**What’s New** ....................................................................................................................................................... xvii
  New features in release 18.1.4.1.0 ................................................................................................................ xvii
  New features in release 18.1.3.1.0 ................................................................................................................ xvii
  New features in release 18.1.2.1.0 ................................................................................................................ xvii
  New features in release 18.1.1.1.0 ................................................................................................................ xviii

1 **Connecting to a TimesTen Database**

Connecting to TimesTen with ODBC and JDBC drivers ............................................................................... 1-1
  Connecting using TimesTen ODBC drivers ............................................................................................... 1-3
  Connecting using the TimesTen JDBC driver and driver manager .......................................................... 1-4

Specifying Data Source Names to identify TimesTen databases ................................................................. 1-4
  Overview of user and system DSNs .......................................................................................................... 1-5
  Defining DSNs for direct or client/server connections ........................................................................... 1-6
  Connection attributes for Data Manager DSNs or Server DSNs ............................................................. 1-7

Creating a DSN on Linux and UNIX for TimesTen Classic ........................................................................ 1-9
  Create a user or system odbc.ini file ....................................................................................................... 1-9
  Using environment variables in database path names ............................................................................. 1-10

Defining Client and Server DSNs .................................................................................................................. 1-10

Resolution path for a DSN .............................................................................................................................. 1-10

DSN examples for TimesTen Classic ............................................................................................................ 1-11
  Creating multiple DSNs to a single TimesTen Classic database ............................................................. 1-11
  Specifying PL/SQL connection attributes in a DSN ................................................................................. 1-12
  Setting up a default DSN in TimesTen Classic .......................................................................................... 1-12

odbc.ini file entry descriptions ..................................................................................................................... 1-14
  ODBC Data Sources ................................................................................................................................ 1-14
  DSN specification ...................................................................................................................................... 1-14
  odbc.ini file example ................................................................................................................................. 1-16

Connecting to a database using a connection string .................................................................................. 1-16
  Using a connection string in TimesTen Scaleout ..................................................................................... 1-17
2 Managing TimesTen Databases

Opening and closing the database for user connections ........................................... 2-1
Loading and unloading the database from memory ................................................... 2-2
Loading a database into memory for TimesTen Classic ......................................... 2-2
Unloading a database from memory for TimesTen Classic ....................................... 2-4
Specifying a RAM policy .......................................................................................... 2-5
Changes to RAM policy after automatic recovery fails ........................................... 2-7
Preventing an automatic reload of the database after failure ................................... 2-7
Disconnecting from a database .................................................................................. 2-8
Disconnecting from a database in TimesTen Scaleout ............................................. 2-8
Disconnecting from a database in TimesTen Classic ................................................ 2-8
Specifying the memory region sizes of a database .................................................. 2-10
Estimating and modifying the memory region sizes for the database ....................... 2-11
Monitoring PermSize and TempSize attributes ...................................................... 2-12
Reducing database size for TimesTen Classic ....................................................... 2-13
Receiving out-of-memory warnings ......................................................................... 2-14
Storage provisioning for TimesTen .......................................................................... 2-14
Storage provisioning for transaction log files ......................................................... 2-15
Bulk copy data using the ttBulkCp utility ............................................................... 2-17
Copying data from a TimesTen table to an ASCII file ........................................... 2-17
Copying data from an ASCII file into a TimesTen table .......................................... 2-17
Running ttBulkCp with the -i option ..................................................................... 2-17
Running ttBulkCp with the -directLoad option on TimesTen Classic ..................... 2-18
Thread programming with TimesTen ....................................................................... 2-19
Defragmenting TimesTen databases ....................................................................... 2-19
Offline defragmentation of a TimesTen Scaleout database .................................... 2-19
Offline defragmentation of a TimesTen Classic database ........................................ 2-19
Online defragmentation of a TimesTen Classic database ....................................... 2-20
Online defragmentation of TimesTen Classic databases in an active standby pair replication scheme ............................................................... 2-21
Online defragmentation of TimesTen Classic databases in a non active standby pair replication scheme ............................................................... 2-24
Verifying if your database is a single-instance or distributed database ................... 2-27

3 Working with the TimesTen Client and Server

Overview of the TimesTen Client/Server ............................................................... 3-1
Restrictions on client/server communication .......................................................... 3-3
Communication protocols for Client/Server communication .................................. 3-3
TCP/IP Communication ......................................................................................... 3-4
Shared memory communication ............................................................................. 3-4
UNIX domain socket communication ..................................................................... 3-4
Configuring TimesTen Client and Server ............................................................... 3-4
Overview of TimesTen Client/Server configuration .............................................. 3-5
Installing and configuring for client/server connections ...................................... 3-6
Configuring Client/Server of the same TimesTen release ..................................... 3-6

# 5 Globalization Support

Overview of globalization support features .............................................................. 5-1  
Choosing a database character set ........................................................................... 5-2  
  Character sets and languages .............................................................................. 5-2  
  Client operating system and application compatibility ....................................... 5-2  
  Performance and storage implications ................................................................ 5-3  
  Character sets and replication .......................................................................... 5-3  
Length semantics and data storage ........................................................................ 5-3  
Connection character set ...................................................................................... 5-4  
Linguistic sorts ...................................................................................................... 5-4  
  Monolingual linguistic sorts .............................................................................. 5-5  
  Multilingual linguistic sorts .......................................................................... 5-5  
  Case-insensitive and accent-insensitive linguistic sorts ..................................... 5-5  
  Performing a linguistic sort ......................................................................... 5-6  
  Using linguistic indexes .............................................................................. 5-6  
SQL string and character functions ...................................................................... 5-7  
Setting globalization support attributes .............................................................. 5-7  
Globalization support during migration .............................................................. 5-8

# 6 Using the ttIsql Utility

Batch mode vs. interactive mode ........................................................................... 6-2  
Defining default settings with the TTISQL environment variable ......................... 6-3  
Customizing the ttIsql command prompt .............................................................. 6-4  
Using the ttIsql online help .................................................................................. 6-5  
Using the ttIsql 'editline' feature for Linux and UNIX only .................................. 6-5  
  Emacs binding ................................................................................................. 6-6  
  vi binding ..................................................................................................... 6-6  
Using the ttIsql command history ....................................................................... 6-7  
  Saving and clearing the ttIsql command history ............................................ 6-8  
Using the ttIsql edit command ............................................................................. 6-8  
  Changing the default text editor for the ttIsql edit command ......................... 6-9  
Working with character sets ............................................................................... 6-9  
Displaying database structure information ......................................................... 6-9  
  Using the ttIsql describe command ................................................................ 6-10  
Using the ttIsql cachegroups command .............................................................. 6-10  
Using the ttIsql dsize command ....................................................................... 6-11  
Using the ttIsql tablesize command .................................................................. 6-11  
Using the ttIsql monitor command ..................................................................... 6-12  
Listing database objects by object type ............................................................... 6-13  
Viewing and setting connection attributes ......................................................... 6-15  
Working with transactions .................................................................................... 6-15  
Working with prepared and parameterized SQL statements ............................... 6-16  
Using, declaring, and setting variables ................................................................. 6-16  
  Declaring and setting bind variables .............................................................. 6-19  
  Automatically creating bind variables for retrieved columns ......................... 6-21  
Creating and executing PL/SQL blocks ............................................................... 6-22  
Passing data from PL/SQL using OUT parameters ............................................. 6-23
7 Transaction Management

Transaction overview .................................................................................................................. 7-1

Transaction implicit commit behavior ....................................................................................... 7-2
  Transaction autocommit behavior ............................................................................................. 7-2
  TimesTen DDL commit behavior .............................................................................................. 7-3

Ensuring ACID semantics ........................................................................................................... 7-3
  Transaction atomicity, consistency, and isolation ...................................................................... 7-4
  Transaction consistency and durability ...................................................................................... 7-4

Concurrency control through isolation and locking ..................................................................... 7-5
  Transaction isolation levels ......................................................................................................... 7-5
  Locking granularities .................................................................................................................. 7-7
    Setting wait time for acquiring a lock ....................................................................................... 7-9

Checkpoint operations ................................................................................................................ 7-9
  Purpose of checkpoints .............................................................................................................. 7-9
  Usage of checkpoint files ........................................................................................................... 7-10
  Types of checkpoints .................................................................................................................. 7-10
    Fuzzy or non-blocking checkpoints .......................................................................................... 7-10
    Blocking checkpoints ............................................................................................................... 7-11
  Setting and managing checkpoints ......................................................................................... 7-11
    Programmatically performing a checkpoint in TimesTen Classic ........................................... 7-11
    Configuring or turning off background checkpointing ............................................................ 7-11
    Displaying checkpoint history and status .............................................................................. 7-12
    Setting the checkpoint rate ...................................................................................................... 7-15
    Setting the number of checkpoint file read threads ............................................................... 7-16

Transaction logging ..................................................................................................................... 7-16
  Managing transaction log buffers and files ................................................................................ 7-17
  Using NFS-mounted systems for checkpoint and transaction log files .................................... 7-18
  Monitoring accumulation of transaction log files .................................................................... 7-18
    Log holds by TimesTen components or operations ............................................................... 7-18
  Purging transaction log files .................................................................................................... 7-20
  Monitoring log holds and log file accumulation ........................................................................ 7-21

Durability options ....................................................................................................................... 7-22
8 Working with Data in a TimesTen Database

Database overview ................................................................................................................ 8-1
Database objects ................................................................................................................... 8-1
Database users and owners .................................................................................................. 8-2
Understanding tables .......................................................................................................... 8-2
Overview of tables ............................................................................................................... 8-2
Column overview ................................................................................................................ 8-3
Inline and out-of-line columns ............................................................................................. 8-3
Default column values ........................................................................................................ 8-3
Table names .......................................................................................................................... 8-4
Table access .......................................................................................................................... 8-4
Primary keys, foreign keys and unique indexes ................................................................. 8-4
Tables in TimesTen Scaleout ................................................................................................. 8-5
System tables ......................................................................................................................... 8-5
Working with tables .............................................................................................................. 8-5
Creating a table .................................................................................................................... 8-5
Dropping a table ................................................................................................................... 8-6
Estimating table size ............................................................................................................ 8-6
Implementing aging in your tables ...................................................................................... 8-7
Usage-based aging ............................................................................................................... 8-7
Time-based aging ................................................................................................................ 8-8
Aging and foreign keys ......................................................................................................... 8-9
Scheduling when aging starts ............................................................................................. 8-10
Aging and replication ........................................................................................................... 8-10
Understanding views ........................................................................................................... 8-10
Creating a view ..................................................................................................................... 8-11
The SELECT query in the CREATE VIEW statement ....................................................... 8-11
Dropping a view ................................................................................................................... 8-12
Restrictions on views and detail tables ............................................................................. 8-12
Understanding materialized views ..................................................................................... 8-12
Overview of materialized views ........................................................................................ 8-12
Working with materialized views ....................................................................................... 8-13
Creating a materialized view .............................................................................................. 8-13
Dropping a materialized view ............................................................................................ 8-14
Restrictions on materialized views and detail tables ....................................................... 8-15
Performance implications of materialized views ............................................................. 8-15
Understanding indexes ......................................................................................................................... 8-16
Overview of index types ......................................................................................................................... 8-17
Creating an index ................................................................................................................................. 8-18
Altering an index .................................................................................................................................. 8-19
Dropping an index ................................................................................................................................. 8-19
Estimating index size .............................................................................................................................. 8-19
Using the Index Advisor to recommend indexes ................................................................................... 8-20
Prepare for executing the Index Advisor .............................................................................................. 8-20
Capture the data used for generating index recommendations ............................................................. 8-21
Retrieve index recommendations and data collection information ....................................................... 8-23
Drop data collected for the index advisor and finalize results ............................................................... 8-24
Example using Index Advisor built-in procedures ................................................................................. 8-25
Understanding rows ................................................................................................................................ 8-26
Inserting rows ....................................................................................................................................... 8-26
Deleting rows .......................................................................................................................................... 8-26
Understanding synonyms ....................................................................................................................... 8-27
Creating synonyms ............................................................................................................................... 8-27
Dropping synonyms .............................................................................................................................. 8-28
Synonyms may cause invalidation or recompilation of SQL queries .................................................... 8-29
Understanding system views .................................................................................................................. 8-29

9 The TimesTen Query Optimizer

When optimization occurs ....................................................................................................................... 9-1
Viewing SQL statements stored in the SQL command cache ................................................................. 9-3
Managing performance and troubleshooting commands ........................................................................ 9-3
Displaying commands stored in the SQL command cache .................................................................. 9-4
Viewing SQL query plans ....................................................................................................................... 9-6
Viewing a query plan from the system PLAN table ................................................................................ 9-6
Instruct TimesTen to store the plan in the system PLAN table ............................................................. 9-7
Reading query plan from the PLAN table ............................................................................................... 9-7
Describing the PLAN table columns ..................................................................................................... 9-8
Viewing query plans associated with commands stored in the SQL command cache ...................... 9-10
Modifying plan generation ..................................................................................................................... 9-13
Why modify an execution plan? ............................................................................................................. 9-13
How hints can influence an execution plan .......................................................................................... 9-13
Use optimizer hints to modify the execution plan ................................................................................ 9-15
Apply statement level optimizer hints for a SQL statement ............................................................... 9-16
Apply transaction level optimizer hints for a transaction ................................................................... 9-16
Apply connection level optimizer hints for a TimesTen connection ............................................... 9-18

10 TimesTen Database Performance Tuning

System and database tuning .................................................................................................................. 10-2
Provide enough memory ......................................................................................................................... 10-2
Avoid paging of the memory used by the database ............................................................................. 10-3
Size your database correctly .................................................................................................................. 10-3
Calculate shared memory size for PL/SQL runtime ............................................................................ 10-3
Set appropriate limit on the number of open files ......................................................... 10-4
Configure log buffer and log file size parameters .......................................................... 10-4
Avoid connection overhead for TimesTen Classic databases ....................................... 10-5
Load the database into RAM when duplicating .............................................................. 10-5
Prevent reloading of the database after automatic recovery fails .................................. 10-5
Reduce contention .......................................................................................................... 10-6
Consider special options for maintenance ..................................................................... 10-6
Check your driver ............................................................................................................ 10-7
Enable tracing only as needed ....................................................................................... 10-7
Use metrics to evaluate performance ............................................................................. 10-7
Migrate data with character set conversions ................................................................... 10-8
Use TimesTen native integer data types if appropriate ............................................... 10-8
Configure the checkpoint files and transaction log files to be on a different physical device...... 10-8

**Client/Server tuning** .................................................................................................. 10-8
Diagnose Client/Server performance ............................................................................... 10-9
Work locally when possible ............................................................................................ 10-9
Choose timeout connection attributes for your client ................................................... 10-9
Choose a lock wait timeout interval ............................................................................... 10-10
Choose the best method of locking ................................................................................. 10-10
  Choose an appropriate lock level .................................................................................. 10-11
  Choose an appropriate isolation level ............................................................................ 10-11
Use shared memory segment as IPC when client and server are on the same system .... 10-12
Enable prefetch close for read-only transactions .......................................................... 10-12
Use a connection handle when calling SQLTransact ..................................................... 10-12
Enable multi-threaded mode to handle concurrent connections ................................... 10-13

**SQL tuning** .............................................................................................................. 10-13
Tune statements and use indexes ................................................................................. 10-13
Collect and evaluate sampling of execution times for SQL statements ........................ 10-14
Select the type of index appropriately .......................................................................... 10-17
Size hash indexes appropriately .................................................................................... 10-18
Use foreign key constraint appropriately ....................................................................... 10-19
Compute exact or estimated statistics ........................................................................... 10-19
Update table statistics for large tables in parallel ......................................................... 10-20
Create script to regenerate current table statistics ....................................................... 10-21
Control the invalidation of commands in the SQL command cache ........................... 10-22
Avoid ALTER TABLE ..................................................................................................... 10-22
Avoid nested queries ..................................................................................................... 10-23
Prepare statements in advance ....................................................................................... 10-23
Avoid unnecessary prepare operations .......................................................................... 10-24
Store data efficiently with column-based compression of tables .................................. 10-24
Control read optimization during concurrent write operations .................................. 10-25
Choose SQL and PL/SQL timeout values ...................................................................... 10-26

**Materialized view tuning** .......................................................................................... 10-27
Limit number of join rows ............................................................................................. 10-28
Use indexes on join columns .......................................................................................... 10-28
Avoid unnecessary updates ............................................................................................ 10-28
Avoid changes to the inner table of an outer join .......................................................... 10-29
Limit number of columns in a view table................................................................. 10-29

Transaction tuning .............................................................................................................. 10-29
Locate checkpoint and transaction log files on separate physical device............... 10-30
Size transactions appropriately...................................................................................... 10-30
Use durable commits appropriately................................................................................ 10-30
Avoid manual checkpoints.............................................................................................. 10-31
Turn off autocommit mode.............................................................................................. 10-31
Avoid transaction roll back.............................................................................................. 10-32
Avoid large DELETE statements .................................................................................... 10-32
  Avoid DELETE FROM statements ................................................................................. 10-32
  Consider using the DELETE FIRST clause .................................................................. 10-32
Increase the commit buffer cache size......................................................................... 10-33

Recovery tuning ................................................................................................................. 10-33
Set RecoveryThreads ...................................................................................................... 10-33
Set CkptReadThreads .................................................................................................... 10-33

Scaling for multiple CPUs .............................................................................................. 10-34
Run the demo applications as a prototype................................................................. 10-34
Limit database-intensive connections per CPU......................................................... 10-34
Use read operations when available .......................................................................... 10-35
Limit prepares, re-prepares and connects .................................................................. 10-35
Allow indexes to be rebuilt in parallel during recovery .............................................. 10-35
Use private commands................................................................................................. 10-35

XLA tuning ......................................................................................................................... 10-36
Increase transaction log buffer size when using XLA ................................................. 10-36
Prefetch multiple update records ................................................................................ 10-36
Acknowledge XLA updates............................................................................................ 10-36

Cache and replication tuning ......................................................................................... 10-37

Index
Oracle TimesTen In-Memory Database (TimesTen) is a relational database that is memory-optimized for fast response and throughput. The database resides entirely in memory at runtime and is persisted to the file system.

- Oracle TimesTen In-Memory Database in classic mode, or TimesTen Classic, refers to single-instance and replicated databases (as in previous releases).
- Oracle TimesTen In-Memory Database in grid mode, or TimesTen Scaleout, refers to a multiple-instance distributed database. TimesTen Scaleout is a grid of interconnected hosts running instances that work together to provide fast access, fault tolerance, and high availability for in-memory data.
- TimesTen alone refers to both classic and grid modes (such as in references to TimesTen utilities, releases, distributions, installations, actions taken by the database, and functionality within the database).
- TimesTen Application-Tier Database Cache, or TimesTen Cache, is an Oracle Database Enterprise Edition option. TimesTen Cache is ideal for caching performance-critical subsets of an Oracle database into cache tables within a TimesTen database for improved response time in the application tier. Cache tables can be read-only or updatable. Applications read and update the cache tables using standard Structured Query Language (SQL) while data synchronization between the TimesTen database and the Oracle database is performed automatically. TimesTen Cache offers all of the functionality and performance of TimesTen Classic, plus the additional functionality for caching Oracle Database tables.
- TimesTen Replication features, available with TimesTen Classic or TimesTen Cache, enable high availability.

TimesTen supports standard application interfaces JDBC, ODBC, and ODP.NET; Oracle interfaces PL/SQL, OCI, and Pro*C/C++; and the TimesTen TTClasses library for C++.

This guide provides:

- Background information to help you understand how TimesTen works
- Step-by-step instructions and examples that show how to perform the most commonly needed tasks

**Audience**

To work with this guide, you should understand how database systems work and have some knowledge of Structured Query Language (SQL).
Related documents

TimesTen documentation is available at:

https://docs.oracle.com/database/timesten-18.1

Oracle Database documentation is also available on the Oracle documentation website. This may be especially useful for Oracle Database features that TimesTen supports but does not attempt to fully document, such as OCI and Pro*C/C++.

Conventions

TimesTen is supported on multiple platforms. Unless otherwise indicated, the information in this guide applies to all supported platforms. The term Windows refers to all supported Windows platforms. The term UNIX applies to all supported UNIX platforms. The term Linux is used separately.

TimesTen Scaleout is only supported on the Linux platform.

See "Platforms and Compilers" in Oracle TimesTen In-Memory Database Release Notes (README.html) in your installation directory for specific platform versions supported by TimesTen.

Note: In TimesTen documentation, the terms "data store" and "database" are equivalent. Both terms refer to the TimesTen database.

This document uses the following text conventions:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface</strong></td>
<td>Boldface type indicates graphical user interface elements associated with an action, or terms defined in text.</td>
</tr>
<tr>
<td><em>italic</em></td>
<td>Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.</td>
</tr>
<tr>
<td>monospace</td>
<td>Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.</td>
</tr>
<tr>
<td><em>italic</em> monospace</td>
<td>Italic monospace type indicates a placeholder or a variable in a code example for which you specify or use a particular value. For example:</td>

<tr>
<td>timesten_home</td>
<td>The path that represents the home directory of a TimesTen instance.</td>
</tr>
<tr>
<td>release or rr</td>
<td>The first two parts in a release number, with or without the dot. The</td>
</tr>
<tr>
<td></td>
<td>first two parts of a release number represent a major TimesTen release.</td>
</tr>
<tr>
<td></td>
<td>For example, 181 or 18.1 represents TimesTen Release 18.1.</td>
</tr>
<tr>
<td>DSN</td>
<td>The data source name.</td>
</tr>
</tbody>
</table>

**Note:** TimesTen release numbers are reflected in items such as TimesTen utility output, file names and directory names. These details are subject to change with every minor or patch release, and the documentation cannot always be up to date. The documentation seeks primarily to show the basic form of output, file names, directory names and other code that may include release numbers. You can confirm the current release number by looking at the Release Notes or executing the ttVersion utility.

---

**Documentation Accessibility**

**Access to Oracle Support**

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit [http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info](http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info) or visit [http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs](http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs) if you are hearing impaired.
What's New

This section summarizes the new features and functionality of Oracle TimesTen In-Memory Database Release 18.1 that are documented in this guide, providing links into the guide for more information.

New features in release 18.1.4.1.0

- In TimesTen Classic, automatic client failover is no longer limited to scenarios that include an active standby pair replication scheme. The client can automatically fail over from one database to another using generic automatic client failover. This is especially useful if you are using a read-only cache groups. See "Using automatic client failover" on page 3-20 for more details.

New features in release 18.1.3.1.0

- When critical events (such as invalidations) occur, TimesTen collects the daemon log entries at the moment of the critical event to help when diagnosing critical failures. See "Critical event logging" on page 4-11 for details.

- You open and close a database in order to direct whether users may connect to that database. For an application to be able to connect to a database, the database needs to be open to accept user connections. See "Opening and closing the database for user connections" on page 2-1 for details.

- Open source languages interact with TimesTen through the Oracle Database Programming Interface for C (ODPI-C). The languages currently supported are Python and Node.js. See "Connecting to TimesTen with ODBC and JDBC drivers" on page 1-1 for more information.

- You can now control how long a SQL statement executes before timing out in either seconds or milliseconds with SQLQueryTimeout or SQLQueryTimeoutMSec. See "Choose SQL and PL/SQL timeout values" on page 10-26 for details.

New features in release 18.1.2.1.0

- You can gracefully shut down the database by disconnecting applications in an orderly fashion. The new forced disconnect option asynchronously disconnects all connected applications from the database, including those that are idle or unresponsive. See "Disconnecting from a database" on page 2-8 for full details.

- The ttCkptHistory built-in procedure was updated to add information about the number of actual transaction log files purged by this checkpoint and the reason for a transaction log hold. See "Displaying checkpoint history and status" on page 7-12 for full details.
New features in release 18.1.1.1.0

- There are now two modes for Oracle TimesTen In-Memory Database.

  Oracle TimesTen In-Memory Database in grid mode (TimesTen Scaleout) is a grid of interconnected hosts running TimesTen Scaleout instances that work together to provide fast access, fault tolerance, and high availability for in-memory data. A grid contains one or more databases and each database is distributed across all instances of the grid. TimesTen Scaleout delivers these features by distributing the data for each in-memory database in the grid across multiple hosts. See the Oracle TimesTen In-Memory Database Scaleout User’s Guide for full details.

  Oracle TimesTen In-Memory Database in classic mode or TimesTen Classic refers to single-instance environments and databases and referred to as TimesTen alone in previous releases.

  Now, when the documentation refers to TimesTen alone (without TimesTen Classic or TimesTen Scaleout), the statement applies to both single-instance and multiple-instance, such as in references to TimesTen utilities, releases, distributions, installations, actions taken by the database, and functionality within the database.

- TimesTen Scaleout is only supported on the Linux platform, while TimesTen Classic is supported on multiple platforms. See the Oracle TimesTen In-Memory Database Release Notes (README.html) in your installation directory for specific platform versions supported by TimesTen.

- You can use the -directload option of the ttBulkCp utility to perform faster copies from large ASCII files to a TimesTen table. For more information see "Copying data from an ASCII file into a TimesTen table" on page 2-17.
Connecting to a TimesTen Database

A TimesTen database is a collection of objects such as tables, views, and sequences. You can access and manipulate the TimesTen database through SQL statements.

In TimesTen Classic, if your database does not exist, then TimesTen Classic creates the database with the specified connection attributes when the instance administrator connects to the database.

In TimesTen Scaleout, you create and open the database before applications can connect to the database. See "Managing a database" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for details.

Once you have created a database, you can perform the following:

- Execute an application that uses the database.
- Use the ttIsql utility to connect to the database and execute a SQL file or start an interactive SQL session. See "Batch mode vs. interactive mode" on page 6-2 for more information.

This chapter describes how to configure to connect to the TimesTen database. The connection attributes include management configuration details for your TimesTen database.

Connecting to TimesTen with ODBC and JDBC drivers

Figure 1–1 shows how an application can use different interfaces and drivers to access the TimesTen database.
Open source languages interact with TimesTen through the Oracle Database Programming Interface for C (ODPI-C). The languages currently supported are Python and Node.js. See the Oracle TimesTen In-Memory Database Open Source Languages Support Guide for more details.

C applications interact with TimesTen by linking directly with the TimesTen ODBC driver, by linking with the Windows ODBC driver manager, or by using the OCI or Pro*C/C++ interfaces that access the ODBC driver.

Java applications interact with TimesTen by loading the JDBC library.

C++ applications interact with TimesTen through a TimesTen-provided set of classes called TTClasses or by using the OCI or Pro*C/C++ interfaces that access the ODBC driver.

C# applications interact with TimesTen through Oracle Data Provider for .NET support for the TimesTen database.

All of these interfaces ultimately use the TimesTen ODBC driver to access a TimesTen database. These interfaces can use the ODBC direct driver, the ODBC client driver, or an ODBC driver manager. See “TimesTen connection options” in the Oracle TimesTen In-Memory Database Introduction for more information.

Consider the following points:

- An application that links directly with a TimesTen ODBC driver (whether it is linked with the direct driver or client driver) is limited to using only the driver with which it is linked. An application linked directly to a TimesTen ODBC driver can connect to multiple databases at the same time. The TimesTen direct and client drivers support multiple connections to multiple TimesTen databases.

  **Note:** This option offers less flexibility but better performance than linking with a driver manager.

- An application can link with more than one TimesTen ODBC driver within the same application, even if the drivers are for different TimesTen databases. If the application loads more than one TimesTen ODBC driver, the application must use a driver manager, such as the Windows ODBC driver manager.

An application might need multiple drivers if it needs to use both the TimesTen direct driver and the TimesTen Client driver.

The Windows ODBC driver manager dynamically loads an ODBC driver at runtime. However, carefully evaluate the benefits of using the ODBC driver...
Connecting to TimesTen with ODBC and JDBC drivers

Connecting to a TimesTen Database

Manager, because it may affect the performance of your application with its additional runtime overhead.

**Note:** An application that is using an ODBC driver manager cannot use XLA.

For more information on how to compile an application that uses the TimesTen driver manager, see "Compiling and linking applications" in the *Oracle TimesTen In-Memory Database C Developer's Guide*, "Compiling Java applications" in the *Oracle TimesTen In-Memory Database Java Developer's Guide*, and "Compiling and linking applications" in the *Oracle TimesTen In-Memory Database TTClasses Guide*.

The following sections describe how to define TimesTen databases:

- **Connecting using TimesTen ODBC drivers**
- **Connecting using the TimesTen JDBC driver and driver manager**

### Connecting using TimesTen ODBC drivers

TimesTen includes the following TimesTen ODBC drivers:

- **TimesTen Data Manager driver**: A TimesTen ODBC driver for use with direct connect applications.
- **TimesTen Client driver**: A TimesTen Client ODBC driver for use with client/server applications.

TimesTen includes the following two versions of the TimesTen Data Manager driver (direct driver):

- **Production**: Use the production version of the TimesTen Data Manager driver for most application development and for all deployment.
- **Debug**: Use the debug version of the TimesTen Data Manager driver only if you encounter problems with TimesTen itself. This version performs additional internal error checking and is slower than the production version. On Linux and UNIX, the TimesTen debug libraries are compiled with the `-g` option to display additional debug information.

For TimesTen Classic support on Windows, you can install the "TimesTen Client 18.1" driver after choosing either the Typical or Custom setup.

On Linux and UNIX, depending on the options selected at install time, TimesTen may install the TimesTen Client driver and both the production version and the debug version of the TimesTen Data Manager driver.

Table 1–1 lists the TimesTen ODBC drivers for Linux and UNIX platforms.

**Table 1–1 ODBC drivers provided for Linux and UNIX platforms**

</table>
The TimesTen JDBC driver enables Java applications to issue SQL statements to TimesTen and process the results. It is the primary interface for data access in the Java programming language.

As shown in Figure 1–1, the TimesTen JDBC driver uses the ODBC driver to access TimesTen databases. For each JDBC method, the driver executes a set of ODBC functions to perform the appropriate operation. Since the JDBC driver depends on ODBC for all database operations, the first step in using JDBC is to define a TimesTen database and the ODBC driver that accesses it on behalf of JDBC.

The TimesTen JDBC API is implemented using native methods to bridge to the TimesTen native API. Java provides a driver manager that can support multiple drivers connecting to separate databases. The Java DriverManager class keeps track of all JDBC drivers that have been loaded and are available to the Java application. The application may load several drivers and access each driver independently. For example, an application can load both a TimesTen Client JDBC driver and an Oracle Database JDBC driver. Then, Java applications can access either the TimesTen or Oracle databases.

For a list of the Java functions supported by TimesTen, see “Support for interfaces in the java.sql package” in the Oracle TimesTen In-Memory Database Java Developer’s Guide.

### Specifying Data Source Names to identify TimesTen databases

When you connect from an application, you use a Data Source Name (DSN) to uniquely identify the particular TimesTen database to which you want to connect. Specifically, a DSN is a character-string name that identifies a TimesTen database and a collection of connection attributes that are to be used when connecting to the database. On Windows, the DSN also specifies the ODBC driver to be used to access the database.

In TimesTen Classic, you can also define a default DSN that can be used when a user or an application either does not specify a DSN or specifies a DSN that is not defined in the odbc.ini file at connect time. For details, see “Setting up a default DSN in TimesTen Classic” on page 1-12.

</tbody>
</table>
Even though the DSN uniquely identifies a TimesTen database, a database can be referenced by multiple DSNs. The difference between each of these unique DSNs is in the specification of the connection attributes to the database. This provides convenient names to different connection configurations for a single database.

A DSN has the following characteristics:

- Its maximum length is 32 characters.
- It is case insensitive.
- It is composed of ASCII characters except for the following: ( ) [ ] { } , ; ? * = ! @ \ / 
- TimesTen does not recommend the use of spaces as part of the DSN. If a DSN contains a space, some TimesTen utilities truncate the DSN at the point where they encounter the space. In addition, a DSN cannot start or end with a space, or consist solely of spaces.

The following sections describe how to configure and manage your DSNs:

- **Overview of user and system DSNs**
- **Defining DSNs for direct or client/server connections**
- **Connection attributes for Data Manager DSNs or Server DSNs**

### Overview of user and system DSNs

DSNs are resolved using a two-tiered naming system, where TimesTen first tries to resolve the DSN within the defined user DSNs and secondly within the defined system DSNs.

- A user DSN can be used only by the user who created the DSN.
  - On Windows, user DSNs are defined from the User DSN tab of the ODBC Data Source Administrator.
  - For TimesTen Classic on Linux and UNIX, define user DSNs in the user odbc.ini file. TimesTen locates this file by first finding if a file is specified by the ODBCINI environment variable. If not, TimesTen locates the $HOME/.odbc.ini file.

TimesTen Classic supports data sources for both TimesTen Data Manager driver and the TimesTen Client driver in the .odbc.ini file.

- For TimesTen Scaleout, define user DSNs within the appropriate database definitions and connectables. See "Managing a database" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for full details.
Although a user DSN is private to the user who created it, it is only the DSN, consisting of the character-string name and its attributes, that is private. The underlying database can be referenced by other users’ user DSNs or by system DSNs.

- **A system DSN can be used by any user on the system on which the system DSN is defined to connect to the TimesTen database.**
  - On Windows, system DSNs are defined from the **System DSN** tab of the ODBC Data Source Administrator.
  - For TimesTen Classic on Linux and UNIX, system DSNs are defined in the *sys.odbc.ini* file, which is referred to as the system *odbc.ini* file.

  TimesTen locates the system DSN file in the following order:
  * The file is located if it is specified by the **SYSODBCINI** environment variable.
  * In an installation, the file is located in *timesten_home/conf/sys.odbc.ini*.
  * If not found in any of these locations, TimesTen looks on the system for the */etc/odbc.ini* file.

- For TimesTen Scaleout, create system DSNs within the appropriate database definitions and connectables. See “Managing a database” in the *Oracle TimesTen In-Memory Database Scaleout User’s Guide* for full details.

### Defining DSNs for direct or client/server connections

DSNs are created to uniquely identify a database, whether local or remote. The following explains the type of DSN to use for either a direct or client/server connection:

- **Data Manager DSN**: A DSN that specifies a local database on a Linux or UNIX host. You can use either the production version or debug version of the TimesTen Data Manager driver.

  A Data Manager DSN refers to a database using a path name and a file name prefix. The database path name specifies the directory location of the database and the prefix for the database, such as `/disk1/databases/AdminDS`.

  **Note:** This path name and prefix does not define a file name, but the name of the directory where the database is located and the prefix for all database files. The actual files used by the database append file suffixes, such as `/disk1/databases/AdminDS.ds0`.

  A Data Manager DSN that refers to a given TimesTen database must be defined on the same system on which the database resides. If multiple Data Manager DSNs refer to the same database, they must all use exactly the same database path name, even if some other path name identifies the same location. For example, you cannot use a symbolic link to refer to the database in one DSN and the actual path name in another DSN.

- **Client DSN**: A Client DSN specifies a remote database and uses the TimesTen client. A Client DSN refers to a TimesTen database indirectly by specifying a hostname, **DSN** pair, where the hostname represents the server system on which TimesTen Server is running and the DSN refers to a Server DSN that specifies the TimesTen database on the server host.
Specifying Data Source Names to identify TimesTen databases

■ **Server DSN:** A Server DSN is always defined as a system DSN and is defined on the server system for each database on that server that can be accessed by client applications. The format and attributes of a Server DSN are very similar to those of a Data Manager DSN.

On Linux and UNIX, all user DSNs including both Client DSNs and Data Manager DSNs that are created by a specific user are defined in the same user odbc.ini file. Similarly, all system DSNs are defined in the same system odbc.ini file.

The following table indicates the types of DSN supported by TimesTen, whether to create a user or system DSN and the location of the DSN.

<table>
<thead>
<tr>
<th>DSN type</th>
<th>User or System DSN?</th>
<th>Location of DSN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Manager DSN</td>
<td>Can be a user or system DSN</td>
<td>Located on the system where the database resides.</td>
</tr>
<tr>
<td>Client DSN</td>
<td>Can be a user or system DSN</td>
<td>Located on any local or remote system.</td>
</tr>
<tr>
<td>Server DSN</td>
<td>Must be a system DSN</td>
<td>Located on the system where the database resides.</td>
</tr>
</tbody>
</table>

For more information about Client DSNs and Server DSNs, see "Working with the TimesTen Client and Server" on page 3-1.

**Connection attributes for Data Manager DSNs or Server DSNs**

On Linux and UNIX, you specify connection attributes in the odbc.ini file. Connection attributes that do not appear in the odbc.ini file assume their default value.

Common types of connection attributes:

---

**Note:** For a complete description of all attributes, see "Connection Attributes" in the Oracle TimesTen In-Memory Database Reference.

---

■ **Data Store attributes** are associated with a database when it is created and cannot be modified by subsequent connections. They can only be changed by destroying and re-creating the database.

The following are the most commonly used data store attributes:

- **DataStore:** Directory name and file name prefix of the database.
- **LogDir:** Directory name of the database transaction log files. Placing the transaction log files and checkpoint files on different file systems can improve system performance.
- **DatabaseCharacterSet:** Required character set specification that defines the storage encoding.

■ **First connection attributes** are used when the TimesTen database is loaded into memory. Only the instance administrator can load a database with first connection attribute settings. By default, TimesTen loads an idle database, which is a database with no connections, into memory when a first connection is made to it. These attributes persist for all subsequent connections until the last connection to the database is closed. First connection attributes can be modified only when the
TimesTen database is unloaded and then the instance administrator reconnects with different values for the first connection attributes.

The following are the most commonly used first connection attributes:

- **PermSize**: Configures the allocated size of the database's permanent memory region. The permanent memory region contains persistent database objects. TimesTen only writes the permanent memory region to the file system during a checkpoint operation.

- **TempSize**: Configures the allocated size of the database's temporary memory region. The temporary memory region contains transient data generated when executing statements.

**Note**: Your system must have sufficient main memory to accommodate the entire database. For more details on setting region sizes, see "Specifying the memory region sizes of a database" on page 2-10.

**General connection attributes** are set by each connection and persist for the duration of the connection. Each concurrent connection can have different values.

The following are the most commonly used general connection attributes:

**Note**: If you provide connection attributes in the connection string, this overrides the connection attributes set in the DSN. See "Connecting to a database using a connection string" on page 1-16 for details.

- **UID**: Specifies the user name to be used for the connection to the database, whether using a direct or client/server connection. To connect as the instance administrator or as an external user, you do not need to specify a user name. When you do not specify a user name, TimesTen assumes that the UID is the user name identified by the operating system.

- **PWD**: Specifies the password that corresponds with the specified UID. For internal users, if you do not set the PWD attribute in the odbc.ini file for the specified DSN or in the connection string, TimesTen prompts for the password. For external users, you do not provide the password as it is verified by the operating system.

  When you initiate a client/server connection, the password sent for the connection is encrypted by the client/server protocol.

- **PWDCrypt**: Specifies the encrypted password that corresponds with the specified UID.

**Note**: For more information on the UID, PWD and PWDCrypt general connection attributes, see "UID and PWD" in the *Oracle TimesTen In-Memory Database Reference*. See the *Oracle TimesTen In-Memory Database Security Guide* for full details on access control.

**TimesTen Cache attributes** enable you to enter the Oracle Service Identifier for the Oracle database instance from which data is loaded into TimesTen.
Creating a DSN on Linux and UNIX for TimesTen Classic

This section includes the following topics for creating a DSN for TimesTen Classic. In TimesTen Scaleout, you would create the DSN within the appropriate database definitions and connectables. See "Managing a database" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for details.

- Create a user or system odbc.ini file
- Using environment variables in database path names

Note: For examples on defining a DSN, see "DSN examples for TimesTen Classic" on page 1-11.

Create a user or system odbc.ini file

On Linux and UNIX, user DSNs are defined in the file \$HOME/.odbc.ini or in a file named by the ODBCINI environment variable. This file is referred to as the user odbc.ini file. System DSNs are defined in the system odbc.ini file, which is located in timesten_home/conf/sys.odbc.ini.

The syntax for user and system odbc.ini files are the same. The syntax is described in "odbc.ini file entry descriptions" on page 1-14. The system odbc.ini file is created when TimesTen is installed on the system. Users must create their own user odbc.ini file.

Perform the following to create the DSN:

1. Specify the DSN in the odbc.ini file. The DSN appears inside square brackets at the top of the DSN definition on a line by itself. For example:

   [AdminDS]

2. Specify the TimesTen ODBC driver.

   Note: JDBC users need to specify the TimesTen ODBC driver to be used by the JDBC driver, as described in "Connecting using the TimesTen JDBC driver and driver manager" on page 1-4.

To set the TimesTen ODBC driver, specify the Driver attribute in the odbc.ini file. The following example provides the TimesTen ODBC driver that this DSN is configured to use, where /disk1/timesten is the timesten_home:

   [AdminDS]
   Driver=/disk1/timesten/lib/libtten.so

   Note: For a list of TimesTen ODBC drivers that you can use, see Table 1–1.
3. Specify the database directory path and prefix in the odbc.ini file. The following example defines /disk1/databases as the database directory path and FixedDs as the prefix for the database files:

```plaintext
DataStore=/disk1/databases/FixedDs
```

**Note:** For more information, see “Specifying Data Source Names to identify TimesTen databases” on page 1-4.

The database directory path can use environment variables, as discussed in “Using environment variables in database path names” on page 1-10.

4. Choose a database character set. The following example defines the database character set in the odbc.ini file as AL32UTF8:

```plaintext
DatabaseCharacterSet=AL32UTF8
```

**Note:** For more information, see “Choosing a database character set” on page 5-2.

5. Set connection attributes in your odbc.ini file. Attributes that do not appear in the odbc.ini file assume their default value.

**Note:** See "Connection Attributes" in Oracle TimesTen In-Memory Database Reference. For examples, see "DSN examples for TimesTen Classic" on page 1-11.

### Using environment variables in database path names

You can use environment variables in the specification of the database path name and transaction log file path name. For example, you can specify $HOME/AdminDS for the location of the database.

Environment variables can be expressed either as $varname or $(varname). The parentheses are optional. A backslash character (\) in the database path name quotes the next character.

**Note:** Environment variable expansion uses the environment of the process connecting to the database. Different processes may have different values for the same environment variables and may therefore expand the database path name differently. Environment variables can only be used in the user odbc.ini file. They cannot be specified in the system sys.odbc.ini file.

### Defining Client and Server DSNs

For directions on how to define Client or Server DSNs for each platform, see "Defining Server DSNs for TimesTen Server on a Linux or UNIX system" on page 3-7 and "Creating Client DSNs on a TimesTen Client system" on page 3-13.

### Resolution path for a DSN

When resolving a specific DSN, TimesTen performs the following:
1. Searches for a user DSN with the specified name in the following files:
   a. The file referenced by the ODBCINI environment variable, if it is set.
   b. The .odbc.ini file in the user’s home directory, if the ODBCINI environment variable is not set.
2. If no matching user DSN is found, TimesTen looks for a system DSN with the specified name.
   a. The file referenced by the SYSODBCINI environment variable, if it is set.
   b. The sys.odbc.ini file in the daemon home directory, if the SYSODBCINI environment variable is not set.
   c. On Linux and UNIX, the file is located in $timesten_home/conf/sys.odbc.ini.

**DSN examples for TimesTen Classic**

This section provides additional examples of how to set up a TimesTen Classic database:

- Creating multiple DSNs to a single TimesTen Classic database
- Specifying PL/SQL connection attributes in a DSN
- Setting up a default DSN in TimesTen Classic

**Creating multiple DSNs to a single TimesTen Classic database**

You can create two or more DSNs that refer to the same TimesTen Classic database but have different connection attributes.

This example creates two DSNs, AdminDSN and GlobalDSN. The DSNs are identical except for their connection character sets. Applications that use the US7ASCII character set can connect to the TTDS database by using AdminDSN. Applications that use multibyte characters can connect to the TTDS database by using GlobalDSN.

The text in square brackets is the data source name. AdminDSN is created with the AL32UTF8 database character set and US7ASCII as the connection character set. GlobalDSN is created with the AL32UTF8 database character and AL32UTF8 as the connection character set. Note that /disk1/timesten is the $timesten_home.

[AdminDSN]
Drivers:/disk1/timesten/lib/libtten.so
Datastore:/disk1/databases/TTDS
DatabaseCharacterSet=AL32UTF8
ConnectionCharacterSet=US7ASCII

[GlobalDSN]

Note:
- If a user DSN and a system DSN with the same name exist, TimesTen retrieves the user DSN.
- On Linux and UNIX, if there are multiple DSNs with the same name in the same odbc.ini file, TimesTen retrieves the first one specified in the file.
Specifying PL/SQL connection attributes in a DSN

For TimesTen Classic, PL/SQL connection attributes exist both as first and general connection attributes.

- **PLSQL_MEMORY_ADDRESS** - A first connection attribute that specifies the virtual address, as a hexadecimal value, at which the PL/SQL shared memory segment is loaded into each process that uses the TimesTen direct drivers. This memory address must be identical in all connections to your database and in all processes that connect to your database.

- **PLSQL_MEMORY_SIZE** - A first connection attribute that determines the size, in megabytes, of the PL/SQL shared memory segment.

- **PLSCOPE_SETTINGS** - A general connection attribute that controls whether the PL/SQL compiler generates cross-reference information.

- **PLSQL_OPTIMIZE_LEVEL** - A general connection attribute that sets the optimization level that is used to compile PL/SQL library units.

This example creates the **PLdsn** DSN and sets the PL/SQL shared memory segment size to 32 MB.

```
[PLdsn]
Datastore=/disk1/databases/PLdsn
PermSize=128
DatabaseCharacterSet=AL32UTF8
ConnectionCharacterSet=AL32UTF8
PLSQL_MEMORY_SIZE=32
```

For more examples, see “PL/SQL connection attributes” in *Oracle TimesTen In-Memory Database PL/SQL Developer’s Guide*. For a complete list of PL/SQL connection attributes, see “Connection Attributes” in the *Oracle TimesTen In-Memory Database Reference*.

Setting up a default DSN in TimesTen Classic

Optionally, you can add a default data source definition in TimesTen Classic. At connect time, if an application specifies a DSN that is not in the odbc.ini file or if the application does not specify a DSN, the default DSN is used to configure the connection to the TimesTen Classic database.

The default data source must be named `default` when defined. The default DSN can be defined with the same attributes as any other data source, which are described in "DSN specification" on page 1-14.

When connecting, TimesTen Classic uses the default DSN in any of the following scenarios:

- When you specify the `DSN=default` keyword-value pair in the connection string.
- When you specify an undefined value for the `DSN` connection attribute in the connection string.
- When you do not specify any value for the `DSN` connection attribute in the connection string.
However, in general, it is best to connect with a specific data source.

When using a default DSN, provide default as the DSN name when performing TimesTen utility operations that require a DSN name, such as destroying the database with the ttDestroy utility.

The following example shows the user invoking ttIsql to connect using an undefined DSN. Since there is no definition for doesNotExist in the odbc.ini file, TimesTen Classic uses the default DSN to create the database and initiate a connection to it. It also demonstrates the user invoking both the ttStatus and ttDestroy utilities with default specified as the DSN. In addition, it shows the error thrown if the user provides doesNotExist as the DSN, instead of default.

```
% ttIsql doesNotExist;
Copyright (c) 1996, 2020 Oracle. All rights reserved.
Type ? or 'help' for help, type 'exit' to quit ttIsql.
connect 'DSN=doesNotExist';
Connection successful:
Command> exit
Disconnecting...
Done.
% ttStatus default
TimesTen status report as of Mon Oct 22 12:27:52 2012

Daemon pid 13623 port 16138 instance myhost
TimesTen Server pid 13632 started on port 16140
-------------------------------------------------------------
Data store /timesten/install/sample_db/default
There are no connections to the data store
Replication policy : Manual
Cache Agent policy : Manual
PL/SQL enabled.
-------------------------------------------------------------
Accessible by group xyz
End of report
% ttDestroy doesNotExist;
Failed to destroy data store: Specified DSN is not found in user and system
odbc.ini files (or registry)
% ttDestroy default;
```

The following example shows how to configure connection attributes for a default DSN. While not necessary, you can configure connection attributes for a default DSN as you would configure any other DSN. Notice that it is not specified in the ODBC Data Sources section. Note that /disk1/timesten is the timesten_home.

```
[ODBC Data Sources]
database1=TimesTen 18.1 Driver
...
[default]
Drivers=/disk1/timesten/lib/libtten.so
DataStore=/disk1/timesten/sample_db/DemoDataStore/default
PermSize=128
TempSize=64
DatabaseCharacterSet=AL32UTF8

[database1]
Drivers=/disk1/timesten/lib/libtten.so
DataStore=/disk1/timesten/sample_db/DemoDataStore/database1
```
odbc.ini file entry descriptions

The following sections describe the entries in the odbc.ini file:

Note: In TimesTen Scaleout, use the `ttGridAdmin gridClientExport` command to create a system or user odbc.ini file to be used by the TimesTen Client instance. See "Establishing client connections from a TimesTen Client" in the Oracle TimesTen In-Memory Database Scaleout User's Guide for details.

- ODBC Data Sources
- DSN specification
- odbc.ini file example

ODBC Data Sources

Each entry in the optional ODBC Data Sources section lists a data source and a description of the driver it uses. The data source section has the following format:

```
[ODBC Data Sources]
DSN=driver-description
```

- The `DSN` is required and it identifies the data source to which the driver connects. You choose this name.
- The `driver-description` is required. It describes the driver that connects to the data source.

The optional Data Sources section, when present in the system DSN file on the TimesTen Server, is used during the setup of Client DSNs. All system DSNs are made available to the Client DSN setup for the ODBC Data Source Administrator on the client, which displays all available DSNs on the TimesTen Server. The user can always add a new system DSN in the ODBC Data Source Administrator. When adding DSNs to the system DSN file, you should only include those DSNs that can be advertised to clients. All system DSNs are potentially accessible through the client/server configuration, even if they are not advertised.

DSN specification

Each DSN listed in the ODBC Data Sources section has its own DSN specification. The DSN specification for Data Manager DSN has the format shown in Table 1–2.

**Table 1–2 Data Source specification format**

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[DSN]</td>
<td>The <code>DSN</code> is required. It is the name of the DSN, as specified in the ODBC Data Sources section of your <code>.odbc.ini</code> file.</td>
</tr>
<tr>
<td>Driver=driver-path-name</td>
<td>The TimesTen driver that is linked with the data source.</td>
</tr>
</tbody>
</table>
Connecting to a TimesTen Database

For example, the database1 DSN could have a specification that includes the following. Note that /disk1/timesten is the timesten_home.

[database1]
Drivers=disk1/timesten/lib/libtten.so
DataStore=disk1/timesten/sample_db/DemoDataStore/database1
...

The database specification for TimesTen Client DSN has the format shown in Table 1–3.

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStore=data-store-path-prefix</td>
<td>The directory path and prefix of the database to access. This is required.</td>
</tr>
<tr>
<td>DatabaseCharacterSet=Database-character-set</td>
<td>The database character set determines the character set in which data is stored. The database character set is required and cannot be altered after the database has been created. For more information, see &quot;Choosing a database character set&quot; on page 5-2.</td>
</tr>
</tbody>
</table>

Optional attributes

See "Connection Attributes" in Oracle TimesTen In-Memory Database Reference for information about attributes.

Note: While the syntax for the TimesTen Client DSN is listed here, full directions for setting the Client DSN and Server DSN are located in "Defining Server DSNs for TimesTen Server on a Linux or UNIX system" on page 3-7 and "Creating Client DSNs on a TimesTen Client system" on page 3-13.

Table 1–3 Database specification for TimesTen Client configurations

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[DSN]</td>
<td>The DSN is required. It is the same DSN specified in the ODBC Data Sources section of the .odbc.ini file.</td>
</tr>
<tr>
<td>TTC_Server=server-name</td>
<td>The server-name is required. It is the DNS name, host name, IP address or logical server name for the TimesTen Server.</td>
</tr>
<tr>
<td>TTC_Server_DSN=server-DSN</td>
<td>The server-DSN is required. It is the name of the data source to access on the TimesTen Server.</td>
</tr>
<tr>
<td>TTC_Timeout=value</td>
<td>Client connection timeout value in seconds.</td>
</tr>
</tbody>
</table>

Note: Most TimesTen driver attributes are ignored for TimesTen Client DSNs.

For example, the client/server data source database1CS that connects to database1 on the TimesTen Server ttserver could have a data source specification that includes the following:

[database1CS]
TTC_Server=ttserver
TTC_SERVER_DSN=database1
TTC_Timeout=30

**odbc.ini file example**

The following example shows portions of a Linux or UNIX .odbc.ini file. Note that `/disk1/timesten` is the *timesten_home*.

...[ODBC Data Sources]
database1=TimesTen 18.1 Driver
...

[database1]
Driver=/disk1/timesten/lib/libtten.so
DataStore=/disk1/timesten/sample_db/DemoDataStore/database1
PermSize=128
TempSize=64
DatabaseCharacterSet=AL32UTF8
...

########################################################################
# This following sample definitions should be in the .odbc.ini file
# that is used for the TimesTen 18.1 Client.
# The Server Name is set in the TTC_SERVER attribute.
# The Server DSN is set in the TTC_SERVER_DSN attribute.
########################################################################

[ODBC Data Sources]
database1CS=TimesTen 18.1 Client Driver
...

[database1CS]
TTC_SERVER=localhost
TTC_SERVER_DSN=database1
...

### Connecting to a database using a connection string ###

TimesTen applications require a DSN or a connection string be specified to connect to a database. For modularity and maintainability, it is better to set attributes in a DSN rather than in a connection string within the application, unless a particular connection requires that specific attribute settings override the settings in the DSN or the default settings.

The syntax for a connection string contains connection attribute definitions, where each attribute is separated by a semicolon.

These precedence rules are used to determine the settings of DSN attributes:

1. Attribute settings specified in a connection string have the highest precedence. If an attribute appears more than once in a connection string, the first specification is used.
2. If an attribute is not specified in the connection string, the attribute settings that are specified in the DSN are used.
3. Default attribute settings have the lowest precedence.

The following sections describe how to use a connection string instead of a DSN:

- Using a connection string in TimesTen Scaleout
- Using a connection string in TimesTen Classic
Connecting to a database using a connection string

Using a connection string in TimesTen Scaleout

In TimesTen Scaleout, you can connect to a specific element by specifying in the connection string the address of the host associated with that element, the database name, and a database user with at least CREATE SESSION privileges. See "Using a connection string to establish a client connection" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for more details.

Using a connection string in TimesTen Classic

You can connect to a TimesTen database without a predefined DSN with any ODBC application or the ttIsql utility if the connection string contains the DataStore, Driver and DatabaseCharacterSet attributes. Define the connection string as follows:

- The name or path name of the ODBC driver using the Driver attribute.
  - On Windows, the value of the Driver attribute should be the name of the TimesTen Client Driver.
  - On UNIX systems, the value of the Driver attribute should be the pathname of the TimesTen ODBC Driver shared library file (as described in Table 1–1). The file resides in the timesten_home/lib directory.
- The database path and file name prefix using the DataStore attribute.
- The character set for the database using the DatabaseCharacterSet attribute.

The following example shows how you can connect providing the Driver, DataStore and DatabaseCharacterSet attributes using a connection string in the ttIsql utility:

Providing the connection attributes on the connect string from a Linux/UNIX client.

Note that /disk1/timesten is the timesten_home.

% ttIsql
Command> connect "Driver=/disk1/timesten/lib/libtten.so;
DataStore=/disk1/databases/database1;DatabaseCharacterSet=AL32UTF8;

Providing the connection attributes on the connect string from a Windows client:

C:\ ttIsql
Copyright (c) 1996, 2016, Oracle and/or its affiliates. All rights reserved.
Type ? or 'help' for help, type 'exit' to quit ttIsql.

Command> connect "Driver=TimesTen Client 18.1;
DataStore=/disk1/databases/database1;DatabaseCharacterSet=AL32UTF8";
Connecting to a database using a connection string
Managing a TimesTen database includes the following:

- Opening and closing the database for user connections
- Loading and unloading the database from memory
- Specifying a RAM policy
- Disconnecting from a database
- Specifying the memory region sizes of a database
- Storage provisioning for TimesTen
- Bulk copy data using the ttBulkCp utility
- Thread programming with TimesTen
- Defragmenting TimesTen databases
- Verifying if your database is a single-instance or distributed database

### Opening and closing the database for user connections

For an application to be able to connect to a database, the database needs to be open. When a database is closed, any new user connection attempts fail.

- By default in TimesTen Classic, the database is automatically opened and user connections can connect.
- By default in TimesTen Scaleout, the database is closed until manually opened. See "Open the database for user connections" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for details.

You can close the database to reject any new user connections to a database.

- TimesTen Classic: Use the `ttAdmin -close` command to close the database to any new user connections.

Since the database can be automatically loaded or unloaded as set by the RAM policy, the status of a database (open or closed) is not aligned with whether the database is currently loaded into memory. Thus, the database could be in an open state as well as unloaded or in a closed state when loaded. See "Loading a database into memory for TimesTen Classic" on page 2-2 for an example of the RAM policy.

You should close a database before manually unloading a database. When loading a closed database into memory, the database cannot be opened until the load operation completes. You can re-open the database with the `ttAdmin -open`
Loading and unloading the database from memory

TimesTen is an in-memory database. As such, a database must first be loaded into memory from the file system to be available for connections. When a database is loaded into memory, the contents of the permanent memory region are read from checkpoint files stored on the file system. The temporary memory region is created when a database is loaded into memory and is destroyed when it is unloaded. See "Specifying the memory region sizes of a database" on page 2-10 for more details on permanent and temporary memory.

- In TimesTen Scaleout: The grid administrator controls how to load and unload the database using the ttGridAdmin utility. See "ttGridAdmin" in the Oracle TimesTen In-Memory Database Reference for details.

- In TimesTen Classic: RAM policies specify how and when a database is loaded into memory, including whether to automatically reload the database into memory if the database is unloaded unexpectedly. See "Specifying a RAM policy" on page 2-5 for full details on the different RAM policies.

Only the instance administrator can load a database manually. By default, TimesTen automatically loads an idle database (which is a database with no connections) into memory when a first connection is made to it. See "Loading a database into memory for TimesTen Classic" on page 2-2 for details.

After a database loads into memory, you may need to explicitly start the cache and replication agents for the database, depending on the functionality you are using and on which cache and replication policies you set with the ttAdmin utility.

Loading and unloading the database from memory for TimesTen Classic is described in these sections:

- Loading a database into memory for TimesTen Classic
- Unloading a database from memory for TimesTen Classic

Loading a database into memory for TimesTen Classic

1. Before you try to load the database into memory for TimesTen Classic, confirm that the TimesTen daemon is running with the ttStatus utility. The following output shows that the TimesTen daemon is not running.

```
% ttStatus
ttStatus: Could not connect to the TimesTen daemon.
If the TimesTen daemon is not running, please start it by running "ttDaemonAdmin -start".
```
2. Start the TimesTen daemon, if necessary.

   % ttDaemonAdmin -start

3. The RAM policy setting is important as it specifies if, how, and when the database is loaded or unloaded from memory. The default RAM policy for a TimesTen database is inUse.

   You can set the RAM policy before loading the database into memory. See "Specifying a RAM policy" on page 2-5 for more information.

   The following example sets the RAM policy of a TimesTen database to manual:

   % ttAdmin -ramPolicy manual database1

   RAM Residence Policy : manual
   Manually Loaded In RAM : False
   Replication Agent Policy : manual
   Replication Manually Started : False
   Cache Agent Policy : manual
   Cache Agent Manually Started : False
   Database state : open

4. Use the ttAdmin utility to load (or reload) the database into memory, or unload the database from memory.

   If the RAM policy is manual for the database database1, then load the TimesTen database into memory with the ttAdmin -ramload utility. The -ramLoad option of the ttAdmin utility can only be used with the manual RAM policy:

   % ttAdmin -ramLoad database1

   RAM Residence Policy : manual
   Manually Loaded In RAM : True
   Replication Agent Policy : manual
   Replication Manually Started : False
   Cache Agent Policy : manual
   Cache Agent Manually Started : False
   Database state : open

   If the RAM policy is manual, you can change it to always to specify that the database is always reloaded.

   ttAdmin -ramPolicy always database1

   If the RAM policy is inUse, then you want the grace period to be greater than 0, so that the database will be kept in memory for that time period when idle:

   % ttAdmin -ramPolicy inUse -ramGrace 200 database1

   RAM Residence Policy : inUse plus grace period
   RAM Residence Grace (Secs) : 200
   Replication Agent Policy : manual
   Replication Manually Started : False
   Cache Agent Policy : manual
   Cache Agent Manually Started : False
   Database state : open

   If the RAM policy is manual for the database database1 and the database was previously closed to incoming connections, then you can both load and open the TimesTen database into memory with the ttAdmin -ramload -open command.
Loading and unloading the database from memory

5. If your database is configured for replication or cache for your database, run the ttAdmin utility to start the replication and cache agents.

   To start replication:
   
   ttAdmin -repStart database1

   To start TimesTen Cache:
   
   ttAdmin -cacheStart database1

   For more information on these utilities, see "ttAdmin" and "ttDaemonAdmin" in the Oracle TimesTen In-Memory Database Reference.

Unloading a database from memory for TimesTen Classic

In TimesTen Classic, a database remains loaded in shared memory if any applications or TimesTen agents, such as the cache agent or replication agent, are connected to it. In TimesTen Classic, a database may also be kept in shared memory for particular RAM policy setting, even when no applications or agents are connected.

Before unloading the database from memory for TimesTen Classic, you must first close the database, close all active connections to the database and then set the RAM policy of the database to manual or inUse.

1. Close the database to reject any new requests to connect to the database.

   ttAdmin -close database1

2. Disconnect all applications from the database.

   To close all active connections to the database, run the ttAdmin -disconnect command. For more information, see "Disconnecting from a database" on page 2-8 in this book and "ttAdmin" in the Oracle TimesTen In-Memory Database Reference.

3. If the replication agent is running on the database, set the replication state to pause and stop the replication agent. The example sets the replication state from the active master database1 to the standby master standbydb to pause, then stops the replication agent on the active master database1.

   ttRepAdmin -receiver -name database1 -state pause standbydb
   ttAdmin -repStop database1

4. If the cache agent is running on the database, stop the cache agent.

   % ttAdmin -ramLoad -open database1

   RAM Residence Policy : manual
   Manually Loaded In RAM : True
   Replication Agent Policy : manual
   Replication Manually Started : False
   Cache Agent Policy : manual
   Cache Agent Manually Started : False
   Database state : open

---

**Note:** The following steps use examples where database1 is the database that is to be unloaded. It is assumed that it is the active master in a replication scheme and has been configured with TimesTen Cache. Note that a database can have both replication and cache configured, and a RAM policy other than manual.
ttAdmin -cacheStop database1

5. Ensure that the RAM policy is set to either manual or inUse. Then unload the database from memory. See "Specifying a RAM policy" on page 2-5 for more information.

If the RAM policy is set to always, change it to manual and then unload the database from memory with the ttAdmin -ramPolicy -ramUnload utility options.

   ttAdmin -ramPolicy manual -ramUnload database1

If the RAM policy is set to manual, unload the database with the ttAdmin -ramUnload utility:

   ttAdmin -ramUnload database1

If the RAM policy is set to inUse and a grace period is set, set the grace period to 0 or wait for the grace period to elapse. This results in the database being unloaded. TimesTen unloads a database with an inUse RAM policy from memory once you close all active connections.

   ttAdmin -ramGrace 0 database1

6. Run the ttStatus utility to verify that the database has been unloaded from memory and the database is closed. The database is unloaded if there are no processes. The database is closed when the output shows "Closed for user connections."

   See "ttStatus" in Oracle TimesTen In-Memory Database Reference for details.

7. Optionally, stop the TimesTen daemon.

   ttDaemonAdmin -stop

   For more information on the ttAdmin utility, see "ttAdmin" in the Oracle TimesTen In-Memory Database Reference.

---

## Specifying a RAM policy

TimesTen Classic allows you to specify a RAM policy that determines when TimesTen Classic databases are loaded and unloaded from main memory. For each TimesTen Classic database, you can have a different RAM policy.

### Note:
TimesTen Scaleout supports the manually loading and unloading of the database through the ttGridAdmin utility by system administrators.

---

The RAM policy options are as follows:

- **manual**: The database is manually loaded and unloaded by system administrators. Once loaded, TimesTen ensures that the database stays loaded until the administrator unloads the database (using ttAdmin -ramUnload) or unless an unrecoverable error condition occurs. The database can only be explicitly loaded into system RAM by the administrator (using the ttAdmin -ramLoad option). This is the recommended RAM policy, because it avoids unnecessary database loading or unloading.

   See "Set database loading policies" in the Oracle TimesTen In-Memory Database Reference for more details on ttAdmin -ramLoad and -ramUnload options. For more
Specifying a RAM policy

details on database error recovery, see "Changes to RAM policy after automatic recovery fails" on page 2-7.

- **inUse**: The database is loaded into memory when the first connection to the database is opened, and it remains in memory as long as it has at least one active connection. When the last connection to the database is closed, the database is unloaded from memory. This is the default policy.

- **inUse with RamGrace**: The database is loaded into memory when the first connection to the database is opened, and it remains in memory as long as it has at least one active connection. When the last connection to the database is closed, the database remains in memory for a "grace period." The database is unloaded from memory only if no processes have connected to the database for the duration of the grace period. The grace period can be set or reset at any time. It stays in effect until the next time the grace period is changed.

---

**Note**: Set the RAM policy to **inUse** or **inUse with RamGrace** if the application requires that the TimesTen database is automatically loaded with the first connection and automatically unloaded with the last disconnection. However, setting RAM policy to **inUse** for production systems with large databases may cause performance issues having the database unload and reload unexpectedly.

---

- **always**: The database always stays in memory. If the TimesTen daemon is restarted, it automatically reloads the database. The database is always automatically reloaded unless an unrecoverable error condition occurs.

  The **always** RAM policy should be used with caution. When failures occur, it may not be beneficial to have your database automatically reload. In addition, it may affect system startup performance if all databases load at the same time when your system boots. See "Changes to RAM policy after automatic recovery fails" on page 2-7 on error recovery and "Preventing an automatic reload of the database after failure" on page 2-7 for what could occur when trying to reload the database.

A system administrator can set the RAM policy or manually load or unload a database in TimesTen Classic with either the ttAdmin utility or the C API RAM policy utilities. For more details, see "ttAdmin" in the Oracle TimesTen In-Memory Database Reference or the "TimesTen Utility API" chapter in the Oracle TimesTen In-Memory Database C Developer’s Guide.

---

**Note**: By default, if an automatic recovery of the database is unsuccessful after a fatal error, TimesTen Classic changes the **always** and **manual** RAM policies to **inUse** to prevent reoccurring failures. For more information on how to prevent the RAM policy from changing, see "Changes to RAM policy after automatic recovery fails" on page 2-7.

---

The following example sets the RAM policy to **manual** for the database identified by the ttdata DSN:

---

**Note**: The first line shows the RAM residence policy set to **manual**. The rest of the output details other policies you can set with the ttAdmin utility. See "ttAdmin" in the Oracle TimesTen In-Memory Database Reference for more information.

---
Changes to RAM policy after automatic recovery fails

If a fatal error invalidates the database and the automatic database recovery performed by TimesTen Classic is unsuccessful, the following occurs by default:

- The RAM policies of manual and always remain unchanged.
- The replication and cache agents are not restarted.
- After several failed attempts to reload the database, TimesTen Classic sets the policyInactive mode, which prevents any more attempts at loading the database.

Note: Reloading a large database into memory when an invalidated database still exists in memory can fill up available RAM. See "Preventing an automatic reload of the database after failure" on page 2-7 on how to stop automatic reloading of the database.

Preventing an automatic reload of the database after failure

After a fatal error that causes the database to be invalidated, TimesTen Classic attempts to reload and recover the database, as long as it is consistent with the settings for the RAM policy, cache agent policy, and replication agent policy. However, user processes could still be connected to the invalidated database if they do not know that the original database has been invalidated. In this case, the invalidated database exists in memory until all user processes close their connections. Thus, the invalidated database could coexist in memory with the newly reloaded database. This can be an issue if the database is large.

Note: Not only does the RAM policy determine whether the database is reloaded and recovered, but the cache agent and replication agent policies also factor into whether the database is reloaded after invalidation. If the cache agent and replication agent policies are set so that the daemon automatically restarts the agent after a failure, the agent initiates a connection to the database. If this is the first connection, the daemon reloads the database and performs a recovery.

For more information on cache agent and replication agent policies, see "Starting and stopping the replication agents" in the Oracle TimesTen In-Memory Database Replication Guide, "Set a cache agent start policy" in the Oracle TimesTen Application-Tier Database Cache User’s Guide, and "ttAdmin" in the Oracle TimesTen In-Memory Database Reference.

You can prevent the database from being automatically reloaded after an invalidation using the ttAdmin -noautoreload command. You can reset to the default automatic database reload behavior with the ttAdmin -autoreload command. See "ttAdmin" in the Oracle TimesTen In-Memory Database Reference for more details.
Any one of the following initiates a reload and recovery of the database so that normal behavior can resume:

- The TimesTen daemon restarts.
- A process connects successfully.
- The administrator executes a `ttAdmin` command for the database that changes the RAM policy, performs a RAM load, or starts either the cache or replication agents.

If you set the behavior to prevent automatic reloads of the database, you may receive the following error when connecting to a database that was not reloaded.

Error 707, "Attempt to connect to a data store that has been manually unloaded from RAM"

### Disconnecting from a database

You can shut down or unload the database by first disconnecting applications in an orderly fashion. The forced disconnect option asynchronously disconnects all connected applications from the database, including those that are idle or unresponsive.

- Reliably disconnects and detaches from the shared memory segment for a database.
- Successfully disconnects any idle or unresponsive connections.

The following sections describe how to disconnect connections from a TimesTen database:

- Disconnecting from a database in TimesTen Scaleout
- Disconnecting from a database in TimesTen Classic

### Disconnecting from a database in TimesTen Scaleout

If you are unable to individually disconnect every application from the TimesTen Scaleout database, use the `ttGridAdmin dbDisconnect` command to disconnect all user connections from the database. See "Unloading a database from memory" in the Oracle TimesTen In-Memory Database Scaleout User's Guide for full details.

### Disconnecting from a database in TimesTen Classic

You can disconnect all connections to a TimesTen Classic database with the `ttAdmin -disconnect` command. However, you must first enable the capability for forced disconnect by setting the `ForceDisconnectEnabled` connection attribute to 1 in the DSN definition within the `sys.odbc.ini` file. See "ForceDisconnectEnabled" in the Oracle TimesTen In-Memory Database Reference for more details.

While control returns to the command prompt, the force disconnect operation may take multiple seconds (or minutes) to complete. Verify the status of the force disconnect operation with the `ttStatus` utility.

---

**Note:** The `ttRamPolicyAutoReloadSet` built-in procedure performs the same actions as `ttAdmin -noautoreload` and `ttAdmin -autoreload`. See "ttRamPolicyAutoReloadSet" in the Oracle TimesTen In-Memory Database Reference for more details.
While the forced disconnect operation is in process, any new connection request is rejected by the main daemon. Once the force disconnect operation completes, new connections are accepted.

You can specify how urgently you need connections to be forced to disconnect with the urgency level:

- The **-transactional** option waits for any open transactions to be committed or rolled back before disconnecting. Does not affect idle connections.
- The **-immediate** option rolls back any open transactions before immediately disconnecting. This option also disconnects idle connections.
- The **-abort** option aborts all direct mode application processes and client/server processes (ttcserv) in order to disconnect.

Most of the time, you should use the transactional and immediate urgency levels. A recommended practice is to run the **-disconnect** command twice, as necessary. First use the transactional urgency level. Then, after allowing some time, use **ttStatus** to confirm whether connections have been closed. If not all connections have been closed yet, then use the immediate urgency level.

The abort urgency level should only be used on the rare occasion when both the transactional and immediate urgency levels fail to successfully disconnect all specified connections. The abort option could result in lost transactions, as the abort operation abruptly causes every user and ttcserv process connected to the database to exit.

You can specify which type of connections to disconnect with the granularity level:

- The **-users** option (default) disconnects every user connection to the database. For example, use this granularity level when preparing to perform database maintenance.
- The **-unload** option disconnects every connection to the database, including subdaemon connections. For example, use this granularity level when attempting to unload the database.

---

**Note:** The always RAM policy conflicts with the unload granularity level. Using these simultaneously returns an error.

See "Force disconnect" in the *Oracle TimesTen In-Memory Database Reference* for more details on using the ttAdmin **--disconnect** command.

### Example 2–1 disconnecting all connections and unloading a TimesTen Classic database

The following script disconnects all connections and unloads the database by first executing ttAdmin **--disconnect** with the transactional urgency level. Then, the script waits a short time to evaluate if the connections disconnected before trying the immediate urgency level.

```bash
#!/bin/sh

# disconnect users and unload the database with the transactional urgency level
ttAdmin -disconnect -transactional -unload database1

# wait 10 seconds for the forced disconnect to finish
COUNT = 0
while [ ttStatus | grep "pending disconnection" ] || [ $COUNT -ne 10 ]
do
```
Specifying the memory region sizes of a database

TimesTen manages database space using two separate memory regions within a single contiguous memory space. One region contains permanent data and the other contains temporary data.

- Permanent data includes the tables and indexes that make up a TimesTen database. When a database is loaded into memory, the contents of the permanent memory region are read from files stored on the file system. The permanent memory region is written to the file system during checkpoint operations. TimesTen stores all data in RAM to achieve exceptional performance. The database throws an error if there is no space left for a new piece of data. PermSize can be increased with a database restart but it cannot be decreased.

- Temporary data includes locks, cursors, compiled commands, and other structures needed for command execution and query evaluation. The temporary memory region is created when a database is loaded into memory and is destroyed when it is unloaded.

The connection attributes that control the size of the database when it is in memory are PermSize and TempSize. The PermSize attribute specifies the size of the permanent memory region and the TempSize attribute specifies the size of the temporary memory region.

---

Note: See "PermSize" and "TempSize" in the Oracle TimesTen In-Memory Database Reference for further description of these attributes.

---

The sizes of the permanent and temporary memory regions are set when a database is loaded into memory and cannot be changed while the database is in memory. To change the size of either region, you must unload the database from memory and then

```bash
sleep 1
COUNT=$((COUNT+1))
done

# increase the urgency level to immediate
if [ ttStatus | grep "pending disconnection" ]; then
ttAdmin -disconnect -immediate -unload database1
fi

Use the ttStatus utility to check progress. During a forced disconnect operation, the output indicates the pending disconnections:

TimesTen status report

Daemon pid 10457 port 6627 instance user1
TimesTen server pid 10464 started on port 6629

------------------------------------------------------------------------
Data store /disk1/databases/database1
Daemon pid 10457 port 6627 instance user1
TimesTen server pid 10464 started on port 6629
There are 14 connections to the data store, ***14 pending disconnection***
Shared Memory KEY 0x0210679b ID 949092358
PL/SQL Memory KEY 0x0310679b ID 949125127 Address 0x5000000000
Type        PID       Context             Connection Name              ConnID
Process      10484   0x00007f3ddfeb4010  tt_181                            1
...```
reconnect using different values for the PermSize or TempSize attributes. See "Loading and unloading the database from memory" on page 2-2 for more information on unloading the database from memory.

Managing the database size is described in these sections:
- Estimating and modifying the memory region sizes for the database
- Monitoring PermSize and TempSize attributes
- Reducing database size for TimesTen Classic
- Receiving out-of-memory warnings

**Estimating and modifying the memory region sizes for the database**

Database operations cannot complete successfully without allocation of sufficient memory. First, determine appropriate sizes for the TimesTen permanent and temporary memory regions and the transaction log buffer.

Use the ttSize utility or run the application until you can make reasonable estimates, then set these TimesTen connection attributes:

- **PermSize**: Size of the permanent memory region, in MB, for the database where the actual data is stored. Make sure PermSize is sufficient to hold all the data. You can increase this value, but not decrease it for this database.

In TimesTen Classic, you can decrease the permanent memory region by re-creating the database with a smaller size. See "Reducing database size for TimesTen Classic" on page 2-13 for more details.

Note: The ttSize utility is optimized for databases in TimesTen Classic. See "Determining the value of the PermSize attribute" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for details on how to evaluate an appropriate value for the PermSize connection attribute for a TimesTen Scaleout database.

- **TempSize**: For TimesTen Classic, TempSize indicates the total amount of memory in MB allocated to the temporary region for the database. For TimesTen Scaleout, TempSize indicates the total amount of memory in MB allocated to the temporary region for an element. Related database operations may fail if TempSize is insufficient. You can change this size with a database restart.

- **LogBufMB**: Size of the internal transaction log buffer, in MB. By default LogBufMB is 64 MB. See "Configure log buffer and log file size parameters" on page 10-4 for details.

See "PermSize", "TempSize", "LogBufMB" and "LogFileSize" in the Oracle TimesTen In-Memory Database Reference for further description of these attributes.

Next, ensure that the maximum shared memory segment size of your system is large enough to contain the database. Use the maximum number of connections that you expect your database to use. All of the values are in MB (megabytes). Make it larger than the following:

\[ \text{PermSize} + \text{TempSize} + \text{LogBufMB} + 1 + (0.043 \times \text{connections}) \]
If there are multiple TimesTen databases on your system, each using its own shared memory segment, the maximum shared memory segment size must be large enough to accommodate the largest database.

Next, determine the total shared memory allocation you will need (converted to appropriate units). If there are multiple TimesTen databases on your system, the total shared memory allocation must be large enough to accommodate all of them, using the above equation for each database. (Then, on Linux for example, divide this value by the page size, typically 4096 bytes, to get total memory allocation in pages.)

Finally, if you want to allow for database invalidations, there must be at least twice as much physical memory as the size of the largest TimesTen database. If you do not allow for this, but an invalidation does occur, you cannot reload the database into memory until all processes and connections that used the database have been found and terminated.

Also see "Linux prerequisites" in Oracle TimesTen In-Memory Database Installation, Migration, and Upgrade Guide.

Monitoring PermSize and TempSize attributes

The SYS.V$MONITOR and SYS.GV$MONITOR system views contains several columns that can be used to monitor usage of PermSize and TempSize. These columns include PERM_ALLOCATED_SIZE, TEMP_ALLOCATED_SIZE, PERM_IN_USE_SIZE, PERM_IN_USE_HIGH_WATER, TEMP_IN_USE_SIZE, and TEMP_IN_USE_HIGH_WATER. Each of these columns show in KB units the currently allocated size of the database and the in-use size of the database. The system updates this information each time a connection is made or released and each time a transaction is committed or rolled back.

For example, you could evaluate the temporary space usage by running a full workload and watching the high water mark (TEMP_IN_USE_HIGH_WATER) of the temporary space usage. The high water mark can be reset using the ttMonitorHighWaterReset built-in procedure. And if necessary, you can change TempSize to a value of the observed TEMP_IN_USE_HIGH_WATER value and add 10%.

Note: You can also use the ttIsql dssize command to provide this information. See "Using the ttIsql dssize command" on page 6-11 and "ttIsql" in the Oracle TimesTen In-Memory Database Reference for more details.
You can monitor block-level fragmentation in the database with the `SYS.V$BLOCK_INFO` or `SYS.GV$BLOCK_INFO` system tables or by calling the `ttBlockInfo` built-in procedure.

See "SYS.GV$MONITOR", "SYS.V$MONITOR", "SYS.GV$BLOCK_INFO" or "SYS.V$BLOCK_INFO" in the *Oracle TimesTen In-Memory Database System Tables and Views Reference* for details on these views. For more details, see "ttBlockInfo" in the *Oracle TimesTen In-Memory Database Reference*.

### Reducing database size for TimesTen Classic

Once a TimesTen Classic database has been defined with a particular size for the permanent region (indicated by the `PermSize` DSN attribute), it cannot be reduced to a smaller size, even if tables or rows are deleted.

To reduce the allocated size of the permanent region of a TimesTen Classic database, run the `ttMigrate` utility to save a copy of the database and then re-create the database with a smaller permanent region size and restore the data.

Perform these steps to reduce the permanent region size of a TimesTen Classic database:

1. Disconnect applications from the database with the `ttAdmin -disconnect` command. For more information, see "Disconnecting from a database in TimesTen Classic" on page 2-8 in this book and "ttAdmin" in the *Oracle TimesTen In-Memory Database Reference*.

2. Use the `ttMigrate -c` option to create a data file for the database.

   ```
   % ttMigrate -c database1 /tmp/database1
   ```

3. Unload the TimesTen Classic database from memory. See "Unloading a database from memory for TimesTen Classic" on page 2-4 for full details for more information.

4. Create a new DSN definition for the new copy of the database with a smaller `PermSize` value. To modify the original DSN rather than create a new one, you must destroy the original TimesTen Classic database using the `ttDestroy` utility before restoring from the backup.

5. Recreate the TimesTen Classic database by using `ttIsql` with `AutoCreate=1`.

   ```
   ttIsql -connstr 'dsn=database1;AutoCreate=1' -e "quit"
   ```

   The database is empty at this point.

6. Restore the backup by using the `ttMigrate -r` and `-relaxedUpgrade` options.

   ```
   % ttMigrate -r -relaxedUpgrade database1 /tmp/database1
   ```

### Notes:

- The permanent region size of a TimesTen Classic database cannot be reduced below the size that is required by the data currently stored in the database. This value can be determined by querying the `perm_in_use_size` column of the `v$monitor` system view.

- You can also use this procedure to compact the TimesTen Classic database in order to reduce fragmentation caused by partially full table pages or fragmentation of the heap buffers that store index nodes and out-of-line values.
Receiving out-of-memory warnings

To receive out-of-memory warnings, applications must call the `ttWarnOnLowMemory` built-in procedure.

TimesTen Classic also provides two general connection attributes that determine when a low memory warning should be issued: `PermWarnThreshold` and `TempWarnThreshold`. Both attributes take a percentage value.

Storage provisioning for TimesTen

Storage provisioning is the process of allocating server storage space.

- **TimesTen installation storage allocation**: A TimesTen installation includes all of the software.
  
  Plan to allocate at least 1.5 GB for each TimesTen installation. If you run multiple instances on the same system, they can all share a single TimesTen installation. In order to incorporate software version upgrades, you should provision double that amount of space, plus some additional space.

- **TimesTen instance storage allocation**: Each TimesTen instance runs its own set of daemon processes (with associated daemon log files).
  
  Plan to allocate at least 256 MB for each TimesTen instance.

- **Checkpoint files**: Each TimesTen database requires disk space for two checkpoint files, each of which is stored in the directory that is specified with the `DataStore` attribute. As each checkpoint file grows on the file system, it never decreases in size. This can result in the size of each checkpoint file being equal to the maximum size that the database has ever reached in the permanent memory region. Thus, you should plan as though each checkpoint file occupies approximately the same amount of space as defined for permanent memory (as defined with the `PermSize` connection attribute).
  
  Plan to allocate twice the total permanent space of your databases plus 30%.

---

**Note:** For TimesTen Classic, you can set the `Preallocate` connection attribute to 1 to have TimesTen reserve file system space at connect time for checkpoint files. This is useful for large databases, which ensures that the file system always has room for the checkpoint files as data is added to the database. For more information, see “Preallocate” in the *Oracle TimesTen In-Memory Database Reference*.

---

- **Transaction log files**: Transaction log files are the most difficult space requirement to estimate. See “Storage provisioning for transaction log files” on page 2-15 for how to plan for space provisioning for transaction log files.

- **Local space to facilitate backup or export files for repositories in TimesTen Scaleout**: When you use an SCP-attached repository, any operations are first saved locally by the target instances before copied to the repository. The target data instances initially store the backup (or export) files to the `$timesten_home/grid/admin/temp` directory. You must ensure that you provision enough storage in this directory to accommodate the maximum size for backup or export files that would end up in a repository.
  
  Plan to allocate space of `PermSize` times the number of replica sets.
Storage provisioning for TimesTen Scaleout.

A single backup file contains one element from each replica set. Thus, the number of backup files needed to contain all of the rows of the tables in the database corresponds to the number of replica sets in your database.

---

**Note:** For hash distributed tables, only a portion of the rows of the tables are included in each backup file. The rows of hash distributed tables are distributed across the number of replica sets.

For duplicated tables, each backup file contains all rows in each table.

---

Plan to allocate space of \( \text{PermSize} \) times the number of replica sets.

### Storage provisioning for transaction log files

---

**Note:** You can generate a more accurate estimate of the transaction log volume within a test environment.

---

Consider the following when estimating the necessary file system space allocation for transaction log files:

- TimesTen keeps enough transaction log files to support recovering from either checkpoint file. Transaction log files may accumulate depending on the settings for background checkpoint operations (defined with the \( \text{CkptLogVolume} \) and \( \text{CkptFrequency} \) first connection attributes). In addition, TimesTen preallocates space for three additional transaction log files.

- TimesTen uses fuzzy checkpoint operations for background operations. Transaction log files can accumulate during fuzzy checkpoint operations. The amount of time taken to create a checkpoint scales with the value assigned to the \( \text{PermSize} \) connection attribute.

- Transaction log files may accumulate between incremental backups.

- In TimesTen Scaleout, each element in each replica set has its own transaction log files to store transaction log records. If a transaction modifies data in a replica set, then the changes are normally recorded in both elements of the replica set. However, if one of the elements in the replica set is down, then the changes are only recorded in the transaction log files for the active element. Transaction log files can accumulate if one element in a replica set is down for a very long time.

- In TimesTen Classic, transaction log files may accumulate on the master during temporary replication outages or if the subscriber is down.

---

**Note:** You can limit the number of transaction log files retained with the \( \text{FAILTHRESHOLD} \) clause on the \( \text{CREATE REPLICATION} \) and \( \text{ALTER REPLICATION} \) statements.

---

See "\( \text{CkptLogVolume} \)," "\( \text{CkptFrequency} \)," and "\( \text{PermSize} \)" in the *Oracle TimesTen In-Memory Database Reference* for more information on these connection attributes. See "\( \text{CREATE REPLICATION} \)" and "\( \text{ALTER REPLICATION} \)" in the *Oracle TimesTen In-Memory Database SQL Reference* for more information on these SQL statements.
The estimate of the transaction log volume depends on the peak update transaction rate and the average complexity of each transaction that modifies the database.

Consider:

- **B** represents the transaction log volume in bytes per transaction.
- **C** represents the number of columns updated. The minimum transaction update (which is an update of a single number column) generates 400 bytes of transaction log data. Each additional number column update generates another 250 bytes.
- **V** represents the average size of larger data inserted or updated (columns of type `CHAR`, `VARCHAR2`, `BINARY`, `VARBINARY` or `LOB`) for each write transaction.

To estimate the transaction log volume for each transaction, use this formula:

\[ B = 400 + ((C-1) \times 250) + V \]

Note that the first column is just 150 bytes more than all subsequent columns, as follows:

\[ B = (C \times 250) + (400-250) + V \]

which simplifies to:

\[ B = (C \times 250) + 150 + V \]

Multiply the estimated transaction log volume value (**B**) by the expected peak transaction rate to find the expected peak transaction log rate.

Where:

- **L** = total storage space to provision for transaction log files in bytes.
- **C** = average number of columns inserted or updated per write transaction.
- **V** = average bytes of large data (`CHAR`, `VARCHAR2`, `BINARY`, or `VARBINARY` columns) inserted or updated for each write transaction.
- **S** = time in seconds of required transaction log retention.
- **T** = peak transaction rate per second averaged over intervals of **S** seconds.
- **f** = fraction of transactions that include insert, update, or delete operations.

Lastly, increase the estimated file system space by an additional 30% for contingencies.

Taking all these factors into account, estimate provisioned transaction log file space in bytes according to this formula:

\[ L = ((C \times 250) + 150 + V) \times S \times T \times f \times 1.3 \]

**Example 2–2 Estimating storage provisioning**

For example, a workload consists of 35% update transactions. Each transaction updates four columns, including two character columns each averaging 30 bytes updated total. The workload runs at 1 million transactions per second and needs enough transaction log space to hold one hour's worth of transactions.

- **C** = 4 columns
- **V** = 30
- **S** = 3600
- **T** = 1,000,000
- **f** = 35% = 0.35
This workload requires:

\[
L = ((4 \times 250) + 150 + 30) \times 3,600 \times 1,000,000 \times 0.35 \times 1.3 = 1.9 \text{ TB}
\]

Thus, provision file system space of 1.9 TB for the transaction log files.

**Bulk copy data using the ttBulkCp utility**

The ttBulkCp utility enables you to copy data between TimesTen tables and ASCII files.

You can manage certain aspects of existing tables in the database with the ttBulkCp utility. With the ttBulkCp utility, you can add rows of data to an existing table, save data to an ASCII file, and load the data rows into a table in a TimesTen database.

The rows you are adding must contain the same number of columns as the table, and the data in each column must be of the type defined for that column.

Because the ttBulkCp utility works on data stored in ASCII files, you can also use this utility to import data from other applications, provided the number of columns and data types are compatible with those in the table in the TimesTen database and that the file found is compatible with ttBulkCp.

- Copying data from a TimesTen table to an ASCII file
- Copying data from an ASCII file into a TimesTen table

**Copying data from a TimesTen table to an ASCII file**

Run the ttBulkCp utility with the `-o` option to copy data from a TimesTen table to an ASCII file.

```
% ttBulkCp -o -connstr "DSN=database1;UID=HR;PWD=hr" hr.employees > employees.dmp
```

For more information about the ttBulkCp utility, see "ttBulkCp" in the Oracle TimesTen In-Memory Database Reference.

**Copying data from an ASCII file into a TimesTen table**

The ttBulkCp utility enables you to copy data from an ASCII file into a database table. The ttBulkCp utility does not copy duplicate rows into a table.

- Running ttBulkCp with the `-i` option
- Running ttBulkCp with the `-directLoad` option on TimesTen Classic

**Running ttBulkCp with the `-i` option**

The ttBulkCp utility with the `-i` option enables you to load data from a file. This option uses standard `INSERT` SQL statements to load data into a specific table of a TimesTen database.
On TimesTen Scaleout, the ttBulkCp utility inserts each row into its corresponding element based on the distribution scheme of the table. For TimesTen Scaleout, you can populate a table from a single location or from several locations. See "Bulk loading data into a database" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for more information on using the ttBulkCp utility in TimesTen Scaleout.

Note: Ensure that your TimesTen user has INSERT privilege on the tables it copies information into.

Example 2–4  ttBulkCp -i mode
This example copies the data from the employees.dmp file into the hr.employees table of the database1 database.

% ttBulkCp -i -connstr "DSN=database1;UID=HR;PWD=hr" hr.employees employees.dmp
employees.dmp:
  107 rows inserted
  0 duplicate rows not inserted
  107 rows total

For more information about the ttBulkCp utility, see "ttBulkCp" in the Oracle TimesTen In-Memory Database Reference.

Running ttBulkCp with the -directLoad option on TimesTen Classic
Run the ttBulkCp utility with the -directLoad option to copy data from an ASCII file into a TimesTen Classic database table. The -directLoad option loads data with standard INSERT SQL statements. The ttBulkCp -directLoad option can only be used by applications using direct connections, which avoids some of the overhead required when using client/server connections resulting in better performance than the -i option.

For improved performance, consider dropping indexes before loading data with the -directLoad option. Use the ttSchema utility to view the definition of all the indexes that are created on the tables of a TimesTen Classic database. Once the load operation is complete, manually re-create the indexes on your table. For more information about the ttSchema utility, see "ttSchema" in the Oracle TimesTen In-Memory Database Reference.

Note: Ensure that your TimesTen user has INSERT privilege on the tables it copies information into.

Example 2–5  ttBulkCp -directLoad option
This example copies the data from the employees.dmp file into the hr.employees table of the database1 database.

% ttBulkCp -directLoad -connstr "DSN=database1;UID=HR;PWD=hr" hr.employees employees.dmp
employees.dmp:
  107 rows inserted
  0 duplicate rows not inserted
  107 rows total
Defragmenting TimesTen databases

For more information about the ttBulkCp utility, see "ttBulkCp" in the Oracle TimesTen In-Memory Database Reference.

Thread programming with TimesTen

TimesTen supports multithreaded application access to databases. When a connection is made to a database, any thread may issue operations on the connection.

Typically, a thread issues operations on its own connection and therefore in a separate transaction from all other threads. In environments where threads are created and destroyed rapidly, better performance may be obtained by maintaining a pool of connections. Threads can allocate connections from this pool on demand to avoid the connect and disconnect overhead.

TimesTen allows multiple threads to issue requests on the same connection and therefore the same transaction. These requests are serialized by TimesTen, although the application may require additional serialization of its own.

TimesTen also allows a thread to issue requests against multiple connections, managing activities in several separate and concurrent transactions on the same or different databases.

Defragmenting TimesTen databases

Under some circumstances, a TimesTen database may develop memory fragmentation such that significant amounts of free memory are allocated to partially filled pages of existing tables. This can result in an inability to allocate memory for other uses (such as new pages for other tables) due to a lack of free memory. In these circumstances, it is necessary to defragment the database in order to make this memory available for other uses.

A secondary table partition is created after a table has been altered with the ALTER TABLE ADD SQL statement. Defragmentation enables you to remove the secondary table partitions and create a single table partition that contains all of the table columns. When secondary table partitions have been created, it is recommended to periodically defragment the database in order to improve space utilization and performance.

The following procedures address both types of database fragmentation:

- Offline defragmentation of a TimesTen Scaleout database
- Offline defragmentation of a TimesTen Classic database
- Online defragmentation of a TimesTen Classic database

Offline defragmentation of a TimesTen Scaleout database

A TimesTen Scaleout database is defragmented as part of the export and import process. Thus, to defragment a TimesTen Scaleout database, use the ttGridAdmin dbExport and dbImport commands. See "Exporting and importing a database" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for details.

Offline defragmentation of a TimesTen Classic database

To defragment a TimesTen Classic database, use the ttMigrate utility as follows:

1. Stop all connections to the database.
2. Save a copy of the database using ttMigrate.
% ttMigrate -c ttdb ttdb.dat

3. As the administration user, rebuild the ttdb database:
% ttMigrate -r -relaxedUpgrade -connstr 'dsn=ttdb' ttdb.dat

---

**Note:** You can achieve maximum table defragmentation with the ttMigrate -r -relaxedUpgrade command. The -relaxedUpgrade option also condenses table partitions. If you do not want to condense table partitions, remove the -relaxedUpgrade option from the ttMigrate -r -relaxedUpgrade command.

---

At this time:
- All the users, cache groups, and the active standby pair have been restored to ttdb.
- The cache groups are in AUTOREFRESH STATE = OFF.
- The cache agent and replication agent are not running.

Table partitions can be added when columns are added to tables with the ALTER TABLE ADD SQL statement. See the notes on "ALTER TABLE" in the *Oracle TimesTen In-Memory Database SQL Reference* for more information. Also see, "Avoid ALTER TABLE" on page 10-22 for performance considerations.

For more information on ttMigrate, see "ttMigrate" in the *Oracle TimesTen In-Memory Database Reference*.

---

**Online defragmentation of a TimesTen Classic database**

Use a combination of the ttMigrate -relaxedUpgrade and ttRepAdmin -duplicate utilities to defragment TimesTen Classic databases (with minimal overall service downtime) that are involved in a replication scheme where TABLE DEFINITION CHECKING is set to RELAXED. In addition, the ttMigrate -relaxedUpgrade option condenses partitions.

---

**Note:** If your TimesTen Classic database uses an active standby pair replication scheme, then you can only defragment these databases if the active standby pair replication scheme either does not contain any cache groups or contains only READONLY cache groups.

---

The following sections describe how to defragment TimesTen Classic databases that are involved in a replication scheme:

---

**Note:** The examples provided in each section assume that you are familiar with the configuration and management of replication schemes. For more information, see "Getting Started" in the *Oracle TimesTen In-Memory Database Replication Guide*.

---

- Online defragmentation of TimesTen Classic databases in an active standby pair replication scheme
Online defragmentation of TimesTen Classic databases in a non active standby pair replication scheme

Online defragmentation of TimesTen Classic databases in an active standby pair replication scheme

The following sections describe how to defragment TimesTen Classic databases that are involved in an active standby pair replication scheme:

- Migrate and rebuild the standby database
- Reverse the active and standby roles
- Destroy and re-create the new standby

The example in this section shows how to perform an online defragmentation with an active standby pair replication scheme where the active database is `ttdb1` and the standby database is `ttdb2`.

Migrate and rebuild the standby database

The following shows how to stop replication to the standby TimesTen database, save a copy of the standby database, and then defragment the standby database.

---

**Note:** While the standby database is defragmented, application processing can continue on the active database.

---

Perform the following to save a copy of the standby database:

1. Stop the replication agent on the standby database (`ttdb2`):
   ```
   % ttAdmin -repStop ttdb2
   ```

2. If there any subscribers, execute `ttRepStateSave` on the active database to set the status of the standby to failed. As long as the standby database is unavailable, updates to the active database are replicated directly to the subscriber databases.
   ```
   Command> call ttRepStateSave('FAILED', 'ttdb2', 'ttsrv2');
   ```

3. Save a copy of the standby database using `ttMigrate`.
   ```
   % ttMigrate -c ttdb2 ttdb2.dat
   ```

4. Stop the cache agent, drop any cache groups, and destroy the standby.
   ```
   % ttAdmin -cacheStop ttdb2
   ```
   While connected as cache manager user, drop all cache groups:
   ```
   Command> DROP CACHE GROUP t_cg;
   ```
   Destroy the standby database:
   ```
   % ttDestroy ttdb2
   ```

5. Rebuild the standby database. Execute the following on the standby as the instance administrator:
   ```
   % ttIsql ttdb2
   ```

6. Create the cache manager user and grant the user `ADMIN` privileges.
   ```
   Command> CREATE USER cacheadmin IDENTIFIED BY cadminpwd;
   ```
Command> GRANT CREATE SESSION, CACHE_MANAGER, CREATE ANY TABLE, DROP ANY TABLE TO cacheadmin;
Command> GRANT ADMIN TO cacheadmin;

**Note:** The cache manager user requires ADMIN privileges in order to execute `ttMigrate -r`. Once migration is completed, you can revoke the ADMIN privilege from this user if desired.

For more information on `ttMigrate`, see "ttMigrate" in the *Oracle TimesTen In-Memory Database Reference*.

7. As the cache manager user, rebuild the `ttdb2` database:

```
% ttMigrate -r -relaxedUpgrade -cacheuid cacheadmin -cachepwd cadminpwd
-connstr "dsn=ttdb2;uid=cacheadmin;pwd=cadminpwd;oraclepwd=oraclepwd" ttdb2.dat
```

At this time:
- All the users, cache groups, and the active standby pair have been restored to `ttdb2`.
- The cache groups are in `AUTOREFRESH STATE = OFF`.
- The cache agent and replication agent are not running.

8. As the cache manager user, start the cache agent on the standby:

```
% ttAdmin –cacheStart ttdb2
```

9. Load any cache groups.

```
Command> ALTER CACHE GROUP t_cg SET AUTOREFRESH STATE PAUSED;
Command> LOAD CACHE GROUP t_cg COMMIT EVERY 256 ROWS PARALLEL <nThreads>;
```

**Note:**
- Choose `nThreads` based on how many CPU cores you use to insert the data into TimesTen for this load operation.
- If there are several read-only cache groups it is recommended that you run several `LOAD` operations in separate sessions in parallel, if the TimesTen and Oracle Database resources are available.

10. After completion, verify the cache group state.

```
Command> cacheGroups;
Cache Group CACHEADMIN.T_CG:
  Cache Group Type: Read Only
  Autorefresh: Yes
  Autorefresh Mode: Incremental
  Autorefresh State: On
  Autorefresh Interval: 10 Seconds

  Autorefresh Status: ok
  Aging: No aging defined

  Root Table: ORATT.T
  Table Type: Read Only

1 cache group found.
```
11. Start the replication agent on the standby database:

```
% ttAdmin -repStart ttdb2
```

12. Check the replication state on the standby:

```
% ttSql ttdb2
Command> call ttRepStateGet;
< STANDBY >
1 row found.
```

The standby database (ttdb2) has been defragmented and both the active and standby databases are functional.

Reverse the active and standby roles

In order to perform the database defragmentation on the active database, switch the roles of the active and standby database. The active (ttdb1) becomes the standby database. The original standby (ttdb2) becomes the active database.

1. Stop all application processing and disconnect all application connections with the ttAdmin -disconnect command. Any query only processing can be moved to work at the ttdb2 TimesTen database. For more information, see "Disconnecting from a database" on page 2-8 in this book and "ttAdmin" in the Oracle TimesTen In-Memory Database Reference.

2. Call the ttRepSubscriberWait built-in procedure at the current active database (ttdb1), with the database name and host of the current standby database (ttdb2) as input parameters. This ensures that all queued updates have been transmitted to the current standby database.

```
Command> call ttRepSubscriberWait(NULL,NULL,'ttdb2','ttsrv2', 100);
```

3. Stop the replication agent on the current active database.

```
Command> call ttRepStop;
```

4. Call the ttRepDeactivate built-in procedure on the current active database. This puts the database in the IDLE state.

```
Command> call ttRepDeactivate;
Command> call ttRepStateGet;
< IDLE >
1 row found.
```
5. Promote the standby to active by calling the `ttRepStateSet('ACTIVE')` built-in procedure on the old standby database. This database now becomes the active database in the active standby pair. Use the `ttRepStateGet` built-on to verify that the database has become active.

   Command> call ttRepStateSet('ACTIVE');
   Command> call ttRepStateGet;
   < ACTIVE >
   1 row found.

6. Stop the replication agent on the database that used to be the active database.

   % ttAdmin -repStop ttdb1

7. Execute `ttRepStateSave` on the new active database to set the status of the old active database to failed. As long as the standby database is unavailable, updates to the active database are replicated directly to the subscriber databases.

   Command> call ttRepStateSave('FAILED', 'ttdb1', 'ttsrv1');

8. Restart the full application workload on the new active database (ttdb2).

   This database now acts as the standby database in the active standby pair.

   **Destroy and re-create the new standby**

   Destroy and recreate the new standby using `ttRepAdmin -duplicate` from the new active. During these steps, application processing can continue at the active database.

   1. Stop the cache agent on the new standby database:

      % ttAdmin -cacheStop ttdb1

   2. As the cache manager user, drop all cache groups:

      Command> DROP CACHE GROUP t_cg;

   3. Destroy the database:

      % ttDestroy ttdb1

   4. Re-create the new standby database by duplicating the new active.

      % ttRepAdmin -duplicate -from ttdb2 -host ttsrv2 -setMasterRepStart -UID ttadmin -PWD ttadminpwd -keepCG -cacheUID cacheadmin -cachePWD cadminpwd ttdb1

   5. Start cache and replication agents on the new standby database:

      % ttAdmin -cacheStart ttdb1
      % ttAdmin -repStart ttdb1

   This process defragments both the active and standby databases with only a few seconds of service interruption.

   **Online defragmentation of TimesTen Classic databases in a non active standby pair replication scheme**

   The following sections describe how to defragment TimesTen Classic databases that are involved in a non active standby pair replication scheme:

   - Migrate and rebuild the standby database
   - Alter the replication scheme
Defragmenting TimesTen databases

■ Destroy and re-create a database

**Note:** These sections discuss how to defragment databases that are involved in a bidirectional replication scheme. In bidirectional replication schemes, each database is both a master and subscriber.

The examples in this section show how to perform an online defragmentation with bidirectional and unidirectional replication schemes with two TimesTen databases named `ttdb1` and `ttdb2`. For the unidirectional replication example, `ttdb1` represents the master and `ttdb2` represents the subscriber.

**Migrate and rebuild a database**

The first step in the procedure is to stop replication on one of the TimesTen Classic databases and then defragment this database.

**Note:** While one of the databases is defragmented, application processing can continue on the other database.

Perform the following to save a copy of the database:

1. Stop the replication agents on one of the databases.
   
   On the `ttdb2` database:
   
   ```
   % ttAdmin -repStop ttdb2
   ```

2. Save a copy of the `ttdb1` database using `ttMigrate`.
   
   ```
   % ttMigrate -c ttdb2 ttdb2.dat
   ```

3. Destroy the database:
   
   ```
   % ttDestroy ttdb2
   ```

4. As a TimesTen user with `ADMIN` privileges, rebuild the `ttdb2` database:
   
   ```
   % ttMigrate -r -relaxedUpgrade -connstr 'dsn=ttdb2;uid=ttadmin;pwd=ttadminpwd' ttdb2.dat
   ```

   At this time:

   ■ All the users have been restored to `ttdb2`.
   ■ The replication agent is not running.

5. Restart the replication agent on `ttdb2`:
   
   ```
   % ttAdmin -repStart ttdb2
   ```

The `ttdb2` TimesTen database has been defragmented.

**Alter the replication scheme**

In order to perform the database defragmentation on the `ttdb1` database, perform the following:

1. Stop all application processing and disconnect all application connections with the `ttAdmin -disconnect` command. Any processing can be moved to work at the `ttdb2` TimesTen database. For more information, see "Disconnecting from a
Defragmenting TimesTen databases

database” on page 2-8 in this book and “ttAdmin” in the Oracle TimesTen In-Memory Database Reference.

2. Call the ttRepSubscriberWait built-in procedure at the database that has not been defragmented (ttdb1), with the database name and host of the defragmented database (ttdb2) as input parameters. This ensures that all queued updates have been transmitted to both databases.

Note: If you set the waitTime to -1, the call waits until all transactions that committed before the call have been transmitted to the subscriber.

However, if you set the waitTime to any value (this value may not be NULL), ensure that the return timeOut parameter value is 0x00 before continuing. If the returned value 0x01, call the ttRepSubscriberWait built-in procedure until all transactions that committed before the call have been transmitted to the subscriber.

For more information about the ttRepSubscriberWait built-in procedure, see “ttRepSubscriberWait” in the Oracle TimesTen In-Memory Database Reference.

On ttdb1:
% ttIsql ttdb1
Command> call ttRepSubscriberWait(NULL,NULL,'ttdb2','ttsrv2', 100);

If you are using a bidirectional replication scheme, skip steps 3-4 and move to step 5.

3. For a unidirectional replication scheme, where ttdb1 is the master and ttdb2 is the subscriber, drop the replication scheme on both TimesTen databases:

On ttdb1:
% ttIsql ttdb1
Command> DROP REPLICATION r1;

On ttdb2:
% ttIsql ttdb2
Command> DROP REPLICATION r1;

4. For a unidirectional replication scheme, drop the replication scheme on the master (ttdb1) and subscriber (ttdb2):

On ttdb1:
% ttIsql ttdb1
Command> DROP REPLICATION r1;

On ttdb2:
% ttIsql ttdb2
Command> DROP REPLICATION r1;
5. Start the replication agent on ttdb2:
   % ttAdmin -repStart ttdb2

6. Stop the replication agent on ttdb1.
   % ttAdmin -repStop ttdb1

   If you modified a unidirectional replication scheme, the ttdb2 database now acts as the master database in the unidirectional scheme; the ttdb1 database acts as the subscriber database in the unidirectional replication scheme.

   **Destroy and re-create a database**

   Destroy and recreate the TimesTen database in the replication scheme that has not yet been defragmented using ttRepAdmin -duplicate. During these steps, application processing can continue on the defragmented database.

   1. Destroy the database:
      % ttDestroy ttdb1

   2. Recreate the new TimesTen Classic database (ttdb1) by duplicating the previously defragmented TimesTen Classic database (ttdb2) involved in the replication scheme.
      % ttRepAdmin -duplicate -from ttdb2 -host ttsrv2 -setMasterRepStart -UID ttadmin -PWD ttadminpwd ttdb1

   3. Start the replication agent on the new standby database:
      % ttAdmin -repStart ttdb1

   This process defragments both of the TimesTen Classic databases involved in either a unidirectional or bidirectional replication scheme with only a few seconds of service interruption.

   **Verifying if your database is a single-instance or distributed database**

   If you want to verify if you are connected to a single-instance (TimesTen Classic) database or a distributed (TimesTen Scaleout) database, call for the value of the ttGridEnable parameter with the ttConfiguration built-in procedure. The built-in procedure returns ttGridEnable=1 for distributed databases and returns ttGridEnable=0 for single instance databases.

   Command> CALL ttConfiguration('ttGridEnable');
   < TTGridEnable, 1 >
   1 row found.
   Command>

   For more information on the ttConfiguration built-in procedure, see "ttConfiguration" in the *Oracle TimesTen In-Memory Database Reference*. 
Verifying if your database is a single-instance or distributed database
You can open client/server connections across a network to the TimesTen database with the TimesTen Client and TimesTen Server.

The following sections describe the TimesTen Client/Server and how to connect using them:

- Overview of the TimesTen Client/Server
- Configuring TimesTen Client and Server
- Running the TimesTen Server
- Accessing a remote database on Linux and UNIX

### Overview of the TimesTen Client/Server

The TimesTen Server is a process that runs on a server system that takes network requests from TimesTen Clients and translates them into operations on databases on the server system. This enables clients to connect to databases that are located on different systems, potentially running a different platform and operating system.

You can install the TimesTen Client on a separate or the same system as the TimesTen Server. If you install the TimesTen Client on the same system as the TimesTen Server, you can use it to access TimesTen databases on the local system.

---

**Note:** You can create a client/server connection between any combination of platforms that TimesTen supports.

TimesTen does not support IP-level failover or load-balancing with Client/Server.

---

*Figure 3–1* demonstrates how the TimesTen Client and TimesTen Server communicate using their respective drivers.
TimesTen Client: To access TimesTen databases on remote systems, link your application with the TimesTen Client ODBC driver. The application then communicates with the TimesTen Server process. Using the TimesTen Client ODBC driver, applications can connect transparently to TimesTen databases on a remote or local system that has TimesTen installed.

You can link a client application directly with the TimesTen Client ODBC driver or with the Windows ODBC driver manager to access the TimesTen database. TimesTen supplies a driver manager for Linux, UNIX, and Windows with the Quick Start sample applications. Note that there are performance considerations in using a driver manager.

Also, you can link a client application through a provided interface, like JDBC, OCI or Pro*C/C++, to access the TimesTen database.

**Note:** For details on how the application can use different drivers and interfaces to access a TimesTen database, see “Connecting to TimesTen with ODBC and JDBC drivers” on page 1-1.

TimesTen Server: On the server system, the TimesTen Server uses the TimesTen Data Manager driver. The server’s responsibility is to listen for requests from a client application, process the request through the TimesTen Data Manager driver, and then send the results and any error information back to the client application.
The following sections describe the restrictions and the communication protocols for client/server communication:

- Restrictions on client/server communication
- Communication protocols for Client/Server communication

Restrictions on client/server communication

The following are the restrictions on client/server communication:

- On Linux and UNIX, some TimesTen utilities only work over direct connections, such as ttAdmin, ttRepAdmin, and ttBackup. The utilities that can be executed over a client/server connection on the Linux and UNIX platforms are named with a suffix of CS, such as ttIsq1CS, ttBulkCpCS, ttMigrateCS and ttSchemaCS. These utilities have been linked with the TimesTen Client driver and can be used to connect to Client DSNs when accessing a database over a client/server connection. Each utility listed in the Oracle TimesTen In-Memory Database Reference provides the name of the client/server version of that utility, if there is one.

- XLA cannot be used over a client/server connection and is only supported within TimesTen Classic.

- The ttCacheUidPwdSet built-in procedure cannot be used over a client/server connection.

- You cannot connect with an external user defined on one host to a TimesTen data source on a remote host. There are no restrictions for connecting with internal users. See "Overview of TimesTen users" in the Oracle TimesTen In-Memory Database Security Guide for details on internal and external users.

- You cannot create or alter internal users over a client/server connection. Thus, you can only issue the CREATE USER or ALTER USER statements using a direct connection to the TimesTen database. Once created, the user that connects from the client to the server must be granted the CREATE SESSION privilege or the connection fails. For more information on how to create the user on the TimesTen database and how the administrator grants the CREATE SESSION privilege, see "Creating or identifying a database user" and "Privileges to connect to the database" in the Oracle TimesTen In-Memory Database Security Guide.

- On Linux and UNIX, TimesTen does not allow a child process to use a connection opened by its parent. Any attempt from a child process using fork() to use a connection opened by the parent process returns an error.

Communication protocols for Client/Server communication

The following sections describe the communication protocols that the TimesTen Client can use with the TimesTen Server:

- TCP/IP Communication
- Shared memory communication

Note: For details on compiling and linking TimesTen applications, see "Compiling Java applications" in the Oracle TimesTen In-Memory Database Java Developer's Guide or "Compiling and linking applications" the Oracle TimesTen In-Memory Database C Developer’s Guide.
Configuring TimesTen Client and Server

- **UNIX domain socket communication**

**TCP/IP Communication**

By default, the TimesTen Client communicates with the TimesTen Server using TCP/IP sockets. This is the only form of communication available when the TimesTen Client and Server are installed on different systems.

**Shared memory communication**

If both the TimesTen Client and Server are installed on the same system, applications using the TimesTen Client ODBC driver may use a shared memory segment for inter-process communication (IPC). Using a shared memory segment provides better performance than TCP/IP communication. To use a shared memory segment as communication, you must:

1. Configure the server attributes to use shared memory communication in the `timesten.conf` file. See "Using shared memory for Client/Server IPC" on page 4-8.
2. Define the Network Address as `ttShmHost` in the logical server name. See "Defining a logical server name" on page 3-10 for details.

---

**Note:** TimesTen supports a maximum of 16 different instances of the shared memory IPC-enabled server. If an application tries to connect to more than 16 different shared memory segments it receives an error.

---

**UNIX domain socket communication**

On Linux and UNIX platforms, if both the TimesTen Client and Server are installed on the same system, you can use UNIX domain sockets for communication. Using a shared memory segment allows for the best performance but slightly greater memory usage. Using UNIX domain sockets allows for improved performance over TCP/IP, but with less memory consumption than a shared memory segment connection. To use domain sockets, you must define the Network Address of the logical server as `ttLocalHost`. See "Defining a logical server name" on page 3-10 for more information.

---

### Configuring TimesTen Client and Server

**Note:** Before configuring the TimesTen Client and Server, read "Connecting to TimesTen with ODBC and JDBC drivers" on page 1-1 and "Specifying Data Source Names to identify TimesTen databases" on page 1-4.

The following sections describe how to connect an application to a TimesTen database using TimesTen Client and Server:

- **Overview of TimesTen Client/Server configuration**
- Installing and configuring for client/server connections
- Defining Server DSNs for TimesTen Server on a Linux or UNIX system
- Defining a logical server name
- Creating Client DSNs on a TimesTen Client system
- Using automatic client failover
Configuring TCP keep-alive parameters

Overview of TimesTen Client/Server configuration

Before the client application can connect to a TimesTen database, the user must configure, as shown in Figure 3–2, the Client DSN, optionally a logical server name, and a Server DSN to uniquely identify the desired TimesTen database.

Figure 3–2 Configuring for a client/server connection

The client application refers to the Client DSN when initiating a connection. With the following details, the connection request is resolved to be able to connect to the intended TimesTen database:

- The Client DSN is configured in either the user odbc.ini file or the system sys.odbc.ini file with the server host name, either the logical server name or the actual server system name, and the Server DSN that identifies the TimesTen database on the server.
- The logical server name is an optional configuration on the client. When used, it specifies the server host name where the TimesTen database is installed. This is used when you want to hide or simplify the server host name. You must use the logical server name when using shared memory IPC or UNIX domain sockets.
- The Server DSN is configured in the system sys.odbc.ini file with the TimesTen database name and its connection attributes. The connection attributes specify how the TimesTen database is loaded and configured, and how the connections to it are to be controlled or managed.
Thus, when these are configured correctly, the client application can use the Client DSN to locate and connect to the TimesTen database. The Client DSN defines the server system and the Server DSN. The Server DSN, in turn, specifies the TimesTen database on that server, how the database is to be loaded, and how connections are to be managed.

**Installing and configuring for client/server connections**

The following sections describe what you must install on which node for client/server connections:

- Configuring Client/Server of the same TimesTen release
- Configuring cross-release TimesTen Client/Server

**Configuring Client/Server of the same TimesTen release**

The following sections describe how to install and configure TimesTen when the Client and Server are of the same TimesTen release:

- Install and configure the TimesTen Server
- Install and configure the TimesTen Client

**Install and configure the TimesTen Server** Perform the following tasks on the system on which the TimesTen database resides. This system is called the server system.

1. Install the TimesTen Server.
   
   For information on how to install the TimesTen Server, see the *Oracle TimesTen In-Memory Database Installation, Migration, and Upgrade Guide*.

2. Create and configure a Server DSN corresponding to the TimesTen database. See "Defining Server DSNs for TimesTen Server on a Linux or UNIX system" on page 3-7. Set TimesTen connection attributes in the Server DSN. See "Connection Attributes" in the *Oracle TimesTen In-Memory Database Reference*.

**Install and configure the TimesTen Client** Perform the following tasks on the system where the client application resides. This system is called the client system.

1. Install the TimesTen Client.
   
   For information on how to install the TimesTen Client, see the *Oracle TimesTen In-Memory Database Installation, Migration, and Upgrade Guide*.

2. If you are using JDBC to connect to the database, install the Java Developer's Kit (JDK) and set up the environment variables, such as `CLASSPATH` and the shared library search path. See "Setting the environment for Java development" in the *Oracle TimesTen In-Memory Database Java Developer’s Guide* for details.

4. For OCI and Pro*C/C++ client/server connections, configure the application to use either `tnsnames.ora` or easy connect as described in "Connecting to a TimesTen database from OCI" in the *Oracle TimesTen In-Memory Database C Developer’s Guide*.

5. Link client/server applications as follows:

   - Link C and C++ client/server applications as described in "Linking options” in the *Oracle TimesTen In-Memory Database C Developer’s Guide*. 

---

3-6  *Oracle TimesTen In-Memory Database Operations Guide*
Link OCI or Pro*C/C++ applications in the same manner as any OCI or Pro*C/C++ direct connect applications, which is described in "TimesTen Support for OCI" and "TimesTen Support for Pro*C/C++" in the Oracle TimesTen In-Memory Database C Developer's Guide.

**Configuring cross-release TimesTen Client/Server**

Most TimesTen clients can connect to a TimesTen Server from a different release. A TimesTen Client 11.2.2 or later release may connect to a TimesTen Server 11.2.2 or later release. However, due to changes in ODBC 3.5 functionality, TimesTen clients of release 18.1 or later can no longer connect to older TimesTen Servers in certain circumstances. For more information about client/server cross-release restrictions, see "Client/server cross-release restrictions with ODBC 3.5" in the Oracle TimesTen In-Memory Database C Developer's Guide.

If you are configuring for a cross-release TimesTen Client/Server connection, install and configure as directed in "Configuring Client/Server of the same TimesTen release" on page 3-6.

The TimesTen Server loads a driver and a TimesTen database of its own release when a TimesTen Client application connects to the TimesTen database. The TimesTen Data Manager driver is automatically installed on the TimesTen Server system.

- If you are using a local client/server connection using UNIX domain sockets through ttLocalHost, then the platforms for the client and the server must be Linux or UNIX. The client must be running on the same host as the server and thus must be on the same platform. The release level for the client and server hosts must be the same.

- If you are using a local client/server connection over a shared memory IPC using ttShmHost, then:
  - The client must be running on the same host as the server and thus must be on the same platform.
  - The platform must be UNIX or Linux; Windows and macOS are not supported for shmipc (since they are client-only platforms).

**Defining Server DSNs for TimesTen Server on a Linux or UNIX system**

Server DSNs identify TimesTen databases that are accessed by a client/server connection. Because a Server DSN identifies databases that are accessed by a TimesTen Server, a Server DSN can be configured using the same connection attributes as a Data Manager DSN. In addition, there are connection attributes that are only allowed within the Server DSN specification. These attributes enable you to specify multiple client/server connections to a single server.

---

**Note:** Some connection attributes can be configured in the TimesTen daemon options file (timesten.conf). If you have set the same connection attributes in both the Server DSN and the daemon options file, the value of the connection attributes in the Server DSN takes precedence.

For a description of the TimesTen daemon options see "Managing TimesTen Client/Server attributes" on page 4-6.

For a complete description of the TimesTen Server connection attributes, see "Connection Attributes" in the Oracle TimesTen In-Memory Database Reference.
A Server DSN must be defined as a system DSN and has the same configuration format and attributes as a Data Manager DSN.

- For TimesTen Scaleout: A DSN is defined within the appropriate database definition and connectable. A connectable enables all data instances to accept connection requests from other data instances in the grid.

However, to establish a client connection from a TimesTen Client that is not part of the grid, create a client DSN in the user odbc.ini file or the system sys.odbc.ini file with the ttGridAdmin gridClientExport command. This command exports every client/server connectable available for the grid into a file that is formatted to replace the odbc.ini file used by the TimesTen Client.

See "Connect to a database using ODBC and JDBC drivers" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for full details.

- With TimesTen Classic, you create each system DSN by creating or editing the user odbc.ini file or the system sys.odbc.ini file. You can add or configure a Server DSN while the TimesTen Server is running. For details on how to create system DSNs for TimesTen Classic on Linux and UNIX, see "Creating a DSN on Linux and UNIX for TimesTen Classic" on page 1-9.

By default, TimesTen creates only one connection to a server per child process. However, you can specify multiple client/server connections to a single TimesTen Server with the connection attributes (described below) or by setting the TimesTen daemon attributes in the timesten.conf file as described in "Specifying multiple connections to the TimesTen Server" on page 4-7. If you have set both the Server connection attributes and the related timesten.conf daemon attributes, the value of the Server connection attributes takes precedence.

---

**Note:** These attributes are read at first connection. Changes to Server settings do not occur until the Server is restarted.

To restart the Server, use the following command. With TimesTen Scaleout, execute this command within the ttGridAdmin instanceExec command.

```
% ttDaemonAdmin -restartserver
```

---

- **Connections attribute:** Sets the upper limit of the number of concurrent connections to the database. The default value is the lesser of 2000 or the number of semaphores specified in the SEMMSL kernel parameter minus 155. TimesTen allocates one semaphore for each expected connection, therefore the SEMMSL kernel parameter has to be set properly. Make sure the connections attribute is set large enough to accommodate the number of concurrent database connections expected. See "Set the semaphore values" and "Configure shmmax and shmall" in the Oracle TimesTen In-Memory Database Installation, Migration, and Upgrade Guide or "Connections" in the Oracle TimesTen In-Memory Database Reference for more details.

- **ServerStackSize:** Set the stack size for each thread on the server.

  The ServerStackSize attribute is ignored unless the MaxConnsPerServer attribute is greater than one. If there is only one connection per Server, the server process uses the process' main stack. Consider setting the ServerStackSize attribute to 1024 KB or greater if you are running complex SQL queries on your client connections.

  See "ServerStackSize" in the Oracle TimesTen In-Memory Database Reference for more details.
■ **MaxConnsPerServer**: Set the maximum number of client connections that are handled by a single server process. Setting `MaxConnsPerServer > 1` enables multithreaded mode for the database so that it can use threads instead of processes to handle client connections. This reduces the time required for applications to establish new connections and increases overall efficiency in configurations that use a large number of concurrent client/server connections.

The server, referenced by the Server DSN, may have multiple server processes, where each process can only have the maximum number of connections as specified by this attribute. A new server process is automatically started if the number of connections exceeds `MaxConnsPerServer`.

See "MaxConnsPerServer" in the *Oracle TimesTen In-Memory Database Reference* for more details.

---

**Note**: If you are running a server in multithreaded mode and a server process fails, then all the client connections being handled by that process are terminated. Consider this when configuring the server for multithreaded mode and choose a value for `MaxConnsPerServer` that balances your requirements for reliability and availability versus the more efficient resource usage of multithreaded mode.

---

■ **ServersPerDSN**: You can have multiple server processes serving multiple incoming connections on the server. The `ServersPerDSN` attribute specifies the number of server processes to spawn in connection with the `MaxConnsPerServer` attribute for distribution of incoming connections.

See "ServersPerDSN" in the *Oracle TimesTen In-Memory Database Reference* for more details.

The `MaxConnsPerServer` and `ServersPerDSN` attributes are related in that they do not limit the number of connections, but control how connections are distributed over server processes. If `ServersPerDSN` is set to `N` where `N > 1`, then the first `N * MaxConnsPerServer` client connections to a Server DSN are distributed in round robin fashion over `N` server processes. If additional client connections beyond `N * MaxConnsPerServer` are opened to the same Server DSN, then those connections are assigned to new server processes sequentially. For example, if you have 12 connections and `MaxConnsPerServer=3`, then there are four server processes.

This results in the following behavior:

1. The first incoming connection spawns a new server process. Each additional incoming connection spawns a new server process up to the `ServersPerDSN` value.

2. The next `ServersPerDSN` number of incoming connections are assigned to the existing server processes in a round-robin fashion up to `MaxConnsPerServer` connections per server.

3. Once the `MaxConnsPerServer` is reached for servers spawned up to `ServersPerDSN`, the next connection spawns another server process and repeats the process detailed in steps 1 and 2.

For example, if `MaxConnsPerServer` is set to 2 and `ServersPerDSN` is set to 5, then the following occurs:

- Connection 1 arrives at the server, the first server process is started for this connection. Connections 2 through 5 arrive at the server, server processes 2 through 5 are initiated where each server process services a connection.
Connection 6 arrives at the server. Since ServersPerDSN is reached, and MaxConnsPerServer is not, connection 6 is given to the first server process. Incoming connections 7 through 10 are given respectively as the second connection to server processes 2 through 5.

Connection 11 arrives at the server. Both ServersPerDSN and MaxConnsPerServer are reached, so server process 6 is started to handle connection 11.

Defining a logical server name

A logical server name is a definition for a server system on the TimesTen Client. In some cases, such as when using a communication protocol other than TCP/IP for local client/server or the TimesTen Server process is not listening on the default TCP/IP port, you must define a logical server name on the client system. In these cases, the Client DSN must refer to the logical server name. However, in most cases when the communication protocol used is TCP/IP, the Client DSN can refer directly to the server host name without having to define a logical server name.

The following sections demonstrate how to define a logical server name on Linux and UNIX platforms:

Creating and configuring a logical server name on Windows

Creating and configuring a logical server name on Linux and UNIX

Creating and configuring a logical server name on Windows

To create and configure a logical server name:

1. On the Windows Desktop from the Start menu, select Control Panel, Administrative Tools, and finally Data Sources (ODBC). This opens the ODBC Data Source Administrator.

2. Click User DSN or System DSN.

3. Select a TimesTen Client DSN and click Configure.

4. Click Servers. This opens the TimesTen Logical Server List dialog.

5. Click Add. This opens the TimesTen Logical Server Name Setup dialog.

6. In the Server Name field, enter a logical server name.

7. In the Description field, enter an optional description for the server.

8. In the Network Address field, enter the host name or IP address of the server system. The Network Address must be one of:

<table>
<thead>
<tr>
<th>Type of connection</th>
<th>Network Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remote client/server connection</td>
<td>The name of the system where the TimesTen Server is running. For example, example.com</td>
</tr>
</tbody>
</table>
9. In the **Network Port** field, TimesTen displays the port number on which the TimesTen Logical Server listens by default. If the TimesTen Server is listening on a different port, enter that port number in the **Network Port** field.

   For example:

10. Click **OK**, then click **Close** in the TimesTen Logical Server List dialog to finish creating the logical server name.

    To delete a server name:

   1. On the Windows Desktop on the client system from the **Start** menu, select **Control Panel**.
   2. Double click **ODBC**. This opens the ODBC Data Source Administrator.
   3. Click either **User DSN** or **System DSN**.
   4. Select a TimesTen Client DSN and click **Configure**. This opens the TimesTen Client DSN Setup dialog.
   5. Click **Servers**. This opens the TimesTen Logical Server List dialog.
   6. Select a server name from the **TimesTen Servers** list.
   7. Click **Delete**.

### Creating and configuring a logical server name on Linux and UNIX

Define logical server names in a file named by the `SYSTTCONNECTINI` environment variable. This file is referred to as the `ttconnect.ini` file. The file contains a description, a network address and a port number.

TimesTen searches for the logical server in this order:

1. In the file specified by the `SYSTTCONNECTINI` environment variable, if it is set
2. In the `timesten_home/conf/sys.ttconnect.ini` file

**Working with the `ttconnect.ini` file** TimesTen uses the `ttconnect.ini` file to define the names and attributes for servers and the mappings between logical server names and their network addresses. This information is stored on the system where the TimesTen
Configuring TimesTen Client and Server

Client is installed. By default, the ttconnect.ini file is *times ten_home/conf/sys/ttconnect.ini*.

To override the name and location of this file at runtime, set the **SYSTCONNECTINI** environment variable to the name and location of the ttconnect.ini file before launching the TimesTen application.

You can define short-hand names for TimesTen Servers on Linux and UNIX in the ttconnect.ini file. The format of a TimesTen Server specification in the ttconnect.ini file is shown in Table 3–1.

**Table 3–1 TimesTen Server format in the ttconnect.ini file**

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ServerName]</td>
<td>Logical server name of the TimesTen Server system</td>
</tr>
<tr>
<td>Description=description</td>
<td>Description of the TimesTen Server</td>
</tr>
<tr>
<td>Network_Address=network-address</td>
<td>The DNS name, host name or IP address of the system on which the TimesTen Server is running.</td>
</tr>
<tr>
<td>TCP_Port=port-number</td>
<td>The TCP/IP port number where the TimesTen Server is running. Default for TimesTen release 18.1 is 6625.</td>
</tr>
</tbody>
</table>

The Network Address must be one of the following:

<table>
<thead>
<tr>
<th>Type of connection</th>
<th>Network address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remote client/server connection</td>
<td>The name of the system where the TimesTen Server is running. For example, server.example.com</td>
</tr>
<tr>
<td>Local client/server connection that uses UNIX domain sockets</td>
<td>ttLocalHost</td>
</tr>
<tr>
<td>Local client/server connection that uses shared memory for inter-process communication</td>
<td>ttShmHost</td>
</tr>
</tbody>
</table>

**Example 3–1 Defining a logical server name**

This example from a ttconnect.ini file defines a logical server name, LogicalServer, for a TimesTen Server running on the system server.example.com and listening on port 6625. The instance name of the TimesTen installation is instance.

```
[LogicalServer]
Description=TimesTen Server 18.1
Network_Address=server.example.com
TCP_Port=6625
```

**Example 3–2 Using UNIX domain sockets for communication**

If both the client and server are on the same Linux or UNIX system, applications using the TimesTen Client driver may improve performance by using UNIX domain sockets for communication.

The logical server name must also define the port number on which the TimesTen Server is listening so that multiple instances of the same version of TimesTen Server can be run on the same system. To achieve this, the logical server name definition in ttconnect.ini file might look like:

```
[LocalHost]
Description=Local TimesTen Server 18.1 through domain sockets
```
Network_Address=ttLocalHost
TCP_Port=6625

Example 3–3 Configuring shared memory for inter-process communication
If both the client and server are on the same system, applications can use shared memory for inter-process communication. This may result in the best performance.

The logical server name must also define the port number on which the TimesTen Server is listening in order to make the initial connection. To achieve this, the logical server name definition in ttconnect.ini file might look like:

[ShmHost]
Description= Local TimesTen Server 18.1 through shared memory
Network_Address=ttShmHost
TCP_Port=6625

Creating Client DSNs on a TimesTen Client system
A Client DSN specifies a remote database and uses the TimesTen Client. The Client DSN can be defined as a user or as a system DSN. A Client DSN refers to a TimesTen database indirectly by specifying a hostname, DSN pair, where the hostname represents the server system on which TimesTen Server is running and the DSN refers to a Server DSN that is defined on that host. These are configured within the Client DSN connection attributes.

Note: For a complete description of the TimesTen Client connection attributes, see "TimesTen Client connection attributes" in the Oracle TimesTen In-Memory Database Reference.

Alternatively, you can configure connection attributes at runtime in the connection string that is passed to the ODBC SQLDriverConnect function or the URL string that is passed to the JDBC DriverManager.getConnection() method. For example, you could use the TTC_Server_DSN attribute in either the connection string or the Client DSN for a client to specify which DSN it should use on the server.

Note: If you configure any of the Server DSN data store or first connection attributes within the definition of the Client DSN, they are ignored. However, the TimesTen Client allows most of the Server DSN attributes (except for the DataStore connection attribute) to be passed in as part of the connection or URL string. These are transparently passed on to the server and overrides what is configured in the Server DSN.

The following sections describe how to create a Client DSN and its attributes on either the Windows or Linux and UNIX platforms:

- Creating and configuring Client DSNs on Windows
- Creating and configuring Client DSNs on Linux and UNIX

Creating and configuring Client DSNs on Windows
On Windows, use the ODBC Data Source Administrator to configure logical server names and to define Client DSNs.

This section includes the following topics:
Creating a Client DSN on Windows

To define a TimesTen Client DSN:

1. On the Windows Desktop from the Start menu, select Control Panel, Administrative Tools, and finally Data Sources (ODBC). This opens the ODBC Data Source Administrator.

2. Choose either User DSN or System DSN. For a description of user DSNs and system DSNs see “Specifying Data Source Names to identify TimesTen databases” on page 1-4.

3. Click Add. This opens the Create New Data Source dialog.

4. Choose TimesTen Client 18.1 to select the TimesTen Client driver. Click Finish. This opens the Oracle TimesTen Client DSN Setup dialog.
5. In the **Client DSN** field, enter a name for the Client DSN. The name must be unique to the current list of defined DSNs on the system where the client application resides and can contain up to 32 characters. To avoid potential conflicts, you may want to use a consistent naming scheme that combines the logical server name with the name of the Server DSN. For example, a corporation might have Client DSNs named *Boston_Accounts* and *Chicago_Accounts* where *Boston* and *Chicago* are logical server names and *Accounts* is a Server DSN.

6. In the **Description** field, enter an optional description for the Client DSN.

7. In the **Server Name** or **Network Address** field, specify the logical server or network address of the server system.
   - The name can be a host name, IP address or logical server name. The logical server names defined on the client system can be found in the drop-down list. To define logical server names, click **Servers**.
   - If you do not specify a logical server name in this field, the TimesTen Client assumes that the TimesTen Server is running on the default TCP/IP port number. Therefore, if your Server is running on a port other than the default port and you do not specify a logical server name in this field, you must specify the port number in the ODBC connection string, using the `TCP_Port` attribute.
For more information on defining logical server names, see "Creating and configuring a logical server name on Windows" on page 3-10.

8. In the **Server DSN** field, enter the Server DSN corresponding to the database that the client application accesses.
   - If you do not know the name of the Server DSN, click **Refresh** to obtain a list of Server DSNs that are defined on the system specified in the **Server Name** or **Network Address** field. Select the Server DSN from the drop-down list.
   - You must have a network connection to the system where the TimesTen Server is running.

See "ODBC Data Sources" on page 1-14 for more information about customizing which Server DSNs show in this list.

9. In the **Connection Character Set** field, choose a character set that matches your terminal settings or your data source. The default connection character set is **AL32UTF8**. For more information, see "ConnectionCharacterSet" in Oracle TimesTen In-Memory Database Reference.

10. If you are using automatic client failover, you would configure the **Failover Server Name**, **Failover Port Range**, **Failover DSN**, and **No Reconnect On Failover**. See "Using automatic client failover" on page 3-20 for more details.

11. If you are using TimesTen Scaleout, you would configure the **TCP KeepAlive Time**, **TCP KeepAlive Interval**, and **TCP KeepAlive Probes**. For details, see "Configuring TCP keep-alive parameters" on page 3-26 in this guide and "TTC_TCP_KEEPALIVE_TIME_MS", "TTC_TCP_KEEPALIVE_INTVL_MS", and "TTC_TCP_KEEPALIVE_PROBES" in the Oracle TimesTen In-Memory Database Reference.

### Setting the network timeout interval and authentication

You can define the user name, password and network timeout interval for the client/server connection in the Client DSN with the **UID**, **PWD**, and **TTC_TIMEOUT** attributes. However, configuring the authentication in the Client DSN is optional, since you can provide the user name and password when connecting. It is strongly discouraged to supply the password in the Client DSN, since the password is stored unencrypted on the client.

For a description of the **UID**, **PWD**, and **TTC_TIMEOUT** attributes, see "Connection Attributes" in the Oracle TimesTen In-Memory Database Reference.

To set the network timeout interval and authentication:

1. In the **User ID** field of the Oracle TimesTen Client DSN Setup dialog box, enter a user name that is defined on the server system.

2. In the **Password** field, enter the password that corresponds to the user ID. Alternatively, you can enter an encrypted password in the **PwdCrypt** field.

3. In the **Network Timeout** field, enter the interval time in seconds. You can enter any non-negative integer. A value of 0 indicates that client/server operations should not time out. The default is 60 seconds. The maximum is 99,999 seconds.

   The **TTC_Timeout** connection attribute sets a maximum time limit for a network operation that is completed by using the TimesTen client and server. The **TTC_Timeout** connection attribute also determines the maximum number of seconds a TimesTen client application waits for the result from the corresponding TimesTen Server process before timing out.

4. Click **OK** to save the setup.
Accessing a remote database on Windows  In this example, the TimesTen Client system is
client.example.com. The client application is accessing the Server DSN on the remote
server system, server.example.com. The logical server name is LogicalServer.

Note: These examples reference the sample DSNs preconfigured in a
fresh TimesTen installation.

1. On the server system server.example.com, use the ttStatus utility to verify that
the TimesTen Server is running and to verify the port number it is listening on.

2. Using the procedure in "Defining Server DSNs for TimesTen Server on a Linux or
UNIX system" on page 3-7, verify that the Server DSN, database1, is defined as a
system DSN on server.example.com.

3. On the client system, client.example.com, create a Logical Server Name entry for
the remote TimesTen Server. In the TimesTen Logical Server Name Setup dialog:
   ■ In the Server Name field, enter LogicalServer.
   ■ In the Network Address field, enter server.example.com.
   ■ In the Network Port field, enter 6625. This is the default port number for the
     TimesTen Server for TimesTen Release 18.1. This value should correspond to
     the value displayed by ttStatus in Step 1.

   See "Creating and configuring a logical server name on Windows" on page 3-10 for
   the procedure to open the TimesTen Server Name dialog and for more details.

4. On the client system, client.example.com, create a Client DSN that corresponds
to the remote Server DSN, database1CS. In the TimesTen Client DSN Setup dialog,
enter the following values:
   ■ In the Client DSN field, enter database1CS.
   ■ In the Server Name or Network Address field, enter LogicalServer.
   ■ In the Description field, enter a description for the server. Entering data into
     this field is optional.
   ■ In the Server DSN field, enter database1.

5. Run the client application from the system client.example.com using the Client
DSN, database1CS. The example below uses the ttIsql program installed with
TimesTen Client.

% ttIsql -connStr "DSN=database1CS"

The next example describes how to access a TimesTen Server that is listening on a port
numbered other than the default port number.

Consider that the network address of the TimesTen Server is server.example.com and
the Server is listening on Port 6625. The following methods can be used to connect to a
Server DS:

1. Define the logical server name LogicalServer with server.example.com as the
Network Address and 6625 as the Network Port. Define Client_DSN as the Client
DSN with LogicalServer as the Server name and Server_DSN as the Server DSN.
Then, execute the command:

% ttIsql -connStr "DSN=Client_DSN"
2. Alternatively, define the logical server name `LogicalServer_tt` with server.example.com as the Network Address and the default port number as the Network Port. Define `Client_DSN` as the Client DSN with `LogicalServer` as the Server name and `Server_DSN` as the Server DSN. Overwrite the port number in the command:

   `% ttIsql -connStr "DSN=Client_DSN;TCP_Port=6625"`

**Testing connections** To test client application connections to TimesTen databases:

1. On the Windows Desktop from the **Start** menu, select **Settings**, and then select **Control Panel**.
2. Double click **ODBC**. This opens the ODBC Data Source Administrator.
3. Click **User DSN** or **System DSN**.
4. Select the TimesTen Client DSN whose connection you want to test and click **Configure**. This opens the TimesTen Client DSN Setup dialog.
5. Click **Test TimesTen Server Connection** to test the connection to TimesTen Server. The ODBC Data Source Administrator attempts to connect to TimesTen Server and displays messages to indicate if it was successful. During this test TimesTen Client verifies that:
   - ODBC, Windows sockets and TimesTen Client are installed on the client system.
   - The server specified in the **Server Name** or **Network Address** field of the TimesTen Client DSN Setup dialog is defined and the corresponding system exists.
   - The TimesTen Server is running on the server system.
6. Click **Test Data Source Connection** to test the connection to the Server DSN. The ODBC Data Source Administrator attempts to connect to the Server DSN and displays messages to indicate whether it was successful. During this test, TimesTen Client verifies that:
   - The Server DSN specified in the **Server DSN** field is defined on the server system.
   - A client application can connect to the Server DSN.

**Creating and configuring Client DSNs on Linux and UNIX**

On Linux and UNIX, you define logical server names by editing the `ttconnect.ini` file; you define Client DSNs by editing the user `odbc.ini` file for user DSN or the system `sys.odbc.ini` file for system DSNs.

---

**Note:** The syntax for defining the Client DSN in the `odbc.ini` file is described in "**odbc.ini file entry descriptions**" on page 1-14. See "**Defining a logical server name**" on page 3-10 for details on the `ttconnect.ini` file. See "**Specifying Data Source Names to identify TimesTen databases**" on page 1-4 for a description of user and system DSNs.
In the ODBC Data Sources section of the odbc.ini file, add an entry for the Client DSN. The Client DSN specifies the location of the TimesTen database with the following attributes:

- TimesTen ODBC client driver to use for the connection.
- The server (and the port number if you do not want to use the default port number) for the database is specified in the TTC_Server attribute.
- The Server DSN that specifies the intended database is specified in the TTC_Server_DSN attribute.

**Note:** The Server DSN is defined on the server system where the database resides.

For each TimesTen database with which the client connects needs to have two entries:

- Define the Client DSN name and provide the name of the TimesTen ODBC client driver to use in the ODBC Data Sources section.

  **Note:** See "Connecting using TimesTen ODBC drivers" on page 1-3 for a list of all available ODBC client drivers.

- Create an entry with the Client DSN you defined in the ODBC Data Sources section. Within this section, specify the server system and the Server DSN.

  The following is the syntax for providing the Client DSN name and the ODBC client driver to use:

  
  ```
  [ODBC Data Sources]
  Client_DSN=Name-of-ODBC-driver
  ```

  For example, to defined database1CS as the Client DSN and associate it with the TimesTen Client ODBC driver, you would make the following entry in the ODBC Data Sources section of the odbc.ini file:

  ```
  [ODBC Data Sources]
  database1CS=TimesTen Client 18.1 Driver
  ```

  After the ODBC Data Sources section, you would add an entry to specify the server system and Server DSN for each data source you defined. Each Client DSN listed in the ODBC Data Sources section of the odbc.ini file requires a its own specification section.

  The following is an example specification of the TimesTen Client DSN database1CS where the server is configured with a server name of server.example.com with port of 6625 and the Server DSN is database1.

  ```
  [database1CS]
  TTC_Server=server.example.com/6625
  TTC_Server_DSN=database1
  ```

  If you want to use logical server names, then the following is an example specification of the TimesTen Client DSN database1CS where the server is configured with a logical server name of LogicalServer and the Server DSN is database1:

  ```
  [database1CS]
  TTC_Server=LogicalServer
  TTC_Server_DSN=database1
  ```
The **TTC_Server** attributes are the main attributes for a Client DSN definition. There are only a few client connection attributes, each of which are for identifying the Server DSN. If you provide any server connection attributes in the client definition, these attributes are ignored. General connection attributes may be specified in the client definition.

**Note:** See "UID and PWD" in the *Oracle TimesTen In-Memory Database Reference* for options on how to provide the user ID when connecting.

Once the TimesTen Client DSN is configured, you can connect to the server using the `ttIsqlCS` utility. The following connects to the server using the `database1CS` DSN.

```bash
% ttIsqlCS -connStr 'DSN=database1CS'
```

For a description of all client and general connection attributes available for use in the `odbc.ini` file, see "Connection Attributes" in the *Oracle TimesTen In-Memory Database Reference*.

### Using automatic client failover

Automatic client failover is for use in high availability client/server scenarios with TimesTen Scaleout or TimesTen Classic. If there is a failure of the TimesTen database to which the client is connected, then failover (connection transfer) to an alternate TimesTen database occurs. Failover connections are created only as needed.

- For TimesTen Scaleout, the connection is transferred to an available data instance from a list of available data instances in the grid (and is not dependent on the DSN configuration in your `odbc.ini` file).

- For TimesTen Classic, you can use automatic client failover in two scenarios:
  - Active standby pair replication scheme: If you have an active standby pair replication configuration, then the connection is transferred to the new active (original standby) master within an active standby pair replication configuration. Consider a scenario where failure of the active master has resulted in the original standby master becoming the new active master. With the automatic client failover feature, failover (transfer) to the new active (original standby) node occurs, and applications are automatically reconnected to the new active master.

**Note:** Automatic client failover in TimesTen Classic (when using an active standby pair replication scheme) is complementary to Oracle Clusterware in situations where Oracle Clusterware is used, but the two features are not dependent on each other. For information about Oracle Clusterware, you can refer to "Using Oracle Clusterware to Manage Active Standby Pairs" in the *Oracle TimesTen In-Memory Database Replication Guide*.

- Generic automatic client failover: If you create more than one database and have a process to ensure that the data is consistent on both databases, then the client can automatically fail over from one database to another. For example, with a suitable TimesTen Cache configuration, TimesTen Cache automatically synchronizes the data in all of the included TimesTen databases with the data...
in the Oracle database. In such a scenario, applications can safely failover between multiple caches without any concern about data consistency.

In each of these scenarios, applications are automatically connected to the failover TimesTen database. TimesTen provides features that enable applications to be alerted when this happens, enabling the application to take appropriate action.

**Note:** If you issue an `ALTER SESSION` statement anytime after the initial connection, you must re-issue the statement after a failover. For information about connection persistence after failover, see "Using automatic client failover in your application" in *Oracle TimesTen In-Memory Database C Developer’s Guide*.

The following sections describe how to use and enable automatic client failover:

- Managing automatic client failover in TimesTen Scaleout
- Managing automatic client failover in TimesTen Classic using an active standby pair
- Managing generic automatic client failover in TimesTen Classic

### Managing automatic client failover in TimesTen Scaleout

By default, if a connection fails in TimesTen Scaleout, then the client automatically attempts to reconnect to another data instance (if possible). See "Client connection failover" in the *Oracle TimesTen In-Memory Database Scaleout User’s Guide* for full details on managing client connection failover in TimesTen Scaleout.

### Managing automatic client failover in TimesTen Classic using an active standby pair

When you use an active standby pair replication scheme in TimesTen Classic and an application connects to the active master, then the connection is registered and this registration is replicated to the standby master. If the active master fails, the standby master becomes the active master and then notifies the client of the failover. At this point, the client has a new connection to the new active master. No state from the original connection, other than the connection handle, is preserved. All client statement handles from the original connection are marked as invalid.

When failover completes, TimesTen makes a callback to a user-defined function that you register. This function takes care of any custom actions you want to occur in a failover situation.

The following items list the behavior of automatic client failover in particular failure scenarios:

- If the client library loses the connection to the active master, it fails over and attempts to switch to the standby master.
- If, for some reason, there is no active master (no failover has occurred at the server side and both servers are either standby or idle), applications cannot connect. But automatic client failover continues to alternate between both servers until it finds an active master or times out.
- If a failover has already occurred and the client is already connected to the new active master, the next failover request results in an attempt to reconnect to the original active master. If that fails, alternating attempts are made to connect to the two servers until it times out.
If the active master fails before the client registration is successfully propagated by replication to the standby master, the client does not receive a failover message and the connection registration is lost. However, the client library eventually notices (through TCP) that its connection to the original active master is lost and initiates a failover attempt.

**Notes:** Using automatic client failover with an active standby pair replication scheme results in one additional database connection per server process. This should be considered when you choose a setting for the TimesTen Connections attribute (the upper limit of the number of concurrent connections to the database). The number of server processes, in turn, is affected by the setting of the MaxConnsPerServer attribute (maximum number of concurrent connections a server process can handle).

For example, if you have 12 connections and MaxConnsPerServer=3, then there are four server processes. Therefore, if some of the connections use automatic client failover, then there are four additional connections.

Managing generic automatic client failover in TimesTen Classic

You can configure generic automatic client failover across any set of TimesTen Classic databases. You can configure a list of failover TimesTen databases in the user or system odbc.ini file. Once configured, the application can try to connect to each of them until a successful connection is made. This feature applies only to client/server connections, not direct connections.

**Note:** You must ensure that automatic client failover is meaningful in your environment. That is, there is no possibility of any data consistency issues when failing over between the included databases. In addition, the client can locate the necessary tables and data in any database to which it fails over.

Consider the following for each TimesTen Classic database included in the failover server list:

- Participating databases must be TimesTen release 18.1.4.1.0 or later.
- The same database username and password must be used for client connections to all databases.
- The failover databases should have the same table and/or cache group definitions. You must have a process to ensure that the data is consistent on all databases for all tables and/or cache group tables.
- To facilitate a fast failover, all of the databases in the client failover list should be loaded in memory.
When using TimesTen Cache, the databases should have operational cache agents at all times.

The databases included in the generic automatic failover do not use an active standby pair replication scheme.

A typical use case for generic automatic failover is a set of databases using read-only caching, where each database has the same set of cached data. For example, if you have several read-only cache groups, then you would create the same read-only cache groups on all TimesTen Classic databases included in the list of failover servers. When the client connection fails over to an alternate TimesTen database, the cached data is consistent since TimesTen Cache automatically refreshes the data (as needed) from the Oracle database. See "Read-only cache group" in the Oracle TimesTen Application-Tier Database Cache User’s Guide for more details on read-only cache groups.

---

**Note:** When failover happens, the application will need to re-prepare all statements.

---

For C developers, details of how to create the callback and to facilitate an automatic client failover are discussed in "Using automatic client failover in your application" in the Oracle TimesTen In-Memory Database C Developer’s Guide. For Java developers, details are discussed in "JDBC support for automatic client failover" in the Oracle TimesTen In-Memory Database Java Developer’s Guide.

### Configuring automatic client failover for TimesTen Classic

A list of failover TimesTen databases can be configured on the client. Then, clients initiate a connection to each failover TimesTen database, until a successful connection is made.

---

**Note:** The failover server information you provide depends on which type of automatic client failover you want to use. That is, the failover server should be either the standby database (when using an active standby pair replication scheme) or a second TimesTen database (when using read-only cache groups). See "Using automatic client failover" on page 3-20 for details on both types of automatic client failover.

---

The following sections describe how to configure for automatic client failover for TimesTen Classic:

- Configuring automatic client failover for TimesTen Classic on Windows
- Configuring automatic client failover for TimesTen Classic on Linux and UNIX

#### Configuring automatic client failover for TimesTen Classic on Windows

In the Oracle TimesTen Client DSN Setup dialog, after you have configured the rest of the Client DSN information as described in "Creating and configuring Client DSNs on Windows" on page 3-13, complete the following fields:

1. In the **Failover Server Name or Network Address** field, specify the logical server or network address of the failover server.
   - The name can be a host name, IP address or logical server. The logical server names defined on the client system can be found in the drop-down list. To define logical server names, click **Servers**.
If you do not specify a logical server name in this field, the TimesTen Client assumes that the TimesTen Server is running on the default TCP/IP port number. Therefore, if the Server is running on a port other than the default port and you do not specify a logical server name in this field, you must specify the port number in the ODBC connection string, using the TCP_Port attribute.

See "Creating and configuring a logical server name on Windows" on page 3-10 for more information on defining logical server names.

2. In the Failover Server DSN field, enter the Server DSN corresponding to the failover server.
   - If you do not know the name of the Server DSN, click Refresh to obtain a list of Server DSNS that are defined on the system specified in the Failover Server Name or Network Address field. Select the Server DSN from the drop-down list.
   - You must have a network connection to the system where the TimesTen database is running.

3. If you are using an active standby pair replication scheme for automatic client failover, then you can optionally specify the Failover Port Range for the port or port range where TimesTen listens for failover notifications. Specifying a port range helps accommodate firewalls between client and server systems. With the active standby pair, the active and standby masters notify the clients to failover.

   By default, TimesTen uses a single port chosen by the operating system. A port range is set as a lower and upper value separated by hyphen.

   You only need to specify a port range if both of these conditions are true:
   - You need multiple ports on the firewall between the server and client hosts.
   - You use multiple client applications configured for automatic client failover on a single client host.

   Each client application configured for automatic client failover on a client host needs to listen on a distinct port for failover notifications.

4. Optionally, select the No Reconnect On Failover check box to have TimesTen perform all the usual client failover processing except for the reconnect. For example, statement and connection handles are marked as invalid. This is useful if the application provides its own connection pooling or manages its own reconnection to the database after client failover.

   Configuring automatic client failover for TimesTen Classic on Linux and UNIX

   On the client, configure the following:

   1. In the odbc.ini file on the client, define the Client DSNs. Specify the failover servers with the TTC_ServerN connection attribute, where N >= 2. The TTC_ServerN connection attribute can specify the DNS name, host name or IP address of the system (with or without the port number).

      Set the TTC_Server_DSNn connection attribute to the name of this database, where n >= 2.

      Setting any of TTC_ServerN or TTC_Server_DSNn implies the following:
      - You intend to use automatic client failover.
      - You understand that a new client thread is created for your application to support the failover mechanism.
If you are using automatic client failover for read-only cache groups, you can specify more than one failover server with the TTC_ServerN and TTC_Server_DSNn connection attributes, where \( N, n \geq 2 \).

You should specify your failover servers (identified by \( N \)) in a sequential order.

For example:

```
[MyDSN]
TTC_Server=server.example.com/6625
TTC_Server_DSN=MyDSN
TTC_Timeout=60
TTC_Server2=server2.example.com/6625
TTC_Server_DSN2=MyDSN_Failover1
TTC_Server3=server3.example.com/6625
TTC_Server_DSN3=MyDSN_Failover2
```

**Notes:**

- Optionally, you can define logical server names for your failover servers in the ttconnect.ini file on the client with the `Network_Address` and `TCP_Port`. See "Creating and configuring a logical server name on Linux and UNIX" on page 3-11 for more information on defining logical server names.

- Like other connection attributes, TTC_ServerN and TTC_Server_DSNn can be specified in the connection string, overriding any settings in the DSN. The default TCP/IP port number is assumed for TCP_Port and TCP_PortN unless you specify a value in the TTC_ServerN connection attribute, in the connection string, or in the logical server definition in ttconnect.ini.

Refer to "TTC_Server or TTC_Server1", "TTC_Server2, TTC_ServerN", "TTC_Server_DSN2, TTC_Server_DSNn", and "TCP_Port2, TCP_PortN" in *Oracle TimesTen In-Memory Database Reference* for more information.

2. If you are using automatic client failover with read-only cache groups and you have specified more than one alternate failover server, you can specify how the client selects the failover server. By default, the client selects from a randomly ordered list of servers provided by TTC_Server and TTC_ServerN attributes.

However, if you set TTC_Random_Selection to 0, then the client selects the first server specified by the TTC_ServerN connection attributes. If the client cannot connect to the first server specified, the client proceeds to the next failover server in the order specified numerically.

**Note:** If you are using an active standby pair for automatic client failover and the client library cannot connect to the active master specified by TTC_Server_DSN, then it tries the standby master specified by TTC_Server_DSN2.

Refer to "TTC_Random_Selection" in *Oracle TimesTen In-Memory Database Reference* for more information.

3. Optionally, set a timeout to specify a duration for all failover recovery attempts in the odbc.ini file on the client.
When TimesTen attempts to recover from failure using automatic client failover, the `TTC_TIMEOUT` connection attribute specifies the duration for all attempts at failover recovery. The connection might be blocked while failover is attempted. For example:

```
[MyDSN]
TTC_Server=server.example.com/6625
TTC_Server_DSN=MyDSN
TTC_Timeout=60
TTC_Server2=server2.example.com/6625
TTC_Server_DSN2=MyDSN_Failover1
TTC_Server3=server3.example.com/6625
TTC_Server_DSN3=MyDSN_Failover2
```

Refer to "TTC_Timeout" in *Oracle TimesTen In-Memory Database Reference* for information.

4. If you are using an active standby pair replication scheme for client failover, then you can optionally configure the `TTC_FailoverPortRange` attribute to specify a port or port range where the failover thread listens for failover notifications. Specifying a port range helps accommodate firewalls between client and server systems. With the active standby pair, the active and standby masters notify the clients to failover.

By default, TimesTen uses a single port chosen by the operating system. A port range is set as a lower and upper value separated by hyphen.

You only need to specify a port range if both of these conditions are true:

- You need multiple ports on the firewall between the server and client hosts.
- You use multiple client applications configured for automatic client failover on a single client host.

Each client application configured for automatic client failover on a client host needs to listen on a distinct port for failover notifications.

5. Optionally, enable the `TTC_NoReconnectOnFailover` attribute to have TimesTen perform typical client failover, but without reconnecting. This is useful where an application does its own connection pooling or attempts to reconnect to the database on its own after failover. The default value is 1 and indicates that TimesTen should attempt to reconnect.

**Configuring TCP keep-alive parameters**

One of the ways that a client connection can fail is with a network failure, such as disconnecting a cable or a host that is hanging or crashing. When the client connection is lost, then client connection failover is initiated. However, when a TCP connection is started, you can configure the TCP keep-alive parameters for the connection to ensure reliable and rapid detection of connection failures.
You can control the per connection keep-alive settings with the following parameters:

- **TTC_TCP_KEEPALIVE_TIME_MS**: The duration time (in milliseconds) between the last data packet sent and the first probe. The default is 10000 milliseconds.

  **Note**: You can also detect that there is a problem with the connection by setting the **TTC_Timeout** attribute, which sets a maximum time limit for a network operation that is completed by using the TimesTen client and server. The **TTC_Timeout** attribute also determines the maximum number of seconds a TimesTen client application waits for the result from the corresponding TimesTen Server process before timing out.

  TimesTen recommends configuring the TCP keep-alive parameters for determining a failed TCP connection in addition to the **TTC_TIMEOUT** attribute, as some database operations may unexpectedly take longer than the value set for the **TTC_TIMEOUT** attribute.

  Refer to "TTC_Timeout" in *Oracle TimesTen In-Memory Database Reference* for more information about that attribute.

- **TTC_TCP_KEEPALIVE_INVL_MS**: The time interval (in milliseconds) between subsequential probes. The default is 10000 milliseconds.

- **TTC_TCP_KEEPALIVE_PROBES**: The number of unacknowledged probes to send before considering the connection as failed and notifying the client. The default is set to 2 unacknowledged probes.

  If you keep the default settings, then TimesTen sends the first probe after 10 seconds (the **TTC_TCP_KEEPALIVE_TIME_MS** setting).

  - If there is a response, then the connection is alive and the **TTC_TCP_KEEPALIVE_TIME_MS** timer is reset.

  - If there is no response, then TimesTen sends another probe after this initial probe at 10 second intervals (the **TTC_TCP_KEEPALIVE_INVL_MS** setting). If no response is received after 2 successive probes, then this connection is aborted and TimesTen redirects the connection to another data instance.

  For example, you could modify the TCP keep alive settings to have a shorter wait time for the initial probe of 50000 milliseconds, and to check for a connection every 20000 milliseconds for a maximum number of 3 times as follows:

  \[
  \begin{align*}
  &\text{TTC_TCP_KEEPALIVE_TIME_MS}=50000 \\
  &\text{TTC_TCP_KEEPALIVE_INVL_MS}=20000 \\
  &\text{TTC_TCP_KEEPALIVE_PROBES}=3
  \end{align*}
  \]

  See the "**TTC_TCP_KEEPALIVE_TIME_MS**, **TTC_TCP_KEEPALIVE_INVL_MS**, and **TTC_TCP_KEEPALIVE_PROBES**" sections in the *Oracle TimesTen In-Memory Database Reference* for more information on these connection attributes.
Running the TimesTen Server

The TimesTen Server is a child process of the TimesTen daemon. If you installed the TimesTen Server, this process is automatically started and stopped when the TimesTen daemon is started or stopped. You can explicitly start or shut down the daemon or service with the ttDaemonAdmin utility (use ttGridAdmin instanceExec to execute this command on TimesTen Scaleout). The TimesTen Server is run as the instance administrator.

The TimesTen Server handles requests from applications linked with the TimesTen Client driver.

The default ports for TimesTen daemon and TimesTen Servers are described in the "The ttInstanceCreate utility" chapter in the Oracle TimesTen In-Memory Database Installation, Migration, and Upgrade Guide. System administrators can change the port number during installation to avoid conflicts or for security reasons. The port range is from 1 - 65535. To connect to the TimesTen Server, Client DSNs are required to specify the port number as part of the logical server name definition or in the connection string.

For instructions on modifying TimesTen Server options, see "Modifying the TimesTen Server attributes" on page 4-7.

Server informational messages

The TimesTen Server records "connect," "disconnect" and various warning, error and informational entries in log files.

On Linux and UNIX, the TimesTen Server logs messages to the timesten_home/diag/ttmesg.log and timesten_home/diag/tterrors.log files by default. Optionally, you can configure TimesTen to log messages to the syslog facility.

See "Error, warning, and informational messages" on page 4-10.

Accessing a remote database on Linux and UNIX

In this example, the TimesTen Client application system is client.example.com. The client application is accessing the Server DSN database1 on the remote server system, server.example.com. The logical server name is LogicalServer. The instance name of the TimesTen installation is instance.

1. On the server system server.example.com, use the ttStatus utility to verify that the TimesTen Server is running and to verify the port number on which it is listening.

2. Verify that the Server DSN database1 exists in the system sys.odbc.ini file on server.example.com.

   There should be an entry in the sys.odbc.ini file as follows. Note that /disk1/timesten is the timesten_home.

   [database1]
   DataStore=/disk1/timesten/server/database1

3. Create a logical server name entry for the remote TimesTen Server in the ttconnect.ini file on client.example.com.

   [LogicalServer]
   Network_Address=server.example.com
   TCP_Port=6625
See "Creating and configuring Client DSNs on Linux and UNIX" on page 3-18 for information on the creating a ttconnect.ini file.

4. On the client system, client.example.com, create a Client DSN corresponding to the remote Server DSN, database1.

There should be an entry in the odbc.ini file as follows:

```
[database1CS]
TTC_Server=LogicalServer
TTC_Server_DSN=database1
```

See "Overview of user and system DSNs" on page 1-5 for information on the location of the proper odbc.ini file.

5. Run the client application from the system client.example.com using the Client DSN, database1CS. The example below uses the ttIsql program that is installed with TimesTen Client.

```
% ttIsqlCS -connStr "DSN=database1CS"
```

The next example describes how to access a TimesTen Server that is listening on a port numbered other than the default port number.

Let us consider the Network Address of the TimesTen Server is server.example.com and the Server is listening on Port 6625. The following methods can be used to connect to a Server DS:

1. Define the logical server name LogicalServer with server.example.com as the Network Address and 6625 as the Network Port. Define Client_DSN as the Client DSN with LogicalServer as the server name and Server_DSN as the Server DSN. Execute the command:

```
% ttIsqlCS -connStr "DSN=Client_DSN"
```

2. Alternatively, define the logical server name logical_server with server.example.com as the Network Address and the default port number as the Network Port. Define a Client DSN with LogicalServer as the server name and Server_DSN as the Server DSN. Overwrite the port number in the command:

```
% ttIsqlCS -connStr "DSN=Client_DSN;TCP_Port=6625"
```

3. Alternatively, define the server in the connection string. In this case you do not need to define a Client DSN, nor a logical server name.

```
% ttIsqlCS -connStr "TTC_Server=server.example.com;TTC_Server_DSN=Server_DSN;TCP_Port=6625"
```

Testing connections

Testing connections

To test client application connections to TimesTen databases:

1. Verify that the client system can access the server system.

2. Run ping from the client system to see if a response is received from the server system.

3. Verify that the TimesTen Server is running on the server system.

   - Use telnet to connect to the port on which the TimesTen Server is listening. For example:

```
% telnet server.example.com 6625
```
- If you successfully connect to the TimesTen Server, you see a message similar to:

```
Connected to server.example.com
```

- If the server system responds to a command, but TimesTen Server does not, the TimesTen Server may not be running. In the case of a failed connection, you see a message similar to:

```
telnet: Unable to connect to remote host: Connection refused
```

- Use the `ttStatus` utility on the server system to determine the status and port number of the TimesTen Server. Generally, the TimesTen Server is started at installation time. If the TimesTen Server is not running, you must start it. For information on starting the TimesTen Server, see "Modifying the TimesTen Server attributes" on page 4-7.

4. Verify that the client application can connect to the database. If you cannot establish a connection to the database, check that the `ttconnect.ini` file contains the correct information.

5. If the information in the `ttconnect.ini` file is correct, check that a Server DSN corresponding to the database has been defined properly in the system `sys.odbc.ini` file on the host where the database resides and where the TimesTen Server is running.
The TimesTen daemon starts when TimesTen is installed. The daemon runs in the background.

The TimesTen daemon performs the following functions:

- Starts the TimesTen Server
- Manages shared memory access
- Coordinates process recovery
- Keeps management statistics on what databases exist, which are in use, and which application processes are connected to which databases
- Manages RAM policy for TimesTen Classic
- If requested, starts replication processes and the cache agent.

Application developers do not interact with the daemon directly. No application code runs in the daemon and application developers do not generally have to be concerned with it. Application programs that access TimesTen databases communicate with the daemon transparently using TimesTen internal routines.

The following sections discuss interaction with the TimesTen daemon:

- **Starting and stopping the daemon**
- **Shutting down a TimesTen application**
- **Managing TimesTen daemon attributes**
- **Managing TimesTen Client/Server attributes**
- **Error, warning, and informational messages**

### Starting and stopping the daemon

You must be the instance administrator to start and stop the TimesTen daemon.

- **Installing the setuproot script**
- **Manually starting and stopping the daemon**

### Installing the setuproot script

Installing the TimesTen daemon startup scripts (the setuproot scripts) automatically starts the daemon whenever the operating system reboots.

Install the setuproot script as root.
In TimesTen Classic, the `setuproot` script is located in the `timesten_home/bin` directory:

```
% cd $TIMESTEN_HOME/bin
% setuproot -install
```

For TimesTen Scaleout, the directions on how to install the `setuproot` script are in the "Setting instances to automatically start at system startup" section in the *Oracle TimesTen In-Memory Database Scaleout User’s Guide*. Also, the daemon is automatically started for each data instance as part of the operations executed for the `ttGridAdmin dbOpen` or `ttGridAdmin modelApply` commands.

The root user can start the daemon by executing the daemon startup script. The following table shows the location of the daemon startup script by platform.

<table>
<thead>
<tr>
<th>Platform</th>
<th>Location of daemon startup script</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td><code>/etc/init.d/tt_instance_name</code></td>
</tr>
<tr>
<td>AIX</td>
<td><code>/etc/init.d/tt_instance_name</code></td>
</tr>
</tbody>
</table>

### Manually starting and stopping the daemon

- For TimesTen Classic, the instance administrator must manually start and stop the daemon, after each system reboot, unless the `setuproot` script has been executed. To manually start and stop the TimesTen main daemon, you can use the `ttDaemonAdmin` utility with the `-start` or `-stop` option.
- For TimesTen Scaleout, if you need to manually start the daemon for a data instance, you can execute the `ttDaemonAdmin` `-start` or `-stop` options within the `ttGridAdmin instanceExec` command.

For more information, see "`ttDaemonAdmin`" and "Execute a command or script on grid instances (instanceExec)" in the *Oracle TimesTen In-Memory Database Reference*.

### Shutting down a TimesTen application

You can shut down your TimesTen application using commands described in the following sections:

- Shutting down an application within TimesTen Classic
- Shutting down applications within TimesTen Scaleout

#### Shutting down an application within TimesTen Classic

A application within TimesTen Classic consists of a database that has been allocated shared memory, user connections, and possibly replication and cache agents for communication with other TimesTen or Oracle databases.

To close all active connections to the TimesTen Classic database, run the `ttAdmin -disconnect` command. For more information, see "Disconnecting from a database" on page 2-8 in this book and "ttAdmin" in the *Oracle TimesTen In-Memory Database Reference*.

If you want to unload the TimesTen Classic database, see "Unloading a database from memory for TimesTen Classic" on page 2-4 for full directions.
Shutting down applications within TimesTen Scaleout

With TimesTen Scaleout, you can perform the following to disconnect all TimesTen applications from the database:

- **Close the database to user connections.** The `ttGridAdmin dbClose` command disables new user connections to a database.
- **Disconnect all applications from the database.** The `ttGridAdmin dbDisconnect` command terminates all user connections to a database.
- **Unload the database from memory.** The `ttGridAdmin dbUnload` command unloads every element of the database from the memory of their respective hosts.

See "Unloading a database from memory" in the *Oracle TimesTen In-Memory Database Scaleout User’s Guide* for more information.

Managing TimesTen daemon attributes

The `timesten.conf` file contains TimesTen daemon attributes.

- In TimesTen Scaleout, you can import the values in the `timesten.conf` file by using the `ttGridAdmin instanceConfigImport` command. For more details, see "Import instance configuration attributes (instanceConfigImport)" in the *Oracle TimesTen In-Memory Database Reference*.
- In TimesTen Classic, you can create or change values for the `timesten.conf` file through connection attributes, through editing this file by hand, or with the `ttInstanceCreate` or `ttInstanceModify` utilities.

Use the `ttInstanceModify` utility to make changes to the `timesten.conf` file for most commonly changed attributes. If you cannot use `ttInstanceModify` to change a particular attribute and must modify the `timesten.conf` file directly, stop the TimesTen daemon before you change the file. Restart the TimesTen daemon after you have finished changing the file. To change TimesTen Server attributes, it is only necessary to stop the server. It is not necessary to stop the TimesTen daemon.

For more information about the `ttInstanceCreate` and `ttInstanceModify` utilities, see "ttInstanceCreate" and "ttInstanceModify" in the *Oracle TimesTen In-Memory Database Reference*.

For more information about the `timesten.conf` file, see "TimesTen Instance Configuration File" in the *Oracle TimesTen In-Memory Database Reference*.

On Linux and UNIX, the `timesten.conf` file is located in the daemon home directory:

```
timesten_home/conf
```

Some features that the `timesten.conf` file controls are:

- The network interfaces on which the daemon listens
- The minimum and maximum number of TimesTen subdaemons that can exist for the TimesTen instance
- Whether or not the TimesTen Server is started
- Whether or not you use shared memory segments for client/server inter-process communication
- The number of Server processes that are prespawned on your system
- The location and size of daemon log files and user log files
Managing TimesTen daemon attributes

- The duration of daemon logging to save for critical events
- Backward compatibility
- The maximum number of users for a TimesTen instance
- Data access across NFS mounted systems. This is for Linux only.
- The TNS_ADMIN value for an application using TimesTen Cache, OCI, Pro*C/C++, or ODP.NET. This option cannot be modified in this file.
- Modifying the default database recovery after a fatal error

The rest of this section includes the following topics:

- Determining the daemon listening address
- Managing subdaemons
- Configuring a range for shared memory keys

Determining the daemon listening address

By default, the TimesTen main daemon, all subdaemons and agents listen on a socket for requests, using any available address. All TimesTen utilities and agents use the loopback address to talk to the main daemon, and the main daemon uses the loopback address to talk to agents.

The `listen_addr` attribute in the `timesten.conf` file tells the TimesTen daemons to listen on the specific address indicated in the value supplied. The address specified with this option can be either a host name or a numerical IP address.

The `listen_addr` attribute exists for situations where a server has multiple network addresses and multiple network cards. In this case it is possible to limit the network addresses on which the TimesTen daemon is listening to a subset of the server's network addresses. This is done by making entries only for those addresses on which the daemon listens. These possibilities exist:

- Given a situation where a server has a "public" network address that is accessible both inside and outside the local network and a "private" address that is accessible only within the local network, adding a `listen_addr` attribute containing only the private address blocks all communications to TimesTen coming on the public address.
- By specifying only the local host, the TimesTen main daemon can be cut off from all communications coming from outside the server and communicate only with local clients and subdaemons.

There is no relationship between TimesTen replication and the `listen_addr` parameter and there is no requirement for enabling the `listen_addr` attribute when replication is enabled. If replication is going to be used in an environment where `listen_addr` is enabled, then the replication nodes need to know the allowable network addresses to use. However, if no `-listenaddr` attribute is enabled replication still works.

To explicitly specify the address on which the daemons should listen on a separate line in the `timesten.conf` file, enter:

```
listen_addr=address
```

For example, if you want to restrict the daemon to listen to just the loopback address, you say either:

```
listen_addr=127.0.0.1
```
or

```
listen_addr=localhost
```

This means that only processes on the local system can communicate with the daemon. Processes from other systems would be excluded, so you would not be able to replicate to or from other systems, or grant client access from other systems.

If you have multiple ethernet cards on different subnets, you can specify `listen_addr` entries to control which systems can connect to the daemon.

You can enter up to four addresses on which to listen by specifying the attribute and a value on up to four separate lines in the `timesten.conf` file. In addition to the addresses you specify, TimesTen always listens on the loopback address.

**Listening on IPv6**

By default, TimesTen uses the IPv4 protocol. To enable the daemon to listen on IPv6, you must enter on a separate line in the `timesten.conf` file:

```
enableIPv6=1
```

and

```
listen_6_addr=address
```

- You can specify an IPv6 address with the `listen_6_addr` attribute to enable IPv6.
- Specifying the `enableIPv6` attribute with one or more `listen_addr` or `listen_6_addr` attributes adds the IPv6 loopback interface to the list.
- If you specify the `enableIPv6` attribute without specifying any addresses with the `listen_addr` or `listen_6_addr` attributes, then the daemon listens on any IPv6 interface as well as any IPv4 interface.

The address specified with this option can be either a host name or a numerical IP address. See "Determining the daemon listening address" on page 4-4 for specifics on the `listen_addr` option.

If one or more `listen_addr` attributes are provided, the daemons listen on the specified IPv4 interfaces, with the IPv4 loopback address being added to the list if not specified. If only `enableIPv6` is specified, the daemons listen on both the IPv4 ANY interface and the IPv6 ANY interface.

You can specify both `listen_addr` and `listen_6_addr` attributes. If you specify one or more `listen_6_addr` attributes, the daemons listen on the specified IPv4 or IPv6 interfaces, with both the IPv4 and IPv6 loopback interfaces being added if not specified. If the name resolver returns multiple IPv4 and/or IPv6 addresses for a name, the daemons listen on all of the names.

**Managing subdaemons**

The main TimesTen daemon spawns subdaemons dynamically as they are needed. You can manually specify a range of subdaemons that the daemon may spawn, by specifying a minimum and maximum.

At any point in time, one subdaemon is potentially needed for TimesTen process recovery for each failed application process that is being recovered at that time.

By default, TimesTen spawns a minimum of 4 subdaemons and specifies the default maximum number of subdaemons at 50. However, you can change these settings by
assigning new values to the `min_subs` and `max_subs` attributes in the `timesten.conf` file.

**Configuring a range for shared memory keys**

You can configure a range for all shared memory keys used by TimesTen with the `shmkey_range` daemon attribute. You can constrain shared memory keys to a specific range to prevent shared memory collisions. However, if you use this option, it is your responsibility to ensure that no other shared memory segments use shared memory keys in the specified range.

---

**Note:** This option is only available on UNIX or Linux platforms. This option cannot be used for Windows platforms.

---

The syntax is as follows:

```
shmkey_range=low-high
```

For example:

```
shmkey_range=0x4000000-0x40FFFFFF
```

There can be no space in the `low-high` clause. The range is inclusive; thus, in the preceding example, both `0x40000000` and `0x40FFFFFF` are valid keys. In addition, the minimum range size is 16.

With this option, it is possible to run out of shared memory keys, especially if there are multiple invalidations or there are more TimesTen databases in use than originally anticipated.

If a user provides any of the following invalid values for the shared memory keys, then the TimesTen daemon aborts the startup process.

- Invalid numeric strings
- Only one number is specified for the range
- The first number is greater than the second number in the range specification
- The range size is less than 16.
- The range is specified incorrectly.

**Managing TimesTen Client/Server attributes**

This section includes the following topics:

- Modifying the TimesTen Server attributes
- Controlling the TimesTen Server
- Prespawning TimesTen Server processes in TimesTen Classic
- Specifying multiple connections to the TimesTen Server
- Using shared memory for Client/Server IPC
- Controlling the TimesTen Server log messages
Modifying the TimesTen Server attributes

The TimesTen Server is a child process of the TimesTen daemon that operates continually in the background. To modify the TimesTen Server attributes, you must do the following:

1. Stop the TimesTen Server.
2. Modify the attributes in the timesten.conf file as described in the following sections.
3. Restart the TimesTen Server.

Controlling the TimesTen Server

The server_port=portno attribute in the timesten.conf file tells the TimesTen daemon to start the TimesTen Server and what port to use. The portno is the port number on which the server listens.

Prespawning TimesTen Server processes in TimesTen Classic

Each TimesTen Client connection requires one server process. By default, a server process is spawned when a client requests a connection. In TimesTen Classic, you can prespawn a pool of reserve server processes by setting the server_pool attribute in the timesten.conf file on the server system. These server processes are immediately available for a client connection, which improves client/server connection performance.

The server_pool=number attribute in the timesten.conf file on the server system tells the TimesTen Server to create number processes. If this option is not specified, no processes are prespawned and kept in the reserve pool.

When a new connection is requested, if there are no items in the server pool, a new process is spawned, as long as you have not met the operating system limit.

If you request more process than allowed by your operating system, a warning is returned. Regardless of the number of processes requested, an error does not occur unless a client requests a connection when no more are available on the system, even if there are no processes remaining in the reserve pool.

Changes to the TimesTen Server take effect when the Server is restarted.

Specifying multiple connections to the TimesTen Server

By default, TimesTen creates only one connection to a Server for each child server process. You can set multiple connections to a single TimesTen Server, either by using the Server connection attributes (as described in “Defining Server DSNs for TimesTen Server on a Linux or UNIX system” on page 3-7 or the “TimesTen Server connection attributes” section in the Oracle TimesTen In-Memory Database Reference) or by setting the TimesTen daemon attributes described in this section.

Changes to TimesTen Server settings do not occur until the TimesTen Server is restarted. To restart the Server, use the following command:

% ttDaemonAdmin -restartserver

Note: In the case that you have set both the Server connection attributes and these daemon attributes, the value of the Server connection attributes takes precedence.
Managing TimesTen Client/Server attributes

Configuring the maximum number of client connections per child server process
To run a child server process in multithreaded mode so that a single server process can service multiple client connections to a database, add the following attribute to the timesten.conf file:

max_conns_per_server=NumberOfClientConnections

See "Defining Server DSNs for TimesTen Server on a Linux or UNIX system" on page 3-7 for more details.

Configuring connection distribution among child server processes
To specify the number of child server processes for a particular Server DSN that will use round-robin connection distribution (when max_conns_per_server >1), add the following attribute to the timesten.conf file:

servers_per_dsn=NumberOfChildServerProcesses

By default (value=1), the first max_conns_per_server client connection to a Server DSN is assigned to a single child server process, the next max_conns_per_server connection is assigned to a second child server process and so on. See "Defining Server DSNs for TimesTen Server on a Linux or UNIX system" on page 3-7 for a full description of how the servers_per_dsn and max_conns_per_server attributes relate to each other to control how connections are distributed over server processes.

Configuring the thread stack size of the child server processes
To set the size of the child server process thread stack for each client connection, add the following attribute to the timesten.conf file:

server_stack_size=ThreadStackSize

See "Defining Server DSNs for TimesTen Server on a Linux or UNIX system" on page 3-7 for more details.

---

**Note:** These changes to the TimesTen Server do not occur until the TimesTen daemon is restarted.

---

Using shared memory for Client/Server IPC

By default, TimesTen uses TCP/IP communication between applications linked with the TimesTen Client driver and the TimesTen Server.

Where the client application resides on the same system as the TimesTen Server, you can alternatively use shared memory for the inter-process communication (IPC), which can increase your performance. Before using shared memory as IPC verify that you have configured your system correctly.

See "Linux prerequisites" in the Oracle TimesTen In-Memory Database Installation, Migration, and Upgrade Guide.

The server_shmipc attribute in the timesten.conf file tells the TimesTen Server to accept a client connection that intends to use a shared memory segment for IPC.

If this attribute is missing, add this line to the timesten.conf file to start the TimesTen Server with shared memory IPC capability when the TimesTen daemon is restarted.

If the attribute exists, change the value of the server_shmipc attribute to 0 to not use shared memory IPC. The TimesTen Server is no longer started with shared memory IPC capability when the TimesTen daemon starts.
Managing the size of the shared memory segment

The `server_shmsize size` attribute in the `timesten.conf` file tells the TimesTen Server to create a shared memory segment of the specified size in MB.

If this attribute is missing, the TimesTen Server creates a shared memory segment of 64MB.

An appropriate value for the shared memory segment depends on:

- The expected number of concurrent client/server connections to all databases that belong to an instance of the TimesTen Server.
- The number of concurrent allocated statements within each such connection.
- The amount of data being transmitted for a query.

Some guidelines for determining the size of the shared memory segment include:

- The maximum size allowed is 1 gigabyte.
- TimesTen needs 1 MB of memory for internal use.
- Each connection needs a fixed block of 16 KB.
- Each statement starts with a block of 16 KB for the IPC. But this size is increased or decreased depending upon the size of the data being transmitted for a query. TimesTen increments the statement buffer size by doubling it and decreases it by halving it.

For example, if the user application anticipates a max of 100 simultaneous shared-memory-enabled client/server connections, and if each connection is anticipated to have a maximum of 50 statements, and the largest query returns 128 KB of data, use this formula to configure the `server_shmsize`:

$$server\_shmsize = 1 \text{ MB} + (100 \times 16) \text{ KB} + (100 \times 50 \times 128) \text{ KB} = 1 \text{ MB} + 2 \text{ MB} + 625 \text{ MB} = 628 \text{ MB}$$

This is the most memory required for this example. The entire memory segment would be used only if all 100 connections have 50 statements each and each statement has a query that returns 128 KB of data in a row of the result.

In this example, if you configured the `server_shmsize` to 128 MB, either a new shared-memory-enabled client/server connection is refused by the TimesTen Server or a query may fail due to lack of resources within the shared memory segment.

Changing the size of the shared memory segment

Once configured, to change the value of the shared memory segment you must stop the TimesTen Server. Stopping the server detaches all existing client/server connections to any database that is associated with that instance of the TimesTen Server. The steps for modifying the value of the `server_shmsize` attribute are:

1. Modify the value of `server_shmsize` in the `timesten.conf` file.
2. Use the `ttDaemonAdmin` utility to restart the TimesTen Server. Only the instance administrator can restart the TimesTen Server.
Controlling the TimesTen Server log messages

The noserverlog attribute in the timesten.conf file tells the TimesTen daemon to turn off logging of connects and disconnects from the client applications.

If the TimesTen Server is installed, you can enable or disable logging of connect and disconnect messages by:

- To enable logging, change the value of the noserverlog attribute to 1.
- To disable logging, change the value of the noserverlog attribute to 0.

Error, warning, and informational messages

As the daemon operates, it generates error, warning, and informational messages. These messages may be useful for TimesTen system administration and for debugging applications.

By default, TimesTen messages and diagnostic information are stored in:

- A user error log that contains error message information. Generally, these messages contain information on actions you may need to take. The default file is timesten_home/diag/tterrors.log.
- A daemon log file containing everything in the user error log plus information used by TimesTen Customer Support. The default file is timesten_home/diag/ttmesg.log.
- An invalidation file containing diagnostic information when TimesTen invalidates a database. This file provides useful troubleshooting information for TimesTen Customer Support. The invalidation file is created and named based on the value specified by the DataStore connection attribute. This connection attribute is not a file name. For example on Linux and UNIX systems, if the DataStore connection attribute is /home/ttuser/AdminData, the actual invalidation file name has a suffix, .inval, /home/ttuser/AdminData.inval. See “Critical event logging” on page 4-11 for more details on the invalidation file.
- Critical events log files contain a collection of daemon log entries at the moment of a critical event to assist when diagnosing critical failures. See “Critical event logging” on page 4-11 for more details.

You can specify the location and size of the daemon log files and user log files, as well as the number of files to keep stored on your system in the TimesTen instance configuration file (the timesten.conf file).

You can also specify the syslog facility used to log TimesTen daemon and subdaemon messages on Linux or UNIX. On a separate line of the timesten.conf file add:

facility=name

Possible name values are: auth, cron, daemon, local0-local7, lpr, mail, news, user, or uucp.

For more information, see "TimesTen Instance Configuration File" in the Oracle TimesTen In-Memory Database Reference.

The ttDaemonLog utility enables you to control the type of events that TimesTen writes to and fetches from the TimesTen user and error logs. You can also display all messages or selected categories of messages from the log to the standard output with this utility. For more information, see "ttDaemonLog" in the Oracle TimesTen In-Memory Database Reference.
Critical event logging

When critical events occur, TimesTen collects the daemon log entries at the moment of the critical event to assist when diagnosing critical failures. An example of critical events include database failure or a log-based catch up failure. Database invalidation occurs when TimesTen detects that the data in the database is corrupt and therefore unusable.

- TimesTen generates critical event files containing a snippet of the daemon log file that was collected at the moment of the critical event. Critical event log files are created and stored in the same directory as the daemon log files (specified by %supportlog configuration attribute in the %timesten.conf% file). Critical event log files are named with the format of ttmesg.log.ts_timestamp.gz where %timestamp% is the current time on the host.

- When a critical event occurs, TimesTen records in the daemon log file that critical event information was collected and the name of the critical event log file.

- If a database invalidation occurs, then TimesTen records in the .inval file that critical event information was collected at the time of the database invalidation and the name of the critical event log file. The .inval file is located in the same directory configured as the %DataStore% directory.

If more than one critical event occurs in quick succession, TimesTen collects only new information for each subsequent event in the next critical event log file.

You can configure the duration of the daemon log collection with the %daemon_log_snippet_interval_in_mins% configuration attribute in the %timesten.conf% file. As with all changes to the %timesten.conf% file, you must restart the main daemon for any change to take effect. See the "TimesTen Instance Configuration File" in the Oracle TimesTen In-Memory Database Reference for details on this configuration attribute.

Example 4–1  Example output in the daemon log when critical events occur

The occurrence of a critical event and the name of the critical event log file are noted in the daemon log file. The following example shows the message you would see in the daemon log file if two critical events occur in quick succession.

17:08:00.224 Err : : 12532: A critical event has happened. Saving last 600 seconds snippet of daemon log at /timesten/instance/diag/ttmesg.log.ts_1568160480.gz.
17:08:00.643 Err : : 12532: Read 543878 bytes from daemon log file and wrote into the daemon log snippet file located at /timesten/instance/diag/ttmesg.log.ts_1568160480.gz

17:11:12.657 Err : : 12532: Part of the daemon log snippet has already been recorded in a prior snippet file ending with timestamp 1568160480.gz
17:11:13.077 Err : : 12532: Read 2678582 bytes from daemon log file and wrote into the daemon log snippet file located at /timesten/instance/diag/ttmesg.log.ts_1568160672.gz

After which, you can evaluate the collected log records in the specified ttmesg.log.ts_timestamp.gz files.

Example 4–2  Example output in the .inval file for database invalidation

Any database invalidation event and the name of the critical event log file are noted in the .inval file. The following example shows the messages you could see in the .inval file if two critical events occur in quick succession.

After which, you can evaluate the collected log records in the specified ttmesg.log.ts__timestamp.gz files.
The following sections describe TimesTen globalization support features:

- Overview of globalization support features
- Choosing a database character set
- Length semantics and data storage
- Connection character set
- Linguistic sorts
- SQL string and character functions
- Setting globalization support attributes
- Globalization support during migration

### Overview of globalization support features

TimesTen globalization support includes the following features:

- Character set support
  
  You must choose a database character set when you create a database. See "Choosing a database character set" on page 5-2 in this book and the "Supported character sets" section in the Oracle TimesTen In-Memory Database Reference for all supported character sets. You can also choose a connection character set for a session. See "Connection character set" on page 5-4.

- Length semantics
  
  You can specify byte semantics or character semantics for defining the storage measurement of character data types. See "Length semantics and data storage" on page 5-3.

- Linguistic sorts and indexes
  
  You can sort data based on linguistic rules. See "Linguistic sorts" on page 5-4. You can use linguistic indexes to improve performance of linguistic sorts. See "Using linguistic indexes" on page 5-6.

- SQL string and character functions
  
  TimesTen provides SQL functions that return information about character strings. TimesTen also provides SQL functions that return a character from an encoded value. See "SQL string and character functions" on page 5-7.

---

**Note:** This release of TimesTen does not support session language and territory.
Choosing a database character set

TimesTen uses the database character set to define the encoding of data stored in character data types, such as CHAR and VARCHAR2.

Use the DatabaseCharacterSet data store attribute to specify the database character set during database creation. You cannot alter the database character set after database creation, and there is no default value for DatabaseCharacterSet. See “Supported character sets” in the Oracle TimesTen In-Memory Database Reference for a list of supported character sets.

Consider the following questions when you choose a character set for a database:

- What languages does the database need to support now and in the future?
- Is the character set available on the operating system?
- What character sets are used on clients?
- How well does the application handle the character set?
- What are the performance implications of the character set?

If you are using TimesTen Cache to cache Oracle database tables, or if you loading Oracle database data into a TimesTen table, you must create the database with the same database character set as the Oracle database.

This section includes the following topics:

- Character sets and languages
- Client operating system and application compatibility
- Performance and storage implications
- Character sets and replication

Character sets and languages

Choosing a database character set determines what languages can be represented in the database.

A group of characters, such as alphabetic characters, ideographs, symbols, punctuation marks, and control characters, can be encoded as a character set. An encoded character set assigns unique numeric codes to each character in the character repertoire. The numeric codes are called code points or encoded values.

Character sets can be single-byte or multibyte. Single-byte 7-bit encoding schemes can define up to 128 characters and normally support just one language. Single-byte 8-bit encoding schemes can define up to 256 characters and often support a group of related languages. Multibyte encoding schemes are needed to support ideographic scripts used in Asian languages like Chinese or Japanese because these languages use thousands of characters. These encoding schemes use either a fixed number or a variable number of bytes to represent each character. Unicode is a universal encoded character set that enables information from any language to be stored using a single character set. Unicode provides a unique code value for every character, regardless of the platform, program, or language.

Client operating system and application compatibility

The database character set is independent of the operating system. On an English operating system, you can create and run a database with a Japanese character set. However, when an application in the client operating system accesses the database, the
client operating system must be able to support the database character set with appropriate fonts and input methods. For example, you cannot insert or retrieve Japanese data on the English Windows operating system without first installing a Japanese font and input method. Another way to insert and retrieve Japanese data is to use a Japanese operating system remotely to access the database server.

If all client applications use the same character set, then that character set is usually the best choice for the database character set. When client applications use different character sets, the database character set should be a superset of all the application character sets. This ensures that every character is represented when converting from an application character set to the database character set.

Performance and storage implications

For best performance, choose a character set that avoids character set conversion and uses the most efficient encoding for the languages desired. Single-byte character sets result in better performance than multibyte character sets and are more efficient in terms of space requirements. However, single-byte character sets limit how many languages you can support.

Character sets and replication

All databases in a replication scheme must have the same database character set. No character set conversion occurs during replication.

Length semantics and data storage

In single-byte character sets, the number of bytes and the number of characters in a string are the same. In multibyte character sets, a character or code point consists of one or more bytes. Calculating the number of characters based on byte lengths can be difficult in a variable-width character set. Calculating column lengths in bytes is called byte semantics, while measuring column lengths in characters is called character semantics.

Character length and byte length semantics are supported to resolve potential ambiguity regarding column length and storage size. Multibyte encoding character sets are supported, such as UTF-8 or AL32UTF8. Multibyte encodings require varying amounts of storage per character depending on the character. For example, a UTF-8 character may require from 1 to 4 bytes. If, for example, a column is defined as CHAR (10), all 10 characters fit in this column regardless of character set encoding. However, for UTF-8 character set encoding, up to 40 bytes are required.

Character semantics is useful for defining the storage requirements for multibyte strings of varying widths. For example, in a Unicode database (AL32UTF8), suppose that you need to define a VARCHAR2 column that can store up to five Chinese characters together with five English characters. Using byte semantics, this column requires 15 bytes for the Chinese characters, where each are three bytes long, and 5 bytes for the English characters, where each are one byte long, for a total of 20 bytes. Using character semantics, the column requires 10 characters.

The expressions in the following list use byte semantics. Note the BYTE qualifier in the CHAR and VARCHAR2 expressions.

- **CHAR (5 BYTE)**
- **VARCHAR2 (20 BYTE)**
The expressions in the following list use character semantics. Note the **CHAR** qualifier in the **VARCHAR2** expression.

- **VARCHAR2(20 CHAR)**
- **SUBSTR(string, 1, 20)**

By default, the **CHAR** and **VARCHAR2** character data types are specified in bytes, not characters. Therefore, the specification **CHAR(20)** in a table definition allows 20 bytes for storing character data.

The **NCHAR** and **NVARCHAR2** character data types are encoded as UTF-16, which requires at least 2 bytes for each character. Thus, **NCHAR(20)** in a table definition allows 40 bytes for storing character data.

The **NLS_LENGTH_SEMANTICS** general connection attribute determines whether a new column of character data type uses byte or character semantics. It enables you to create **CHAR** and **VARCHAR2** columns using either byte-length or character-length semantics without having to add the explicit qualifier. **NCHAR** and **NVARCHAR2** columns are always character-based. Existing columns are not affected.

The default value for **NLS_LENGTH_SEMANTICS** is **BYTE**. Specifying the **BYTE** or **CHAR** qualifier in a data type expression overrides the **NLS_LENGTH_SEMANTICS** value.

### Connection character set

The database character set determines the encoding of **CHAR** and **VARCHAR2** character data types. The connection character set is used to describe the encoding of the incoming and outgoing application data, so that TimesTen can perform the necessary character set conversion between the application and the database. For example, a non-Unicode application can communicate with a Unicode (**AL32UTF8**) database.

The **ConnectionCharacterSet** general connection attribute sets the character encoding for the connection, which can be different than the database character set. The connection uses the connection character set for information that passes through the connection, such as parameters, SQL query text, results and error messages. Choose a connection character set that matches the application environment or the character set of your data source.

Best performance results when the connection character set and the database character set are the same because no conversion occurs. When the connection character set and the database character set are different, data conversion is performed in the ODBC layer. Characters that cannot be converted to the target character set are changed to replacement characters.

The default connection character set is **US7ASCII**. This setting applies to both direct and client connections.

### Linguistic sorts

Different languages have different sorting rules. Text is conventionally sorted inside a database according to the binary codes used to encode the characters. Typically, this does not produce a sort order that is linguistically meaningful. A linguistic sort handles the complex sorting requirements of different languages and cultures. It enables text in character data types, such as **CHAR**, **VARCHAR2**, **NCHAR**, and **NVARCHAR2**, to be sorted according to specific linguistic conventions.

A linguistic sort operates by replacing characters with numeric values that reflect each character's proper linguistic order. TimesTen offers two kinds of linguistic sorts: monolingual and multilingual.
This section includes the following topics:

- Monolingual linguistic sorts
- Multilingual linguistic sorts
- Case-insensitive and accent-insensitive linguistic sorts
- Performing a linguistic sort
- Using linguistic indexes

**Monolingual linguistic sorts**

TimesTen compares character strings in two steps for monolingual sorts. The first step compares the major value of the entire string from a table of major values. Usually, letters with the same appearance have the same major value. The second step compares the minor value from a table of minor values. The major and minor values are defined by TimesTen. TimesTen defines letters with accent and case differences as having the same major value but different minor values.

Monolingual linguistic sorting is available only for single-byte and Unicode database character sets. If a monolingual linguistic sort is specified when the database character set is non-Unicode multibyte, then the default sort order is the binary sort order of the database character set.

For a list of supported sorts, see "NLS_SORT" in the *Oracle TimesTen In-Memory Database Reference*.

**Multilingual linguistic sorts**

TimesTen provides multilingual linguistic sorts so that you can sort data for multiple languages in one sort. Multilingual linguistic sort is based on the ISO/OEC 14651 - International String Ordering and the Unicode Collation algorithm standards. This framework enables the database to handle languages that have complex sorting rules, such as those in Asian languages, as well as providing linguistic support for databases with multilingual data.

In addition, multilingual sorts can handle canonical equivalence and supplementary characters. Canonical equivalence is a basic equivalence between characters or sequences of characters. For example, ç is equivalent to the combination of c and ğ.

For example, TimesTen supports a monolingual French sort (FRENCH), but you can specify a multilingual French sort (FRENCH_M). _M represents the ISO 14651 standard for multilingual sorting. The sorting order is based on the GENERIC_M sorting order and can sort accents from right to left. TimesTen recommends using a multilingual linguistic sort if the tables contain multilingual data. If the tables contain only French, then a monolingual French sort may have better performance because it uses less memory. It uses less memory because fewer characters are defined in a monolingual French sort than in a multilingual French sort. There is a trade-off between the scope and the performance of a sort.

For a list of supported multilingual sorts, see "NLS_SORT" in the *Oracle TimesTen In-Memory Database Reference*.

**Case-insensitive and accent-insensitive linguistic sorts**

Operations inside a database are sensitive to the case and the accents of the characters. Sometimes you might need to perform case-insensitive or accent-insensitive comparisons.
To specify a case-insensitive or accent-insensitive sort:

- Append _CI to a TimesTen sort name for a case-insensitive sort. For example:
  BINARY_CI: accent-sensitive and case-insensitive binary sort
  GENERIC_M_CI: accent-sensitive and case-insensitive GENERIC_M sort
- Append _AI to a TimesTen sort name for an accent-insensitive and case-insensitive sort. For example:
  BINARY_AI: accent-insensitive and case-insensitive binary sort
  FRENCH_M_AI: accent-insensitive and case-insensitive FRENCH_M sort

### Performing a linguistic sort

The NLS_SORT data store connection attribute indicates which collating sequence to use for linguistic comparisons. The NLS_SORT value affects the SQL string comparison operators and the ORDER BY clause.

You can use the ALTER SESSION statement to change the value of NLS_SORT:

```
Command> ALTER SESSION SET NLS_SORT=SWEDISH;
Command> SELECT product_name FROM product ORDER BY product_name;
```

PRODUCT NAME
------------
aerial
Antenne
Lcd
ächzen
Ähre

You can also override the NLS_SORT setting by using the NLSSORT SQL function to perform a linguistic sort:

```
Command> SELECT * FROM test ORDER BY NLSSORT(name,'NLS_SORT=SPANISH');
```

**Note:** For materialized views and cache groups, TimesTen recommends that you explicitly specify the collating sequence using the NLSSORT() SQL function rather than using this attribute in the connection string or DSN definition.

For more details, see "NLS_SORT" in the Oracle TimesTen In-Memory Database Reference. For more extensive examples of using NLSSORT, see "NLSSORT" in the Oracle TimesTen In-Memory Database SQL Reference.

### Using linguistic indexes

You can create a linguistic index to achieve better performance during linguistic comparisons. A linguistic index requires storage for the sort key values.

To create a linguistic index, use a statement similar to the following:

```
Command> CREATE INDEX german_index ON employees
(NLSSORT(employee_id, 'NLS_SORT=GERMAN'));
```

The optimizer chooses the appropriate index based on the values for NLSSORT and NLS_SORT.
You must create multiple linguistic indexes if you want more than one linguistic sort on a column. For example, if you want both GERMAN and GERMAN_CI sorts against the same column, create two linguistic indexes.

For more information, see "CREATE INDEX" in the Oracle TimesTen In-Memory Database SQL Reference.

### SQL string and character functions

There are many SQL functions that operate on character strings, which are detailed in the following sections in the Oracle TimesTen In-Memory Database SQL Reference:

- "Character functions returning character values”.
- "Character functions returning number values”.
- "String functions”.
- "LOB functions”.
- "Conversion functions" (describing some functions that operate on character strings).
- "General comparison functions" (describing some functions that operate on character strings but not on LOB data types).

### Setting globalization support attributes

The globalization support attributes are summarized in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DatabaseCharacterSet</td>
<td>Indicates the character encoding used by a database.</td>
</tr>
<tr>
<td>ConnectionCharacterSet</td>
<td>Determines the character encoding for the connection, which may be different from the database character set.</td>
</tr>
<tr>
<td>NLS_SORT</td>
<td>Indicates the collating sequence to use for linguistic comparisons.</td>
</tr>
<tr>
<td>NLS_LENGTH_SEMANTICS</td>
<td>Sets the default length semantics.</td>
</tr>
<tr>
<td>NLS_NCHAR_CONV_EXCP</td>
<td>Determines whether an error is reported when there is data loss during an implicit or explicit data type conversion between NCHAR/NVARCHAR2 data and CHAR/VARCHAR2 data.</td>
</tr>
</tbody>
</table>

DatabaseCharacterSet must be set during database creation. There is no default. See "Choosing a database character set" on page 5-2.

The rest of the attributes are set during connection to a database. For more information about ConnectionCharacterSet, see "Connection character set” on page 5-4.

You can use the ALTER SESSION statement to change the following attributes during a session:

- NLS_SORT
- NLS_LENGTH_SEMANTICS
- NLS_NCHAR_CONV_EXCP

For more information, see "ALTER SESSION" in the Oracle TimesTen In-Memory Database SQL Reference and "Connection Attributes" in the Oracle TimesTen In-Memory Database Reference.
Globalization support during migration

Globalization support may cause issues during migration. For complete details, see "Backup, Restore, and Migrate Data in TimesTen Classic" in the Oracle TimesTen In-Memory Database Installation, Migration, and Upgrade Guide and the description of "ttMigrate" in the Oracle TimesTen In-Memory Database Reference.
Using the ttIsql Utility

The TimesTen ttIsql utility is a general tool for working with a TimesTen data source. The ttIsql command line interface is used to issue SQL statements and built-in ttIsql commands to perform various operations. Some common tasks that are typically accomplished using ttIsql include:

- Database setup and maintenance. Creating tables and indexes, altering existing tables and updating table statistics can be performed quickly and easily using ttIsql.

- Retrieval of information on database structures. The definitions for tables, indexes and cache groups can be retrieved using built-in ttIsql commands. In addition, the current size and state of the database can be displayed.

- Optimizing database operations. The ttIsql utility can be used to alter and display query optimizer plans for the purpose of tuning SQL operations. The time required to execute various ODBC function calls can also be displayed.

The following sections describe how the ttIsql utility is used to perform these types of tasks:

- Batch mode vs. interactive mode
- Defining default settings with the TTISQL environment variable
- Customizing the ttIsql command prompt
- Using the ttIsql online help
- Using the ttIsql 'editline' feature for Linux and UNIX only
- Using the ttIsql command history
- Using the ttIsql edit command
- Working with character sets
- Displaying database structure information
- Listing database objects by object type
- Viewing and setting connection attributes
- Working with transactions
- Working with prepared and parameterized SQL statements
- Using, declaring, and setting variables
- Creating and executing PL/SQL blocks
- Passing data from PL/SQL using OUT parameters
Batch mode vs. interactive mode

The ttIsql utility can be used in two distinctly different ways: batch mode or interactive mode. When ttIsql is used in interactive mode, users type commands directly into ttIsql from the console. When ttIsql is used in batch mode, a prepared script of ttIsql commands is executed by specifying the name of the file containing the commands.

Batch mode is commonly used for the following types of tasks:

- Performing periodic maintenance operations including the updating of table statistics, compacting the database and purging log files.
- Initializing a database by creating tables, indexes and cache groups and then populating the tables with data.
- Generating simple reports by executing common queries.

Interactive mode is suited for the following types of tasks:

- Experimenting with TimesTen features, testing design alternatives and improving query performance.
- Solving database problems by examining database statistics.
- Any other database tasks that are not performed routinely.

By default, when starting ttIsql from the shell, ttIsql is in interactive mode. The ttIsql utility prompts you to type in a valid ttIsql built-in command or SQL statement by printing the Command> prompt. The following example starts ttIsql in interactive mode and then connects to a TimesTen database by executing the connect command with the MY_DSN DSN.

C:\>ttIsql

Copyright (c) 1996, 2020 Oracle. All rights reserved.
Type ? or "help" for help, type 'exit' to quit ttIsql.

Command> connect MY_DSN;
Connection successful: DSN=MY_DSN;DataStore=/disk1/databases/MY_DSN;
DRIVER=E:\WINNT\System32\TTdv181.dll;
(Default setting AutoCommit=1)

Command>

When connecting to the database using ttIsql, you can also specify the DSN or connection string on the ttIsql command line. The connect command is implicitly executed.

C:\>ttIsql -connstr 'DSN=MY_DSN'
Defining default settings with the TTISQL environment variable

The ttIsql utility can be customized to automatically execute a set of command line options every time a ttIsql session is started from the command prompt. This is accomplished by setting an environment variable called TTISQL to the value of the ttIsql command line that you prefer. A summary of ttIsql command line options is shown below. For a complete description of the ttIsql command line options, see the "ttIsql" section in the Oracle TimesTen In-Memory Database Reference.

Usage: ttIsql [-h | -help | -helpcmds | -helpfull | -V]

Defining default settings with the TTISQL environment variable

Batch mode can be accessed in two different ways. The most common way is to specify the -f option on the ttIsql command line followed by the name of file to run.

For example, executing a file containing a CREATE TABLE statement looks like the following:

```
C:\>ttIsql -f create.sql -connstr "DSN=MY_DSN"
```

```
CONNECT SUCCESSFUL: DSN=MY_DSN;DataStore=/disk1/databases/MY_DSN;DRIVER=E:\WINNT\System32\TTdv181.dll;
(Default setting AutoCommit=1)
```

```
run 'create.sql'
```

```
CREATE TABLE LOOKUP (KEY NUMBER NOT NULL PRIMARY KEY, VALUE CHAR (64))
```

```
exit;
Disconnecting...
Done.
```

C:\>

The other way to use batch mode is to enter the run command directly from the interactive command prompt. The run command is followed by the name of the file containing ttIsql built-in commands and SQL statements to execute:

```
Command> run 'create.sql';
```

```
CREATE TABLE LOOKUP (KEY NUMBER NOT NULL PRIMARY KEY, VALUE CHAR (64))
Command>
```
Customizing the ttIsql command prompt

The TTISQL environment variable has the same syntax requirements as the ttIsql command line. When ttIsql starts up it reads the value of the TTISQL environment variable and applies all options specified by the variable to the current ttIsql session. If a particular command line option is specified in both the TTISQL environment variable and the command line, then the command line version always takes precedence.

The procedure for setting the value of an environment variable differs based on the platform and shell that ttIsql is started from. As an example, setting the TTISQL environment variable on Windows could look like this:

```
C:\>set TTISQL=-connStr "DSN=MY_DSN" -e "autocommit 0;dssize;"
```

In this example, ttIsql automatically connects to a DSN called MY_DSN, turns off autocommit, and displays the size of the database, as shown below:

```
C:\>ttIsql

Copyright (c) 1996, 2020 Oracle. All rights reserved.
Type ? or "help" for help, type 'exit' to quit ttIsql.

Command> connect "DSN=MY_DSN";

Connection successful: DSN=MY_DSN;DataStore=/disk1/databases/MY_DSN; DRIVER=E:\WINNT\System32\TTdv181.dll;
(Default setting AutoCommit=1)
Command> autocommit 0;
Command> dssize;
The following values are in KB:

PERM_ALLOCATED_SIZE: 40960
PERM_IN_USE_SIZE: 9453
PERM_IN_USE_HIGH_WATER: 9453
TEMP_ALLOCATED_SIZE: 32768
TEMP_IN_USE_SIZE: 9442
TEMP_IN_USE_HIGH_WATER: 9885
```

**Customizing the ttIsql command prompt**

You can customize the ttIsql command prompt by using the set command with the prompt attribute:

```
Command> set prompt MY_DSN;
MY_DSN
```

You can specify a string format (%c) that returns the name of the current connection:

```
Command> set prompt %c;
con1
```

If you want to embed spaces, you must quote the string:

```
Command> set prompt 'MY_DSN %c> '; MY_DSN con1>
```
Using the ttIsql online help

The ttIsql utility has an online version of command syntax definitions and descriptions for all built-in ttIsql commands. To access this online help from within ttIsql use the help command. To view a detailed description of any built-in ttIsql commands type the help command followed by one or more ttIsql commands to display help for. The example below displays the online description for the connect and disconnect commands.

Command> help connect disconnect
Arguments in <> are required.
Arguments in [] are optional.

Command Usage: connect [DSN|connection_string] [as <connection_id>]
Command Aliases: (none)
Description: Connects to the data source specified by the optional DSN or connection string argument. If an argument is not given, then the DSN or connection string from the last successful connection is used. A connection ID may optionally be specified, for use in referring to the connection when multiple connections are enabled. The DSN is used as the default connection ID. If that ID is already in use, the connection will be assigned the ID "conN", where N is some number larger than 0.
Requires an active connection: NO
Requires autocommit turned off: NO
Reports elapsed execution time: YES
Works only with a TimesTen data source: NO
Example: connect; -or- connect RunData; -or- connect "DSN=RunData";
- or- connect RunData as rundata1;

Command Usage: disconnect [all]
Command Aliases: (none)
Description: Disconnects from the currently connected data source or all connections when the "all" argument is included. If a transaction is active when disconnecting then the transaction will be rolled back automatically. If a connection exists when executing the "bye", "quit" or "exit" commands then the 'disconnect' command will be executed automatically.
Requires an active connection: NO
Requires autocommit turned off: NO
Reports elapsed execution time: YES
Works only with a TimesTen data source: NO
Example: disconnect;

To view a short description of all ttIsql built-in commands type the help command without an argument. To view a detailed description of all built-in ttIsql commands type the help command followed by the all argument.

To view the list of attributes that can be set or shown by using ttIsql, enter:

Command> help attributes

Using the ttIsql 'editline' feature for Linux and UNIX only

On Linux and UNIX systems, you can use the 'editline' library to set up emacs (default) or vi bindings that enable you to scroll through previous ttIsql commands, as well as edit and resubmit them. This feature is not available or needed on Windows.

To disable the 'editline' feature in ttIsql, use the ttIsql command set editline off.

The set up and keystroke information is described for each type of editor:
- **Emacs binding**
- **vi binding**

**Emacs binding**

To use the emacs binding, create a file `~/.editrc` and put "bind" on the last line of the file, run `ttIsql`. The editline lib prints the current bindings.

The keystrokes when using `ttIsql` with the emacs binding are:

<table>
<thead>
<tr>
<th>Keystroke</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Left-Arrow&gt;</td>
<td>Move the insertion point left. Back up.</td>
</tr>
<tr>
<td>&lt;Right-Arrow&gt;</td>
<td>Move the insertion point right. Move forward.</td>
</tr>
<tr>
<td>&lt;Up-Arrow&gt;</td>
<td>Scroll to the command prior to the one being displayed. Places the cursor at the end of the line.</td>
</tr>
<tr>
<td>&lt;Down-Arrow&gt;</td>
<td>Scroll to a more recent command history item and put the cursor at the end of the line.</td>
</tr>
<tr>
<td>&lt;Ctrl-A&gt;</td>
<td>Move the insertion point to the beginning of the line.</td>
</tr>
<tr>
<td>&lt;Ctrl-E&gt;</td>
<td>Move the insertion point to the end of the line.</td>
</tr>
<tr>
<td>&lt;Ctrl-K&gt;</td>
<td>&quot;Kill&quot; (Save and erase) the characters on the command line from the current position to the end of the line.</td>
</tr>
<tr>
<td>&lt;Ctrl-Y&gt;</td>
<td>&quot;Yank&quot; (Restore) the characters previously saved and insert them at the current insertion point.</td>
</tr>
<tr>
<td>&lt;Ctrl-F&gt;</td>
<td>Forward char - move forward 1 (see Right Arrow).</td>
</tr>
<tr>
<td>&lt;Ctrl-B&gt;</td>
<td>Backward char - move back 1 (see Left Arrow).</td>
</tr>
<tr>
<td>&lt;Ctrl-P&gt;</td>
<td>Previous History (see Up Arrow).</td>
</tr>
<tr>
<td>&lt;Ctrl-N&gt;</td>
<td>Next History (see up Down Arrow).</td>
</tr>
</tbody>
</table>

**vi binding**

To use the vi bindings, create a file `${HOME}/.editrc` and put "bind-v" in the file, run `ttIsql`. To get the current settings, create a file `${HOME}/.editrc` and put "bind" on the last line of the file. When you execute `ttIsql`, the editline lib prints the current bindings.

The keystrokes when using `ttIsql` with the vi binding are:

<table>
<thead>
<tr>
<th>Keystroke</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Left-Arrow&gt;, h</td>
<td>Move the insertion point left (back up).</td>
</tr>
<tr>
<td>&lt;Right-Arrow&gt;, l</td>
<td>Move the insertion point right (forward).</td>
</tr>
<tr>
<td>&lt;Up-Arrow&gt;, k</td>
<td>Scroll to the prior command in the history and put the cursor at the end of the line.</td>
</tr>
<tr>
<td>&lt;Down-Arrow&gt;, j</td>
<td>Scroll to the next command in the history and put the cursor at the end of the line.</td>
</tr>
<tr>
<td>ESC</td>
<td>Vi Command mode.</td>
</tr>
<tr>
<td>0, $</td>
<td>Move the insertion point to the beginning of the line, Move to end of the line.</td>
</tr>
<tr>
<td>i, I</td>
<td>Insert mode, Insert mode at beginning of the line.</td>
</tr>
</tbody>
</table>
Using the ttIsq1 command history

The ttIsq1 utility stores a list of the last 100 commands executed within the current ttIsq1 session. The commands in this list can be viewed or executed again without having to type the entire command over. Both SQL statements and built-in ttIsq1 commands are stored in the history list. Use the history command (“h”) to view the list of previously executed commands. For example:

Command> h;
8 INSERT INTO T3 VALUES (3)
9 INSERT INTO T1 VALUES (4)
10 INSERT INTO T2 VALUES (5)
11 INSERT INTO T3 VALUES (6)
12 autocommit 0
13 showplan
14 SELECT * FROM T1, t2, t3 WHERE A=B AND B=C AND A=B
15 trytbllocks 0
16 tryserial 0
17 SELECT * FROM T1, t2, t3 WHERE A=B AND B=C AND A=B
Command>

The history command displays the last 10 SQL statements or ttIsq1 built-in commands executed. To display more than that last 10 commands specify the maximum number to display as an argument to the history command.

Each entry in the history list is identified by a unique number. The ! character followed by the number of the command can be used to execute the command again. For example:

Command> ! 12;
autocommit 0
Command>

To execute the last command again simply type a sequence of two ! characters:

Command> !!;
autocommit 0
Command>

To execute the last command that begins with a given string type the ! character followed by the first few letters of the command. For example:

Command> ! auto;

Keystroke | Action
--- | ---
a, A | Add (“Insert after”) mode, Append at end of line
R | Replace mode.
C | Change to end of line.
B | Move to previous word.
e | Move to end of word.
<Ctrl-P> | Previous History (see Up Arrow).
<Ctrl-N> | Next History (see up Down Arrow).

Keystroke Action
--- | ---
a, A | Add (“Insert after”) mode, Append at end of line
R | Replace mode.
C | Change to end of line.
B | Move to previous word.
e | Move to end of word.
<Ctrl-P> | Previous History (see Up Arrow).
<Ctrl-N> | Next History (see up Down Arrow).
Using the ttIsql edit command

autocommit 0
Command>

**Saving and clearing the ttIsql command history**

You can save the list of commands that ttIsql stores by using the `savehistory` command:

```
Command> savehistory history.txt;
```

If the output file already exists, use the `-a` option to append the new command history to the file or the `-f` option to overwrite the file. The next example shows how to append new command history to an existing file.

```
Command> savehistory -a history.txt;
```

You can clear the list of commands that ttIsql stores by using the `clearhistory` command:

```
Command> clearhistory;
```

**Using the ttIsql edit command**

You can use the `ttIsql edit` command to edit a file or edit ttIsql commands in a text editor. The `ttIsql edit` command starts a text editor such as `emacs`, `gedit`, or `vi`. For more information on changing the default text editor, see "Changing the default text editor for the ttIsql edit command" on page 6-9.

The syntax for the `ttIsql edit` command is as follows:

```
Command> edit [ file | !history_search_command ]
```

You can only use one parameter at a time. The `history_search_command` parameter is defined as the `!` character followed by the number of the command or a search string. If you do not specify a `!` character, the `ttIsql edit` command interprets the parameter as `file`. `file` is the name of the file that you want to edit. If you do not specify a parameter or specify `!!`, the last `ttIsql` command is edited.

When you specify a `file` parameter, the editor edits the specified file. If TimesTen does not find an exact file match for the specified `file` parameter in the current working directory, it searches for `file.sql`. If neither file exists, the editor creates the specified file in the current working directory. You can specify a path in the `file` parameter.

The following example edits the `new.sql` file:

```
Command> edit new.sql;
```

The following example edits the `new.sql` file in the `/scripts` directory:

```
Command> edit /scripts/new.sql;
```

If you execute the `ttIsql edit` command with a `file` parameter, ttIsql does not execute the contents of the file after you exit the editor.

You can edit a SQL statement that is stored in the history list of the current `ttIsql` session. When calling the `ttIsql edit` command specify the `!` character followed by the number of the command or a search string. The editor opens the `ttIsql` command in a temporary file that you can save in a preferred location. For more information on using the `ttIsql history` command, see "Using the ttIsql command history" on page 6-7.
The following example edits ttSql command 2:
Command> edit !2;

The following example searches for and edits the last ttSql command that contains
the search string create:
Command> edit !create;

The following example executes a CREATE TABLE statement and then uses the edit
command to edit the CREATE TABLE statement in a text editor:
Command> CREATE TABLE t1
(c1 VARCHAR(10) NOT INLINE NOT NULL, c2 VARCHAR(144) INLINE NOT NULL);
Command> edit;

The prior example is equivalent to using the ttSql edit command with the !!
parameter:
Command> CREATE TABLE t1
(c1 VARCHAR(10) NOT INLINE NOT NULL, c2 VARCHAR(144) INLINE NOT NULL);
Command> edit !!;

If you execute the ttSql edit command with a history_search_command parameter,
ttSql executes the contents of the file after you exit the editor. The contents of the file
are executed as a single ttSql command. If you do not want to execute the contents
of the file, delete the contents of the file and save the file before you exit the editor.

Changing the default text editor for the ttSql edit command
You can specify the default editor by defining the ttSql _EDITOR define alias. The
following example sets the default editor to vi:
Command> DEFINE _EDITOR=vi

If you do not define the _EDITOR define alias, ttSql uses the editor specified by the
VISUAL environment variable. If the _EDITOR define alias and the VISUAL environment
variables are not set, ttSql uses the editor specified by the EDITOR environment
variable. When _EDITOR, VISUAL, and EDITOR are not set, vi is used for Linux and
UNIX and notepad.exe is used for Windows.

Working with character sets
The ttSql utility supports the character sets listed in "Supported character sets" in
the Oracle TimesTen In-Memory Database Reference. The ability of ttSql to display
characters depends on the native operating system locale settings of the terminal on
which you are using ttSql.

To override the locale-based output format, use the ncharencoding option or the -N
option. The valid values for these options are LOCALE (the default) and ASCII. If you
choose ASCII and ttSql encounters a Unicode character, it displays it in escaped
format.

You do not need to have an active connection to change the output method.

Displaying database structure information
There are several ttSql commands that display information on database structures.
The most useful commands are summarized below:
■ describe - Displays information on database objects.
■ cachegroups - Displays the attributes of cache groups.
■ dssize - Reports the current sizes of the permanent and temporary database memory regions.
■ tablesiz - Displays the size of tables that have been analyzed with the ttComputeTabSizes tool.
■ monitor - Displays a summary of the current state of the database.

Using the ttIsql describe command

Use the describe command to display information on individual database objects. Displays parameters for prepared SQL statements and built-in procedures. The argument to the describe command can be the name of a table, cache group, view, materialized view, sequence, synonym, a built-in procedure, a SQL statement or a command ID for a previously prepared SQL statement, a PL/SQL function, PL/SQL procedure or PL/SQL package.

The describe command requires a semicolon character to terminate the command.

Command> CREATE TABLE t1 (KEY NUMBER NOT NULL PRIMARY KEY, VALUE CHAR (64));
Command> describe t1;

Table USER.T1:
Columns:
  *KEY                            NUMBER NOT NULL
  VALUE                          CHAR (64)
1 table found.

(primary key columns are indicated with *)
Command> describe SELECT * FROM T1 WHERE KEY=?;

Prepared Statement:
Parameters:
  Parameter 1                    NUMBER
Columns:
  KEY NUMBER                     NOT NULL
  VALUE                          CHAR (64)
Command> describe ttOptUseIndex;

Procedure TTOPTUSEINDEX:
Parameters:
  Parameter INDOPTION            VARCHAR (1024)
Columns:
  (none)
1 procedure found.
Command>

Using the ttIsql cachegroups command

The cachegroups command is used to provide detailed information on cache groups defined in the current database. The attributes of the root and child tables defined in the cache group are displayed in addition to the WHERE clauses associated with the cache group. The argument to the cachegroups command is the name of the cache group that you want to display information for.

Command> cachegroups;
Cache Group CACHEUSER.READCACHE:
- Cache Group Type: Read Only
- Autorefresh: Yes
- Autorefresh Mode: Incremental
- Autorefresh State: Paused
- Autorefresh Interval: 5 Seconds
- Autorefresh Status: ok
- Aging: No aging defined
- Root Table: ORATT.READTAB
- Table Type: Read Only

Cache Group CACHEUSER.WRITECACHE:
- Cache Group Type: Asynchronous Writethrough (Dynamic)
- Autorefresh: No
- Aging: LRU on
- Root Table: ORATT.WRITETAB
- Table Type: Propagate

2 cache groups found.

Using the ttIsql dssize command

The dssize command is used to report the current memory status of the permanent and temporary memory regions as well as the maximum, allocated and in-use sizes for the database. However, for TimesTen Scaleout, the dssize command only reports on the current memory status for the current element.

The dssize command reports the same information that is displayed in the SYS.V$MONITOR and SYS.GV$MONITOR system views.

The following example uses the k option to print the database size information in KB:

Command> dssize k;
The following values are in KB:

- PERM_ALLOCATED_SIZE: 40960
- PERM_IN_USE_SIZE: 9742
- PERM_IN_USE_HIGH_WATER: 9742
- TEMP_ALLOCATED_SIZE: 32768
- TEMP_IN_USE_SIZE: 9442
- TEMP_IN_USE_HIGH_WATER: 9505

For more information on the dssize command, see "ttIsql" in the Oracle TimesTen In-Memory Database Reference.

Using the ttIsql tablesize command

The tablesize command displays the detailed analysis of the amount of space used by a table. Once you call the ttComputeTabSizes built-in procedure, which analyzes the table size of the indicated tables, the tablesize command displays the total size data for all analyzed tables.

Executing the tablesize command with no arguments displays available sizing information for all tables that have had the ttComputeTabSizes computation run. When you provide a table as an argument, tablesize displays available sizing only for the indicated table.

Note: For more details, see "ttComputeTabSizes" in the Oracle TimesTen In-Memory Database Reference.
The syntax for `tablesize` is as follows:

```
tablesize [owner_name_pattern.]table_name_pattern]
```

The following example invokes the `ttComputeTabSizes` built-in procedure to calculate the table size of the `employees` table. Then, the `tablesize` command displays the sizing information gathered for the `employees` table.

```
Command> call ttComputeTabSizes('employees');
Command> tablesize employees;
```

Sizes of USER1.EMPLOYEES:

- **INLINE_ALLOC_BYTES**: 60432
- **NUM_USED_ROWS**: 107
- **NUM_FREE_ROWS**: 149
- **AVG_ROW_LEN**: 236
- **OUT_OF_LINE_BYTES**: 0
- **METADATA_BYTES**: 1304
- **TOTAL_BYTES**: 61736

1 table found.

These values provide insights into overhead and how the total space is used for the table.

For example:

- The **NUM_FREE_ROWS** value describes the number of rows allocated for the table, but not currently in use. Space occupied by free rows cannot be used by the system for storing other system objects or structures.
- Use the **TOTAL_BYTES** value to calculate how much permanent space your table occupies.
- The **LAST_UPDATED** is the time of the last size computation. If you want a more recent computation, re-execute `ttComputeTabSizes` and display the new output.

You can find a description for each calculated value in the "SYS.ALL_TAB_SIZES" section in the *Oracle TimesTen In-Memory Database System Tables and Views Reference*.

### Using the `tlsq1` `monitor` command

The `monitor` command displays all of the information provided by the `dssize` command plus additional statistics on the number of connections, checkpoints, lock timeouts, commits, rollback operations and other information collected since the last time the database was loaded into memory.

```
Command> monitor;
TIME_OF_1ST_CONNECT: Wed Apr 20 10:34:17 2011
DS_CONNECTS: 11
DS_DISCONNECTS: 0
DS_CHECKPOINTS: 0
DS_CHECKPOINTS_FUZZY: 0
DS_COMPACTS: 0
PERM_ALLOCATED_SIZE: 40960
PERM_IN_USE_SIZE: 5174
PERM_IN_USE_HIGH_WATER: 5174
TEMP_ALLOCATED_SIZE: 18432
TEMP_IN_USE_SIZE: 4527
TEMP_IN_USE_HIGH_WATER: 4527
```
You can use ttIsql to list tables, indexes, views, sequences, synonyms, PL/SQL functions, procedures and packages in a database. Commands prefixed by all display all of this type of object. For example, the functions command lists PL/SQL functions that are owned by the user, whereas allfunctions lists all PL/SQL functions.

You can optionally specify patterns for object owners and object names.

Use these commands to list database objects:
Listing database objects by object type

- **tables and alltables** - Lists tables.
- **indexes and allindexes** - Lists indexes.
- **views and allviews** - Lists views.
- **sequences and allsequences** - Lists sequences.
- **synonyms and allsynonyms** - Lists synonyms.
- **functions and allfunctions** - Lists PL/SQL functions.
- **procedures and allprocedures** - Lists PL/SQL procedures.
- **packages and allpackages** - Lists PL/SQL packages.

**Note:** For details on each of these commands, see the "ttIsqI" section in the *Oracle TimesTen In-Memory Database Reference*.

The following example demonstrates the **procedures and allprocedures** commands. User **TERRY** creates a procedure called **proc1** while connected to **myDSN**. Note that a slash character (/) is entered on a new line following the PL/SQL statements.

The **procedures command** and the **allprocedures command** show that it is the only PL/SQL procedure in the database.

```sql
% ttIsqI myDSN
Copyright (c) 1996, 2020 Oracle. All rights reserved.
Type ? or "help" for help, type 'exit' to quit ttIsqI.
connect "DSN=myDSN";
Connection successful:
DSN=myDSN;UID=terry;DataStore=/disk1/databases/myDSN;DatabaseCharacterSet=AL32UTF8;
ConnectionCharacterSet=US7ASCII;PermSize=128;
(Default setting AutoCommit=1)
Command> create or replace procedure proc1 as begin null; end;
> /
Procedure created.
Command> procedures;
 TERRY.PROC1
1 procedure found.
Command> allprocedures;
 TERRY.PROC1
1 procedure found.
```

Now connect to the same DSN as **Pat** and create a procedure called **q**. The **allprocedures command** shows the PL/SQL procedures created by **Terry** and **Pat**.

```sql
% ttIsqI "dsn=myDSN;uid=PAT"
Copyright (c) 1996, 2020 Oracle. All rights reserved.
Type ? or "help" for help, type 'exit' to quit ttIsqI.
connect "dsn=myDSN;uid=PAT";
Connection successful: DSN=myDSN;UID=PAT;
DataStore=/disk1/databases/myDSN;DatabaseCharacterSet=AL32UTF8;
ConnectionCharacterSet=US7ASCII;PermSize=128;
(Default setting AutoCommit=1)
Command> create or replace procedure q as begin null; end;
> /
Procedure created.
Command> procedures;
 PAT.Q
1 procedure found.
```
Command> allprocedures;
        TERRY.PROC1
        PAT.Q
    2 procedures found.

Viewing and setting connection attributes

You can view and set connection attributes with the ttiSqi show and set commands. For a list of the attributes that you can view and set with ttiSqi, see "Connection Attributes" in Oracle TimesTen In-Memory Database Reference.

To view the setting for the Passthrough attribute, enter:

Command> show passthrough;
PassThrough = 0

To change the Passthrough setting, enter:

Command> set passthrough 1;

Working with transactions

The ttiSqi utility has several built-in commands for managing transactions. These commands are summarized below:

- **autocommit** - Turns on or off the autocommit feature. This can also be set as an attribute of the set command.
- **commit** - Commits the current transaction.
- **commitdurable** - Commits the current transaction and ensures that the committed work is recovered in case of database failure.
- **rollback** - Rolls back the current transaction.
- **isolation** - Changes the transaction isolation level. This can also be set as an attribute of the set command.
- **sqlquerytimeout** - Specifies the number of seconds to wait for a SQL statement to execute before returning to the application. This can also be set as an attribute of the set command.

When starting ttiSqi, the autocommit feature is turned on by default, even within a SQL script. In this mode, every SQL operation against the database is committed automatically.

To turn the autocommit feature off, execute the ttiSqi autocommit command with an argument of 0. When autocommit is turned off, transactions must be committed or rolled back manually by executing the ttiSqi commit, commitdurable or rollback commands. The commitdurable command ensures that the transaction's effect is preserved in case of database failure. If autocommit is off when ttiSqi exits, any uncommitted statements are rolled back and reported by ttiSqi.

The ttiSqi isolation command can be used to change the current connection's transaction isolation properties. The isolation can be changed only at the beginning of a transaction. The isolation command accepts one of the following constants: READ_COMMITTED and SERIALIZABLE. If the isolation command is modified without an argument then the current isolation level is reported.

The ttiSqi sqlquerytimeout command sets the timeout period for SQL statements. If the execution time of a SQL statement exceeds the number of seconds set by the sqlquerytimeout command, the SQL statement is not executed and an 6111 error is
Working with prepared and parameterized SQL statements

Preparing a SQL statement just once and then executing it multiple times is much more efficient for TimesTen applications than re-preparing the statement each time it is to be executed. ttIsql has a set of built-in commands to work with prepared SQL statements. These commands are summarized below:

- **prepare** - Prepares a SQL statement. Corresponds to a SQLPrepare ODBC call.
- **exec** - Executes a previously prepared statement. Corresponds to a SQLExecute ODBC call.
- **execandfetch** - Executes a previously prepared statement and fetches all result rows. Corresponds to a SQLExecute call followed by one or more calls to SQLFetch.

Note: TimesTen roll back and query timeout features do not stop TimesTen Cache operations that are being processed on the Oracle database. This includes passthrough statements, flushing, manual loading, manual refreshing, synchronous writethrough, propagating and dynamic loading.

The following example demonstrates the common use of the ttIsql built-in transaction management commands.

E:\>ttIsql
Copyright (c) 1996, 2020 Oracle. All rights reserved.
Type ? or "help" for help, type 'exit' to quit ttIsql.

Command> connect 'DSN=MY_DSN';
Connection successful: DSN=MY_DSN;DataStore=/disk1/databases/MY_DSN;
DRIVER=E:\WINNT\System32\TTdv181.dll;
(Default setting AutoCommit=1)
Command> autocommit 0;
Command> CREATE TABLE LOOKUP (KEY NUMBER NOT NULL PRIMARY KEY, VALUE CHAR (64));
Command> commit;
Command> INSERT INTO LOOKUP VALUES (1, 'ABC');
1 row inserted.
Command> SELECT * FROM LOOKUP;
< 1, ABC >
1 row found.
Command> rollback;
Command> SELECT * FROM LOOKUP;
0 rows found.
Command> isolation;
isolation = READ_COMMITTED
Command> commitdurable;
Command> sqlquerytimeout 10;
Command> sqlquerytimeout;
Query timeout = 10 seconds
Command> disconnect;
Disconnecting...
Command> exit;
Done.
- `fetchall` - Fetches all result rows for a previously executed statement. Corresponds to one or more `SQLFetch` calls.
- `fetchone` - Fetches only one row for a previously executed statement. Corresponds to exactly one `SQLFetch` call.
- `close` - Closes the result set cursor on a previously executed statement that generated a result set. Corresponds to a `SQLFreeStmt` call with the `SQL_CLOSE` option.
- `free` - Closes a previously prepared statement. Corresponds to a `SQLFreeStmt` call with the `SQL_DROP` option.
- `describe` - Describes the prepared statement including the input parameters and the result columns.

The `ttIsql` utility prepared statement commands also handle SQL statement parameter markers. When parameter markers are included in a prepared SQL statement, `ttIsql` automatically prompts for the value of each parameter in the statement at execution time.

The example below uses the prepared statement commands of the `ttIsql` utility to prepare an `INSERT` statement into a table containing a `NUMBER` and a `CHAR` column. The statement is prepared and then executed twice with different values for each of the statement's two parameters. The `ttIsql` utility `timing` command is used to display the elapsed time required to executed the primary ODBC function call associated with each command.

```
Command> connect "DSN=MY_DSN";
Connection successful: DSN=MY_DSN;DataStore=/disk1/databases/MY_DSN;
DRIVER=E:\WINNT\System32\TTdv181.dll;
(Default setting AutoCommit=1)
Command> timing 1;
Command> create table t1 (key number not null primary key, value char(20));
Execution time (SQLExecute) = 0.007247 seconds.
Command> prepare insert into t1 values (:f, :g);
Execution time (SQLPrepare) = 0.000603 seconds.
Command> exec;
Type '?' for help on entering parameter values.
Type '*' to end prompting and abort the command.
Type '-' to leave the parameter unbound.
Type '/' to leave the remaining parameters unbound and execute the command.
Enter Parameter 1 'F' (NUMBER) > 1;
Enter Parameter 2 'G' (CHAR) > 'abc';
1 row inserted.
Execution time (SQLExecute) = 0.000454 seconds.
Command> exec;
Type '?' for help on entering parameter values.
Type '*' to end prompting and abort the command.
Type '-' to leave the parameter unbound.
Type '/' to leave the remaining parameters unbound and execute the help command.
Enter Parameter 1 'F' (NUMBER) > 2;
Enter Parameter 2 'G' (CHAR) > 'def';
1 row inserted.
Execution time (SQLExecute) = 0.000300 seconds.
Command> free;
Command> select * from t1;
< 1, abc >
```
In the example above, the `prepare` command is immediately followed by the SQL statement to prepare. Whenever a SQL statement is prepared in `ttIsql`, a unique command ID is assigned to the prepared statement. The `ttIsql` utility uses this ID to keep track of multiple prepared statements. A maximum of 256 prepared statements can exist in a `ttIsql` session simultaneously. When the `free` command is executed, the command ID is automatically disassociated from the prepared SQL statement.

To see the command IDs generated by `ttIsql` when using the prepared statement commands, set the verbosity level to 4 using the `verbosity` command before preparing the statement, or use the `describe *` command to list all prepared statements with their IDs.

Command IDs can be referenced explicitly when using `ttIsql`'s prepared statement commands. For a complete description of the syntax of `ttIsql`'s prepared statement commands see the "ttIsql" section in the Oracle TimesTen In-Memory Database Reference or type `help` at the `ttIsql` command prompt.

The example below prepares and executes a `SELECT` statement with a predicate containing one `NUMBER` parameter. The `fetchone` command is used to fetch the result row generated by the statement. The `showplan` command is used to display the execution plan used by the TimesTen query optimizer when the statement is executed. In addition, the verbosity level is set to 4 so that the command ID used by `ttIsql` to keep track of the prepared statement is displayed.

```sql
Command> connect 'DSN=MY_DSN';
Connection successful: DSN=MY_DSN;DataStore=/disk1/databases/MY_DSN;
DRIVER=E:\WINNT\System32\TTdv181.dll;
(Default setting AutoCommit=1)
The command succeeded.
Command> CREATE TABLE T1 (KEY NUMBER NOT NULL PRIMARY KEY, VALUE CHAR (64));
The command succeeded.
Command> INSERT INTO T1 VALUES (1, 'abc');
1 row inserted.
The command succeeded.
Command> autocommit 0;
Command> showplan 1;
Command> verbosity 4;
The command succeeded.
Command> prepare SELECT * FROM T1 WHERE KEY=?;
Assigning new prepared command id = 0.

Query Optimizer Plan:

<table>
<thead>
<tr>
<th>STEP</th>

<tr>
<td>INDEXED CONDITION</td>
<td>T1.KEY = _QMARK_1</td>
</tr>
<tr>
<td>NOT INDEXED</td>
<td>&lt;NULL&gt;</td>
</tr>
</tbody>
</table>

The command succeeded.

```
Using, declaring, and setting variables

The following sections describe how to declare, set and use bind variables in ttIsql:

- Declaring and setting bind variables
- Automatically creating bind variables for retrieved columns

Declaring and setting bind variables

You can declare and set variables and arrays in ttIsql that can be referenced in a SQL statement, SQL script, or PL/SQL block. The variables declared using the variable and setvariable command must be one of the following data types: NUMBER, CHAR, NCHAR, VARCHAR2, NVARCHAR2, CLOB, NCLOB, BLOB, or REFCURSOR. However, when binding arrays, TimesTen supports only binding arrays of the NUMBER, CHAR, NCHAR, VARCHAR2, or NVARCHAR2 data types.

Note: All variables that are declared exist for the life of the ttIsql session. However, if you declare a new variable with the same name, the new variable replaces the old variable.
The following examples declare bind variables with the `variable` or `var` command for a number, character string, and an array. Each is assigned a value either when declared or by using the `setvariable` or `setvar` command.

**Note:** For details on the syntax for these commands, see "ttIsql" in the *Oracle TimesTen In-Memory Database Reference*.

```
Command> VARIABLE house_number NUMBER := 268;
Command> PRINT house_number;
   HOUSE_NUMBER : 268

Command> VARIABLE street_name VARCHAR2(15);
Command> SETVARIABLE street_name := 'Oracle Parkway';

Command> VARIABLE occupants[5] VARCHAR2(15);
Command> SETVARIABLE occupants[1] := 'Pat';
Command> PRINT occupants;
   OCCUPANTS : ARRAY [ 5 ] (Current Size 2)
   OCCUPANTS[1] : Pat
   OCCUPANTS[2] : Terry
```

The following is an example of binding multiple values in an array using square brackets to delineate the values and commas to separate each value for the array:

```
Command> PRINT occupants;
   OCCUPANTS : ARRAY [ 5 ] (Current Size 2)
   OCCUPANTS[1] : Pat
   OCCUPANTS[2] : Terry
```

When using array binds, PL/SQL enables you to bind each variable to a PL/SQL variable with the following declaration, where `TypeName` is any unique identifier for the PL/SQL data type and `DataType` can be specified as `CHAR`, `NCHAR`, `VARCHAR2`, or `NVARCHAR2`.

```
TYPE TypeName IS TABLE OF DataType(<precision>) INDEX BY BINARY_INTEGER;
```

If the variable is declared as array of `NUMBER`, you can bind it to a PL/SQL variable of the following data types: `NUMBER`, `INTEGER`, `FLOAT`, or `DOUBLE PRECISION`. To do so, use the appropriate declaration:

```
TYPE TypeName IS TABLE OF NUMBER INDEX BY BINARY_INTEGER;
TYPE TypeName IS TABLE OF INTEGER INDEX BY BINARY_INTEGER;
TYPE TypeName IS TABLE OF FLOAT INDEX BY BINARY_INTEGER;
TYPE TypeName IS TABLE OF DOUBLE PRECISION INDEX BY BINARY_INTEGER;
```

The following example declares the `occupants VARCHAR2` array, which is then declared and used within a PL/SQL block:

```
Command> VARIABLE occupants[5] VARCHAR2(15);
Command> SETVARIABLE occupants[1] := 'Pat';
Command> DECLARE
   TYPE occuname IS TABLE OF VARCHAR2(15) INDEX BY BINARY_INTEGER;
   x occuname;
   BEGIN
   x := :occupants;
   FOR LROW IN x.FIRST..x.LAST LOOP
```
Using, declaring, and setting variables

```plsql
x[LROW] := x[LROW] || ' Doe';
END LOOP;
:occupants := x;
END;
/

PL/SQL procedure successfully completed.

Command> PRINT occupants;

```

```
OCCUPANTS            : ARRAY [ 5 ] (Current Size 2)
OCCUPANTS[1] : Pat Doe
OCCUPANTS[2] : Terry Doe

Automatically creating bind variables for retrieved columns

When you set `autovariables` on in `ttIsql`, TimesTen creates an automatic bind variable named after each column in the last fetched row. An automatic bind variable can be used in the same manner of any bind variable.

The following example selects all rows from the `employees` table. Since all columns are retrieved, automatic variables are created and named for each column. The bind variable contains the last value retrieved for each column.

```
Command> SET AUTOVARIABLES ON;
Command> SELECT * FROM employees;

```

```
... < 204, Hermann, Baer, HBAER, 515.123.8888, 1994-06-07 00:00:00, PR_REP, 10000, <NULL>, 101, 70 > < 205, Shelley, Higgins, SHIGGINS, 515.123.8080, 1994-06-07 00:00:00, AC_MGR, 12000, <NULL>, 101, 110 > < 206, William, Gietz, WGIETZ, 515.123.8181, 1994-06-07 00:00:00, AC_ACCOUNT, 8300, <NULL>, 205, 110 >

Command> PRINT;

```

```
EMPLOYEE_ID          : 206
FIRST_NAME           : William
LAST_NAME            : Gietz
EMAIL                : WGIETZ
PHONE_NUMBER         : 515.123.8181
HIRE_DATE            : 1994-06-07 00:00:00
JOB_ID               : AC_ACCOUNT
SALARY               : 8300
COMMISSION_PCT       : <NULL>
MANAGER_ID           : 205
DEPARTMENT_ID        : 110

If you provide an alias for a column name, the automatic bind variable name uses the alias, rather than the column name.

```
Command> SET AUTOVARIABLES ON;
Command> SELECT employee_id ID, First_name SURNAME, last_name LASTNAME FROM employees;

```

```
... < 204, Hermann, Baer > < 205, Shelley, Higgins > < 206, William, Gietz >
107 rows found.
Command> PRINT;

```

```
ID                   : 206
```
For any query that fetches data without a known named column, set columnlabels on to show the column names. The following example shows that the columns returns from ttConfiguration built-in procedure are paramname and paramvalue.

```
Command> SET AUTOVARIABLES ON;
Command> SET COLUMNLABELS ON;
Command> call TTCONFIGURATION('LockLevel');
```

```
PARAMNAME, PARAMVALUE
< LockLevel, 0 >
1 row found.
```

```
Command> IF :paramvalue = 1 THEN 'e:Database-level locking is enabled';
Command> IF NOT :paramvalue = 1 THEN 'e:Row-level locking is enabled';
Row-level locking is enabled
```

You can also use the describe command to show the column names. The following example uses the describe command to display the column names for the ttConfiguration built-in procedure.

```
Command> DESCRIBE TTCONFIGURATION;
```

```
Procedure TTCONFIGURATION:
Parameters:
    PARAMNAME            TT_VARCHAR (30)
Columns:
    PARAMNAME             TT_VARCHAR (30) NOT NULL
    PARAMVALUE            TT_VARCHAR (1024)
```

1 procedure found.

## Creating and executing PL/SQL blocks

You can create and execute PL/SQL blocks from the ttIsql command line.

Set serveroutput on to display results generated from the PL/SQL block:

```
Command> set serveroutput on
```

Create an anonymous block that puts a text line in the output buffer. Note that the block must be terminated with a slash (/).

```
Command> BEGIN
    DBMS_OUTPUT.put_line('Welcome!');
END;
/
Welcome!
```

PL/SQL procedure successfully completed.

```
Command>
```

See the *Oracle TimesTen In-Memory Database PL/SQL Developer’s Guide* for more examples. For information on error handling in ttIsql for PL/SQL objects, see "Showing errors in ttIsql" in the *Oracle TimesTen In-Memory Database PL/SQL Developer’s Guide*. 

---

SURNAME : William
LASTNAME : Gietz
Passing data from PL/SQL using OUT parameters

You can pass data back to applications from PL/SQL by using OUT parameters. This example returns information about how full a TimesTen database is.

Create the `tt_space_info` PL/SQL procedure and use SQL to provide values for the `permpct`, `permmaxpct`, `temppct`, and `tempmaxpct` parameters.

```sql
Command> CREATE OR REPLACE PROCEDURE tt_space_info
  (permpct OUT PLS_INTEGER,
   permmaxpct OUT PLS_INTEGER,
   temppct OUT PLS_INTEGER,
   tempmaxpct OUT PLS_INTEGER) AS
  monitor sys.monitor%ROWTYPE;
BEGIN
  SELECT * INTO monitor FROM sys.monitor;
  permpct := monitor.perm_in_use_size * 100 / monitor.perm_allocated_size;
  permmaxpct := monitor.perm_in_use_high_water * 100 / monitor.perm_allocated_size;
  temppct := monitor.temp_in_use_size * 100 / monitor.temp_allocated_size;
  tempmaxpct := monitor.temp_in_use_high_water * 100 / monitor.temp_allocated_size;
END;
/
Procedure created.
```

Declare the variables and call `tt_space_info`. The parameter values are passed back to `ttIsql` so they can be printed:

```sql
Command> VARIABLE permpct NUMBER
Command> VARIABLE permpctmax NUMBER
Command> VARIABLE temppct NUMBER
Command> VARIABLE temppctmax NUMBER
Command> BEGIN
  tt_space_info(:permpct, :permpctmax, :temppct, :temppctmax);
END;
/
PL/SQL procedure successfully completed.
```

You can also pass back a statement handle that can be executed by a PL/SQL statement with an OUT refcursor parameter. The PL/SQL statement can choose the query associated with the cursor. The following example opens a refcursor, which randomly chooses between ascending or descending order.

```sql
Command> VARIABLE ref REFCURSOR;
```
Conditional control with the IF-THEN-ELSE command construct

The IF-THEN-ELSE command construct enables you to implement conditional branching logic in a ttIsql session. The IF command tests a condition and decides whether to execute commands within the THEN clause or the optional ELSE clause. The commands executed can be SQL statements, SQL scripts, PL/SQL blocks, or TimesTen utilities.

The following example creates and tests a bind variable to see which type of locking is enabled for the TimesTen database. It uses the autovariables command to create the bind variable from the result of the call to ttConfiguration. The value can be tested within the IF-THEN-ELSE conditional by testing the paramvalue variable.

Note: For more details on the autovariables command, see "Automatically creating bind variables for retrieved columns" on page 6-21.

Command> SET AUTOVARIABLES ON;
Command> CALL TTCONFIGURATION('LockLevel');
PARAMNAME, PARAMVALUE
< LockLevel, 0 >
Loading data from an Oracle database into a TimesTen table

You can load the results of a SQL query from a back-end Oracle database into a single table on TimesTen without creating a cache group and cache table to contain the results. TimesTen provides tools that execute a user-provided SELECT statement on the Oracle database and load the result set into a table on TimesTen.

The following are the major steps that are performed to accomplish this task:

1. Create a table with the correct columns and data types on TimesTen.
2. Provide a SELECT statement that is executed on the Oracle database to generate the desired result set.
3. Load the result set into the table on TimesTen.

TimesTen provides two methods to accomplish these tasks:

- The ttIsql utility provides the createandloadfromoraquery command that, once provided the TimesTen table name and the SELECT statement, automatically creates the TimesTen table, executes the SELECT statement on the Oracle database, and loads the result set into the TimesTen table. This command is described fully in "Use ttIsql to create a table and load SQL query results" on page 6-27.

- The ttTableSchemaFromOraQueryGet built-in procedure evaluates the user-provided SELECT statement to generate a CREATE TABLE statement that can be executed to create a table on TimesTen, which would be appropriate to receive the result set from the SELECT statement. The ttLoadFromOracle built-in procedure executes the SELECT statement on the Oracle database and loads the result set into the TimesTen table. These built-in procedures are described in "Use TimesTen built-in procedures to recommend a table and load SQL query results" on page 6-29.

Both methods require the following:

- Both the TimesTen and Oracle databases involved must be configured with the same national database character set.

- When you connect to the TimesTen database, the connection must contain the same connection attributes that are required when using cache groups, as follows:
  - The user name, which must be the same on both the TimesTen and Oracle databases.

---

**Note:** The correct privileges must be granted to these users on each database for the SQL statements that are executed on their behalf.
- The correct passwords for each user as appropriate in the PWD and OraclePWD connection attributes
- The OracleNetServiceName connection attributes that identifies the Oracle database instance

For either method, the user provides the following:

- The table name on the TimesTen database where the results of the SQL query is loaded. If the owner of the table is not provided, the table is created with the current user as the owner. The table name is not required to be the same name as the table name on the Oracle database against which the SQL statement is executed. This table does not require a primary key. If the table already exists, a warning is issued and the retrieved rows are appended to the table.

- The SQL SELECT statement that is executed against the Oracle database to obtain the required rows. The tables specified within this SELECT statement must be fully qualified, unless the tables are within the schema of the current Oracle Database user. The query cannot have any parameter bindings.

The SELECT list should contain either simple column references or column aliases. For example, any expressions in the SELECT list should be provided with a column alias. You can also use the column alias to avoid duplication of column names in the result table. For example, instead of using SELECT C1+1 FROM T1, use SELECT C1 + 1 C2 FROM T1, which would create a column named C2.

TimesTen evaluates the SELECT statement and uses the column names, data types, and nullability information to create the table on TimesTen into which the result set is loaded. The column names and data types (either the same or mapped) are taken from the tables on the Oracle database involved in the SELECT statement. However, other Oracle Database table definition information (such as DEFAULT values, primary key, foreign key relationships, and so on) are not used when creating the CREATE TABLE statement for the TimesTen table.

**Note:** If the evaluation returns any unsupported data types or if the query cannot be executed on the Oracle database, such as from a syntax error, a warning is logged and a comment is displayed for the unsupported column in the output. However, if the data type is not supported by TimesTen, you can cast the data type directly in the SELECT list to a TimesTen supported data type.

The load process does not check that the column data types and sizes in the TimesTen table match the data types and sizes of the result set. Instead, the insert is attempted and if the column data types cannot be mapped or the Oracle Database data from the SQL query exceeds the TimesTen column size, TimesTen returns an error.

The load is automatically committed every 256 rows. If an error is encountered during the load, it terminates the load, but does not roll back any committed transactions. Any errors returned from the Oracle database are reported in the same manner as when using cache groups.

Because you can use the createandloadfromoraquery command and the ttLoadFromOracle built-in procedure to load into an existing TimesTen table, the following restrictions apply:
You cannot load into system tables, dictionary tables, temporary tables, detail
tables of views, materialized view tables, tables, or tables already in a cache group.
In addition, you cannot use a synonym for the table name.

If you load the result set into an existing table that is the referencing table (child
table) of a foreign key constraint, the constraint is not validated. As a result, rows
that are missing a parent row may be loaded. Instead, you should verify all foreign
keys after the table is loaded. However, the ttLoadFromOracle built-in procedure
enables you to ignore constraint violations by setting the options parameter to
IgnoreDuplicates=Y.

The following sections provide more details on each individual method:

- Use ttIsql to create a table and load SQL query results
- Use TimesTen built-in procedures to recommend a table and load SQL query
  results

Use ttIsql to create a table and load SQL query results

The ttIsql utility provides the createandloadfromoraquery command, which takes a
table name, the number of parallel threads, and a SELECT statement that is to be
executed on the Oracle database as input parameters. From these parameters,
TimesTen performs the following:

1. Evaluates the SQL query and creates an appropriate table, if not already created,
   with the provided table name where the columns are those named in the SQL
   query with the same (or mapped) data types as those in the Oracle Database tables
   from which the resulting data is retrieved.

2. Loads the results of the SQL query as executed on the Oracle database into this
table. The call returns a single number indicating the number of rows loaded. Any
subsequent calls to this command append retrieved rows to the table.

   Note: See the createandloadfromoraquery command in "ttIsql" in
   the Oracle TimesTen In-Memory Database Reference for full details on
   syntax, requirements, restrictions, and required privileges.

The following ttIsql example connects providing the DSN, user name, password for
the user on TimesTen, and the password for the same user name on the Oracle
database. Then, it executes the createandloadfromoraquery command to evaluate the
SELECT statement. The employees table is created on TimesTen with the same column
names and data types as the columns and data types of the retrieved rows. Then, the
table is populated with the result set from the Oracle database over two parallel
threads.

% ttisql -connstr 'DSN=database1;UID=hr;PWD=hr;OraclePWD=oracle'
Copyright (c) 1996, 2020 Oracle. All rights reserved.
Type ? or 'help' for help, type 'exit' to quit ttIsql
connect -connstr "DSN=database1;UID=hr;PWD=********;OraclePWD=********";
Connection successful: DSN=database1;UID=hr;
DataBase=/timesten/install/sample_db/DemoDataStore/database1;
DataBaseCharacterSet=AL32UTF8;
ConnectionCharacterSet=US7ASCII;DRIVER=/timesten/install/lib/libtten.so;
PermSize=128;TempSize=64;OracleNetServiceName=inst1;
(Developer setting AutoCommit=1)
Command> createandloadfromoraquery employees 2 SELECT * FROM hr.employees;
Mapping query to this table:
CREATE TABLE 'HR'."EMPLOYEES" (  "EMPLOYEE_ID" number(6,0) NOT NULL,  "FIRST_NAME" varchar2(20 byte),  "LAST_NAME" varchar2(25 byte) NOT NULL,  "EMAIL" varchar2(25 byte) NOT NULL,  "PHONE_NUMBER" varchar2(20 byte),  "HIRE_DATE" date NOT NULL,  "JOB_ID" varchar2(10 byte) NOT NULL,  "SALARY" number(8,2),  "COMMISSION_PCT" number(2,2),  "MANAGER_ID" number(6,0),  "DEPARTMENT_ID" number(4,0)  )

Table employees created
< 107, 0, 0, Started=2015-09-11 21:12:45 (GMT); Ended=2015-09-11 21:12:46 (GMT);
Load successfully completed; OracleSCN=779534; Rows Loaded=107; Errors=0;
Statement=ttLoadFromOracle(HR, EMPLOYEES, SELECT * FROM hr.employees, 2) > 1 row found.

Issue the DESCRIBE command to show the new table:

Note: In this example, the table owner is not specified, so it defaults to the current user. In this example, the current user is hr.

Command> DESCRIBE employees;

Table HR.EMPLOYEES:
Columns:
  EMPLOYEE_ID                     NUMBER (6) NOT NULL
  FIRST_NAME                      VARCHAR2 (20) INLINE
  LAST_NAME                       VARCHAR2 (25) INLINE NOT NULL
  EMAIL                           VARCHAR2 (25) INLINE NOT NULL
  PHONE_NUMBER                    VARCHAR2 (20) INLINE
  HIRE_DATE                       DATE NOT NULL
  JOB_ID                          VARCHAR2 (10) INLINE NOT NULL
  SALARY                          NUMBER (8,2)
  COMMISSION_PCT                  NUMBER (2,2)
  MANAGER_ID                      NUMBER (6)
  DEPARTMENT_ID                   NUMBER (4)

1 table found.
( primary key columns are indicated with * )

Command> SELECT * FROM employees;
< 114, Den, Raphaely, DRAPHEAL, 515.127.4561, 2002-12-07 00:00:00, PU_MAN, 11000, <NULL>, 100, 30 >
< 115, Alexander, Khoo, AKHOO, 515.127.4562, 2003-05-18 00:00:00, PU_CLERK, 3100, <NULL>, 205, 110 >
...
< 205, Shelley, Higgins, SHIGGINS, 515.123.8080, 2002-06-07 00:00:00, AC_MGR, 12008, <NULL>, 101, 110 >
< 206, William, Gietz, WGIETZ, 515.123.8181, 2002-06-07 00:00:00, AC_ACCOUNT, 8300, <NULL>, 205, 110 >
107 rows found.

The following example uses the createandloadfromoraquery command to create the emp table on TimesTen and populate it in parallel over four threads with data from the hr.employees table on the Oracle database, where employee_id is less than 200.
Command> createandloadfromoraquery emp 4 SELECT * FROM hr.employees
WHERE employee_id < 200;
Mapping query to this table:
   CREATE TABLE "HR"."EMP" (
   "EMPLOYEE_ID" number(6,0) NOT NULL,
   "FIRST_NAME" varchar2(20 byte),
   "LAST_NAME" varchar2(25 byte) NOT NULL,
   "EMAIL" varchar2(25 byte) NOT NULL,
   "PHONE_NUMBER" varchar2(20 byte),
   "HIRE_DATE" date NOT NULL,
   "JOB_ID" varchar2(10 byte) NOT NULL,
   "SALARY" number(8,2),
   "COMMISSION_PCT" number(2,2),
   "MANAGER_ID" number(6,0),
   "DEPARTMENT_ID" number(4,0)
   )
Table emp created
< 100, 0, 0, Started=2015-09-11 21:30:56 (GMT); Ended=2015-09-11 21:30:57 (GMT);
Load successfully completed; OracleSCN=780073; Rows Loaded=100; Errors=0;
Statement=ttLoadFromOracle(HR, EMP, SELECT * FROM hr.employees
WHERE employee_id < 200, 4) >
1 row found.

Then, the following createandloadfromoraquery retrieves all employees whose id is > 200 and the result set is appended to the existing table in TimesTen. A warning tells you that the table already exists and that 6 rows were added to it.

Command> createandloadfromoraquery emp 4 SELECT * FROM hr.employees
WHERE employee_id > 200;
Warning 2207: Table HR.EMP already exists
< 6, 0, 0, Started=2015-09-11 21:34:31 (GMT); Ended=2015-09-11 21:34:31 (GMT);
Load successfully completed; OracleSCN=780176; Rows Loaded=6; Errors=0;
Statement=ttLoadFromOracle(HR, EMP, SELECT * FROM hr.employees
WHERE employee_id > 200, 4) >
1 row found.

A parallel load operation may take a long time to execute and you may want to cancel the operation. For more information on cancelling a parallel load operation, see "Cancel a parallel load operation" on page 6-32.

Use TimesTen built-in procedures to recommend a table and load SQL query results

While the createandloadfromoraquery command automatically performs all of the tasks for creating the TimesTen table and loading the result set from the Oracle database into it, the following two built-in procedures separate the same functionality into the following two steps:

1. The ttTableSchemaFromOraQueryGet built-in procedure evaluates the SQL query and generates the CREATE TABLE SQL statement that you can choose to issue. In order to issue this statement, the user should have all required privileges to issue the query on the Oracle database. This enables you to view the table structure without execution. However, it does require you to issue the recommended CREATE TABLE statement yourself.

2. The ttLoadFromOracle built-in procedure executes the SQL query on the back-end Oracle database and then loads the result set into the TimesTen table. It requires the TimesTen table name where the results are loaded, the Oracle Database SQL SELECT statement to obtain the required rows, and the number of parallel threads.
that you would like to be used in parallel when loading the table with this result set. Optionally, you can specify error threshold options to avoid issues such as uniqueness violations and data conversion issues with the `IgnoreDuplicates` option.

**Note:** See "ttTableSchemaFromOraQueryGet" and "ttLoadFromOracle" in the *Oracle TimesTen In-Memory Database Reference* for full details on syntax, requirements, restrictions, and required privileges.

The following example connects providing the DSN, user name, password for the user on TimesTen, the password for a user with the same name on the Oracle database, and the `OracleNetServiceName` for the Oracle database instance. Then, it calls the `ttTableSchemaFromOraQueryGet` built-in procedure to evaluate the `SELECT` statement and return a recommended `CREATE TABLE` statement for the employees table. Then, the `CREATE TABLE` statement is executed. Finally, the example calls the `ttLoadFromOracle` built-in procedure to load the employees table with the result set from the Oracle database. The load is performed in parallel over four threads, which is the default.

**Note:** If `autocommit` is set to off, then the user must either commit or roll back manually after loading the table.

```sql
% ttisql -connstr "DSN=database1;uid=hr;pwd=hr;OraclePWD=oracle"
Connection successful: DSN=database1;UID=hr;
DataStore=/timesten/install/sample_db/DemoDataStore/database1;
DatabaseCharacterSet=AL32UTF8;
ConnectionCharacterSet=US7ASCII;DRIVER=/timesten/install/lib/libtten.so;
PermSize=128;TempSize=64;OracleNetServiceName=inst1;

Command> call ttTableSchemaFromOraQueryGet('hr','employees', 'SELECT * FROM hr.employees');
< CREATE TABLE "HR"."EMPLOYEES" (
 "EMPLOYEE_ID" number(6,0) NOT NULL,
 "FIRST_NAME" varchar2(20 byte),
 "LAST_NAME" varchar2(25 byte) NOT NULL,
 "EMAIL" varchar2(25 byte) NOT NULL,
 "PHONE_NUMBER" varchar2(20 byte),
 "HIRE_DATE" date NOT NULL,
 "JOB_ID" varchar2(10 byte) NOT NULL,
 "SALARY" number(8,2),
 "COMMISSION_PCT" number(2,2),
 "MANAGER_ID" number(6,0),
 "DEPARTMENT_ID" number(4,0)
) >
1 row found.

Command> CREATE TABLE 'HR'..'EMPLOYEES' ( 
 'EMPLOYEE_ID' number(6,0) NOT NULL,
 'FIRST_NAME' varchar2(20 byte),
 'LAST_NAME' varchar2(25 byte) NOT NULL,
 'EMAIL' varchar2(25 byte) NOT NULL,
 'PHONE_NUMBER' varchar2(20 byte),
 'HIRE_DATE' date NOT NULL,
 'JOB_ID' varchar2(10 byte) NOT NULL,
 'SALARY' number(8,2),
 'COMMISSION_PCT' number(2,2),
 'MANAGER_ID' number(6,0),
 'DEPARTMENT_ID' number(4,0)
 ) >
```
Loading data from an Oracle database into a TimesTen table

Using the ttIsql Utility

The following example creates a table on the Oracle database, where employee_id is a column with a PRIMARY KEY constraint and email is a column with a UNIQUE constraint.

```
SQL> CREATE TABLE employees
  2 (employee_id NUMBER(6) PRIMARY KEY,
  3 first_name VARCHAR2(20),
  4 last_name VARCHAR2(25) NOT NULL,
  5 email VARCHAR2(25) NOT NULL UNIQUE,
  6 phone_number VARCHAR2(20),
  7 hire_date DATE NOT NULL,
  8 job_id VARCHAR2(10) NOT NULL,
  9 salary NUMBER(8,2),
 10 commission_pct NUMBER(2,2),
 11 manager_id NUMBER(6),
 12 department_id NUMBER(4));
```
Table created.

Then, the following ttTableSchemaFromOraQueryGet built-in procedure evaluates the SQL query and generates a CREATE TABLE SQL statement. Note that in the suggested CREATE TABLE SQL statement the PRIMARY KEY and UNIQUE constraints are not carried over from the Oracle database. Nullability constraints are carried over from the Oracle database. This also applies to the createandloadfromoraquery command.

```
Command> call ttTableSchemaFromOraQueryGet ('hr', 'employees',
  'SELECT * FROM hr.employees', 4) >
1 row found.
```

```
Command> SELECT * FROM hr.employees;
< 100, Steven, King, SKING, 515.123.4567, 2003-06-17 00:00:00, AD_PRES, 24000,
 <NULL>, <NULL>, 90 >
< 101, Neena, Kochhar, NKOCHHAR, 515.123.4568, 2005-09-21 00:00:00, AD_VP, 17000,
 <NULL>, 100, 90 >
...
< 205, Shelley, Higgins, SHIGGINS, 515.123.8080, 2002-06-07 00:00:00, AC_MGR,
12008, <NULL>, 205, 110 >
< 206, William, Gietz, WGIETZ, 515.123.8181, 2002-06-07 00:00:00, AC_ACCOUNT,
8300, <NULL>, 205, 110 >
```
107 rows found.

The following example creates a table on the Oracle database, where employee_id is a column with a PRIMARY KEY constraint and email is a column with a UNIQUE constraint.

```
SQL> CREATE TABLE employees
  2 (employee_id NUMBER(6) PRIMARY KEY,
  3 first_name VARCHAR2(20),
  4 last_name VARCHAR2(25) NOT NULL,
  5 email VARCHAR2(25) NOT NULL UNIQUE,
  6 phone_number VARCHAR2(20),
  7 hire_date DATE NOT NULL,
  8 job_id VARCHAR2(10) NOT NULL,
  9 salary NUMBER(8,2),
 10 commission_pct NUMBER(2,2),
 11 manager_id NUMBER(6),
 12 department_id NUMBER(4));
```
Table created.

Then, the following ttTableSchemaFromOraQueryGet built-in procedure evaluates the SQL query and generates a CREATE TABLE SQL statement. Note that in the suggested CREATE TABLE SQL statement the PRIMARY KEY and UNIQUE constraints are not carried over from the Oracle database. Nullability constraints are carried over from the Oracle database. This also applies to the createandloadfromoraquery command.

```
Command> call ttTableSchemaFromOraQueryGet ('hr', 'employees',
  'SELECT * FROM hr.employees');
< CREATE TABLE "HR"."EMPLOYEES" {
  'EMPLOYEE_ID' number(6,0) NOT NULL,
  'FIRST_NAME' varchar2(20 byte),
  'LAST_NAME' varchar2(25 byte) NOT NULL,
  'EMAIL' varchar2(25 byte) NOT NULL,
  'PHONE_NUMBER' varchar2(20 byte),
  'HIRE_DATE' date NOT NULL,
```
A parallel load operation may take a long time to execute and you may want to cancel the operation. For more information on cancelling a parallel load operation, see "Cancel a parallel load operation" on page 6-32.

**Cancel a parallel load operation**

You can cancel and cleanly stop all threads that are performing a parallel load operation with either the SQLCancel(hstmt) ODBC function (this applies for ODBC 2.5 and ODBC 3.5) or by pressing Ctrl-C in the ttIsql utility. For more information, see "TimesTen ODBC Support" in the Oracle TimesTen In-Memory Database C Developer’s Guide and "Canceling ODBC functions" on page 6-38 in this book.

A parallel load operation periodically commits, so any successful operations are not rolled back. When you issue the cancel command, TimesTen performs the cancel operation:

- Before insert threads are spawned.
- After an insert batch commit (every 256 rows)
- After the main thread completes a fetch from the Oracle database.

To retry a cancelled parallel load operation, delete previously inserted rows from the TimesTen database to avoid duplicate rows.

**Viewing and changing query optimizer plans**

The following sections describe how to view the query optimizer plans, commands in the SQL command cache, or query plans for commands in the SQL command cache:

- Using the showplan command
- Viewing commands and explain plans from the SQL command cache

**Using the showplan command**

The built-in showplan command is used to display the query optimizer plans used by TimesTen for executing queries. In addition, ttIsql contains built-in query optimizer hint commands for altering the query optimizer plan. By using the showplan command in conjunction with the ttIsql commands summarized below, the optimum execution plan can be designed. For detailed information on the TimesTen query optimizer see "The TimesTen Query Optimizer" on page 9-1.

- optprofile - Displays the current optimizer hint settings and join order.
- setjoinorder - Sets the join order.
- setuseindex - Sets the index hint.
- tryhash - Enables or disables the use of hash indexes.
- trymergejoin - Enables or disables merge joins.
- trynestedloopjoin - Enables or disables nested loop joins.
- tryserial - Enables or disables serial scans.
- trytmphash - Enables or disables the use of temporary hash indexes.
- trytmptable - Enables or disables the use of an intermediate results table.
- trytmprange - Enables or disables the use of temporary range indexes.
- tryrange - Enables or disables the use of range indexes.
- tryrowid - Enables or disables the use of rowid scans.
- trytbllocks - Enables or disables the use of table locks.
- unsetjoinorder - Clears the join order.
- unsetuseindex - Clears the index hint.

When using the showplan command and the query optimizer hint commands the autocommit feature must be turned off. Use the ttIsql autocommit command to turn off autocommit.

The example below shows how these commands can be used to change the query optimizer execution plan.

Command> CREATE TABLE T1 (A NUMBER);
Command> CREATE TABLE T2 (B NUMBER);
Command> CREATE TABLE T3 (C NUMBER);
Command> INSERT INTO T1 VALUES (3);
1 row inserted.
Command> INSERT INTO T2 VALUES (3);
1 row inserted.
Command> INSERT INTO T3 VALUES (3);
1 row inserted.
Command> INSERT INTO T1 VALUES (4);
1 row inserted.
Command> INSERT INTO T2 VALUES (5);
1 row inserted.
Command> INSERT INTO T3 VALUES (6);
1 row inserted.
Command> autocommit 0;
Command> showplan;
Command> SELECT * FROM T1, T2, T3 WHERE A=B AND B=C AND A=B;

Query Optimizer Plan:

```
STEP:                1
LEVEL:               3
OPERATION:           TblLkSerialScan
TBLNAME:             T2
IXNAME:              <NULL>
INDEXED CONDITION:   <NULL>
NOT INDEXED:         <NULL>

STEP:                2
LEVEL:               3
OPERATION:           TblLkSerialScan
TBLNAME:             T3
IXNAME:              <NULL>
INDEXED CONDITION:   <NULL>
NOT INDEXED:         T2.B = T3.C
```
Viewing and changing query optimizer plans

STEP: 3
LEVEL: 2
OPERATION: NestedLoop
TBLNAME: <NULL>
IXNAME: <NULL>
INDEXED CONDITION: <NULL>
NOT INDEXED: <NULL>

STEP: 4
LEVEL: 2
OPERATION: TblLkSerialScan
TBLNAME: T1
IXNAME: <NULL>
INDEXED CONDITION: <NULL>

STEP: 5
LEVEL: 1
OPERATION: NestedLoop
TBLNAME: <NULL>
IXNAME: <NULL>
INDEXED CONDITION: <NULL>
NOT INDEXED: <NULL>

< 3, 3, 3 >
1 row found.

Command> trytbllocks 0;
Command> tryserial 0;
Command> SELECT * FROM T1, T2, T3 WHERE A=B AND B=C AND A=B;

Query Optimizer Plan:

STEP: 1
LEVEL: 3
OPERATION: TmpRangeScan
TBLNAME: T2
IXNAME: <NULL>
INDEXED CONDITION: <NULL>
NOT INDEXED: <NULL>

STEP: 2
LEVEL: 3
OPERATION: RowLkSerialScan
TBLNAME: T3
IXNAME: <NULL>
INDEXED CONDITION: <NULL>
NOT INDEXED: T2.B = T3.C

STEP: 3
LEVEL: 2
OPERATION: NestedLoop
TBLNAME: <NULL>
IXNAME: <NULL>
INDEXED CONDITION: <NULL>
NOT INDEXED: <NULL>
In this example a query against three tables is executed and the query optimizer plan is displayed. The first version of the query simply uses the query optimizer's default execution plan. However, in the second version the trytbllocks and tryserial ttIsq1 built-in hint commands have been used to alter the query optimizer's plan. Instead of using serial scans and nested loop joins the second version of the query uses temporary index scans, serial scans and nested loops.

In this way the showplan command in conjunction with ttIsq1's built-in query optimizer hint commands can be used to quickly determine which execution plan should be used to meet application requirements.

Viewing commands and explain plans from the SQL command cache

The following sections describe how to view commands and their explain plans:

- View commands in the SQL command cache
- Display query plan for statement in SQL command cache

View commands in the SQL command cache

The ttIsq1 cmdcache command invokes the ttSqlCmdCacheInfo built-in procedure to display the contents of the TimesTen SQL command cache. See "Displaying commands stored in the SQL command cache" on page 9-4 for full details on this procedure.

If you execute the cmdcache command without parameters, the full SQL command cache contents are displayed. Identical to the ttSqlCmdCacheInfo built-in procedure, you can provide a command ID to specify a specific command to be displayed.

In addition, the ttIsq1 cmdcache command can filter the results so that only those commands that match a particular owner or query text are displayed.

The syntax for the cmdcache command is as follows:

cmdcache [ [[by {sqlcmdid | querytext | owner}] <query_substring>]

If you provide the owner parameter, the results are filtered by the owner, identified by the <query_substring>, displayed within each returned command. If you provide the querytext parameter, the results are filtered so that all queries are displayed that
contain the substring provided within the `<query_substring>`. If only the `<query_substring>` is provided, such as cmdcache `<query_substring>`, the command assumes to filter the query text by the `<query_substring>`.

Display query plan for statement in SQL command cache

The ttIsql explain command displays the query plan for an individual command.

- If you provide a command ID from the SQL command cache, the explain command invokes the ttSqlCmdQueryPlan built-in procedure to display the query plan for an individual command in the TimesTen SQL command cache. If you want the explain plan displayed in a formatted method, execute the explain command instead of calling the ttSqlCmdQueryPlan built-in procedure. Both provide the same information, but the ttSqlCmdQueryPlan built-in procedure provides the data in a raw data format. See "Viewing query plans associated with commands stored in the SQL command cache" on page 9-10 for full details on the ttSqlCmdQueryPlan built-in procedure.

- If you provide a SQL statement or the history item number, the explain command compiles the SQL statements necessary to display the explain plan for this particular SQL statement.

The syntax for the explain command is as follows:

```
explain [plan for] {[<Connid>].}<ttisqlcmdid> | sqlcmdid <sqlcmdid> | <sqlstmt>
| !<historyitem>
```

Identical to the ttSqlCmdQueryPlan built-in procedure, you can provide a command ID to specify a specific command to be displayed. The command ID can be retrieved with the cmdcache command, as described in "View commands in the SQL command cache" on page 6-35.

The following example provides an explain plan for command ID 38001456:

```
Command> EXPLAIN SQLCMDID 38001456;
```

Query Optimizer Plan:
Query Text: select * from all_objects where object_name = 'DBMS_OUTPUT'

```
STEP:       1
LEVEL:      12
OPERATION:  TblLkRangeScan
TABLENAME:  OBJ$
TABLEOWNERNAME:  SYS
INDEXNAME:  USER$.I_OBJ
INDEXEDPRED:
NONINDEXEDPRED:  (RTRIM( NAME ))  = DBMS_OUTPUT;NOT( 10 = TYPE#) ;
( FLAGS ^ 128 = 0 ) ;

STEP:       2
LEVEL:      12
OPERATION:  RowLkRangeScan
TABLENAME:  OBJAUTH$
TABLEOWNERNAME:  SYS
INDEXNAME:  OBJAUTH$.I_OBJAUTH1
INDEXEDPRED:  ( (GRANTEE#=1 ) OR (GRANTEE#=10 ) ) AND { (PRIVILEGE#=8 ) }
NONINDEXEDPRED:  OBJ# = OBJ#;

STEP:       3
```
In addition, the `ttIsql explain` command can generate an explain plan for any SQL query you provide. For example, the following shows the explain plan for the SQL query: "SELECT * FROM employees;"

Command> EXPLAIN SELECT * FROM employees;

Query Optimizer Plan:

```
STEP:                1
LEVEL:               1
OPERATION:           TblLkRangeScan
TBLNAME:             EMPLOYEES
IXNAME:              EMP_NAME_IX
INDEXED CONDITION:   <NULL>
NOT INDEXED:         <NULL>
```

You can also retrieve explain plans based upon the command history. The following example shows how you explain a previously executed SQL statement using the history command ID:

Command> SELECT * FROM all_objects WHERE object_name = 'DBMS_OUTPUT';
3 rows found.
Command> HISTORY;
1     connect 'DSN=cache';
2     help cmdcache;
3     cmdcache;
4     explain select * from dual;
5     select * from all_objects where object_name = 'DBMS_OUTPUT';
Command> EXPLAIN !5;
```
STEP:                1
LEVEL:               10
OPERATION:           TblLkRangeScan
TBLNAME:             SYS.OBJ$
```
Managing ODBC functions

You can perform the following on ODBC functions within ttIsql:

- Canceling ODBC functions
- Timing ODBC function calls

Canceling ODBC functions

The ttIsql command attempts to cancel an ongoing ODBC function when the user presses Ctrl-C.
Timing ODBC function calls

Information on the time required to execute common ODBC function calls can be displayed by using the ttIsql timing command. When the timing feature is enabled many built-in ttIsql commands report the elapsed execution time associated with the primary ODBC function call corresponding to the ttIsql command that is executed.

For example, when executing the ttIsql connect command several ODBC function calls are executed, however, the primary ODBC function call associated with connect is SQLDriverConnect and this is the function call that is timed and reported as shown below.

```
Command> timing 1;
Command> connect "DSN=MY_DSN";
Connection successful: DSN=MY_DSN;DataStore=/disk1/databases/MY_DSN;
DRIVER=E:\WINNT\System32\TTdv181.dll;
(Default setting AutoCommit=1)
Execution time (SQLDriverConnect) = 1.2626 seconds.
Command>
```

In the example above, the SQLDriverConnect call took about 1.26 seconds to execute.

When using the timing command to measure queries, the time required to execute the query plus the time required to fetch the query results is measured. To avoid measuring the time to format and print query results to the display, set the verbosity level to 0 before executing the query.

```
Command> timing 1;
Command> verbosity 0;
Command> SELECT * FROM t1;
Execution time (SQLExecute + FetchLoop) = 0.064210 seconds.
Command>
```

Error recovery with WHENEVER SQLERROR

Issue the WHENEVER SQLERROR command to prescribe what to do when a SQL error occurs. WHENEVER SQLERROR can be used to set up a recovery action for SQL statements, SQL script, or PL/SQL block.

By default, if a SQL error occurs while in ttIsql, the error information is displayed and ttIsql continues so that you can enter a new command. The default setting is WHENEVER SQLERROR CONTINUE NONE. You can also specify that ttIsql exits each time an error occurs, which may not be the best action for interactive use or when executing a SQL script or a PL/SQL block.

```
The following example uses EXIT to return an error code of 255 and executes a COMMIT statement to save all changes to the current connection before exiting ttIsql. The example retrieves the error code using the C shell echo $status command.

Command> WHENEVER SQLERROR EXIT 255 COMMIT;
Command> SELECT emp_id FROM employee;
  2206: Table PAT.EMPLOYEE not found
WHENEVER SQLERROR exiting.
% echo $status
  255
```
The following example demonstrates how the WHENEVER SQLERROR command can execute ttsql commands or TimesTen utilities when an error occurs, even if the error is from another TimesTen utility:

```
Command> WHENEVER SQLERROR EXEC 'DSSIZE;CALL TTSQLCMDCACHEINFOGET();';
Command> call TTCACHEPOLICYGET;
5010: No OracleNetServiceName specified in DSN
The command failed.
DSSIZE;

PERM_ALLOCATED_SIZE: 32768
PERM_IN_USE_SIZE: 9204
PERM_IN_USE_HIGH_WATER: 9204
TEMP_ALLOCATED_SIZE: 40960
TEMP_IN_USE_SIZE: 7785
TEMP_IN_USE_HIGH_WATER: 7848

CALL TTSQLCMDCACHEINFOGET();

CMDCOUNT, FREEABLECOUNT, SIZE
< 10, 7, 41800 >
1 row found.
```

The following demonstrates the SUPPRESS command option. It suppresses all error messages and continues to the next command. The example shows that the error messages can be turned back on in the existing connection with another command option, which in this case is the EXIT command.

```
Command> WHENEVER SQLERROR SUPPRESS;
Command> SELECT *
Command> WHENEVER SQLERROR EXIT;
Command> SELECT *
1001: Syntax error in SQL statement before or at: "", character position: 9
select *
WHENEVER SQLERROR exiting.
```

The following example sets a bind variable called retcode, the value of which is returned when a SQL error occurs:

```
Command> VARIABLE retcode NUMBER := 111;
Command> WHENEVER SQLERROR EXIT :retcode;
Command> INSERT INTO EMPLOYEES VALUES (202, 'Pat', 'Fay', 'PFAY', '603.123.6666', TO_DATE ('17-AUG-1997', 'DD-MON-YYYY'), 'MK_REP', 6000, NULL, 201, 20);
907: Unique constraint (EMPLOYEES on PAT.EMPLOYEES) violated at Rowid
<EMUFVUACACAAAAbB>
WHENEVER SQLERROR exiting.
% echo $status;
111
TimesTen supports transactions that provide atomic, consistent, isolated and durable (ACID) access to data. The following sections describe how you can configure transaction features.

- Transaction overview
- Transaction implicit commit behavior
- Ensuring ACID semantics
- Concurrency control through isolation and locking
- Checkpoint operations
- Transaction logging
- Durability options
- Transaction reclaim operations
- Recovery with checkpoint and transaction log files

### Transaction overview

All operations on a TimesTen database, even those that do not modify or access application data, are executed within a transaction. When running an operation and there is no outstanding transaction, one is started automatically on behalf of the application. Transactions are completed by an explicit or implicit commit or rollback. When completed, resources (such as locks and result sets) that were acquired or opened by the transaction are released and freed.

When using SQL statements or supported APIs (such as ODBC and JDBC) to commit or rollback your transaction:

- When you commit the current transaction, updates made in the transaction are made available to concurrent transactions.
- When you rollback the current transaction, all updates made in the transaction are undone.

Read-only transactions hold minimal resources, so you do not need to commit every read operation. When executing write operations, commit transactions to release locks. When possible, keep write transactions short in duration. Any long-running transactions can reduce concurrency and decrease throughput because locks are held for a longer period of time, which blocks concurrent transactions. Also, long-running transactions can prevent transaction log files from being purged, causing these files to accumulate on the file system.
A connection can have only one outstanding transaction at any time and cannot be explicitly closed if it has an open transaction.

**Transaction implicit commit behavior**

The following sections describe how you can configure whether the application enables implicit commit behavior or requires explicit commit behavior for DML or DDL statements:

- Transaction autocommit behavior
- TimesTen DDL commit behavior

**Transaction autocommit behavior**

Autocommit configures whether TimesTen issues an implicit commit after DML or DDL statements. Some database APIs (such as ODBC and JDBC) support autocommit, which is enabled by default when using those APIs. Other APIs (such as OCI) do not provide an autocommit feature.

When autocommit is on, the following behavior occurs:

- An implicit commit is issued immediately after a statement executes successfully.
- An implicit rollback is issued immediately after a statement execution fails, such as a primary key violation.
- If the statement generates a result set, the automatic commit is not issued until that result set and any other open result set in the transaction have been explicitly closed. Any statements executed while a result set is open is not committed until all result sets have been closed.

Fetching all rows of a result set does not automatically close the result set. After the result set has been processed, the result set must be explicitly closed if using the read committed isolation level or the transaction must be explicitly committed or rolled back if using serializable isolation level.

**Note:** Even with durable commits and autocommit enabled, you could lose work if there is a failure or the application exits without closing result sets.

- If you are using ODBC or JDBC batch operations to INSERT, UPDATE or DELETE several rows in one call when autocommit is on, a commit occurs after the entire batch operation has completed. If there is an error during the batch operation, those rows that have been successfully modified are committed within this transaction. If an error occurs due to a problem on a particular row, only the successfully modified rows preceding the row with the error are committed in this transaction. The pirow parameter to the ODBC SQLParamOptions function contains the number of the rows in the batch that had a problem.

Commits can be costly for performance and intrusive if they are implicitly executed after every statement. TimesTen recommends you disable autocommit so that all commits are intentional. Disabling autocommit provides control over transactional boundaries, enables multiple statements to be executed within a single transaction, and improves performance, since there is no implicit commit after every statement.

If autocommit is disabled, transactions must be explicitly completed with a commit or rollback after any of the following:
Ensuring ACID semantics

- Completing all the work that was to be done in the transaction.
- Issuing a transaction-consistent (blocking) checkpoint request.
- Updating column and table statistics to be used by the query optimizer.
- Calling a TimesTen built-in procedure that does not generate a result set in order for the new setting specified in the procedure to take effect, such as the `ttLockWait` procedure.

You must establish a connection to a database before changing the autocommit setting. To disable autocommit, perform one of the following:

- In ODBC-based applications, execute `SQLSetConnectOption` function with `SQL_AUTOCOMMIT_OFF`.
- In JDBC applications, `Connection.setAutoCommit(false)` method.
- When running `ttIsql`, issue the `autocommit 0` command.

TimesTen DDL commit behavior

The TimesTen database issues an implicit `COMMIT` before and after any DDL statement. A durable commit is performed after the execution of each DDL statement. This behavior is the same as the Oracle database.

DDL statements include the following:

- `CREATE`, `ALTER` and `DROP` statements for any database object, including tables, views, users, procedures and indexes.
- `TRUNCATE`
- `GRANT` and `REVOKE`

There are certain things to keep into consideration:

- DDL changes cannot be rolled back.
- DDL statements delete records from global temporary tables unless the tables were created with the `ON COMMIT PRESERVE ROWS` clause.
- Tables created with the `CREATE TABLE ... AS SELECT` statement are visible immediately.
- `TRUNCATE` statements are committed automatically. However, the truncate of the parent and child tables must be truncated in separate transactions, with the child table truncated first. You cannot truncate a parent table unless the child table is empty.

Ensuring ACID semantics

As a relational database, TimesTen is ACID compliant:

- **Atomic**: All TimesTen transactions are atomic: Either all database operations in a single transaction occur or none of them occur.
- **Consistent**: Any transaction can bring the database from one consistent state to another.
- **Isolated**: Transactions can be isolated. TimesTen has two isolation levels: read committed and serializable, which together with row level locking provide multi-user concurrency control.
- **Durable**: Once a transaction has been committed, it remains committed.
The following sections detail how TimesTen ensures ACID semantics for transactions:

- **Transaction atomicity, consistency, and isolation**
- **Transaction consistency and durability**

### Transaction atomicity, consistency, and isolation

Locking and transaction logs are used to ensure ACID semantics as a transaction modifies data in a database as follows:

- **Locking:** TimesTen acquires locks on data items that the transaction writes and, depending on the transaction isolation level, data items that the transaction reads. See "Concurrency control through isolation and locking" on page 7-5 for details.

- **Transaction logging:** All TimesTen transactions are atomic. Either all or none of the effects of the transaction are applied to the database. Modifications to the database are recorded in a transaction log. Atomicity is implemented by using the transaction log to undo the effects of a transaction if it is rolled back. Rollback can be caused explicitly by the application or during database recovery because the transaction was not committed at the time of failure. See "Transaction logging" on page 7-16 for details.

The following table shows how TimesTen uses locks and transaction logs:

<table>
<thead>
<tr>
<th>If</th>

### Transaction consistency and durability

TimesTen provides consistency and durability with a combination of checkpointing and transaction logging.

- A checkpoint operation writes the current in-memory database image to a checkpoint file on the file system.
  - For TimesTen Classic, a successful checkpoint operation makes all transactions that have been committed at the time of the checkpoint operation consistent and durable.
In TimesTen Scaleout, the data in your database is distributed across elements. Each element keeps its own checkpoint and transaction log files. As a result, the data stored in each element is independently durable.

Each data instance in a grid manages one element of a database. In the event of a failure, a data instance can automatically recover the data stored in its element from the checkpoint and transaction logs files while the remaining data instances continue to service applications. If the K-safety value is 2 or greater, then a failed element can be recovered from another element in its replica set.

All transactions are logged to an in-memory transaction log buffer, which is written to the file system either with durable or nondurable transactions. See “Durability options” on page 7-22 for more details.

Note: Checkpointing and logging are further described in "Checkpoint operations" on page 7-9 and "Transaction logging" on page 7-16.

Concurrency control through isolation and locking

TimesTen transactions support ANSI Serializable and ANSI Read Committed levels of isolation. ANSI Serializable isolation is the most stringent transaction isolation level. ANSI Read Committed allows greater concurrency. Read Committed is the default and is an appropriate isolation level for most applications.

The following sections describe transaction isolation and locking levels:

- **Transaction isolation levels**
- **Locking granularities**

**Transaction isolation levels**

Transaction isolation enables each active transaction to operate as if there were no other transactions active in the system. Isolation levels determine if row-level locks are acquired when performing read operations. When a statement is issued to update a table, locks are acquired to prevent other transactions from modifying the same data until the updating transaction commits or rolls back and then releases its locks.

The Isolation connection attribute sets the isolation level for a connection. The isolation level cannot be changed in the middle of a transaction.

TimesTen supports the following two transaction isolation levels:

- **ANSI Read Committed isolation**: The read committed isolation level is the recommended mode of operation for most applications, and is the default mode. It enables transactions that are reading data to execute concurrently with a transaction that is updating the same data. TimesTen makes multiple versions of data items to allow non-serializable read and write operations to proceed in parallel.

  Read operations do not block write operations and write operations do not block read operations, even when they read and write the same data. Read operations do not acquire locks on scanned rows. Write operations acquire locks that are held until the transaction commits or rolls back. Readers share a committed copy of the data, whereas a writer has its own uncommitted version. Therefore, when a transaction reads an item that is being updated by another in-progress transaction,
it sees the committed version of that item. It cannot see an uncommitted version of an in-progress transaction.

Read committed isolation level provides for better concurrency at the expense of decreased isolation because of the possibility of non-repeatable reads or phantom rows within a transaction. If an application executes the same query multiple times within the same transaction, the commit of an update from another transaction may cause the results from the second read operation to retrieve different results. A phantom row can appear (in modified form) in two different read operations within the same transaction, as the result of an early release of read locks during the transaction.

To set read committed isolation level, if previously modified since this is the default, do one of the following:

- Connect with the Isolation connection attribute set to 1. You can also modify this value with the ALTER SESSION SQL statement.

```sql
ALTER SESSION SET ISOLATION_LEVEL=READ COMMITTED;
```

See "Isolation" in the Oracle TimesTen In-Memory Database Reference or "ALTER SESSION" in Oracle TimesTen In-Memory Database SQL Reference for more information.

- When using ttIsql, execute isolation 1 or isolation READ_COMMITTED.

- ODBC applications can execute the SQLSetConnectOption ODBC function with the SQL_TXN_ISOLATION flag set to SQL_TXN_READ_COMMITTED. See "Option support for ODBC 2.5 SQLSetConnectOption and SQLGetConnectOption" in the Oracle TimesTen In-Memory Database C Developer’s Guide for more information.

- JDBC applications can execute the setTransactionIsolation JDBC method of the Connection object to TRANSACTION_READ_COMMITTED.

ANSI Serializable isolation: All locks acquired within a transaction by a read or write operation are held until the transaction commits or rolls back. Read operations block write operations, and write operations block read operations. But read operations do not block other read operations.

- If an initial transaction reads a row, a second transaction can also read the row.

- A row that has been read by an initial transaction cannot be updated or deleted by a second transaction until the initial transaction commits or rolls back. However, the second transaction can insert rows that are not in the same range that are locked by the first transaction. For example, if the first transaction is reading rows 1 through 10, then the second transaction cannot update rows 1 through 10. However, the second transaction can insert into rows greater than 10.

- A row that has been inserted, updated or deleted by an initial transaction cannot be accessed in any way by a second transaction until the initial transaction either commits or rolls back.

Serializable isolation level provides for repeatable reads and increased isolation at the expense of decreased concurrency. A transaction that executes the same query multiple times within the same transaction is guaranteed to see the same result set each time. Other transactions cannot update or delete any of the returned rows, nor can they insert a new row that satisfies the query predicate.

To set the isolation level to serializable isolation, do one of the following:
Concurrent control through isolation and locking

- Connect with the Isolation connection attribute set to 0. You can also modify this value with the ALTER SESSION SQL statement.

```
ALTER SESSION SET ISOLATION_LEVEL=SERIALIZABLE ;
```

See "Isolation" in the Oracle TimesTen In-Memory Database Reference or "ALTER SESSION" in Oracle TimesTen In-Memory Database SQL Reference for more information.

- When using ttIsql, execute isolation 0 or isolation SERIALIZABLE.

- ODBC applications can execute the SQLSetConnectOption ODBC function with the SQL_TXN_ISOLATION flag set to SQL_TXN_SERIALIZABLE.

- JDBC applications can execute the setTransactionIsolation JDBC method of the Connection object to TRANSACTION_SERIALIZABLE.

To ensure that materialized views are always in a consistent state, all view maintenance operations are performed under serializable isolation, even when the transaction is in read committed isolation. This means that the transaction obtains read locks for any data items read during view maintenance. However, the transaction releases the read locks at the end of the INSERT, UPDATE or CREATE VIEW statement that triggered the view maintenance, instead of holding them until the end of the transaction.

---

**Note:** The ttXactAdmin utility generates a report showing lock holds and lock waits for all outstanding transactions. It can be used to troubleshoot lock contention problems where operations are being blocked, or encountering lock timeout or deadlock errors. It can also be used to rollback a specified transaction.

---

**Locking granularities**

TimesTen supports row-level locks, table-level locks and database-level locks.

Different connections can coexist with different levels of locking, but the presence of even one connection using database-level locking leads to reduced concurrency. For performance information, see "Choose the best method of locking" on page 10-10.

---

**Note:** When multiple locks have been obtained within the same transaction, the locks are released sequentially when the transaction ends.

---

- **Row-level locking:** Transactions usually obtain locks on the individual rows that they access. Row-level locking is the recommended mode of operation because it provides the finest granularity of concurrency control. It allows concurrent transactions to update different rows of the same table. However, row-level locking requires space in the database’s temporary memory region to store lock information.

Row-level locking is the default. However, if it has been modified to another type of locking and you want to re-enable row-level locking, do one of the following:

- Set the LockLevel connection attribute to 0.

- In TimesTen Classic, call the ttLockLevel built-in procedure with the lockLevel parameter set to Row. This procedure changes the lock level...
between row-level and database-level locking on the next transaction and for all subsequent transactions for this connection.

- Execute the `ttOptSetFlag` built-in procedure to set the `RowLock` parameter to 1, which enables the optimizer to consider using row locks.

---

**Note:** See “LockLevel”, “ttLockLevel”, and “ttOptSetFlag” in the Oracle TimesTen In-Memory Database Reference for more information.

---

Table-level locking: Table-level locking is recommended when concurrent transactions access different tables or a transaction accesses most of the rows of a particular table. Table-level locking provides better concurrency than database-level locking. Row-level locking provides better concurrency than table-level locking. Table-level locking requires only a small amount of space in the temporary memory region to store lock information.

Table-level locking provides the best performance for the following:
- Queries that access a significant number of rows of a table
- When there are very few concurrent transactions that access a table
- When temporary space is inadequate to contain all row locks that an operation, such as a large insert or a large delete, might acquire

To enable table-level locking, execute the `ttOptSetFlag` procedure to set the `TblLock` parameter to 1, which enables the optimizer to consider using table locks. In addition, set `RowLock` to 0 so that the optimizer does not consider row-level locks.

If both table-level and row-level locking are disabled, TimesTen defaults to row-level locking. If both table-level and row-level locking are enabled, TimesTen chooses the locking scheme that is more likely to have better performance. Even though table-level locking provides better performance than row-level locking because of reduced locking overhead, the optimizer often chooses row-level locking for better concurrency. For more information, see “ttOptSetFlag” in the Oracle TimesTen In-Memory Database Reference.

Database-level locking: Database-level locking serializes all transactions, which effectively allows no concurrency on the database. When a transaction is started, it acquires an exclusive lock on the database, which ensures that there is no more than one active transaction in the database at any given time. It releases the lock when the transaction is completed.

Database-level locking can provide better performance than row-level locking, due to reduced locking overhead. In addition, it provides higher throughput than row-level locking when running a single stream of transactions such as a bulk load operation. However, its applicability is limited to applications that never execute multiple concurrent transactions. With database-level locking, every transaction effectively runs in ANSI Serializable isolation, since concurrent transactions are disallowed.

To enable database-level locking, do one of the following:
- Set the `LockLevel` connection attribute to 1.
- In TimesTen Classic, call the `ttLockLevel` built-in procedure with the `lockLevel` parameter set to `DS`. This procedure changes the lock level between row-level and database-level locking on the next transaction and for all subsequent transactions for this connection.
Setting wait time for acquiring a lock

Set the LockWait connection attribute to the maximum amount of time that a statement waits to acquire a lock before it times out. The default is 10 seconds. If a statement within a transaction waits for a lock and the lock wait interval has elapsed, an error is returned. After receiving the error, the application can reissue the statement.

Lock wait intervals are imprecise due to the scheduling of the database’s managing subdaemon process to detect lock timeouts. This imprecision does not apply to zero-second timeouts, which are always immediately reported. The lock wait interval does not apply to blocking checkpoints.

The database’s managing subdaemon process checks every two seconds to see if there is a deadlock in the database among concurrent transactions. If a deadlock occurs, an error is returned to one of the transactions involved in the deadlock cycle. The transaction that receives the error must rollback in order to allow the other transactions involved in the deadlock to proceed.

When running a workload of high lock-contention potential, consider setting the LockWait connection attribute to a smaller value for faster return of control to the application, or setting LockWait to a larger value to increase the successful lock grant ratio (with a risk of decreased throughput).

For more information, see "LockWait" in Oracle TimesTen In-Memory Database Reference.

Checkpoint operations

A checkpoint operation saves the in-memory image of a database to files, known as checkpoint files. By default, TimesTen performs background checkpoints at regular intervals. Checkpointing may generate a large amount of I/O activity and have a long execution time depending on the size of the database and the number of database changes since the most recent checkpoint.

---

**Note:** Applications can programmatically initiate checkpoint operations. See "Setting and managing checkpoints" on page 7-11 for more details.

---

The following sections describe checkpoint operations and how you can manage them:

- Purpose of checkpoints
- Usage of checkpoint files
- Types of checkpoints
- Setting and managing checkpoints

Purpose of checkpoints

A checkpoint operation has two primary purposes.

- Decreases the amount of time required for database recovery, because it provides a more up-to-date database image on which recovery can begin.
- Makes a portion of the transaction log unneeded for any future database recovery operation, typically allowing one or more transaction log files to be deleted.

Both of these functions are very important to TimesTen applications. The reduction in recovery time is important, as the amount of a transaction log needed to recover a database has a direct impact on the amount of downtime seen by an application after a
system failure. The removal of unneeded transaction log files is important because it frees file system space that can be used for new transaction log files. If these files were never purged, they would eventually consume all available space in the transaction log files directory, causing database operations to fail due to log space exhaustion.

Usage of checkpoint files

TimesTen creates two checkpoint files for each database, named \textit{dsname}.ds0 and \textit{dsname}.ds1, where \textit{dsname} is the database path name and file name prefix specified in the database DSN. During a checkpoint operation, TimesTen determines which checkpoint file contains the most recent consistent image and then writes the next in-memory image of the database to the other file. Thus, the two files contain the two most recent database images.

- In TimesTen Classic, the database maintains one set of checkpoint and transaction log files.
- In TimesTen Scaleout, each element maintains its own independent set of checkpoint and transaction log files. See "Understanding Distributed Transactions in TimesTen Scaleout" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for more information.

TimesTen uses the most recent checkpoint file and transaction log files to recover the database to its most recent transaction-consistent state after a database shutdown or system failure. (The most recent transaction log files are those written since the checkpoint was done.) If any errors occur during this process, or if the more recent checkpoint image is incomplete, then recovery restarts using the other checkpoint file. For more information on transaction logging, see "Transaction logging" on page 7-16.

Types of checkpoints

TimesTen uses the most recent checkpoint file to recover the database to transaction-consistent state at the time of the last successful checkpoint operation completed. It uses the transaction log files to recover the database to its most recent transaction-consistent state after a database shutdown or system failure.

TimesTen supports two types of database checkpoint operations:

- Fuzzy or non-blocking checkpoints
- Blocking checkpoints

Fuzzy or non-blocking checkpoints

Fuzzy checkpoints, or non-blocking checkpoints, allow transactions to execute against the database while the checkpoint is in progress. Fuzzy checkpoints do not obtain locks, and therefore have a minimal impact on other database activity. Because transactions may modify the database while a checkpoint operation is in progress, the resulting checkpoint file may contain both committed and uncommitted transactions. Furthermore, different portions of the checkpoint image may reflect different points in time. For example, one portion may have been written before a given transaction committed, while another portion was written afterward. The term "fuzzy checkpoint" derives its name from this fuzzy state of the database image.

To recover the database when the checkpoint files were generated from fuzzy checkpoint operations, TimesTen requires the most recent checkpoint file and the transaction log to bring the database into its most recent transaction-consistent state.
Checkpoint operations

Blocking checkpoints
Blocking checkpoints obtain an exclusive lock on the database for a portion of the checkpoint operation, which blocks all access to the database during that time. The resulting checkpoint image contains all committed transactions prior to the time the checkpoint operations acquired the exclusive lock on the database. Because no transactions can be active while the database lock is held, no modifications made by in-progress transactions are included in the checkpoint image.

Requesting a blocking checkpoint in TimesTen Classic
In TimesTen Classic, an application uses the `ttCkptBlocking` built-in procedure to request a blocking checkpoint. The actual checkpoint is delayed until the requesting transaction commits or rolls back. If a blocking checkpoint is requested for a database for which both checkpoint files are already up to date then the checkpoint request is ignored.

Setting and managing checkpoints
The default behavior for TimesTen checkpoints is as follows:

- TimesTen performs periodic fuzzy checkpoints in the background. You can modify this behavior. See "Configuring or turning off background checkpointing" on page 7-11 for more information.
- TimesTen performs a blocking checkpoint operation of a database just before the database is unloaded from memory. See "Blocking checkpoints" on page 7-11 for more information.

The following sections describe how to manage checkpointing:

- Programmatically performing a checkpoint in TimesTen Classic
- Configuring or turning off background checkpointing
- Displaying checkpoint history and status
- Setting the checkpoint rate
- Setting the number of checkpoint file read threads

Programmatically performing a checkpoint in TimesTen Classic
By default, TimesTen performs periodic fuzzy checkpoints in the background. Therefore, applications rarely need to issue manual checkpoints. However, if an application wishes to issue a manual checkpoint against a TimesTen Classic database, it can call the `ttCkpt` built-in procedure to request a fuzzy checkpoint or the `ttCkptBlocking` built-in procedure to request a blocking checkpoint. This is not recommended. See "ttCkpt" and "ttCkptBlocking" in the Oracle TimesTen In-Memory Database Reference for more information.

Configuring or turning off background checkpointing
Using connection attributes or built-in procedures, you can configure TimesTen to checkpoint either when the transaction log files contain a certain amount of data or at a specific frequency.

To configure checkpointing in TimesTen, do the following:

Configure the `CkptFrequency` and `CkptLogVolume` connection attributes as follows:

- The `CkptFrequency` connection attribute controls how often, in seconds, that TimesTen performs a background checkpoint. The default is 600 seconds. Set the
Checkpoint operations

The CkptLogVolume connection attribute controls how much data, in megabytes, that collects in the transaction log file between background checkpoints. By increasing this amount, you can delay the frequency of the checkpoint. The default is 0. Set the CkptFrequency connection attribute to 0 if you want to control background checkpointing with the CkptLogVolume connection attribute.

In most cases, it is recommended to use CkptLogVolume over CkptFrequency since CkptFrequency does not take into account the rate of transactions the rate of database transactions. If both CkptFrequency and CkptLogVolume attributes are set with a value greater than 0, then a checkpoint is performed when either of the two conditions becomes true.

Alternatively, you can configure background checkpointing or turn it off by calling the ttCkptConfig built-in procedure. The values set by ttCkptConfig take precedence over those set with the connection attributes.

Note: For information on default values and usage, see "CkptFrequency", "CkptLogVolume", and "ttCkptConfig" in the Oracle TimesTen In-Memory Database Reference.

Displaying checkpoint history and status

Select from the SYS.GV$CKPT_HISTORY or SYS.V$CKPT_HISTORY system views to display information on the most recent eight checkpoints and checkpoint attempts.

Note: You can also use the ttCkptHistory built-in procedure to display this information.

For example, some of the information that you can confirm:

- The amount of time a checkpoint takes (subtract the completion time of the checkpoint from the start time).
- The type of the checkpoint: fuzzy, blocking, static or none. See "Types of checkpoints" on page 7-10 for details.
- The status of the checkpoint: in-progress, completed, or failed. When examining checkpoint history, verify whether any recent checkpoints failed (indicated with status of FAILED). If a checkpoint has failed, the reason is displayed in the error or additional details columns.
- The initiator of the checkpoint. From a user-level application (including TimesTen utilities), from a background checkpoint request, or the managing subdaemon of the database.
- The reason why the checkpoint occurred. The most popular reasons are after database creation, after recovery, final checkpoint after shutdown, after the user runs a built-in procedure, or after a flush operation.
- The reason for a failure if a checkpoint fails.
- The amount of data (total number of bytes) written by a typical checkpoint.
- The checkpoint rate. See "Setting the checkpoint rate" on page 7-15 for details on how to calculate the checkpoint rate from the data provided.
Checkpoint operations

- The percentage of the checkpoint that has been completed. If there is an in-progress checkpoint, indicates the percentage of the checkpoint that has been completed.

- The number of actual transaction log files purged by this checkpoint. If this column displays a zero, this does not mean that no log records were purged within the transaction log file. Instead, log records can be purged continually within a transaction log file. This column displays the actual number of transaction log files purged to show when file system space is freed.

There are times when TimesTen may not be able to purge some of the transaction files if there is a hold set on the transaction log. For example, this value may show when the checkpoint cannot purge transaction log files due to a long-running transaction or a replication bookmark located far back in the transaction log files.

- The bookmark name (the reason for the transaction log hold) that is preventing the removal of one or more transaction logs. This name can help identify why transaction log files are remaining on the file system longer than expected. See "Log holds by TimesTen components or operations" on page 7-18 for details on the different bookmark (transaction log hold) names.

If this information does not provide enough context on why transaction logs are not purged, then you can also execute the ttXactAdmin built-in procedure for more details on the transaction logs.

See "SYS.GV$CKPT_HISTORY", "SYS.V$CKPT_HISTORY", "SYS.GV$LOG_HOLDS" or "SYS.V$LOG_HOLDS" in the Oracle TimesTen In-Memory Database System Tables and Views Reference for details on these views. For more information on the built-in procedures, see "ttCkptHistory", "ttLogHolds" or "ttXactAdmin" in the Oracle TimesTen In-Memory Database Reference.

Example 7–1  Checkpoint in progress

This example shows a checkpoint in progress:

```sql
% SELECT * FROM SYS.V$CKPT_HISTORY;

< 2019-02-05 16:56:34.169520, <NULL>,
Fuzzy , In Progress , User ,
BuiltIn , <NULL>,
0, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>,
<NULL>, <NULL>, <NULL>, 13, 6, 0, <NULL>, <NULL> >

Fuzzy , Completed , Checkpointer ,
Background , <NULL>,
1, 0, 8964304, 294, 33554432, 291, 5677288, 27, 1019512, 1065408, <NULL>, 5, 0, Checkpoint, <NULL> >

< 2019-02-05 16:54:41.633792, 2019-02-05 16:54:42.568469,
Blocking , Completed , User ,
BuiltIn , <NULL>,
1, 0, 8958160, 294, 33554432, 291, 5677288, 31, 1162112, 6604976, <NULL>, 3, 0, Checkpoint, <NULL> >
```
This example shows that an error occurred during the most recent checkpoint attempt, which was a user-initiated checkpoint:

% SELECT * FROM SYS.V$CKPT_HISTORY;

Builtin , 847, 1, <NULL>, <NULL>, 0, 0, 0, 0, 0, 0, 0, 0, 0, <NULL>, 7, 0, <NULL>,

< 2019-02-05 16:56:34.169520, 2019-02-05 16:56:59.715451, Fuzzy , Completed , User ,
Builtin , <NULL>, 0, 0, 8966472, 294, 33554432, 291, 5677288, 256, 522000,
532928, <NULL>, 6, 0, Checkpoint, <NULL> >

Background , <NULL>, 1, 0, 8964304, 294, 33554432, 291, 5677288, 256, 1019512,
1065408, <NULL>, 5, 0, Checkpoint, <NULL> >

< 2019-02-05 16:54:47.106110, 2019-02-05 16:54:47.723379, Static , Completed , Subdaemon ,
FinalCkpt , <NULL>, 0, 0, 8960328, 294, 33554432, 291, 5677288, 256, 3315712,
5321548, <NULL>, 4, 0, Checkpoint, <NULL> >

< 2019-02-05 16:54:41.633792, 2019-02-05 16:54:42.568469, Blocking , Completed , User ,
Builtin , <NULL>, 1, 0, 8958160, 294, 33554432, 291, 5677288, 31, 1162112,
6604976, <NULL>, 3, 0, Checkpoint, <NULL> >

< 2019-02-05 16:54:37.438827, 2019-02-05 16:54:37.977301, Static , Completed , User ,
DbCreate , <NULL>, 0, 0, 1611984, 93, 33554432, 92, 1853848, 93, 33554432,
1854052, <NULL>, 2, 0, Checkpoint, <NULL> >

< 2019-02-05 16:54:36.861728, 2019-02-05 16:54:37.438376, Static , Completed , User ,
DbCreate , <NULL>, 1, 0, 1609936, 93, 33554432, 92, 1853848, 93, 33554432,
1854052, <NULL>, 1, 0, Checkpoint, <NULL> >
Example 7–2  Understanding checkpoint history output

This example uses the `ttCkptHistory` built-in procedure to select specific columns from the checkpoint history:

```sql
% SELECT type, reason, bookmarkname, logsPurged FROM ttCkptHistory;
```

```
< Fuzzy       , BuiltIn       , Oldest Transaction Undo, 0 >
< Static      , FinalCkpt     , Checkpoint, 6 >
< Blocking    , BuiltIn       , Checkpoint, 0 >
< Blocking    , BuiltIn       , Checkpoint, 0 >
< Blocking    , BuiltIn       , Checkpoint, 0 >
< Blocking    , BuiltIn       , Backup, 5 >
< Blocking    , BuiltIn       , Backup, 0 >
< Blocking    , BuiltIn       , Backup, 0 >
```

The output from this example shows that the oldest checkpoints (the last rows displayed) did not purge any transaction log files (indicated by a 0 in the `logsPurged` column) because there was a log hold set by an incremental backup. The backup caused a transaction log file accumulation. However, eventually, the log hold was removed and five transaction log files could be purged.

A checkpoint operation is started on the fourth row from the bottom. The checkpoint places a log hold that prevents transaction log files from being purged. Six transaction log files were purged by the final checkpoint (`FinalCkpt`) operation.

The most recent checkpoint shows that it is a fuzzy checkpoint with the log hold of `Oldest Transaction Undo`. This hold marks a point for the transaction that the checkpoint log purge operation cannot pass. If you see this message over several consecutive rows, then this may indicate a long running transaction that could be causing a transaction log file accumulation.

Setting the checkpoint rate

By default, there is no limit to the rate at which checkpoint data is written to the file system. You can use the `CkptRate` connection attribute or the `ttCkptConfig` built-in procedure to set the maximum rate at which background checkpoint data is written to the file system. Checkpoints taken during recovery and final checkpoints do not honor this rate; in those situations, the rate is unlimited.

Setting a rate too low can cause checkpoints to take an excessive amount of time and cause the following problems:

- Delay the purging of unneeded transaction log files.
- Delay the start of backup operations.

Setting a rate too high can cause checkpoints to consume too much of the file system buffer cache bandwidth that could result in the following:

- Reduce overall database transaction throughput, as transaction logs are prevented from writing to the file system as quickly as they normally would.
- Cause contention with other file system I/O operations.

When choosing a rate, you should take into consideration the amount of data written by a typical checkpoint and the amount of time checkpoints usually take. Both of these
pieces of information are available through the `SYS.GV$CKPT_HISTORY` or `SYS.V$CKPT_HISTORY` system views or the `ttCkptHistory` built-in procedure.

If a running checkpoint appears to be progressing too slowly, you evaluate the progress of this checkpoint with the `Percent_Complete` column of the `SYS.GV$CKPT_HISTORY` or `SYS.V$CKPT_HISTORY` system views. The rate can be increased by calling the `ttCkptConfig` built-in procedure. If a call to `ttCkptConfig` changes the rate, the new rate takes effect immediately, affecting even the running checkpoint.

Calculate the checkpoint rate (by viewing the `SYS.GV$CKPT_HISTORY` or `SYS.V$CKPT_HISTORY` system views or calling the `ttCkptHistory` built-in procedure):

1. For any given checkpoint, subtract the `starttime` from the `endtime`.
2. Divide the number of bytes written by this elapsed time in seconds to get the number of bytes per second.
3. Divide this number by $1024 \times 1024$ to get the number of megabytes per second.

When setting the checkpoint rate, you should consider the following:

- The specified checkpoint rate is only approximate. The actual rate of the checkpoint may be below the specified rate, depending on the hardware, system load and other factors.
- The above method may underestimate the actual checkpoint rate, because the `starttime` and `endtime` interval includes other checkpoint activities in addition to the writing of dirty blocks to the checkpoint file.
- The `Percent_Complete` field may show 100 percent before the checkpoint is actually complete. The `Percent_Complete` field shows only the progress of the writing of dirty blocks and does not include additional bookkeeping at the end of the checkpoint.
- When adjusting the checkpoint rate, you may also need to adjust the checkpoint frequency, as a slower rate makes checkpoints take longer, which effectively increases the minimum time between checkpoint beginnings.

**Setting the number of checkpoint file read threads**

By default, TimesTen reads checkpoint files serially with a single thread. Use the `CkptReadThreads` connection attribute to set the number of threads that TimesTen uses to read the checkpoint files when loading the database into memory.

When using $n$ number of threads, TimesTen divides the checkpoint file into $n$ portions of equal size. Each thread concurrently reads a portion of the file into memory. Once all threads are done reading their portion of the checkpoint file successfully, TimesTen checks the database for consistency.

---

Note: For more information, see “Set CkptReadThreads” on page 10-33 in this book, and "CkptReadThreads" in the Oracle TimesTen In-Memory Database Reference.

---

**Transaction logging**

TimesTen maintains a transaction log for each database to track all updates made within each transaction, so that those updates can be undone if the transaction is rolled back. TimesTen recovers transactions using both the most recent checkpoint file and the most recent transaction log, which was written from the time of the last checkpoint operation after a system failure.
A transaction log record is created for each database modification, commit, and rollback. However, transaction log records are not generated for read-only transactions. Log records are first written to the transaction log buffer, which resides in the same shared memory segment as the database. The contents of the log buffer are then subsequently flushed to the latest transaction log file.

The transaction log is a logically ordered sequence of transaction log records, but physically consists of a set of one or more transaction log files and the in-memory log buffer within the TimesTen database. This log is shared by all concurrent connections.

The following sections describe how to manage and monitor the transaction log buffers and file:

- Managing transaction log buffers and files
- Using NFS-mounted systems for checkpoint and transaction log files
- Monitoring accumulation of transaction log files

### Managing transaction log buffers and files

The following describes how to configure transaction log buffers and files:

- **Transaction log buffers:** There is one transaction log buffer for each database and the size of the transaction log buffer can be configured using the `LogBufMB` DSN connection attribute.

  Strands divide the transaction log buffer available memory into a number of different regions, which can be accessed concurrently by different connections. The number of transaction log buffer strands is configured with the `LogBufParallelism` connection attribute. After which, each connection can execute data independent DML statements in parallel using those strands as if each has its own transaction log buffer. See "LogBufParallelism" in the *Oracle TimesTen In-Memory Database Reference* for more details.

- **Transaction log files:** The transaction log files are created in the location that the `LogDir` connection attribute specifies.

---

**Note:** The `LogDir` connection attribute is optional and if it is not specified, the transaction log files are created in the same directory as the checkpoint files. However, for best performance, TimesTen recommends that you use the `LogDir` connection attribute to place the transaction log files in a different physical device from the checkpoint files. If separated, I/O operations for checkpoints do not block I/O operations to the transaction log and vice versa.

If the database is already loaded into RAM and the transaction log files and checkpoint files for your database are on the same physical device, TimesTen writes a message to the daemon log file.

See "LogDir" in the *Oracle TimesTen In-Memory Database Reference* and "Check transaction log file use of file system space" in the *Oracle TimesTen In-Memory Database Troubleshooting Guide* for more details.

You can configure the maximum size for the transaction log files with the `LogFileSize` DSN connection attribute. The default value is 64 MB. See "LogFileSize" in the *Oracle TimesTen In-Memory Database Reference* for more details.
The transaction log file names have the form `dbname.log`. The `dbname` is the
database path name that is specified by the DataStore DSN connection attribute
and is provided within the database's DSN. The suffix `n` is the transaction log file
number, starting at zero.

When the database is created, TimesTen creates reserve files named `dbname.res0`,
`dbname.res1`, and `dbname.res2`. These files contain pre-allocated space that serves
as reserved transaction log space. Reserved transaction log space allows for a
limited continuation of transaction logging if the file system that holds the
transaction log files becomes full. If the file system that contains the transaction
logs becomes full, the database does not allow any new transactions to begin.
Transactions that are in progress are allowed to continue by using the reserve files
until they either commit or rollback. If there are transactions that are still in
progress and the reserve files are all consumed, all database operations that
generate log files are blocked.

**Using NFS-mounted systems for checkpoint and transaction log files**

To enable TimesTen checkpoint and transaction log files to be located on NFS-mounted
file systems (on Linux platforms only), ensure that `allow_network_files=1`
in the `timesten.conf` file. The `allow_network_files=1` configuration is the default
setting.

See "Optional attributes" in Chapter 1, "TimesTen Instance Configuration File" in the
*Oracle TimesTen In-Memory Database Reference* for full details.

**Monitoring accumulation of transaction log files**

It is important to verify at frequent intervals that there are no transaction log holds
that could result in an excessive accumulation of transaction log files. If too many
transaction log files accumulate and fill up available file system space, new
transactions in the TimesTen database cannot begin until the transaction log hold is
advanced and transaction log files are purged by the next checkpoint operation.

The following sections describe transaction log operations, log holds, and
accumulation of log files:

- Log holds by TimesTen components or operations
- Purging transaction log files
- Monitoring log holds and log file accumulation

**Log holds by TimesTen components or operations**

Several TimesTen components or operations can cause transaction log holds. A
transaction log hold prevents log files, beyond a certain point, from being purged until
they are no longer needed. In normal circumstances, the log hold position is regularly
advanced and log files are purged appropriately. However, if operations are not
functioning properly and the hold position does not advance, there can be an excessive
accumulation of log files beyond the hold position that can no longer be purged,
which eventually fills available file system space.

These components and operations include the following:

- Transactions writing log records to the transaction log file have been committed or
  rolled back. These can be either local database transactions or XA transactions.
- Changes recorded in the transaction log file have been written to both checkpoint
  files.
Replication: There is a transaction log hold until the transmitting replication agent confirms that the log files have been fully processed by the receiving host.

Possible failure modes include the following:

- The network is down or there is a standby crash and replication is unable to deliver data to one or more subscribers. If necessary, the application can direct that logs no longer be held, then duplicate the master database to the standby when normal operations resume. Criteria for when to do this includes the amount of time required to duplicate, the amount of available file system space on the master for log files, and the transaction log growth rate.

- The overall database transaction rate exceeds the ability of replication to keep the active and standby databases synchronized. An application can reduce the application transaction rate or the number of replicated tables.

For more information, see "Improving Replication Performance" in the Oracle TimesTen In-Memory Database Replication Guide and "Troubleshooting Replication" in the Oracle TimesTen In-Memory Database Troubleshooting Guide.

XLA: There is a transaction log hold until the XLA bookmark advances.

A possible failure mode occurs when the bookmark becomes stuck, which can occur if an XLA application terminates unexpectedly or if it disconnects without first deleting its bookmark or disabling change-tracking. If a bookmark gets too far behind, the application can delete it. If the XLA reader process is still active, it must first be terminated, so that another XLA process can connect and delete the bookmark.

Active standby pairs that replicate AWT cache groups: There is a transaction log hold until the replication agent confirms that the transaction corresponding to the log hold has been committed on the Oracle Database. With an active standby pair, the active database typically receives the confirmation from the standby database. If the standby database is down, the replication agent receives confirmation from Oracle Database directly.

Possible failure modes include the following:

- Oracle Database is down or there is a lock or resource contention.
- The network is down, slow, or saturated.
- With an active standby pair, replication to the standby database falls behind. Check log holds on the standby database.
- The transaction rate to TimesTen exceeds the maximum sustainable rate that TimesTen can propagate to Oracle Database.

For more information, see "Monitoring AWT cache groups" in the Oracle TimesTen Application-Tier Database Cache User’s Guide and "Troubleshooting AWT Cache Groups" in the Oracle TimesTen In-Memory Database Troubleshooting Guide.

Cache groups configured with AUTOREFRESH: There is a transaction log hold until the replication agent on the active database confirms the log files have been fully processed by the standby database.

Possible failure modes include the following:

- Replication from the active database to the standby database is impacted because the standby database falls behind due to large workloads resulting from AUTOREFRESH mode.
- The standby database is down or recovering, but has not been marked as FAILED through a call, initiated by either the user application or Oracle.
Clusterware, to the ttRepStateSave built-in procedure. The active database does not take over propagation to the Oracle Database until the state of the standby database is marked as FAILED. While the standby database is down or recovering, transaction log files are held for the Oracle Database.

For more information, see “Monitoring autorefresh cache groups” in the Oracle TimesTen In-Memory Database Troubleshooting Guide.

- Incremental TimesTen backup: There is a log hold until you manually run an incremental backup and until that backup completes.

The most likely failure is if you configure incremental backups (which starts TimesTen holding log files), but you do not actually run an incremental backup, which would free the log file hold.

Another possible failure mode can occur if the incremental backup falls too far behind the most recent entries in the transaction log. For example, ensure that an unexpected burst of transaction activity cannot fill up available transaction log file system space due to the backup holding a log file that is too old. An application can perform another incremental backup to work around this situation.

- Long-running transaction or XA transaction: There is a transaction log hold until the transaction commits or rolls back.

A possible failure mode can occur if an application transaction does not commit or rollback for a long time, so that it becomes necessary for the application to terminate the long-running transaction.

Alternatively, you can rollback a transaction using the ttXactAdmin utility with the -xactIdRollback option. See "ttXactAdmin" in Oracle TimesTen In-Memory Database Reference.

- Oldest transaction undo: Each transaction that has not yet committed or rolled back establishes a log hold. This hold starts with the first (oldest) log record of the transaction and marks a point for the transaction that the checkpoint log purge operation cannot pass. You can retrieve this log hold information from the SYS.GV$CKPT_HISTORY or SYS.V$CKPT_HISTORY system views or from the output of the ttCkptHistory built-in procedure.

Purging transaction log files

Any transaction log file is kept until TimesTen determines it can be purged. Under normal TimesTen operating conditions, unneeded transaction log files are purged each time a checkpoint is initiated. A checkpoint can be initiated either through a configurable time interval with the CkptFrequency connection attribute or a configurable log volume with the CkptLogVolume connection attribute. In TimesTen Classic, you can also initiate a checkpoint (either manually or in a background checkpointing application thread) with the ttCkpt built-in function.

If you are running out of file system space because of log files accumulating, use the CkptLogVolume connection attribute instead of the CkptFrequency connection attribute. In addition, you can tell if reclamation is blocked when frequently selecting from the SYS.GV$LOG_HOLDS or SYS.V$LOG_HOLDS system views or calling the ttLogHolds built-in procedure.

**Note:** To improve performance, locate your log files on a separate physical device from the one on which the checkpoint files are located. See "Managing transaction log buffers and files" on page 7-17 for more details.
See “Checkpointing” in the Oracle TimesTen In-Memory Database Introduction for general information on checkpointing. See "Configuring or turning off background checkpointing" on page 7-11 for more details on CkptFrequency and CkptLogVolume connection attributes.

For more information on log holds, see "SYS.GV$LOG_HOLDS" or "SYS.V$LOG_HOLDS" in the Oracle TimesTen In-Memory Database SQL Reference or "ttLogHolds" in the Oracle TimesTen In-Memory Database Reference.

Also, see the sections for "CkptFrequency", "CkptLogVolume", and "ttCkpt" in the Oracle TimesTen In-Memory Database Reference.

Monitoring log holds and log file accumulation

Options for periodic monitoring of excessive transaction log accumulation include the following:

- For details of all log holds, select from the SYS.GV$LOG_HOLDS or SYS.V$LOG_HOLDS system views or call the ttLogHolds built-in procedure. The information includes the following, as applicable:
  - Log file number, the offset of the hold position, and the type of hold, which can be checkpoint, replication, backup, XLA, long-running transaction, or long-running XA transaction
  - Name of the checkpoint file for a checkpoint hold
  - Name of the subscriber and the parallel track ID it uses for replication
  - Backup path for a backup hold
  - Name of the persistent subscription and process ID of the last process to open it for XLA
  - Transaction ID for a long-running transaction
  - XA XID for a long-running XA transaction

For more information, see "SYS.GV$LOG_HOLDS" or "SYS.V$LOG_HOLDS" in the Oracle TimesTen In-Memory Database SQL Reference or "ttLogHolds" in the Oracle TimesTen In-Memory Database Reference.

- Select from the SYS.GV$CKPT_HISTORY or SYS.V$CKPT_HISTORY system views or call the ttCkptHistory built-in procedure to check the last several checkpoints to confirm none of the returned rows has a status of FAILED.

For more information, see "SYS.GV$CKPT_HISTORY" or "SYS.V$CKPT_HISTORY" in the Oracle TimesTen In-Memory Database SQL Reference or "ttCkptHistory" in the Oracle TimesTen In-Memory Database Reference.

- Check the SYS.SYSTEMSTATS table for operational metrics. Each transaction log file has a unique sequence number, which starts at 0 for the first log file and increments by 1 for each subsequent log file. The number of the current log file is available in SYS.SYSTEMSTATS.log.file.latest. The number of the oldest log file not yet purged is available in SYS.SYSTEMSTATS.log.file.earliest. You should raise an error or warning if the difference in the sequence numbers exceeds an inappropriate threshold.

For more information, see “SYS.SYSTEMSTATS” in the Oracle TimesTen In-Memory Database System Tables and Views Reference.

- For XLA, check the SYS.TRANSACTION_LOG_API table that provides bookmark information, such as the process ID of the connected application, which could help diagnose the reason why a bookmark may be stuck or lagging.
Durability options

Databases in TimesTen are persistent across power failures and crashes. TimesTen accomplishes durability by periodically saving to disk:

- Checkpoint files: A checkpoint operation writes the current database image to a checkpoint file on the file system, which has the effect of making all transactions that committed before the checkpoint durable.

- Transaction log files: For transactions that committed after the last checkpoint, TimesTen uses conventional logging techniques to make them durable. As each transaction progresses, it records its database modifications in an in-memory transaction log. At commit time, the relevant portion of the transaction log is flushed to the file system. This log flush operation makes that transaction, and all previously-committed transactions, durable.

Control returns to the application after the transaction log data has been durably written to the file system. A durably committed transaction is not lost even in the event of a system failure.

Any recovery uses the last checkpoint image together with the transaction log to reconstruct the latest transaction-consistent state of the database.

When committing transactions, TimesTen reduces the performance cost for durable commits with a group commit of multiple concurrently executing transactions. TimesTen performs a single file system write operation to commit a group of concurrent transactions durably. Group commit does not improve the response time of any given commit operation, as each durable commit must wait for the file system write operation to complete, but it can significantly improve the throughput of a series of concurrent transactions.

The following sections describe the durability implementation options for TimesTen Scaleout and TimesTen Classic:

- Durability for TimesTen Scaleout
- Durability for TimesTen Classic

Durability for TimesTen Scaleout

In TimesTen Scaleout, the data in your database is distributed into elements. Each element keeps its own checkpoint and transaction log files. As a result, the data stored in each element is independently durable. Each data instance in a grid manages one element of a database. In the event of a failure, a data instance can automatically recover the data stored in its element from the checkpoint and transaction log files while the remaining data instances continue to service applications.

TimesTen Scaleout also enables you to keep multiple copies of your data to increase durability and fault tolerance. If the K-safety value is 2 or greater, then a failed element can be recovered from another element in its replica set. For more information on K-safety, see “High availability and fault tolerance” and “Creating a grid” in the Oracle TimesTen In-Memory Database Scaleout User’s Guide.

In addition, you can change the durability settings of a database according to your performance and data durability needs. For example, you may choose if data is flushed to disk with every commit or periodically in batches in order to operate at a higher performance level. The following sections describe these durability settings:
Guaranteed durability for TimesTen Scaleout

In TimesTen Scaleout, you configure how durable your transactions are with the Durability connection attribute. If you set the Durability attribute to 1, participants write durable prepare-to-commit log records and nondurable commit log records for distributed transactions. Having the Durability attribute set to 1 ensures that committed transactions are recoverable in the case of a failure. See "Durability settings" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for more information.

Non-durable distributed transactions for TimesTen Scaleout

Set the Durability connection attribute to 0 so that participants write nondurable prepare-to-commit and commit log records for distributed transactions.

K-safety provides a method for failure recovery. K-safety enables you to achieve near-continuous availability or workload distribution by providing two copies of the data. Thus, if one copy fails, another copy of the data exists.

If any element of a replica set has failed the other element in the replica set writes durable prepare-to-commit log records until the failed element recovers. This ensures that transactions in a grid with K-safety set to 2 and Durability=0 are durable under normal conditions. A transaction may become nondurable only if both elements of the replica set fail simultaneously.

TimesTen Scaleout periodically promotes transactions to epoch transactions. An epoch transaction and all transactions committed before it are more resilient to catastrophic failures, since you can recover a database to the globally consistent point marked by the epoch transaction. Each epoch commit log record is associated to a specific checkpoint file on every element. In the case of an unexpected failure of an element, the recovery process must use the checkpoint file on each element that is associated with the latest epoch commit log record, which is not necessarily the latest checkpoint available on the element.

By default, TimesTen Scaleout generates one epoch transaction every second. You can configure how often epoch transactions are automatically generated with the EpochInterval first connection attribute. In addition, you can use the ttEpochCreate or ttDurableCommit built-in procedures to manually promote a transaction to an epoch transaction.

See "Durability set to 0" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for more information on epoch transactions and how to promote a transaction to an epoch transaction.

Durability for TimesTen Classic

TimesTen Classic provides durability by using the last checkpoint image together with the transaction log to reconstruct the latest transaction-consistent state of the database. Transaction log records are written to disk asynchronously or synchronously to the completion of the transaction and controlled by the application at the transaction level.

- You can create an environment for guaranteed durability with no loss of data for those cases where data integrity must be preserved.
- You can create an environment for durability for those cases where maximum throughput is paramount but can also tolerate minimal exposure to some data loss.
TimesTen Classic replication makes data highly available to applications with minimal performance impact. Replication enables you to achieve near-continuous availability or workload distribution by sending updates between two or more hosts. A master host is configured to asynchronously send updates and a subscriber host is configured to receive them.

**Note:** For the highest availability for TimesTen Classic, use the active standby pair replication scheme configuration. See "Active standby pair with read-only subscribers" in the *Oracle TimesTen In-Memory Database Replication Guide* for details on active standby pair replication schemes.

With an Asynchronous WriteThrough (AWT) cache group, TimesTen Cache transmits committed updates between the TimesTen cache tables and the cached Oracle Database tables to keep these tables in the two databases synchronized. See "Asynchronous WriteThrough (AWT) cache group" in the *Oracle TimesTen Application-Tier Database Cache User's Guide* for details on asynchronous writethrough cache groups.

- Guaranteed durability for TimesTen Classic
- Nondurable transactions for TimesTen Classic

**Guaranteed durability for TimesTen Classic**

Guaranteed durability ensures that there is no loss of data (at the cost of some performance) for those cases where data integrity must be preserved.

To guarantee durability for all transactions, you should do at least one of the following. (There is very little advantage in using both of these options.)

- Use replication enabled with the return twosafe service to replicate transactions. The return twosafe service provides a fully synchronous option by blocking the application until replication confirms that the update has been both received and committed on the subscriber before it is committed on the master. This provides applications a higher level of confidence that the effects of a committed transaction are durable, even if the master subsequently fails. This option is normally faster than the durable commit. See "Return twosafe replication" *Oracle TimesTen In-Memory Database Replication Guide* for more details.

- Configure durable commit operations by setting the `DurableCommits` connection attribute to 1, which ensures that the transaction is synchronously written to the transaction log file while the application waits. See "DurableCommits" in the *Oracle TimesTen In-Memory Database Reference* for more information on this connection attribute.

**Note:** If most of your transactions commit durably, you may want to set the `LogFlushMethod` first connection attribute to 1. This connection attribute configures how TimesTen writes and synchronizes log data to transaction log files. For more information, see "Use durable commits appropriately" on page 10-30.
Nondurable transactions for TimesTen Classic

Nondurable transactions execute considerably faster than durable transactions. Connections that use nondurable transactions can coexist with connections that use guaranteed durability.

As with guaranteed durability, each transaction enters records into the in-memory transaction log buffer as it makes modifications to the database. However, when a transaction commits in nondurable mode, it does not wait for the transaction log buffer to be written to the file system before returning control to the application. Thus, unless you have configured asynchronous replication or an asynchronous writethrough cache group, a nondurable transaction may be lost in the event of a database failure. Eventually, transactions are flushed to the file system into the transaction log files by the database subdaemon process or when the in-memory transaction log buffer is full.

If your transactions require extremely high throughput with minimal exposure to data loss, then consider doing BOTH of these options:

- Use one of these methods to perform an asynchronous write operation of your data to another database: a TimesTen database or an Oracle database.
  - Use the default asynchronous replication that replicates committed transactions from the master to the subscriber. With the default asynchronous replication, an application updates a master database and continues working without waiting for the updates to be received and applied by the subscribers. While asynchronous replication provides the best performance, it does not provide the application with confirmation that the replicated updates were committed on subscriber databases. See “Copying updates between databases” Oracle TimesTen In-Memory Database Replication Guide for more details.
  - Set up an Asynchronous WriteThrough (AWT) cache group to cause committed updates on TimesTen cache tables to be automatically and asynchronously propagated to the cached Oracle Database tables. A transaction commit operation on the TimesTen database occurs asynchronously from the commit on the Oracle database. This enables an application to continue issuing transactions on the TimesTen database without waiting for the Oracle Database transaction to complete. However, your application cannot ensure when the transactions are completed on the Oracle database. See "Asynchronous WriteThrough (AWT) cache group" in the Oracle TimesTen Application-Tier Database Cache User’s Guide for details on AWT cache groups.

- Configure for nondurable transactions by setting the DurableCommits connection attribute to 0, which asynchronously writes nondurable commit log records to the transaction log file.
  
  See "DurableCommits" in the Oracle TimesTen In-Memory Database Reference for more information.

The only transactions vulnerable to loss in the event of a system failure are those that committed non-durably after the last durable commit and were not replicated prior to the failure.

However, if you have critical transactions that cannot be exposed to any data loss, you can either:

- Replicate those transactions synchronously from the master database to the subscriber database by running the ttRepSubscriberWait built-in procedure.
Running the `ttRepSubscriberWait` built-in procedure on the master database using the DSN and host of the subscriber database causes the caller to wait until all transactions that committed before the call have been transmitted to the subscriber. See "ttRepSubscriberWait" in the *Oracle TimesTen In-Memory Database Reference* for more information.

- Force the individual transactions to commit durably to the transaction log files with the `ttDurableCommits` built-in procedure. Committing a transaction durably makes that transaction and all previous transactions durable. However, this does not wait for the transaction to be replicated.

When a durable commit is needed, the application can call the `ttDurableCommit` built-in procedure before committing. The `ttDurableCommit` built-in procedure does not actually commit the transaction; it merely causes the commit to be durable when it occurs.

This maintains a smaller window of vulnerability to transaction loss as opposed to all transactions being committed non-durably. By committing only every \( n \)th transaction durably or performing a durable commit every \( n \) seconds, an application can achieve a quicker response time while maintaining a small window of vulnerability to transaction loss. A user can elect to perform a durable commit of a critical transaction, such as one that deals with financial exchange, that cannot be vulnerable to loss.

See "ttDurableCommit" in the *Oracle TimesTen In-Memory Database Reference* for more information.

**Transaction reclaim operations**

After a transaction is marked by TimesTen as committed, there is a *reclaim* phase of the commit.

- About reclaim operations
- Configuring the commit buffer for reclaim operations

**About reclaim operations**

TimesTen resource cleanup occurs during the reclaim phase of a transaction commit. Consider a transaction with `DELETE` operations, for example. The SQL operation marks the deleted rows as deleted, but the space occupied by these rows are not actually freed until the reclaim phase of the transaction commit.

During reclaim, TimesTen reexamines all the transaction log records starting from the beginning of the transaction to determine the reclaim operations that must be performed, then performs those operations.

To improve performance, a number of transaction log records can be cached to reduce the need to access the transaction log files. This cache is referred to as the commit buffer and its size is configurable, as described in the next section, "Configuring the commit buffer for reclaim operations".
Configuring the commit buffer for reclaim operations

The reclaim phase of a large transaction commit results in a large amount of processing and is very resource intensive. (For this reason, smaller transactions are generally recommended.) You can improve performance, however, by increasing the maximum size of the commit buffer, which is the cache of transaction log records used during reclaim operations.

You can use the TimesTen \texttt{CommitBufferSizeMax} connection attribute to specify the maximum size of the commit buffer, in megabytes. This setting has the scope of your current session. For efficiency, initial memory allocation will be significantly less than the maximum, but will automatically increase as needed in order to fit all the relevant log records into the commit buffer, until the allocation reaches the maximum. The allocation is then reduced back to the initial allocation after each reclaim phase. By default, the maximum is 128 KB with an initial allocation of 16 KB. See "CommitBufferSizeMax" in \textit{Oracle TimesTen In-Memory Database Reference} for more information.

Be aware that an increase in the maximum size of the commit buffer may result in a corresponding increase in temporary space consumption. There is no particular limit to the maximum size you can specify, aside from the maximum value of an integer, but exceeding the available temporary space will result in an error.

Note the following related features:

- During the course of a session, you can use \texttt{ALTER SESSION} to change the maximum size of the commit buffer as follows, where \( n \) is the desired maximum, in megabytes. See "ALTER SESSION" in \textit{Oracle TimesTen In-Memory Database SQL Reference} for more information.

\begin{verbatim}
ALTER SESSION SET COMMIT_BUFFER_SIZE_MAX = n
\end{verbatim}

- You can use the \texttt{ttCommitBufferStats} built-in procedure to gather statistics for your connection to help you tune the commit buffer maximum size. This built-in takes no parameters and returns the total number of commit buffer overflows and the highest amount of memory used by reclaim operations for transaction log records, in bytes. If there are buffer overflows, you may consider increasing the commit buffer maximum size. If there are no overflows and the highest amount of

Notes:

- The reclaim phase occurs as part of commit processing. Thus, once the reclaim phase has begun, the transaction is considered to be committed and can no longer be rolled back.

- If an application is terminated during the reclaim phase, the cleanup operation completes the reclaim.

Note: It is not recommended that you perform an extremely large transaction commit (such as 1 million rows) as it is very resource intensive. In case that you are committing an extremely large transaction, do not cancel this transaction as it could cause the transaction to take even longer to complete. This is due to the fact that if you cancel a transaction while it has not completed, TimesTen has to perform rollback operations.
memory usage is well under the commit buffer maximum size, you may consider decreasing the maximum size.

In TimesTen Classic, you can use the `ttCommitBufferStatsReset` built-in procedure to reset these statistics to 0 (zero). This is useful, for example, if you have set a new value for the commit buffer maximum size and want to restart the statistics.

See "ttCommitBufferStats" and "ttCommitBufferStatsReset" in Oracle TimesTen In-Memory Database Reference for more information.

- The system-wide number of commit buffer overflows is also recorded in the TimesTen statistic `txn.commits.buf.overflowed` in the `SYS.SYSTEMSTATS` table. See "SYS.SYSTEMSTATS" in Oracle TimesTen In-Memory Database System Tables and Views Reference for more information.

- You can check the current setting of `CommitBufferSizeMax` by calling the `ttConfiguration` built-in procedure.

## Recovery with checkpoint and transaction log files

If a database becomes invalid or corrupted by a system or process failure, every connection to the database is invalidated. When an application reconnects to a failed database, the subdaemon allocates a new memory segment for the database and recovers its data from the checkpoint and transaction log files.

During recovery, the latest checkpoint file is read into memory. All transactions that have been committed since the last checkpoint and whose log records are on the file system are rolled forward from the appropriate transaction log files. Note that such transactions include all transactions that were committed durably as well as all transactions whose log records aged out of the in-memory log buffer. Uncommitted or rolled-back transactions are not recovered. See "Checkpoint operations" on page 7-9, "Transaction logging" on page 7-16 and "Error, warning, and informational messages" on page 4-10 for details on checkpoint and transaction log files.
This chapter provides detailed information on the basic objects in a TimesTen database and simple examples of how you can use SQL to manage these objects. For more information about SQL, see the *Oracle TimesTen In-Memory Database SQL Reference*. For information on how to issue SQL from within an application, see the appropriate TimesTen developer’s guide.

This chapter includes the following topics:

- Database overview
- Understanding tables
- Understanding views
- Understanding materialized views
- Understanding indexes
- Understanding rows
- Understanding synonyms
- Understanding system views

**Database overview**

The following sections describe the main TimesTen database objects and features:

- Database objects
- Database users and owners

**Database objects**

A TimesTen database has the following permanent objects:

- **Tables**. The primary objects of a TimesTen database are the tables that contain the application data. See "Understanding tables" on page 8-2 for more information.

- **Materialized Views**. Read-only tables that hold a summary of data selected from one or more "regular" TimesTen tables. See "Understanding materialized views" on page 8-12 for more information.

- **Views**. Logical tables that are based on one or more tables called *detail tables*. A view itself contains no data. See "Understanding views" on page 8-10 for more information.
Indexes. Indexes on one or more columns of a table may be created for faster access to tables. See "Understanding indexes" on page 8-16 for more information.

Rows. Every table consists of 0 or more rows. A row is a formatted list of values. See "Understanding rows" on page 8-26 for more information.

Synonyms. Aliases for a database object. Synonyms are often used for security and convenience, because they can be used to mask object name and object owner. See "Understanding synonyms" on page 8-27 for more information.

System tables and views. System tables and views contain TimesTen metadata, such as a table of all tables. See “System tables” on page 8-5 and "Understanding system views" on page 8-29 for more information.

There are also many temporary objects, including prepared commands, cursors and locks.

Database users and owners

TimesTen authenticates user names with passwords. Applications should choose one UID for the application itself because by default the login name that is being used to run the application becomes the owner of objects in the database. If you omit the UID connection attribute in the connection string, TimesTen uses the current user's login name. TimesTen converts all user names to upper case characters. Ensure that you use the fully qualified name of a database object, for example owner.table_name, whenever you issue a SQL statement.

Users cannot access TimesTen databases as user SYS. TimesTen determines the user name by the value of the UID connection attribute, or if not present, then by the login name of the connected user. If a user's login is SYS, set the UID connection to override the login name.

Understanding tables

A TimesTen table consists of rows that have a common format or structure. This format is described by the table's columns.

The following sections describes tables, its columns and how to manage them:

- Overview of tables
- Working with tables
- Implementing aging in your tables

Overview of tables

This section includes the following topics:

- Column overview
- Inline and out-of-line columns
- Default column values
- Table names
- Table access
- Primary keys, foreign keys and unique indexes
- Tables in TimesTen Scaleout
Understanding tables

Column overview
When you create the columns in the table, the column names are case-insensitive.
Each column has the following:

- A data type
- Optional nullability, primary key and foreign key properties
- An optional default value

Unless you explicitly declare a column NOT NULL, columns are nullable. If a column in a table is nullable, it can contain a NULL value. Otherwise, each row in the table must have a non-NULL value in that column.

The format of TimesTen columns cannot be altered. It is possible to add or remove columns but not to change column definitions. To add or remove columns, use the ALTER TABLE statement. To change column definitions, an application must first drop the table and then recreate it with the new definitions.

Inline and out-of-line columns
The in-memory layout of the rows of a table is designed to provide fast access to rows while minimizing wasted space. TimesTen designates each VARBINARY, NVARCHAR2 and VARCHAR2 column of a table as either inline or out-of-line.

- An inline column has a fixed length. All values of fixed-length columns of a table are stored row wise.
- A not inline column (also referred to as an out-of-line column) has a varying length. Some VARCHAR2, NVARCHAR2 or VARBINARY data type columns are stored out-of-line. Out-of-line columns are not stored contiguously with the row but are allocated. By default, TimesTen stores VARCHAR2, NVARCHAR2 and VARBINARY columns whose declared column length is > 128 bytes as out-of-line. In addition, all LOB data types are stored out-of-line. By default, TimesTen stores variable-length columns whose declared column length is <= 128 bytes as inline.

Most operations are slightly slower when performed on an out-of-line column instead of an inline column. There are several performance considerations when you use out-of-line columns instead of inline columns:

- Accessing data is slower because TimesTen does not store data from out-of-line columns contiguously with the row.
- Populating data is slower because TimesTen generates more logging operations.
- Deleting data is slower because TimesTen performs more reclaim and logging operations. If you are deleting a large number of rows (100,000 or more) consider using multiple smaller DELETE FROM statements, or the DELETE FIRST clause. For more information, see "Avoid large DELETE statements" on page 10-32.

The maximum sizes of inline and out-of-line portions of a row are listed in "Using the ttlsql tablesize command" on page 6-11.

Default column values
When you create a table, you can specify default values for the columns. The default value you specify must be compatible with the data type of the column. You can specify one of the following default values for a column:

- NULL for any column type
A constant value

SYSDATE for DATE and TIMESTAMP columns

USER for CHAR columns

CURRENT_USER for CHAR columns

SYSTEM_USER for CHAR columns

If you use the DEFAULT clause of the CREATE TABLE statement but do not specify the default value for one or more columns, those default values for those columns are NULL. See "CREATE TABLE" in the Oracle TimesTen In-Memory Database SQL Reference.

Table names

A TimesTen table is identified uniquely by its owner name and table name. Every table has an owner. By default, TimesTen defines the owner as the user who created the table. Tables created by TimesTen, such as system tables, have the owner name SYS or TTREP.

To uniquely refer to a table, specify both its owner and name separated by a period ("."), such as MARY.PAYROLL. If an application does not specify an owner, TimesTen looks for the table under the user name of the caller, then under the user name SYS.

A name is an alphanumeric value that begins with a letter. A name can include underscores. The maximum length of a table name is 30 characters. The maximum length of an owner name is also 30 characters. TimesTen displays all table, column and owner names to upper case characters. See "Names, Namespace and Parameters" in the Oracle TimesTen In-Memory Database SQL Reference for additional information.

Table access

Applications access tables through SQL statements. The TimesTen query optimizer automatically chooses the optimal way to access tables. It uses existing indexes or, if necessary, creates temporary indexes to speed up access. For improved performance, applications should explicitly create indexes for frequently searched columns because the automatic creation and destruction of temporary indexes incurs a performance overhead. For more details, see "Tune statements and use indexes" on page 10-13. You can use optimizer hints (statement or transaction level) to tune the TimesTen execution plan for a specific application. For more information on optimizer hints, see "Use optimizer hints to modify the execution plan" on page 9-15.

Primary keys, foreign keys and unique indexes

You can create a primary key on one or more columns to indicate that duplicate values for that set of columns should be rejected. Primary key columns must be declared NOT NULL. A table can have at most one primary key. TimesTen automatically creates a range index on the primary key to enforce uniqueness on the primary key and to improve access speeds through the primary key. Once a row is inserted, its primary key columns cannot be modified, except to change a range index to a hash index.

Note: Indexes are discussed in "Understanding indexes" on page 8-16.

Although a table may have only one primary key, additional uniqueness properties may be added to the table using unique indexes. See "CREATE INDEX" in the Oracle TimesTen In-Memory Database SQL Reference for more information.
Understanding tables

A table may also have one or more foreign keys through which rows correspond to rows in another table. Foreign keys relate to a primary key or uniquely indexed columns in the other table. Foreign keys use a range index on the referencing columns. See “CREATE TABLE” in the Oracle TimesTen In-Memory Database SQL Reference for more information.

Tables in TimesTen Scaleout
In TimesTen Scaleout, tables are the objects used to define how to distribute data in your database. TimesTen Scaleout manages the distribution of data according to the defined distribution scheme of the table. When you create the table, it exists on every element of the database. Rows of data in the table exist on different elements of the database. See “Working with tables” in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for more information.

System tables
In addition to tables created by applications, a TimesTen database contains system tables. System tables contain TimesTen metadata such as descriptions of all tables and indexes in the database, as well as other information such as optimizer plans. Applications may query system tables just as they query user tables. Applications may not directly update system tables. TimesTen system tables are described in the “System Tables and Views” chapter in the Oracle TimesTen In-Memory Database System Tables and Views Reference.

Working with tables
To perform any operation that creates, drops or manages a table, the user must have the appropriate privileges, which are described along with the syntax for all SQL statements in the "SQL Statements” chapter in the Oracle TimesTen In-Memory Database SQL Reference.

This section includes the following topics:

- Creating a table
- Dropping a table
- Estimating table size

Creating a table
To create a table, use the SQL statement CREATE TABLE. The syntax for all SQL statements is provided in the Oracle TimesTen In-Memory Database SQL Reference. TimesTen converts table names to upper case characters.

Example 8–1 Create a table
The following SQL statement creates a table, called customer, with two columns: cust_id and cust_name of two different data types.
Command> CREATE TABLE customer (cust_id TT_INTEGER, cust_name VARCHAR2(50));

**Example 8–2  Create a table with a hash index**

This example creates a table, called `customer`, with the columns: `cust_id`, `cust_name`, `addr`, `zip`, and `region`. The `cust_id` column is designated as the primary key, so that the `CustId` value in a row uniquely identifies that row in the table, as described in "Primary keys, foreign keys and unique indexes" on page 8-4.

The `UNIQUE HASH ON custId PAGES` value indicates that there are 30 pages in the hash index. This means that the expected number of rows in the table is 30 * 256 = 7680. If the table ends up with significantly more rows than this, performance can be degraded, and the hash index should be resized. For more details on pages in a hash index, see information for `SET PAGES` in the "ALTER TABLE" section in the Oracle TimesTen In-Memory Database SQL Reference. For details on how to size pages in a hash table, see "Size hash indexes appropriately" on page 10-18.

Command> CREATE TABLE customer (cust_id NUMBER NOT NULL PRIMARY KEY, cust_name CHAR(100) NOT NULL, addr CHAR(100), zip NUMBER, region CHAR(10)) UNIQUE HASH ON (cust_id) PAGES = 30;

**Dropping a table**

To drop a TimesTen table, call the SQL statement `DROP TABLE`.

**Example 8–3  Drop a table**

The following example drops the table `customer`.

Command> DROP TABLE customer;

**Estimating table size**

Increasing the size of a TimesTen database can be done on first connect. To avoid having to increase the size of a database, it is important not to underestimate the eventual database size. Use the `ttSize` utility to estimate table size.

The following example shows that the `ttSize` utility estimates the rows, inline row bytes, size of any indexes on the table, and the total size of the table:

```
% ttSize -tbl pat.tab1 mydb
Rows = 2
Total in-line row bytes = 17524
Indexes:
   Index PAT adds 6282 bytes
      Total index bytes = 6282

Total = 23806
```

You can also calculate the size of an existing table with the `ttIsql tablesize` command. For more information, see "Using the `ttIsql tablesize` command" on page 6-11.
Implementing aging in your tables

You can define an aging policy for one or more tables in your database. An aging policy refers to the type of aging and the aging attributes, as well as the aging state (ON or OFF). You can specify one of the following types of aging policies: usage-based or time-based. Usage-based aging removes least recently used (LRU) data within a specified database usage range. Time-based aging removes data based on the specified data lifetime and frequency of the aging process. You can define only one type of aging for a specified table.

You can define an aging policy for a new table with the CREATE TABLE statement. You can add an aging policy to an existing table with the ALTER TABLE statement if the table does not already have an aging policy defined. You can change the aging policy by dropping aging and adding a new aging policy.

You cannot specify aging on the following types of tables:

- Global temporary tables
- Detail tables of materialized views

You can also implement aging in cache groups. See "Implementing aging in a cache group" in the Oracle TimesTen Application-Tier Database Cache User’s Guide.

Note: There is no support to specify aging policies for tables within TimesTen Scaleout. See "Comparison between TimesTen Scaleout and TimesTen Classic" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for details.

This section includes the following topics:

- Usage-based aging
- Time-based aging
- Aging and foreign keys
- Scheduling when aging starts
- Aging and replication

Usage-based aging

Usage-based aging enables you to maintain the amount of memory used in a database within a specified threshold by removing the least recently used (LRU) data.

Define LRU aging for a new table by using the AGING LRU clause of the CREATE TABLE statement. Aging begins automatically if the aging state is ON.

Call the ttAgingLRUConfig built-in procedure to specify the LRU aging attributes. The attribute values apply to all tables in the database that have an LRU aging policy. If you do not call the ttAgingLRUConfig built-in procedure, then the default values for the attributes are used.

Note: The ttAgingLRUConfig built-in procedure requires that the user have ADMIN privilege if you want to modify any attributes. You do not need any privileges for viewing existing attributes. For more information, see "Built-In Procedures" in the Oracle TimesTen In-Memory Database Reference.
The following table summarizes the LRU aging attributes:

<table>
<thead>
<tr>
<th>LRU Aging Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LowUsageThreshold</td>
<td>The percent of the database PermSize at which LRU aging is deactivated.</td>
</tr>
<tr>
<td>HighUsageThreshold</td>
<td>The percent of the database PermSize at which LRU aging is activated.</td>
</tr>
<tr>
<td>AgingCycle</td>
<td>The number of minutes between aging cycles.</td>
</tr>
</tbody>
</table>

If you set a new value for AgingCycle after an LRU aging policy has already been defined, aging occurs based on the current time and the new cycle time. For example, if the original aging cycle is 15 minutes and LRU aging occurred 10 minutes ago, aging is expected to occur again in 5 minutes. However, if you change the AgingCycle parameter to 30 minutes, then aging occurs 30 minutes from the time you call the ttAgingLRUConfig procedure with the new value for AgingCycle.

If a row has been accessed or referenced since the last aging cycle, it is not eligible for LRU aging. A row is considered to be accessed or referenced if one of the following is true:

- The row is used to build the result set of a SELECT statement.
- The row has been flagged to be updated or deleted.
- The row is used to build the result set of an INSERT SELECT statement.

You can use the ALTER TABLE statement to perform the following tasks:

- Enable or disable the aging state on a table that has an aging policy defined by using the ALTER TABLE statement with the SET AGING {ON | OFF} clause.
- Add an LRU aging policy to an existing table by using the ALTER TABLE statement with the ADD AGING LRU {ON | OFF} clause.
- Drop aging on a table by using the ALTER TABLE statement with the DROP AGING clause.

Call the ttAgingScheduleNow built-in procedure to schedule when aging starts. For more information, see “Scheduling when aging starts” on page 8-10.

To change aging from LRU to time-based on a table, first drop aging on the table by using the ALTER TABLE statement with the DROP AGING clause. Then add time-based aging by using the ALTER TABLE statement with the ADD AGING USE clause.

**Note:** When you drop LRU aging or add LRU aging to tables that are referenced in commands, TimesTen marks the compiled commands invalid. The commands need to be recompiled.

---

**Time-based aging**

Time-based aging removes data from a table based on the specified data lifetime and frequency of the aging process. Specify a time-based aging policy for a new table with the AGING USE clause of the CREATE TABLE statement. Add a time-based aging policy to an existing table with the ADD AGING USE clause of the ALTER TABLE statement.

The AGING USE clause has a ColumnName argument. ColumnName is the name of the column that is used for time-based aging, also called the *timestamp column*. The timestamp column must be defined as follows:
Understanding tables

- ORA_TIMESTAMP, TT_TIMESTAMP, ORA_DATE or TT_DATE data type
- NOT NULL

Your application updates the values of the timestamp column. If the value of this column is unknown for some rows and you do not want the rows to be aged, then define the column with a large default value. You can create an index on the timestamp column for better performance of the aging process.

**Note:** You cannot add or modify a column in an existing table and then use that column as a timestamp column because you cannot add or modify a column and define it to be NOT NULL.

You cannot drop the timestamp column from a table that has a time-based aging policy.

If the data type of the timestamp column is ORA_TIMESTAMP, TT_TIMESTAMP, or ORA_DATE, you can specify the lifetime in days, hours, or minutes in the LIFETIME clause of the CREATE TABLE statement. If the data type of the timestamp column is TT_DATE, specify the lifetime in days.

The value in the timestamp column is subtracted from SYSDATE. The result is truncated the result using the specified unit (minute, hour, day) and compared with the specified LIFETIME value. If the result is greater than the LIFETIME value, then the row is a candidate for aging.

Use the CYCLE clause to indicate how often the system should examine the rows to remove data that has exceeded the specified lifetime. If you do not specify CYCLE, aging occurs every five minutes. If you specify 0 for the cycle, then aging is continuous. Aging begins automatically if the state is ON.

Use the ALTER TABLE statement to perform the following tasks:
- Enable or disable the aging state on a table with a time-based aging policy by using the SET AGING {ON | OFF} clause.
- Change the aging cycle on a table with a time-based aging policy by using the SET AGING CYCLE clause.
- Change the lifetime by using the SET AGING LIFETIME clause.
- Add time-based aging to an existing table with no aging policy by using the ADD AGING USE clause.
- Drop aging on a table by using the DROP AGING clause.

Call the ttAgingScheduleNow built-in procedure to schedule when aging starts. For more information, see "Scheduling when aging starts" on page 8-10.

To change the aging policy from time-based aging to LRU aging on a table, first drop time-based aging on the table. Then add LRU aging by using the ALTER TABLE statement with the ADD AGING LRU clause.

**Aging and foreign keys**
Tables that are related by foreign keys must have the same aging policy.
- If LRU aging is in effect and a row in a child table is recently accessed, then neither the parent row nor the child row is deleted.
- If time-based aging is in effect and a row in a parent table is a candidate for aging out, then the parent row and all of its children are deleted.
■ If a table has ON DELETE CASCADE enabled, the setting is ignored.

**Scheduling when aging starts**

Call the ttAgingScheduleNow built-in procedure to schedule the aging process. The aging process starts as soon as you call the procedure unless there is already an aging process in progress, in which case it begins when that aging process has completed.

When you call ttAgingScheduleNow, the aging process starts regardless of whether the state is ON or OFF.

The aging process starts only once as a result of calling ttAgingScheduleNow does not change the aging state. If the aging state is OFF when you call ttAgingScheduleNow, then the aging process starts, but it does not continue after the process is complete. To continue aging, you must call ttAgingScheduleNow again or change the aging state to ON.

If the aging state is already set to ON, then ttAgingScheduleNow resets the aging cycle based on the time ttAgingScheduleNow was called.

You can control aging externally by disabling aging by using the ALTER TABLE statement with the SET AGING OFF clause. Then use ttAgingScheduleNow to start aging at the desired time.

Use ttAgingScheduleNow to start or reset aging for an individual table by specifying its name when you call the procedure. If you do not specify a table name, then ttAgingScheduleNow starts or resets aging on all of the tables in the database that have aging defined.

**Aging and replication**

For active standby pairs, implement aging on the active master database. Deletes that occur as a result of aging are replicated to the standby master database and the read-only subscribers. If a failover to the standby master database occurs, aging is enabled on the database after its role changes to ACTIVE.

For all other types of replication schemes, implement aging separately on each node. The aging policy must be the same on all nodes.

If you implement LRU aging on a multimaster replication scheme used as a hot standby, LRU aging may provide unintended results. After a failover, you may not have all of the desired data because aging occurs locally.

**Understanding views**

A view is a logical table that is based on one or more tables. The view itself contains no data. It is sometimes called a non-materialized view to distinguish it from a materialized view, which does contain data that has already been calculated from detail tables. Views cannot be updated directly, but changes to the data in the detail tables are immediately reflected in the view.

A view is basically a SQL statement that is stored in a database which enables you to treat the results of a SQL query as a table itself. TimesTen generates the results of a view every time you query that view, so a view always has the latest data results. You can query a view just like you would query a regular table.

A materialized view enables you to precompute expensive SQL operations. There are cases where primarily read-only databases can increase the speed of their SELECT operations by precomputing the results of queries and storing them in a materialized view. The downside in this case is that the materialized view requires additional
storage space. Keep in mind that when you perform DML operations on the detail
tables of a materialized view, these DML operations are more resource intensive and
more storage is required to store the materialized view rows. If you use too many
materialized views on a table, this may reduce the performance of that table.

To perform any operation that creates, drops or manages a view, the user must have
the appropriate privileges, which are described along with the syntax for all SQL
statements in the "SQL Statements" chapter in the *Oracle TimesTen In-Memory Database
SQL Reference*.

This section includes the following topics:

- Creating a view
- Dropping a view
- Restrictions on views and detail tables

### Creating a view

To create a view, use the `CREATE VIEW` SQL statement. The syntax for all SQL
statements is provided in the "SQL Statements" chapter in the *Oracle TimesTen
In-Memory Database SQL Reference*.

```
CREATE VIEW ViewName AS SelectQuery;
```

This selects columns from the detail tables to be used in the view.

For example, create a view from the table `t1`:

```
Command> CREATE VIEW v1 AS SELECT * FROM t1;
```

Now create a view from an aggregate query on the table `t1`:

```
Command> CREATE VIEW v1 (max1) AS SELECT max(x1) FROM t1;
```

### The SELECT query in the CREATE VIEW statement

The `SELECT` query used to define the contents of a materialized view is similar to the
top-level SQL `SELECT` statement described in "SQL Statements" in the *Oracle TimesTen
In-Memory Database SQL Reference*, with the following restrictions:

- A `SELECT *` query in a view definition is expanded at view creation time. Any
columns added after a view is created do not affect the view.
- The following cannot be used in a `SELECT` statement that is creating a view:
  - DISTINCT
  - FIRST
  - ORDER BY
  - Arguments
  - Temporary tables

Each expression in the select list must have a unique name. A name of a simple
column expression would be that column's name unless a column alias is defined.
`RowId` is considered an expression and needs an alias.

- No `SELECT FOR UPDATE` or `SELECT FOR INSERT` statements can be used on a view.
- Certain TimesTen query restrictions are not checked when a non-materialized
  view is created. Views that violate those restrictions may be allowed to be created,
but an error is returned when the view is referenced later in an executed statement.

**Dropping a view**

The `DROP VIEW` statement deletes the specified view.

The following statement drops the `cust_order` view:

```
Command> DROP VIEW cust_order;
```

**Restrictions on views and detail tables**

Views have the following restrictions:

- When a view is referenced in the `FROM` clause of a `SELECT` statement, its name is replaced by its definition as a derived table during SQL compilation. The content of the derived table is said to be **materialized**, but this materialization is temporary and only exists for the duration of the SQL statement. For example, if both the view and the referencing select specify aggregates, the view is **materialized** before its result can be joined with other tables of the select.

- A view cannot be dropped with a `DROP TABLE` statement. You must use the `DROP VIEW` statement.

- A view cannot be altered with an `ALTER TABLE` statement.

- Referencing a view can fail due to dropped or altered detail tables.

**Understanding materialized views**

The following sections describes materialized views and how to manage them:

- **Overview of materialized views**
- **Working with materialized views**

**Overview of materialized views**

A materialized view is a read-only table that maintains a summary of data selected from one or more regular TimesTen tables. The TimesTen tables queried to make up the result set for the materialized view are called detail tables.

**Note:** Materialized views are not supported on cache tables.

Figure 8–1 shows a materialized view created from detail tables. An application updates the detail tables and can select data from the materialized view.
The synchronous materialized view updates the result set data from the detail tables at the time of the detail table transaction. Every time data is updated in the detail tables, the result set is updated. Thus, the materialized view is never out of sync with the detail tables. However, this can affect your performance. A single transaction, the user transaction, executes the updates for both the detail table and any materialized views.

In TimesTen Scaleout, materialized views provide a second mechanism for distributing rows of data. Also, materialized views in TimesTen Scaleout are useful as global indexes to reduce or eliminate multi-element access (broadcasts). See "Understanding materialized views" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for more information on using materialized views in TimesTen Scaleout.

**Working with materialized views**

This section includes the following topics:

- Creating a materialized view
- Dropping a materialized view
- Restrictions on materialized views and detail tables
- Performance implications of materialized views

**Creating a materialized view**

To create a materialized view, use the SQL statement `CREATE MATERIALIZED VIEW`. 
Understanding materialized views

Note: In order to create a materialized view, the user must have the appropriate privileges, which are described along with the syntax for all SQL statements in the "SQL Statements" chapter in the Oracle TimesTen In-Memory Database SQL Reference.

If the owner has these privileges revoked for any of the detail tables on which the materialized view is created, the materialized view becomes invalid. See "Object privileges for materialized views" in the Oracle TimesTen In-Memory Database Security Guide.

When creating a materialized view, you can establish primary keys and the size of the hash table in the same manner as described for tables in "Primary keys, foreign keys and unique indexes" on page 8-4.

The materialized view examples are based on the following two tables:

Command> CREATE TABLE customer
(cust_id INT NOT NULL,
cus_name CHAR(100) NOT NULL,
addr CHAR(100),
zip INT,
region CHAR(10),
PRIMARY KEY (cust_id));

CREATE TABLE book_order
(order_id INT NOT NULL,
cust_id INT NOT NULL,
book CHAR(100),
PRIMARY KEY (order_id),
FOREIGN KEY (cust_id) REFERENCES customer(cust_id));

The following sections provide details and examples for creating materialized views:

- Creating a synchronous materialized view
- The SELECT query in the CREATE MATERIALIZED VIEW statement

Creating a synchronous materialized view  A synchronous materialized view is automatically updated each time the detail tables are updated. You can create a synchronous materialized view with the CREATE MATERIALIZED VIEW statement.

The following creates a synchronous materialized view, named sample_mv, that generates a result set from selected columns in the customer and book_order detail tables described above.

Command> CREATE MATERIALIZED VIEW sample_mv AS
SELECT customer.cust_id, cust_name, order_id, book
FROM customer, book_order
WHERE customer.cust_id=book_order.cust_id;

The SELECT query in the CREATE MATERIALIZED VIEW statement  The SELECT query used to define the contents of a materialized view is similar to the top-level SQL SELECT statement described in "SQL Statements" in the Oracle TimesTen In-Memory Database SQL Reference with some restrictions, which are described in "CREATE MATERIALIZED VIEW" in the Oracle TimesTen In-Memory Database SQL Reference.

Dropping a materialized view
To drop any materialized view, issue the DROP VIEW statement.

Note: In order to create a materialized view, the user must have the appropriate privileges, which are described along with the syntax for all SQL statements in the "SQL Statements" chapter in the Oracle TimesTen In-Memory Database SQL Reference.

If the owner has these privileges revoked for any of the detail tables on which the materialized view is created, the materialized view becomes invalid. See "Object privileges for materialized views" in the Oracle TimesTen In-Memory Database Security Guide.

When creating a materialized view, you can establish primary keys and the size of the hash table in the same manner as described for tables in "Primary keys, foreign keys and unique indexes" on page 8-4.

The materialized view examples are based on the following two tables:

Command> CREATE TABLE customer
(cust_id INT NOT NULL,
cus_name CHAR(100) NOT NULL,
addr CHAR(100),
zip INT,
region CHAR(10),
PRIMARY KEY (cust_id));

CREATE TABLE book_order
(order_id INT NOT NULL,
cust_id INT NOT NULL,
book CHAR(100),
PRIMARY KEY (order_id),
FOREIGN KEY (cust_id) REFERENCES customer(cust_id));

The following sections provide details and examples for creating materialized views:

- Creating a synchronous materialized view
- The SELECT query in the CREATE MATERIALIZED VIEW statement

Creating a synchronous materialized view  A synchronous materialized view is automatically updated each time the detail tables are updated. You can create a synchronous materialized view with the CREATE MATERIALIZED VIEW statement.

The following creates a synchronous materialized view, named sample_mv, that generates a result set from selected columns in the customer and book_order detail tables described above.

Command> CREATE MATERIALIZED VIEW sample_mv AS
SELECT customer.cust_id, cust_name, order_id, book
FROM customer, book_order
WHERE customer.cust_id=book_order.cust_id;

The SELECT query in the CREATE MATERIALIZED VIEW statement  The SELECT query used to define the contents of a materialized view is similar to the top-level SQL SELECT statement described in "SQL Statements" in the Oracle TimesTen In-Memory Database SQL Reference with some restrictions, which are described in "CREATE MATERIALIZED VIEW" in the Oracle TimesTen In-Memory Database SQL Reference.

Dropping a materialized view
To drop any materialized view, issue the DROP VIEW statement.
The following statement drops the sample_mv materialized view.

Command> DROP VIEW sample_mv;

The syntax for all SQL statements is provided in the "SQL Statements" chapter in the Oracle TimesTen In-Memory Database SQL Reference.

Restrictions on materialized views and detail tables
A materialized view is a read-only table that cannot be updated directly. This means a materialized view cannot be updated by an INSERT, DELETE, or UPDATE statement, nor can it be updated by replication, XLA, or the cache agent.

For example, any attempt to update a row in a materialized view generates the following error:

805: Update view table directly has not been implemented

Readers familiar with other implementations of materialized views should note the following characteristics of TimesTen materialized views:

■ Detail tables can be replicated, but materialized views cannot.
■ Neither a materialized view nor its detail tables can be part of a cache group.
■ You cannot create a foreign key to reference a table or another materialized view. Regular tables cannot use a foreign key to refer to a materialized view.
■ To drop a materialized view must use the DROP VIEW statement.
■ You cannot alter a materialized view. You must use the DROP VIEW statement and then create a new materialized view with a CREATE MATERIALIZED VIEW statement.
■ Materialized views must be explicitly created by the application.
■ The TimesTen query optimizer does not rewrite queries on the detail tables to reference materialized views. Application queries must directly reference views, if they are to be used.
■ There are some restrictions to the SQL used to create materialized views. See "CREATE MATERIALIZED VIEW" in the Oracle TimesTen In-Memory Database SQL Reference for details.

Performance implications of materialized views
The performance of UPDATE, INSERT, and DELETE operations may be impacted if the updated table is referenced in a materialized view. The performance impact depends on many factors, such as the following:

■ Nature of the materialized view: How many detail tables, whether outer join or aggregation, are used.
■ Which indexes are present on the detail table and on the materialized view.
■ How many materialized view rows are affected by the change.

A materialized view is a persistent, up-to-date copy of a query result. To keep the materialized view up to date, TimesTen must perform "materialized view maintenance" when you change a materialized view’s detail table. For example, if you have a materialized view named V that selects from tables T1, T2, and T3, then any time you insert into T1, or update T2, or delete from T3, TimesTen performs "materialized view maintenance."
Materialized view maintenance needs appropriate indexes just like regular database operations. If they are not there, materialized view maintenance performs poorly.

All update, insert, or delete statements on detail tables have execution plans, as described in "The TimesTen Query Optimizer" on page 9-1. For example, an update of a row in T1 initiates the first stage of the plan where it updates the materialized view V, followed by a second stage where it updates T1.

For fast materialized view maintenance, you should evaluate the plans for all the operations that update the detail tables, as follows:

1. Examine all the WHERE clauses for the update or delete statements that frequently occur on the detail tables. Note any clause that uses an index key. For example, if the operations that an application performs 95 percent of the time are as follows:

   UPDATE T1 set A=A+1 WHERE K1=? AND K2=?
   DELETE FROM T2 WHERE K3=?

   Then the keys to note are (K1, K2) and K3.

2. Ensure that the view selects all of those key columns. In this example, the materialized view should select K1, K2, and K3.

3. Create an index on the materialized view on each of those keys. In this example, the view should have two indexes, one on (V.K1, V.K2) and one on V.K3. The indexes do not have to be unique. The names of the view columns can be different from the names of the table columns, though they are the same in this example.

With this method, when you update a detail table, your WHERE clause is used to do the corresponding update of the view. This allows maintenance to be executed in a batch, which has better performance.

The above method may not always work, however. For example, an application may have many different methods to update the detail tables. The application would have to select far too many items in the view or create too many indexes on the materialized view, taking up more space or more performance than you might wish. An alternative method is as follows:

1. For each table in the materialized view’s FROM clause (each detail table), check which ones are frequently changed by UPDATE, INSERT and CREATE VIEW statements. For example, a materialized view’s FROM clause may have tables T1, T2, T3, T4, and T5, but of those, only T2 and T3 are frequently changed.

2. For each of those tables, make sure the materialized view selects its rowids. In this example, the materialized view should select T2.rowid and T3.rowid.

3. Create an index on the materialized view on each of those rowid columns. In this example, the columns might be called T2.rowid and T3.rowid, and indexes would be created on V.T2rowid and V.T3rowid.

With this method, materialized view maintenance is done on a row-by-row basis, rather than on a batch basis. But the rows can be matched very efficiently between a materialized view and its detail tables, which speeds up the maintenance. It is generally not as fast as the first method, but it is still good.

Understanding indexes

Indexes are auxiliary data structures that greatly improve the performance of table searches. You can use the Index Advisor to recommend indexes for a particular SQL workload. For more details, see "Using the Index Advisor to recommend indexes" on page 8-20.
Indexes are used automatically by the query optimizer to speed up the execution of a query. For information about the query optimizer, see "The TimesTen Query Optimizer" on page 9-1.

You can designate an index as unique, which means that each row in the table has a unique value for the indexed column or columns. Unique indexes can be created over nullable columns. In conformance with the SQL standard, multiple null values are permitted in a unique index, which enables a unique index to have multiple rows with the same set of values.

On TimesTen Scaleout, indexed access that does not include all columns of the distribution key requires multi-element access (a broadcast across all elements). See "Understanding indexes" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for more information on how to avoid broadcasts and optimize index access.

When sorting data values, TimesTen considers null values to be larger than all non-null values. For more information on null values, see "Null values" in the Oracle TimesTen In-Memory Database SQL Reference.

To perform any operation that creates, drops, or alters an index, the user must have the appropriate privileges, which are described along with the syntax for all SQL statements in the "SQL Statements" chapter in the Oracle TimesTen In-Memory Database SQL Reference.

The following sections describe how to manage your index:

- Overview of index types
- Creating an index
- Altering an index
- Dropping an index
- Estimating index size
- Using the Index Advisor to recommend indexes

Overview of index types

TimesTen provides three types of indexes to enable fast access to tables. You can create up to 500 range or hash indexes on a table.

- **Range Indexes.** Range indexes are useful for finding rows with column values within a certain range. You can create range indexes over one or more columns of a table.

  Range indexes and equijoins can be used for equality and range searches, such as greater than or equal to, less than or equal to, and so on. If you have a primary key on a field and want to see if FIELD > 10, then the primary key index does not expedite finding the answer, but a separate index will.

  See the "CREATE INDEX" section of the Oracle TimesTen In-Memory Database SQL Reference for more information on how to create range indexes.

- **Hash Indexes.** Hash indexes are useful for equality searches. A hash index is created with either of the following:
  
  - You can create a hash index or a unique hash index on one or more columns of a table or materialized view with the CREATE INDEX statement.
  
  - You can create a unique hash index on the primary key of a table during table creation with the CREATE TABLE... UNIQUE HASH ON statement.
Understanding indexes

See the "CREATE INDEX" and "CREATE TABLE" sections of the Oracle TimesTen In-Memory Database SQL Reference for details on creating hash indexes. For an example of how to create a hash index, see Example 8–4. For details on how to size a hash table, see "Size hash indexes appropriately" on page 10-18.

---

**Note:** Hash indexes are faster than range indexes for exact match lookups, but they require more space than range indexes. Hash indexes can only be used for exact value lookups. Hash indexes cannot be used if the SQL query returns a range of values. Also, hash indexes are not useful for sorting values that come from a table scan.

Range indexes are optimized for in-memory data management and provide efficient sorting by column value.

TimesTen may create temporary hash and range indexes automatically during query processing to speed up query execution.

---

**Note:** Alternatively, you can perform lookups by RowID for fast access to data. For more information, see "ROWID data type" in the Oracle TimesTen In-Memory Database SQL Reference.

---

Creating an index

To create an index, issue the SQL statement CREATE INDEX. TimesTen converts index names to upper case characters.

When you create an index on TimesTen Scaleout, it creates the index on all elements that are in the distribution map. TimesTen Scaleout populates each element's index with the rows that are stored on that element.

Every index has an owner. The owner is the user who created the underlying table. Indexes created by TimesTen itself, such as indexes on system tables, are created with the user name SYS or with the user name TTREP for indexes on replication tables.

---

**Note:** You cannot create an index on LOB columns.

---

**Example 8–4  Create an index**

The following creates an index ixid over column cust_id of table customer.

Command> CREATE INDEX ixid ON customer (cust_id);

The following creates a unique hash index on the customer table as part of the table creation:

Command> CREATE TABLE customer
(cust_id NUMBER NOT NULL PRIMARY KEY,
cust_name CHAR(100) NOT NULL,
addr CHAR(100),
zip NUMBER,
region CHAR(10))
UNIQUE HASH ON (cust_id) PAGES = 30;

The following creates a nonunique hash index on the customer table over the customer name:

---
Understanding indexes

Command> CREATE HASH INDEX custname_idx ON customer(cust_name);

For more examples on the different indexes and how to create them, see “CREATE INDEX” and “ALTER TABLE” in the Oracle TimesTen In-Memory Database SQL Reference.

Altering an index

You can use the ALTER TABLE statement to add (or change) a primary key constraint to use either a range or hash index.

---

**Note:** You cannot alter an index to be transformed from a hash to a range index or from a range to a hash index if it was created with the CREATE INDEX statement.

---

You can change a primary key constraint to use a range index instead of a hash index with the USE RANGE INDEX clause of the ALTER TABLE statement; you can change a primary key constraint to use a hash index instead of a range index with the USE HASH INDEX of the ALTER TABLE statement. See “ALTER TABLE” in the Oracle TimesTen In-Memory Database SQL Reference.

Dropping an index

To uniquely refer to an index, an application must specify both its owner and name. If the application does not specify an owner, TimesTen looks for the index first under the user name of the caller, then under the user name SYS.

**Example 8–5  Drop an index**

The following drops the index named ixid.

Command> DROP INDEX ixid;

To drop a TimesTen index, issue the DROP INDEX SQL statement. When you drop an index on TimesTen Scaleout, it drops the index on all elements.

---

**Note:** All indexes in a table are dropped automatically when the table is dropped.

---

Estimating index size

Increasing the size of a TimesTen database can be done on first connect. Use the ttSize utility to estimate database size, including any indexes. Correctly estimating the size of a database helps you to avoid having to resize the database in the future.

The following example shows that the ttSize utility estimates the rows, inline row bytes, size of any indexes on the table, and the total size of the table:

`% ttSize -tbl pat.tab1 mydb`

Rows = 2

Total in-line row bytes = 17524

Indexes:

Index PAT adds 6282 bytes

Total index bytes = 6282

---
Using the Index Advisor to recommend indexes

The right set of indexes can make a difference in query performance. The Index Advisor can be used to recommend indexes for improving the performance of a specific SQL workload. The Index Advisor is intended for read-intensive complex queries. The use of the Index Advisor is not recommended for a write-intensive workload.

The Index Advisor evaluates a SQL workload and recommends indexes that can improve the performance for the following: joins, single table scans, and ORDER BY or GROUP BY operations. The Index Advisor does not differentiate tables that are used for specific intentions, such as the base table for a materialized view or as a table within a cache group. As long as the table is used in queries in the SQL workload, the Index Advisor may recommend indexes on that table.

The Index Advisor generates the CREATE statement for each recommended index, which you can choose to issue. A database administrator should review each CREATE statement recommended for new indexes before they are applied since the Index Advisor may recommend the following:

- Indexes that are duplicates of existing indexes.
- Indexes for tables or columns of tables that are created and dropped during a SQL workload. However, you could add the CREATE statement for the recommended index in the SQL workload after the DDL that creates the tables or columns of tables and before they are dropped.
- Indexes that cannot be created, such as a unique index for a data set where the data is not unique. In this case, you should ignore this recommendation.
- Index creation options where you can create an index as either a UNIQUE or non-unique index. The Index Advisor suggests both index types. You can only create one of the indexes as both suggested indexes have the same index name. While the optimizer thinks that the UNIQUE index is better for the specified workload, you can choose to create the non-unique index. Consider creating the UNIQUE index if the column only contains unique values. Consider creating the non-unique index if the column contains non-unique value.

The Index Advisor does not cover the following:

- It does not optimize for memory use.
- It does not consider maintenance costs.
- It does not recommend that existing indexes be dropped if they are not useful.
- It does not recommend indexes for global temporary tables.

The recommended steps to use the Index Advisor are as follows:

- Prepare for executing the Index Advisor
- Capture the data used for generating index recommendations
- Retrieve index recommendations and data collection information
- Drop data collected for the index advisor and finalize results

Prepare for executing the Index Advisor

Before you execute the Index Advisor, you should optionally perform the following:
1. Since the Index Advisor relies on the query plan, set any relevant optimizer hints that you would use for the SQL workload before enabling the Index Advisor and running the workload. For more details on optimizer hints, see "Use optimizer hints to modify the execution plan" on page 9-15.

2. Update statistics for tables included in the SQL workload and force statements to be re-prepared during the capture. This provides the most up-to-date statistics for the data collection and causes the statements to be re-prepared based on the latest statistics.

Update statistics for tables included in the SQL workload with one of the following built-in procedures: ttOptUpdateStats, ttOptEstimateStats, or ttOptSetTblStats. In the built-in procedures, set the invalidate parameter to 1 to invalidate all commands that reference the indicated tables and force these commands to be automatically prepared again when re-executed. This ensures that statistics are up to date.

- The ttOptUpdateStats built-in procedure provides a full update of all statistics for the tables. However, it can be time consuming.
- The ttOptEstimateStats evaluates statistics based upon a small percentage of rows in the indicated tables.
- The ttOptSetTblStats sets the statistics to known values provided by you.

**Note:** For more information on these built-in procedures, see "ttOptUpdateStats", "ttOptEstimateStats", and "ttOptSetTblStats" in the Oracle TimesTen In-Memory Database Reference.

The following example estimates statistics for all tables for the current user by evaluating a random sample of ten percent of the rows in these tables. It also invalidates all commands already prepared that reference these tables.

```
Command> call ttOptEstimateStats ( '', 1, '10 PERCENT' );
```

**Capture the data used for generating index recommendations**

Call the ttIndexAdviceCaptureStart and ttIndexAdviceCaptureEnd built-in procedures to capture the information needed by the Index Advisor to generate index recommendations, as follows:

1. Call the ttIndexAdviceCaptureStart built-in procedure to start the process to collect index information.

2. Run the SQL workload.

3. Call the ttIndexAdviceCaptureEnd built-in procedure to end the index information collection process.

**Note:** After the data collection process ends, you can retrieve the index recommendations as described in "Retrieve index recommendations and data collection information" on page 8-23.

When you call the ttIndexAdviceCaptureStart built-in procedure to initiate the data collection process, provide the following:

- In the captureLevel parameter, specify whether the index information is to be collected for the current connection or for the entire database. You can execute multiple connection-level captures concurrently for independent connections.
without conflict. A database-level capture can take place in parallel with a connection-level capture. Since there is no conflict between a database-level and a connection-level capture, any outstanding connection-level captures that are already in progress when a database-level capture is initiated completes as intended. However, an error is returned if you initiate a second request for a database-level capture while the first is still active; an error is also returned if a second request for a connection-level capture from the same connection is initiated while the first connection-level capture is still active.

If you invoke `ttIndexAdviceCaptureStart` for a database-level capture, any outstanding connection-level captures that are already in progress complete.

- The `captureMode` parameter designates that you want the data collection performed on one of the following scenarios:
  
  - Perform the collection of index information using the current execution of the SQL workload.
  
  - Base the collection of index information not on a current execution of the SQL workload, but on existing computed statistics and query plan analysis. In this scenario, the SQL statements have been prepared, but not executed. This mode can only be executed with a connection-level capture.

To complete the capture, call the `ttIndexAdviceCaptureEnd` built-in procedure that ends either an active connection-level capture from the same connection or an active database-level capture. Completing a database-level capture requires the `ADMIN` privilege.

If a connection fails during a capture, the following occurs:

- If the capture is a connection-level capture, the capture ends and all associated resources are freed.
- If the capture is a database-level capture, the capture continues until another user with `ADMIN` privileges connects and invokes the `ttIndexAdviceCaptureEnd` built-in procedure to end a database-level capture.

If temporary space becomes full during a capture, an active capture ends and the data collected during the capture is saved.

---

**Note:** Execute `ttIndexAdviceCaptureDrop` to free the temporary space after a capture. See "Drop data collected for the index advisor and finalize results" on page 8-24 for more information on `ttIndexAdviceCaptureDrop`.

---

The following example starts a collection for the Index Advisor at the connection-level for the current execution of a SQL workload:

Command> call ttIndexAdviceCaptureStart(0,0);

The following example ends the collection for the connection-level capture:

Command> call ttIndexAdviceCaptureEnd(0);

---

**Note:** For more information on these built-in procedures, see "ttIndexAdviceCaptureStart" and "ttIndexAdviceCaptureEnd" in the *Oracle TimesTen In-Memory Database Reference*. 

---
Retrieve index recommendations and data collection information

1. Call the `ttIndexAdviceCaptureInfoGet` built-in procedure to retrieve data collection overview information for the Index Advisor.

2. Call the `ttIndexAdviceCaptureOutput` built-in procedure to retrieve the recommended indexes.

   **Note:** These built-in procedures retrieve the data collection overview and Index Advisor recommendations. Execute either or both for the data you want.

3. After a DBA has evaluated the recommended index creation statements, apply the desired index creation recommendations.

Retrieve data collection information with `ttIndexAdviceCaptureInfoGet` The `ttIndexAdviceCaptureInfoGet` built-in procedure retrieves information about the data collected for the Index Advisor. For both a connection-level capture and a database-level capture, only a single row is returned.

   **Note:** The database-level capture row can only be returned to a user with ADMIN privileges.

The `ttIndexAdviceCaptureInfoGet` built-in procedure captures data if:

- The data capture was started and has not ended.
- A previous capture that was started and stopped, and the data was not deleted.

   **Note:** If no capture is in progress or no data exists, then no rows are returned.

The rows returned include the following information:

- The capture state: Returns 0 if a capture is completed. Returns 1 if a capture is still in progress.
- The connection identifier, if appropriate.
- The capture level and mode set for this capture.
- The number of prepared and executed statements during the capture interval.
- The time that the capture was started and stopped.

The following shows capture information for a completed connection-level capture for 363 prepared statements and 369 executed statements:

Command> call ttIndexAdviceCaptureInfoGet();
< 0, 1, 0, 0, 363, 369, 2012-07-27 11:44:08.136833, 2012-07-27 12:07:35.410993 >
1 row found.

   **Note:** For more details and syntax for this built-in procedure, see "ttIndexAdviceCaptureInfoGet" in the Oracle TimesTen In-Memory Database Reference.
Retrieve index recommendations with ttIndexAdviceCaptureOutput  The ttIndexAdviceCaptureOutput built-in procedure retrieves the list of index recommendations from the last recorded capture at the specified level (connection or database-level). The list contains the CREATE statement for each recommended index.

To request index recommendations for a connection-level capture, execute ttIndexAdviceCaptureOutput with captureLevel set to 0 in the same connection that initiated the capture. For a database-level capture, execute ttIndexAdviceCaptureOutput with captureLevel set to 1 in a connection where the user has ADMIN privilege.

The returned row contains:

- stmtCount - The number of times the index would be useful to speed up the executed SQL workload.
- createStmt - The executable statement that can be used to create the recommended index. All database object names in these statements are fully qualified.

The following example provides the CREATE statement for an index called PURCHASE_i1 on the HR.PURCHASE table, which would be useful 4 times for this SQL workload.

```sql
CALL ttIndexAdviceCaptureOutput();
< 4, create index PURCHASE_i1 on HR.PURCHASE(AMOUNT); >
1 row found.
```

Note:  For more information and syntax for this built-in procedure, see "ttIndexAdviceCaptureOutput" in the Oracle TimesTen In-Memory Database Reference.

Drop data collected for the index advisor and finalize results

After you have applied the CREATE statements for the new indexes that have been approved by the DBA, you can drop the captured data collected for the Index Advisor. The ttIndexAdviceCaptureDrop built-in procedure drops the existing data collected for the specified captureLevel, which can either be a connection or database-level capture.

Call ttIndexAdviceCaptureDrop(0); You must call this built-in procedure twice to drop both a connection-level and database-level capture. You may not invoke this built-in procedure while a capture at the same level is in progress.

Note:  For more information and syntax for this built-in procedure, see "ttIndexAdviceCaptureDrop" in the Oracle TimesTen In-Memory Database Reference.

You can repeat the steps in "Prepare for executing the Index Advisor" on page 8-20 and "Retrieve index recommendations and data collection information" on page 8-23 until a SQL workload is executed with no more index recommendations. You can keep updating the statistics for the tables on which the new indexes were applied and re-execute the Index Advisor to see if any new indexes are now recommended.
Example using Index Advisor built-in procedures

The following shows the flow of a data collection for a SQL workload and the resulting index advice provided by the Index Advisor built-in procedures.

Command> call ttOptUpdateStats();

Command> call ttIndexAdviceCaptureStart();

Command> SELECT employee_id, first_name, last_name FROM employees;
< 100, Steven, King >
< 101, Neena, Kochhar >
< 102, Lex, De Haan >
< 103, Alexander, Hunold >
< 104, Bruce, Ernst >
...
< 204, Hermann, Baer >
< 205, Shelley, Higgins >
< 206, William, Gietz >
107 rows found.

Command> SELECT MAX(salary) AS MAX_SALARY FROM employees
WHERE employees.hire_date > '2000-01-01 00:00:00';
< 10500 >
1 row found.

Command> SELECT employee_id, job_id FROM job_history
WHERE (employee_id, job_id) NOT IN (SELECT employee_id, job_id
FROM employees);
< 101, AC_ACCOUNT >
< 101, AC_MGR >
< 102, IT_PROG >
< 114, ST_CLERK >
< 122, ST_CLERK >
< 176, SA_MAN >
< 200, AC_ACCOUNT >
< 201, MK_REP >
8 rows found.

Command> WITH dept_costs AS
(SELECT department_name, SUM(salary) dept_total
FROM employees e, departments d
WHERE e.department_id = d.department_id
GROUP BY department_name),
avg_cost AS
(SELECT SUM(dept_total)/COUNT(*) avg
FROM dept_costs)
SELECT * FROM dept_costs
WHERE dept_total > (SELECT avg FROM avg_cost)
ORDER BY department_name;
< Sales, 304500 >
< Shipping, 156400 >
2 rows found.

Command> call ttIndexAdviceCaptureEnd();

Command> call ttIndexAdviceCaptureInfoGet();
< 0, 1, 0, 0, 9, 6, 2012-07-27 11:44:08.136833, 2012-07-27 12:07:35.410993 >
1 row found.
Understanding rows

Rows are used to store TimesTen data. TimesTen supports several data types for fields in a row, including:

- One-byte, two-byte, four-byte and eight-byte integers.
- Four-byte and eight-byte floating-point numbers.
- Fixed-length and variable-length character strings, both ASCII and Unicode.
- Fixed-length and variable-length binary data.
- Fixed-length fixed-point numbers.
- Time represented as hh:mm:ss [AM|am|PM|pm].
- Date represented as yyyy-mm-dd.
- Timestamp represented as yyyy-mm-dd hh:mm:ss:fffffff.

The "Data Types" section in the Oracle TimesTen In-Memory Database SQL Reference contains a detailed description of these data types.

To perform any operation for inserting or deleting rows, the user must have the appropriate privileges, which are described along with the syntax for all SQL statements in the "SQL Statements" chapter in the Oracle TimesTen In-Memory Database SQL Reference.

The following sections describe how to manage your rows:

- Inserting rows
- Deleting rows

Inserting rows

To insert a row, issue INSERT or INSERT SELECT. You can also use the ttBulkCp utility.

*Example 8–6 Insert a row in a table*

To insert a row in the table customer, enter:

Command> INSERT INTO customer VALUES(23125, 'John Smith';

**Note:** When inserting multiple rows into a table, it is more efficient to use prepared commands and parameters in your code. Create Indexes after the bulk load is completed.

Deleting rows

To delete a row, issue the DELETE statement.
Example 8–7  Delete a row

The following deletes all the rows from the table customer for names that start with the letter “S.”

Command> DELETE FROM customer WHERE cust_name LIKE 'S%';

Understanding synonyms

A synonym is an alias for a database object. Synonyms are often used for security and convenience, because they can be used to mask object name and object owner. In addition, you can use a synonym to simplify SQL statements. Synonyms provide independence in that they permit applications to function without modification regardless of which object a synonym refers to. Synonyms can be used in DML statements and some DDL and TimesTen cache statements.

Synonyms are categorized into two classes:

- Private synonyms: A private synonym is owned by a specific user and exists in the schema of a specific user. A private synonym shares the same namespace as other object names, such as table names, view names, sequence names, and so on. Therefore, a private synonym cannot have the same name as a table name or a view name in the same schema.

- Public synonyms: A public synonym is owned by all users and every user in the database can access it. A public synonym is accessible for all users and it does not belong to any user schema. Therefore, a public synonym can have the same name as a private synonym name or a table name.

In order to create and use synonyms, the user must have the correct privileges, which are described in "Object privileges for synonyms" in the Oracle TimesTen In-Memory Database Security Guide.

After synonyms are created, they can be viewed using the following views:

- SYS.ALL_SYNONYMS: describes the synonyms accessible to the current user. For more information, see "SYS.ALL_SYNONYMS" in the Oracle TimesTen In-Memory Database System Tables and Views Reference.

- SYS.DBA_SYNONYMS: describes all synonyms in the database. For more information, see "SYS.DBA_SYNONYMS" in the Oracle TimesTen In-Memory Database System Tables and Views Reference.

- SYS.USER_SYNONYMS: describes the synonyms owned by the current user. For more information, see "SYS.USER_SYNONYMS" in the Oracle TimesTen In-Memory Database System Tables and Views Reference.

Creating synonyms

Create the synonym with the CREATE SYNONYM statement. You can use the CREATE OR REPLACE SYNONYM statement to change the definition of an existing synonym without needing to drop it first. The CREATE SYNONYM and CREATE OR REPLACE SYNONYM statements specify the synonym name and the schema name in which the synonym is created. If the schema is omitted, the synonym is created in the user’s schema. However, when creating public synonyms, do not provide the schema name as it is defined in the PUBLIC namespace.

In order to issue the CREATE SYNONYM or CREATE OR REPLACE SYNONYM statements, the user must have the appropriate privileges, as described in "Object privileges for synonyms" in the Oracle TimesTen In-Memory Database Security Guide.
Object types for synonyms: The CREATE SYNONYM and CREATE OR REPLACE SYNONYM statements define an alias for a particular object, which can be one of the following object types: table, view, synonym, sequence, PL/SQL stored procedure, PL/SQL function, PL/SQL package, materialized view, or cache group.

Note: If you try to create a synonym for unsupported object types, you may not be able to use the synonym.

Naming considerations: A private synonym shares the same namespace as all other object names, such as table names and so on. Therefore, a private synonym cannot have the same name as a table name or other objects in the same schema.

A public synonym is accessible for all users and does not belong to any particular user schema. Therefore, a public synonym can have the same name as a private synonym name or other object name. However, you cannot create a public synonym that has the same name as any objects in the SYS schema.

In the following example, the user creates a private synonym of synjobs for the jobs table. Issue a SELECT statement on both the jobs table and the synjobs synonym to show that selecting from synjobs is the same as selecting from the jobs table. Finally, to display the private synonym, the example executes a SELECT statement on the SYS.USER_SYNONYMS table.

Command> CREATE SYNONYM synjobs FOR jobs;
  Synonym created.

Command> SELECT FIRST 2 * FROM jobs;
  < AC_ACCOUNT, Public Accountant, 4200, 9000 >
  < AC_MGR, Accounting Manager, 8200, 16000 >
  2 rows found.

Command> SELECT FIRST 2 * FROM synjobs;
  < AC_ACCOUNT, Public Accountant, 4200, 9000 >
  < AC_MGR, Accounting Manager, 8200, 16000 >
  2 rows found.

Command> SELECT * FROM sys.user_synonyms;
  < SYNJOBS, TTUSER, JOBS, <NULL> >
  1 row found.

For full details, more examples, and rules on creating or replacing a synonym, see the "CREATE SYNONYM" section in the Oracle TimesTen In-Memory Database SQL Reference.

Dropping synonyms

Use the DROP SYNONYM statement to drop an existing synonym from the database. A user cannot be dropped unless all objects, including synonyms, owned by this user are dropped.

For example, the following drops the public synonym pubemp:

Command> DROP PUBLIC SYNONYM pubemp;
  Synonym dropped.

In order drop a public synonym or a private synonym in another user's schema, the user must have the appropriate privileges. For full details, more examples, and rules on creating or replacing a synonym, see the "DROP SYNONYM" section in the Oracle TimesTen In-Memory Database SQL Reference.
Synonyms may cause invalidation or recompilation of SQL queries

When a synonym or object is newly created or dropped, some SQL queries and DDL statements may be invalidated or recompiled. The following lists the invalidation and recompilation behavior for SQL queries and DDL statements:

1. All SQL queries that depend on a public synonym are invalidated if you create a private synonym with the same name for one of the following objects:
   - private synonym
   - table
   - view
   - sequence
   - materialized view
   - cache group
   - PL/SQL object including procedures, functions, and packages

2. All SQL queries that depend on a private synonym or schema object are invalidated when a private synonym or schema object is dropped.

Understanding system views

There are several local (V$) global (GV$) system views you can query to retrieve metadata information about your database.

In TimesTen Scaleout:
- The V$ views contain data for the element to which your application is connected.
- The GV$ views contain the contents of the V$ view for every element of the database.

In TimesTen Classic:
- The V$ views contain rows of data for the database to which your application is connected.
- The GV$ views contain the same contents as their corresponding V$ view.

In addition, there are several views that you can query that are based on TimesTen built-in procedures. See "System Tables and Views" in the Oracle TimesTen In-Memory Database System Tables and Views Reference for more information.
The TimesTen query optimizer is a cost-based optimizer that determines the most efficient way to execute a given query by considering possible query plans. The query optimizer uses information about an application’s tables and their available indexes to choose a fast path to the data.

A query plan in TimesTen Scaleout is affected by the distribution scheme and the distribution keys of a hash distribution scheme as well as the column and table statistics, the presence or absence of indexes, the volume of data, the number of unique values, and the selectivity of predicates.

Application developers can examine the plan chosen by the optimizer to check that indexes are used appropriately. If necessary, application developers can provide hints to influence the optimizer’s behavior so that it considers a different plan.

This chapter includes the following topics:

- When optimization occurs
- Viewing SQL statements stored in the SQL command cache
- Viewing SQL query plans
- Modifying plan generation

### When optimization occurs

TimesTen invokes the optimizer for SQL statements when more than one execution plan is possible. The optimizer chooses what it thinks is the optimum plan. This plan persists until the statement is either invalidated or dropped by the application.

A statement is automatically invalidated under the following circumstances:

- An object that the command uses is dropped
- An object that the command uses is altered
- An index on a table or view that the command references is dropped
- An index is created on a table or view that the command references

You can manually invalidate statements with either of the following methods:

- Use the `ttOptCmdCacheInvalidate` built-in procedure to invalidate statements in the SQL command cache. For more information, see “Control the invalidation of commands in the SQL command cache” on page 10-22.
- Set the `invalidation` option to 1 in the `ttOptUpdateStats` or the `ttOptEstimateStats` built-in procedures. These built-in procedures also update statistics for either a specified table or all of the current user’s tables.
When optimization occurs

An invalid statement is usually reprepared automatically just before it is re-executed. This means that the optimizer is invoked again at this time, possibly resulting in a new plan. Thus, a single statement may be prepared several times.

**Note:** When using JDBC, you must manually reprepare statement when a table has been altered.

A statement may have to be prepared manually if, for example, the table that the statement referenced was dropped and a new table with the same name was created. When you prepare a statement manually, you should commit the prepare statement so it can be shared. If the statement is recompiled because it was invalid, and if recompilation involves DDL on one of the referenced tables, then the prepared statement must be committed to release the command lock.

For example, in ODBC a command joining tables T1 and T2 may undergo the following changes:

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLPrepare</td>
<td>Command is prepared.</td>
</tr>
<tr>
<td>SQLExecute</td>
<td>Command is executed.</td>
</tr>
<tr>
<td>SQLExecute</td>
<td>Command is re-executed.</td>
</tr>
<tr>
<td>Create Index on T1</td>
<td>Command is invalidated.</td>
</tr>
<tr>
<td>SQLExecute</td>
<td>Command is reprepared, then executed.</td>
</tr>
<tr>
<td>SQLExecute</td>
<td>Command is re-executed.</td>
</tr>
<tr>
<td>ttOptUpdateStats on T1</td>
<td>Command is invalidated if the invalidate flag is passed to the ttOptUpdateStats procedure.</td>
</tr>
<tr>
<td>SQLExecute</td>
<td>Command is reprepared, then executed.</td>
</tr>
<tr>
<td>SQLExecute</td>
<td>Command is re-executed.</td>
</tr>
<tr>
<td>SQLTransact</td>
<td>Command is committed.</td>
</tr>
<tr>
<td>SQLFreeStmt</td>
<td>Command is dropped.</td>
</tr>
</tbody>
</table>

In JDBC, a command joining tables T1 and T2 may undergo the following changes:

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection.prepareStatement()</td>
<td>Command is prepared.</td>
</tr>
<tr>
<td>PreparedStatement.executeQuery()</td>
<td>Command is executed.</td>
</tr>
<tr>
<td>PreparedStatement.executeQuery()</td>
<td>Command is re-executed.</td>
</tr>
<tr>
<td>Create Index on T1</td>
<td>Command is invalidated.</td>
</tr>
<tr>
<td>PreparedStatement.executeQuery()</td>
<td>Command is reprepared, then executed.</td>
</tr>
<tr>
<td>PreparedStatement.executeQuery()</td>
<td>Command is re-executed.</td>
</tr>
</tbody>
</table>
As illustrated, optimization is generally performed at prepare time, but it may also be performed later when indexes are dropped or created, or when statistics are modified. Optimization does not occur if a prepare can use a command in the cache.

If a command was prepared with the `genPlan` flag set, it is recompiled with the same flag set. Thus, the plan is generated even though the plan for another query was found in the `SYS.PLAN` table.

If an application specifies optimizer hints to influence the optimizer’s behavior, these hints persist until the command is deleted. See "Modifying plan generation" on page 9-13 for more information. For example, when the ODBC `SQLPrepare` function or JDBC `Connection.prepareStatement()` method is called again on the same handle or when the `SQLFreeStmt` function or `PreparedStatement.close()` method is called. This means that any intermediate reprepare operations that occur because of invalidations use those same hints.

### Viewing SQL statements stored in the SQL command cache

All commands executed—SQL statements, built-in procedures, and so on—are stored in the SQL command cache, which uses temporary memory. The commands are stored up until the limit of the SQL command cache is reached, then the new commands are stored after the last used commands are removed. You can retrieve one or more of these commands that are stored in the SQL command cache.

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ttOptUpdateStats on T1</code></td>
<td>Command is invalidated if the invalidate flag is passed to the <code>ttOptUpdateStats</code> procedure.</td>
</tr>
<tr>
<td><code>PreparedStatement.execute()</code></td>
<td>Command is reprepared, then executed.</td>
</tr>
<tr>
<td><code>PreparedStatement.execute()</code></td>
<td>Command is re-executed.</td>
</tr>
<tr>
<td><code>Connection.commit()</code></td>
<td>Command is committed.</td>
</tr>
<tr>
<td><code>PreparedStatement.close()</code></td>
<td>Command is dropped.</td>
</tr>
</tbody>
</table>

As illustrated, optimization is generally performed at prepare time, but it may also be performed later when indexes are dropped or created, or when statistics are modified. Optimization does not occur if a prepare can use a command in the cache.

If a command was prepared with the `genPlan` flag set, it is recompiled with the same flag set. Thus, the plan is generated even though the plan for another query was found in the `SYS.PLAN` table.

If an application specifies optimizer hints to influence the optimizer’s behavior, these hints persist until the command is deleted. See "Modifying plan generation" on page 9-13 for more information. For example, when the ODBC `SQLPrepare` function or JDBC `Connection.prepareStatement()` method is called again on the same handle or when the `SQLFreeStmt` function or `PreparedStatement.close()` method is called. This means that any intermediate reprepare operations that occur because of invalidations use those same hints.

### Viewing SQL statements stored in the SQL command cache

All commands executed—SQL statements, built-in procedures, and so on—are stored in the SQL command cache, which uses temporary memory. The commands are stored up until the limit of the SQL command cache is reached, then the new commands are stored after the last used commands are removed. You can retrieve one or more of these commands that are stored in the SQL command cache.

**Note**: This section describes viewing the commands stored in the SQL command cache. For details on how to view the query plans associated with these commands, see "Viewing query plans associated with commands stored in the SQL command cache" on page 9-10.

The following sections describe how to view commands cached in the SQL command cache:

- Managing performance and troubleshooting commands
- Displaying commands stored in the SQL command cache

### Managing performance and troubleshooting commands

You can view all one or more commands or details of their query plans with the `ttSQLCmdCacheInfo` and `ttSQLCmdQueryPlan` built-in procedures. Use the query plan information to monitor and troubleshoot your queries.

Viewing commands and query plans can help you perform the following:

- Detect updates or deletes that are not using an index scan.
Monitor query plans of executing queries to ensure all plans are optimized.

Detect applications that do not prepare SQL statements or that re-prepare the same statement multiple times.

Detect the percentage of space used in the command cache for performance evaluation.

### Displaying commands stored in the SQL command cache

The commands executed against the TimesTen database are cached in the SQL command cache. The `ttSQLCmdCacheInfo` built-in procedure displays a specific or all cached commands in the TimesTen SQL command cache. By default, all commands are displayed; if you specify a command id, then only this command is retrieved for display.

The command data is saved in the following format:

- Command identifier, which is used to retrieve a specific command or its associated query plan.
- Private connection identifier.
- Counter for the number of executions.
- Counter for the number of times the user prepares this statement.
- Counter for the number of times the user re-prepares this SQL statement.
- Freeable status, where if the value is one, then the subdaemon can free the space with the garbage collector. A value of zero determines that the space is not able to be freed.
- Total size in bytes allocated for this command in the cache.
- User who created the command.
- Query text up to 1024 characters.
- Number of fetch executions performed internally for this statement.
- The timestamp when the statement started.
- The maximum execution time in seconds for the statement.
- Last measured execution time in seconds for the statement.
- The minimum execution time in seconds for the statement.
- The unique identifier of the statement compiled across the TimesTen.
- Total temporary size in bytes used for this TimesTen statement the last time it was executed.
- The maximum temporary size in bytes ever used to execute this TimesTen statement.

At the end of the list of all commands, a status is printed of how many commands were in the cache.

The following examples show how to display all or a single command from the SQL command cache using the `ttSQLCmdCacheInfo` built-in utility:

- **Displaying all commands in the SQL command cache**
- **Displaying a single SQL command**
Example 9–1  Displaying all commands in the SQL command cache

This example executes within `ttIsq1` the `ttSQLCmdCacheInfo` built-in procedure without arguments to show all cached commands. The commands are displayed in terse format. To display the information where each column is prepended with the column name, execute `vertical` on before calling the `ttSQLCmdCacheInfo` procedure.

```sql
Command> vertical 1;
Command> call ttSQLCmdCacheInfo;
```

| SQLCMDID:                        | 43402480 |
| PRIVATE_COMMAND_CONNECTION_ID:   | -1       |
| EXECUTIONS:                      | 1        |
| PREPARES:                        | 1        |
| REPREPARES:                      | 0        |
| FREEABLE:                        | 1        |
| SIZE:                            | 4344     |
| OWNER:                           | HR       |
| FETCHCOUNT:                      | 0        |
| MAXEXECUTETIME:                  | 0        |
| LASTEXECUTETIME:                 | 0        |
| MINEXECUTETIME:                  | 0        |
| GRIDCMDID:                       | <NULL>   |
| TEMPSPACEUSAGE:                  | 0        |
| MAXTEMPSPACEUSAGE:               | 0        |

| SQLCMDID:                        | 43311000 |
| PRIVATE_COMMAND_CONNECTION_ID:   | -1       |
| EXECUTIONS:                      | 1        |
| PREPARES:                        | 1        |
| REPREPARES:                      | 0        |
| FREEABLE:                        | 1        |
| SIZE:                            | 4328     |
| OWNER:                           | HR       |
Example 9–2 Displaying a single SQL command

If you provide a command id as the input for the \ttSQLCmdCacheInfo\ built-in procedure, the single command is displayed from within the SQL command cache. If no command id is provided to the \ttSQLCmdCacheInfo\ built-in procedure, then it displays information about all current commands, where the command id is the first column of the output.

The following example displays the command identified by Command ID of 527973892. It is displayed in terse format; to view with the column headings prepended, execute \vertical\ on before calling the \ttSQLCmdCacheInfo\ built-in.

Command> call ttSQLCmdCacheInfo(43311000);
< 43311000, -1, 1, 0, 0, 4328, HR, INSERT INTO employees VALUES ( 171, 'William', 'Smith', 'WSMITH', '011.44.1343.629268', TO_DATE('23-FEB-1999', 'dd-MON-yyyy'), 'SA_REP', 7400, .15, 148, 80), 0, 2015-04-09 15:22:22.139000, 0, 0, <NULL>, 0, 0 >
1 row found.

Viewing SQL query plans

You can view the query plan for a command in one of two ways: storing the latest query plan into the system PLAN table or viewing all cached commands and their query plans in the SQL command cache. Both methods are described in the following sections:

- Viewing a query plan from the system PLAN table
- Viewing query plans associated with commands stored in the SQL command cache

Viewing a query plan from the system PLAN table

The optimizer prepares the query plans. For the last SQL statement to be executed, you can instruct that the plan be stored in the system PLAN table:

1. Instruct TimesTen to generate the plan and store it in the system PLAN table.
2. Prepare the statement means calling the ODBC SQLPrepare function or JDBC Connection.prepareStatement() method on the statement. TimesTen stores the plan into the PLAN table.
3. Read the generated plan within the SYS.PLAN table.

The stored plan is updated automatically whenever the command is reprepared. Re-preparation occurs automatically if one or more of the following occurs:

- A table in the statement is altered.
- If indexes are created or dropped.
The application invalidates commands when statistics are updated with the invalidate option in the `ttOptUpdateStats` built-in procedure.

The user invalidates commands with the `ttOptCmdCacheInvalidate` built-in procedure.

---

**Note:** For more information, see "Control the invalidation of commands in the SQL command cache" on page 10-22. For more information on the built-in procedures, see "ttOptUpdateStats" and "ttOptCmdCacheInvalidate" in the Oracle TimesTen In-Memory Database Reference.

---

For these cases, read the **PLAN** table to view how the plan has been modified.

### Instruct TimesTen to store the plan in the system **PLAN** table

Before you can view the plan in the system **PLAN** table, enable the creation of entries in the **PLAN** table with the plan generation option as follows:

- For transaction level optimizer hints, call the built-in `ttOptSetFlag` procedure and enable the GenPlan flag.
- For statement level optimizer hints, set `TT_GENPLAN(1)`, which is only in effect for the statement. After the statement executes, the plan generation option takes on the value of the GenPlan transaction level optimizer hint.

---

**Note:** See "Use optimizer hints to modify the execution plan" on page 9-15 for details on statement level and transaction level optimizer hints.

---

This informs TimesTen that all subsequent calls to the ODBC `SQLPrepare` function or JDBC `Connection.prepareStatement()` method in the transaction should store the resulting plan in the current **SYS.PLAN** table.

The **SYS.PLAN** table only stores one plan, so each call to the ODBC `SQLPrepare` function or JDBC `Connection.prepareStatement()` method overwrites any plan currently stored in the table.

If a command is prepared with plan generation option set, it is also recompiled for plan generation. Thus, the plan is generated even though the plan for another query was found in the **SYS.PLAN** table.

You can use `showplan` in `ttIsql` to test the query and optimizer hints, which enables plan generation as well as shows the query plan for the statements in the transaction. Autocommit must be off.

```
Command> autocommit 0;
Command> showplan 1;
```

### Reading query plan from the **PLAN** table

Once plan generation has been turned on and a command has been prepared, one or more rows in the **SYS.PLAN** table store the plan for the command. The number of rows in the table depends on the complexity of the command. Each row has seven columns, as described in "System Tables and Views" in the Oracle TimesTen In-Memory Database System Tables and Views Reference.
**Example 9–3 Generating a query plan**

This example uses the following query:

```
Command> SELECT COUNT(*) FROM t1, t2, t3
WHERE t3.b/t1.b > 1
AND t2.b <> 0
AND t1.a = -t2.a
AND t2.a = t3.a
```

The optimizer generates the five SYS.PLAN rows shown in the following table. Each row is one step in the plan and reflects an operation that is performed during query execution.

<table>
<thead>
<tr>
<th>Step</th>
<th>Level</th>
<th>Operation</th>
<th>TblNames</th>
<th>IXName</th>
<th>Pred</th>
<th>Other Pred</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>TblLkRangeScan</td>
<td>t1</td>
<td>IX1</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>TblLkRangeScan</td>
<td>t2</td>
<td>IX2(D)</td>
<td>t2.b &lt;&gt; 0</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>MergeJoin</td>
<td>N/A</td>
<td>N/A</td>
<td>t1.a = -t2.a</td>
<td>N/A</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>TblLkRangeScan</td>
<td>t3</td>
<td>IX3(D)</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>MergeJoin</td>
<td>N/A</td>
<td>N/A</td>
<td>t2.a = t3.a</td>
<td>t3.b / t1.b &gt; 1</td>
</tr>
</tbody>
</table>

For details about each column in the SYS.PLAN table, see "Describing the PLAN table columns" on page 9-8.

**Describing the PLAN table columns**

The SYS.PLAN table has seven columns.

**Column 1 (Step)** Indicates the order of operation, which always starts with one. Example 9–3 uses a table lock range scan in the following order:

1. Table locking range scan of IX1 on table t1.
2. Table locking range scan of IX2 on t2.
3. Merge join of t1 and t2 and so forth.

**Column 2 (Level)** Indicates the position of the operation in the join-tree diagram that describes the execution. For Example 9–3, the join tree is as follows:
Column 3 (Operation) Indicates the type of operation being executed. For a description of the potential values in this field and the type of table scan each represents, see `SYS.PLAN` in "System Tables and Views" in the Oracle TimesTen In-Memory Database System Tables and Views Reference.

Not all operations the optimizer performs are visible to the user. Only operations significant to performance analysis are shown in the `SYS.PLAN` table. `TblLk` is an optimizer hint that is honored at execution time in Serializable or Read Committed isolation. Table locks are used during a scan only if row locks are disabled during preparation.

Column 4 (TblNames) Indicates the table that is being scanned. This column is used only when the operation is a scan. In all other cases, this column is `NULL`.

Column 5 (IXName) Indicates the index that is being used. This column is used only when the operation is an index scan using an existing index—such as a hash or range scan. In all other cases, this column is `NULL`. Names of range indexes are followed with "(D)" if the scan is descending—from large to small rather than from small to large.

Column 6 (Pred) Indicates the predicate that participates in the operation, if there is one. Predicates are used only with index scan and `MergeJoin` operations. The predicate character string is limited to 1,024 characters.

This column may be `NULL`—indicating no predicate—for a range scan. The optimizer may choose a range scan over a table scan because, in addition to filtering, it has two useful properties:

- Rows are returned in sorted order, on index key.
- Rows may be returned faster, especially if the table is sparse.

In Example 9–3, the range scans are used for their sorting capability; none of them evaluates a predicate.
**Column 7 (Other Pred)** Indicates any other predicate that is applied while the operation is being executed. These predicates do not participate directly in the scan or join but are evaluated on each row returned by the scan or join.

For example, at step two of the plan generated for Example 9–3, a range scan is performed on table t2. When that scan is performed, the predicate t2.b <> 0 is also evaluated. Similarly, once the final merge-join has been performed, it is then possible to evaluate the predicate t3.b / t1.b > 1.

**Viewing query plans associated with commands stored in the SQL command cache**

Use the query plan information to monitor and troubleshoot your queries.

---

**Note:** For more reasons why to use the ttSQLCmdQueryPlan built-in procedure, see "Managing performance and troubleshooting commands" on page 9-3.

---

The ttSQLCmdQueryPlan built-in procedure displays the query plan of a specific statement or all statements in the command cache. It displays the detailed run-time query plans for the cached SQL queries. By default, all query plans are displayed; if you specify the command id taken from the command output, only the query plan for the specified command is displayed.

---

**Note:** If you want to display a query plan for a specific command, you must provide the command identifier that is displayed with the ttSQLCmdCacheInfo built-in procedure. See "Displaying commands stored in the SQL command cache" on page 9-4 for full details.

---

The plan data displayed when you invoke this built-in procedure is as follows:

- Command identifier
- Query text up to 1024 characters
- Step number of the current operation in the run-time query plan
- Level number of the current operation in the query plan tree
- Operation name of current step
- Name of table used
- Owner of the table
- Name of index used
- If used and available, the index predicate
- If used and available, the non-indexed predicate

---

**Note:** For more information on how to view this information, see "Reading query plan from the PLAN table" on page 9-7. The source of the data may be different, but the mapping and understanding of the material is the same as the query plan in the system PLAN table.

---

The ttSQLCmdQueryPlan built-in process displays the query plan in a raw data format. Alternatively, you can execute the ttIsql explain command for a formatted version.
of this output. For more information, see "Display query plan for statement in SQL command cache" on page 6-36.

The following examples show how to display all or a single SQL query plan from the SQL command cache using the ttSQLCmdQueryPlan built-in procedure:

- Displaying all SQL query plans
- Displaying a single SQL query plan

**Example 9–4  Displaying all SQL query plans**

You can display all SQL query plans associated with commands stored in the command cache with the ttSQLCmdQueryPlan built-in procedure within the ttIsql utility.

The following example shows the output when executing the ttSQLCmdQueryPlan built-in procedure without arguments, which displays detailed run-time query plans for all valid queries. For invalid queries, there is no query plan; instead, the query text is displayed.

The query plans are displayed in terse format. To view with the column headings prepended, execute `vertical` on before calling the ttSQLCmdQueryPlan built-in procedure.

**Note:** For complex expressions, there may be some difficulties in printing out the original expressions.

```sql
Command> call ttSQLCmdQueryPlan();
```

```
< 528079360, select * from t7 where x7 is not null or exists (select 1 from t2,t3 where not 'tuf' like 'abc'), <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, >
< 528079360, <NULL>, 0, 2, RowLkSerialScan , T7 , PAT , , , >
< 528079360, <NULL>, 1, 3, RowLkRangeScan , T2 , PAT , I2 , , NOT(LIKE( tuf ,abc ,NULL )) >
< 528079360, <NULL>, 2, 3, RowLkRangeScan , T3 , PAT , I2 , , >
< 528079360, <NULL>, 3, 2, NestedLoop , , , , , , >
< 528079360, <NULL>, 4, 1, NestedLoop(Left OuterJoin) , , , , , , >
< 528079360, <NULL>, 5, 0, Filter , , , , , X7 , , , , >
< 527576540, call ttSQLCmdQueryPlan(527973892), <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, >
< 527576540, <NULL>, 0, 0, Procedure Call , , , , , , , , , >
< 528054656, create table t2(x2 int,y2 int, z2 int), <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, >
< 528066648, insert into t2 select * from t1, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, >
< 528066648, <NULL>, 0, 0, Insert , T2 , PAT , , , >
< 528013192, select * from t1 where exists (select * from t2 where x1=x2) or y1=1, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, >
< 528061248, create index i1 on t3(y3), <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, >
< 528070368, call ttOptSetOrder('t3 t4 t2 t1'), <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, >
```
Example 9–5 Displaying a single SQL query plan

You can display any query plan associated with a command by providing the command id of the command as the input for the `ttSQLCmdQueryPlan` built-in procedure. The single query plan is displayed from within the SQL command cache. If no command id is supplied, the `ttSQLCmdCacheInfo` built-in procedure displays information about all current commands in the TimesTen cache.

The following example displays the query plan of the command identified by command id of 528078576. It is displayed in terse format; to view with the column headings prepended, execute `vertical` on before calling the `ttSQLCmdQueryPlan` built-in procedure.

Note: for complex expressions, there are some difficulties to print original expressions.

Command> call ttSQLCmdQueryPlan(528078576);
< 528078576, select * from t1 where 1=2 or (x1 in (select x2 from t2, t5 where y2 in (select y3 from t3)) and y1 in (select x4 from t4)), <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL>, <NULL> >
< 528078576, <NULL>, 0, 4, RowLkSerialScan , T1 , PAT , , , , , >

Modifying plan generation

If you decide that you want to modify a query plan, you can only modify the query plan that exists in the system PLAN table as described in "Viewing a query plan from the system PLAN table" on page 9-6. Once you do modify the query plan, it does not replace the query plan, but creates a new query plan with your changes.

The following sections describe why you may want to modify execution plans and then how to modify them:

- Why modify an execution plan?
- How hints can influence an execution plan
- Use optimizer hints to modify the execution plan

Why modify an execution plan?

Applications may want to modify an execution plan for two reasons:

- The plan is optimally fast but is ill-suited for the application. The optimizer may select the fastest execution path, but this path may not be desirable from the application's point of view. For example, if the optimizer chooses to use certain indexes, these choices may prevent other operations—such as certain update or delete operations—from occurring simultaneously on the indexed tables. In this case, an application can prevent the use of those indexes.

The plan chosen by the optimizer may also consume more memory than is available or than the application wants to allocate. For example, this may happen if the plan stores intermediate results or requires the creation of temporary indexes.

- The plan is not optimally performant. The query optimizer chooses the plan that it estimates will execute the fastest based on its knowledge of the tables' contents, available indexes, statistics, and the relative costs of various internal operations. The optimizer often has to make estimates or generalizations when evaluating this information, so there can be instances where it does not choose the fastest plan. In this case, an application can adjust the optimizer's behavior to try to produce a better plan.

How hints can influence an execution plan

You can apply hints to pass instructions to the TimesTen query optimizer. The optimizer considers these hints when choosing the best execution plan for your query.
Transaction level hints are in effect for all calls to the ODBC SQLPrepare function or JDBC PreparedStatement objects in the transaction.

- If a command is prepared with certain hints in effect, those hints continue to apply if the command is reprepared automatically, even when this happens outside the initial prepare transaction. This can happen when a table is altered, or an index is dropped or created, or when statistics are modified, as described in "When optimization occurs" on page 9-1.

- If a command is prepared without hints, subsequent hints do not affect the command if it is reprepared automatically. An application must call the ODBC SQLPrepare function or JDBC Connection.prepareStatement() method a second time so that hints have an effect.

**Example 9-6 Tuning a join when using ODBC**

When using ODBC, a developer tuning a join on T1 and T2 might go through the steps shown in the following figure.

![Diagram of plan generation process for ODBC](image)

During execution, the application may then go through the steps shown in the following figure.

![Diagram of execution process for ODBC](image)

**Example 9-7 Tuning a join when using JDBC**

When using JDBC, a developer tuning a join on T1 and T2 might go through the steps shown in the following figure.
During execution, the application may then go through the steps shown in the following figure.

Use optimizer hints to modify the execution plan

You can apply hints to pass instructions to the TimesTen query optimizer as follows:

- To apply a hint only for a particular SQL statement, use a statement level optimizer hint.
- To apply a hint for an entire transaction, use a transaction level optimizer hint with the appropriate TimesTen built-in procedure.
- To apply a hint for an entire TimesTen connection, use a connection level optimizer hint.

The order of precedence for optimizer hints is statement level hints, transaction level hints and then connection level hints.
Directions for applying hints are described in the following sections:

- Apply statement level optimizer hints for a SQL statement
- Apply transaction level optimizer hints for a transaction
- Apply connection level optimizer hints for a TimesTen connection

**Apply statement level optimizer hints for a SQL statement**

A statement level optimizer hint is a specially formatted SQL comment containing instructions for the SQL optimizer. A statement level optimizer hint can be specified within the SQL statement that it is to be applied against with one of the following methods:

- /*+ */ The hints can be defined over multiple lines. The hints must be enclosed in the comment syntax. The plus sign (+) denotes the start of a hint.
- ---+ The hint must be defined on a single line after the plus sign (+).

The statement level optimizer hint can be specified in the `SELECT`, `INSERT`, `UPDATE`, `MERGE`, `DELETE`, `CREATE TABLE AS SELECT`, or `INSERT ... SELECT` statements. You must specify the hint within comment syntax immediately following the SQL VERB.

See "Statement level optimizer hints" in the Oracle TimesTen In-Memory Database SQL Reference for information specific to statement level optimizer hints. See "Using optimizer hints" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for optimizer hints that are specific to TimesTen Scaleout.

**Note:** If you specify any statement level optimizer hints incorrectly, TimesTen ignores these hints and does not provide an error. If you define conflicting hints, the rightmost hint overrides any conflicting hints for the statement.

**Apply transaction level optimizer hints for a transaction**

To change the query optimizer behavior for all statements in a transaction, an application calls one of the following built-in procedures using the ODBC procedure call interface:

---

 Zotot concurrently processes read and write operations optimally. Your read operations can be optimized for read-only concurrency when you use transaction level optimizer hints such as `ttOptSetFlag ('tblLock',1)` or statement level optimizer hints such as `/*+ tt_tbllock(1) tt_rowlock(0) */`. Write operations that operate concurrently with read optimized operations may result in contention.

You can control read optimization during periods of concurrent write operations with the `ttDbWriteConcurrencyModeSet` built-in procedure. For more information, see "Control read optimization during concurrent write operations" on page 10-25.
Modifying plan generation

- **ttOptSetFlag**—Sets certain optimizer parameters. Provides the optimizer with transaction level optimizer hints with a recommendation on how to best optimize a particular query.
- **ttOptGetFlag**—View the existing transaction level hints set for a database.
- **ttOptSetOrder**—Enables an application to specify the table join order.
- **ttOptUseIndex**—Enables an application to specify that an index be used or to disable the use of certain indexes; that is, to specify which indexes should be considered for each correlation in a query.
- **ttOptClearStats, ttOptEstimateStats, ttOptSetColIntvlStats, ttOptSetTblStats, ttOptUpdateStats**—Manipulate statistics that TimesTen maintains on the application's data that are used by the query optimizer to estimate costs of various operations.

Some of these built-in procedures require that the user have privileges to the objects on which the utility executes. For full details on these built-in procedures and any privileges required, see "Built-In Procedures" in the *Oracle TimesTen In-Memory Database Reference*.

The following examples provide an ODBC and JDBC method on how to use the ttOptSetFlag built-in procedure:

**Note:** Make sure autocommit is off for transaction level optimizer hints. All optimizer flags are reset to their default values when the transaction has been committed or rolled back. If optimizer flags are set while autocommit is on, the optimizer flags are ignored because each statement is executed within its own transaction.

- **Example 9–8, "Using ttOptSetFlag in JDBC"**
- **Example 9–9, "Using ttOptSetFlag in ODBC"**

**Example 9–8 Using ttOptSetFlag in JDBC**

This JDBC example illustrates the use of ttOptSetFlag to prevent the optimizer from choosing a merge join.

```java
import java.sql.*;
class Example {
    public void myMethod() {
        CallableStatement cStmt;
        PreparedStatement pStmt;
        try {
            try {
                // Prevent the optimizer from choosing Merge Join
                cStmt = con.prepareCall("CALL ttOptSetFlag('MergeJoin', 0)"");
                cStmt.execute();
            }
        }
    }
}
```

**Note:** You can also experiment with optimizer settings using the ttIsql utility. The commands that start with "try" control transaction level optimizer hints. To view current transaction level optimizer hint settings, use the optprofile command.
// Next prepared query
pStmt=con.prepareStatement(
'\*SELECT \* FROM Tbl1, Tbl2 WHERE Tbl1.ssn=Tbl2.ssn');

. . . . .
catch (SQLException ex) {
    ex.printStackTrace();
}   
. . . . .
}

Example 9–9 Using ttOptSetFlag in ODBC
This ODBC example illustrates the use of ttOptSetFlag to prevent the optimizer from choosing a merge join.

#include <sql.h>
SQLRETURN rc;
SQLHSTMT hstmt; fetchStmt;
....
rc = SQLExecDirect (hstmt, (SQLCHAR *)
"(CALL ttOptSetFlag (MergeJoin, 0))",
SQL_NTS)
/* check return value */
....
rc = SQLPrepare (fetchStmt, ...)
/* check return value */
....

Apply connection level optimizer hints for a TimesTen connection
To change the query optimizer behavior for all statements of a specific connection, define the OptimizerHint connection attribute. The value of the OptimizerHint connection attribute is a string that uses the same format as a statement level optimizer hint but without the delimiters of /*+, */-, and --+.

You cannot include comments with connection level optimizer hints.

Transaction level optimizer hints overwrite connection level optimizer hints for the current transaction. After a commit, the transaction level optimizer hints are lost and the connection level optimizer hints take effect. Statement level optimizer hints overwrite transaction level optimizer hints and connection level optimizer hints for the scope of the statement. Since this is a connection attribute, the ttConfiguration utility shows the connection level optimizer hints.

Note: In a client server setting, the client connection setting of this connection attribute overwrites the Server DSN setting of this attribute.

Example 9–10 Using connection level optimizer hints
This example illustrates the use of TT_RowLock, TT_TblLock, and TT_MergeJoin to enable row locking, disable table locking, and disable merge joins. Note that /disk1/timesten is the timesten_home.

....
[database1]
Driver=/disk1/timesten/install/lib/libtten.so
DataStore=/disk1/timesten/info/DemoDataStore/database1
PermSize=128

9-18 Oracle TimesTen In-Memory Database Operations Guide
Example 9–11  Using TT_INDEX as a connection level optimizer hint

TimesTen does not support the use of the semicolon (;) character in connection attributes. Therefore, when you want to use more than one TT_INDEX optimizer hint at the connection level, you cannot use the same syntax that you use for the statement level.

For example, `TT_INDEX(EMPLOYEES,EMP_NAME_IX,1;EMPLOYEES,EMP_MANAGER_IX,1)` is a valid statement level optimizer hint, but it is an invalid connection level optimizer hint. TimesTen merges multiple TT_INDEX optimizer hints if they are specified on the same line. Therefore, `TT_INDEX(EMPLOYEES,EMP_NAME_IX,1) TT_INDEX(EMPLOYEES,EMP_MANAGER_IX,1)` is equivalent to `TT_INDEX(EMPLOYEES,EMP_NAME_IX,1;EMPLOYEES,EMP_MANAGER_IX,1)`.

This example illustrates the use of multiple TT_INDEX optimizer hints at the connection level. Note that `/disk1/timesten` is the timesten_home.

...[database1]
Driver=/disk1/timesten/install/lib/libtten.so
DataStore=/disk1/databases/info/DemoDataStore/database1
PermSize=128
TempSize=64
DatabaseCharacterSet=AL32UTF8
OptimizerHint= TT_INDEX(EMPLOYEES,EMP_NAME_IX,1) TT_INDEX(EMPLOYEES,EMP_MANAGER_IX,1)
...
Modifying plan generation
An application using TimesTen should obtain an order of magnitude performance improvement in its data access over an application using a traditional RDBMS. However, poor application design and tuning can erode the TimesTen advantage. This chapter discusses factors that can affect the performance of a TimesTen application. These factors range from subtle, such as data conversions, to more overt, such as preparing a command at each execution.

This chapter explains the full range of these factors, with a section on each factor indicating:

- How to detect problems.
- How large is the potential performance impact.
- Where are the performance gains.
- What are the tradeoffs.

The following sections describe how to tune and identify performance issues:

- System and database tuning
- Client/Server tuning
- SQL tuning
- Materialized view tuning
- Transaction tuning
- Recovery tuning
- Scaling for multiple CPUs
- XLA tuning
- Cache and replication tuning

For information on tuning TimesTen Java applications, see "Java Application Tuning" in the Oracle TimesTen In-Memory Database Java Developer’s Guide. For information on tuning TimesTen C applications, see "ODBC Application Tuning" in the Oracle TimesTen In-Memory Database C Developer’s Guide.

Note: You can also identify performance issues by examining the SYS.SYSTEMSTATS table.
System and database tuning

The following sections include tips for tuning your system and databases:

- Provide enough memory
- Avoid paging of the memory used by the database
- Size your database correctly
- Calculate shared memory size for PL/SQL runtime
- Set appropriate limit on the number of open files
- Configure log buffer and log file size parameters
- Avoid connection overhead for TimesTen Classic databases
- Load the database into RAM when duplicating
- Prevent reloading of the database after automatic recovery fails
- Reduce contention
- Consider special options for maintenance
- Check your driver
- Enable tracing only as needed
- Use metrics to evaluate performance
- Migrate data with character set conversions
- Use TimesTen native integer data types if appropriate
- Configure the checkpoint files and transaction log files to be on a different physical device

Provide enough memory

Performance impact: Large

Configure your system so that the entire database fits in main memory. The use of virtual memory substantially decreases performance. The database or working set does not fit if a performance monitoring tool shows excessive paging or virtual memory activity. You may have to add physical memory or configure the system software to allow a large amount of shared memory to be allocated to your process(es).

For Linux systems, you must configure shared memory so that the maximum size of a shared memory segment is large enough to contain the size of the total shared memory segment for the database.

In TimesTen Classic, the entire database resides in a single shared memory segment. In TimesTen Scaleout, you set settings for the shared memory segment of each host. Set the appropriate operating system kernel parameters for shmax, shmall, memlock, and HugePages. See "Operating system prerequisites" in the Oracle TimesTen In-Memory Database Installation, Migration, and Upgrade Guide and "Configuring the operating system kernel parameters" in the Oracle TimesTen In-Memory Database Scaleout User’s Guide for more details.

TimesTen includes the ttSize utility to help you estimate the size of tables in your database. For more information, see "ttSize" in the Oracle TimesTen In-Memory Database Reference.
Avoid paging of the memory used by the database

Performance impact: Variable

On Linux, the `MemoryLock` connection attribute specifies whether the real memory used by the database should be locked while the database is loaded into memory. Set `MemoryLock` to 4 to avoid paging of the memory used by the database. If `MemoryLock` is not set to 4, parts of the shared memory segment used by the database may be paged out to the swap area, resulting in poor database performance. See "MemoryLock" in the Oracle TimesTen In-Memory Database Reference for more information.

Size your database correctly

Performance impact: Variable

When you create a database, you are required to specify a database size. Specifically, you specify sizes for the permanent and temporary memory regions of the database. For details on how to size the database and shared memory, see "Specifying the memory region sizes of a database" on page 2-10 in this book and "Configure shmmax and shmall" in the Oracle TimesTen In-Memory Database Installation, Migration, and Upgrade Guide for details.

Calculate shared memory size for PL/SQL runtime

Performance impact: Variable

The PL/SQL runtime system uses an area of shared memory to hold metadata about PL/SQL objects in TimesTen and the executable code for PL/SQL program units that are currently being executed or that have recently been executed. The size of this shared memory area is controlled by the `PLSQL_MEMORY_SIZE` first connect attribute.

When a new PL/SQL program unit is prepared for execution, it is loaded into shared memory. If shared memory space is not available, the cached recently-executed program units are discarded from memory until sufficient shared memory space is available. If all of the PL/SQL shared memory is being used by currently executing program units, then attempts by a new connection to execute PL/SQL may result in out of space errors, such as `ORA-04031`. If this happens, increase the `PLSQL_MEMORY_SIZE`.

Even if such out of space errors do not occur, the `PLSQL_MEMORY_SIZE` may be too small. It is less expensive in CPU time to execute a PL/SQL procedure that is cached in shared memory than one that is not cached. In a production application, the goal should be for `PLSQL_MEMORY_SIZE` to be large enough so that frequently-executed PL/SQL units are always cached. The TimesTen built-in procedure `ttPLSQLMemoryStats` can be used to determine how often this occurs. The `PinHitRatio` value returned is a real number between 0 and 1.

- 1.0: A value of 1.0 means that every PL/SQL execution occurred from the cache.
- 0.0: A value of 0.0 means that every execution required that the program unit be loaded into shared memory.

The proper value of `PLSQL_MEMORY_SIZE` for a given application depends on the application. If only a small number of PL/SQL program units are repeatedly executed, then the size requirements can be small. If the application uses hundreds of PL/SQL program units, memory requirements increase.

Performance increases dramatically as the `PinHitRatio` goes up. In one set of experiments, an application program repeatedly executed a large number of PL/SQL stored procedures. With a larger value for `PLSQL_MEMORY_SIZE`, the application results
in a PinHitRatio of around 90%, and the average execution time for a PL/SQL procedure was 0.02 seconds. With a smaller value for PLSQL_MEMORY_SIZE, there was more contention for the cache, resulting in a PinHitRatio of 66%. In this experiment the average execution time was 0.26 seconds.

The default value for PLSQL_MEMORY_SIZE is 128 MB on Linux and UNIX systems. This should be sufficient for several hundred PL/SQL program units of reasonable complexity to execute. After running a production workload for some time, check the value of PinHitRatio. If it is less than 0.90, consider increasing PLSQL_MEMORY_SIZE.

Set appropriate limit on the number of open files

Performance impact: Variable

For multithreaded applications that maintain many concurrent TimesTen database connections, the default number of open files permitted to each process by the operating system may be too low. See "Limits on number of open files" in the Oracle TimesTen In-Memory Database Reference for details on how to set new limits for the number of open files.

Configure log buffer and log file size parameters

Performance impact: Large

Increasing the value of LogBufMB and LogFileSize could have a substantial positive performance impact. LogBufMB is related to the LogFileSize connection attribute, which should be set to the same value or integral multiples of LogBufMB for best performance.

Log buffer waits occur when application processes cannot insert transaction data to the log buffer and must stall to wait for log buffer space to be freed. The usual reason for this is that the log flusher thread has not cleared out data fast enough. This may indicate that log buffer space is insufficient, file system transfer rate is insufficient, writing to the file system is taking too long, or the log flusher is CPU-bound.

- A small LogBufMB could slow down write transactions when these transactions have to wait for a log flush operation to make space for redo logging. An oversized log buffer has no impact other than consuming extra memory. The value of LOG_BUFFER_WAITS shows the number of times a thread was delayed while trying to insert a transaction log record into the log buffer because the log buffer was full. Generally, if this value is increasing, it indicates that the log buffer is too small.

- The LogFileSize attribute specifies the maximum size of each transaction log file in megabytes. If LogFileSize is too small, then TimesTen has to create multiple log files within a transaction log flush operation. The overhead of file creation often leads to LOG_BUF_WAITS events, which could significantly impact performance.

You can observe the value of the LOG_BUFFER_WAITS metric (using either the SYS.MONITOR table or the ttIsql monitor command) to see if it increases while running a workload. After which, you can increase the value of LogBufMB to improve the database performance.

The trade-off from increasing the value of LogBufMB is that more transactions are buffered in memory and may be lost if the process crashes. If DurableCommits are enabled, increasing the value of LogBufMB value does not improve performance.

If log buffer waits still persist after increasing the LogBufMB and LogFileSize values, then review the other possible issues mentioned above.
The LogBufParallelism connection attribute specifies the number of transaction log buffer strands. This attribute improves transaction throughput when multiple connections execute write transactions concurrently. Configure this to the lesser value of the number of CPU cores on the system and the number of concurrent connections executing write transactions.

Note: For more details, see "LogBufMB", "LogFileSize" and "LogBufParallelism" in the Oracle TimesTen In-Memory Database Reference.

Avoid connection overhead for TimesTen Classic databases

Performance impact: Large

An idle database is a database with no connections. By default, TimesTen loads an idle database into memory when a first connection is made to it. When the final application disconnects from a database, a delay occurs when the database is written to the file system. If applications are continually connecting and disconnecting from a database, the database may be loaded to and unloaded from memory continuously, resulting in excessive file system I/O and poor performance. Similarly, if you are using a very large database you may want to pre-load the database into memory before any applications attempt to use it.

To avoid the latency of loading a database into memory, you can change the RAM policy of a TimesTen Classic database to enable databases to always remain in memory. The trade-off is that since the TimesTen Classic database is never unloaded from memory, a final disconnect checkpoint never occurs. So, applications should configure frequent checkpoints with the ttCkptConfig built-in procedure. See "ttCkptConfig" in the Oracle TimesTen In-Memory Database Reference for more information.

Alternatively, you can specify that the TimesTen Classic database remain in memory for a specified interval of time and accept new connections. If no new connections occur in this interval, TimesTen Classic unloads the database from memory and checkpoints it. You can also specify a setting to enable a system administrator to load and unload the database from memory manually.

To change the RAM policy of a TimesTen Classic database, use the ttAdmin utility. For more details on the RAM policy and the ttAdmin utility, see "Specifying a RAM policy" on page 2-5 in this book and the "ttAdmin" section in the Oracle TimesTen In-Memory Database Reference.

Load the database into RAM when duplicating

Performance impact: Large

Load a TimesTen Classic database into memory with the ttAdmin -ramLoad command before you duplicate this database with the ttRepAdmin -duplicate utility. This places the database in memory, available for connections, instead of unloading it with a blocking checkpoint. For more information, see "Avoid connection overhead for TimesTen Classic databases" on page 10-5 in this book and the "ttAdmin" and "ttRepAdmin" sections in the Oracle TimesTen In-Memory Database Reference.

Prevent reloading of the database after automatic recovery fails

Performance impact: Large
When TimesTen Classic recovers after a database is invalidated, a new database is reloaded. However, the invalidated database is only unloaded after all connections to this database are closed. Thus, both the invalidated database and the recovered database could exist in RAM at the same time.

Reloading a large database into memory when an invalidated database still exists in memory can fill up available RAM. See "Preventing an automatic reload of the database after failure" on page 2-7 on how to stop automatic reloading of the database.

Reduce contention

Performance impact: Large

Database contention can substantially impede application performance.

To reduce contention in your application:

- Choose the appropriate locking method. See "Choose the best method of locking" on page 10-10.
- Distribute data strategically in multiple tables or databases.

If your application suffers a decrease in performance because of lock contention and a lack of concurrency, reducing contention is an important first step in improving performance.

The `lock.locks_granted.immediate`, `lock.locks_granted.wait` and `lock.timeouts` columns in the `SYS.SYSTEMSTATS` table provide some information on lock contention:

- `lock.locks_granted.immediate` counts how often a lock was available and was immediately granted at lock request time.
- `lock.locks_granted.wait` counts how often a lock request was granted after the requestor had to wait for the lock to become available.
- `lock.timeouts` counts how often a lock request was not granted because the requestor did not want to wait for the lock to become available.

If limited concurrency results in a lack of throughput, or if response time is an issue, an application can reduce the number of threads or processes making API (JDBC, ODBC, or OCI) calls. Using fewer threads requires some queuing and scheduling on the part of the application, which has to trade off some CPU time for a decrease in contention and wait time. The result is higher performance for low-concurrency applications that spend the bulk of their time in the database.

Consider special options for maintenance

Performance impact: Medium

During special operations such as initial loading, you can choose different options than you would use during normal operations. In particular, consider using database-level locking for bulk loading; an example would be using `ttBulkCp` or `ttMigrate`. These choices can improve loading performance by a factor of two.

An alternative to database-level locking is to exploit concurrency. Multiple copies of `ttBulkCp -i` can be run using the `-notblLock` option. Optimal batching for `ttBulkCp` occurs by adding the `-xp 256` option.

For more details, see "ttBulkCp" and "ttMigrate" in the Oracle TimesTen In-Memory Database Reference.
Check your driver

Performance impact: Large

There are two versions of the TimesTen Data Manager driver for each platform: a debug and production version. Unless you are debugging, use the production version. The debug library can be significantly slower. See “Creating a DSN on Linux and UNIX for TimesTen Classic” on page 1-9 and “Connecting to TimesTen with ODBC and JDBC drivers” on page 1-1 for a description of the TimesTen Data Manager drivers for the different platforms.

On Windows, make sure that applications that use the ODBC driver manager use a DSN that accesses the correct TimesTen driver. Make sure that applications are linked with the correct TimesTen driver. For direct connect applications, use the TimesTen Data Manager driver. An application can call the ODBC SQLGetInfo function with the SQL_DRIVER_NAME argument to determine which driver it is using.

Enable tracing only as needed

Performance impact: Large

Both ODBC and JDBC provide a trace facility to help debug applications. For performance runs, make sure that tracing is disabled except when debugging applications.

To turn the JDBC tracing on, use:

```java
DriverManager.setLogStream method:
DriverManager.setLogStream(new PrintStream(System.out, true));
```

By default tracing is off. You must call this method before you load a JDBC driver. Once you turn the tracing on, you cannot turn it off for the entire execution of the application.

Use metrics to evaluate performance

Performance impact: Variable

You can use the ttStats utility to collect and display database metrics. The ttStats utility can perform the following functions.

- Monitor and display database performance metrics in real-time, calculating rates of change during each preceding interval.
- Collect and store snapshots of metrics to the database then produce reports with values and rates of change from specified pairs of snapshots. (These functions are performed through calls to the TT_STATS PL/SQL package.)

The ttStats utility gathers metrics from TimesTen system tables, views, and built-in procedures. In reports, this includes information such as a summary of memory usage, connections, and load profile, followed by metrics (as applicable) for SQL statements, transactions, PL/SQL memory, replication, logs and log holds, checkpoints, cache groups, latches, locks, XLA, and TimesTen connection attributes.

Call the ttStatsConfig built-in procedure to modify statistics collection parameters that affect the ttStatus utility. For more information on the parameters of the ttStatsConfig built-in procedure, see “ttStatsConfig” in the Oracle TimesTen In-Memory Database Reference.
For details on the "ttStats" utility, see "ttStats" in the Oracle TimesTen In-Memory Database Reference. For more details on the TT_STATS PL/SQL package, see "TT_STATS" in the Oracle TimesTen In-Memory Database PL/SQL Packages Reference.

Migrate data with character set conversions

Performance impact: Variable

If character set conversion is requested when migrating databases, performance may be slower than if character set conversion is not requested.

Use TimesTen native integer data types if appropriate

Performance impact: Variable

Declare the column types of a table with TimesTen native integer data types, TT_SMALLINT, TT_INTEGER, or TT_BIGINT instead of the NUMBER data type to save space and improve the performance of calculations. TimesTen internally maps the SMALLINT, INTEGER, INT, DECIMAL, NUMERIC, and NUMBER data types to the NUMBER data type. When you define the column types of a table, ensure that you choose the appropriate native integer data type for your column to avoid overflow. For more information on native integer data types and the NUMBER data type, see "Numeric data types" in the Oracle TimesTen In-Memory Database SQL Reference.

If you use a TimesTen native integer data type when you create a TimesTen cache group that reads and writes to an Oracle database, ensure that the data type of the columns of the TimesTen cache group and the Oracle database are compatible. For more information about the mapping between Oracle Database and TimesTen data types, see "Mappings between Oracle Database and TimesTen data types" in the Oracle TimesTen Application-Tier Database Cache User’s Guide.

Configure the checkpoint files and transaction log files to be on a different physical device

Performance impact: Large

For best performance, TimesTen recommends that you use the LogDir connection attribute to place the transaction log files on a different physical device from the checkpoint files. This is important if your application needs to have consistent response times and throughput. TimesTen places the checkpoint files in the location specified by the DataStore connection attribute, which is the full path name of the database and the file name prefix. If the transaction log files and checkpoint files are on different physical devices, I/O operations for checkpoints do not block I/O operations to the transaction log and vice versa. For more information on transaction logging, see “Transaction logging” on page 7-16.

For more information about the LogDir and DataStore connection attributes, see "LogDir" and "DataStore” in the Oracle TimesTen In-Memory Database Reference.

Note: If the database is already loaded into RAM and the transaction log files and checkpoint files for your database are on the same physical device, TimesTen writes a message to the daemon log file.

Client/Server tuning

The following sections include tips for Client/Server tuning:
Diagnose Client/Server performance

Performance impact: Variable

You can analyze your Client/Server performance with the following statistics that are tracked in the `SYS.SYSTEMSTATS` table that can also be viewed with either the `ttStats` utility or the `TT_STATS` PL/SQL package:

- Total number of executions from a Client/Server application.
- Total number of `INSERT`, `UPDATE`, `DELETE`, `SELECT`, `MERGE`, `ALTER`, `CREATE`, `DROP` statements executed by the server.
- Total number of transactions committed or rolled back by the server.
- Total number of table rows inserted, updated, or deleted by the server.
- Total number of Client/Server roundtrips.
- Total number of Client/Server disconnects.

Work locally when possible

Performance impact: Large

Using TimesTen Client to access databases on a remote server system adds network overhead to your connections. Whenever possible, write your applications to access TimesTen locally using a direct driver, and link the application directly with TimesTen.

Choose timeout connection attributes for your client

Performance impact: Variable

By default, connections wait 60 seconds for TimesTen Client and Server to complete a network operation. The `TTC_Timeout` attribute determines the maximum number of...
seconds a TimesTen Client application waits for the result from the corresponding TimesTen Server process before timing out.

The `TTC_ConnectTimeout` attribute specifies the maximum number of seconds the client waits for a `SQLDriverConnect` or `SQLDisconnect` request. It overrides the value of `TTC_Timeout` for those requests. Set the `TTC_ConnectTimeout` when you want connection requests to timeout with a different timeframe than the timeout provided for query requests. For example, you can set a longer timeout for connections if you know that it takes a longer time to connect, but set a shorter timeout for all other queries.

The overall elapsed time allotted for the `SQLDriverConnect` call depends on if automatic client failover is configured:

- If there is just one `TTC_SERVERn` connection attribute defined, then there is no automatic client failover configured and the overall elapsed time allotted for the initial connection attempt is limited to 10 seconds.
- If automatic client failover is defined and there is more than one `TTC_SERVERn` connection attribute configured, then the overall elapsed time is four times the value of the timeout (whether `TTC_Timeout` or `TTC_ConnectTimeout`). For example, if the user specifies `TTC_TIMEOUT=10` and there are multiple `TTC_SERVERn` servers configured, then the `SQLDriverConnect` call could take up to 40 seconds.

However, within this overall elapsed timeout, each connection attempt can take the time specified by the `TTC_Timeout` or `TTC_ConnectTimeout` value, where the `TTC_ConnectTimeout` value overrides the `TTC_Timeout` value.

See "Choose SQL and PL/SQL timeout values" on page 10-26 for information about how `TTC_Timeout` and `TTC_ConnectTimeout` relates to SQL and PL/SQL timeouts.

For more details, see "TTC_Timeout" and "TTC_ConnectTimeout" in the Oracle TimesTen In-Memory Database Reference.

### Choose a lock wait timeout interval

**Performance impact: Variable**

By default, connections wait 10 seconds to acquire a lock. To change the timeout interval for locks, set the `LockWait` connection attribute or use the `ttLockWait` built-in procedure. When running a workload of high lock-contention potential, consider setting the `LockWait` connection attribute to a smaller value for faster return of control to the application, or setting `LockWait` to a larger value to increase the successful lock grant ratio (with a risk of decreased throughput).

For more details, see "Setting wait time for acquiring a lock" on page 7-9 in this book or "LockWait" or "ttLockWait" in the Oracle TimesTen In-Memory Database Reference.

### Choose the best method of locking

**Performance impact: Variable**

When multiple connections access a database simultaneously, TimesTen uses locks to ensure that the various transactions operate in apparent isolation. TimesTen supports the isolation levels described in Chapter 7, "Transaction Management". It also supports the locking levels: database-level locking, table-level locking and row-level locking.

You can use the `LockLevel` connection attribute to indicate whether database-level locking or row-level locking should be used. Use the `ttOptSetFlag` procedure to set optimizer hints that indicate whether table locks should be used. The default lock granularity is row-level locking.
Choose an appropriate lock level

If there is very little contention on the database, use table-level locking. It provides better performance and deadlocks are less likely. There is generally little contention on the database when transactions are short or there are few connections. In that case, transactions are not likely to overlap.

- Table-level locking is also useful when a statement accesses nearly all the rows on a table. Such statements can be queries, updates, deletes or multiple inserts done in a single transaction.
- Database-level locking completely restricts database access to a single transaction, and it is not recommended for ordinary operations. A long-running transaction using database-level locking blocks all other access to the database, affecting even the various background tasks needed to monitor and maintain the database.
- Row-level locking is generally preferable when there are many concurrent transactions that are not likely to need access to the same row. On modern systems with a sufficient number of processors using high-concurrency, for example, multiple ttBulkCp processes, row-level locking generally outperforms database-level locking.

Choose an appropriate isolation level

When using row-level locking, applications can run transactions at the \texttt{SERIALIZABLE} or \texttt{READ_COMMITTED} isolation level. The default isolation level is \texttt{READ_COMMITTED}. You can use the \texttt{Isolation} connection attribute to specify one of these isolation levels for new connections.

When running at \texttt{SERIALIZABLE} transaction isolation level, TimesTen holds all locks for the duration of the transaction.

- Any transaction updating a row blocks writers until the transaction commits.
- Any transaction reading a row blocks out writers until the transaction commits.

When running at \texttt{READ_COMMITTED} transaction isolation level, TimesTen only holds update locks for the duration of the transaction.

- Any transaction updating a row blocks out writers to that row until the transaction commits. A reader of that row receives the previously committed version of the row.
- Phantoms are possible. A phantom is a row that appears during one read but not during another read, or appears in modified form in two different reads, in the same transaction, due to early release of read locks during the transaction.

You can determine if there is an undue amount of contention on your system by checking for time-out and deadlock errors (errors 6001, 6002, and 6003). Information is also available in the \texttt{lock.timeouts} and \texttt{lock.deadlocks} columns of the \texttt{SYS.SYSTEMSTATS} table.

For more details on isolation levels, see "Transaction isolation levels" on page 7-5.
Use shared memory segment as IPC when client and server are on the same system

Performance impact: Variable

The TimesTen Client normally communicates with TimesTen Server using TCP/IP sockets. If both the TimesTen Client and TimesTen Server are on the same system, client applications show improved performance by using a shared memory segment or a UNIX domain socket for inter-process communication (IPC).

To use a shared memory segment as IPC, you must set the server options in the `timesten.conf` file. For a description of the server options, see "Modifying the TimesTen Server attributes" on page 4-7.

In addition, applications that use shared memory for IPC must use a logical server name for the Client DSN with `ttShmHost` as the Network Address. For more information, see "Creating and configuring Client DSNs on Linux and UNIX" on page 3-18.

This feature may require a significant amount of shared memory. The TimesTen Server pre-allocates the shared memory segment irrespective of the number of existing connections or the number of statements within all connections.

If your application is running on a Linux or UNIX system and you are concerned about memory usage, the applications using TimesTen Client ODBC driver may improve the performance by using UNIX domain sockets for communication. The performance improvement when using UNIX domain sockets is not as large as when using `ShmIPC`.

Applications that take advantage of UNIX domain sockets for local connections must use a logical server name for the Client DSN with `ttLocalHost` as the Network Address. For more information, see "Creating and configuring Client DSNs on Linux and UNIX" on page 3-18. In addition, make sure that your system kernel parameters are configured to allow the number of connections you require.

For more information, see "Linux prerequisites" in the Oracle TimesTen In-Memory Database Installation, Migration, and Upgrade Guide.

Enable prefetch close for read-only transactions

Performance impact: Variable

A TimesTen extension enables applications to optimize read-only query performance in client/server applications. When you enable prefetch close, the server closes the cursor and commits the transaction after the server has fetched the entire result set for a read-only query. This enhances performance by decreasing the network round-trips between client and server

- **ODBC**: Use the `SQLSetConnectOption` to set the `TT_PREFETCH_CLOSE` ODBC connection option. See "Optimizing query performance" in the Oracle TimesTen In-Memory Database C Developer's Guide for details.

Use a connection handle when calling `SQLTransact`

Performance impact: Large

You should always call `SQLTransact` with a valid HDBC and a null environment handle:
It is possible to call `SQLTransact` with a non-null environment handle and a null connection handle, but that usage is not recommended as it abruptly commits or rolls back every transaction for the process, which is slow and can cause unexpected application behavior.

### Enable multi-threaded mode to handle concurrent connections

The `MaxConnsPerServer` connection attribute sets the maximum number of concurrent connections allowed for a TimesTen server process. By default, `MaxConnsPerServer` equals to 1, meaning that each TimesTen server process can only handle one client connection.

Setting `MaxConnsPerServer > 1` enables multi-threaded mode for the database so that it can use threads instead of processes to handle client connections. This reduces the time required for applications to establish new connections and increases overall efficiency in configurations that use a large number of concurrent client/server connections.

See "Defining Server DSNs for TimesTen Server on a Linux or UNIX system" on page 3-7 for full details.

### SQL tuning

After you have determined the overall locking and I/O strategies, make sure that the individual SQL statements are executed as efficiently as possible. The following sections describe how to streamline your SQL statements:

- Tune statements and use indexes
- Collect and evaluate sampling of execution times for SQL statements
- Select the type of index appropriately
- Size hash indexes appropriately
- Use foreign key constraint appropriately
- Compute exact or estimated statistics
- Create script to regenerate current table statistics
- Control the invalidation of commands in the SQL command cache
- Avoid `ALTER TABLE`
- Avoid nested queries
- Prepare statements in advance
- Avoid unnecessary prepare operations
- Store data efficiently with column-based compression of tables
- Control read optimization during concurrent write operations
- Choose SQL and PL/SQL timeout values

### Tune statements and use indexes

**Performance impact: Large**
Verify that all statements are executed efficiently. For example, use queries that reference only the rows necessary to produce the required result set. If only \texttt{col1} from table \texttt{t1} is needed, use the statement:

\begin{verbatim}
SELECT col1 FROM t1;
\end{verbatim}

instead of using:

\begin{verbatim}
SELECT * FROM t1;
\end{verbatim}

Chapter 9, "The TimesTen Query Optimizer" describes how to view the plan that TimesTen uses to execute a statement. Alternatively, you can use the \texttt{ttIsql showplan} command to view the plan. View the plan for each frequently executed statement in the application. If indexes are not used to evaluate predicates, consider creating new indexes or rewriting the statement or query so that indexes can be used. For example, indexes can only be used to evaluate \texttt{WHERE} clauses when single columns appear on one side of a comparison predicate (equalities and inequalities), or in a \texttt{BETWEEN} predicate.

If this comparison predicate is evaluated often, it would therefore make sense to rewrite

\begin{verbatim}
WHERE c1+10 < c2+20
\end{verbatim}

to

\begin{verbatim}
WHERE c1 < c2+10
\end{verbatim}

and create an index on \texttt{c1}.

The presence of indexes does slow down write operations such as \texttt{UPDATE}, \texttt{INSERT}, \texttt{DELETE} and \texttt{CREATE VIEW}. If an application does few reads but many writes to a table, an index on that table may hurt overall performance rather than help it.

Occasionally, the system may create a temporary index to speed up query evaluation. If this happens frequently, it is better for the application itself to create the index. The \texttt{CMD_TEMP_INDEXES} column in the \texttt{MONITOR} table indicates how often a temporary index was created during query evaluation.

If you have implemented time-based aging for a table or cache group, create an index on the timestamp column for better performance of aging. See "Time-based aging" on page 8-8.

**Collect and evaluate sampling of execution times for SQL statements**

**Performance impact: Variable**

TimesTen provides built-in procedures that measure the execution time of SQL operations to determine the performance of SQL statements. Instead of tracing, the built-in procedures sample the execution time of SQL statements during execution. The built-in procedures measure the execution time of SQL statements by timing the execution within the \texttt{SQLExecute} API.

You can configure the sampling rate and how the execution times are collected with the \texttt{ttStatsConfig} built-in procedure and the following name-value pairs:

\begin{verbatim}
Note: For full details, see "ttStatsConfig" in the Oracle TimesTen In-Memory Database Reference.
\end{verbatim}
The following are examples of how to set the name-value pairs with the `ttStatsConfig` built-in procedure:

```sql
Sample every 5th statement on connection 1.
Command> call ttStatsConfig('ConnSampleFactor', '1,5');
< CONNSAMPLEFACTOR, 1,5 >
1 row found.

Turn off sampling on connection 1.
Command> call ttStatsConfig('ConnSampleFactor', '1,0');
< CONNSAMPLEFACTOR, 1,0 >
1 row found.

Sample every command:
Command> call ttStatsConfig('SqlCmdSampleFactor',1);
< SQLCMDSAMPLEFACTOR, 1 >
1 row found.

Check whether sampling:
Command> call ttStatsConfig('SqlCmdSampleFactor');
< SQLCMDSAMPLEFACTOR, 1 >
1 row found.
```

### Table 10–1: `ttStatsConfig` parameter and value descriptions

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLCmdSampleFactor</td>
<td>Configures how often a SQL statement execution timing sample is taken. The default is 0, which means that the sampling is turned off. For example, when set to 10, TimesTen captures the wall clock time of the SQL statement execution for every 10th statement.</td>
</tr>
<tr>
<td>ConnSampleFactor</td>
<td>Configures how often a SQL statement sample is taken for an individual connection. The value includes two parameters separated by a comma within quotes, so that it appears as a single value. The first number is the connection ID; the second is the same as the <code>SQLCmdSampleFactor</code> as a number that designates how often the command sample is taken. By default, sampling is turned off (set to zero) for individual connections.</td>
</tr>
<tr>
<td>SQLCmdHistogramReset</td>
<td>When set to a nonzero value, clears the SQL execution time histogram data.</td>
</tr>
<tr>
<td>StatsLevel</td>
<td>Sets the level of statistics to be taken. Values can be set to either NONE, BASIC, TYPICAL, or ALL. The default is TYPICAL. Setting the level to ALL could negatively impact your performance.</td>
</tr>
</tbody>
</table>

Note: You can achieve the best results by choosing representative connections with the `ConnSampleFactor` parameter in the `ttStatsConfig` built-in procedure, rather than sampling all transactions. Sampling all transactions with a small sample factor can affect your performance negatively.

For meaningful results, the database should remain in memory since unloading and re-loading the database empties the SQL command cache.
Check the current database statistics collection level.

Command>
call ttStatsConfig('StatsLevel');
< STATSLEVEL, TYPICAL >
1 row found.

Turn off database statistics collection by setting to NONE.

Command>
call ttStatsConfig('StatsLevel','None');
< STATSLEVEL, NONE >
1 row found.

Once you have configured the statistics that you want collected, the collected statistics are displayed with the ttSQLCmdCacheInfo built-in procedure. To display the execution time histogram at either the command or database levels, use the ttSQLExecutionTimeHistogram built-in procedure.

The ttSQLCmdCacheInfo built-in procedure displays the following information relating to SQL execution time statistics:

- Number of fetch executions performed internally for this statement.
- The timestamp when the statement started.
- The maximum wall clock execute time in seconds of this statement.
- Last measured execution time in seconds of the statement.
- The minimum execute time in seconds of the statement.

In the following example, the display shows these statistics as the last five values:

Command> vertical call ttSQLCmdCacheInfo(135680792);

| SQLCMDID:                        | 135680792 |
| PRIVATE_COMMAND_CONNECTION_ID:   | -1        |
| EXECUTIONS:                      | 97414     |
| PREPARES:                        | 50080     |
| REPREPARES:                      | 1         |
| FREEABLE:                        | 1         |
| SIZE:                            | 3880      |
| OWNER:                           | ORATT     |
| QUERYTEXT:                       | select min(unique2) from big1 |
| FETCHCOUNT:                      | 40        |
| STARTTIME:                       | 2018-04-10 13:10:46.808000 |
| MAXEXECUTETIME:                  | .001319   |
| LASTEXECUTETIME:                 | .000018   |
| MINEEXECUTETIME:                 | .000017   |
| EXECLOC:                         | 0         |
| GRIDCMDID:                       | 00000000000000000000 |
| TEMPSPACEUSAGE:                  | 0         |
| MAXTEMPSPACEUSAGE:               | 0         |

1 row found.

For more information on the ttSQLCmdCacheInfo built-in procedure, see "ttSQLCmdCacheInfo" in the Oracle TimesTen In-Memory Database Reference.

The ttSQLExecutionTimeHistogram built-in procedure displays a histogram of SQL execution times for either a single SQL command or all SQL commands in the command cache, assuming that sampling is enabled where SQLCmdSampleFactor is greater than zero.

The histogram displays a single row for each bucket of the histogram. Each row includes the following information:
The number of SQL statement execution time operations that have been measured since either the TimesTen database was started or after the ttStatsConfig built-in procedure was used to reset statistics.

- Accumulated wall clock execution time.
- The execution time limit that denotes each time frame.
- The last row shows the number of SQL statements that executed in a particular time frame.

The following example shows the output for the ttSQLExecutionTimeHistogram built-in procedure:

The following example of the ttSQLExecutionTimeHistogram built-in procedure shows that a total of 1919 statements executed. The total time for all 1919 statements to execute was 1.090751 seconds. This example shows that SQL statements ran in the following time frames:

- 278 statements executed in a time frame that was less than or equal to .00001562 seconds.
- 1484 statements executed in a time frame that was greater than .00001562 seconds and less than or equal to .000125 seconds.
- 35 statements executed in a time frame that was greater than .000125 seconds and less than or equal to .001 seconds.
- 62 statements executed in a time frame that was greater than .001 seconds and less than or equal to .008 seconds.
- 60 statements executed in a time frame that was greater than .008 seconds and less than or equal to .064 seconds.

Command> call ttSQLExecutionTimeHistogram;
< 1919, 1.090751, .00001562, 278 >
< 1919, 1.090751, .000125, 1484 >
< 1919, 1.090751, .001, 35 >
< 1919, 1.090751, .008, 62 >
< 1919, 1.090751, .064, 60 >
< 1919, 1.090751, .512, 0 >
< 1919, 1.090751, 4.096, 0 >
< 1919, 1.090751, 32.768, 0 >
< 1919, 1.090751, 262.144, 0 >
< 1919, 1.090751, 9.999999999E+125, 0 >
10 rows found.

Select the type of index appropriately

Performance impact: Variable

The TimesTen database supports hash and range indexes. The following details when it is appropriate to use each type of index.

Hash indexes are useful for finding rows with an exact match on one or more columns. Hash indexes are useful for doing equality searches. A hash index is created with either of the following:

- You can create a hash index or a unique hash index with the CREATE [UNIQUE] HASH INDEX statement.
- You can create a unique hash index when creating your table with the CREATE TABLE... UNIQUE HASH ON statement. The unique hash index is specified over the primary key columns of the table.
Range indexes are created by default with the CREATE TABLE statement or created with the CREATE [UNIQUE] HASH INDEX statement. Range indexes can speed up exact key lookups but are more flexible and can speed up other queries as well. Select a range index if your queries include LESS THAN or GREATER THAN comparisons. Range indexes are effective for high-cardinality data: that is, data with many possible values, such as CUSTOMER_NAME or PHONE_NUMBER. Range indexes are optimized for in-memory data management.

Range indexes can also be used to speed up "prefix" queries. A prefix query has equality conditions on all but the last key column that is specified. The last column of a prefix query can have either an equality condition or an inequality condition.

Consider the following table and index definitions:

Command> CREATE TABLE T(i1 tt_integer, i2 tt_integer, i3 tt_integer, ...);
Command> CREATE INDEX IXT on T(i1, i2, i3);

The index IXT can be used to speed up the following queries:

Command> SELECT * FROM T WHERE i1>12;
Command> SELECT * FROM T WHERE i1=12 and i2=75;
Command> SELECT * FROM T WHERE i1=12 and i2 BETWEEN 10 and 20;
Command> SELECT * FROM T WHERE i1=12 and i2=75 and i3>30;

The index IXT is not used for the following queries, because the prefix property is not satisfied:

Command> SELECT * FROM T WHERE i2=12;

There is no equality condition for i1.

The index IXT is used, but matching only occurs on the first two columns for queries like the following:

Command> SELECT * FROM T WHERE i1=12 and i2<50 and i3=630;

Range indexes have a dynamic structure that adjusts itself automatically to accommodate changes in table size. A range index can be either unique or nonunique and can be declared over nullable columns. It also allows the indexed column values to be changed once a record is inserted. A range index is likely to be more compact than an equivalent hash index.

Size hash indexes appropriately

Performance impact: Variable

TimesTen uses hash indexes as both primary key constraints and when specified as part of the CREATE INDEX statement. The size of the hash index is determined by the PAGES parameter specified in the UNIQUE HASH ON clause of the CREATE TABLE and CREATE INDEX statements. The value for PAGES should be the expected number of rows in the table divided by 256; for example, a 256,000 row table should have PAGES = 1000. A smaller value may result in a greater number of hash collisions, decreasing performance, while a larger value may provide somewhat increased performance at the cost of extra space used by the index.

If the number of rows in the table varies dramatically, and if performance is the primary consideration, it is best to create a large index. If the size of a table cannot be accurately predicted, consider using a range index. Also, consider the use of unique indexes when the indexed columns are large CHAR or binary values or when many columns are indexed. Unique indexes may be faster than hash indexes in these cases.
If the performance of record inserts degrades as the size of the table gets larger, it is very likely that you have underestimated the expected size of the table. You can resize the hash index by using the `ALTER TABLE` statement to reset the `PAGES` value in the `UNIQUE HASH ON` clause. See information about `SET PAGES` in the "ALTER TABLE" section in the Oracle TimesTen In-Memory Database SQL Reference.

Use foreign key constraint appropriately

Performance impact: Variable

The declaration of a foreign key has no performance impact on `SELECT` queries, but it slows down the `INSERT` and `UPDATE` operations on the table that the foreign key is defined on and the `UPDATE` and `DELETE` operations on the table referenced by the foreign key. The slow down is proportional to the number of foreign keys that either reference or are defined on the table.

Compute exact or estimated statistics

Performance impact: Large

If statistics are available on the data in the database, the TimesTen optimizer uses them when preparing a command to determine the optimal path to the data. If there are no statistics, the optimizer uses generic guesses about the data distribution.

---

**Note:** See Chapter 9, "The TimesTen Query Optimizer" for more information.

---

You should compute statistics before preparing your statements, since the information is likely to result in a more efficient query optimizer plan. When gathering statistics, you need to determine when and how often to gather new statistics as performance is affected by the statistics collection process. The frequency of collection should balance the task of providing accurate statistics for the optimizer against the processing overhead incurred by the statistics collection process.

Since computing statistics is a time-consuming operation, you should compute statistics with the following guidelines:

- Update statistics after loading your database or after major application upgrades.
- Do not update statistics during a heavy transaction load.
- Update statistics when there is substantial creation or alteration on tables, columns, or PL/SQL objects.

If you have created or altered a substantial number of tables, columns, or PL/SQL objects in your database, you should update the data dictionary optimizer statistics for the following system tables: `SYS.TABLES`, `SYS.COLUMNS`, and `SYS.OBJ$`.

- When you substantially modify tables in batch operations, such as a bulk load or bulk delete, you can gather statistics on these tables as part of the batch operation.
- Update statistics infrequently, such as once a week or once a month, when tables are only incrementally modified.
- Update statistics as part of a regularly executed script or batch job during low transaction load times.
- When updating the statistics for multiple large tables, see "Update table statistics for large tables in parallel" on page 10-20.
Use the following for computing statistics: \texttt{ttIsql statsupdate} command, \texttt{ttOptUpdateStats}, or \texttt{ttOptEstimateStats}. Providing an empty string as the table name updates statistics for all tables in the current user’s schema.

- The \texttt{statsupdate} command within \texttt{ttIsql} evaluates every row of the table(s) in question and computes exact statistics.
- The \texttt{ttOptUpdateStats} built-in procedure evaluates every row of the table(s) in question and computes exact statistics.
- The \texttt{ttOptEstimateStats} procedure evaluates only a sampling of the rows of the table(s) in question and produces estimated statistics. This can be faster, but may result in less accurate statistics. Computing statistics with a sample of 10 percent is about ten times faster than computing exact statistics and generally results in the same execution plans.

\textbf{Note:} For more details on \texttt{ttIsql} or the built-in procedures, see "\texttt{ttIsql}" and "Built-In Procedures" in the \textit{Oracle TimesTen In-Memory Database Replication Guide}.

**Update table statistics for large tables in parallel**

\textbf{Performance impact: Large}

It is important to keep table statistics up to date for all TimesTen tables. However, this process can be time-consuming and performance intensive when used on large tables. Consider calling the \texttt{ttOptUpdateStats} built-in procedure in parallel when updating the statistics for multiple large tables.

\textbf{Note:} A TimesTen table is considered a small table when it contains less than 1 million rows. A TimesTen table is considered a large table when it contains over 100 million rows.

Call the \texttt{ttOptUpdateStats} built-in procedure for all of the large tables where you want to update table statistics. Make sure to call each \texttt{ttOptUpdateStats} built-in procedure in parallel. For more information on the \texttt{ttOptUpdateStats} built-in procedure, see "\texttt{ttOptUpdateStats}" in the \textit{Oracle TimesTen In-Memory Database Reference}.

\begin{verbatim}
Command> call ttOptUpdateStats('table1',0,0);
Command> call ttOptUpdateStats('table2',0,0);
...;
Command> call ttOptUpdateStats('finaltable',0,0);
\end{verbatim}

Once the \texttt{ttOptUpdateStats} built-in procedure calls have completed, determine how many transactions are accessing the large TimesTen tables for which you updated table statistics. During low transaction load times execute the \texttt{ttOptCmdCacheInvalidate('',1)} built-in procedure. For more information on the \texttt{ttOptCmdCacheInvalidate} built-in procedure, see "\texttt{ttOptCmdCacheInvalidate}" in the \textit{Oracle TimesTen In-Memory Database Reference}. During high transaction load times execute the following built-in procedures and make sure to call each \texttt{ttOptCmdCacheInvalidate} built-in procedure in parallel:

\begin{verbatim}
Note: For performance reasons, TimesTen does not hold a lock on tables or rows when computing statistics.
\end{verbatim}
Command> call ttOptCmdCacheInvalidate('table1',1);
Command> call ttOptCmdCacheInvalidate('table2',1);
... ...
Command> call ttOptCmdCacheInvalidate('finaltable',1);

The table statistics of your tables are now up to date and compiled commands in the SQL command cache are invalidated.

**Create script to regenerate current table statistics**

**Performance impact: Variable**

You can generate a SQL script with the `ttOptStatsExport` built-in procedure from which you can restore the table statistics to the current state. When you apply these statements, you re-create the same environment. Recreating the table statistics could be used for diagnosing SQL performance.

Call the `ttOptStatsExport` built-in procedure to return the set of statements required to restore the table statistics to the current state. If no table is specified, `ttOptStatsExport` returns the set of statements required to restore the table statistics for all user tables that the calling user has permission to access.

**Note:** For more information and syntax for this built-in procedure, see “ttOptStatsExport” in the *Oracle TimesTen In-Memory Database Reference*.

The following example returns a set of built-in procedure commands that would be required to be executed to restore the statistics for the employees table:

Command> call ttOptStatsExport('hr.employees');

```sql
< call ttoptsetcolIntvlstats('HR.EMPLOYEES', 'EMPLOYEE_ID', 0, (6, 0, 107, 107, (20, 20, 1 ,100, 120, 101), (20, 20, 1 ,121, 141, 122), (20, 20, 1 ,142, 162, 143), (20, 20, 1 ,163, 183, 164), (20, 20, 1 ,184, 204, 185), (1, 1, 1 ,205, 206, 205))); >
< call ttoptsetcolIntvlstats('HR.EMPLOYEES', 'FIRST_NAME', 0, (1, 0, 89, 107, (89, 107, 0 ,‘Adam’, ‘Winston’, ‘Adam’))); >
< call ttoptsetcolIntvlstats('HR.EMPLOYEES', 'LAST_NAME', 0, (1, 0, 97, 107, (97, 107, 0 ,‘Abel’, ‘Zlotkey’, ‘Abel’))); >
< call ttoptsetcolIntvlstats('HR.EMPLOYEES', 'PHONE_NUMBER', 0, (1, 0, 103, 107, (103, 107, 0 ,‘011.44.1343.329268’, ‘011.44.1343.329268’))); >
< call ttoptsetcolIntvlstats('HR.EMPLOYEES', 'HIRE_DATE', 0, (1, 0, 90, 107, (90, 107, 0 ,‘1987-06-17 00:00:00’, ‘2000-04-21 00:00:00’, ‘1987-06-17 00:00:00’))); >
< call ttoptsetcolIntvlstats('HR.EMPLOYEES', 'SALARY', 0, (1, 0, 57, 107, (57, 107, 0 ,‘2100’, ‘24000’, ‘2100’))); >
< call ttoptsetcolIntvlstats('HR.EMPLOYEES', 'COMMISSION_PCT', 0, (1, 72, 7, 107, (7, 35, 0 ,0.1, 0.4, 0.1))); >
< call ttoptsetcolIntvlstats('HR.EMPLOYEES', 'MANAGER_ID', 0, (1, 1, 18, 107,
Control the invalidation of commands in the SQL command cache

Performance impact: Variable

TimesTen caches compiled commands in the SQL command cache. These commands can be invalidated. An invalidated command is usually reprepared automatically just before it is re-executed. A single command may be prepared several times.

Note: See "When optimization occurs" on page 9-1 for more information on how commands are automatically invalidated.

When you compute statistics, the process of updating and compiling commands may compete for the same locks on certain tables. If statistics are collected in multiple transactions and commands are invalidated after each statistics update, the following issues may occur:

- A join query that references multiple tables might be invalidated and recompiled more than once.
- Locks needed for recompilation could interfere with updating statistics, which could result in a deadlock.

You can avoid these issues by controlling when commands are invalidated in the SQL command cache. In addition, you may want to hold off invalidation of all commands if you know that the table and index cardinalities will be changing significantly.

You can control invalidation of the commands, as follows:

1. Compute statistics without invalidating the commands in the SQL command cache. Set the invalidate option to 0 in either the ttIsql statsupdate command, the ttOptUpdateStats built-in procedure, or the ttOptEstimateStats built-in procedure.
2. Manually invalidate the commands in the SQL command cache once all statistics have been compiled with the ttOptCmdCacheInvalidate built-in procedure.

The ttOptCmdCacheInvalidate built-in procedure can invalidate commands associated solely with a table or all commands within the SQL command cache. In addition, you can specify whether the invalidated commands are to be recompiled or marked as unusable.

Note: For complete details on when to optimally calculate statistics, see "Compute exact or estimated statistics" on page 10-19. In addition, see "ttIsql", "ttOptUpdateStats", "ttOptEstimateStats", or "ttOptCmdCacheInvalidate" in the Oracle TimesTen In-Memory Database Reference.

Avoid ALTER TABLE

Performance impact: Variable
The `ALTER TABLE` statement allows applications to add columns to a table and to drop columns from a table. Although the `ALTER TABLE` statement itself runs very quickly in most cases, the modifications it makes to the table can cause subsequent DML statements and queries on the table to run more slowly. The actual performance degradation that the application experiences varies with the number of times the table has been altered and with the particular operation being performed on the table.

Dropping `VARCHAR2` and `VARBINARY` columns is slower than dropping columns of other data types since a table scan is required to free the space allocated to the existing `VARCHAR2` and `VARBINARY` values in the column to be dropped.

### Avoid nested queries

**Performance impact: Variable**

If you can, it is recommended that you should rewrite your query to avoid nested queries that need materialization of many rows.

The following are examples of nested queries that may need to be materialized and result in multiple rows:

- Aggregate nested query with `GROUP BY`
- Nested queries that reference `ROWNUM`
- Union, intersect, or minus nested queries
- Nested queries with `ORDER BY`

For example, the following aggregate nested query results in an expensive performance impact:

```
Command> SELECT * FROM (SELECT SUM(x1) sum1 FROM t1 GROUP BY y1),
(SELECT sum(x2) sum2 FROM t2 GROUP BY y2) WHERE sum1=sum2;
```

The following is an example of a nested query that references `ROWNUM`:

```
Command> SELECT * FROM (SELECT rownum rc, x1 FROM t1 WHERE x1>100),
(SELECT ROWNUM rc, x2 FROM t2 WHERE x2>100) WHERE x1=x2;
```

The following is an example of a union nested query:

```
Command> SELECT * FROM (SELECT x1 FROM t1 UNION SELECT x2 FROM t2),
(SELECT x3 FROM t3 GROUP BY x3) WHERE x1=x3;
```

For more information on subqueries, see “Subqueries” in the *Oracle TimesTen In-Memory Database SQL Reference*.

### Prepare statements in advance

**Performance impact: Large**

If you have applications that generate a statement multiple times searching for different values each time, prepare a parameterized statement to reduce compile time. For example, if your application generates statements like:

```
SELECT A FROM B WHERE C = 10;
SELECT A FROM B WHERE C = 15;
```

You can replace these statements with the single statement:

```
SELECT A FROM B WHERE C = ?;
```
TimesTen shares prepared statements automatically after they have been committed. As a result, an application request to prepare a statement for execution may be completed very quickly if a prepared version of the statement already exists in the system. Also, repeated requests to execute the same statement can avoid the prepare overhead by sharing a previously prepared version of the statement.

Even though TimesTen allows prepared statements to be shared, it is still a good practice for performance reasons to use parameterized statements. Using parameterized statements can further reduce prepare overhead, in addition to any savings from sharing statements.

**Avoid unnecessary prepare operations**

**Performance impact: Large**

Because preparing SQL statements is an expensive operation, your application should minimize the number of calls to the prepare API. Most applications prepare a set of statements at the beginning of a connection and use that set for the duration of the connection. This is a good strategy when connections are long, consisting of hundreds or thousands of transactions. But if connections are relatively short, a better strategy is to establish a long-duration connection that prepares the statements and executes them on behalf of all threads or processes. The trade-off here is between communication overhead and prepare overhead, and can be examined for each application. Prepared statements are invalidated when a connection is closed.

See "ttSQLCmdCacheInfoGet" in the *Oracle TimesTen In-Memory Database Reference* for related information.

**Store data efficiently with column-based compression of tables**

**Performance impact: Large**

TimesTen provides the ability to compress tables at the column level, which stores the data more efficiently at the cost of lower performance. This mechanism provides space reduction for tables by eliminating the redundant storage of duplicate values within columns and improves the performance of SQL queries that perform full table scans.

When compressing columns of a TimesTen table, consider the following:

- Compress a column if values are repeated throughout such as the name of countries or states.
- Compress a column group if you often access multiple columns together.
- Do not compress columns that contain data types that require a small amount of storage such as TT_TINYINT.
- TimesTen does not compress NULL values.

You can define one or more columns in a table to be compressed together, which is called a compressed column group. You can define one or more compressed column groups in each table.

A dictionary table is created for each compressed column group that contains a column with all the distinct values of the compressed column group. The compressed column group now contains a pointer to the row in the dictionary table for the appropriate value. The width of this pointer can be 1, 2, or 4 bytes long depending on the maximum number of entries you defined for the dictionary table. So if the sum of the widths of the columns in a compressed column group is wider than the 1, 2, or 4 byte pointer width, and if there are a lot of duplicate values of those column values, you have reduced the amount of space used by the table.
Figure 10–1 shows the compressed column group in the table pointing to the appropriate row in the dictionary table.

**Figure 10–1  Column-based compression of tables**

The dictionary table has a column of pointers to each of the distinct values. When the user configures the maximum number of distinct entries for the compressed column group, the size of the compressed column group is set as follows:

- 1 byte for a maximum number of entries of 255 \(2^{8}-1\). When the maximum number is between 1 and 255, the dictionary size is set to 255 \(2^{8}-1\) values and the compressed column group pointer column is 1 byte.
- 2 bytes for a maximum number of entries of 65,535 \(2^{16}-1\). When the maximum number is between 256 and 65,535, the dictionary size is set to 65,535 \(2^{16}-1\) values and the compressed column group pointer column is 2 bytes.
- 4 bytes for a maximum number of entries of 4,294,967,295 \(2^{32}-1\). When the maximum number is between 65,536 and 4,294,967,295, the dictionary size is set to 4,294,967,295 \(2^{32}-1\) values and the compressed column group pointer column is 4 bytes. This is the default.

Compressed column groups can be added at the time of table creation or added later using `ALTER TABLE`. You can drop the entire compressed column group with the `ALTER TABLE` statement. For more information, see "ALTER TABLE" and "CREATE TABLE" in the *Oracle TimesTen In-Memory Database SQL Reference*.

You can call the `ttSize` built-in procedure to review the level of compression that TimesTen achieved on your compressed table. For more information on the `ttSize` built-in procedure, see "ttSize" in the *Oracle TimesTen In-Memory Database Reference*.

### Control read optimization during concurrent write operations

**Performance impact: Variable**

TimesTen concurrently processes read and write operations optimally. Your read operations can be optimized for read-only concurrency when you use transaction level optimizer hints such as `ttOptSetFlag('tblLock',1)` or statement level optimizer hints such as `/*+ tt_tbllock(1) tt_rowlock(0) */`. Write operations that operate concurrently with read optimized queries may result in contention.

You can control read optimization during periods of concurrent write operations with the `ttDBWriteConcurrencyModeSet` built-in procedure. This built-in procedure enables you to switch between a standard mode and an enhanced write concurrent mode. In the standard mode, the optimizer respects read optimization hints. In the enhanced write concurrent mode, the optimizer ignores read optimization hints and does not use shared read table locks or write table locks.
Set the mode of the ttDBWriteConcurrentModeSet built-in procedure to 1 to enable the enhanced write concurrent mode and disable read optimization. Set the mode to 0 to disable the enhanced write concurrent mode and re-enable read optimization.

When the mode is set to 1, all transaction and statement table lock optimizer hints are ignored. This affects the following:

- Shared read table-level locks for SELECT query and subqueries that are triggered by optimizer hints.
- Write table locks for DML statements that are triggered by optimizer hints.

Regardless of the mode setting, table locks that are not triggered by optimizer hints are not affected.

Set the wait of the ttDBWriteConcurrentModeSet built-in procedure to 0 to perform a mode switch without notifications. Set the wait of the ttDBWriteConcurrentModeSet built-in procedure to 1 to force the built-in procedure to wait until the mode transition is complete.

Execution of certain SQL statements causes the mode of the ttDBWriteConcurrentModeSet built-in procedure to remain in transition. Such SQL statements must match the following two conditions:

- Affected by the write concurrency mode.
- Compiled in a different write concurrency mode.

The mode of the ttDBWriteConcurrentModeSet built-in procedure remains in transition until all such SQL statements complete. The ttDBWriteConcurrentModeSet built-in procedure uses lock acquisition to wait during the mode transition. An error is returned if the ttDBWriteConcurrentModeSet built-in procedure is not granted a lock within the timeout interval of the current connection.

Choose SQL and PL/SQL timeout values

Performance impact: Variable

When setting timeout values, consider the relationship between these attributes:

- SQLQueryTimeout or SQLQueryTimeoutMSec: Controls how long a SQL statement executes before timing out.
By default, SQL statements do not time out. In some cases, you may want to specify a value for either the SQLQueryTimeout or SQLQueryTimeoutMSec connection attribute to set the time limit in seconds or milliseconds within which the database should execute SQL statements. (Note that this applies to any SQL statement, not just queries.)

Both SQLQueryTimeout and SQLQueryTimeoutMsec attributes are internally mapped to one timeout value in milliseconds. If different values are specified for these attributes, only one value is retained. For more details, see “SQLQueryTimeout” and “SQLQueryTimeoutMsec” in the Oracle TimesTen In-Memory Database Reference.

- **PLSQL_TIMEOUT**: Controls how long a PL/SQL block executes before timing out.
  
  By default, PL/SQL program units (PL/SQL procedures, anonymous blocks and functions) are allowed to run for 30 seconds before being automatically terminated. In some cases, you may want to modify the PLSQL_TIMEOUT connection attribute value to allow PL/SQL program units additional time to run. You can also modify this attribute with an “ALTER SESSION” statement during runtime.

  For more details, see "PLSQL_TIMEOUT" in the Oracle TimesTen In-Memory Database Reference.

- **TTC_Timeout**: Controls how long a TimesTen client waits for a response from the TimesTen Server when the client has requested the server to execute a SQL statement or PL/SQL block.

- **TTC_ConnectTimeout**: Controls how long the client waits for a SQLDriverConnect or SQLDisconnect request. It overrides the value of TTC_Timeout for those requests.

  Also see “Choose timeout connection attributes for your client” on page 10-9.

If you use TimesTen Client/Server, then SQLQueryTimeout (or SQLQueryTimeoutMSec) and PLSQL_TIMEOUT (relevant for PL/SQL) should be set to significantly lower values than TTC_Timeout, to avoid the possibility of the client mistaking a long-running SQL statement or PL/SQL block for a non-responsive server.

If you use PL/SQL, the relationship between SQLQueryTimeout (or SQLQueryTimeoutMSec) and PLSQL_TIMEOUT depends on how many SQL statements you use in your PL/SQL blocks. If none, there is no relationship. If the maximum number of SQL statements in a PL/SQL block is \( n \), then PLSQL_TIMEOUT should presumably equal at least \( n \times \text{SQLQueryTimeout} \) (or \( n \times 1000 \times \text{SQLQueryTimeoutMSec} \)), including consideration of processing time in PL/SQL.

---

**Note:** If SQLQueryTimeout (or SQLQueryTimeoutMSec) and PLSQL_TIMEOUT are not set sufficiently less than TTC_Timeout, and the client mistakes a long-running SQL statement or PL/SQL block for a non-responsive server and terminates the connection, the server will cancel the SQL statement or PL/SQL block as soon as it notices the termination of the connection.

---

**Materialized view tuning**

The following sections include tips for improving performance of materialized views:

- Limit number of join rows
- Use indexes on join columns
- Avoid unnecessary updates
Materialized view tuning

- Avoid changes to the inner table of an outer join
- Limit number of columns in a view table

Limit number of join rows

Performance impact: Variable

Larger numbers of join rows decrease performance. You can limit the number of join rows and the number of tables joined by controlling the join condition. For example, use only equality conditions that map one row from one table to one or at most a few rows from the other table.

Use indexes on join columns

Performance impact: Variable

Create indexes on the columns of the detail table that are specified in the SELECT statement that creates the join. Also consider creating an index on the materialized view itself. This can improve the performance of keeping the materialized view updated.

If an UPDATE or DELETE operation on a detail table is often based on a condition on a column, try to create an index on the materialized view on this column if possible.

For example, cust_order is a materialized view of customer orders, based on two tables. The tables are customer and book_order. The former has two columns (cust_id and cust_name) and the latter has three columns (order_id, book, and cust_id). If you often update the book_order table to change a particular order by using the condition book_order.order_id=const, then create an index on cust_order.order_id. On the other hand, if you often update based on the condition book_order.cust_id=const, then create an index on Cust_order.cust_id.

If you often update using both conditions and cannot afford to create both indexes, you may want to add book_order.ROWID in the view and create an index on it instead. In this case, TimesTen updates the view for each detail row update instead of updating all of the rows in the view directly and at the same time. The scan to find the row to be updated is an index scan instead of a row scan, and no join rows need to be generated.

If ViewUniqueMatchScan is used in the execution plan, it is a sign that the execution may be slower or require more space than necessary. A ViewUniqueMatchScan is used to handle an update or delete that cannot be translated to a direct update or delete of a materialized view, and there is no unique mapping between a join row and the associated row in the materialized view. This can be fixed by selecting a unique key for each detail table that is updated or deleted.

Avoid unnecessary updates

Performance impact: Variable

Try not to update a join column or a GROUP BY column because this involves deleting the old value and inserting the new value.

Try not to update an expression that references more than one table. This may disallow direct update of the view because TimesTen may perform another join operation to get the new value when one value in this expression is updated.

View maintenance based on an update or delete is more expensive when:

- The view cannot be updated directly. For example, not all columns specified in the detail table UPDATE or DELETE statement are selected in the view, or
■ There is not an indication of a one-to-one mapping from the view rows to the join rows.

For example:

Command> CREATE MATERIALIZED VIEW v1 AS SELECT x1 FROM t1, t2 WHERE x1=x2;
Command> DELETE FROM t1 WHERE y1=1;

The extra cost comes from the fact that extra processing is needed to ensure that one and only one view row is affected due to a join row.

The problem is resolved if either x1 is UNIQUE or a unique key from t1 is included in the select list of the view. ROWID can always be used as the unique key.

Avoid changes to the inner table of an outer join

Performance impact: Variable

Since outer join maintenance is more expensive when changes happen to an inner table, try to avoid changes to the inner table of an outer join. When possible, perform INSERT operations on an inner table before inserting into the associated join rows into an outer table. Likewise, when possible perform DELETE operations on the outer table before deleting from the inner table. This avoids having to convert non-matching rows into matching rows or vice versa.

Limit number of columns in a view table

Performance impact: Variable

The number of columns projected in the view SelectList can impact performance. As the number of columns in the select list grows, the time to prepare operations on detail tables increases. In addition, the time to execute operations on the view detail tables also increases. Do not select values or expressions that are not needed.

The optimizer considers the use of temporary indexes when preparing operations on detail tables of views. This can significantly slow down prepare time, depending upon the operation and the view. If prepare time seems slow, consider using ttOptSetFlag to turn off temporary range indexes and temporary hash scans.

Transaction tuning

The following sections describe how to increase performance when using transactions:

■ Locate checkpoint and transaction log files on separate physical device
■ Size transactions appropriately
■ Use durable commits appropriately
■ Avoid manual checkpoints
■ Turn off autocommit mode
■ Avoid transaction roll back
■ Avoid large DELETE statements
■ Increase the commit buffer cache size
**Locate checkpoint and transaction log files on separate physical device**

To improve performance, locate your transaction log files on a separate physical device from the one on which the checkpoint files are located. The `LogDir` connection attribute determines where log files are stored. For more information, see "Managing transaction log buffers and files" on page 7-17 in this book or "LogDir" in the Oracle TimesTen In-Memory Database Reference.

**Size transactions appropriately**

*Performance impact: Large*

Each transaction, when it generates transaction log records (for example, a transaction that does an `INSERT`, `DELETE` or `UPDATE`), incurs a file system write operation when the transaction commits. File system I/O affects response time and may affect throughput, depending on how effective group commit is.

Performance-sensitive applications should avoid unnecessary file system write operations at commit. Use a performance analysis tool to measure the amount of time your application spends in file system write operations (versus CPU time). If there seems to be an excessive amount of I/O, there are two steps you can take to avoid writes at commit:

- Adjust the transaction size.
- Adjust whether file system write operations are performed at transaction commit.

See "Use durable commits appropriately" on page 10-30.

Long transactions perform fewer file system write operations per unit of time than short transactions. However, long transactions also can reduce concurrency, as discussed in Chapter 7, "Transaction Management".

- If only one connection is active on a database, longer transactions could improve performance. However, long transactions may have some disadvantages, such as longer rollback operations.
- If there are multiple connections, there is a trade-off between transaction log I/O delays and locking delays. In this case, transactions are best kept to the natural length, as determined by requirements for atomicity and durability.

**Use durable commits appropriately**

*Performance impact: Large*

By default, each TimesTen transaction results in a file system write operation at commit time. This practice ensures that no committed transactions are lost because of system or application failures. Applications can avoid some or all of these file system write operations by performing nondurable commits. Nondurable commits do everything that a durable commit does except write the transaction log to the file system. Locks are released and cursors are closed, but no file system write operation is performed.

---

**Note:** Some drivers only write data into cache memory or write to the file system some time after the operating system receives the write completion notice. In these cases, a power failure may cause some information that you thought was durably committed to be lost. To avoid this loss of data, configure your file system to write to the recording media before reporting completion or use an uninterruptible power supply.
The advantage of nondurable commits is a potential reduction in response time and increase in throughput. The disadvantage is that some transactions may be lost in the event of system failure. An application can force the transaction log to be persisted to the file system by performing an occasional durable commit or checkpoint, thereby decreasing the amount of potentially lost data. In addition, TimesTen itself periodically flushes the transaction log to the file system when internal buffers fill up, limiting the amount of data that could be lost.

Transactions can be made durable or can be made nondurable on a connection-by-connection basis. Applications can force a durable commit of a specific transaction by calling the `ttDurableCommit` procedure.

Applications that use durable commits can benefit from using synchronous writes in place of write and flush. To turn on synchronous writes set the first connection attribute `LogFlushMethod=1`. The `LogFlushMethod` attribute controls how TimesTen writes and synchronizes data to transaction log files. Although application performance can be affected by this attribute, transaction durability is not affected. For more information, see "LogFlushMethod" in the Oracle TimesTen In-Memory Database Reference.

The `txn.commits.durable` column of the `SYS.SYSTEMSTATS` table indicates the number of transactions that were durably committed.

### Avoid manual checkpoints

**Performance impact: Large**

Manual checkpoints only apply to TimesTen Classic. Manual checkpoints are not supported in TimesTen Scaleout.

If possible it is best to avoid performing manual checkpoints. You should configure background checkpoints with the `ttCkptConfig` built-in procedure. Background checkpoints are less obtrusive and use non-blocking (or "fuzzy") checkpoints.

If a manual checkpoint is deemed necessary, it is generally better to call `ttCkpt` to perform a non-blocking (or "fuzzy") checkpoint than to call `ttCkptBlocking` to perform a blocking checkpoint. Blocking or ("transaction-consistent") checkpoints can have a significant performance impact because they require exclusive access to the database. Non-blocking checkpoints may take longer, but they permit other transactions to operate against the database at the same time and thus impose less overall overhead. You can increase the interval between successive checkpoints (`ckptLogVolume` parameter of the `ttCkptConfig` built-in procedure) by increasing the amount of file system space available for accumulating transaction log files.

As the transaction log increases in size (if the interval between checkpoints is large), recovery time increases accordingly. If reducing recovery time after a system crash or application failure is important, it is important to properly tune the `ttCkptConfig` built-in procedure. The `ckpt.completed` column of the `SYS.SYSTEMSTATS` table indicates how often checkpoints have successfully completed.

For more information, see "ttCkptConfig" in the Oracle TimesTen In-Memory Database Reference.

### Turn off autocommit mode

**Performance impact: Large**

`AUTOCOMMIT` mode forces a commit after each statement, and is enabled by default. Committing each statement after execution, however, can significantly degrade...
performance. For this reason, it is generally advisable to disable AUTOCOMMIT, using the appropriate API for your programming environment.

The `txn.commits.count` column of the `SYS.SYSTEMSTATS` table indicates the number of transaction commits.

---

**Note:** If you do not include any explicit commits in your application, the application can use up important resources unnecessarily, including memory and locks. All applications should do periodic commits.

---

### Avoid transaction roll back

**Performance impact: Large**

When transactions fail due to erroneous data or application failure, they are rolled back by TimesTen automatically. In addition, applications often explicitly roll back transactions to recover from deadlock or timeout conditions. This is not desirable from a performance point of view, as a roll back consumes resources and the entire transaction is wasted.

Applications should avoid unnecessary rollback operations. This may mean designing the application to avoid contention and checking application or input data for potential errors in advance, if possible. The `txn.rollback` column of the `SYS.SYSTEMSTATS` table indicates the number of transactions that were rolled back.

### Avoid large DELETE statements

**Performance impact: Large**

Consider the following ways to avoid large delete statements:

- **Avoid DELETE FROM statements**
- **Consider using the DELETE FIRST clause**

### Avoid DELETE FROM statements

If you attempt to delete a large number of rows (100,000 or more) from a table with a single SQL statement the operation can take a long time. TimesTen logs each row deleted, in case the operation needs to be rolled back, and writing all of the transaction log records to the file system can be very time-consuming.

Another problem with such a large delete operation is that other database operations will be slowed down while the write-intensive delete transaction is occurring. Deleting millions of rows in a single transaction can take minutes to complete.

Another problem with deleting millions of rows at once occurs when the table is being replicated. Because replication transmits only committed transactions, the replication agent can be slowed down by transmitting a single, multi-hundred MB (or GB) transaction. TimesTen replication is optimized for lots of small transactions and performs slowly when millions of rows are deleted in a single transaction.

For more information about the DELETE SQL statement, see "DELETE" in the *Oracle TimesTen In-Memory Database SQL Reference.*

### Consider using the DELETE FIRST clause

If you want to delete a large number of rows and TRUNCATE TABLE is not appropriate, consider using the DELETE FIRST `NumRows` clause to delete rows from a table in batches.
The **DELETE FIRST** *NumRows* syntax allows you to change “**DELETE FROM TableName WHERE ...**” into a sequence of “**DELETE FIRST 10000 FROM TableName WHERE ...**” operations.

By splitting a large **DELETE** operation into a batch of smaller operations, the rows will be deleted much faster, and the overall concurrency of the system and replication will not be affected.

For more information about the **DELETE FIRST** clause, see ”**DELETE**” in the *Oracle TimesTen In-Memory Database SQL Reference*.

---

**Increase the commit buffer cache size**

**Performance impact: Large**

TimesTen resource cleanup occurs during the reclaim phase of a transaction commit. During reclaim, TimesTen reexamines all the transaction log records starting from the beginning of the transaction to determine the reclaim operations that must be performed.

The reclaim phase of a large transaction commit results in a large amount of processing and is very resource intensive. You can improve performance, however, by increasing the maximum size of the commit buffer, which is the cache of transaction log records used during reclaim operations.

You can use the TimesTen **CommitBufferSizeMax** connection attribute to specify the maximum size of the commit buffer, in megabytes. This setting has the scope of your current session.

See ”**Configuring the commit buffer for reclaim operations**” on page 7-27 for information.

---

**Recovery tuning**

The following sections include tips for improving performance of database recovery after database shutdown or system failure:

- **Set RecoveryThreads**
- **Set CkptReadThreads**

**Set RecoveryThreads**

**Performance impact: Large**

**RecoveryThreads** defines the number of parallel threads used to rebuild indexes during database recovery time. For performance reasons, TimesTen does not log changes to indexes. In the event of a crash, all indexes need to be rebuilt. To reduce the index rebuild time, set the **RecoveryThreads** attribute to the number of CPUs to improve recovery performance. See ”**RecoveryThreads**” in the *Oracle TimesTen In-Memory Database Reference* for more details.

**Set CkptReadThreads**

**Performance impact: Large**

When a database has large checkpoint files (hundreds of gigabytes), first connection or recovery operations may not perform well and, in extreme cases, may take hours to complete. To improve recovery performance, use the **CkptReadThreads** connection attribute to increase the number of concurrent threads used for reading the checkpoint...
files during the loading of the database into memory. This reduces the amount of time it takes to load the TimesTen database to memory by enabling parallel threads to read the TimesTen database checkpoint files.

For more information on the CkptReadThreads attribute, see "CkptReadThreads" in the Oracle TimesTen In-Memory Database Reference.

Scaling for multiple CPUs

The following sections include tips for improving performance for multiple CPUs:

- Run the demo applications as a prototype
- Limit database-intensive connections per CPU
- Use read operations when available
- Limit prepares, re-prepares and connects
- Allow indexes to be rebuilt in parallel during recovery
- Use private commands

Run the demo applications as a prototype

Performance impact: Variable

One way to determine the approximate scaling you can expect from TimesTen is to run one of the scalable demo applications, such as tptbm, on your system.

The tptbm application implements a multi-user throughput benchmark. It enables you to control how it executes, including options to vary the number of processes that execute TimesTen operations and the transaction mix of SELECTs, UPDATEs, and INSERTs, for example. Run tptbm -help to see the full list of options.

By default the demo executes one operation per transaction. You can specify more operations per transaction to better model your application. Larger transactions may scale better or worse, depending on the application profile.

Run multi-processor versions of the demo to evaluate how your application can be expected to perform on systems that have multiple CPUs. If the demo scales well but your application scales poorly, you might try simplifying your application to see where the issue is. Some users comment out the TimesTen calls and find they still have bad scaling due to issues in the application.

You may also find, for example, that some simulated application data is not being generated properly, so that all the operations are accessing the same few rows. That type of localized access greatly inhibits scalability if the accesses involve changes to the data.

See the Quick Start home page at installation_dir/quickstart.html for additional information about tptbm and other demo applications. Go to the ODBC link under "Sample Programs".

Limit database-intensive connections per CPU

Performance impact: Variable

Check the lock.timeouts or lock.locks_granted.wait fields in the SYS.SYSTEMSTATS table. If they have high values, this may indicate undue contention, which can lead to poor scaling.
Because TimesTen is quite CPU-intensive, optimal scaling is achieved by having at most one database-intensive connection per CPU. If you have a 4-CPU system or a 2-CPU system with hyperthreading, then a 4-processor application executes well, but an 8-processor application does not perform well. The contention between the active threads is too high. The only exception to this rule is when many transactions are committed durably. In this case, the connections are not very CPU-intensive because of the increase in I/O operations to the file system, and so the system can support many more concurrent connections.

**Use read operations when available**

**Performance impact:** Variable

Read operations scale better than write operations. Make sure that the read and write balance reflects the real-life workload of your application.

**Limit prepares, re-prepares and connects**

**Performance impact:** Variable

Prepares are resource-intensive operations that do not scale well compared to SQL execution operations. Ensure that you use parameterized SQL statements wherever possible and always pre-prepare statements that are executed more than once. The `stmt.prepares.count` column of the `SYS.SYSTEMSTATS` table indicates how often statements were prepared directly by an application. If the `stmt.prepares.count` column has a high value, ensure the following:

- Your application uses parametrized statements.
- Your application only prepares any given SQL statement once and not for every single execution.
- Your application does not connect and disconnect frequently from the database. If that is the case, consider using long lived connections.

Connect and disconnect operations are resource-intensive operations that do not scale well. Ensure that your application minimizes the number of connect and disconnect operations. Use long lived connections with parameterized and pre-prepared SQL statements to improve performance.

If your application cannot avoid frequent connect and disconnect operations or you are unable to modify the application to use long-lived connections, consider using connection pooling. Connection pooling can reduce the frequency of connect and disconnect operations and improve the utilization of prepared statements compared to the case where an application frequently connects and disconnects from the database.

**Allow indexes to be rebuilt in parallel during recovery**

**Performance impact:** Variable

On multi-processor systems, set `RecoveryThreads` to minimum(number of CPUs available, number of indexes) to allow indexes to be rebuilt in parallel if recovery is necessary. If a rebuild is necessary, progress can be viewed in the user log. Setting `RecoveryThreads` to a number larger than the number of CPUs available can cause recovery to take longer than if it were single-threaded.

**Use private commands**

**Performance impact:** Variable
When multiple connections execute the same command, they access common command structures controlled by a single command lock. To avoid sharing their commands and possibly placing contention on the lock, you can set PrivateCommands=1. The use of private commands increases the amount of temporary space used, but provides better scaling at the cost.

For more information, see "PrivateCommands" in the Oracle TimesTen In-Memory Database Reference.

XLA tuning

The following sections include tips for improving XLA performance:

- Increase transaction log buffer size when using XLA
- Prefetch multiple update records
- Acknowledge XLA updates

Increase transaction log buffer size when using XLA

**Performance impact: Large**

A larger transaction log buffer size is appropriate when using XLA. When XLA is enabled, additional transaction log records are generated to store additional information for XLA. To ensure the transaction log buffer is properly sized, one can watch for changes in the `SYS.MONITOR` table entries `LOG_FS_READS` and `LOG_BUFFER_WAITS`. For optimal performance, both of these values should remain 0. Increasing the transaction log buffer size may be necessary to ensure the values remain 0. For more information on how to resize the transaction log buffer size, see "LogBufMB" in the Oracle TimesTen In-Memory Database Reference.

Prefetch multiple update records

**Performance impact: Medium**

Prefetching multiple update records at a time is more efficient than obtaining each update record from XLA individually. Because updates are not prefetched when you use `AUTO_ACKNOWLEDGE` mode, it can be slower than the other modes. If possible, you should design your application to tolerate duplicate updates so you can use `DUPS_OK_ACKNOWLEDGE`, or explicitly acknowledge updates. Explicitly acknowledging updates usually yields the best performance if the application can tolerate not acknowledging each message individually.

Acknowledge XLA updates

**Performance impact: Medium**

To explicitly acknowledge an XLA update, you call `acknowledge` on the update message. Acknowledging a message implicitly acknowledges all previous messages. Typically, you receive and process multiple update messages between acknowledgements. If you are using the `CLIENT_ACKNOWLEDGE` mode and intend to reuse a durable subscription in the future, you should call `acknowledge` to reset the bookmark to the last-read position before exiting.
Cache and replication tuning

For recommendations on improving performance for when using a replication scheme, see "Improving Replication Performance" in the Oracle TimesTen In-Memory Database Replication Guide.

For recommendations on improving performance when using cache groups, see "Cache Performance" in the Oracle TimesTen Application-Tier Database Cache User’s Guide.
