause allows you to limit the rows returned by the query. You can specify an offset, and the number of rows or percentage of rows to return. You can use this clause to implement top-N reporting. For consistent results, specify the order_by_clause to ensure a deterministic sort order.

OFFSET

Use this clause to specify the number of rows to skip before row limiting begins. offset must be a number or an expression that evaluates to a numeric value. If you specify a negative number, then offset is treated as 0. If you specify NULL, or a number greater than or equal to the number of rows returned by the query, then 0 rows are returned. If offset includes a fraction, then the fractional portion is truncated. If you do not specify this clause, then offset is 0 and row limiting begins with the first row.

ROW I ROWS  These keywords can be used interchangeably and are provided for semantic clarity.

FETCH

Use this clause to specify the number of rows or percentage of rows to return. If you do not specify this clause, then all rows are returned, beginning at row offset + 1.
FIRST | NEXT  These keywords can be used interchangeably and are provided for semantic clarity.

**rowcount | percent PERCENT**  Use rowcount to specify the number of rows to return. rowcount must be a number or an expression that evaluates to a numeric value. If you specify a negative number, then rowcount is treated as 0. If rowcount is greater than the number of rows available beginning at row offset + 1, then all available rows are returned. If rowcount includes a fraction, then the fractional portion is truncated. If rowcount is NULL, then 0 rows are returned.

Use percent PERCENT to specify the percentage of the total number of selected rows to return. percent must be a number or an expression that evaluates to a numeric value. If you specify a negative number, then percent is treated as 0. If percent is NULL, then 0 rows are returned.

If you do not specify rowcount or percent PERCENT, then 1 row is returned.

**ROW | ROWS**  These keywords can be used interchangeably and are provided for semantic clarity.

**ONLY | WITH TIES**  Specify ONLY to return exactly the specified number of rows or percentage of rows.

Specify WITH TIES to return additional rows with the same sort key as the last row fetched. If you specify WITH TIES, then you must specify the order_by_clause. If you do not specify the order_by_clause, then no additional rows will be returned.

**Restrictions on the row_limiting_clause**  This clause is subject to the following restrictions:

- You cannot specify this clause with the for_update_clause.
- If you specify this clause, then the select list cannot contain the sequence pseudocolumns CURRVAL or NEXTVAL.
- Materialized views are not eligible for an incremental refresh if the defining query contains the row_limiting_clause.
- If the select list contains columns with identical names and you specify the row_limiting_clause, then an ORA-00918 error occurs. This error occurs whether the identically named columns are in the same table or in different tables. You can work around this issue by specifying unique column aliases for the identically named columns.

See Also:  "Row Limiting: Examples" on page 19-65

**for_update_clause**  The FOR UPDATE clause lets you lock the selected rows so that other users cannot lock or update the rows until you end your transaction. You can specify this clause only in a top-level SELECT statement, not in subqueries.

---

**Note:**  Prior to updating a LOB value, you must lock the row containing the LOB. One way to lock the row is with an embedded SELECT ... FOR UPDATE statement. You can do this using one of the programmatic languages or DBMS_LOB package. For more information on lock rows before writing to a LOB, see Oracle Database SecureFiles and Large Objects Developer's Guide.
Nested table rows are not locked as a result of locking the parent table rows. If you want the nested table rows to be locked, then you must lock them explicitly.

**Restrictions on the FOR UPDATE Clause**  This clause is subject to the following restrictions:

- You cannot specify this clause with the following other constructs: the `DISTINCT` operator, `CURSOR` expression, set operators, `group_by_clause`, or aggregate functions.

- The tables locked by this clause must all be located on the same database and on the same database as any `LONG` columns and sequences referenced in the same statement.

  **See Also:** "Using the FOR UPDATE Clause: Examples" on page 19-66

**Using the FOR UPDATE Clause on Views**  In general, this clause is not supported on views. However, in some cases, a `SELECT ... FOR UPDATE` query on a view can succeed without any errors. This occurs when the view has been merged to its containing query block internally by the query optimizer, and `SELECT ... FOR UPDATE` succeeds on the internally transformed query. The examples in this section illustrate when using the `FOR UPDATE` clause on a view can succeed or fail.

- **Using the `FOR UPDATE` clause on merged views**

  An error can occur when you use the `FOR UPDATE` clause on a merged view if both of the following conditions apply:

  - The underlying column of the view is an expression
  - The `FOR UPDATE` clause applies to a column list

  The following statement succeeds because the underlying column of the view is not an expression:

  ```sql
  SELECT employee_id FROM (SELECT * FROM employees) FOR UPDATE OF employee_id;
  ```

  The following statement succeeds because, while the underlying column of the view is an expression, the `FOR UPDATE` clause does not apply to a column list:

  ```sql
  SELECT employee_id FROM (SELECT employee_id+1 AS employee_id FROM employees) FOR UPDATE;
  ```

  The following statement fails because the underlying column of the view is an expression and the `FOR UPDATE` clause applies to a column list:

  ```sql
  SELECT employee_id FROM (SELECT employee_id+1 AS employee_id FROM employees) FOR UPDATE OF employee_id;
  ```

  Error at line 2:

  ORA-01733: virtual column not allowed here

- **Using the `FOR UPDATE` clause on non-merged views**

  Since the `FOR UPDATE` clause is not supported on views, anything that prevents view merging, such as the `NO_MERGE` hint, parameters that disallow view merging, or something in the query structure that prevents view merging, will result in an `ORA-02014` error.
In the following example, the GROUP BY statement prevents view merging, which causes an error:

```sql
SELECT avgsal
FROM (SELECT AVG(salary) AS avgsal FROM employees GROUP BY job_id)
FOR UPDATE;
```

```
FROM (SELECT AVG(salary) AS avgsal FROM employees GROUP BY job_id)
* 
ERROR at line 2:
ORA-02014: cannot select FOR UPDATE from view with DISTINCT, GROUP BY, etc.
```

**Note:** Due to the complexity of the view merging mechanism, Oracle recommends against using the FOR UPDATE clause on views.

**OF ... column**

Use the `OF ... column` clause to lock the select rows only for a particular table or view in a join. The columns in the `OF` clause only indicate which table or view rows are locked. The specific columns that you specify are not significant. However, you must specify an actual column name, not a column alias. If you omit this clause, then the database locks the selected rows from all the tables in the query.

**NOWAIT | WAIT**

The `NOWAIT` and `WAIT` clauses let you tell the database how to proceed if the `SELECT` statement attempts to lock a row that is locked by another user.

- Specify `NOWAIT` to return control to you immediately if a lock exists.
- Specify `WAIT` to instruct the database to wait `integer` seconds for the row to become available and then return control to you.

If you specify neither `WAIT` nor `NOWAIT`, then the database waits until the row is available and then returns the results of the `SELECT` statement.

**SKIP LOCKED**

`SKIP LOCKED` is an alternative way to handle a contending transaction that is locking some rows of interest. Specify `SKIP LOCKED` to instruct the database to attempt to lock the rows specified by the `WHERE` clause and to skip any rows that are found to be already locked by another transaction. This feature is designed for use in multiconsumer queue environments, such as Oracle Streams Advanced Queuing. It enables queue consumers to skip rows that are locked by other consumers and obtain unlocked rows without waiting for the other consumers to finish. Oracle recommends that you use the Oracle Streams Advanced Queuing APIs instead of directly using the `SKIP LOCKED` functionality. Refer to Oracle Database Advanced Queuing User’s Guide for more information.

**Note on the WAIT and SKIP LOCKED Clauses**

If you specify `WAIT` or `SKIP LOCKED` and the table is locked in exclusive mode, then the database will not return the results of the `SELECT` statement until the lock on the table is released. In the case of `WAIT`, the `SELECT FOR UPDATE` clause is blocked regardless of the wait time specified.

**row_pattern_clause**

The `MATCH_RECOGNIZE` clause lets you perform pattern matching. Use this clause to recognize patterns in a sequence of rows in `table`, which is called the row pattern input table. The result of a query that uses the `MATCH_RECOGNIZE` clause is called the row pattern output table.
The MATCH_RECOGNIZE enables you to do the following tasks:

- Logically partition and order the data with the PARTITION BY and ORDER BY clauses.
- Define measures, which are expressions usable in other parts of the SQL query, in the MEASURES clause.
- Define patterns of rows to seek using the PATTERN clause. These patterns use regular expression syntax, a powerful and expressive feature, applied to the pattern variables you define.
- Specify the logical conditions required to map a row to a row pattern variable in the DEFINE clause.

See Also:

- Oracle Database Data Warehousing Guide for more information on pattern matching
- "Row Pattern Matching: Example" on page 19-77

**row_pattern_partition_by**

Specify PARTITION BY to divide the rows in the row pattern input table into logical groups called row pattern partitions. Use column to specify one or more partitioning columns. Each partition consists of the set of rows in the row pattern input table that have the same value(s) on the partitioning column(s).

If you specify this clause, then matches are found within partitions and do not cross partition boundaries. If you do not specify this clause, then all rows of the row input table constitute a single row pattern partition.

**row_pattern_order_by**

Specify ORDER BY to order rows within each row pattern partition. Use column to specify one or more ordering columns. If you specify multiple columns, then Oracle Database first sorts rows based on their values for the first column. Rows with the same value for the first column are then sorted based on their values for the second column, and so on. Oracle Database sorts nulls following all others in ascending order.

If you do not specify this clause, then the result of the row_pattern_clause is nondeterministic and you may get inconsistent results each time you run the query.

**row_pattern_measures**

Use the MEASURES clause to define one or more row pattern measure columns. These columns are included in the row pattern output table and contain values that are useful for analyzing data.

When you define a row pattern measure column, using the row_pattern_measure_column clause, you specify its pattern measure expression. The values in the column are calculated by evaluating the pattern measure expression whenever a match is found.

**row_pattern_measure_column**

Use this clause to define a row pattern measure column.

- For expr, specify the pattern measure expression. A pattern measure expression is an expression as described in Chapter 5, "Expressions" that can contain only the following elements:
  - Constants: Text literals and numeric literals
- References to any column of the row pattern input table

- The CLASSIFIER function, which returns the name of the primary row pattern variable to which the row is mapped. Refer to row_pattern_classifier_func on page 19-51 for more information.

- The MATCH_NUMBER function, which returns the sequential number of a row pattern match within the row pattern partition. Refer to row_pattern_match_num_func on page 19-51 for more information.

- Row pattern navigation functions: PREV, NEXT, FIRST, and LAST. Refer to row_pattern_navigation_func on page 19-51 for more information.

- Row pattern aggregate functions: AVG, COUNT, MAX, MIN, or SUM. Refer to row_pattern_aggregate_func on page 19-53 for more information.

- For c_alias, specify the alias for the pattern measure expression. Oracle Database uses this alias in the column heading of the row pattern output table. The AS keyword is optional. The alias can be used in other parts of the query, such as the SELECT ... ORDER BY clause.

row_pattern_rows_per_match

This clause lets you specify whether the row pattern output table includes summary or detailed data about each match.

- If you specify ONE ROW PER MATCH, then each match produces one summary row. This is the default.

- If you specify ALL ROWS PER MATCH, then each match that spans multiple rows will produce one output row for each row in the match.

row_pattern_skip_to

This clause lets you specify the point to resume row pattern matching after a non-empty match is found.

- Specify AFTER MATCH SKIP TO NEXT ROW to resume pattern matching at the row after the first row of the current match.

- Specify AFTER MATCH SKIP PAST LAST ROW to resume pattern matching at the next row after the last row of the current match. This is the default.

- Specify AFTER MATCH SKIP TO FIRST variable_name to resume pattern matching at the first row that is mapped to pattern variable variable_name. The variable_name must be defined in the DEFINE clause.

- Specify AFTER MATCH SKIP TO LAST variable_name to resume pattern matching at the last row that is mapped to pattern variable variable_name. The variable_name must be defined in the DEFINE clause.

- SPECIFIC MATCH SKIP TO variable_name has the same behavior as AFTER MATCH SKIP TO LAST variable_name.

See Also: Oracle Database Data Warehousing Guide for more information on the AFTER MATCH SKIP clauses

PATTERN

Use the PATTERN clause to define which pattern variables must be matched, the sequence in which they must be matched, and the quantity of rows that must be matched for each pattern variable.
A row pattern match consists of a set of contiguous rows in a row pattern partition. Each row of the match is mapped to a pattern variable. The mapping of rows to pattern variables must conform to the regular expression specified in the row_pattern clause, and all conditions in the DEFINE clause must be true.

---

**Note:** It is outside the scope of this document to explain regular expression concepts and details. If you are not familiar with regular expressions, then you are encouraged to familiarize yourself with the topic using other sources.

---

The precedence of the elements that you specify in the regular expression of the PATTERNS clause, in decreasing order, is as follows:

- Row pattern elements (specified in the row_pattern_primary clause)
- Row pattern quantifiers (specified in the row_pattern_quantifier clause)
- Concatenation (specified in the row_pattern_term clause)
- Alternation (specified in the row_pattern clause)

**See Also:** Oracle Database Data Warehousing Guide for more information on the PATTERNS clause

**row_pattern**

Use this clause to specify the row pattern. A row pattern is a regular expression that can take one of the following forms:

- A single row pattern term
  For example: PATTERN(A)

- A row pattern, a vertical bar, and a row pattern term
  For example: PATTERN(A|B)

- A recursively built row pattern, a vertical bar, and a row pattern term
  For example: PATTERN(A|B|C)

The vertical bar in this clause represents **alternation**. Alternation matches a single regular expression from a list of several possible regular expressions. Alternatives are preferred in the order they are specified. For example, if you specify PATTERN(A|B|C), then Oracle Database attempts to match A first. If A is not matched, then it attempts to match B. If B is not matched, then it attempts to match C.

**row_pattern_term**

This clause lets you specify a row pattern term. A row pattern term can take one of the following forms:

- A single row pattern factor
  For example: PATTERN(A)

- A row pattern term followed by a row pattern factor.
  For example: PATTERN(A B)

- A recursively built row pattern term followed by a row pattern factor
  For example: PATTERN(A B C)
The syntax used in the second and third examples represents **concatenation**. Concatenation is used to list two or more items in a pattern to be matched and the order in which they are to be matched. For example, if you specify `PATTERN(A B C)`, then Oracle Database first matches `A`, then uses the resulting matched rows to match `B`, then uses the resulting matched rows to match `C`. Only rows that match `A`, `B`, and `C`, are included in the row pattern match.

**row_pattern_factor**

This clause lets you specify a row pattern factor. A row pattern factor consists of a row pattern element, specified using the `row_pattern_primary` clause, and an optional row pattern quantifier, specified using the `row_pattern_quantifier` clause.

**row_pattern_primary**

Use this clause to specify the row pattern element. Table 19–1 lists the valid row pattern elements and their descriptions.

<table>
<thead>
<tr>
<th>Row Pattern Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>variable_name</code></td>
<td>Specify a primary pattern variable name that is defined in the <code>row_pattern_definition</code> clause. You cannot specify a union pattern variable that is defined in the <code>row_pattern_subset_item</code> clause.</td>
</tr>
<tr>
<td><code>^</code></td>
<td>^ matches the position before the first row in the partition. This element is an anchor. Anchors work in terms of positions rather than rows.</td>
</tr>
<tr>
<td><code>\$</code></td>
<td>$ matches the position after the last row in the partition. This element is an anchor. Anchors work in terms of positions rather than rows.</td>
</tr>
<tr>
<td><code>([row_pattern])</code></td>
<td>Use <code>row_pattern</code> to specify the row pattern to be matched. An empty pattern () matches an empty set of rows.</td>
</tr>
<tr>
<td><code>{~ row_pattern ~}</code></td>
<td>Exclusion syntax. Use <code>row_pattern</code> to specify parts of the pattern to be excluded from the output of <code>ALL ROWS PER MATCH</code>.</td>
</tr>
<tr>
<td><code>row_pattern_permute</code></td>
<td>Use <code>row_pattern_permute</code> to specify a pattern that is a permutation of row pattern elements. Refer to <code>row_pattern_permute</code> on page 19-48 for the full semantics of this clause.</td>
</tr>
</tbody>
</table>

**row_pattern_permute**

Use the `PERMUTE` clause to express a pattern that is a permutation of the specified row pattern elements. For example, `PATTERN (PERMUTE (A, B, C))` is equivalent to an alternation of all permutations of the three row pattern elements `A`, `B`, and `C`, similar to the following:

```
PATTERN (A B C | A C B | B A C | B C A | C A B | C B A)
```

Note that the row pattern elements are expanded lexicographically and that each element to permute must be separated by a comma from the other elements.

**See Also:** Oracle Database Data Warehousing Guide for more information on permutations

**row_pattern_quantifier**

Use this clause to specify the row pattern quantifier, which is a postfix operator that defines the number of iterations accepted for a match.
Row pattern quantifiers are referred to as greedy; they will attempt to match as many instances of the regular expression on which they are applied as possible. The exception is row pattern quantifiers that have a question mark (?) as a suffix, which are referred to as reluctant. They will attempt to match as few instances as possible of the regular expression on which they are applied.

Table 19–2 lists the valid row pattern quantifiers and the number of iterations they accept for a match. In this table, \( n \) and \( m \) represent unsigned integers.

<table>
<thead>
<tr>
<th>Row Pattern Quantifier</th>
<th>Number of Iterations Accepted for a Match</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>0 or more iterations (greedy)</td>
</tr>
<tr>
<td>*?</td>
<td>0 or more iterations (reluctant)</td>
</tr>
<tr>
<td>+</td>
<td>1 or more iterations (greedy)</td>
</tr>
<tr>
<td>+?</td>
<td>1 or more iterations (reluctant)</td>
</tr>
<tr>
<td>?</td>
<td>0 or 1 iterations (greedy)</td>
</tr>
<tr>
<td>??</td>
<td>0 or 1 iterations (reluctant)</td>
</tr>
<tr>
<td>((n,))</td>
<td>( n ) or more iterations, ( (n &gt;= 0) ) (greedy)</td>
</tr>
<tr>
<td>((n,)?)</td>
<td>( n ) or more iterations, ( (n &gt;= 0) ) (reluctant)</td>
</tr>
<tr>
<td>((n,m))</td>
<td>Between ( n ) and ( m ) iterations, inclusive, ( (0 &lt;= n &lt;= m, 0 &lt; m) ) (greedy)</td>
</tr>
<tr>
<td>((n,m)?)</td>
<td>Between ( n ) and ( m ) iterations, inclusive, ( (0 &lt;= n &lt;= m, 0 &lt; m) ) (reluctant)</td>
</tr>
<tr>
<td>((,m))</td>
<td>Between 0 and ( m ) iterations, inclusive ( (m &gt; 0) ) (greedy)</td>
</tr>
<tr>
<td>((,m)?)</td>
<td>Between 0 and ( m ) iterations, inclusive ( (m &gt; 0) ) (reluctant)</td>
</tr>
<tr>
<td>((n)?)</td>
<td>( n ) iterations, ( (n &gt; 0) )</td>
</tr>
</tbody>
</table>

See Also: Oracle Database Data Warehousing Guide for more information on row pattern quantifiers

**row_pattern_subset_clause**

The `SUBSET` clause lets you specify one or more union row pattern variables. Use the `row_pattern_subset_item` clause to declare each union row pattern variable.

You can specify union row pattern variables in the following clauses:

- **MEASURES** clause: In the expression for a row pattern measure column. That is, in expression `expr` of the `row_pattern_measure_column` clause.
- **DEFINE** clause: In the condition that defines a primary pattern variable. That is, in condition of the `row_pattern_definition` clause

**row_pattern_subset_item**

This clause lets you create a grouping of multiple pattern variables that can be referred to with a variable name of its own. The variable name that refers to this grouping is called a union row pattern variable.

- For `variable_name` on the left side of the equal sign, specify the name of the union row pattern variable.
On the right side of the equal sign, specify a comma-separated list of distinct primary row pattern variables within parentheses. This list cannot include any union row pattern variables.

**See Also:** Oracle Database Data Warehousing Guide for more information on defining union row pattern variables

### DEFINE

Use the `DEFINE` clause to specify one or more row pattern definitions. A row pattern definition specifies the conditions that a row must meet in order to be mapped to a specific pattern variable.

The `DEFINE` clause only supports running semantics.

**See Also:**
- Oracle Database Data Warehousing Guide for more information on the `DEFINE` clause
- Oracle Database Data Warehousing Guide for more information on running and final semantics

#### row_pattern_definition_list

This clause lets you specify one or more row pattern definitions.

#### row_pattern_definition

This clause lets you specify a row pattern definition, which contains the conditions that a row must meet in order to be mapped to the specified pattern variable.

- For `variable_name`, specify the name of the pattern variable.
- For `condition`, specify a condition as described in Chapter 6, "Conditions", with the following extension: `condition` can contain any of the functions described by `row_pattern_navigation_func::= on page 19-16` and `row_pattern_aggregate_func::= on page 19-17`.

#### row_pattern_rec_func

This clause comprises the following clauses, which let you specify row pattern recognition functions:

- `row_pattern_classifier_func`: Use this clause to specify the `CLASSIFIER` function, which returns a character string whose value is the name of the variable to which the row is mapped.
- `row_pattern_match_num_func`: Use this clause to specify the `MATCH_NUMBER` function, which returns a numeric value with scale 0 (zero) whose value is the sequential number of the match within the row pattern partition.
- `row_pattern_navigation_func`: Use this clause to specify functions that perform row pattern navigation operations.
- `row_pattern_aggregate_func`: Use this clause to specify an aggregate function in the expression for a row pattern measure column or in the condition that defines a primary pattern variable.

You can specify row pattern recognition functions in the following clauses:

- `MEASURES` clause: In the expression for a row pattern measure column. That is, in expression `expr` of the `row_pattern_measure_column` clause.
- **DEFINE clause**: In the condition that defines a primary pattern variable. That is, in condition of the `row_pattern_definition` clause.

A row pattern recognition function may behave differently depending whether you specify it in the **MEASURES** or **DEFINE** clause. These details are explained in the semantics for each clause.

### `row_pattern_classifier_func`

The `CLASSIFIER` function returns a character string whose value is the name of the variable to which the row is mapped.

- **In the **MEASURES** clause:**
  - If you specify **ONE ROW PER MATCH**, then the query uses the last row of the match when processing the **MEASURES** clause, so the `CLASSIFIER` function returns the name of the pattern variable to which the last row of the match is mapped.
  - If you specify **ALL ROWS PER MATCH**, then for each row of the match found, the `CLASSIFIER` function returns the name of the pattern variable to which the row is mapped.

  For empty matches—that is, matches that contain no rows, the `CLASSIFIER` function returns NULL.

- **In the **DEFINE** clause**, the `CLASSIFIER` function returns the name of the primary pattern variable to which the current row is mapped.

### `row_pattern_match_num_func`

The `MATCH_NUMBER` function returns a numeric value with scale 0 (zero) whose value is the sequential number of the match within the row pattern partition.

Matches within a row pattern partition are numbered sequentially starting with 1 in the order in which they are found. If multiple rows satisfy a match, then they are all assigned the same match number. Note that match numbering starts over again at 1 in each row pattern partition, because there is no inherent ordering between row pattern partitions.

- **In the **MEASURES** clause**: You can use `MATCH_NUMBER` to obtain the sequential number of the match within the row pattern.

- **In the **DEFINE** clause**: You can use `MATCH_NUMBER` to define conditions that depend upon the match number.

### `row_pattern_navigation_func`

This clause lets you perform the following row pattern navigation operations:

- Navigate among the group of rows mapped to a pattern variable using the `FIRST` and `LAST` functions of the `row_pattern_nav_logical` clause.

- Navigate among all rows in a row pattern partition using the `PREV` and `NEXT` functions of the `row_pattern_nav_physical` clause.

- Nest the `FIRST` or `LAST` function within the `PREV` or `NEXT` function using the `row_pattern_nav_compound` clause.

### `row_pattern_nav_logical`

This clause lets you use the `FIRST` and `LAST` functions to navigate among the group of rows mapped to a pattern variable using an optional logical offset.
The **FIRST** function returns the value of expression *expr* when evaluated in the first row of the group of rows mapped to the pattern variable that is specified in *expr*. If no rows are mapped to the pattern variable, then the **FIRST** function returns NULL.

The **LAST** function returns the value of expression *expr* when evaluated in the last row of the group of rows mapped to the pattern variable that is specified in *expr*. If no rows are mapped to the pattern variable, then the **LAST** function returns NULL.

Use *expr* to specify the expression to be evaluated. It must contain at least one row pattern column reference. If it contains more than one row pattern column reference, then all must refer to the same pattern variable.

Use the optional *offset* to specify the logical offset within the set of rows mapped to the pattern variable. When specified with the **FIRST** function, the offset is the number of rows from the first row, in ascending order. When specified with the **LAST** function, the offset is the number of rows from the last row in descending order. The default offset is 0.

For *offset*, specify a non-negative integer. It must be a runtime constant (literal, bind variable, or expressions involving them), but not a column or subquery.

If you specify an *offset* that is greater than or equal to the number of rows mapped to the pattern variable minus 1, then the function returns NULL.

You can specify running or final semantics for the **FIRST** and **LAST** functions as follows:

- The **MEASURES** clause supports running and final semantics. Specify **RUNNING** for running semantics. Specify **FINAL** for final semantics. The default is **RUNNING**.
- The **DEFINE** clause supports only running semantics. Therefore, running semantics will be used whether you specify or omit **RUNNING**. You cannot specify **FINAL**.

### See Also:
- Oracle Database Data Warehousing Guide for more information on the **FIRST** and **LAST** functions
- Oracle Database Data Warehousing Guide for more information on running and final semantics

**row_pattern_nav_physical**

This clause lets you use the **PREV** and **NEXT** functions to navigate all rows in a row pattern partition using an optional physical offset.

- The **PREV** function returns the value of expression *expr* when evaluated in the previous row in the partition. If there is no previous row in the partition, then the **PREV** function returns NULL.
- The **NEXT** function returns the value of expression *expr* when evaluated in the next row in the partition. If there is no next row in the partition, then the **NEXT** function returns NULL.
- Use *expr* to specify the expression to be evaluated. It must contain at least one row pattern column reference. If it contains more than one row pattern column reference, then all must refer to the same pattern variable.
- Use the optional *offset* to specify the physical offset within the partition. When specified with the **PREV** function, it is the number of rows before the current row. When specified with the **NEXT** function, it is the number of rows after the current row.
row. The default is 1. If you specify an offset of 0, then the current row is evaluated.

For offset, specify a non-negative integer. It must be a runtime constant (literal, bind variable, or expressions involving them), but not a column or subquery.

The PREV and NEXT functions always use running semantics. Therefore, you cannot specify the RUNNING or FINAL keywords with this clause.

**See Also:**
- Oracle Database Data Warehousing Guide for more information on the PREV and NEXT functions
- Oracle Database Data Warehousing Guide for more information on running and final semantics

**row_pattern_nav_compound**

This clause lets you nest the row_pattern_nav_logical clause within the row_pattern_nav_physical clause. That is, it lets you nest the FIRST or LAST function within the PREV or NEXT function. The row_pattern_nav_logical clause is evaluated first and then the result is supplied to the row_pattern_nav_physical clause.

Refer to row_pattern_nav_logical on page 19-51 and row_pattern_nav_physical on page 19-52 for the full semantics of these clauses.

**See Also:** Oracle Database Data Warehousing Guide for more information on nesting the FIRST and LAST functions within the PREV and NEXT functions

**row_pattern_aggregate_func**

This clause lets you use an aggregate function in the expression for a row pattern measure column or in the condition that defines a primary pattern variable.

For aggregate_function, specify any one of the AVG, COUNT, MAX, MIN, or SUM functions. The DISTINCT keyword is not supported.

You can specify running or final semantics for aggregate functions as follows:

- The MEASURES clause supports running and final semantics. Specify RUNNING for running semantics. Specify FINAL for final semantics. The default is RUNNING.
- The DEFINE clause supports only running semantics. Therefore, running semantics will be used whether you specify or omit RUNNING. You cannot specify FINAL.

**See Also:**
- Oracle Database Data Warehousing Guide for more information on aggregate functions
- Oracle Database Data Warehousing Guide for more information on running and final semantics

**Examples**

**Using a PL/SQL Function in the WITH Clause: Examples** The following example declares and defines a PL/SQL function get_domain in the WITH clause. The get_domain function returns the domain name from a URL string, assuming that the URL string has the "www" prefix immediately preceding the domain name, and the domain
name is separated by dots on the left and right. The SELECT statement uses get_domain to find distinct catalog domain names from the orders table in the oe schema.

WITH
FUNCTION get_domain(url VARCHAR2) RETURN VARCHAR2 IS
  pos BINARY_INTEGER;
  len BINARY_INTEGER;
BEGIN
  pos := INSTR(url, 'www.);
  len := INSTR(SUBSTR(url, pos + 4), '.') - 1;
  RETURN SUBSTR(url, pos + 4, len);
END;
SELECT DISTINCT get_domain(catalog_url)
FROM product_information;
/

Subquery Factoring: Example The following statement creates the query names dept_costs and avg_cost for the initial query block containing a join, and then uses the query names in the body of the main query.

WITH
depth_costs AS {
  SELECT department_name, SUM(salary) dept_total
  FROM employees e, departments d
  WHERE e.department_id = d.department_id
  GROUP BY department_name,
  avg_cost AS {
  SELECT SUM(dept_total)/COUNT(*) avg
  FROM dept_costs
  SELECT * FROM dept_costs
  WHERE dept_total >
   (SELECT avg FROM avg_cost)
  ORDER BY department_name;

DEPARTMENT_NAME DEPT_TOTAL
--------------------- ----------
Sales              304500
Shipping           156400

Recursive Subquery Factoring: Examples The following statement shows the employees who directly or indirectly report to employee 101 and their reporting level.

WITH
reports_to_101 (eid, emp_last, mgr_id, reportLevel) AS
{
  SELECT employee_id, last_name, manager_id, 0 reportLevel
  FROM employees
  WHERE employee_id = 101
  UNION ALL
  SELECT e.employee_id, e.last_name, e.manager_id, reportLevel+1
  FROM reports_to_101 r, employees e
  WHERE r.eid = e.manager_id
}
SELECT eid, emp_last, mgr_id, reportLevel
FROM reports_to_101
ORDER BY reportLevel, eid;

EID EMP_LAST MGR_ID REPORTLEVEL
---------- ------------------ ------------
101 Kochhar 100           0
108 Greenberg 101          1
The following statement shows employees who directly or indirectly report to employee 101, their reporting level, and their management chain.

WITH
  reports_to_101 (eid, emp_last, mgr_id, reportLevel, mgr_list) AS
  {
    SELECT employee_id, last_name, manager_id, 0 reportLevel,
           CAST(manager_id AS VARCHAR2(2000))
    FROM employees
    WHERE employee_id = 101
    UNION ALL
    SELECT e.employee_id, e.last_name, e.manager_id, reportLevel+1,
           CAST(mgr_list || ',' || manager_id AS VARCHAR2(2000))
    FROM reports_to_101 r, employees e
    WHERE r.eid = e.manager_id
  }

SELECT eid, emp_last, mgr_id, reportLevel, mgr_list
FROM reports_to_101
ORDER BY reportLevel, eid;

The following statement shows the employees who directly or indirectly report to employee 101 and their reporting level. It stops at reporting level 1.

WITH
  reports_to_101 (eid, emp_last, mgr_id, reportLevel) AS
  {
    SELECT employee_id, last_name, manager_id, 0 reportLevel
    FROM employees
    WHERE employee_id = 101
    UNION ALL
    SELECT e.employee_id, e.last_name, e.manager_id, reportLevel+1
    FROM reports_to_101 r, employees e
    WHERE r.eid = e.manager_id
  }

SELECT eid, emp_last, mgr_id, reportLevel
FROM reports_to_101
ORDER BY reportLevel, eid;

SELECT
200 Whalen        101  1
203 Mavris         101  1
204 Baer           101  1
205 Higgins        101  1
109 Faviet         108  2
110 Chen           108  2
111 Sciarra        108  2
112 Urman          108  2
113 Popp           108  2
206 Gietz          205  2

The following statement shows the employees who directly or indirectly report to employee 101 and their reporting level. It stops at reporting level 1.

WITH
  reports_to_101 (eid, emp_last, mgr_id, reportLevel) AS
  {
    SELECT employee_id, last_name, manager_id, 0 reportLevel
    FROM employees
    WHERE employee_id = 101
    UNION ALL
    SELECT e.employee_id, e.last_name, e.manager_id, reportLevel+1
    FROM reports_to_101 r, employees e
    WHERE r.eid = e.manager_id
  }

SELECT eid, emp_last, mgr_id, reportLevel
FROM reports_to_101
ORDER BY reportLevel, eid;

SELECT

</table>
**Simple Query Examples**  The following statement selects rows from the `employees` table with the department number of 30:

```
SELECT *
FROM employees
WHERE department_id = 30
ORDER BY last_name;
```

The following statement selects the name, job, salary and department number of all employees except purchasing clerks from department number 30:

```
SELECT last_name, job_id, salary, department_id
FROM employees
WHERE NOT (job_id = 'PU_CLERK' AND department_id = 30)
ORDER BY last_name;
```

The following statement selects from subqueries in the `FROM` clause and for each department returns the total employees and salaries as a decimal value of all the departments:

```
SELECT a.department_id 'Department',
       a.num_emp/b.total_count 'Employees',
       a.sal_sum/b.total_sal 'Salary'
FROM
(SELECT department_id, COUNT(*) num_emp, SUM(salary) sal_sum
     FROM employees
     GROUP BY department_id) a,
(SELECT COUNT(*) total_count, SUM(salary) total_sal
     FROM employees) b
ORDER BY a.department_id;
```

**Selecting from a Partition: Example**  You can select rows from a single partition of a partitioned table by specifying the keyword `PARTITION` in the `FROM` clause. This SQL statement assigns an alias for and retrieves rows from the `sales_q2_2000` partition of the sample table `sh.sales`:

```
SELECT * FROM sales PARTITION (sales_q2_2000) s
WHERE s.amount_sold > 1500
ORDER BY cust_id, time_id, channel_id;
```

The following example selects rows from the `oe.orders` table for orders earlier than a specified date:

```
SELECT * FROM orders
WHERE order_date < TO_DATE('2006-06-15', 'YYYY-MM-DD');
```

**Selecting a Sample: Examples**  The following query estimates the number of orders in the `oe.orders` table:

```
SELECT COUNT(*) * 10 FROM orders SAMPLE (10);
```

```
COUNT(*)*10
-----------
  70
```

Because the query returns an estimate, the actual return value may differ from one query to the next.

```
SELECT COUNT(*) * 10 FROM orders SAMPLE (10);
```
The following query adds a seed value to the preceding query. Oracle Database always returns the same estimate given the same seed value:

```
SELECT COUNT(*) * 10 FROM orders SAMPLE(10) SEED (1);
```

```
COUNT(*)*10
-----------
130
```

```
SELECT COUNT(*) * 10 FROM orders SAMPLE(10) SEED(4);
```

```
COUNT(*)*10
-----------
120
```

```
SELECT COUNT(*) * 10 FROM orders SAMPLE(10) SEED (1);
```

```
COUNT(*)*10
-----------
130
```

**Using Flashback Queries: Example**  The following statements show a current value from the sample table `hr.employees` and then change the value. The intervals used in these examples are very short for demonstration purposes. Time intervals in your own environment are likely to be larger.

```
SELECT salary FROM employees
  WHERE last_name = 'Chung';
```

```
SALARY
----------
3800
```

```
UPDATE employees SET salary = 4000
  WHERE last_name = 'Chung';
1 row updated.
```

```
SELECT salary FROM employees
  WHERE last_name = 'Chung';
```

```
SALARY
----------
4000
```

To learn what the value was before the update, you can use the following Flashback Query:

```
SELECT salary FROM employees
  AS OF TIMESTAMP (SYSTIMESTAMP - INTERVAL '1' MINUTE)
  WHERE last_name = 'Chung';
```

```
SALARY
----------
3800
```
To learn what the values were during a particular time period, you can use a version Flashback Query:

SELECT salary FROM employees
VERSIONS BETWEEN TIMESTAMP SYSTIMESTAMP - INTERVAL '10' MINUTE AND SYSTIMESTAMP - INTERVAL '1' MINUTE
WHERE last_name = 'Chung';

To revert to the earlier value, use the Flashback Query as the subquery of another UPDATE statement:

UPDATE employees SET salary =
(SELECT salary FROM employees
AS OF TIMESTAMP (SYSTIMESTAMP - INTERVAL '2' MINUTE)
WHERE last_name = 'Chung')
WHERE last_name = 'Chung';
1 row updated.

SELECT salary FROM employees
WHERE last_name = 'Chung';

SALARY
----------
3800

Using the GROUP BY Clause: Examples
To return the minimum and maximum salaries for each department in the employees table, issue the following statement:

SELECT department_id, MIN(salary), MAX(salary)
FROM employees
GROUP BY department_id
ORDER BY department_id;

To return the minimum and maximum salaries for the clerks in each department, issue the following statement:

SELECT department_id, MIN(salary), MAX(salary)
FROM employees
WHERE job_id = 'PU_CLERK'
GROUP BY department_id
ORDER BY department_id;

Using the GROUP BY CUBE Clause: Example
To return the number of employees and their average yearly salary across all possible combinations of department and job category, issue the following query on the sample tables hr.employees and hr.departments:

SELECT DECODE(GROUPING(department_name), 1, 'All Departments', department_name) AS department_name,
    DECODE(GROUPING(job_id), 1, 'All Jobs', job_id) AS job_id,
    COUNT(*) "Total Empl", AVG(salary) * 12 "Average Sal"
FROM employees e, departments d
WHERE d.department_id = e.department_id
GROUP BY CUBE (department_name, job_id)
ORDER BY department_name, job_id;

<table>
<thead>
<tr>
<th>DEPARTMENT_NAME</th>
<th>JOB_ID</th>
<th>Total Empl</th>
<th>Average Sal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accounting</td>
<td>AC_ACCOUNT</td>
<td>1</td>
<td>99600</td>
</tr>
<tr>
<td>Accounting</td>
<td>AC_MGR</td>
<td>1</td>
<td>144000</td>
</tr>
</tbody>
</table>
Using the GROUPING SETS Clause: Example  The following example finds the sum of sales aggregated for three precisely specified groups:

- (channel_desc, calendar_month_desc, country_id)
- (channel_desc, country_id)
- (calendar_month_desc, country_id)

Without the GROUPING SETS syntax, you would have to write less efficient queries with more complicated SQL. For example, you could run three separate queries and UNION them, or run a query with a CUBE(channel_desc, calendar_month_desc, country_id) operation and filter out five of the eight groups it would generate.

```
SELECT channel_desc, calendar_month_desc, co.country_id,
       TO_CHAR(sum(amount_sold) , '9,999,999,999') SALES$
FROM sales, customers, times, channels, countries co
WHERE sales.time_id=times.time_id
  AND sales.cust_id=customers.cust_id
  AND sales.channel_id= channels.channel_id
  AND customers.country_id = co.country_id
  AND channels.channel_desc IN ('Direct Sales', 'Internet')
  AND times.calendar_month_desc IN ('2000-09', '2000-10')
  AND co.country_iso_code IN ('UK', 'US')
GROUP BY GROUPING SETS(
    (channel_desc, calendar_month_desc, co.country_id),
    (channel_desc, co.country_id),
    (calendar_month_desc, co.country_id) );
```

<table>
<thead>
<tr>
<th>CHANNEL_DESC</th>
<th>CALENDAR</th>
<th>COUNTRY_ID</th>
<th>SALES$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Internet</td>
<td>2000-09</td>
<td>52790</td>
<td>124,224</td>
</tr>
<tr>
<td>Direct Sales</td>
<td>2000-09</td>
<td>52790</td>
<td>638,201</td>
</tr>
<tr>
<td>Internet</td>
<td>2000-10</td>
<td>52790</td>
<td>137,054</td>
</tr>
<tr>
<td>Direct Sales</td>
<td>2000-10</td>
<td>52790</td>
<td>682,297</td>
</tr>
<tr>
<td></td>
<td>2000-09</td>
<td>52790</td>

<td>52790</td>
<td></td>
<td>1,320,497</td>
</tr>
</tbody>
</table>

See Also: The functions GROUP_ID, GROUPING, and GROUPING_ID on page 7-130 for more information on those functions

Hierarchical Query Examples  The following query with a CONNECT BY clause defines a hierarchical relationship in which the employee_id value of the parent row is equal to the manager_id value of the child row:

```
SELECT last_name, employee_id, manager_id FROM employees
  CONNECT BY employee_id = manager_id
ORDER BY last_name;
```

In the following CONNECT BY clause, the PRIOR operator applies only to the employee_id value. To evaluate this condition, the database evaluates employee_id values for the parent row and manager_id, salary, and commission_pct values for the child row:
SELECT last_name, employee_id, manager_id FROM employees
    CONNECT BY PRIOR employee_id = manager_id
    AND salary > commission_pct
    ORDER BY last_name;

To qualify as a child row, a row must have a manager_id value equal to the employee_id value of the parent row and it must have a salary value greater than its commission_pct value.

Using the HAVING Condition: Example  To return the minimum and maximum salaries for the employees in each department whose lowest salary is less than $5,000, issue the next statement:

```
SELECT department_id, MIN(salary), MAX(salary)
    FROM employees
    GROUP BY department_id
    HAVING MIN(salary) < 5000
    ORDER BY department_id;
```

<table>
<thead>
<tr>
<th>DEPARTMENT_ID</th>
<th>MIN(SALARY)</th>
<th>MAX(SALARY)</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>4400</td>
<td>4400</td>
</tr>
<tr>
<td>30</td>
<td>2500</td>
<td>11000</td>
</tr>
<tr>
<td>50</td>
<td>2100</td>
<td>8200</td>
</tr>
<tr>
<td>60</td>
<td>4200</td>
<td>9000</td>
</tr>
</tbody>
</table>

The following example uses a correlated subquery in a HAVING clause that eliminates from the result set any departments without managers and managers without departments:

```
SELECT department_id, manager_id
    FROM employees
    GROUP BY department_id, manager_id HAVING (department_id, manager_id) IN
    (SELECT department_id, manager_id FROM employees x
    WHERE x.department_id = employees.department_id)
    ORDER BY department_id;
```

Using the ORDER BY Clause: Examples  To select all purchasing clerk records from employees and order the results by salary in descending order, issue the following statement:

```
SELECT *
    FROM employees
    WHERE job_id = 'PU_CLERK'
    ORDER BY salary DESC;
```

To select information from employees ordered first by ascending department number and then by descending salary, issue the following statement:

```
SELECT last_name, department_id, salary
    FROM employees
    ORDER BY department_id ASC, salary DESC, last_name;
```

To select the same information as the previous SELECT and use the positional ORDER BY notation, issue the following statement, which orders by ascending department_id, then descending salary, and finally alphabetically by last_name:

```
SELECT last_name, department_id, salary
    FROM employees
    ORDER BY 2 ASC, 3 DESC, 1;
```
The MODEL clause: Examples   The view created below is based on the sample sh schema and is used by the example that follows.

CREATE OR REPLACE VIEW sales_view_ref AS

The next example creates a multidimensional array from sales_view_ref with columns containing country, product, year, and sales. It also:

- Assigns the sum of the sales of the Mouse Pad for years 1999 and 2000 to the sales of the Mouse Pad for year 2001, if a row containing sales of the Mouse Pad for year 2001 exists.
- Assigns the value of sales of the Standard Mouse for year 2001 to sales of the Standard Mouse for year 2002, creating a new row if a row containing sales of the Standard Mouse for year 2002 does not exist.

</tbody>
</table>

18 rows selected.

The first rule uses UPDATE behavior because symbolic referencing is used on the left-hand side of the rule. The rows represented by the left-hand side of the rule exist, so the measure columns are updated. If the rows did not exist, then no action would have been taken.

The second rule uses UPSERT behavior because positional referencing is used on the left-hand side and a single cell is referenced. The rows do not exist, so new rows are inserted and the related measure columns are updated. If the rows did exist, then the measure columns would have been updated.

See Also: Oracle Database Data Warehousing Guide for an expanded discussion and examples

The next example uses the same sales_view_ref view and the analytic function SUM to calculate a cumulative sum (csum) of sales per country and per year.

SELECT country, year, sale, csum
FROM
(SELECT country, year, SUM(sale) sale
     FROM sales_view_ref
     GROUP BY country, year
   )
MODEL DIMENSION BY {country, year}
MEASURES (sale, 0 csum)

8 rows selected.

**Row Limiting: Examples** The following statement returns the 5 employees with the lowest `employee_id` values:

```sql
SELECT employee_id, last_name
FROM employees
ORDER BY employee_id
FETCH FIRST 5 ROWS ONLY;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>King</td>
</tr>
<tr>
<td>101</td>
<td>Kochhar</td>
</tr>
<tr>
<td>102</td>
<td>De Haan</td>
</tr>
<tr>
<td>103</td>
<td>Hunold</td>
</tr>
<tr>
<td>104</td>
<td>Ernst</td>
</tr>
</tbody>
</table>

The following statement returns the next 5 employees with the lowest `employee_id` values:

```sql
SELECT employee_id, last_name
FROM employees
ORDER BY employee_id
OFFSET 5 ROWS FETCH NEXT 5 ROWS ONLY;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>105</td>
<td>Austin</td>
</tr>
<tr>
<td>106</td>
<td>Pataballa</td>
</tr>
<tr>
<td>107</td>
<td>Lorentz</td>
</tr>
<tr>
<td>108</td>
<td>Greenberg</td>
</tr>
<tr>
<td>109</td>
<td>Faviet</td>
</tr>
</tbody>
</table>

The following statement returns the 5 percent of employees with the lowest salaries:

```sql
SELECT employee_id, last_name, salary
FROM employees
ORDER BY salary
FETCH FIRST 5 PERCENT ROWS ONLY;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>132</td>
<td>Olson</td>
<td>2100</td>
</tr>
<tr>
<td>128</td>
<td>Markle</td>
<td>2200</td>
</tr>
</tbody>
</table>
Because **WITH TIES** is specified, the following statement returns the 5 percent of employees with the lowest salaries, plus all additional employees with the same salary as the last row fetched in the previous example:

```
SELECT employee_id, last_name, salary
FROM employees
ORDER BY salary
FETCH FIRST 5 PERCENT ROWS WITH TIES;
```

<table>
<thead>
<tr>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
<th>SALARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>132 Olson</td>
<td>2100</td>
<td></td>
</tr>
<tr>
<td>128 Markle</td>
<td>2200</td>
<td></td>
</tr>
<tr>
<td>136 Philtanker</td>
<td>2200</td>
<td></td>
</tr>
<tr>
<td>127 Landry</td>
<td>2400</td>
<td></td>
</tr>
<tr>
<td>135 Gee</td>
<td>2400</td>
<td></td>
</tr>
<tr>
<td>119 Colmenares</td>
<td>2500</td>
<td></td>
</tr>
<tr>
<td>131 Marlow</td>
<td>2500</td>
<td></td>
</tr>
<tr>
<td>140 Patel</td>
<td>2500</td>
<td></td>
</tr>
<tr>
<td>144 Vargas</td>
<td>2500</td>
<td></td>
</tr>
<tr>
<td>182 Sullivan</td>
<td>2500</td>
<td></td>
</tr>
<tr>
<td>191 Perkins</td>
<td>2500</td>
<td></td>
</tr>
</tbody>
</table>

**Using the FOR UPDATE Clause: Examples**  The following statement locks rows in the **employees** table with purchasing clerks located in Oxford, which has **location_id** 2500, and locks rows in the **departments** table with departments in Oxford that have purchasing clerks:

```
SELECT e.employee_id, e.salary, e.commission_pct
FROM employees e, departments d
WHERE job_id = 'SA_REP'
AND e.department_id = d.department_id
AND location_id = 2500
ORDER BY e.employee_id
FOR UPDATE;
```

The following statement locks only those rows in the **employees** table with purchasing clerks located in Oxford. No rows are locked in the **departments** table:

```
SELECT e.employee_id, e.salary, e.commission_pct
FROM employees e JOIN departments d
USING (department_id)
WHERE job_id = 'SA_REP'
AND location_id = 2500
ORDER BY e.employee_id
FOR UPDATE OF e.salary;
```

**Using the WITH CHECK OPTION Clause: Example**  The following statement is legal even though the third value inserted violates the condition of the subquery **where clause**:

```
INSERT INTO (SELECT department_id, department_name, location_id
FROM departments WHERE location_id < 2000)
VALUES (9999, 'Entertainment', 2500);
```
However, the following statement is illegal because it contains the WITH CHECK OPTION clause:

```sql
INSERT INTO (SELECT department_id, department_name, location_id
  FROM departments WHERE location_id < 2000 WITH CHECK OPTION)
VALUES (9999, 'Entertainment', 2500);
```

* ERROR at line 2:
ORA-01402: view WITH CHECK OPTION where-clause violation

**Using PIVOT and UNPIVOT: Examples** The oe.orders table contains information about when an order was placed (order_date), how it was placed (order_mode), and the total amount of the order (order_total), as well as other information. The following example shows how to use the PIVOT clause to pivot order_mode values into columns, aggregating order_total data in the process, to get yearly totals by order mode:

```sql
CREATE TABLE pivot_table AS
SELECT * FROM (SELECT EXTRACT(YEAR FROM order_date) year, order_mode, order_total FROM orders)
PIVOT (SUM(order_total) FOR order_mode IN ('direct' AS Store, 'online' AS Internet));
```

```sql
SELECT * FROM pivot_table ORDER BY year;
```

<table>
<thead>
<tr>
<th>YEAR</th>
<th>STORE</th>
<th>INTERNET</th>
</tr>
</thead>
<tbody>
<tr>
<td>2004</td>
<td>5546.6</td>
<td></td>
</tr>
<tr>
<td>2006</td>
<td>371895.5</td>
<td>100056.6</td>
</tr>
<tr>
<td>2007</td>
<td>1274078.8</td>
<td>1271019.5</td>
</tr>
<tr>
<td>2008</td>
<td>252108.3</td>
<td>393349.4</td>
</tr>
</tbody>
</table>

The UNPIVOT clause lets you rotate specified columns so that the input column headings are output as values of one or more descriptor columns, and the input column values are output as values of one or more measures columns. The first query that follows shows that nulls are excluded by default. The second query shows that you can include nulls using the INCLUDE NULLS clause.

```sql
SELECT * FROM pivot_table
UNPIVOT (yearly_total FOR order_mode IN (store AS 'direct',
  internet AS 'online'))
ORDER BY year, order_mode;
```

```sql
SELECT * FROM pivot_table
UNPIVOT INCLUDE NULLS
  (yearly_total FOR order_mode IN (store AS 'direct',
    internet AS 'online'))
ORDER BY year, order_mode;
```

7 rows selected.

```sql
SELECT * FROM pivot_table
UNPIVOT INCLUDE NULLS
  (yearly_total FOR order_mode IN (store AS 'direct',
    internet AS 'online'))
ORDER BY year, order_mode;
```

<table>
<thead>
<tr>
<th>YEAR</th>
<th>ORDER_ YEARLY_TOTAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>2004</td>
<td>5546.6</td>
</tr>
<tr>
<td>2006</td>
<td>371895.5</td>
</tr>
<tr>
<td>2006</td>
<td>100056.6</td>
</tr>
<tr>
<td>2007</td>
<td>1274078.8</td>
</tr>
<tr>
<td>2007</td>
<td>1271019.5</td>
</tr>
<tr>
<td>2008</td>
<td>252108.3</td>
</tr>
<tr>
<td>2008</td>
<td>393349.4</td>
</tr>
</tbody>
</table>

7 rows selected.
8 rows selected.

**Using Join Queries: Examples**  The following examples show various ways of joining tables in a query. In the first example, an equijoin returns the name and job of each employee and the number and name of the department in which the employee works:

```sql
SELECT last_name, job_id, departments.department_id, department_name
FROM employees, departments
WHERE employees.department_id = departments.department_id
ORDER BY last_name, job_id;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>JOB_ID</th>
<th>DEPARTMENT_ID</th>
<th>DEPARTMENT_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abel</td>
<td>SA_REP</td>
<td>80</td>
<td>Sales</td>
</tr>
<tr>
<td>Ande</td>
<td>SA_REP</td>
<td>80</td>
<td>Sales</td>
</tr>
<tr>
<td>Atkinson</td>
<td>ST_CLERK</td>
<td>50</td>
<td>Shipping</td>
</tr>
<tr>
<td>Austin</td>
<td>IT_PROG</td>
<td>60</td>
<td>IT</td>
</tr>
</tbody>
</table>

You must use a join to return this data because employee names and jobs are stored in a different table than department names. Oracle Database combines rows of the two tables according to this join condition:

```sql
employees.department_id = departments.department_id
```

The following equijoin returns the name, job, department number, and department name of all sales managers:

```sql
SELECT last_name, job_id, departments.department_id, department_name
FROM employees, departments
WHERE employees.department_id = departments.department_id
AND job_id = 'SA_MAN'
ORDER BY last_name;
```

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>JOB_ID</th>
<th>DEPARTMENT_ID</th>
<th>DEPARTMENT_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cambrault</td>
<td>SA_MAN</td>
<td>80</td>
<td>Sales</td>
</tr>
<tr>
<td>Errazuriz</td>
<td>SA_MAN</td>
<td>80</td>
<td>Sales</td>
</tr>
<tr>
<td>Partners</td>
<td>SA_MAN</td>
<td>80</td>
<td>Sales</td>
</tr>
<tr>
<td>Russell</td>
<td>SA_MAN</td>
<td>80</td>
<td>Sales</td>
</tr>
<tr>
<td>Zlotkey</td>
<td>SA_MAN</td>
<td>80</td>
<td>Sales</td>
</tr>
</tbody>
</table>

This query is identical to the preceding example, except that it uses an additional where clause condition to return only rows with a job value of ‘SA_MAN’.

**Using Subqueries: Examples**  To determine who works in the same department as employee 'Lorentz', issue the following statement:

```sql
SELECT last_name, department_id FROM employees
WHERE department_id =
```

8 rows selected.
(SELECT department_id FROM employees
  WHERE last_name = 'Lorentz')
ORDER BY last_name, department_id;

To give all employees in the employees table a 10% raise if they have changed jobs—if they appear in the job_history table—issue the following statement:

UPDATE employees
  SET salary = salary * 1.1
  WHERE employee_id IN (SELECT employee_id FROM job_history);

To create a second version of the departments table new_departments, with only three of the columns of the original table, issue the following statement:

CREATE TABLE new_departments
  (department_id, department_name, location_id)
AS SELECT department_id, department_name, location_id
  FROM departments;

Using Self Joins: Example  

The following query uses a self join to return the name of each employee along with the name of the employee's manager. A WHERE clause is added to shorten the output.

SELECT e1.last_name||' works for '|e2.last_name
  "Employees and Their Managers"
FROM employees e1, employees e2
WHERE e1.manager_id = e2.employee_id
  AND e1.last_name LIKE 'R%'
ORDER BY e1.last_name;

Employees and Their Managers
-------------------------------
Rajs works for Mourgos
Raphaely works for King
Rogers works for Kaufling
Russell works for King

The join condition for this query uses the aliases e1 and e2 for the sample table employees:

e1.manager_id = e2.employee_id

Using Outer Joins: Examples  

The following example shows how a partitioned outer join fills data gaps in rows to facilitate analytic function specification and reliable report formatting. The example first creates a small data table to be used in the join:

SELECT d.department_id, e.last_name
  FROM departments d LEFT OUTER JOIN employees e
    ON d.department_id = e.department_id
ORDER BY d.department_id, e.last_name;

Users familiar with the traditional Oracle Database outer joins syntax will recognize the same query in this form:

SELECT d.department_id, e.last_name
  FROM departments d, employees e
    WHERE d.department_id = e.department_id(+)
ORDER BY d.department_id, e.last_name;

Users familiar with the traditional Oracle Database outer joins syntax will recognize the same query in this form:

SELECT d.department_id, e.last_name
  FROM departments d, employees e
    WHERE d.department_id = e.department_id(+)
ORDER BY d.department_id, e.last_name;

Oracle strongly recommends that you use the more flexible FROM clause join syntax shown in the former example.
The left outer join returns all departments, including those without any employees. The same statement with a right outer join returns all employees, including those not yet assigned to a department:

```
SELECT d.department_id, e.last_name
FROM departments d RIGHT OUTER JOIN employees e
ON d.department_id = e.department_id
ORDER BY d.department_id, e.last_name;
```

<table>
<thead>
<tr>
<th>DEPARTMENT_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>. . .</td>
<td></td>
</tr>
<tr>
<td>110</td>
<td>Gietz</td>
</tr>
<tr>
<td>110</td>
<td>Higgins</td>
</tr>
<tr>
<td>Grant</td>
<td>Zeuss</td>
</tr>
</tbody>
</table>

It is not clear from this result whether employees Grant and Zeuss have `department_id` NULL, or whether their `department_id` is not in the `departments` table. To determine this requires a full outer join:

```
SELECT d.department_id as d_dept_id, e.department_id as e_dept_id, e.last_name
FROM departments d FULL OUTER JOIN employees e
ON d.department_id = e.department_id
ORDER BY d.department_id, e.last_name;
```

<table>
<thead>
<tr>
<th>D_DEPT_ID</th>
<th>E_DEPT_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>. . .</td>
<td>. . .</td>
<td></td>
</tr>
<tr>
<td>110</td>
<td>110</td>
<td>Gietz</td>
</tr>
<tr>
<td>110</td>
<td>110</td>
<td>Higgins</td>
</tr>
<tr>
<td>260</td>
<td>270</td>
<td></td>
</tr>
<tr>
<td>999</td>
<td>260</td>
<td>Zeuss</td>
</tr>
<tr>
<td>999</td>
<td>270</td>
<td>Grant</td>
</tr>
</tbody>
</table>

Because the column names in this example are the same in both tables in the join, you can also use the common column feature by specifying the `USING` clause of the join syntax. The output is the same as for the preceding example except that the `USING` clause coalesces the two matching columns `department_id` into a single column output:

```
SELECT department_id AS d_e_dept_id, e.last_name
FROM departments d FULL OUTER JOIN employees e
USING (department_id)
ORDER BY department_id, e.last_name;
```

<table>
<thead>
<tr>
<th>D_E_DEPT_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>. . .</td>
<td>. . .</td>
</tr>
<tr>
<td>110</td>
<td>Higgins</td>
</tr>
<tr>
<td>110</td>
<td>Gietz</td>
</tr>
</tbody>
</table>

Note: The employee Zeuss was added to the employees table for these examples, and is not part of the sample data.
Using Partitioned Outer Joins: Examples  The following example shows how a partitioned outer join fills in gaps in rows to facilitate analytic calculation specification and reliable report formatting. The example first creates and populates a simple table to be used in the join:

```sql
CREATE TABLE inventory (time_id DATE, product VARCHAR2(10), quantity NUMBER);
```

```sql
INSERT INTO inventory VALUES (TO_DATE('01/04/01', 'DD/MM/YY'), 'bottle', 10);
INSERT INTO inventory VALUES (TO_DATE('06/04/01', 'DD/MM/YY'), 'bottle', 10);
INSERT INTO inventory VALUES (TO_DATE('01/04/01', 'DD/MM/YY'), 'can', 10);
INSERT INTO inventory VALUES (TO_DATE('04/04/01', 'DD/MM/YY'), 'can', 10);
```

```sql
SELECT times.time_id, product, quantity FROM inventory
PARTITION BY (product)
RIGHT OUTER JOIN times ON (times.time_id = inventory.time_id)
WHERE times.time_id BETWEEN TO_DATE('01/04/01', 'DD/MM/YY')
AND TO_DATE('06/04/01', 'DD/MM/YY')
ORDER BY 2,1;
```

<table>
<thead>
<tr>
<th>TIME_ID</th>
<th>PRODUCT</th>
<th>QUANTITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>01-APR-01</td>
<td>bottle</td>
<td>10</td>
</tr>
<tr>
<td>02-APR-01</td>
<td>bottle</td>
<td></td>
</tr>
<tr>
<td>03-APR-01</td>
<td>bottle</td>
<td></td>
</tr>
<tr>
<td>04-APR-01</td>
<td>bottle</td>
<td></td>
</tr>
<tr>
<td>05-APR-01</td>
<td>bottle</td>
<td></td>
</tr>
<tr>
<td>06-APR-01</td>
<td>bottle</td>
<td>10</td>
</tr>
<tr>
<td>01-APR-01</td>
<td>can</td>
<td>10</td>
</tr>
<tr>
<td>02-APR-01</td>
<td>can</td>
<td></td>
</tr>
<tr>
<td>03-APR-01</td>
<td>can</td>
<td></td>
</tr>
<tr>
<td>04-APR-01</td>
<td>can</td>
<td>10</td>
</tr>
<tr>
<td>05-APR-01</td>
<td>can</td>
<td></td>
</tr>
<tr>
<td>06-APR-01</td>
<td>can</td>
<td></td>
</tr>
</tbody>
</table>

12 rows selected.

The data is now more dense along the time dimension for each partition of the product dimension. However, each of the newly added rows within each partition is null in the quantity column. It is more useful to see the nulls replaced by the preceding non-NULL value in time order. You can achieve this by applying the analytic function LAST_VALUE on top of the query result:

```sql
SELECT time_id, product, LAST_VALUE(quantity IGNORE NULLS)
OVER (PARTITION BY product ORDER BY time_id) quantity
FROM ( SELECT times.time_id, product, quantity
FROM inventory PARTITION BY (product)
RIGHT OUTER JOIN times ON (times.time_id = inventory.time_id)
WHERE times.time_id BETWEEN TO_DATE('01/04/01', 'DD/MM/YY')
AND TO_DATE('06/04/01', 'DD/MM/YY')
ORDER BY 2,1;
```

<table>
<thead>
<tr>
<th>TIME_ID</th>
<th>PRODUCT</th>
<th>QUANTITY</th>
</tr>
</thead>
</table>

12 rows selected.

The data is now more dense along the time dimension for each partition of the product dimension. However, each of the newly added rows within each partition is null in the quantity column. It is more useful to see the nulls replaced by the preceding non-NULL value in time order. You can achieve this by applying the analytic function LAST_VALUE on top of the query result:
Using Antijoins: Example  The following example selects a list of employees who are not in a particular set of departments:

```sql
SELECT * FROM employees
WHERE department_id NOT IN
(SELECT department_id FROM departments
 WHERE location_id = 1700)
ORDER BY last_name;
```

Using Semijoins: Example  In the following example, only one row needs to be returned from the departments table, even though many rows in the employees table might match the subquery. If no index has been defined on the salary column in employees, then a semijoin can be used to improve query performance.

```sql
SELECT * FROM departments
WHERE EXISTS
(SELECT * FROM employees
 WHERE departments.department_id = employees.department_id
 AND employees.salary > 2500)
ORDER BY department_name;
```

Using CROSS APPLY and OUTER APPLY Joins: Examples  The following statement uses the CROSS APPLY clause of the `cross_outer_apply_clause`. The join returns only rows from the table on the left side of the join (departments) that produce a result from the inline view on the right side of the join. That is, the join returns only the departments that have at least one employee. The WHERE clause restricts the result set to include only the Marketing, Operations, and Public Relations departments. However, the Operations department is not included in the result set because it has no employees.

```sql
SELECT d.department_name, v.employee_id, v.last_name
FROM departments d CROSS APPLY (SELECT * FROM employees e
 WHERE e.department_id = d.department_id) v
WHERE d.department_name IN ('Marketing', 'Operations', 'Public Relations')
ORDER BY d.department_name, v.employee_id;
```

<table>
<thead>
<tr>
<th>DEPARTMENT_NAME</th>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Marketing</td>
<td>201</td>
<td>Hartstein</td>
</tr>
<tr>
<td>Marketing</td>
<td>202</td>
<td>Fay</td>
</tr>
<tr>
<td>Public Relations</td>
<td>204</td>
<td>Baer</td>
</tr>
</tbody>
</table>

See Also: Oracle Database Data Warehousing Guide for an expanded discussion on filling gaps in time series calculations and examples of usage.
The following statement uses the OUTER APPLY clause of the `cross_outer_apply_clause`. The join returns all rows from the table on the left side of the join (departments) regardless of whether they produce a result from the inline view on the right side of the join. That is, the join returns all departments regardless of whether the departments have any employees. The WHERE clause restricts the result set to include only the Marketing, Operations, and Public Relations departments. The Operations department is included in the result set even though it has no employees.

```
SELECT d.department_name, v.employee_id, v.last_name
FROM departments d OUTER APPLY (SELECT * FROM employees e
    WHERE e.department_id = d.department_id) v
WHERE d.department_name IN ('Marketing', 'Operations', 'Public Relations')
ORDER by d.department_name, v.employee_id;
```

<table>
<thead>
<tr>
<th>DEPARTMENT_NAME</th>
<th>EMPLOYEE_ID</th>
<th>LAST_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Marketing</td>
<td>201</td>
<td>Hartstein</td>
</tr>
<tr>
<td>Marketing</td>
<td>202</td>
<td>Fay</td>
</tr>

**Using Lateral Inline Views: Example**  The following example shows a join with two operands. The second operand is an inline view that specifies the first operand, table \( e \), in the WHERE clause. This results in an error.

```
SELECT * FROM employees e, (SELECT * FROM departments d
    WHERE e.department_id = d.department_id);
ORA-00904: "E"."DEPARTMENT_ID": invalid identifier
```

The following example shows a join with two operands. The second operand is a lateral inline view that specifies the first operand, table \( e \), in the WHERE clause and succeeds without an error.

```
SELECT * FROM employees e, LATERAL(SELECT * FROM departments d
    WHERE e.department_id = d.department_id);
```

**Table Collections: Examples**  You can perform DML operations on nested tables only if they are defined as columns of a table. Therefore, when the `query_table_expr_clause` of an INSERT, DELETE, or UPDATE statement is a table_collection_expression, the collection expression must be a subquery that uses the TABLE collection expression to select the nested table column of the table. The examples that follow are based on the following scenario:

Suppose the database contains a table hr_info with columns department_id, location_id, and manager_id, and a column of nested table type people which has last_name, department_id, and salary columns for all the employees of each respective manager:

```
CREATE TYPE people_typ AS OBJECT {
    last_name      VARCHAR2(25),
    department_id  NUMBER(4),
    salary         NUMBER(8,2));
/
CREATE TYPE people_tab_typ AS TABLE OF people_typ;
/
CREATE TABLE hr_info {
    department_id   NUMBER(4),
    location_id     NUMBER(4),
    manager_id      NUMBER(6),

```
NESTED TABLE people STORE AS people_stor_tab;

INSERT INTO hr_info VALUES (280, 1800, 999, people_tab_typ());

The following example inserts into the `people` nested table column of the `hr_info` table for department 280:

```
INSERT INTO TABLE(SELECT h.people FROM hr_info h
    WHERE h.department_id = 280)
VALUES ('Smith', 280, 1750);
```

The next example updates the department 280 `people` nested table:

```
UPDATE TABLE(SELECT h.people FROM hr_info h
    WHERE h.department_id = 280) p
SET p.salary = p.salary + 100;
```

The next example deletes from the department 280 `people` nested table:

```
DELETE TABLE(SELECT h.people FROM hr_info h
    WHERE h.department_id = 280) p
WHERE p.salary > 1700;
```

**Collection Unnesting: Examples** To select data from a nested table column, use the `TABLE` collection expression to treat the nested table as columns of a table. This process is called collection unnesting.

You could get all the rows from `hr_info`, which was created in the preceding example, and all the rows from the `people` nested table column of `hr_info` using the following statement:

```
SELECT t1.department_id, t2.* FROM hr_info t1, TABLE(t1.people) t2
    WHERE t2.department_id = t1.department_id;
```

Now suppose that `people` is not a nested table column of `hr_info`, but is instead a separate table with columns `last_name`, `department_id`, `address`, `hiredate`, and `salary`. You can extract the same rows as in the preceding example with this statement:

```
SELECT t1.department_id, t2.*
    FROM hr_info t1, TABLE(CAST(MULTISET(
        SELECT t3.last_name, t3.department_id, t3.salary
        FROM people t3
        WHERE t3.department_id = t1.department_id)
    AS people_tab_typ)) t2;
```

Finally, suppose that `people` is neither a nested table column of table `hr_info` nor a table itself. Instead, you have created a function `people_func` that extracts from various sources the name, department, and salary of all employees. You can get the same information as in the preceding examples with the following query:

```
SELECT t1.department_id, t2.*
    FROM hr_info t1, TABLE(CAST(people_func( ... ) AS people_tab_typ)) t2;
```

**See Also:** Oracle Database Object-Relational Developer’s Guide for more examples of collection unnesting.

**Using the LEVEL Pseudocolumn: Examples** The following statement returns all employees in hierarchical order. The root row is defined to be the employee whose job
The child rows of a parent row are defined to be those who have the employee number of the parent row as their manager number.

```
SELECT LPAD(' ',2*(LEVEL-1)) || last_name org_chart,
  employee_id, manager_id, job_id
FROM employees
START WITH job_id = 'AD_VP'
CONNECT BY PRIOR employee_id = manager_id;
```

<table>
<thead>
<tr>
<th>ORG_CHART</th>
<th>EMPLOYEE_ID</th>
<th>MANAGER_ID</th>
<th>JOB_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kochhar</td>
<td>101</td>
<td>100</td>
<td>AD_VP</td>
</tr>
<tr>
<td>Greenberg</td>
<td>108</td>
<td>101</td>
<td>FI_MGR</td>
</tr>
<tr>
<td>Faviet</td>
<td>109</td>
<td>108</td>
<td>FI_ACCOUNT</td>
</tr>
<tr>
<td>Chen</td>
<td>110</td>
<td>108</td>
<td>FI_ACCOUNT</td>
</tr>
<tr>

</tr>
</tbody>
</table>

The following statement is similar to the previous one, except that it does not select employees with the job FI_MGR.

```
SELECT LPAD(' ',2*(LEVEL-1)) || last_name org_chart,
  employee_id, manager_id, job_id
FROM employees
WHERE job_id != 'FI_MGR'
START WITH job_id = 'AD_VP'
CONNECT BY PRIOR employee_id = manager_id;
```

<table>
<thead>
<tr>
<th>ORG_CHART</th>
<th>EMPLOYEE_ID</th>
<th>MANAGER_ID</th>
<th>JOB_ID</th>
</tr>
</thead>
<tbody>
<tr>

Oracle Database does not return the manager Greenberg, although it does return employees who are managed by Greenberg.

The following statement is similar to the first one, except that it uses the LEVEL pseudocolumn to select only the first two levels of the management hierarchy:

```
SELECT LPAD(' ',2*(LEVEL-1)) || last_name org_chart,
       employee_id, manager_id, job_id
FROM employees
START WITH job_id = 'AD_PRES'
CONNECT BY PRIOR employee_id = manager_id AND LEVEL <= 2;
```

</tbody>
</table>

**Using Distributed Queries: Example**  This example shows a query that joins the departments table on the local database with the employees table on the remote database:

```
SELECT last_name, department_name
FROM employees@remote, departments
WHERE employees.department_id = departments.department_id;
```

**Using Correlated Subqueries: Examples**  The following examples show the general syntax of a correlated subquery:

```
SELECT select_list
FROM table1 t_alias1
WHERE expr operator
(SELECT column_list
FROM table2 t_alias2
WHERE t_alias1.column operator t_alias2.column);

UPDATE table1 t_alias1
SET column =
(SELECT expr
FROM table2 t_alias2
WHERE t_alias1.column = t_alias2.column);

DELETE FROM table1 t_alias1
WHERE column operator
(SELECT expr
FROM table2 t_alias2
WHERE t_alias1.column = t_alias2.column);
```
The following statement returns data about employees whose salaries exceed their department average. The following statement assigns an alias to employees, the table containing the salary information, and then uses the alias in a correlated subquery:

```
SELECT department_id, last_name, salary
FROM employees x
WHERE salary > (SELECT AVG(salary)
               FROM employees
               WHERE x.department_id = department_id)
ORDER BY department_id;
```

For each row of the employees table, the parent query uses the correlated subquery to compute the average salary for members of the same department. The correlated subquery performs the following steps for each row of the employees table:

1. The department_id of the row is determined.
2. The department_id is then used to evaluate the parent query.
3. If the salary in that row is greater than the average salary of the departments of that row, then the row is returned.

The subquery is evaluated once for each row of the employees table.

**Selecting from the DUAL Table: Example**

The following statement returns the current date:

```
SELECT SYSDATE FROM DUAL;
```

You could select SYSDATE from the employees table, but the database would return 14 rows of the same SYSDATE, one for every row of the employees table. Selecting from DUAL is more convenient.

**Selecting Sequence Values: Examples**

The following statement increments the employees_seq sequence and returns the new value:

```
SELECT employees_seq.nextval
FROM DUAL;
```

The following statement selects the current value of employees_seq:

```
SELECT employees_seq.currval
FROM DUAL;
```

**Row Pattern Matching: Example**

This example uses row pattern matching to query stock price data. The following statements create table Ticker and inserts stock price data into the table:

```
CREATE TABLE Ticker (SYMBOL VARCHAR2(10), tstamp DATE, price NUMBER);

INSERT INTO Ticker VALUES('ACME', '01-Apr-11', 12);
INSERT INTO Ticker VALUES('ACME', '02-Apr-11', 17);
INSERT INTO Ticker VALUES('ACME', '03-Apr-11', 19);
INSERT INTO Ticker VALUES('ACME', '04-Apr-11', 21);
INSERT INTO Ticker VALUES('ACME', '05-Apr-11', 25);
INSERT INTO Ticker VALUES('ACME', '06-Apr-11', 12);
INSERT INTO Ticker VALUES('ACME', '07-Apr-11', 15);
INSERT INTO Ticker VALUES('ACME', '08-Apr-11', 20);
INSERT INTO Ticker VALUES('ACME', '09-Apr-11', 24);
INSERT INTO Ticker VALUES('ACME', '10-Apr-11', 25);
INSERT INTO Ticker VALUES('ACME', '11-Apr-11', 19);
INSERT INTO Ticker VALUES('ACME', '12-Apr-11', 15);
```
The following query uses row pattern matching to find all cases where stock prices dipped to a bottom price and then rose. This is generally called a V-shape. The resulting output contains only three rows because the query specifies one row per match, and three matches were found.

```
SELECT *
FROM Ticker MATCH_RECOGNIZE (
    PARTITION BY symbol
    ORDER BY tstamp
    MEASURES STRT.tstamp AS start_tstamp,
             LAST(DOWN.tstamp) AS bottom_tstamp,
             LAST(UP.tstamp) AS end_tstamp
    ONE ROW PER MATCH
    AFTER MATCH SKIP TO LAST UP
    PATTERN (STRT DOWN+ UP+)
    DEFINE
        DOWN AS DOWN.price < PREV(DOWN.price),
        UP AS UP.price > PREV(UP.price)
) MR
ORDER BY MR.symbol, MR.start_tstamp;
```

<table>
<thead>
<tr>
<th>SYMBOL</th>
<th>START_TST</th>
<th>BOTTOM_TS</th>
<th>END_TSTAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACME</td>
<td>05-APR-11</td>
<td>06-APR-11</td>
<td>10-APR-11</td>
</tr>
<tr>
<td>ACME</td>
<td>10-APR-11</td>
<td>12-APR-11</td>
<td>13-APR-11</td>
</tr>
<tr>
<td>ACME</td>
<td>14-APR-11</td>
<td>16-APR-11</td>
<td>18-APR-11</td>
</tr>
</tbody>
</table>
SET CONSTRAINT[S]

Purpose

Use the `SET CONSTRAINTS` statement to specify, for a particular transaction, whether a deferrable constraint is checked following each DML statement (IMMEDIATE) or when the transaction is committed (DEFERRED). You can use this statement to set the mode for a list of constraint names or for ALL constraints.

The `SET CONSTRAINTS` mode lasts for the duration of the transaction or until another `SET CONSTRAINTS` statement resets the mode.

**Note:** You can also use an `ALTER SESSION` statement with the `SET CONSTRAINTS` clause to set all deferrable constraints. This is equivalent to making issuing a `SET CONSTRAINTS` statement at the start of each transaction in the current session.

Prerequisites

To specify when a deferrable constraint is checked, you must have the `READ` or `SELECT` privilege on the table to which the constraint is applied unless the table is in your schema.

Syntax

```
set_constraints ::= ...
```

Semantics

**constraint**

Specify the name of one or more integrity constraints.

**ALL**

Specify ALL to set all deferrable constraints for this transaction.

**IMMEDIATE**

Specify IMMEDIATE to cause the specified constraints to be checked immediately on execution of each constrained DML statement. Oracle Database first checks any constraints that were deferred earlier in the transaction and then continues immediately checking constraints of any further statements in that transaction, as long
as all the checked constraints are consistent and no other SET CONSTRAINTS statement is issued. If any constraint fails the check, then an error is signaled. At that point, a COMMIT statement causes the whole transaction to undo.

Making constraints immediate at the end of a transaction is a way of checking whether COMMIT can succeed. You can avoid unexpected rollbacks by setting constraints to IMMEDIATE as the last statement in a transaction. If any constraint fails the check, you can then correct the error before committing the transaction.

**DEFERRED**
Specify DEFERRED to indicate that the conditions specified by the deferrable constraint are checked when the transaction is committed.

| Note: | You can verify the success of deferrable constraints prior to committing them by issuing a SET CONSTRAINTS ALL IMMEDIATE statement. |

**Examples**

**Setting Constraints: Examples** The following statement sets all deferrable constraints in this transaction to be checked immediately following each DML statement:

```sql
SET CONSTRAINTS ALL IMMEDIATE;
```

The following statement checks three deferred constraints when the transaction is committed. This example fails if the constraints were specified to be NOT DEFERRABLE.

```sql
SET CONSTRAINTS emp_job_nn, emp_salary_min,
     hr.jhist_dept_fk@remote DEFERRED;
```
SET ROLE

Purpose

When a user logs on to Oracle Database, the database enables all privileges granted explicitly to the user and all privileges in the user's default roles. During the session, the user or an application can use the `SET ROLE` statement any number of times to enable or disable the roles currently enabled for the session.

You cannot enable more than 148 user-defined roles at one time.

Notes:

- For most roles, you cannot enable or disable a role unless it was granted to you either directly or through other roles. However, a secure application role can be granted and enabled by its associated PL/SQL package. See the `CREATE ROLE` semantics for `USING package` on page 15-89 and Oracle Database Security Guide for information about secure application roles.

- `SET ROLE` succeeds only if there are no definer's rights units on the call stack. If at least one DR unit is on the call stack, then issuing the `SET ROLE` command causes ORA-06565. See Oracle Database PL/SQL Language Reference for more information about definer's rights units.

- To run the `SET ROLE` command from PL/SQL, you must use dynamic SQL, preferably the `EXECUTE IMMEDIATE` statement. See Oracle Database PL/SQL Language Reference for more information about this statement.

You can see which roles are currently enabled by examining the `SESSION_ROLES` data dictionary view.

See Also:

- `CREATE ROLE` on page 15-87 for information on creating roles
- `ALTER USER` on page 13-6 for information on changing a user's default roles
- Oracle Database Reference for information on the `SESSION_ROLES` session parameter

Prerequisites

You must already have been granted the roles that you name in the `SET ROLE` statement.
Syntax

```
set_role ::= 
```

Semantics

**role**

Specify one or more roles to be enabled for the current session. All roles not specified are disabled for the current session or until another `SET ROLE` statement is issued in the current session.

In the `IDENTIFIED BY password` clause, specify the password for a role. If the role has a password, then you must specify the password to enable the role.

**Restriction on Setting Roles** You cannot specify a role identified globally. Global roles are enabled by default at login, and cannot be reenabled later.

**ALL Clause**

Specify `ALL` to enable all roles granted to you for the current session except those optionally listed in the `EXCEPT` clause.

Roles listed in the `EXCEPT` clause must be roles granted directly to you. They cannot be roles granted to you through other roles.

If you list a role in the `EXCEPT` clause that has been granted to you both directly and through another role, then the role remains enabled by virtue of the role to which it has been granted.

**Restrictions on the ALL Clause** The following restrictions apply to the `ALL` clause:

- You cannot specify this clause if you have been directly granted any roles with passwords. Doing so will result in an ORA-01979 error.
- You cannot use this clause to enable a secure application role, which is a role that can be enabled only by applications using an authorized package. Refer to *Oracle Database Security Guide* for information on creating a secure application role and *Oracle Database 2 Day + Security Guide* for a tutorial.

**NONE**

Specify `NONE` to disable all roles for the current session, including the `DEFAULT` role.

Examples

**Setting Roles: Examples** To enable the role `dw_manager` identified by the password `warehouse` for your current session, issue the following statement:
SET ROLE dw_manager IDENTIFIED BY warehouse;

To enable all roles granted to you for the current session, issue the following statement:
SET ROLE ALL;

To enable all roles granted to you except dw_manager, issue the following statement:
SET ROLE ALL EXCEPT dw_manager;

To disable all roles granted to you for the current session, issue the following statement:
SET ROLE NONE;
SET TRANSACTION

Purpose
Use the SET TRANSACTION statement to establish the current transaction as read-only or read/write, establish its isolation level, assign it to a specified rollback segment, or assign a name to the transaction.

A transaction implicitly begins with any operation that obtains a TX lock:
- When a statement that modifies data is issued
- When a SELECT ... FOR UPDATE statement is issued
- When a transaction is explicitly started with a SET TRANSACTION statement or the DBMS_TRANSACTION package

Issuing either a COMMIT or ROLLBACK statement explicitly ends the current transaction.

The operations performed by a SET TRANSACTION statement affect only your current transaction, not other users or other transactions. Your transaction ends whenever you issue a COMMIT or ROLLBACK statement. Oracle Database implicitly commits the current transaction before and after executing a data definition language (DDL) statement.

See Also: COMMIT on page 13-57 and ROLLBACK on page 18-110

Prerequisites
If you use a SET TRANSACTION statement, then it must be the first statement in your transaction. However, a transaction need not have a SET TRANSACTION statement.

Syntax

\[
\text{set\_transaction} ::= \\
\]

Semantics

**READ ONLY**
The READ ONLY clause establishes the current transaction as a read-only transaction. This clause established transaction-level read consistency.

All subsequent queries in that transaction see only changes that were committed before the transaction began. Read-only transactions are useful for reports that run multiple queries against one or more tables while other users update these same tables.
SET TRANSACTION

This clause is not supported for the user SYS. Queries by SYS will return changes made during the transaction even if SYS has set the transaction to be READ ONLY.

Restriction on Read-only Transactions  Only the following statements are permitted in a read-only transaction:

- Subqueries—SELECT statements without the for_update_clause
- LOCK TABLE
- SET ROLE
- ALTER SESSION
- ALTER SYSTEM

READ WRITE
Specify READ WRITE to establish the current transaction as a read/write transaction. This clause establishes statement-level read consistency, which is the default.

Restriction on Read/Write Transactions  You cannot toggle between transaction-level and statement-level read consistency in the same transaction.

ISOLATION LEVEL Clause
Use the ISOLATION LEVEL clause to specify how transactions containing database modifications are handled.

- The SERIALizable setting specifies serializable transaction isolation mode as defined in the SQL standard. If a serializable transaction contains data manipulation language (DML) that attempts to update any resource that may have been updated in a transaction uncommitted at the start of the serializable transaction, then the DML statement fails.

- The READ COMMITTED setting is the default Oracle Database transaction behavior. If the transaction contains DML that requires row locks held by another transaction, then the DML statement waits until the row locks are released.

USE ROLLBACK SEGMENT Clause

**Note:** This clause is relevant and valid only if you are using rollback segments for undo. Oracle strongly recommends that you use automatic undo management to handle undo space. If you follow this recommendation and run your database in automatic undo mode, then Oracle Database ignores this clause.

Specify USE ROLLBACK SEGMENT to assign the current transaction to the specified rollback segment. This clause also implicitly establishes the transaction as a read/write transaction.

Parallel DML requires more than one rollback segment. Therefore, if your transaction contains parallel DML operations, then the database ignores this clause.

NAME Clause
Use the NAME clause to assign a name to the current transaction. This clause is especially useful in distributed database environments when you must identify and resolve in-doubt transactions. The string value is limited to 255 bytes.
If you specify a name for a distributed transaction, then when the transaction commits, the name becomes the commit comment, overriding any comment specified explicitly in the COMMIT statement.

**See Also:** Oracle Database Concepts for more information about transaction naming

### Examples

**Setting Transactions: Examples** The following statements could be run at midnight of the last day of every month to count the products and quantities on hand in the Toronto warehouse in the sample Order Entry (oe) schema. This report would not be affected by any other user who might be adding or removing inventory to a different warehouse.

```sql
COMMIT;

SET TRANSACTION READ ONLY NAME 'Toronto';

SELECT product_id, quantity_on_hand FROM inventories
  WHERE warehouse_id = 5
  ORDER BY product_id;

COMMIT;
```

The first COMMIT statement ensures that SET TRANSACTION is the first statement in the transaction. The last COMMIT statement does not actually make permanent any changes to the database. It simply ends the read-only transaction.
TRUNCATE CLUSTER

Purpose

Use the TRUNCATE CLUSTER statement to remove all rows from a cluster. By default, Oracle Database also performs the following tasks:

- Deallocates all space used by the removed rows except that specified by the MINEXTENTS storage parameter
- Sets the NEXT storage parameter to the size of the last extent removed from the segment by the truncation process

Removing rows with the TRUNCATE statement can be more efficient than dropping and re-creating a cluster. Dropping and re-creating a cluster invalidates dependent objects of the cluster, requires you to regrant object privileges on the cluster, and requires you to re-create the indexes and cluster on the table and respecify its storage parameters. Truncating has none of these effects.

Removing rows with the TRUNCATE CLUSTER statement can be faster than removing all rows with the DELETE statement, especially if the cluster has numerous indexes and other dependencies.

See Also:

- DELETE on page 17-28 and DROP CLUSTER on page 17-40 for information on other ways of dropping data from a cluster
- TRUNCATE TABLE on page 19-89 for information on truncating a table

Prerequisites

To truncate a cluster, the cluster must be in your schema or you must have DROP ANY TABLE system privilege.

See Also: "Restrictions on Truncating Tables" on page 19-91

Syntax

```
truncate_cluster ::=           
```

Semantics

CLUSTER Clause

Specify the schema and name of the cluster to be truncated. You can truncate only an indexed cluster, not a hash cluster. If you omit schema, then the database assumes the cluster is in your own schema.
When you truncate a cluster, the database also automatically deletes all data in the indexes of the cluster tables.

**STORAGE Clauses**

The `STORAGE` clauses let you determine what happens to the space freed by the truncated rows. The `DROP STORAGE` clause and `REUSE STORAGE` clause also apply to the space freed by the data deleted from associated indexes.

**DROP STORAGE**  Specify `DROP STORAGE` to deallocate all space from the deleted rows from the cluster except the space allocated by the `MINEXTENTS` parameter of the cluster. This space can subsequently be used by other objects in the tablespace. Oracle Database also sets the `NEXT` storage parameter to the size of the last extent removed from the segment in the truncation process. This is the default.

**REUSE STORAGE**  Specify `REUSE STORAGE` to retain the space from the deleted rows allocated to the cluster. Storage values are not reset to the values when the table or cluster was created. This space can subsequently be used only by new data in the cluster resulting from insert or update operations. This clause leaves storage parameters at their current settings.

If you have specified more than one free list for the object you are truncating, then the `REUSE STORAGE` clause also removes any mapping of free lists to instances and resets the high-water mark to the beginning of the first extent.

**Examples**

**Truncating a Cluster: Example**  The following statement removes all rows from all tables in the `personnel` cluster, but leaves the freed space allocated to the tables:

```
TRUNCATE CLUSTER personnel REUSE STORAGE;
```

The preceding statement also removes all data from all indexes on the tables in the `personnel` cluster.
TRUNCATE TABLE

Purpose

Caution: You cannot roll back a TRUNCATE TABLE statement, nor can you use a FLASHBACK TABLE statement to retrieve the contents of a table that has been truncated.

Use the TRUNCATE TABLE statement to remove all rows from a table. By default, Oracle Database also performs the following tasks:

- Deallocates all space used by the removed rows except that specified by the MINEXTENTS storage parameter
- Sets the NEXT storage parameter to the size of the last extent removed from the segment by the truncation process

Removing rows with the TRUNCATE TABLE statement can be more efficient than dropping and re-creating a table. Dropping and re-creating a table invalidates dependent objects of the table, requires you to regrant object privileges on the table, and requires you to re-create the indexes, integrity constraints, and triggers on the table and respecify its storage parameters. Truncating has none of these effects.

Removing rows with the TRUNCATE TABLE statement can be faster than removing all rows with the DELETE statement, especially if the table has numerous triggers, indexes, and other dependencies.

See Also:

- DELETE on page 17-28 and DROP TABLE on page 18-5 for information on other ways of removing data from a table
- TRUNCATE CLUSTER on page 19-87 for information on truncating a cluster

Prerequisites

To truncate a table, the table must be in your schema or you must have the DROP ANY TABLE system privilege.

To specify the CASCADE clause, all affected child tables must be in your schema or you must have the DROP ANY TABLE system privilege.

See Also: "Restrictions on Truncating Tables" on page 19-91
Syntax

\textit{truncation\_table::=}

Semantics

\textbf{TABLE Clause}

Specify the schema and name of the table to be truncated. This table cannot be part of a cluster. If you omit \textit{schema}, then Oracle Database assumes the table is in your own schema.

- You can truncate index-organized tables and temporary tables. When you truncate a temporary table, only the rows created during the current session are removed.
- Oracle Database changes the \texttt{NEXT} storage parameter of \textit{table} to be the size of the last extent deleted from the segment in the process of truncation.
- Oracle Database also automatically truncates and resets any existing \texttt{UNUSABLE} indicators for the following indexes on \textit{table}: range and hash partitions of local indexes and subpartitions of local indexes.
- If \textit{table} is not empty, then the database marks \texttt{UNUSABLE} all nonpartitioned indexes and all partitions of global partitioned indexes on the table. However, when the table is truncated, the index is also truncated, and a new high water mark is calculated for the index segment. This operation is equivalent to creating a new segment for the index. Therefore, at the end of the truncate operation, the indexes are once again \texttt{USABLE}.
- For a domain index, this statement invokes the appropriate truncate routine to truncate the domain index data.

\textbf{See Also: } \textit{Oracle Database Data Cartridge Developer’s Guide} for more information on domain indexes

- If a regular or index-organized table contains LOB columns, then all LOB data and LOB index segments are truncated.
- If \textit{table} is partitioned, then all partitions or subpartitions, as well as the LOB data and LOB index segments for each partition or subpartition, are truncated.
Note: When you truncate a table, Oracle Database automatically removes all data in the table’s indexes and any materialized view direct-path INSERT information held in association with the table. This information is independent of any materialized view log. If this direct-path INSERT information is removed, then an incremental refresh of the materialized view may lose data.

- All cursors are invalidated.

Restrictions on Truncating Tables  This statement is subject to the following restrictions:

- You cannot roll back a TRUNCATE TABLE statement.
- You cannot flash back to the state of the table before the truncate operation.
- You cannot individually truncate a table that is part of a cluster. You must either truncate the cluster, delete all rows from the table, or drop and re-create the table.
- You cannot truncate the parent table of a enabled foreign key constraint. You must disable the constraint before truncating the table. An exception is that you can truncate the table if the integrity constraint is self-referential.
- If a domain index is defined on table, then neither the index nor any index partitions can be marked IN_PROGRESS.
- You cannot truncate the parent table of a reference-partitioned table. You must first drop the reference-partitioned child table.

MATERIALIZED VIEW LOG Clause
The MATERIALIZED VIEW LOG clause lets you specify whether a materialized view log defined on the table is to be preserved or purged when the table is truncated. This clause permits materialized view master tables to be reorganized through export or import without affecting the ability of primary key materialized views defined on the master to be fast refreshed. To support continued fast refresh of primary key materialized views, the materialized view log must record primary key information.

Note: The keyword SNAPSHOT is supported in place of MATERIALIZED VIEW for backward compatibility.

PRESERVE  Specify PRESERVE if any materialized view log should be preserved when the master table is truncated. This is the default.

PURGE    Specify PURGE if any materialized view log should be purged when the master table is truncated.

See Also: Oracle Database Advanced Replication for more information about materialized view logs and the TRUNCATE statement

STORAGE Clauses
The STORAGE clauses let you determine what happens to the space freed by the truncated rows. The DROP STORAGE clause, DROP ALL STORAGE clause, and REUSE STORAGE clause also apply to the space freed by the data deleted from associated indexes.
**TRUNCATE TABLE**

**DROP STORAGE**  Specify DROP STORAGE to deallocate all space from the deleted rows from the table except the space allocated by the MINEXTENTS parameter of the table. This space can subsequently be used by other objects in the tablespace. Oracle Database also sets the NEXT storage parameter to the size of the last extent removed from the segment in the truncation process. This setting, which is the default, is useful for small and medium-sized objects. The extent management in locally managed tablespace is very fast in these cases, so there is no need to reserve space.

**DROP ALL STORAGE**  Specify DROP ALL STORAGE to deallocate all space from the deleted rows from the table, including the space allocated by the MINEXTENTS parameter. All segments for the table, as well as all segments for its dependent objects, will be deallocated.

**Restrictions on DROP ALL STORAGE**  This clause is subject to the same restrictions as described in "Restrictions on Deferred Segment Creation" on page 16-44.

**REUSE STORAGE**  Specify REUSE STORAGE to retain the space from the deleted rows allocated to the table. Storage values are not reset to the values when the table was created. This space can subsequently be used only by new data in the table resulting from insert or update operations. This clause leaves storage parameters at their current settings.

This setting is useful as an alternative to deleting all rows of a very large table—when the number of rows is very large, the table entails many thousands of extents, and when data is to be reinserted in the future.

This clause is not valid for temporary tables. A session becomes unbound from the temporary table when the table is truncated, so the storage is automatically dropped.

If you have specified more than one free list for the object you are truncating, then the REUSE STORAGE clause also removes any mapping of free lists to instances and resets the high-water mark to the beginning of the first extent.

**CASCADE**  If you specify CASCADE, then Oracle Database truncates all child tables that reference table with an enabled ON DELETE CASCADE referential constraint. This is a recursive operation that will truncate all child tables, grandchild tables, and so on, using the specified options.

**Examples**

**Truncating a Table: Example**  The following statement removes all rows from a hypothetical copy of the sample table hr.employees and returns the freed space to the tablespace containing employees:

```sql
TRUNCATE TABLE employees_demo;
```

The preceding statement also removes all data from all indexes on employees and returns the freed space to the tablespaces containing them.

**Preserving Materialized View Logs After Truncate: Example**  The following statements are examples of TRUNCATE statements that preserve materialized view logs:

```sql
TRUNCATE TABLE sales_demo PRESERVE MATERIALIZED VIEW LOG;

TRUNCATE TABLE orders_demo;
```
UPDATE

Purpose

Use the UPDATE statement to change existing values in a table or in the base table of a view or the master table of a materialized view.

Prerequisites

For you to update values in a table, the table must be in your own schema or you must have the UPDATE object privilege on the table.

For you to update values in the base table of a view:

- You must have the UPDATE object privilege on the view, and
- Whoever owns the schema containing the view must have the UPDATE object privilege on the base table.

The UPDATE ANY TABLE system privilege also allows you to update values in any table or in the base table of any view.

To update values in an object on a remote database, you must also have the READ or SELECT object privilege on the object.

If the SQL92_SECURITY initialization parameter is set to TRUE and the UPDATE operation references table columns, such as the columns in a where_clause, then you must also have the SELECT object privilege on the object you want to update.

Syntax

update::=  
  UPDATE  
  dml_table_expression_clause  
  t_alias  
  update_set_clause  
  where_clause  
  returning_clause  
  error_logging_clause  

(DML_table_expression_clause::= on page 19-94, update_set_clause::= on page 19-94, where_clause::= on page 19-95, returning_clause::= on page 19-95, error_logging_clause::= on page 19-95)
DML_table_expression_clause::=

(partition_extension_clause::= on page 19-94, subquery::= on page 19-5--part of SELECT, subquery_restriction_clause::= on page 19-94, table_collection_expression::= on page 19-94)

partition_extension_clause::=

subquery_restriction_clause::=

table_collection_expression::=

update_set_clause::=
**Semantics**

**hint**
Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

You can place a parallel hint immediately after the **UPDATE** keyword to parallelize both the underlying scan and **UPDATE** operations.

See Also:
- "Hints" on page 2-77 for the syntax and description of hints
- Oracle Database Concepts for detailed information about parallel execution

**DML_table_expression_clause**
The **ONLY** clause applies only to views. Specify **ONLY** syntax if the view in the **UPDATE** clause is a view that belongs to a hierarchy and you do not want to update rows from any of its subviews.

See Also: "Restrictions on the DML_table_expression_clause" on page 19-97 and "Updating a Table: Examples" on page 19-100

**schema**
Specify the schema containing the object to be updated. If you omit **schema**, then the database assumes the object is in your own schema.

**table | view | materialized_view | subquery**
Specify the name of the table, view, materialized view, or the columns returned by a subquery to be updated. Issuing an **UPDATE** statement against a table fires any **UPDATE** triggers associated with the table.
If you specify `view`, then the database updates the base table of the view. You cannot update a view except with `INSTEAD OF` triggers if the defining query of the view contains one of the following constructs:

- A set operator
- A `DISTINCT` operator
- An aggregate or analytic function
- A `GROUP BY`, `ORDER BY`, `MODEL`, `CONNECT BY`, or `START WITH` clause
- A collection expression in a `SELECT` list
- A subquery in a `SELECT` list
- A subquery designated `WITH READ ONLY`
- A recursive `WITH` clause
- Joins, with some exceptions, as documented in Oracle Database Administrator’s Guide

You cannot update more than one base table through a view.

In addition, if the view was created with the `WITH CHECK OPTION`, then you can update the view only if the resulting data satisfies the view’s defining query.

If `table` or the base table of `view` contains one or more domain index columns, then this statement executes the appropriate indextype update routine.

You cannot update rows in a read-only materialized view. If you update rows in a writable materialized view, then the database updates the rows from the underlying container table. However, the updates are overwritten at the next refresh operation. If you update rows in an updatable materialized view that is part of a materialized view group, then the database also updates the corresponding rows in the master table.

See Also:
- Oracle Database Data Cartridge Developer’s Guide for more information on the indextype update routines
- CREATE MATERIALIZED VIEW on page 15-4 for information on creating updatable materialized views

**partition_extension_clause**

Specify the name or partition key value of the partition or subpartition within `table` targeted for updates. You need not specify the partition name when updating values in a partitioned table. However in some cases specifying the partition name can be more efficient than a complicated `where_clause`.

See Also: "References to Partitioned Tables and Indexes" on page 2-128 and "Updating a Partition: Example" on page 19-101

**dblink**

Specify a complete or partial name of a database link to a remote database where the object is located. You can use a database link to update a remote object only if you are using Oracle Database distributed functionality.

If you omit `dblink`, then the database assumes the object is on the local database.

See Also: "References to Objects in Remote Databases" on page 2-126 for information on referring to database links
**subquery_restriction_clause**

Use the **subquery_restriction_clause** to restrict the subquery in one of the following ways:

**WITH READ ONLY**  Specify **WITH READ ONLY** to indicate that the table or view cannot be updated.

**WITH CHECK OPTION**  Specify **WITH CHECK OPTION** to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the **FROM** clause but not in subquery in the **WHERE** clause.

**CONSTRAINT constraint**  Specify the name of the **CHECK OPTION** constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form SYS_Cn, where n is an integer that makes the constraint name unique within the database.

See Also:  "Using the WITH CHECK OPTION Clause: Example" on page 19-66

**table_collection_expression**

The **table_collection_expression** lets you inform Oracle that the value of **collection_expression** should be treated as a table for purposes of query and DML operations. The **collection_expression** can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called **collection unnesting**.

The optional plus (+) is relevant if you are joining the **TABLE** collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

---

**Note:** In earlier releases of Oracle, when **collection_expression** was a subquery, **table_collection_expression** was expressed as THE subquery. That usage is now deprecated.

---

You can use a **table_collection_expression** to update rows in one table based on rows from another table. For example, you could roll up four quarterly sales tables into a yearly sales table.

**t_alias**

Specify a **correlation name** (alias) for the table, view, or subquery to be referenced elsewhere in the statement. This alias is required if the **DML_table_expression_clause** references any object type attributes or object type methods.

See Also:  "Correlated Update: Example" on page 19-102

**Restrictions on the DML_table_expression_clause**  This clause is subject to the following restrictions:

- You cannot execute this statement if **table** or the base table of **view** contains any domain indexes marked **IN_PROGRESS** or **FAILED**.
You cannot insert into a partition if any affected index partitions are marked UNUSABLE.

You cannot specify the order_by_clause in the subquery of the DML_table_expression_clause.

If you specify an index, index partition, or index subpartition that has been marked UNUSABLE, then the UPDATE statement will fail unless the SKIP_UNUSABLE_INDEXES session parameter has been set to TRUE.

**See Also:** ALTER SESSION on page 11-65 for information on the SKIP_UNUSABLE_INDEXES session parameter

**update_set_clause**
The update_set_clause lets you set column values.

**column**
Specify the name of a column of the object that is to be updated. If you omit a column of the table from the update_set_clause, then the value of that column remains unchanged.

If column refers to a LOB object attribute, then you must first initialize it with a value of empty or null. You cannot update it with a literal. Also, if you are updating a LOB value using some method other than a direct UPDATE SQL statement, then you must first lock the row containing the LOB. See for_update_clause on page 19-42 for more information.

If column is a virtual column, you cannot specify it here. Rather, you must update the values from which the virtual column is derived.

If column is part of the partitioning key of a partitioned table, then UPDATE will fail if you change a value in the column that would move the row to a different partition or subpartition, unless you enable row movement. Refer to the row_movement_clause of CREATE TABLE on page 16-6 or ALTER TABLE on page 12-2.

In addition, if column is part of the partitioning key of a list-partitioned table, then UPDATE will fail if you specify a value for the column that does not already exist in the partition_key_value list of one of the partitions.

**subquery**
Specify a subquery that returns exactly one row for each row updated.

- If you specify only one column in the update_set_clause, then the subquery can return only one value.

- If you specify multiple columns in the update_set_clause, then the subquery must return as many values as you have specified columns.

- If the subquery returns no rows, then the column is assigned a null.

- If this subquery refers to remote objects, then the UPDATE operation can run in parallel as long as the reference does not loop back to an object on the local database. However, if the subquery in the DML_table_expression_clause refers to any remote objects, then the UPDATE operation will run serially without notification.

You can use the flashback_query_clause within the subquery to update table with past data. Refer to the flashback_query_clause of SELECT on page 19-22 for more information on this clause.
**Update Field**

**expr**
Specify an expression that resolves to the new value assigned to the corresponding column.

See Also:
- SELECT on page 19-4 and "Using Subqueries" on page 9-14
- parallel_clause on page 16-86 in the CREATE TABLE documentation

**DEFAULT**
Specify DEFAULT to set the column to the value previously specified as the default value for the column. If no default value for the corresponding column has been specified, then the database sets the column to null.

**Restriction on Updating to Default Values**
You cannot specify DEFAULT if you are updating a view.

**VALUE Clause**
The VALUE clause lets you specify the entire row of an object table.

**Restriction on the VALUE clause**
You can specify this clause only for an object table.

**where_clause**
The where_clause lets you restrict the rows updated to those for which the specified condition is true. If you omit this clause, then the database updates all rows in the table or view. Refer to Chapter 6, "Conditions" for the syntax of condition.

The where_clause determines the rows in which values are updated. If you do not specify the where_clause, then all rows are updated. For each row that satisfies the where_clause, the columns to the left of the equality operator (=) in the update_set_clause are set to the values of the corresponding expressions to the right of the operator. The expressions are evaluated as the row is updated.

**returning_clause**
The returning clause retrieves the rows affected by a DML statement. You can specify this clause for tables and materialized views and for views with a single base table.

When operating on a single row, a DML statement with a returning_clause can retrieve column expressions using the affected row, rowid, and REFS to the affected row and store them in host variables or PL/SQL variables.

When operating on multiple rows, a DML statement with the returning_clause stores values from expressions, rowids, and REFS involving the affected rows in bind arrays.

See Also:
- "Updating an Object Table: Example" on page 19-101

**Note:** If you insert string literals into a RAW column, then during subsequent queries, Oracle Database will perform a full table scan rather than using any index that might exist on the RAW column.
Each item in the expr list must be a valid expression syntax.

The INTO clause indicates that the values of the changed rows are to be stored in the variable(s) specified in data_item list.

each data_item is a host variable or PL/SQL variable that stores the retrieved expr value.

For each expression in the RETURNING list, you must specify a corresponding type-compatible PL/SQL variable or host variable in the INTO list.

The following restrictions apply to the RETURNING clause:

- The expr is restricted as follows:
  - For UPDATE and DELETE statements each expr must be a simple expression or a single-set aggregate function expression. You cannot combine simple expressions and single-set aggregate function expressions in the same returning clause. For INSERT statements, each expr must be a simple expression. Aggregate functions are not supported in an INSERT statement RETURNING clause.
  - Single-set aggregate function expressions cannot include the DISTINCT keyword.
- If the expr list contains a primary key column or other NOT NULL column, then the update statement fails if the table has a BEFORE UPDATE trigger defined on it.
- You cannot specify the returning_clause for a multitable insert.
- You cannot use this clause with parallel DML or with remote objects.
- You cannot retrieve LONG types with this clause.
- You cannot specify this clause for a view on which an INSTEAD OF trigger has been defined.

See Also: Oracle Database PL/SQL Language Reference for information on using the BULK COLLECT clause to return multiple values to collection variables

The error_logging_clause has the same behavior in an UPDATE statement as it does in an INSERT statement. Refer to the INSERT statement error_logging_clause on page 18-73 for more information.

See Also: "Inserting Into a Table with Error Logging: Example" on page 18-74

Examples

The following statement gives null commissions to all employees with the job SH_CLERK:

```sql
UPDATE employees
SET commission_pct = NULL
WHERE job_id = 'SH_CLERK';
```

The following statement promotes Douglas Grant to manager of Department 20 with a $1,000 raise:
UPDATE employees SET 
    job_id = 'SA_MAN', salary = salary + 1000, department_id = 120 
WHERE first_name||' '||last_name = 'Douglas Grant';

The following statement increases the salary of an employee in the employees table on the remote database:

UPDATE employees@remote 
    SET salary = salary*1.1 
WHERE last_name = 'Baer';

The next example shows the following syntactic constructs of the UPDATE statement:

- Both forms of the update_set_clause together in a single statement
- A correlated subquery
- A where_clause to limit the updated rows

UPDATE employees a 
SET department_id = 
    (SELECT department_id 
    FROM departments 
    WHERE location_id = '2100'), 
(salary, commission_pct) = 
    (SELECT 1.1*AVG(salary), 1.5*AVG(commission_pct) 
    FROM employees b 
    WHERE a.department_id = b.department_id) 
WHERE department_id IN 
    (SELECT department_id 
    FROM departments 
    WHERE location_id = 2900 
    OR location_id = 2700);

The preceding UPDATE statement performs the following operations:

- Updates only those employees who work in Geneva or Munich (locations 2900 and 2700)
- Sets department_id for these employees to the department_id corresponding to Bombay (location_id 2100)
- Sets each employee's salary to 1.1 times the average salary of their department
- Sets each employee's commission to 1.5 times the average commission of their department

Updating a Partition: Example The following example updates values in a single partition of the sales table:

UPDATE sales PARTITION (sales_q1_1999) s 
SET s.promo_id = 494 
WHERE amount_sold > 1000;

Updating an Object Table: Example The following statement creates two object tables, people_demo1 and people_demo2, of the people_typ object created in Table Collections: Examples on page 19-73. The example shows how to update a row of people_demo1 by selecting a row from people_demo2:

CREATE TABLE people_demo1 OF people_typ;

CREATE TABLE people_demo2 OF people_typ;
UPDATE people_demo1 p SET VALUE(p) =
(SELECT VALUE(q) FROM people_demo2 q
  WHERE p.department_id = q.department_id)
  WHERE p.department_id = 10;

The example uses the VALUE object reference function in both the SET clause and the subquery.

**Correlated Update: Example**  For an example that uses a correlated subquery to update nested table rows, refer to “Table Collections: Examples” on page 19-73.

**Using the RETURNING Clause During UPDATE: Example**  The following example returns values from the updated row and stores the result in PL/SQL variables bnd1, bnd2, bnd3:

```sql
UPDATE employees
  SET job_id = 'SA_MAN', salary = salary + 1000, department_id = 140
  WHERE last_name = 'Jones'
  RETURNING salary*0.25, last_name, department_id
  INTO bnd1, bnd2, bnd3;
```

The following example shows that you can specify a single-set aggregate function in the expression of the returning clause:

```sql
UPDATE employees
  SET salary = salary * 1.1
  WHERE department_id = 100
  RETURNING SUM(salary) INTO :bnd1;
```
This appendix describes how to read syntax diagrams.

**Graphic Syntax Diagrams**

Syntax diagrams are drawings that illustrate valid SQL syntax. To read a diagram, trace it from left to right, in the direction shown by the arrows.

Commands and other keywords appear in UPPERCASE inside rectangles. Type them exactly as shown in the rectangles. Parameters appear in lowercase inside ovals. Variables are used for the parameters. Punctuation, operators, delimiters, and terminators appear inside circles.

If the syntax diagram has more than one path, then you can choose any path. For example, in the following syntax you can specify either `NOPARALLEL` or `PARALLEL`:

```
parallel_clause ::= [NOPARALLEL | PARALLEL integer]
```

If you have the choice of more than one keyword, operator, or parameter, then your options appear in a vertical list. For example, in the following syntax diagram, you can specify one or more of the four parameters in the stack:

```
physical_attributes_clause ::= [PCTFREE integer | PCTUSED integer | INITRANS integer | storage_clause]
```

The following table shows parameters that appear in the syntax diagrams and provides examples of the values you might substitute for them in your statements:
Required Keywords and Parameters

Required keywords and parameters can appear singly or in a vertical list of alternatives. Single required keywords and parameters appear on the main path, which is the horizontal line you are currently traveling. In the following example, `library_name` is a required parameter:

```
drop_library::= 
```

---

**Table A–1 Syntax Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>table</strong></td>
<td>The substitution value must be the name of an object of the type specified by the parameter. For a list of all types of objects, see the section, “Schema Objects” on page 2-118.</td>
<td>employees</td>
</tr>
<tr>
<td><strong>c</strong></td>
<td>The substitution value must be a single character from your database character set.</td>
<td>T s</td>
</tr>
<tr>
<td><strong>'text'</strong></td>
<td>The substitution value must be a text string in single quotation marks. See the syntax description of ‘text’ in “Text Literals” on page 2-48.</td>
<td>'Employee records'</td>
</tr>
<tr>
<td><strong>char</strong></td>
<td>The substitution value must be an expression of data type CHAR or VARCHAR2 or a character literal in single quotation marks.</td>
<td>last_name 'Smith'</td>
</tr>
<tr>
<td><strong>condition</strong></td>
<td>The substitution value must be a condition that evaluates to TRUE or FALSE. See the syntax description of condition in Chapter 6, “Conditions”.</td>
<td>last_name &gt;'A'</td>
</tr>
<tr>
<td><strong>date</strong></td>
<td>The substitution value must be a date constant or an expression of DATE data type.</td>
<td>TO_DATE('01-Jan-2002', 'DD-MON-YYYY')</td>
</tr>
<tr>
<td><strong>expr</strong></td>
<td>The substitution value can be an expression of any data type as defined in the syntax description of expr in “About SQL Expressions” on page 5-1.</td>
<td>salary + 1000</td>
</tr>
<tr>
<td><strong>integer</strong></td>
<td>The substitution value must be an integer as defined by the syntax description of integer in &quot;Integer Literals&quot; on page 2-50.</td>
<td>72</td>
</tr>
<tr>
<td><strong>number</strong></td>
<td>The substitution value must be an expression of NUMBER data type or a number constant as defined in the syntax description of number in &quot;Numeric Literals&quot; on page 2-50.</td>
<td>AVG(salary) 15 * 7</td>
</tr>
<tr>
<td><strong>raw</strong></td>
<td>The substitution value must be an expression of data type RAW.</td>
<td>HEXTORAW('7D')</td>
</tr>
<tr>
<td><strong>subquery</strong></td>
<td>The substitution value must be a SELECT statement that will be used in another SQL statement. See SELECT on page 19-4.</td>
<td>SELECT last_name FROM employees</td>
</tr>
<tr>
<td><strong>db_name</strong></td>
<td>The substitution value must be the name of a nondefault database in an embedded SQL program.</td>
<td>sales_db</td>
</tr>
<tr>
<td><strong>db_string</strong></td>
<td>The substitution value must be the database identification string for an Oracle Net database connection. For details, see the user’s guide for your specific Oracle Net protocol.</td>
<td>—</td>
</tr>
</tbody>
</table>
If there is a library named HQ_LIB, then, according to the diagram, the following statement is valid:

DROP LIBRARY hq_lib;

If multiple keywords or parameters appear in a vertical list that intersects the main path, then one of them is required. You must choose one of the keywords or parameters, but not necessarily the one that appears on the main path. In the following example, you must choose ALL, STANDBY, or NONE:

```
security_clause ::= 

  ALL
   \-- GUARD
     \-- STANDBY
     \-- NONE
```

**Optional Keywords and Parameters**

If keywords and parameters appear in a vertical list above the main path, then they are optional. In the following example, instead of traveling down a vertical line, you can continue along the main path:

```
deallocate_unused_clause ::= 

  DEALLOCATE Unused KEEP size_clause
```

```
size_clause ::= 

  K
   \-- M
     \-- G
       \-- T
         \-- P
           \-- E
```

According to the diagrams, all of the following statements are valid:

DEALLOCATE UNUSED;
DEALLOCATE UNUSED KEEP 1000;
DEALLOCATE UNUSED KEEP 10G;
DEALLOCATE UNUSED 8T;

**Syntax Loops**

Loops let you repeat the syntax within them as many times as you like. In the following example, after choosing one value expression, you can go back repeatedly to choose another, separated by commas.
### query_partition_clause::=

```
PARTITION BY expr, expr
```

### Multipart Diagrams

Read a multipart diagram as if all the main paths were joined end to end. The following example is a three-part diagram:

### alter_java::=

```
ALTER JAVA SOURCE schema.object_name \\
RESOLVER (match_string, schema_name) \\
COMPILE RESOLVE invoker_rights_clause
```

According to the diagram, the following statement is valid:

```
ALTER JAVA SOURCE jsourc_1 COMPILE;
```

### Database Objects

The names of Oracle identifiers, such as tables and columns, must not exceed 30 characters in length. The first character must be a letter, but the rest can be any combination of letters, numerals, dollar signs ($), pound signs (#), and underscores (_).

However, if an Oracle identifier is enclosed by double quotation marks ("), then it can contain any combination of legal characters, including spaces but excluding quotation marks. Oracle identifiers are not case sensitive except within double quotation marks.

**See Also:** "Database Object Naming Rules" on page 2-119 for more information
Automatic and Manual Locking Mechanisms During SQL Operations

This appendix describes mechanisms that lock data either automatically or as specified by the user during SQL statements. For a general discussion of locking mechanisms in the context of data concurrency and consistency, see Oracle Database Concepts.

This appendix contains the following sections:

- Automatic Locks in DML Operations
- Automatic Locks in DDL Operations
- Manual Data Locking

Automatic Locks in DML Operations

The purpose of a DML lock, also called a data lock, is to guarantee the integrity of data being accessed concurrently by multiple users. For example, a DML lock can prevent multiple customers from buying the last copy of a book available from an online bookseller. DML locks prevent destructive interference of simultaneous conflicting DML or DDL operations.

DML statements automatically acquire locks at both the table level and the row level. In the sections that follow, the acronym in parentheses after each type of lock or lock mode is the abbreviation used in the Locks Monitor of Oracle Enterprise Manager. Enterprise Manager might display "TM" for any table lock, rather than indicate the mode of table lock (such as RS or SRX).

The types of row and table locks are summarized here. For a more complete discussion of the types of row and table locks, see Oracle Database Concepts.

Row Locks (TX) A row lock, also called a TX lock, is a lock on a single row of a table. A transaction acquires a row lock for each row modified by one of the following statements: INSERT, UPDATE, DELETE, MERGE, and SELECT ... FOR UPDATE. The row lock exists until the transaction commits or rolls back.

When a transaction obtains a row lock for a row, the transaction also acquires a table lock for the table in which the row resides. The table lock prevents conflicting DDL operations that would override data changes in a current transaction.

Table Locks (TM) A transaction automatically acquires a table lock (TM lock) when a table is modified with the following statements: INSERT, UPDATE, DELETE, MERGE, and SELECT ... FOR UPDATE. These DML operations require table locks to reserve DML access to the table on behalf of a transaction and to prevent DDL operations that would conflict with the transaction. You can explicitly obtain a table lock using the LOCK
Automatic Locks in DML Operations

A table lock can be held in any of the following modes:

- **A row share lock (RS), also called a subshare table lock (SS),** indicates that the transaction holding the lock on the table has locked rows in the table and intends to update them. An SS lock is the least restrictive mode of table lock, offering the highest degree of concurrency for a table.

- **A row exclusive lock (RX), also called a subexclusive table lock (SX),** indicates that the transaction holding the lock has updated table rows or issued `SELECT ... FOR UPDATE`. An SX lock allows other transactions to query, insert, update, delete, or lock rows concurrently in the same table. Therefore, SX locks allow multiple transactions to obtain simultaneous SX and SS locks for the same table.

- **A share table lock (S) held by one transaction allows other transactions to query the table (without using `SELECT ... FOR UPDATE`) but allows updates only if a single transaction holds the share table lock.** Multiple transactions may hold a share table lock concurrently, so holding this lock is not sufficient to ensure that a transaction can modify the table.

- **A share row exclusive table lock (SRX), also called a share-subexclusive table lock (SSX),** is more restrictive than a share table lock. Only one transaction at a time can acquire an SSX lock on a given table. An SSX lock held by a transaction allows other transactions to query the table (except for `SELECT ... FOR UPDATE`) but not to update the table.

- **An exclusive table lock (X) is the most restrictive mode of table lock, allowing the transaction that holds the lock exclusive write access to the table.** Only one transaction can obtain an X lock for a table.

**See Also:** "Manual Data Locking" on page B-5

**Locks in DML Operations**

Oracle Database automatically obtains row-level and table-level locks on behalf of DML operations. The type of operation determines the locking behavior. **Table B–1** summarizes the information in this section.

---

**Note:** The implicit SX locks shown for the DML statements in **Table B–1** can sometimes be exclusive (X) locks for a short time owing to side effects from constraints.

---

**Table B–1  Summary of Locks Obtained by DML Statements**

<table>

</tbody>
</table>
Locks When Rows Are Queried

A query can be explicit, as in the `SELECT` statement, or implicit, as in most `INSERT`, `MERGE`, `UPDATE`, and `DELETE` statements. The only DML statement that does not necessarily include a query component is an `INSERT` statement with a `VALUES` clause. Because queries only read data, they are the SQL statements least likely to interfere with other SQL statements.

The following characteristics apply to a query without the `FOR UPDATE` clause:

- The query acquires no data locks. Therefore, other transactions can query and update a table being queried, including the specific rows being queried. Because queries without the `FOR UPDATE` clause do not acquire any data locks to block other operations, such queries are often referred to as nonblocking queries.
- The query does not have to wait for any data locks to be released. Therefore, the query can always proceed. An exception to this rule is that queries may have to wait for data locks in some very specific cases of pending distributed transactions.

Locks When Rows Are Modified

Some databases use a lock manager to maintain a list of locks in memory. Oracle Database, in contrast, stores lock information in the data block that contains the locked row. Each row lock affects only a single row.

Oracle Database uses a queuing mechanism for acquisition of row locks. If a transaction requires a row lock, and if the row is not already locked, then the transaction acquires a lock in the row’s data block. The transaction itself has an entry in the interested transaction list (ITL) section of the block header. Each row modified by this transaction points to a copy of the transaction ID stored in the ITL. Thus, 100 rows in the same block modified by a single transaction require 100 row locks, but all 100 rows reference a single transaction ID.

When a transaction ends, the transaction ID remains in the ITL section of the data block header. If a new transaction wants to modify a row, it uses the transaction ID to determine whether the lock is active. If the lock is active, then the session of the new transaction asks to be notified when the lock is released; otherwise, the new transaction acquires the lock.

The characteristics of `INSERT`, `UPDATE`, `DELETE`, and `SELECT ... FOR UPDATE` statements are as follows:

- A transaction containing a DML statement acquires exclusive row locks on the rows modified by the statement. Therefore, other transactions cannot update or delete the locked rows until the locking transaction either commits or rolls back.
In addition to these row locks, a transaction containing a DML statement that modifies data also requires at least a subexclusive table lock (SX) on the table that contains the affected rows. If the transaction already holds an S, SRX, or X table lock for the table, which are more restrictive than an SX lock, then the SX lock is not needed and is not acquired. If the containing transaction already holds only an SS lock, however, then Oracle Database automatically converts the SS lock to an SX lock.

A transaction that contains a DML statement does not require row locks on any rows selected by a subquery or an implicit query.

In the following sample UPDATE statement, the SELECT statement in parentheses is a subquery, whereas the WHERE \( a > 5 \) clause is an implicit query:

```sql
UPDATE t SET x = ( SELECT y FROM t2 WHERE t2.z = t.z ) WHERE a > 5;
```

A subquery or implicit query inside a DML statement is guaranteed to be consistent as of the start of the query and does not see the effects of the DML statement of which it forms a part.

A query in a transaction can see the changes made by previous DML statements in the same transaction, but not the uncommitted changes of other transactions.

See Also: Oracle Database Concepts for information on locks in foreign keys

### Automatic Locks in DDL Operations

A data dictionary (DDL) lock protects the definition of a schema object while it is acted upon or referred to by an ongoing DDL operation. For example, when a user creates a procedure, Oracle Database automatically acquires DDL locks for all schema objects referenced in the procedure definition. The DDL locks prevent these objects from being altered or dropped before procedure compilation is complete.

Oracle Database acquires a DDL lock automatically on behalf of any DDL transaction requiring it. Users cannot explicitly request DDL locks. Only individual schema objects that are modified or referenced are locked during DDL operations. The whole data dictionary is never locked.

DDL operations also acquire DML locks on the schema object to be modified.

### Exclusive DDL Locks

An exclusive DDL lock prevents other session from obtaining a DDL or DML lock. Most DDL operations require exclusive DDL locks to prevent destructive interference with other DDL operations that might modify or reference the same schema object. For example, a DROP TABLE operation is not allowed to drop a table while an ALTER TABLE operation is adding a column to it, and vice versa. However, a query against the table is not blocked.

Exclusive DDL locks last for the duration of DDL statement execution and automatic commit. During the acquisition of an exclusive DDL lock, if another DDL lock is already held on the schema object by another operation, then the acquisition waits until the older DDL lock is released and then proceeds.

### Share DDL Locks

A share DDL lock for a resource prevents destructive interference with conflicting DDL operations, but allows data concurrency for similar DDL operations.
For example, when a CREATE PROCEDURE statement is run, the containing transaction acquires share DDL locks for all referenced tables. Other transactions can concurrently create procedures that reference the same tables and acquire concurrent share DDL locks on the same tables, but no transaction can acquire an exclusive DDL lock on any referenced table.

A share DDL lock lasts for the duration of DDL statement execution and automatic commit. Thus, a transaction holding a share DDL lock is guaranteed that the definition of the referenced schema object is constant for the duration of the transaction.

Breakable Parse Locks

A parse lock is held by a SQL statement or PL/SQL program unit for each schema object that it references. Parse locks are acquired so that the associated shared SQL area can be invalidated if a referenced object is altered or dropped. A parse lock is called a breakable parse lock because it does not disallow any DDL operation and can be broken to allow conflicting DDL operations.

A parse lock is acquired in the shared pool during the parse phase of SQL statement execution. The lock is held as long as the shared SQL area for that statement remains in the shared pool.

Manual Data Locking

Oracle Database always performs locking automatically to ensure data concurrency, data integrity, and statement-level read consistency. However, you can override the Oracle default locking mechanisms. This can be useful in situations such as the following:

- When your application requires consistent data for the duration of the transaction, not reflecting changes by other transactions, you can achieve transaction-level read consistency by using explicit locking, read-only transactions, serializable transactions, or by overriding default locking.
- When your application requires that a transaction have exclusive access to a resource so that the transaction does not have to wait for other transactions to complete, you can explicitly lock the data for the duration of the transaction.

You can override automatic locking at two levels:

- **Transaction.** You can override transaction-level locking with the following SQL statements:
  - SET TRANSACTION ISOLATION LEVEL
  - LOCK TABLE
  - SELECT ... FOR UPDATE

  Locks acquired by these statements are released after the transaction commits or rolls back.

- **Session.** A session can set the required transaction isolate level with an ALTER SESSION SET ISOLATION LEVEL statement.
Note: When overriding Oracle default locking, the database administrator or application developer should ensure that data integrity is guaranteed, data concurrency is acceptable, and deadlocks are not possible or, if possible, are appropriately handled. For more information on these criteria, see Oracle Database Concepts.
This appendix discusses Oracle’s conformance with the SQL:2008, SQL:2011 and SQL:2012 standards. Note that the SQL standard consists of ten parts; one part (SQL/RPR:2012) is new in 2012; five other parts were revised in 2011; for the other four parts, the 2008 version remains in place.

The mandatory portion of SQL:2011 is known as Core SQL:2011 and is found in SQL:2011 Part 2 (Foundation) and Part 11 (Schemata). The Foundation features are analyzed in Annex F of Part 2 in the table “Feature taxonomy and definition for mandatory features of SQL/Foundation”. The Schemata features are analyzed in Annex E of Part 11 in the table “Feature taxonomy and definition for mandatory features of SQL/Schemata”. There is no mandatory portion of SQL:2008 that has not been superseded by SQL:2011. There is no mandatory portion of SQL/RPR:2012.

This appendix declares Oracle’s conformance to the SQL standards established by the American National Standards Institute (ANSI) and the International Organization for Standardization (ISO). SQL/RPR:2012 is ANSI-only; otherwise the ANSI and ISO SQL standards are identical.

This appendix contains the following sections:

- ANSI Standards
- ISO Standards
- Oracle Compliance To Core SQL:2011
- Oracle Support for Optional Features of SQL/Foundation:2011
- Oracle Compliance with SQL/CLI:2008
- Oracle Compliance with SQL/PSM:2011
- Oracle Compliance with SQL/MED:2008
- Oracle Compliance with SQL/OLB:2008
- Oracle Compliance with SQL/JRT:2008
- Oracle Compliance with SQL/XML:2011
- Oracle Compliance with SQL/RPR:2012
- Oracle Compliance with FIPS 127-2
- Oracle Extensions to Standard SQL
- Oracle Compliance with Older Standards
- Character Set Support
The following documents of the American National Standards Institute (ANSI) relate to SQL:

These standards are identical to the corresponding ISO standards listed in the next section.

Also, in 2012, ANSI adopted this part, which is not an ISO standard:

- INCITS 500:2012, Information technology—Database languages—SQL—Part 14: Row Pattern Recognition (SQL/RPR)

You can obtain a copy of ANSI standards from this address:

American National Standards Institute
25 West 43rd Street, fourth floor
New York, NY 10036 USA
Telephone: +1.212.642.4900
Fax: +1.212.398.0023
Web site: http://www.ansi.org/

You can also obtain the standards from their Web site:

http://webstore.ansi.org/default.aspx

A subset of ANSI standards, including the SQL standard, are INCITS standards. You can obtain these from the InterNational Committee for Information Technology Standards (INCITS) at:

http://www.incits.org/
ISO Standards

The following documents of the International Organization for Standardization (ISO) relate to SQL:

You can obtain a copy of ISO standards from this address:

Oracle Compliance To Core SQL:2011

The ANSI and ISO SQL standards require conformance claims to state the type of conformance and the implemented facilities. The minimum claim of conformance is called Core SQL:2011 and is defined in Part 2, SQL/Foundation, and Part 11, SQL/Schemata, of the standard. The following products provide full or partial conformance with Core SQL:2011 as described in the tables that follow:

- Oracle Database server, release 12.1
- OTT (Oracle Type Translator), release 12.1
- Pro*C/C++, release 12.1
- Pro*C/COBOL, release 12.1

The SQL standards conformance features can be used either as a guide to portability, or as a guide to functionality. From the standpoint of portability, the user is interested
in conformance to both the precise syntax and semantics of the standard feature. From the standpoint of functionality, the user is less concerned about the precise syntax and more concerned with issues of semantics. The tables in this appendix use the following terms regarding support for standard syntax and semantics:

- **Full Support**: The feature is supported with standard syntax and semantics.
- **Partial Support**: Some, but not all, of the standard syntax is supported; whatever is supported has standard semantics.
- **Enhanced Supported**: The standard semantics is supported, as well as additional functionality.
- **Equivalent Support**: The standard semantics is supported using non-standard syntax.
- **Similar Support**: Neither the standard’s syntax nor semantics are supported precisely, but similar functionality is provided.

Oracle’s support for the features of Core SQL:2011 is listed in Table C–1:

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>E011, Numeric data types</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>E021, Character data types</td>
<td>Oracle fully supports these subfeatures:</td>
</tr>
<tr>
<td></td>
<td>■ E021-01, CHARACTER data type</td>
</tr>
<tr>
<td></td>
<td>■ E021-07, Character concatenation</td>
</tr>
<tr>
<td></td>
<td>■ E021-08, UPPER and LOWER functions</td>
</tr>
<tr>
<td></td>
<td>■ E021-09, TRIM function</td>
</tr>
<tr>
<td></td>
<td>■ E021-10, Implicit casting among character data types</td>
</tr>
<tr>
<td></td>
<td>Oracle partially supports these subfeatures:</td>
</tr>
<tr>
<td></td>
<td>■ E021-02, CHARACTER VARYING data type (Oracle does not distinguish a zero-length VARCHAR string from NULL)</td>
</tr>
<tr>
<td></td>
<td>■ E021-03, Character literals (Oracle regards the zero-length literal ” as being null)</td>
</tr>
<tr>
<td></td>
<td>■ E021-12, Character comparison (Oracle’s rules for padding the shorter of two strings to be compared differs from the standard)</td>
</tr>
<tr>
<td></td>
<td>Oracle has equivalent functionality for these subfeatures:</td>
</tr>
<tr>
<td></td>
<td>■ E021-04, CHARACTER_LENGTH function: use LENGTH function instead</td>
</tr>
<tr>
<td></td>
<td>■ E021-05, OCTET_LENGTH function: use LENGTHB function instead</td>
</tr>
<tr>
<td></td>
<td>■ E021-06, SUBSTRING function: use SUBSTR function instead</td>
</tr>
<tr>
<td></td>
<td>■ E021-11, POSITION function: use INSTR function instead</td>
</tr>
<tr>
<td>E031, Identifiers</td>
<td>Oracle supports this feature, with the following exceptions:</td>
</tr>
<tr>
<td></td>
<td>■ Oracle does not support the escape sequence to permit a double quote within a quoted identifier</td>
</tr>
<tr>
<td></td>
<td>■ A non-quoted identifier may not be equivalent to an Oracle reserved word (the list of Oracle reserved words differs from the standard’s list)</td>
</tr>
<tr>
<td></td>
<td>■ A column name may not be ROWID, even as a quoted identifier</td>
</tr>
<tr>
<td></td>
<td>Oracle extends this feature as follows:</td>
</tr>
<tr>
<td></td>
<td>■ An identifier may be up to 30 characters long</td>
</tr>
<tr>
<td></td>
<td>■ A non-quoted identifier may have dollar sign ($) or pound sign (#)</td>
</tr>
<tr>
<td>Feature ID, Feature</td>
<td>Support</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| E051, Basic query specification | Oracle fully supports the following subfeatures:  
  - E051-01, SELECT DISTINCT  
  - E051-02, GROUP BY clause  
  - E051-04, GROUP BY can contain columns not in SELECT list  
  - E051-05, SELECT list items can be renamed  
  - E051-06, HAVING clause  
  - E051-07, Qualified * in SELECT list  
Oracle partially supports the following subfeatures:  
  - E051-08, Correlation names in FROM clause (Oracle supports correlation names, but not the optional AS keyword)  
Oracle has equivalent functionality for the following subfeature:  
  - E051-09, Rename columns in the FROM clause (column names can be renamed in a subquery in the FROM clause) |
| E061, Basic predicates and search conditions | Oracle fully supports this feature, except that Oracle comparison of character strings differs from the standard as follows: In the standard, two character strings of unequal length are compared by either padding the shorter string with spaces or a fictitious character that is less than all actual characters. The decision on padding is made on the basis of the character set. In Oracle, the decision is based on whether the comparands are of fixed or varying length. |
| E071, Basic query expressions | Oracle fully supports the following subfeatures:  
  - E071-01, UNION DISTINCT table operator  
  - E071-02, UNION ALL table operator  
  - E071-05, Columns combined by table operators need not have exactly the same type  
  - E071-06, table operators in subqueries  
Oracle has equivalent functionality for the following subfeature:  
  - E071-03, EXCEPT DISTINCT table operator: Use MINUS instead of EXCEPT DISTINCT |
| E081, Basic privileges | Oracle fully supports all subfeatures of this feature, except E081-09, USAGE privileges. In the standard, the USAGE privilege permits the user to use domains, collations, character sets, transliterations, user-defined types and sequence generators. Oracle does not support domains or transliterations. No privileges are required to access collations and character sets. The Oracle privilege to use a user-defined type is EXECUTE. The Oracle privilege to use a sequence type is SELECT. |
| E091, Set functions | Oracle fully supports this feature. |
| E101, Basic data manipulation | Oracle fully supports this feature. |
| E111, Single row SELECT statement | Oracle fully supports this feature. |
### Table C–1  (Cont.) Oracle Support of Core SQL:2011 Features

<table>

</table>
Oracle Compliance To Core SQL:2011

Table C–1  (Cont.) Oracle Support of Core SQL:2011 Features

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
</table>
| F021, Basic information schema | Oracle does not have any of the views in this feature. However, Oracle makes the same information available in other metadata views:  
  - Instead of TABLES, use ALL_TABLES.  
  - Instead of COLUMNS, use ALL_TAB_COLUMNS.  
  - Instead of VIEWS, use ALL_VIEWS.  
  
However, Oracle’s ALL_VIEWS does not display whether a user view was defined WITH CHECK OPTION or if it is updatable. To see whether a view has WITH CHECK OPTION, use ALL_CONSTRAINTS, with TABLE_NAME equal to the view name and look for CONSTRAINT_TYPE equal to 'V'.  
  - Instead of TABLE_CONSTRAINTS, REFERENTIAL_CONSTRAINTS, and CHECK_CONSTRAINTS, use ALL_CONSTRAINTS.  
  
However, Oracle’s ALL_CONSTRAINTS does not display whether a constraint is deferrable or initially deferred. |
| F031, Basic schema manipulation | Oracle fully supports these subfeatures:  
  - F031-01, CREATE TABLE statement to create persistent base tables  
  - F031-02, CREATE VIEW statement  
  - F031-03, GRANT statement  
  
Oracle provides equivalent support for this subfeature:  
  - F031-04, ALTER TABLE statement: ADD COLUMN clause (Oracle does not support the optional keyword COLUMN in this syntax. Also, Oracle requires the column definition to be enclosed in parentheses, unlike the standard.)  
  
Oracle does not support these subfeatures (because Oracle does not support the keyword RESTRICT):  
  - F031-13, DROP TABLE statement: RESTRICT clause  
  - F031-16, DROP VIEW statement: RESTRICT clause  
  - F031-19, REVOKE statement: RESTRICT clause  
  
(Oracle DROP commands enhance the standard by invalidating dependent objects, so that they can be subsequently revalidated without user action, rather than either cascading all drops to dependent objects or prohibiting a drop if there is a dependent object.) |
| F041, Basic joined table | Oracle fully supports this feature. |
| F051, Basic date and time | Oracle fully supports this feature, except the following subfeatures are not supported:  
  - F051-02, TIME data type  
  - F051-07, LOCALTIME |
| F081, UNION and EXCEPT in views | Oracle fully supports UNION in views. The equivalent in Oracle of the standard’s EXCEPT is called MINUS, which is fully supported in views. |
| F131, Grouped operations | Oracle fully supports this feature. |
| F181, Multiple module support | Oracle fully supports this feature. |
| F201, CAST function | Oracle fully supports this feature. |
Oracle Compliance To Core SQL:2011

### Table C–1 (Cont.) Oracle Support of Core SQL:2011 Features

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>F221, Explicit defaults</td>
<td>Oracle’s <code>DEFAULT ON NULL</code> capability in a column definition provides equivalent functionality for the <code>INSERT</code> statement though not for the <code>UPDATE</code> statement.</td>
</tr>
<tr>
<td>F261, <code>CASE</code> expressions</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>F311, Schema definition statement</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>F471, Scalar subquery values</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>F481, Expanded null predicate</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>F501, Feature and conformance views</td>
<td>Oracle does not support this feature.</td>
</tr>
<tr>
<td>F812, Basic flagging</td>
<td>Oracle has a flagger, but it flags SQL-92 compliance rather than SQL:2011 compliance.</td>
</tr>
<tr>
<td>S011, Distinct types</td>
<td>Distinct types are strongly typed scalar types. A distinct type can be emulated in Oracle using an object type with only one attribute. The standard’s Information Schema view called <code>USER_DEFINED_TYPES</code> is equivalent to Oracle’s metadata view <code>ALL_TYPES</code>.</td>
</tr>
</tbody>
</table>
| T321, Basic SQL-invoked routines | Oracle fully supports these subfeatures:  
  - T321-03, function invocation  
  - T321-04, `CALL` statement  
Oracle supports these subfeatures with syntactic differences:  
  - T321-01, user-defined functions with no overloading  
  - T321-02, user-defined procedures with no overloading  
The Oracle syntax for `CREATE FUNCTION` and `CREATE PROCEDURE` differs from the standard as follows:  
  - In the standard, the mode of a parameter (IN, OUT, or INOUT) comes before the parameter name, whereas in Oracle it comes after the parameter name.  
  - The standard uses INOUT, whereas Oracle uses IN OUT.  
  - Oracle requires either IS or AS after the return type and before the definition of the routine body, while the standard lacks these keywords.  
  - If the routine body is in C (for example), then the standard uses the keywords `LANGUAGE C EXTERNAL NAME` to name the routine, whereas Oracle uses `LANGUAGE C NAME`.  
  - If the routine body is in SQL, then Oracle uses its proprietary procedural extension called PL/SQL.  
Oracle supports the following subfeature in PL/SQL but not in Oracle SQL:  
  - T321-05, `RETURN` statement  
Oracle provides equivalent functionality for the following subfeatures:  
  - T321-06, `ROUTINES` view: Use the `ALL PROCEDURES` metadata view.  
  - T321-07, `PARAMETERS` view: Use the `ALL_ARGUMENTS` and `ALL_METHOD_PARAMS` metadata views. |
Oracle Support for Optional Features of SQL/Foundation:2011

Oracle’s support for optional features of SQL/Foundation:2011 is listed in Table C–2:

### Table C–2 Oracle Support for Optional Features of SQL/Foundation:2011

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>B012, Embedded C</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>B013, Embedded COBOL</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>B021, Direct SQL</td>
<td>Oracle fully supports this feature, as SQL*Plus.</td>
</tr>
</tbody>
</table>
| B031, Basic dynamic SQL | Oracle supports dynamic SQL in two styles, documented in the embedded language manuals as "Oracle dynamic SQL" and "ANSI dynamic SQL."
  ANSI dynamic SQL is an implementation of the standard, with the following restrictions:
  - Oracle supports a subset of the descriptor items.
  - For `<input using clause>`, Oracle only supports `<using input descriptor>`.  
  - For `<output using clause>`, Oracle only supports `<into descriptor>`.  
  - Dynamic parameters are indicated by a colon followed by an identifier rather than a question mark.  
  Oracle dynamic SQL is similar to standard dynamic SQL, with the following modifications:
  - Parameters are indicated by a colon followed by an identifier, instead of a question mark.
  - Oracle’s `DESCRIBE SELECT LIST FOR` statement replaces the standard’s `DESCRIBE OUTPUT`.
  - Oracle provides `DECLARE STATEMENT` if you want to declare a cursor using a dynamic SQL statement physically prior to the `PREPARE` statement that prepares the dynamic SQL statement. |
| B032, Extended dynamic SQL | In ANSI dynamic SQL, Oracle only implements the ability to declare global statements and global cursors from this feature; the rest of the feature is not supported.  In Oracle dynamic SQL, Oracle’s `DESCRIBE BIND VARIABLES` is equivalent to the standard’s `DESCRIBE INPUT`; the rest of this feature is not supported. |
| B122, Routine language C | Oracle supports external routines written in C, though Oracle does not support the standard syntax for creating such routines. |
| B128, Routine language SQL | Oracle supports routines written in PL/SQL, which is Oracle’s equivalent to the standard procedural language SQL/PSM. |
| F032, CASCADE drop behavior | In Oracle, a `DROP` command invalidates all of the dropped object’s dependent objects. Invalidated objects are effectively unusable until the dropped object is redefined in such a way to allow successful recompilation of the invalidated object. |
### Table C–2 (Cont.) Oracle Support for Optional Features of SQL/Foundation:2011

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>F033, ALTER TABLE statement: DROP COLUMN clause</td>
<td>Oracle provides a DROP COLUMN clause, but without the RESTRICT or CASCADE options found in the standard.</td>
</tr>
</tbody>
</table>
| F034, Extended REVOKE statement | Oracle supports the following parts of this feature:  
  - F034-01, REVOKE statement performed by other than the owner of a schema object  
  - F034-03, REVOKE statement to revoke a privilege that the grantee has WITH GRANT OPTION  
Oracle provides equivalent functionality for the following parts of this feature:  
  - CASCADE: In Oracle, a REVOKE invalidates all dependent objects, which become effectively unusable until the metadata is changed through subsequent CREATE and GRANT commands enabling the invalidated object to be successfully recompiled. |
| F052, Intervals and datetime arithmetic | Oracle only supports the INTERVAL YEAR TO MONTH and INTERVAL DAY TO SECOND data types. |
| F111, Isolations levels other than SERIALIZABLE | In addition to SERIALIZABLE, Oracle supports the READ COMMITTED isolation level. |
| F121, Basic diagnostics management | Much of the functionality of this feature is provided through the SQLCA in embedded languages. |
| F191, Referential delete actions | Oracle supports ON DELETE CASCADE and ON DELETE SET NULL. |
| F200, TRUNCATE TABLE | Oracle fully supports this feature, and extends it by permitting truncation of a table that references itself in a referential integrity constraint, and the ability to cascade to child tables with enabled ON DELETE CASCADE referential constraints. |
| F231, Privilege tables | Oracle makes this information available in the following metadata views:  
  - Instead of TABLE_PRIVILEGES, use ALL_TAB_PRIVS.  
  - Instead of COLUMN_PRIVILEGES, use ALL_COL_PRIVS.  
  - Oracle does not support USAGE privileges so there is no equivalent to USAGE_PRIVILEGES. |
| F281, LIKE enhancements | Oracle fully supports this feature. |
| F291, UNIQUE predicate | The IS A SET condition may be used to test whether a multiset is a set; that is, each row is unique. Thus, the equivalent of  
  \[
  \text{UNIQUE <table subquery>}
  \]
  is  
  \[
  \text{CAST (<table subquery> AS MULTISET) IS A SET}
  \] |
| F302, INTERSECT table operator | Oracle supports INTERSECT but not INTERSECT ALL. Syntactically, Oracle differs from the standard in that UNION, INTERSECT, and MINUS have the same precedence. |
### Table C–2  (Cont.) Oracle Support for Optional Features of SQL/Foundation:2011

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
</table>
| F312, MERGE statement | The Oracle MERGE statement is almost the same as the standard, with these exceptions:  
  - Oracle does not support the optional `AS` keyword before a table alias.  
  - Oracle does not support the ability to rename columns of the table specified in the `USING` clause with a parenthesized list of column names following the table alias.  
  - Oracle does not support the `<override clause>`.

#### F314, MERGE statement with DELETE branch
Oracle has similar functionality, though in Oracle you must first update a row, after which you can delete it if the revised row meets a condition.

#### F321, User authorization
Oracle provides equivalent functionality for the following subfeatures:  
- Use `SYS_CONTEXT('USERENV','SESSION_USER')` instead of `SESSION_USER`  
- Use `SYS_CONTEXT('USERENV','CURRENT_USER')` instead of `CURRENT_USER`  
Oracle does not support the following subfeatures:  
- `SYSTEM_USER`  
- `SET SESSION AUTHORIZATION` statement

#### F341, Usage tables
Oracle makes this information available in the views `ALL_DEPENDENCIES`, `DBA_DEPENDENCIES`, and `USER_DEPENDENCIES`.

#### F381, Extended schema manipulation
Oracle fully supports the following element of this feature:  
- Oracle supports the standard syntax to add a table constraint using `ALTER TABLE`.
Oracle partially supports the following element of this feature:  
- Oracle supports the standard syntax to drop a table constraint, except that Oracle does not support `RESTRICT`.  
Oracle provides equivalent functionality for the following element of this feature:  
- To alter the default value of a column, use the `MODIFY` option of `ALTER TABLE`.
Oracle does not support the following parts of this feature:  
- `DROP SCHEMA` statement  
- `ALTER ROUTINE` statement

#### F382, Alter column data type
Oracle supports this functionality, though with non-standard syntax. As an extension to the standard, Oracle allows you to reduce the size or precision of a column.

#### F383, Set column not null clause
Oracle provides equivalent functionality for the two subfeatures of this feature:  
- To add a `NOT NULL` constraint to an existing column, use `ALTER TABLE ... MODIFY`  
- To drop a `NOT NULL` constraint, use `ALTER TABLE` to drop the constraint by name

#### F384, Drop identity property clause
Oracle provides equivalent functionality using `ALTER TABLE ... MODIFY (...) DROP IDENTITY`
Oracle provides equivalent functionality. Oracle’s syntax and semantics are the same as the standard, with this exception:

- Oracle does not support `RESTART`; use `START WITH` instead.
- When restarting an identity column, the values of the other parameters for the identity column are reset to their defaults unless explicitly set in the `ALTER TABLE` statement.

Oracle’s `START WITH LIMIT VALUE` option is an extension on the standard.

Oracle supports identifiers up to 30 characters in length.

The Oracle `UNISTR` function supports numeric escape sequences for all Unicode characters.

This feature adds the keywords `NFC`, `NFD`, `NFKC`, and `NFKD` to the `NORMALIZE` function and the `IS NORMAL` predicate. Without these keywords, `NFC` is the default (see Feature T061, UCS support). Oracle supports all four normalization forms, with nonstandard syntax, as follows:

- For `NFC`, use `COMPOSE`
- For `NFD`, use `DECOMPOSE` with the `CANONICAL` option
- For `NFKD`, use `DECOMPOSE` with the `COMPATIBILITY` option
- For `NFKC`, use `DECOMPOSE` with the `CANONICAL` option followed by `COMPOSE`

Oracle does not support the `IS NORMAL` predicate.

Oracle supports full outer joins, `CROSS` joins, and `NATURAL` joins.

Oracle supports named column joins for columns whose declared type is nested table. Oracle does not support named column joins for LOBs or arrays.

Oracle supports this feature, except with `FULL` outer joins.

Oracle fully supports `TIMESTAMP WITH TIME ZONE`, but does not support `TIME WITH TIME ZONE`.

Oracle fully supports this feature.

Oracle fully supports this feature.

Oracle supports the following parts of this feature:

- The ability in the `WHERE` clause to reference a column that is defined using an aggregate, either in a view or an inline view
- `COUNT` without `DISTINCT` of an expression
- Aggregates that reference columns that are outer references with respect to the aggregating query. However, Oracle defines the aggregating query as the innermost query containing the aggregate, rather than the innermost query that defines a range variable referenced in the aggregate.

Oracle fully supports this feature.

Oracle supports many character sets with Oracle-defined names. Oracle does not support any other aspect of this feature.

Oracle fully supports this feature.

</tr>
<tr>
<td>S024, Enhanced structured types</td>
<td>Oracle’s syntax is non-standard, but provides equivalents for the following:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>■ NOT INSTANTIABLE</td>
<td></td>
</tr>
<tr>
<td>■ STATIC methods</td>
<td></td>
</tr>
<tr>
<td>■ RELATIVE, MAP, and STATE orderings. The keyword in Oracle for RELATIVE orderings is ORDER. There is no keyword for STATE orderings (this is the default, if no other ordering is defined). Unlike the standard, Oracle does not support EQUALS ONLY on non-STATE orderings. (See also Feature S251, User-defined orderings.)</td>
<td></td>
</tr>
<tr>
<td>■ SELF AS RESULT in the signature of constructor methods</td>
<td></td>
</tr>
<tr>
<td>S025, Final structured types</td>
<td>Oracle’s final object types are equivalent to final structured types in the standard.</td>
</tr>
<tr>
<td>S026, Self-referencing structured types</td>
<td>In Oracle, an object type OT may have a reference that references OT.</td>
</tr>
<tr>
<td>S041, Basic reference types</td>
<td>Oracle’s reference types are equivalent to reference types in the standard. To dereference a reference, dot notation is used, instead of -&gt; as in the standard.</td>
</tr>
<tr>
<td>S043, Enhanced reference types</td>
<td>Oracle supports the following elements of this feature:</td>
</tr>
<tr>
<td>■ DEREF operator to return the object referenced by a reference</td>
<td></td>
</tr>
<tr>
<td>■ SCOPE clause as a constraint on columns of tables or materialized views</td>
<td></td>
</tr>
<tr>
<td>■ Adding and dropping the scope of a column</td>
<td></td>
</tr>
<tr>
<td>■ References that are either system-generated or derived from the primary key (but not from any other list of columns, nor from a list of attributes of the type)</td>
<td></td>
</tr>
<tr>
<td>S051, Create table of type</td>
<td>Oracle’s object tables are equivalent to tables of structured type in the standard.</td>
</tr>
<tr>
<td>S081, Subtables</td>
<td>Oracle supports hierarchies of object views, but not of object base tables. To emulate a hierarchy of base tables, create a hierarchy of views on those base tables.</td>
</tr>
</tbody>
</table>
### Table C–2  (Cont.) Oracle Support for Optional Features of SQL/Foundation:2011

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>S091, Array types</td>
<td>Oracle VARRAY types are equivalent to array types in the standard. However, Oracle does not support storage of arrays of LOBs. To access a single element of an array using a subscript, you must use PL/SQL. Oracle supports the following aspects of this feature with nonstandard syntax:</td>
</tr>
<tr>
<td></td>
<td>■ To construct an instance of varray type, including an empty array, use the varray type constructor.</td>
</tr>
<tr>
<td></td>
<td>■ To unnest a varray in the FROM clause, use the TABLE operator.</td>
</tr>
<tr>
<td></td>
<td>■ To get the cardinality of a varray, use the COUNT method in PL/SQL.</td>
</tr>
<tr>
<td>S092, Arrays of user-defined types</td>
<td>Oracle supports VARRAYs of object types.</td>
</tr>
<tr>
<td>S094, Arrays of reference types</td>
<td>Oracle supports VARRAYs of references.</td>
</tr>
<tr>
<td>S095, Array constructors by query</td>
<td>Oracle supports this using CAST (MULTISET (SELECT ...) AS varray_type) AS varray_type. The ability to order the elements of the array using ORDER BY is not supported.</td>
</tr>
<tr>
<td>S097, Array element assignment</td>
<td>In PL/SQL, you can assign to array elements, using syntax that is similar to the standard (SQL/PSM).</td>
</tr>
<tr>
<td>S098, ARRAY_AGG</td>
<td>Oracle does not have an aggregate that results in a varray. Instead, the COLLECT aggregate may be used to create a multiset, which can be cast to an array of the element type.</td>
</tr>
<tr>
<td>S111, ONLY in query expressions</td>
<td>Oracle supports the ONLY clause for view hierarchies; Oracle does not support hierarchies of base tables.</td>
</tr>
<tr>
<td>S151, Type predicate</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>S161, Subtype treatment</td>
<td>Supported, with a minor syntactic difference: The standard requires parentheses around the referenced type's name; Oracle does not support parentheses in this position.</td>
</tr>
<tr>
<td>S162, Subtype treatment for references</td>
<td>The standard requires parentheses around the referenced type's name; Oracle does not support parentheses in this position.</td>
</tr>
<tr>
<td>S201, SQL-invoked routines on arrays</td>
<td>PL/SQL provides the ability to pass arrays as parameters and return arrays as the result of functions. Procedures and functions written in C may pass arrays and return arrays as the result of functions using the Oracle Type Translator (OTT).</td>
</tr>
<tr>
<td>S202, SQL-invoked routines on multisets</td>
<td>A PL/SQL routine may have nested tables as parameters, and may return a nested table. Routines written in C may pass arrays and return arrays as the result of functions using the Oracle Type Translator.</td>
</tr>
<tr>
<td>S232, Array locators</td>
<td>Oracle Type Translator supports descriptors for arrays, which achieve the same purpose as locators.</td>
</tr>
<tr>
<td>S233, Multiset locators</td>
<td>Oracle supports locators for nested tables.</td>
</tr>
<tr>
<td>S241, Transform functions</td>
<td>The Oracle Type Translator provides the same capability as transforms.</td>
</tr>
</tbody>
</table>
Oracle Support for Optional Features of SQL/Foundation:2011

Table C–2  (Cont.) Oracle Support for Optional Features of SQL/Foundation:2011

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
</table>
| S251, User-defined orderings | Oracle’s object type ordering capabilities correspond to the standard’s capabilities as follows:  
  ■ Oracle’s MAP ordering corresponds to the standard’s ORDER FULL BY MAP ordering.  
  ■ Oracle’s ORDER ordering corresponds to the standard’s ORDER FULL BY RELATIVE ordering.  
  ■ If an Oracle object type has neither MAP nor ORDER declared, then this corresponds to EQUALS ONLY BY STATE in the standard.  
  ■ Oracle does not have unordered object types; you can alter the ordering but you cannot drop it. |
| S261, Specified type method | The GetTypeName method of the ANYDATA type may be used to learn the name of a type. |
| S271, Basic multiset support | Multisets in the standard are supported as nested table types in Oracle. The Oracle nested table data type based on a scalar type ST is equivalent, in standard terminology, to a multiset of rows having a single field of type ST and named column_value. The Oracle nested table type based on an object type is equivalent to a multiset of structured type in the standard. Oracle supports the following elements of this feature on nested tables using the same syntax as the standard has for multisets:  
  ■ The CARDINALITY function  
  ■ The SET function  
  ■ The MEMBER predicate  
  ■ The IS A SET predicate  
  ■ The COLLECT aggregate  
All other aspects of this feature are supported with non-standard syntax, as follows:  
  ■ To create an empty multiset, denoted MULTISET[] in the standard, use an empty constructor of the nested table type.  
  ■ To obtain the sole element of a multiset with one element, denoted ELEMENT (multiset value expression) in the standard, use a scalar subquery to select the single element from the nested table.  
  ■ To construct a multiset by enumeration, use the constructor of the nested table type.  
  ■ To construct a multiset by query, use CAST with a multiset argument, casting to the nested table type.  
  ■ To unnest a multiset, use the TABLE operator in the FROM clause. |
| S272, Multisets of user-defined types | Oracle’s nested table type permits a multiset of structured types. Oracle does not have distinct types, so a multiset of distinct types is not supported. |
| S274, Multisets of reference types | A nested table type can have one or more columns of reference type. |
S275, Advanced multiset support
Oracle supports the following elements of this feature on nested tables using the same syntax as the standard has for multisets:

- The `MULTISET UNION`, `MULTISET INTERSECTION`, and `MULTISET EXCEPT` operators
- The `SUBMULTISET` predicate
- `=` and `<>` predicates

Oracle does not support the `FUSION` or `INTERSECTION` aggregates.

S281, Nested collection types
Oracle permits nesting of its collection types (varray and nested table).

S401, Distinct types based on array types
Oracle’s varray types are strongly typed.

S403, MAX_CARDINALITY
In PL/SQL, the `LIMIT` method of a varray returns its maximum cardinality.

S404, TRIM_ARRAY
In PL/SQL, the `TRIM` method of a varray can be used to trim the varray.

T041, Basic LOB data type support
Oracle supports the following aspects of this feature:

- The keywords `BLOB`, `CLOB`, and `NCLOB`
- Concatenation, `UPPER`, `LOWER`, and `TRIM` on `CLOBs`

Oracle provides equivalent support for the following aspects of this feature:

- Use `INSTR` instead of `POSITION`.
- Use `LENGTH` instead of `CHAR_LENGTH`.
- Use `SUBSTR` instead of `SUBSTRING`.

Oracle does not support the following aspects of this feature:

- The keywords `BINARY LARGE OBJECT`, `CHARACTER LARGE OBJECT`, and `NATIONAL CHARACTER LARGE OBJECT` as synonyms for `BLOB`, `CLOB`, and `NCLOB`, respectively
- `<binary string literal>`
- The ability to specify an upper bound on the length of a `BLOB` or `CLOB`
- Concatenation of `BLOBs`

T042, Extended LOB support
Oracle fully supports the following element of this feature:

- `TRIM` function on a `CLOB` argument

Oracle provides equivalent functionality for the following elements of this feature:

- `BLOB` and `CLOB` substring, supported using `SUBSTR`
- `SIMILAR` predicate, supported using `REGEXPR_LIKE` to perform pattern matching with a Perl-like syntax

The following elements of this feature are not supported:

- Comparison predicates with `BLOB` or `CLOB` operands
- `CAST` with a `BLOB` or `CLOB` operand
- `OVERLAY` (This may be emulated using `SUBSTR` and string concatenation.)
- `LIKE` predicate with `BLOB` or `CLOB` operands

T051, Row types
Oracle object types can be used in place of the standard’s row types.
**Table C–2 (Cont.) Oracle Support for Optional Features of SQL/Foundation:2011**

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
</table>
| T061, UCS support   | Oracle provides equivalent functionality for the following elements of this feature:  
  - Oracle supports the keyword `CHAR` instead of `CHARACTERS`, and `BYTE` instead of `OCTETS`, in a character data type declaration.  
  - The Oracle `COMPOSE` function is equivalent to the standard's `NORMALIZE` function. Oracle does not support the `IS NORMALIZED` predicate. |
| T071, BIGINT data type | On many implementations, `BIGINT` refers to a binary integer type with 64 bits, which supports almost 19 decimal digits. The Oracle `NUMBER` type supports 39 decimal digits. |
| T111, Updatable joins, unions and columns | Oracle's updatable join views are similar to the standard's updatable join capabilities. Unlike the standard, Oracle does not require an updatable join view to display the strong candidate key in the `SELECT` list. Although an updatable join view might have more than one key-preserved table, only one of them may be modified using an `UPDATE` or `DELETE`, unlike the standard, which modifies all key-preserved tables of an updatable join. |
| T121, `WITH` (excluding `RECURSIVE`) in query expression | Oracle fully supports this feature. |
| T122, `WITH` (excluding `RECURSIVE`) in subquery | Oracle fully supports this feature. |
| T131, Recursive query | Oracle supports the use of a `WITH` clause element that references itself, but without the `RECURSIVE` keyword. Alternatively, Oracle's `START` with `CONNECT` clauses can be used to perform many recursive queries. |
| T132, Recursive query in subquery | Oracle supports the use of a `WITH` clause element that references itself, but without the `RECURSIVE` keyword. Alternatively, Oracle's `START` with `CONNECT` clauses can be used to perform many recursive queries. |
| T141, `SIMILAR` predicate | Oracle provides `REGEXP_LIKE` for pattern matching with a Perl-like syntax. |
| T172, `AS` subquery clause in table definition | Oracle's `AS` subquery feature of `CREATE TABLE` has substantially the same functionality as the standard, though there are some syntactic differences. |
| T174, Identity columns | Oracle supports this feature, with the following syntactic differences:  
  - Oracle uses `NOMINVALUE` and `NOMAXVALUE` instead of the standard's `NO MINVALUE` and `NO MAXVALUE`.  
  - To restart an identity column, in an `ALTER TABLE MODIFY` statement, use `START WITH LIMIT VALUE` to restart at the highest value (for an increasing identity column) or the lowest value (for a decreasing identity column); use `START WITH number` to restart at a specific number.  
  **GENERATED BY DEFAULT ON NULL** is an Oracle extension. |
| T175, Generated columns | Oracle supports this feature, with the following restrictions:  
  - Generated columns are not supported in temporary tables.  
  - The data type of a generated column may not be LOB or XML. |
<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>T176, Sequence generator support</td>
<td>Oracle’s sequences have the same capabilities as the standard’s, though with different syntax.</td>
</tr>
<tr>
<td>T178, Identity columns: simple restart option</td>
<td>Oracle’s START WITH LIMIT VALUE is the same as the standard’s simple restart if the identity column has not cycled.</td>
</tr>
<tr>
<td>T180, System-versioned tables</td>
<td>Oracle’s Flashback capability is substantially the same as the standard’s system-versioned tables. Some key differences are:</td>
</tr>
<tr>
<td></td>
<td>• In Oracle you do not need to designate particular tables for journaling; all tables are journaled.</td>
</tr>
<tr>
<td></td>
<td>• In Oracle, LOB columns need to be individually designated for journaling, because of the potential for large amounts of data. The standard has no analogous provision.</td>
</tr>
<tr>
<td></td>
<td>• In Oracle you need a privilege in order to read historical data.</td>
</tr>
<tr>
<td></td>
<td>• In Oracle, the retention period is specified through DBA actions, rather than DDL at the table level.</td>
</tr>
<tr>
<td></td>
<td>• In the standard, journaled tables have columns to record the start and end timestamps for the row. In Oracle, this is provided through pseudocolumns.</td>
</tr>
<tr>
<td>T201, Comparable data types for referential constraints</td>
<td>Oracle fully supports this feature.</td>
</tr>
<tr>
<td>T211, Basic trigger capability</td>
<td>Oracle’s triggers differ from the standard as follows:</td>
</tr>
<tr>
<td></td>
<td>• Oracle does not provide the optional syntax FOR EACH STATEMENT for the default case, the statement trigger.</td>
</tr>
<tr>
<td></td>
<td>• Oracle does not support OLD TABLE and NEW TABLE; the transition tables specified in the standard (the multiset of before and after images of affected rows) are not available.</td>
</tr>
<tr>
<td></td>
<td>• The trigger body is written in PL/SQL, which is functionally equivalent to the standard’s procedural language PSM, but not the same.</td>
</tr>
<tr>
<td></td>
<td>• In the trigger body, the new and old transition variables are referenced beginning with a colon.</td>
</tr>
<tr>
<td></td>
<td>• Oracle’s row triggers are executed as the row is processed, instead of buffering them and executing all of them after processing all rows. The standard’s semantics are deterministic, but Oracle’s in-flight row triggers are more performant.</td>
</tr>
<tr>
<td></td>
<td>• Oracle’s before-row and before-statement triggers can perform DML statements, which is forbidden in the standard. However, Oracle’s after-row statements cannot perform DML, while it is permitted in the standard.</td>
</tr>
<tr>
<td></td>
<td>• When multiple triggers apply, the standard says they are executed in order of definition. In Oracle the execution order is nondeterministic, unless specified using FOLLOWS.</td>
</tr>
<tr>
<td></td>
<td>• Oracle uses the system privileges CREATE TRIGGER and CREATE ANY TRIGGER to regulate creation of triggers, instead of the standard’s TRIGGER privilege, which is a table privilege.</td>
</tr>
<tr>
<td>T212, Enhanced trigger capability</td>
<td>This feature permits statements triggers, which Oracle supports, as described for feature T211, Basic trigger capability.</td>
</tr>
</tbody>
</table>
T213, INSTEAD OF triggers Oracle supports INSTEAD OF triggers on views, with syntax and semantics agreeing with the standard except as noted for feature T211, Basic trigger capability. Oracle permits an INSTEAD OF trigger on a view that specified WITH CHECK OPTION, unlike the standard.

T241, START TRANSACTION statement Oracle’s SET TRANSACTION statement starts a transaction making it equivalent to the standard’s START TRANSACTION rather than the standard’s SET TRANSACTION. Oracle’s READ ONLY transactions are at SERIALIZABLE isolation level.

T271, Savepoints Oracle supports this feature, except:
- Oracle does not support RELEASE SAVEPOINT.
- Oracle does not support savepoint levels.

T285, Enhanced derived column names This feature pertains only to derived columns in a SELECT list with no column alias and consisting of a SQL parameter reference. In that case, the column name defaults to the parameter name, the same as in the standard.

T323, Explicit security for external routines The Oracle syntax AUTHID { CURRENT USER | DEFINER } when used when creating an external function, procedure, or package is equivalent to the standard’s EXTERNAL SECURITY { DEFINER | INVOKER }.

T324, Explicit security for SQL routines Oracle’s syntax AUTHID { CURRENT USER | DEFINER } when used when creating a PL/SQL function, procedure, or package is equivalent to the standard’s SQL SECURITY { DEFINER | INVOKER }.

T325, Qualified SQL parameter reference PL/SQL supports the use of a routine name to qualify a parameter name.

T326, Table functions Oracle provides equivalents for the following elements of this feature:
- <multiset value constructor by query> is supported using CAST (MULTISET (query expression) AS <nested table type>)
- <table function derived table> is supported using the TABLE operator in the FROM clause with a varray or nested table as the argument
- <collection value expression> is equivalent to an Oracle expression resulting in a varray or nested table
- <returns table type> is equivalent to a PL/SQL function that returns a nested table

T331, Basic roles Oracle supports this feature, except for REVOKE ADMIN OPTION FOR <role name>.

T341, Overloading of SQL-invoked functions and procedures Oracle supports overloading of functions and procedures. However, the rules for handling certain data type combinations are not the same as the standard. For example, the standard permits the coexistence of two functions of the same name differing only in the numeric types of the arguments, whereas Oracle does not permit this.

T351, Bracketed comments Oracle fully supports this feature.

T431, Extended grouping capabilities Oracle fully supports this feature.

T432, Nested and concatenated GROUPING SETS Oracle supports concatenated GROUPING SETS, but not nested GROUPING SETS.

Oracle Compliance with SQL/CLI:2008
The Oracle ODBC driver conforms to SQL/CLI:2008.

Oracle Compliance with SQL/PSM:2011
Oracle PL/SQL provides functionality equivalent to SQL/PSM:2011, with minor syntactic differences, such as the spelling or arrangement of keywords.

Oracle Compliance with SQL/MED:2008
Oracle does not comply with SQL/MED:2008.

Oracle Compliance with SQL/OLB:2008
Oracle SQLJ conforms to SQL/OLB:1999 and not yet to SQL/OLB 2008.

Oracle Compliance with SQL/JRT:2008
Oracle fully supports stored routines and SQL types implemented in Java(TM). Oracle provides equivalent support for the creation and maintenance of such types and
Oracle Compliance with SQL/XML:2011

The XML data type in the standard is XML. The Oracle equivalent data type is XMLType. A feature of the standard is considered to be fully supported if the only difference between Oracle and the standard is the spelling of the data type name.

Table C–3 describes Oracle’s support for the features of SQL/XML:2011

<table>
<thead>
<tr>
<th>Feature ID, Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>X010, XML type</td>
<td>Oracle fully supports this feature.</td>

<tr>
<td>X144, IS VALID predicate: schema location</td>
<td>The XMLISVALID method is equivalent to the IS VALID predicate, and supports the specification of a schema location for a registered XML Schema.</td>
</tr>
<tr>
<td>X145, IS VALID predicate outside check constraints</td>
<td>The XMLISVALID method is equivalent to the IS VALID predicate, and may be used outside check constraints.</td>
</tr>
<tr>
<td>X151, IS VALID predicate with DOCUMENT option</td>
<td>The XMLISVALID method is equivalent to the IS VALID predicate, and performs validation equivalent to the DOCUMENT clause. (XMLISVALID does not support &quot;content&quot; validation.)</td>
</tr>
<tr>
<td>X156, IS VALID predicate: optional NAMESPACE with ELEMENT clause</td>
<td>The XMLISVALID method is equivalent to the IS VALID predicate, and may be used to validate against an element in any namespace.</td>
</tr>
</tbody>
</table>
The XMLISVALID method is equivalent to the IS VALID predicate, and may be used to validate against an element in the "no name" namespace.

The Oracle static data dictionary view ALL_XML_SCHEMAS provides a list of the registered XML schemas that are accessible to the current user. The ALL_XML_SCHEMAS.SCHEMA_URL column corresponds to the standard XML_SCHEMAS.XML_SCHEMA_LOCATION column. The target namespace of the registered XML Schemas can be learned by examining ALL_XML_SCHEMAS.SCHEMA. Oracle has no equivalents for the other columns of the standard's XML_SCHEMAS.

Oracle does not have static data dictionary views corresponding to XML_SCHEMA_NAMESPACES and XML_SCHEMA_ELEMENTS in the standard. However, all the information about registered XML Schemas may be learned by examining the actual XML Schema, which is found in the ALL_XML_SCHEMAS.SCHEMA column. This may also be examined to learn whether a registered XML Schema is nondeterministic, and which of its namespaces and elements are nondeterministic.

Oracle does not support this syntax. However, a column of a table can be constrained by a registered XML Schema, in which case all values of the column will be of XML(DOCUMENT(XMLSCHEMA)) type.

Oracle fully supports the following elements of this feature:
- X201, XMLQuery: RETURNING CONTENT
- X203, XMLQuery: passing a context item
- X204, XMLQuery: initializing an XQuery variable
- X206, XMLQuery: NULL ON EMPTY option

Oracle only supports passing by value, so the keywords BY VALUE are optional at the beginning of the PASSING clause, and not supported on individual arguments.

Oracle supports the BY VALUE clause in XMLQuery, XMLTable and XMLExists. In these, BY VALUE is supported as optional syntax at the beginning of an argument list, but not as a modifier on an individual argument or column.

Oracle does not support this syntax as a type modifier, but the Oracle XMLType supports this data type for transient values. Persistent values are of type XML(DOCUMENT(ANY)), which is a subset of XML(CONTENT(ANY)).

Oracle does not support this syntax. In Oracle, the behavior of the publishing functions (XMLAgg, XMLComment, XMLConcat, XElement, XMLForest, and XMLPi) is always RETURNING CONTENT.
<table>
<thead>

</table>
INCITS 500:2012, also known as SQL/RPR:2012 (for "Row Pattern Recognition"), was adopted in 2012. Oracle fully supports Feature R010, "Row pattern recognition: FROM clause" defined in this standard.

Oracle Compliance with FIPS 127-2

Oracle complied fully with last Federal Information Processing Standard (FIPS), which was FIPS PUB 127-2. That standard is no longer published. However, for users whose applications depend on information about the sizes of some database constructs that were defined in FIPS 127-2, the details of our compliance are listed in Table C–4.

### Table C–4  Sizing for Database Constructs

<table>
<thead>
<tr>
<th>Database Constructs</th>

</tr>
<tr>
<td>Values in an INSERT statement</td>
<td>100</td>
<td>1,000</td>
</tr>
<tr>
<td>SET clauses in an UPDATE statement (Note 1)</td>
<td>20</td>
<td>1,000</td>
</tr>
<tr>
<td>Length of a row (Note2, Note 3)</td>
<td>2,000</td>
<td>2,000,000</td>
</tr>
<tr>
<td>Columns in a UNIQUE constraint</td>
<td>6</td>
<td>32</td>
</tr>
<tr>
<td>Length of a UNIQUE constraint (Note 2)</td>
<td>120</td>
<td>(Note 4)</td>
</tr>
<tr>
<td>Length of foreign key column list (Note 2)</td>
<td>120</td>
<td>(Note 4)</td>
</tr>
<tr>
<td>Columns in a GROUP BY clause</td>
<td>6</td>
<td>255 (Note 5)</td>
</tr>
<tr>
<td>Length of GROUP BY column list</td>
<td>120</td>
<td>(Note 5)</td>
</tr>
<tr>
<td>Sort specifications in ORDER BY clause</td>
<td>6</td>
<td>255 (Note 5)</td>
</tr>
<tr>
<td>Length of ORDER BY column list</td>
<td>120</td>
<td>(Note 5)</td>
</tr>
<tr>
<td>Columns in a referential integrity constraint</td>
<td>6</td>
<td>32</td>
</tr>
<tr>
<td>Tables referenced in a SQL statement</td>
<td>15</td>
<td>No limit</td>
</tr>
</tbody>
</table>
Table C–4  (Cont.)  Sizing for Database Constructs

<table>
<thead>
<tr>
<th>Database Constructs</th>
<th>FIPS</th>
<th>Oracle Database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cursors simultaneously open</td>
<td>10</td>
<td>(Note 6)</td>
</tr>
<tr>
<td>Items in a SELECT list</td>
<td>100</td>
<td>1,000</td>
</tr>
</tbody>
</table>

Note 1: The number of SET clauses in an UPDATE statement refers to the number items separated by commas following the SET keyword.

Note 2: The FIPS PUB defines the length of a collection of columns to be the sum of: twice the number of columns, the length of each character column in bytes, decimal precision plus 1 of each exact numeric column, binary precision divided by 4 plus 1 of each approximate numeric column.

Note 3: The Oracle limit for the maximum row length is based on the maximum length of a row containing a LONG value of length 2 gigabytes and 999 VARCHAR2 values, each of length 4000 bytes: \(2(254) + 231 + (999(4000))\).

Note 4: The Oracle limit for a UNIQUE key is half the size of an Oracle data block (specified by the initialization parameter \(DB\_BLOCK\_SIZE\)) minus some overhead.

Note 5: Oracle places no limit on the number of columns in a GROUP BY clause or the number of sort specifications in an ORDER BY clause. However, the sum of the sizes of all the expressions in either a GROUP BY clause or an ORDER BY clause is limited to the size of an Oracle data block (specified by the initialization parameter \(DB\_BLOCK\_SIZE\)) minus some overhead.

Note 6: The Oracle limit for the number of cursors simultaneously opened is specified by the initialization parameter \(OPEN\_CURSORS\). The maximum value of this parameter depends on the memory available on your operating system and exceeds 100 in all cases.

Oracle Extensions to Standard SQL

Oracle supports numerous features that extend beyond standard SQL. If you are concerned with the portability of your applications to other implementations of SQL, then use Oracle’s FIPS Flagger to help identify the use of Oracle extensions to Entry SQL-92 in your embedded SQL programs. The FIPS Flagger is part of the Oracle precompilers and the SQL*Module compiler. The FIPS Flagger can also be enabled in SQL*Plus by using ALTER SESSION SET FLAGGER = ENTRY. While SQL-92 has been superseded by SQL:2011, there has been no conformance testing authority for any version of SQL since SQL-92; hence, Entry SQL-92 offers you the most assurance of portability.

See Also:  Pro*COBOL Programmer’s Guide and Pro*C/C++ Programmer’s Guide for information on how to use the FIPS Flagger

Oracle Compliance with Older Standards

This release of Oracle Database conforms to SQL:2008 and SQL:2011, the most recent editions of the SQL standard, as itemized in preceding sections of this appendix. Oracle does not formally claim that this release of the database conforms to SQL-92—and in particular, to SQL-92 Entry Level—or to SQL:1999, because those standards have been superseded by SQL:2008 and SQL:2011. Some, mostly minor, changes between editions of the SQL standard might affect applications. The SQL standard, or a reference discussing that standard, can be consulted to determine the details of any incompatibilities that have been introduced. One important source is

In some cases, this release of Oracle Database might continue to recognize constructs from older editions of SQL. Such recognition is often allowed as a valid vendor extension. It is the general policy of Oracle to keep incompatibilities between versions of the database as few as possible. This policy extends to retention of older forms when that is feasible. In any case, the differences between older SQL and SQL:2011 (as noted above) are relatively inconsequential.

Character Set Support

Oracle supports most national, international, and vendor-specific encoded character set standards. A complete list of character sets supported by Oracle appears in Oracle Database Globalization Support Guide.

Unicode is a universal encoded character set that lets you store information from any language using a single character set. Unicode is required by modern standards such as XML, Java, JavaScript, and LDAP. Unicode is compliant with ISO/IEC standard 10646. For information on ISO standards, visit the Web site of the International Organization for Standardization:

http://www.iso.ch/

Oracle Database 12c Release 1 (12.1.0.1) complies with version 6.1 of the Unicode Standard. Oracle Database 12c Release 1 (12.1.0.2) expands the compliance to version 6.2 of the Unicode Standard. For up-to-date information on the Unicode Standard, visit the Web site of the Unicode Consortium:

http://www.unicode.org

Oracle supports the UTF-8 encoding scheme of the Unicode Standard through the AL32UTF8 character set, the UTF-16BE encoding scheme through the AL16UTF16 character set, and the UTF-16LE encoding scheme through the AL16UTF16LE character set. AL32UTF8 is valid as the client and database character set on ASCII-based platforms. AL16UTF16 is valid as the national (NCHAR) character set on all platforms. AL16UTF16LE is not valid as the client, database, or national character set.

Oracle implements two deprecated Unicode compatibility encoding forms: CESU-8 through the UTF8 character set and UTF-EBCDIC through the UTFE character set. The UTF8 and UTFE character sets are not guaranteed to include updates to the Unicode standard beyond version 3.0. UTF8 is valid as the client and database character set on ASCII-based platforms and as the national (NCHAR) character set on all platforms. UTFE is valid as the database character set on EBCDIC-based platforms.

All mentioned Oracle character sets are supported in conversion functions.

Oracle recommends that databases on ASCII-based platforms are created with the AL32UTF8 character set and the AL16UTF16 national (NCHAR) character set. Oracle recommends that you avoid the use of the NCHAR data types and the associated national character set as they are not supported by some RDBMS components, such as Oracle Text and Oracle XDB.

See Also: Oracle Database Globalization Support Guide for details on Oracle character set support
Oracle’s implementation of regular expressions conforms with the IEEE Portable Operating System Interface (POSIX) regular expression standard and to the Unicode Regular Expression Guidelines of the Unicode Consortium.

This appendix contains the following sections:

- Multilingual Regular Expression Syntax
- Regular Expression Operator Multilingual Enhancements
- Perl-influenced Extensions in Oracle Regular Expressions

**Multilingual Regular Expression Syntax**

Table D–1 lists the full set of operators defined in the POSIX standard Extended Regular Expression (ERE) syntax. Oracle follows the exact syntax and matching semantics for these operators as defined in the POSIX standard for matching ASCII (English language) data. For more complete descriptions of the operators, examples of their use, and Oracle multilingual enhancements of the operators, refer to Oracle Database Development Guide. Notes following the table provide more complete descriptions of the operators and their functions, as well as Oracle multilingual enhancements of the operators. Table D–2 summarizes Oracle support for and multilingual enhancement of the POSIX operators.

**Table D–1 Regular Expression Operators and Metasymbols**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\</td>
<td>The backslash character can have four different meanings depending on the context. It can:</td>
</tr>
<tr>
<td></td>
<td>- Stand for itself</td>
</tr>
<tr>
<td></td>
<td>- Quote the next character</td>
</tr>
<tr>
<td></td>
<td>- Introduce an operator</td>
</tr>
<tr>
<td></td>
<td>- Do nothing</td>
</tr>
<tr>
<td>*</td>
<td>Matches zero or more occurrences</td>
</tr>
<tr>
<td>+</td>
<td>Matches one or more occurrences</td>
</tr>
<tr>
<td>?</td>
<td>Matches zero or one occurrence</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>^</td>
<td>Matches the beginning of a string by default. In multiline mode, it matches the beginning of any line anywhere within the source string.</td>
</tr>
</tbody>
</table>
When applied to multilingual data, Oracle’s implementation of the POSIX operators extends beyond the matching capabilities specified in the POSIX standard. Table D–2 shows the relationship of the operators in the context of the POSIX standard.

- The first column lists the supported operators.
- The second and third columns indicate whether the POSIX standard (Basic Regular Expression—BRE and Extended Regular Expression—ERE, respectively) defines the operator.
- The fourth column indicates whether Oracle’s implementation extends the operator’s semantics for handling multilingual data.

Oracle lets you enter multibyte characters directly, if you have a direct input method, or you can use functions to compose the multibyte characters. You cannot use the Unicode hexadecimal encoding value of the form ‘\xxxx’. Oracle evaluates the characters based on the byte values used to encode the character, not the graphical representation of the character. All accented characters are considered word characters.

| Table D–2 POSIX and Multilingual Operator Relationships |

Perl-influenced Extensions in Oracle Regular Expressions

Oracle Database regular expression functions and conditions accept a number of Perl-influenced operators that are in common use, although not part of the POSIX standard. Table D–3 lists those operators. For more complete descriptions with examples, refer to Oracle Database Development Guide.

This appendix contains the following sections:

- Oracle SQL Reserved Words
- Oracle SQL Keywords

Oracle SQL Reserved Words

This section lists Oracle SQL reserved words. You cannot use Oracle SQL reserved words as nonquoted identifiers. Quoted identifiers can be reserved words, although this is not recommended.

**Note:** In addition to the following reserved words, Oracle uses system-generated names beginning with "SYS_" for implicitly generated schema objects and subobjects. Oracle discourages you from using this prefix in the names you explicitly provide to your schema objects and subobjects to avoid possible conflict in name resolution.

The V$RESERVED_WORDS data dictionary view provides additional information on each reserved word, including whether it is always reserved or is reserved only for particular uses. Refer to Oracle Database Reference for more information.

Words followed by an asterisk (*) are also ANSI reserved words.

Note 1: This keyword is only reserved for use as an attribute name.

Note 2: You cannot use the uppercase word ROWID, either quoted or nonquoted, as a column name. However, you can use the uppercase word as a quoted identifier that is not a column name, and you can use the word with one or more lowercase letters (for example, "Rowid" or "rowid") as any quoted identifier, including a column name.

Oracle SQL Keywords

Oracle SQL keywords are not reserved. However, Oracle uses them internally in specific ways. Therefore, if you use these words as names for objects and object parts, then your SQL statements may be more difficult to read and may lead to unpredictable results.

You can obtain a list of keywords by querying the V$RESERVED_WORDS data dictionary view. All keywords in the view that are not listed as always reserved or reserved for a
specific use are Oracle SQL keywords. Refer to *Oracle Database Reference* for more information.
Extended Examples

The body of the SQL Language Reference contains examples for almost every reference topic. This appendix contains lengthy examples that are not appropriate in the context of a single SQL statement. These examples are intended to provide uninterrupted the series of steps that you would use to take advantage of particular Oracle functionality. They do not replace the syntax diagrams and semantics found for each individual SQL statement in the body of the reference. Use the cross-references provided to access additional information, such as privileges required and restrictions, as well as syntax.

This appendix contains the following sections:

- Using Extensible Indexing
- Using XML in SQL Statements

Using Extensible Indexing

This section provides examples of the steps entailed in a simple but realistic extensible indexing scenario.

Suppose you want to rank the salaries in the HR.employees table and then find those that rank between 10 and 20. You could use the DENSE_RANK function, as follows:

```
SELECT last_name, salary FROM
(SELECT last_name, DENSE_RANK() OVER
 (ORDER BY salary DESC) rank_val, salary FROM employees)
WHERE rank_val BETWEEN 10 AND 20;
```

This nested query is somewhat complex, and it requires a full scan of the employees table as well as a sort. An alternative would be to use extensible indexing to achieve the same goal. The resulting query will be simpler. The query will require only an index scan and a table access by rowid, and will therefore perform much more efficiently.

The first step is to create the implementation type position_im, including method headers for index definition, maintenance, and creation. Most of the type body uses PL/SQL, which is shown in italics.

The type must created with the AUTHID CURRENT_USER clause because of the EXECUTE IMMEDIATE statement inside the function ODCIINDEXCREATE(). By default that function runs with the definer rights. When the function is called in the subsequent creation of the domain index, the invoker does not have the same rights.

See Also: DENSE_RANK on page 7-97

    storage_tab_name || ') */ DISTINCT ' ||
    'col_val FROM ' || storage_tab_name || ' ORDER BY ' ||
    'col_val DESC) WHERE rownum <= ' || lower_pos;
EXECUTE IMMEDIATE upper_bound_stmt INTO upper_bound;
  IF (lower_pos != upper_pos) THEN
    lower_bound_stmt := 'Select MIN(col_val) FROM (Select /*+ INDEX_DESC(' ||
      storage_tab_name || ') */ DISTINCT ' ||
      'col_val FROM ' || storage_tab_name || ' WHERE col_val < ' || upper_bound || ' ORDER BY ' ||
      'col_val DESC) WHERE rownum <= ' ||
      (upper_pos - lower_pos);
EXECUTE IMMEDIATE lower_bound_stmt INTO lower_bound;
  ELSE
    lower_bound := upper_bound;
  END IF;
  IF (lower_bound IS NULL) THEN
    lower_bound := upper_bound;
  END IF;
  /* Store the lower and upper bounds for future function invocations for the positions. */
  scanctx := position_im(0, 0, lower_bound, upper_bound);
END IF;
/* Fetch the column value corresponding to the rowid, and see if it falls within the determined range. */
  col_val_stmt := 'Select col_val FROM ' || storage_tab_name ||
    ' WHERE base_rowid = ''' || indexctx.Rid || '''';
EXECUTE IMMEDIATE col_val_stmt INTO column_value;
  IF (column_value <= scanctx.upper_bound AND
      column_value >= scanctx.lower_bound AND
      scanflg = ODCICONST.RegularCall) THEN
    RETURN 1;
  ELSE
    RETURN 0;
END IF;
Next, create the `position_between` operator, which uses the `function_for_position_between` function. The operator takes an indexed `NUMBER` column as the first argument, followed by a `NUMBER` lower and upper bound as the second and third arguments.

```
CREATE OR REPLACE OPERATOR position_between
  BINDING (NUMBER, NUMBER, NUMBER) RETURN NUMBER
  WITH INDEX CONTEXT, SCAN CONTEXT position_im
  USING function_for_position_between;
```

In this `CREATE OPERATOR` statement, the `WITH INDEX CONTEXT, SCAN CONTEXT position_im` clause is included so that the index context and scan context are passed in to the functional evaluation, which is index based.

Now create the `position_indextype` index type for the `position_operator`:

```
CREATE INDEXTYPE position_indextype
  FOR position_between(NUMBER, NUMBER, NUMBER)
  USING position_im;
```

The operator `position_between` uses an index-based functional implementation. Therefore, a domain index must be defined on the referenced column so that the index information can be passed into the functional evaluation. So the final step is to create the domain index `salary_index` using the `position_indextype` index type:

```
CREATE INDEX salary_index ON employees(salary)
  INDEXTYPE IS position_indextype;
```

Now you can use the `position_between` operator function to rewrite the original query as follows:

```
SELECT last_name, salary FROM employees
  WHERE position_between(salary, 10, 20)=1
  ORDER BY salary DESC, last_name;
```

```
<table>

</table>
```
Using XML in SQL Statements

This section describes some of the ways you can use XMLType data in the database.

**XMLType Tables**

The sample schema `oe` contains a table `warehouses`, which contains an XMLType column `warehouse_spec`. Suppose you want to create a separate table with the `warehouse_spec` information. The following example creates a very simple XMLType table with one CLOB column:

```
CREATE TABLE xwarehouses OF XMLTYPE
    XMLTYPE STORE AS CLOB;
```

You can insert into such a table using XMLType syntax, as shown in the next statement. (The data inserted in this example corresponds to the data in the `warehouse_spec` column of the sample table `oe.warehouses` where `warehouse_id = 1`.)

```
INSERT INTO xwarehouses VALUES
    (xmltype('<?xml version="1.0"?>
    <Warehouse>
        <WarehouseId>1</WarehouseId>
        <WarehouseName>Southlake, Texas</WarehouseName>
        <Building>Owned</Building>
        <Area>25000</Area>
        <Docks>2</Docks>
        <DockType>Rear load</DockType>
        <WaterAccess>true</WaterAccess>
        <RailAccess>N</RailAccess>
        <Parking>Street</Parking>
        <VClearance>10</VClearance>
    </Warehouse>'));
```

You can query this table with the following statement:

```
SELECT e.getClobVal() FROM xwarehouses e;
```

CLOB columns are subject to all of the restrictions on LOB columns. To avoid these restrictions, create an XMLSchema-based table. The XMLSchema maps the XML elements to their object-relational equivalents. The following example registers an XMLSchema locally. The XMLSchema (`xwarehouses.xsd`) reflects the same structure as the `xwarehouses` table. (XMLSchema declarations use PL/SQL and the `DBMS_XMLSCHEMA` package, so the example is shown in italics.)

**See Also:** Oracle XML DB Developer’s Guide for information on XMLType and its member methods

You can query this table with the following statement:

```
SELECT e.getClobVal() FROM xwarehouses e;
```
See Also: Oracle XML DB Developer’s Guide for information on creating XMLSchemas

```
begin
dbms_xmlschema.registerSchema('http://www.example.com/xwarehouses.xsd','
'"<schema xmlns="http://www.w3.org/2001/XMLSchema"
   targetNamespace="http://www.example.com/xwarehouses.xsd"
   xmlns:who="http://www.example.com/xwarehouses.xsd"
   version="1.0">
   <simpleType name="RentalType">
   <restriction base="string">
   <enumeration value="Rented"/>
   <enumeration value="Owned"/>
   </restriction>
   </simpleType>
   
   <simpleType name="ParkingType">
   <restriction base="string">
   <enumeration value="Street"/>
   <enumeration value="Lot"/>
   </restriction>
   </simpleType>
   
   <element name = "Warehouse">
   <complexType>
   <sequence>
   <element name = "WarehouseId"   type = "positiveInteger"/>
   <element name = "WarehouseName" type = "string"/>
   <element name = "Building"      type = "who:RentalType"/>
   <element name = "Area"          type = "positiveInteger"/>
   <element name = "Docks"         type = "positiveInteger"/>
   <element name = "DockType"      type = "string"/>
   <element name = "WaterAccess"   type = "boolean"/>
   <element name = "RailAccess"    type = "boolean"/>
   <element name = "Parking"       type = "who:ParkingType"/>
   <element name = "VClearance"    type = "positiveInteger"/>
   
   </sequence>
   </complexType>
   
   </element>
   
   </schema>', TRUE, TRUE, FALSE, FALSE);
end;
```

Now you can create an XMLSchema-based table, as shown in the following example:

```
CREATE TABLE xwarehouses OF XMLTYPE
XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
ELEMENT "Warehouse";
```

By default, Oracle stores this as an object-relational table. Therefore, you can insert into it as shown in the example that follows. (The data inserted in this example corresponds to the data in the warehouse_spec column of the sample table oe.warehouses where warehouse_id = 1.)

```
INSERT INTO xwarehouses VALUES(
xmltype.createxml('<?xml version="1.0"?>
   <who:Warehouse xmlns:who="http://www.example.com/xwarehouses.xsd"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
```

```
You can define constraints on an XMLSchema-based table. To do so, you use the XMLDATA pseudocolumn to refer to the appropriate attribute within the Warehouse XML element:

```sql
ALTER TABLE xwarehouses ADD (PRIMARY KEY(XMLDATA."WarehouseId"));
```

Because the data in xwarehouses is stored object relationally, Oracle rewrites queries to this XMLType table to go to the underlying storage when possible. Therefore the following queries would use the index created by the primary key constraint in the preceding example:

```sql
SELECT * FROM xwarehouses x
WHERE EXISTSNODENAME(VALUE(x), '/Warehouse[WarehouseId=1]
'xmlns:who="http://www.example.com/xwarehouses.xsd") = 1;

SELECT * FROM xwarehouses x
WHERE EXTRACTVALUE(VALUE(x), '/Warehouse/WarehouseId,
'xmlns:who="http://www.example.com/xwarehouses.xsd") = 1;
```

You can also explicitly create indexes on XMLSchema-based tables, which greatly enhance the performance of subsequent queries. You can create object-relational views on XMLType tables, and you can create XMLType views on object-relational tables.

- Creating an Index on an XMLType Table: Example on page 14-97

**XMLType Columns**

The sample table oe.warehouses was created with a warehouse_spec column of type XMLType. The examples in this section create a shortened form of the oe.warehouses table, using two different types of storage.

The first example creates a table with an XMLType table stored as a CLOB. This table does not require an XMLSchema, so the content structure is not predetermined:

```sql
CREATE TABLE xwarehouses (  
    warehouse_id NUMBER,  
    warehouse_spec XMLTYPE)  
XMLTYPE warehouse_spec STORE AS CLOB  
(TABLESPACE example  
STORAGE (INITIAL 6144)  
CHUNK 4000
```
NOCACHE LOGGING);

The following example creates a similar table, but stores the XMLType data in an object-relational XMLType column whose structure is determined by the specified XMLSchema:

```
CREATE TABLE xwarehouses {
  warehouse_id  NUMBER,
  warehouse_spec  XMLTYPE
}
XMLTYPE warehouse_spec STORE AS OBJECT RELATIONAL
  XMLSCHEMA 'http://www.example.com/xwarehouses.xsd'
  ELEMENT 'Warehouse';
```

granting system privileges for, 18-51
INSTEAD OF
dropping, 17-17
re-creating, 16-119
removing from the database, 18-12
renaming, 13-3
TRIM function, 7-386
TRUNC (date) function, 7-387
format models, 7-437
TRUNC (number) function, 7-388
TRUNCATE PARTITION clause
of ALTER TABLE, 12-86
TRUNCATE SUBPARTITION clause
of ALTER TABLE, 12-86
TRUNCATE_CLUSTER statement, 19-87
TRUNCATE_TABLE statement, 19-89
type constructor expressions, 5-16
TYPES clause
of ASSOCIATE STATISTICS, 13-27, 13-28
do DISASSOCIATE STATISTICS, 17-36
types. See object types or data types
TZ_OFFSET function, 7-389

U

UID function, 7-390
unary operators, 4-2
UNDER ANY TYPE system privilege, 18-52
UNDER ANY VIEW system privilege, 18-52
UNDER clause
of CREATE VIEW, 17-21
UNDER object privilege
on a type, 18-56
on a view, 18-59
UNDER_PATH condition, 6-20
undo
rollback, 11-60, 14-39
system managed, 11-60, 14-39
UNDO tablespace clause
of CREATE DATABASE, 14-39
of CREATE TABLESPACE, 16-114
undo tables
creating, 14-39, 16-114
dropping, 18-10
modifying, 12-117
preserving unexpired data, 12-124, 16-114
UNDO_RETENTION initialization parameter
setting with ALTER SYSTEM, 18-29
unified audit policies
comments on, 13-55
creating, 14-2
dropping, 17-38
modifying, 10-24
unified auditing
ALTER AUDIT POLICY statement, 10-24
AUDIT statement, 13-45
CREATE AUDIT POLICY statement, 14-2
DROP AUDIT POLICY statement, 17-38
NOAUDIT statement, 18-92
UNIFORM clause
of CREATE TABLESPACE, 16-111
UNION ALL set operator, 4-5, 19-40
UNION set operator, 4-5, 19-40
UNIQUE clause
of CREATE INDEX, 14-81
of CREATE TABLE, 16-41
of SELECT, 19-20
unique constraints
conditional, 14-99
enabling, 16-83
index on, 16-83
unique elements of, 7-298
unique indexes, 14-81
unique queries, 19-20
UNISTR function, 7-391
universal rowids. See urowids
UNLIMITED TABLESPACE system privilege, 18-51
UNNEST hint, 2-115
unnesting collections, 19-26
examples, 19-74
unnesting subqueries, 9-15
unpivot operations, 19-28
examples, 19-67
ten syntax, 19-8
UNQUIESCE clause
of ALTER SYSTEM, 11-90
UNRECOVERABLE, 10-115, 16-51
See also NOLOGGING clause
unsorted indexes, 14-88
UNUSABLE clause
of ALTER INDEX, 10-120
UNUSABLE LOCAL INDEXES clause
of ALTER MATERIALIZED VIEW, 11-12
of ALTER TABLE, 12-95
UPDATE ANY CUBE BUILD PROCESS system
privilege, 18-49
UPDATE ANY CUBE DIMENSION system
privilege, 18-48
UPDATE ANY CUBE system privilege, 18-48
UPDATE ANY TABLE system privilege, 18-51
UPDATE BLOCK REFERENCES clause
of ALTER INDEX, 10-121, 10-123
UPDATE GLOBAL INDEXES clause
of ALTER TABLE, 12-95
UPDATE object privilege
on a table, 18-58
on a view, 18-59
on an OLAP cube, 18-57
on an OLAP cube dimension, 18-57
update operations
  collecting supplemental log data for, 10-58
UPDATE SET clause
  of MERGE, 18-83
UPDATE statement, 19-93
updates
  and simultaneous insert, 18-82
    using MERGE, 18-83, 18-84
UPDATEXML function, 7-392
UPGRADE clause
  of ALTER DATABASE, 10-44
    of ALTER TABLE, 12-49
UPPER function, 7-394
