   set db_create_online_log_dest_1='$redoLoc'
   set db_recovery_file_dest='$recoLoc'
   set audit_file_dest = '$auditFileDest'
   reset control_files
   nofilenamecheck
   ;
   EOF

Preparing to Register the Database

Before you register the database:
1. Make sure the database COMPATIBLE parameter value is acceptable.
   For a 11.2 database, the minimum compatibility value is 11.2.0.4.
   For a 12c database, the minimum compatibility value is 12.1.0.2.
   If the value is less than the minimum, the database cannot be registered until you upgrade the database compatibility.
2. Use the following command to verify that the database has registered with the local listener and service name.
   ```bash
   lsnrctl services
   ```
3. Use the following command to verify that the password file was restored or created for a new database.
   ```bash
   ls -ltr $ORACLE_HOME/dbs/orapw<$ORACLE_SID>
   ```
   If the file does not exist, create it using the orapwd command.
   ```bash
   orapwd file=$ORACLE_HOME/dbs/orapw<$ORACLE_SID> password=<sys_password>
   ```
4. Use the following command to verify that the restored database is open in read write mode.
   ```sql
   select open_mode from v$database;
   ```
   Read write mode is required to register the database later. Any PDBs must also be in read write mode.
5. From oracle home on the migrated database host, use the following command verify the connection to SYS.
   ```sql
   conn sys/<password>@<service_name> as sysdba
   ```
   This connection is required to register the database later. Fix any connection issues before continuing.
6. Copy the folder $ORACLE_HOME/sqlpatch from source database to the target database. This will enable the dbcli register-database command to rollback any conflicting patches.
   ```plaintext
   Note:
   If you are migrating a version 11.2 database, additional steps are required after you register the database. For more information, see Rolling Back Patches on a Version 11.2 Database on page 2407.
   ```
7. Use the following SQL*Plus command to make sure the database is using the spfile.
   ```sql
   SHOW PARAMETERS SPFILE
   ```

**Registering the Database on the DB System**

The Database Commands on page 2264 command registers the migrated database to the dcs-agent so it can be managed by the dcs-agent stack.

```plaintext
Note:
The dbcli register-database command is not available on 2-node RAC DB Systems.
```

As the root user, use the dbcli register-database command to register the database on the DB system, for example:
```bash
[root@dbsys ~]# dbcli register-database --dbclass OLTP --dbshape odb1 --servicename crmdb.example.com --syspassword
Password for SYS:
{
   "jobId" : "317b430f-ad5f-42ae-bb07-13f053d266e2",
   "status" : "Created",
   "message" : null,
```
Migrating a Version 12.1 or Later Database That Includes SQL Patch Components

For a 1-node DB system at version 12.1 or higher, the `dbcli register-database` command automates the datapatch execution. Before executing the `dbcli register-database` command, open all PDBs in read-write mode. If you have already run the `dbcli register-database` command and did not open all PDBs, or did not copy the `SORACLE_HOME/sqlpatch` directory from the source database home, manually rerun the datapatch utility to configure the SQL portion of existing interim patches. This can be done by executing the command `$ORACLE_HOME/OPatch/opatch datapatch`.

**Tip:**

If the source database includes patch 23170620 and the target database is running with the October 2017 patch or a later one, the `$ORACLE_HOME/sqlpatch` directory does not need to be copied to the target database, because the contents of the patch are already installed in the target database.

Rolling Back Patches on a Version 11.2 Database

For version 11.2 databases, the sqlpatch application is not automated, so any interim patches (previously known as a "one-off" patches) applied to the source database that are not part of the installed PSU must be rolled back manually in the target database. After registering the database, execute the `catbundle.sql` script and then the `postinstall.sql` script with the corresponding PSU patch (or the overlay patch on top of the PSU patch), as described below.

**Tip:**

Some interim patches may include files written to the `SORACLE_HOME/rdbms/admin` directory as well as the `SORACLE_HOME/sqlpatch` directory. Oracle recommends that you roll back these patches in the source database using the instructions in the patch read-me prior to migrating the database to OCI environment. Contact Oracle Support if you need assistance with rolling back these patches.

1. On the DB System, use the `dbcli list-dbhomes` command to find the PSU patch number for the version 11.2 database home. In the following sample command output, the PSU patch number is the second number in the DB Version column:

   ```
   [root@dbsys ~]# dbcli list-dbhomes
   
   ID                                   Name               DB Version               Status
   Home Location                             Status
   ------------------------------------ ----------------- ------------
   59d9bc6f-3880-4d4f-b5a6-c140f16f8c64 OraDB11204_home1 11.2.0.4.160719
   (23054319, 23054359)   /u01/app/oracle/product/11.2.0.4/dbhome_1
   Configured
   
   (The first patch number, 23054319 in the example above, is for the OCW component in the database home.)
   
   2. Find the overlay patch, if any, by using the `lsinventory` command. In the following example, patch number 24460960 is the overlay patch on top of the 23054359 PSU patch.

   ```
   $ $ORACLE_HOME/OPatch/opatch lsinventory
   ...
   ```
Installed Top-level Products (1):

Oracle Database 11g
11.2.0.4.0
There are 1 products installed in this Oracle Home.

Interim patches (5):

Patch 24460960: applied on Fri Sep 02 15:28:17 UTC 2016
Unique Patch ID: 20539912
Created on 31 Aug 2016, 02:46:31 hrs PST8PDT
Bugs fixed:
23513711, 23065323, 21281607, 24006821, 23315889, 22551446, 21174504
This patch overlays patches:
23054359
This patch needs patches:
23054359
as prerequisites

3. Start SQL*Plus and execute the catbundle.sql script, for example:

   SQL> startup
   SQL> connect / as sysdba
   SQL> @$ORACLE_HOME/rdbms/admin/catbundle.sql psu apply
   exit

4. Apply the sqlpatch, using the overlay patch number from the previous step, for example:

   SQL> connect / as sysdba
   SQL> @$ORACLE_HOME/sqlpatch/24460960/postinstall.sql
   exit

Creating a Backup Configuration (Optional)

If you would like to manage the database backup with the dbcli command line interface, you can associate a new or existing backup configuration with the migrated database when you register it or after you register it. A backup configuration defines the backup destination and recovery window for the database. As the root user, use the following commands to create, list, and display backup configurations:

- Backupconfig Commands on page 2250
- Backupconfig Commands on page 2250
- Backupconfig Commands on page 2250

Post Migration Checklist

After the database is migrated and registered on the DB system, use the following checklist to verify the results of the migration and perform any post-migration customizations.

1. Make sure the database files were restored in OMF format.
2. Make sure the database is listed in the Database Commands on page 2264 command output.
3. Check for the following external references in the database and update them if necessary:
   - External tables: If the source database uses external tables, back up that data and migrate it to the target host.
   - Directories: Customize the default directories as needed for the migrated database.
   - Database links: Make sure all the required TNS entries are updated in the tnsnames.ora file in ORACLE_HOME.
   - Email and URLs: Make sure any email addresses and URLs used in the database are still accessible from the DB system.
   - Scheduled jobs: Review the jobs scheduled in source database and schedule similar jobs as needed in the migrated database.
4. If you associated a backup configuration when you registered the database, run a test back up using the Backup Commands on page 2247 command.
5. Verify that patches have been applied to all PDBs if the migrated database contains CDB and PDBs.
6. Validate the database performance by using Database Replay and SQL Performance Analyzer for SQL. For more information, see the Database Testing Guide.

SQL Developer and INSERT Statements to Migrate Selected Objects

You can use SQL Developer to create a cart into which you add selected objects to be loaded into an Oracle Database 12c database in the Oracle Cloud Infrastructure Database service.

In this method, you use SQL INSERT statements to load the data into your cloud database.

To migrate selected objects to an Oracle Database 12c database in a Database service deployment using SQL Developer and INSERT statements, you perform these tasks:

1. Launch SQL Developer, connect to your on-premises database and create a cart containing the objects you want to migrate.
2. In SQL Developer, click the Export Cart icon and select “Insert” in the Format menu.
3. In SQL Developer, open a connection to the Oracle Database 12c database in the Database service and execute the generated script to create the database objects.
4. In SQL Developer, open a connection to the Oracle Database 12c database in the Database service and run the generated script to create the objects and load the data.

SQL Developer and SQL*Loader to Migrate Selected Objects

You can use SQL Developer to create a cart into which you add selected objects to be loaded into an Oracle Database 12c database in the Oracle Cloud Infrastructure Database.

In this method, you use SQL*Loader to load the data into your cloud database.

To migrate selected objects to an Oracle Database 12c database in the Database service deployment using SQL Developer and SQL*Loader, you perform these tasks:

1. Launch SQL Developer, connect to your on-premises database and create a cart containing the objects you want to load into your cloud database.
2. In SQL Developer, click the Export Cart icon and select “loader” in the Format menu.
3. In SQL Developer, open a connection to the Oracle Database 12c database on the Database service and execute the generated script to create the database objects.
4. Use a secure copy utility to transfer the SQL*Loader control files and the SQL*Loader data files to the Database service compute node.
5. On the Database service compute node, invoke SQL*Loader to load the data using the SQL*Loader control files and data files for each object.

Unplugging/Plugging a PDB

You can use this method only if the on-premises platform is little endian, and the on-premises database and the Oracle Cloud Infrastructure Database service database have compatible database character sets and national character sets.

You can use the unplug/plug method to migrate an Oracle Database 12c PDB to a PDB in an Oracle Database 12c database on a Database service database deployment.

To migrate an Oracle Database 12c PDB to a PDB in the Oracle Database 12c database on an Oracle Cloud Infrastructure Database service database deployment using the plug/unplug method, you perform these tasks:

1. On the on-premises database host, invoke SQL*Plus and close the on-premises PDB.
2. On the on-premises database host, execute the ALTER PLUGGABLE DATABASE UNPLUG command to generate an XML file containing the list of datafiles that will be plugged in to the database on the Database service.
3. Use a secure copy utility to transfer the XML file and the datafiles to the Databaseservice compute node.
4. On the Database service compute node, invoke SQL*Plus and execute the `CREATE PLUGGABLE DATABASE` command to plug the database into the CDB.

5. On the Database service compute node, open the new PDB by executing the `ALTER PLUGGABLE DATABASE OPEN` command.

For more information, see "Creating a PDB by Plugging an Unplugged PDB into a CDB" in *Oracle Database Administrator's Guide* for Release 12.2 or 12.1.

**Unplugging/Plugging Non-CDB**

You can use this method only if the on-premises platform is little endian, and the on-premises database and the Oracle Cloud Infrastructure Database database have compatible database character sets and national character sets.

You can use the unplug/plug method to migrate an Oracle Database 12c non-CDB database to a PDB in an Oracle Database 12c database on a Database service database deployment. This method provides a way to consolidate several non-CDB databases into a single Oracle Database 12c multitenant database on the Database service.

To migrate an Oracle Database 12c non-CDB database to the Oracle Database 12c database on a Database service deployment using the plug/unplug method, you perform these tasks:

1. On the on-premises database host, invoke SQL*Plus and set the on-premises database to `READ ONLY` mode.
2. On the on-premises database host, execute the `DBMS_PDB.DESCRIBE` procedure to generate an XML file containing the list of datafiles that will be plugged in on the cloud database.
3. Use a secure copy utility to transfer the XML file and the datafiles to the Database service compute node.
4. On the Database service compute node, invoke SQL*Plus and execute the `CREATE PLUGGABLE DATABASE` command to plug the database into the CDB.
5. On the Database service compute node, execute the `$ORACLE_HOME/rdbms/admin/noncdb_to_pdb.sql` script to delete unnecessary metadata from the `SYSTEM` tablespace of the new PDB.
6. On the Database service compute node, open the new PDB by executing the `ALTER PLUGGABLE DATABASE OPEN` command.
7. Optionally, on the on-premises database host invoke SQL*Plus and set the on-premises database back to `READ WRITE` mode.

For more information, see "Creating a PDB Using a Non-CDB" in *Oracle Database Administrator's Guide* for Release 12.2 or 12.1.

**Troubleshooting**

The topics in this section cover common issues you might run into and how to resolve them.

**Bare Metal and Virtual Machine DB Systems**

This section covers troubleshooting common issues for bare metal and virtual machine DB systems:

- Backup Failures on Bare Metal and Virtual Machine DB Systems on page 2410
- Patching Failures on Bare Metal and Virtual Machine DB Systems on page 2424
- Shape Change Failures for Virtual Machine DB Systems on page 2428

**Tip:**

For bare metal and virtual machine DB systems, you can create serial console connections to troubleshoot your system in single-user mode. See To create a serial console connection to your database system on page 2135 for information on creating a serial console connection in the Oracle Cloud Infrastructure Console.

**Backup Failures on Bare Metal and Virtual Machine DB Systems**

Database backups can fail for various reasons. Typically, a backup fails because either the database host cannot access the object store, or there are problems on the host or with the database configuration.
This topic includes information to help you determine the cause of a failure and fix the problem. The section that includes troubleshooting information is organized into several subsections, based on the error condition. If you already know the cause, you can skip to the section with the suggested solution. Otherwise, use the procedure in Finding the Problem on page 2411 to get started.

Finding the Problem

In the Console, a failed database backup either displays a status of Failed or hangs in the Backup in Progress or Creating state. If the error message does not contain enough information to point you to a solution, you can use the database CLI and log files to gather more data. Then, refer to the applicable section in this topic for a solution.

To identify the root cause of the backup failure

1. Log on to the host as the root user and navigate to /opt/oracle/dcs/bin/.
2. Determine the sequence of operations performed on the database.
   
   `dbname`

   `dbcli list-jobs | grep -i <dbname>`

   Note the last job ID listed with a status other than Success.

   3. With the job ID you noted from the previous step, use the following command to check the details of that job:

   `dbcli describe-job -i <job_ID> -j`

   Typically, running this command is enough to reveal the root cause of the failure.

4. If you require more information, review the /opt/oracle/dcs/log/dcs-agent.log file.

   You can find the job ID in this file by using the timestamp returned by the job report in step 2.

5. If the problem details suggest an RMAN issue, review the RMAN logs in the /opt/oracle/dcs/log/<hostname>/rman/bkup/<db_unique_name>/rman_backup/<yyyy-mm-dd> directory.

   **Note:**

   If the database failure is on a 2-node RAC database, perform steps 3 and 4 on both nodes.

Database Service Agent Issues

Your Oracle Cloud Infrastructure Database makes use of an agent framework to allow you to manage your database through the cloud platform. Occasionally you might need to restart the dcsagent program if it has the status of stop/waiting to resolve a backup failure.

To restart the database service agent

1. From a command prompt, check the status of the agent:

   `initctl status initdcsagent`

2. If the agent is in the stop/waiting state, try to restart the agent:

   `initctl start initdcsagent`

3. Check the status of the agent again to confirm that it has the start/running status:

   `initctl status initdcsagent`

Oracle Clusterware Issues

Oracle Clusterware enables servers to communicate with each other so that they can function as a collective unit. Occasionally you might need to restart the Clusterware program to resolve a backup failure.

To restart the Oracle Clusterware
1. From command prompt, check the status of Oracle Clusterware:

   crsctl check crs
   crsctl stat res -t

2. If Oracle Clusterware is not online, try to restart the program:

   crsctl start crs

3. Check the status of Oracle Clusterware to confirm that it is online:

   crsctl check crs

Object Store Connectivity Issues

Backing up your database to Oracle Cloud Infrastructure Object Storage requires that the host can connect to the applicable Swift endpoint. You can test this connectivity by using a Swift user.

To ensure your database host can connect to the object store

1. Create a Swift user in your tenancy. See Working with Auth Tokens.
2. With the user you created in the previous step, use the following command to verify the host can access the object store.

   curl -v -X HEAD -u <user_ID>:<auth_token> https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/<object_storage_namespace>

   See Object Storage FAQ for the correct region to use. See Understanding Object Storage Namespaces on page 4947 for information about your Object Storage namespace.
3. If you cannot connect to the object store, refer to Prerequisites on page 2184 for how to configure object store connectivity.

Host Issues

One or more of the following conditions on the database host can cause backups to fail:

Interactive Commands in the Oracle Profile

If an interactive command such as oraenv, or any command that might return an error or warning message, was added to the .bash_profile file for the grid or oracle user, Database service operations like automatic backups can be interrupted and fail to complete. Check the .bash_profile file for these commands, and remove them.

The File System Is Full

Backup operations require space in the /u01 directory on the host file system. Use the df -h command on the host to check the space available for backups. If the file system has insufficient space, you can remove old log or trace files to free up space.

Incorrect Version of the Oracle Database Cloud Backup Module

Your system might not have the required version of the backup module (opc_installer.jar). See Unable to use Managed Backups in your DB System for details about this known issue. To fix the problem, you can follow the procedure in that section or simply update your DB system and database with the latest bundle patch.
Changes to the Site Profile File (glogin.sql)

Customizing the site profile file ($ORACLE_HOME/sqlplus/admin/glogin.sql) can cause managed backups to fail in Oracle Cloud Infrastructure. In particular, interactive commands can lead to backup failures. Oracle recommends that you not modify this file for databases hosted in Oracle Cloud Infrastructure.

Database Issues

An improper database state or configuration can lead to failed backups.

Database Not Running During Backup

The database must be active and running (ideally on all nodes) while the backup is in progress.

To check that the database is active and running:

Use the following command to check the state of your database, and ensure that any problems that might have put the database in an improper state are resolved:

```
srvctl status database -d <db_unique_name> -verbose
```

The system returns a message including the database's instance status. The instance status must be **Open** for the backup to succeed. If the database is not running, use the following command to start it:

```
srvctl start database -d <db_unique_name> -o open
```

If the database is mounted but does not have the **Open** status, use the following commands to access the SQL*Plus command prompt and set the status to **Open**:

```
sqlplus / as sysdba
alter database open;
```

Archiving Mode Set to NOARCHIVELOG

When you provision a new database, the archiving mode is set to **ARCHIVELOG** by default. This is the required archiving mode for backup operations. Check the archiving mode setting for the database and change it to **ARCHIVELOG**, if applicable.

To check and set the archiving mode:

Open an SQL*Plus command prompt and enter the following command:

```
select log_mode from v$database;
```

If you need to set the archiving mode to **ARCHIVELOG**, start the database in **Mount** status (and not **Open** status), and use the following command at the SQL*Plus command prompt:

```
alter database archivelog;
```

Confirm that the `db_recovery_file_dest` parameter points to +RECO, and that the `log_archive_dest_1` parameter is set to USE_DB_RECOVERY_FILE_DEST.

For RAC databases, one instance must have the **Mount** status when enabling archivelog mode. To enable archivelog mode for a RAC database, perform the following steps:

1. Shut down all database instances:

```
srvctl stop database -d
```
2. Start one of the database instances in mount state:
   
   ```
   srvctl start instance -d <db_unique_name> -i <instance_name> -o mount
   ```

3. Access the SQL*Plus command prompt:
   
   ```
   sqlplus / as sysdba
   ```

4. Enable archive log mode:
   
   ```
   alter database archivelog;
   ```

5. Stop the database:
   
   ```
   srvctl stop instance -d <db_unique_name> -i <instance_name>
   ```

6. Restart all database instances:
   
   ```
   srvctl start database -d <db_unique_name>
   ```

7. At the SQL*Plus command prompt, confirm the archiving mode is set to ARCHIVELOG:
   
   ```
   select log_mode from v$database;
   ```

**Stuck Database Archiver Process and Backup Failures**

Backups can fail when the database instance has a stuck archiver process. For example, this can happen when the flash recovery area (FRA) is full. You can check for this condition using the `srvctl status database - db <db_unique_name> -v` command. If the command returns the following output, you must resolve the stuck archiver process issue before backups can succeed:

```
Instance <instance_identifier> is running on node *<node_identifier>.
Instance status: Stuck Archiver
```

Refer to ORA-00257:Archiver Error (Doc ID 2014425.1) for information on resolving a stuck archiver process.

After resolving the stuck process, the command should return the following output:

```
Instance <instance_identifier> is running on node *<node_identifier>.
Instance status: Open
```

If the instance status does not change after you resolve the underlying issue with the device or resource being full or unavailable, try one of the following workarounds:

- Restart the database using the `srvctl` command to update the status of the database in the clusterware
- Upgrade the database to the latest patchset levels

**Temporary Tablespace Errors**

If fixed table statistics are not up to date on the database, backups can fail with errors referencing temporary tablespace present in the `dcs-agent.log` file. For example:

```
select status from v$run_status where COMMAND_ID=<backup_id>

ERROR at line 1:
ORA-01652: unable to extend temp segment by 128 in tablespace TEMP
```
Gather your fixed table statics as follows to resolve this issue:

```
conn / as sysdba
exec dbms_stats.gather_fixed_objects_stats();
```

**RMAN Configuration and Backup Failures**

Editing certain RMAN configuration parameters can lead to backup failures in Oracle Cloud Infrastructure. To check your RMAN configuration, use the `show all` command at the RMAN command line prompt.

See the following list of parameters for details about RMAN the configuration settings that should not be altered for databases in Oracle Cloud Infrastructure.

**RMAN configuration settings that should not be altered**

```
CONFIGURE RETENTION POLICY TO RECOVERY WINDOW OF 30 DAYS;
CONFIGURE CONTROLFILE AUTOBACKUP ON;
CONFIGURE DEVICE TYPE 'SBT_TAPE' PARALLELISM 5 BACKUP TYPE TO COMPRESSED BACKUPSET;
CONFIGURE CHANNEL DEVICE TYPE DISK MAXPIECESIZE 2 G;
CONFIGURE CHANNEL DEVICE TYPE 'SBT_TAPE' MAXPIECESIZE 2 G FORMAT '%d_%I_%U_%T_%t' PARM'S 'SBT_LIBRARY=/opt/oracle/dcs/commonstore/pkgrepos/oss/odbcs/libopc.so ENV=(OPC_PFILE=/opt/oracle/dcs/commonstore/objectstore/opc_pfile/1578318329/opc_tiger_iad3c8.ora)';
CONFIGURE ARCHIVELOG DELETION POLICY TO BACKED UP 1 TIMES TO 'SBT_TAPE';
CONFIGURE CHANNEL DEVICE TYPE DISK MAXPIECESIZE 2 G;
CONFIGURE ENCRYPTION FOR DATABASE ON;
```

**RMAN Retention Policy and Backup Failures**

The RMAN retention policy configuration can be the source of backup failures. Using the REDUNDANCY retention policy configuration instead of the RECOVERY WINDOW policy can lead to backup failures. Be sure to use the RECOVERY WINDOW OF 30 DAYS configuration.

To configure the RMAN retention policy setting

1. Find the database ID using the following command:

   `dbcli list-databases`

2. Find the `BackupConfigId` value for the database using the following command:

   `dbcli describe-database -i <database_id>`

3. Update the retention policy configuration to `RECOVERY WINDOW OF 30 DAYS`:

   `dbcli update-backupconfig -i <backup_config_id> --recoverywindow 30`
**Loss of Object Store Wallet File and Backup Failures**

RMAN backups fail when an object store wallet file is lost. The wallet file is necessary to enable connectivity to the object store.

To confirm that the object store wallet file exists and has the correct permissions

1. Find the database ID using the following command:
   ```
   dbcli list-databases
   ```
2. Find the `BackupConfigId` value for the database using the following command:
   ```
   dbcli describe-database -i <database_id>
   ```
3. Find the `BackupLocation` value for the database using the following command:
   ```
   dbcli describe-backupconfig <backup_config_id>
   ```
4. Find the file path of the backup config parameter file (opc_<backup_location_value>_BC.ora) using the following command:
   ```
   locate opc_<backup_location_value>_BC.ora
   ```
   For example:
   ```
   [root@orcl 13aef284-9d6b-4eb6-8751-2988aexample]# locate opc_b9naijWMAXzi9example_BC.ora
   /opt/oracle/dcs/commonstore/objectstore/
   opc_pfile/13aef284-9d6b-4eb6-8751-2988a9example/
   opc_b9naijWMAXzi9example_BC.ora
   ```
5. Find the file path to the wallet file in the backup config parameter file by inspecting the value stored in the `OPC_WALLET` parameter. To do this, navigate to the directory containing the backup config parameter file and use the following `cat` command:
   ```
   cat <backup_config_parameter_file>
   ```
   For example:
   ```
   [root@orcl 13aef284-9d6b-4eb6-8751-2988aexample]# cat
   opc_b9naijWMAXzi9example_BC.ora
   OPC_HOST=https://swiftobjectstorage.us-ashburn-1.oraclecloud.com/
   v1/dbbackupiad
   OPC_WALLET='LOCATION=file:/opt/oracle/dcs/commonstore/objectstore/
   wallets/13aef284-9d6b-4eb6-8751-2988aexample CREDENTIAL_ALIAS=alias_opc'
   OPC_CONTAINER=b9naijWMAXzi9example
   ```
6. Confirm that the `cwallet.sso` file exists in the directory specified in the `OPC_WALLET` parameter, and confirm that the file has the correct permissions. The file permissions should have the octal value of "600" (-rw------). Use the following command:
   ```
   ls -ltr /opt/oracle/dcs/commonstore/objectstore/wallets/<backup_config_id>
   ```
   For example:
**TDE Wallet and Backup Failures**

**Incorrect TDE Wallet Location Specification**

For backup operations to work, the $ORACLE_HOME/network/admin/sqlnet.ora file must contain the ENCRYPTION_WALLET_LOCATION parameter formatted exactly as follows:

```
ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE) (METHOD_DATA=(DIRECTORY=/opt/oracle/dcs/commonstore/wallets/tde/$ORACLE_UNQNAME)))
```

**Important:**

In this wallet location entry, $ORACLE_UNQNAME is an environment variable and should not be replaced with an actual value.

To check the TDE wallet location specification

Use the cat command to check the TDE wallet location specification. For example:

```
[oracle@orcl tde]$ cat $ORACLE_HOME/network/admin/sqlnet.ora
ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE) (METHOD_DATA=(DIRECTORY=/opt/oracle/dcs/commonstore/wallets/tde/$ORACLE_UNQNAME)))
```

**Incorrect State of the TDE Wallet**

Database backups fail if the TDE wallet is not in the proper state. The following scenarios can cause this problem:

The ORACLE_UNQNAME environment variable was not set when the database was started using SQL*Plus

If the database was started using SQL*Plus, and the ORACLE_UNQNAME environment variable was not set, the wallet is not opened correctly.

To fix the problem, start the database using the srvctl utility:

```
srvctl start database -d <db_unique_name>
```

A pluggable database was added with an incorrectly configured master encryption key

In a multitenant environment for Oracle Database versions that support PDB-level keystore, each PDB has its own master encryption key. This encryption key is stored in a single keystore used by all containers. After you create or plug in a new PDB, you must create and activate a master encryption key for it. If you do not do so, the STATUS column in the v$encryption_wallet view shows the value OPEN_NO_MASTER_KEY.

To check the master encryption key status and create a master key, do the following:

1. Review the the STATUS column in the v$encryption_wallet view, as shown in the following example:

```
SQL> alter session set container=pdb2;
```
Session altered.

```
SQL> select WRL_TYPE,WRL_PARAMETER,STATUS,WALLET_TYPE from v$encryption_wallet;
```

<table>
<thead>
<tr>
<th>WRL_TYPE</th>
<th>WRL_PARAMETER</th>
<th>STATUS</th>
<th>WALLET_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE</td>
<td>/opt/oracle/dcs/commonstore/wallets/tde/example_iadxyz/</td>
<td>OPEN_NO_MASTER_KEY AUTOLOGIN</td>
<td></td>
</tr>
</tbody>
</table>

2. Confirm that the PDB is in READ WRITE open mode and is not restricted, as shown in the following example:

```
SQL> show pdbs
```

<table>
<thead>
<tr>
<th>CON_ID</th>
<th>CON_NAME</th>
<th>OPEN MODE</th>
<th>RESTRICTED</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>PDB$SEED</td>
<td>READ ONLY</td>
<td>NO</td>
</tr>
<tr>
<td>3</td>
<td>PDB1</td>
<td>READ WRITE</td>
<td>NO</td>
</tr>
<tr>
<td>4</td>
<td>PDB2</td>
<td>READ WRITE</td>
<td>NO</td>
</tr>
</tbody>
</table>

The PDB cannot be open in restricted mode (the RESTRICTED column must show NO). If the PDB is currently in restricted mode, review the information in the PDB_PLUGIN_IN_VIOLATIONS view and resolve the issue before continuing. For more information on the PDB_PLUGIN_IN_VIOLATIONS view and the restricted status, review the documentation on pluggable database for your Oracle database version.

3. Run the following DBCLI commands to change the status to OPEN:

```
$ sudo su –
# dbcli list-database
# dbcli update-tdekey -i <database_ID> -n <PDB_name> -p
```

The update-tdekey command shown will prompt you for the admin password.

4. Confirm that the status of the wallet has changed from OPEN_NO_MASTER_KEY to OPEN by querying the v$encryption_wallet view as shown in step 1.

**Incorrect Configuration Related to the TDE Wallet**

Several configuration parameters related to the TDE wallet can cause backups to fail.

To check configuration related to the TDE wallet:

- Check that the environment's database unique name parameter (ORACLE_UNQNAME) is set correctly using the following command:

```
srvctl getenv database -d <db_unique_name>
```

For example:

```
[oracle@orcl tde]$ srvctl getenv database -d orclbkp_iadxyz
orclbkp_iadxyz:
```
• Check your sqlnet.ora settings to confirm that the file has an ENCRYPTION_WALLET_LOCATION parameter with the correct DIRECTORY value. Use the following command: cat $ORACLE_HOME/network/admin/sqlnet.ora

For example:

```
[oracle@orcl tde]$ cat $ORACLE_HOME/network/admin/sqlnet.ora

ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)
(METHOD_DATA=(DIRECTORY=/opt/oracle/dcs/commonstore/wallets/tde/
$ORACLE_UNQNAME)))
```

• Confirm that the wallet status is open and the wallet type is auto login by checking the v $encryption_wallet view. For example:

```
SQL> select status, wrl_parameter,wallet_type from v
$encryption_wallet;

STATUS          WALLET_TYPE
------------------ ------------------------
OPEN             /opt/oracle/dcs/commonstore/wallets/tde/example_iadxyz/ AUTOLOGIN
```

For pluggable databases (PDBs), be sure that you switch to the appropriate container before querying v $encryption_wallet view. For example:

```
[oracle@paulo ~]$ sqlplus / as sysdba

SQL> alter session set container=pdb1;

Session altered.

SQL> select WRL_TYPE,WRL_PARAMETER,STATUS,WALLET_TYPE from v
$encryption_wallet;

WRL_TYPE   WRL_PARAMETER
STATUS     WALLET_TYPE
---------- --------------------------------------------------------
---------- --------------------
FILE       /opt/oracle/dcs/commonstore/wallets/tde/tiger_iad3c8/
OPEN      AUTOLOGIN
```
**Missing TDE Wallet File**

The TDE wallet file (ewallet.p12) can cause backups to fail if it is missing, or if it has incompatible file system permissions or ownership. Check the file as shown in the following example:

```
[oracle@orcl tde]$ ls -ltr /opt/oracle/dcs/commonstore/wallets/tde/
$ORACLE_UNQNAME/ewallet.p12
-rwx------ 1 oracle oinstall 5680 Apr 18 13:09 /opt/oracle/dcs/
commonstore/wallets/tde/orclbkp_iadxzy/ewallet.p12
```

The TDE wallet file should have file permissions with the octal value "700" (-rwx------), and the owner of this file should be a part of the oinstall operating system group.

**Missing Auto Login Wallet File**

The auto login wallet file (cwallet.sso) can cause backups to fail if it is missing, or if it has incompatible file system permissions or ownership. Check the file as shown in the following example:

```
[oracle@orcl tde]$ ls -ltr /opt/oracle/dcs/commonstore/wallets/tde/
$ORACLE_UNQNAME/cwallet.sso
-rwx------ 1 oracle oinstall 5725 Apr 18 13:09 /opt/oracle/dcs/
commonstore/wallets/tde/orclbkp_iadxzy/cwallet.sso
```

The auto login wallet file should have file permissions with the octal value "700" (-rwx------), and the owner of this file should be a part of the oinstall operating system group.

**Other Causes of Backup Failures**

**Unmounted Commonstore Mount Point**

The mount point /opt/oracle/dcs/commonstore must be mounted, or backups will fail.

To check the commonstore mount point

Confirm that the mount point /opt/oracle/dcs/commonstore is mounted, as shown in the following example:

```
[root@orcl ~]# srvctl config filesystem -volume commonstore -diskgroup data
Volume device: /dev/asm/commonstore-5
Diskgroup name: data
Volume name: commonstore
Canonical volume device: /dev/asm/commonstore-5
Accelerator volume devices:
Mountpoint path: /opt/oracle/dcs/commonstore
Mount point owner: oracle
Mount users:
Type: ACFS
```
To confirm that ora.data.commonstore.acfs is online

The state for ora.data.commonstore.acfs must be online, or backups will fail. Confirm as shown in the following example:

```
[root@orcl ~]# crsctl stat resource ora.data.commonstore.acfs -v
NAME=ora.data.commonstore.acfs
TYPE=ora.acfs.type
LAST_SERVER=orcl
STATE=OFFLINE
TARGET=OFFLINE
...
STATE_DETAILS=admin unmounted /opt/oracle/dcs/commonstore
...
[root@orcl ~]# ls -ltr /opt/oracle/dcs/commonstore
```

If the STATE_DETAILS value is unmounted, mount the file system as shown in the following example:

```
[root@orcl ~]# srvctl start filesystem -volume commonstore -diskgroup data
```

Confirm that the change was successful as shown in the following example:

```
[root@orcl ~]# crsctl stat resource ora.data.commonstore.acfs -v
NAME=ora.data.commonstore.acfs
TYPE=ora.acfs.type
LAST_SERVER=orcl
STATE=ONLINE on orcl
TARGET=ONLINE
CARDINALITY_ID=ONLINE
...
STATE_DETAILS=mounted on /opt/oracle/dcs/commonstore
```

List the contents of the commonstore directory to confirm that it is mounted, as shown in the following example:

```
[root@orcl ~]# ls -ltr /opt/oracle/dcs/commonstore
```

```
total 220
drwx------ 2 root   root     65536 Apr 18 10:50 lost+found
drwx------ 3 oracle oinstall 20480 Apr 18 11:02 wallets
```
The Database Is Not Properly Registered

Database backups fail if the database is not registered with the dcs-agent. This scenario can occur if you manually migrate the database to Oracle Cloud Infrastructure and do not run the `dbcli register-database` command.

To check whether the database is properly registered, review the information returned by running the `srvctl config database` command and the `dbcli list-databases` command. If either command does not return a record of the database, contact Oracle Support Services.

For instructions on how to register the database, refer to the following topics:

- Registering the Database on the DB System on page 2207
- Database Commands on page 2264

Getting Help

If you were unable to resolve the problem using the information in this topic, follow the procedures below to collect relevant database and diagnostic information. After you have collected this information, contact Oracle Support.

To collect database information for use in problem reports

Use the following commands to collect details about your database. Record the output of each command for reference:

```
dbcli list-databases

dbcli describe-database -i <database_id>

dbcli describe-component
```

To collect diagnostic information regarding failed jobs

1. Log on to the host as the root user and navigate to the `/opt/oracle/dcs/bin/` directory.
2. Run the following two commands to generate information about the failed job:

```
dbcli list-jobs | grep -i <dbname>

dbcli describe-job -i <job_ID> -j
```

The `<job_ID>` in the second command should be the ID of the latest failed job reported from the first command.

3. Run the diagnostics collector script to create a zip file with the diagnostic information for Oracle Support Services.

```
diagcollector.py
```

This command creates a file named `diagLogs-<timestamp>.zip` in the `/tmp` directory.

To collect DCS agent log files

To collect DCS agent log files, do the following:

1. Log in as opc user.
2. Run the following command:

```
sudo /opt/oracle/dcs/bin/diagcollector.py
```
3. The system returns a message indicating that agent logs are available in a zip file at a specified directory. For example:

```
[opc@prodpr ~]$ sudo /opt/oracle/dcs/bin/diagcollector.py
Log files collected to :/tmp/dcsdiag/diagLogs-1234567890.zip
Logs are being collected to:
/tmp/dcsdiag/diagLogs-1234567890.zip
```

To collect TDE configuration details

1. Run the `srvctl getenv database -d <db_unique_name>` command and record the output for reference.

2. Record the output of the view `v$encryption_wallet`. For example:

```
SQL> select status, wrl_parameter, wallet_type from v$encryption_wallet;

STATUS          WRL_PARAMETER
--------------- -----------------------------------------
OPEN            /opt/oracle/dcs/commonstore/wallets/tde/
example_iadxyz/ AUTOLOGIN
```

3. Record the output of the `ls -ltr <wrl_parameter>` command. For example:

```
[oracle@patchtst ~]$ ls -ltr /opt/oracle/dcs/commonstore/wallets/tde/example_iadxyz/
 total 28
-rw------- 1 oracle asmadmin 2400 May  2 09:42 ewallet_2018050209420381_defaultTag.p12
-rw------- 1 oracle asmadmin 5680 May  2 09:42 ewallet.p12
-rw------- 1 oracle asmadmin 5723 May  2 09:42 cwallet.sso
```

To collect the RMAN backup report file

Generate RMAN Backup Report File using the following command:

```
dbcli create-rmanbackupreport -i <db_id> -w detailed -rn <report_name>
```

For example:

```
[root@patchtst ~]# dbcli create-rmanbackupreport -i 57fvwxyz-9dc4-45d3-876b-5f850example -w detailed -rn bkpreport1
```

Locate the report file using the `dbcli describe-rmanbackupreport -in <report_name>` command. The location of the report is given in output. For example:

```
[root@patchtst ~]# dbcli describe-rmanbackupreport -in bkpreport1
```
Patching Failures on Bare Metal and Virtual Machine DB Systems

Patching operations can fail for various reasons. Typically, an operation fails because a database node is down, there
is insufficient space on the file system, or the database host cannot access the object store.

This topic includes information to help you determine the cause of the failure and fix the problem. The information
is organized into several sections, based on the error condition. If you already know the cause, you can skip to the
section with the suggested solution. Otherwise, use the procedure in Determining the Problem on page 2424 to get
started.

Determining the Problem

In the Console, you can identify a failed patching operation by viewing the patch history of a DB system or an
individual database. A patch that was not successfully applied displays a status of Failed and includes a brief
description of the error that caused the failure. If the error message does not contain enough information to point you
to a solution, you can use the database CLI and log files to gather more data. Then, refer to the applicable section in
this topic for a solution.

To identify the root cause of the patching operation failure

1. Log on to the host as the root user and navigate to the /opt/oracle/dcs/bin/ directory.
2. Determine the sequence of operations performed on the database.

   ```
   dbcli list-jobs
   ```

   Note the last job ID listed with a status other than Success.
3. With the job ID you noted from the previous step, use the following command to check the details of that job:

   ```
   dbcli describe-job -i <job_ID> -j
   ```

   Typically, running this command is enough to reveal the root cause of the failure.
4. If you require more information, review the /opt/oracle/dcs/log/dcs-agent.log file.
   You can find the job ID in this file by using the timestamp returned by the job report in step 2.
5. If the patching failure is on a 2-node RAC database, perform steps 3 and 4 on both nodes.

Database Service Agent Issues

Your Oracle Cloud Infrastructure Database makes use of an agent framework to allow you to manage your database
through the cloud platform.

Resolving Patching Failures Caused By a Stopped Agent

Occasionally you might need to restart the dcsagent program if it has the status of stop/waiting to resolve a patching
failure.
To restart the database service agent

1. From a command prompt, check the status of the agent:

   ```bash
   initctl status initdcsagent
   ```

2. If the agent is in the **stop/waiting** state, try to restart the agent:

   ```bash
   initctl start initdcsagent
   ```

3. Check the status of the agent again to confirm that it has the **start/running** status:

   ```bash
   initctl status initdcsagent
   ```

---

**Resolving Patching Failures Caused By an Agent That Needs to Be Updated**

Patching can also fail if your agent needs to be updated. The system gives the following error message for this failure:

```
Current DcsAgent version is less than or equal to minimum required version.
```

To resolve this issue, perform the steps in **To have Oracle Support update the Oracle Cloud Infrastructure Database service agent** on page 2425.

**To have Oracle Support update the Oracle Cloud Infrastructure Database service agent**

1. Confirm that the agent (dcsagent) and DCS Admin program (dcsadmin) are running using the following commands:

   ```bash
   initctl status initdcsagent
   ```

   ```bash
   initctl status initdcsadmin
   ```

   If these programs are not running, use the following commands to restart them:

   ```bash
   initctl start initdcsagent
   ```

   ```bash
   initctl start initdcsadmin
   ```

2. Follow the instructions in **Obtaining Further Assistance** on page 2427 to collect your DCS agent log files.

3. Contact **Oracle Support** for assistance with updating the agent.

---

**Object Store Connectivity Issues**

Oracle Cloud Infrastructure DB system and database patches are stored in Oracle Cloud Infrastructure Object Storage. Therefore, successful patching operations require connectivity between the DB system host and the Object Storage location from which the patches are downloaded.

To ensure your database host can connect to Oracle Cloud Infrastructure Object Storage

1. Use the following command to verify the host can access Oracle Cloud Infrastructure Object Storage:

   ```bash
   dbcli describe-latestpatch
   ```

   Example output indicating success:

   ```
   [root@<host> ~]# dbcli describe-latestpatch
   componentType availableVersion
   --------------------------
   gi 12.2.0.1.180417
   gi 12.1.0.2.180417
   ```
Example output indicating failure:

```
[root@<host> ~]# dbcli describe-latestpatch
DCS-10032: Resource patch metadata is not found. Failed to download patchmetadata from objectstore
```

2. If you cannot connect to the object store, refer to Prerequisites on page 2184 for how to configure object store connectivity.

**Host and Oracle Clusterware Issues**

One or more of the following conditions on the database host can cause patching operations to fail:

**Database Node Not Running During the Patching Operation**

All nodes of the database must be active and running while a patching operation is in progress, whether you are patching the DB system or the database home. Use the Console to check that the status of each node is AVAILABLE, and start the node, if needed.

**The File System Is Full**

Patching operations require a minimum of 15 GB of free space in the `/u01` directory on the host file system. Use the `df -h` command on the host to check the available space. If the file system has insufficient space, you can remove old log or trace files to free up space.

**The Oracle Clusterware Is Not Running**

Oracle Clusterware enables servers to communicate with each other so that they can function as a collective unit. The cluster software program must be up and running on the DB system for patching operations to complete. Occasionally you might need to restart the Oracle Clusterware to resolve a patching failure.

To restart the Oracle Clusterware

1. From command prompt, check the status of Oracle Clusterware:

   ```
crsctl check crs
   ```

   Example output:

   ```
   [grid@<host> ~]$ crsctl check crs
   CRS-4638: Oracle High Availability Services is online
   CRS-4537: Cluster Ready Services is online
   CRS-4529: Cluster Synchronization Services is online
   CRS-4533: Event Manager is online
   ```

   For more detailed status information, you can run `crsctl stat res -t`.

2. If Oracle Clusterware is not online, try to restart the program:

   ```
crsctl start crs
   ```
3. Check the status of Oracle Clusterware to confirm that it is online:

```
crsctl check crs
```

**The Oracle Grid Infrastructure (GI) Is Not Updated**

This problem occurs when you try to patch a database before you patch the DB system of that database. The error description indicates that the Oracle Grid Infrastructure must be updated first. To resolve this issue, patch the DB system to latest available version. After you patch the DB system, you can retry the database patching operation.

To get the current and latest-available GI versions for the DB system, use the following command:

```
dbcli describe-component
```

**Database Issues**

An improper database state can lead to patching failures.

**Database Not Running During the Patching Operation**

The database must be active and running for all of the patching tasks to complete. Otherwise, you must run the datapatch task manually.

To check that the database is active and running

Use the following command to check the state of your database, and ensure that any problems that might have put the database in an improper state are resolved:

```
srvctl status database -d <db_unique_name> -verbose
```

The system returns a message including the database instance status. The instance status must be **Open** for the patching operation to succeed.

If the database is not running, use the following command to start it:

```
srvctl start database -d <db_unique_name> -o open
```

If the database is mounted but does not have the **Open** status, use the following commands to access the SQL*Plus command prompt and set the status to **Open**:

```
sqlplus / as sysdba
alter database open;
```

To run the datapatch task

Before you run the `datapatch` command, ensure that all pluggable databases (PDBs) are open. To open a PDB, you can use SQL*Plus to execute `ALTER PLUGGABLE DATABASE <pdb_name> OPEN READ WRITE;` against the PDB.

```
$ORACLE_HOME/OPatch/datapatch
```

The datapatch command should be run on each database home.

**Obtaining Further Assistance**

If you were unable to resolve the problem using the information in this topic, follow the procedures below to collect relevant database and diagnostic information. After you have collected this information, contact Oracle Support.

To collect diagnostic information regarding failed jobs
1. Log on to the host as the root user and navigate to the `/opt/oracle/dcs/bin/` directory.
2. Run the following two commands to generate information about the failed job:
   
   ```
   dbcli list-jobs
   dbcli describe-job -i <job_ID> -j
   ```

   The `<job_ID>` in the second command should be the ID of the latest failed job reported from the first command.

3. Run the diagnostics collector script to create a zip file with the diagnostic information for Oracle Support Services.
   
   ```
   diagcollector.py
   ```

   This command creates a file named `diagLogs-<timestamp>.zip` in the `/tmp` directory.

To collect DCS agent log files

To collect DCS agent log files, do the following:

1. Log in as opc user.
2. Run the following command:
   
   ```
   sudo /opt/oracle/dcs/bin/diagcollector.py
   ```

3. The system returns a message indicating that agent logs are available in a zip file at a specified directory. For example:
   
   ```
   [opc@prodpr ~]$ sudo /opt/oracle/dcs/bin/diagcollector.py
   Log files collected to :/tmp/dcsdiag/diagLogs-1234567890.zip
   Logs are being collected to:
   /tmp/dcsdiag/diagLogs-1234567890.zip
   ```

To collect Oracle Grid Infrastructure and Database log files

If an Oracle Grid Infrastructure or Oracle Database patch failed, you can find log files for these failures in the following locations:

**Oracle Grid Infrastructure**

$GI_HOME/cfgtoollogs/

**Oracle Database**

$ORACLE_HOME/cfgtoollogs/

**Shape Change Failures for Virtual Machine DB Systems**

If your virtual machine DB system shape change does not successfully complete, you can use the procedures in this topic to troubleshoot and fix the issue. For multi-node DB systems, shape change operations proceed in a rolling fashion. Depending on where in the shape change operation the failure occurs, you may be able to re-try the operation using the console.

**Using the Console to Troubleshoot**

If your shape change operation fails, a message banner appears on the DB System Details page to provide details about the failure. If the failure happens on the first node of a multi-node system, and the operation is rolled back successfully, the Change Shape button remains available and the system remains online, in the Available state.
Contact Oracle Support to get additional details about the failure. You can also follow the steps in Using dbcli to Troubleshoot on page 2429 to learn more about the failure and what issues need to be resolved. After determining that no issues remain, you can try the operation again.

If the failure leaves the system in a state where the operation cannot be rolled back, the system state is Needs Attention. In this case, contact Oracle Support as soon as you are aware of the issue so Oracle can help you resolve the issue and complete the shape change operation.

Using dbcli to Troubleshoot

**Determine What Stage of the Shape Change Operation Failed**

1. Login to the DB system as the root user.
2. Navigate to `/opt/oracle/dcs/bin`
   ```bash
cd /opt/oracle/dcs/bin
   ```
3. Update the CLI tool:
   ```bash
./cliadm update-dbcli
   ```
4. List the failed jobs:
   ```bash
dbcli list-jobs | grep -i failed
   ```
5. Note if the failed job (or jobs) occurred during the `pre_action`, `action`, or `post_action` stage. Also note the `job_id` value of the failed job, which you will need to resolve the issue.

**Troubleshooting Failures That Occur in the Pre_action Stage**

1. Use the `job_id` value to get more information about the failure:
   ```bash
dbcli describe-job -i <job_id>
   ```
2. Search for the error in the `dcs-agent.log` and `dcs-agent-debug.log` files (which are located in the `/opt/oracle/dcs/log/` directory):
   ```bash
cd /opt/oracle/dcs/log
grep -ir "DCS-10063:Failed to get node names from olsnodes." *
   ```
3. Using the information about the error recorded in the log file, correct the system configuration if possible.
4. Re-try the shape change operation. If the operation is still not successful, follow the instructions in Getting Additional Help on page 2429.

**Getting Additional Help**

If your failure occurs in the `post_action` stage, or if you are unable to resolve failures that occur in the `pre_action` stage, do the following:

1. Gather the information listed in the document Diagnostic Data Collection For Oracle Database Cloud Service Instance (OCI) (Doc ID 2397481.1)
2. Open a Support Request with My Oracle Support

**Exadata Systems**

This section covers troubleshooting common issues for Exadata systems:

- Backup Failures in Exadata Cloud Service on page 2430
- Troubleshooting Oracle Data Guard in Exadata Cloud Service Systems
**Backup Failures in Exadata Cloud Service**

If your Exadata managed backup does not successfully complete, you can use the procedures in this topic to troubleshoot and fix the issue. The most common causes of backup failure are the following:

- The host cannot access Object Storage
- The database configuration on the host is not correct

The information that follows is organized by the error condition. If you already know the cause, you can skip to the section with the suggested solution. Otherwise, use the procedure in Determining the Problem on page 2430 to get started.

**Determining the Problem**

In the Console, a failed database backup either displays a status of **Failed** or hangs in the **Backup in Progress** or **Creating** state. If the error message does not contain enough information to point you to a solution, you can gather more information by using the `dbascli` and by viewing the log files. Then, refer to the applicable section in this topic for a solution.

To identify the root cause of the backup failure:

Database backups can fail during the **RMAN** configuration stage or during a running **RMAN** backup job. **RMAN** configuration tasks include validating object store connectivity, backup module installation, and **RMAN** configuration changes. The log files you examine depend on which stage the failure occurs.

1. Log on to the host as the root user.
2. Check the applicable log file:
   - If the failure occurred during **RMAN** configuration, navigate to the `/var/opt/oracle/log/<database_name>/bkup/` directory and check the `bkup.log` file.
   - If the failure occurred during the backup job, navigate to the `/var/opt/oracle/log/<database_name>/obkup/` directory and check the `obkup.log` file.

**Note:**
- Each execution of `bkup` and `obkup` commands generates a separate log file but `bkup.log` and `obkup.log` are symbolic links that point to the most recently generated log file.
- Ensure that you check the log files on all of the Exadata DB system compute nodes because all nodes send backup pieces to Object Storage.

**Database Service Agent Issues**

Your Oracle Cloud Infrastructure Database makes use of an agent framework to allow you to manage your database through the cloud platform. Occasionally you might need to restart the `dcsagent` program if it has the status of **stop/waiting** to resolve a backup failure. View the `/opt/oracle/dcs/log/dcs-agent.log` file to identify issues with the agent.

To restart the database service agent:

1. From a command prompt, check the status of the agent:

   ```bash
   systemctl status dbcsagent.service
   ```

2. If the agent is in the **stop/waiting** state, try to restart the agent:

   ```bash
   systemctl start dbcsagent.service
   ```

3. Check the status of the agent again to confirm that it has the **start/running** status:

   ```bash
   systemctl status dbcsagent.service
   ```
Object Store Connectivity Issues

Backing up your database to Oracle Cloud Infrastructure Object Storage requires that the host can connect to the applicable Swift endpoint. Though Oracle controls the actual Swift user credentials for the storage bucket for managed backups, verifying general connectivity to Object Storage in your region is a good indicator that object store connectivity is not the issue. You can test this connectivity by using another Swift user.

To ensure your database host can connect to the object store

1. Create a Swift user in your tenancy. See Working with Auth Tokens.
2. With the user you created in the previous step, use the following command to verify the host can access the object store.

```
curl -v -X HEAD -u <user_ID>:<auth_token>' https://swiftobjectstorage.<region_name>.oraclecloud.com/v1/<object_storage_namespace>
```

See Object Storage FAQ for the correct region to use. See Understanding Object Storage Namespaces on page 4947 for information about your Object Storage namespace.

3. If you cannot connect to the object store, refer to the Prerequisites on page 2020 section of the Managing Exadata Database Backups on page 2019 topic for information on configuring object store connectivity.

Host Issues

One or more of the following conditions on the database host can cause backups to fail:

Interactive Commands in the Oracle Profile

If an interactive command such as `oraenv`, or any command that might return an error or warning message, was added to the `.bash_profile` file for the grid or oracle user, Database service operations like automatic backups can be interrupted and fail to complete. Check the `.bash_profile` file for these commands, and remove them.

The File System Is Full

Backup operations require space in the `/u01` directory on the host file system. Use the `df -h` command on the host to check the space available for backups. If the file system has insufficient space, you can remove old log or trace files to free up space.

Incorrect Version of the Oracle Database Cloud Backup Module

Your system might not have the required version of the backup module (opc_installer.jar). See Unable to use Managed Backups in your DB System for details about this known issue. To fix the problem, you can follow the procedure in that section or simply update your DB system and database with the latest bundle patch.

Changes to the Site Profile File (glogin.sql)

Customizing the site profile file (`$ORACLE_HOME/sqlplus/admin/glogin.sql`) can cause managed backups to fail in Oracle Cloud Infrastructure. In particular, interactive commands can lead to backup failures. Oracle recommends that you not modify this file for databases hosted in Oracle Cloud Infrastructure.

Database Issues

An improper database state or configuration can lead to failed backups.

Database Not Running During Backup

The database must be active and running (ideally on all nodes) while the backup is in progress.

To check that the database is active and running
Use the following command to check the state of your database, and ensure that any problems that might have put the database in an improper state are resolved:

```
srvctl status database -d <db_unique_name> -verbose
```

The system returns a message including the database's instance status. The instance status must be **Open** for the backup to succeed. If the database is not running, use the following command to start it:

```
srvctl start database -d <db_unique_name> -o open
```

If the database is mounted but does not have the **Open** status, use the following commands to access the SQL*Plus command prompt and set the status to **Open**:

```
sqlplus / as sysdba
alter database open;
```

**Archiving Mode Set to NOARCHIVELOG**

When you provision a new database, the archiving mode is set to **ARCHIVELOG** by default. This is the required archiving mode for backup operations. Check the archiving mode setting for the database and change it to **ARCHIVELOG**, if applicable.

To check and set the archiving mode

Open an SQL*Plus command prompt and enter the following command:

```
select log_mode from v$database;
```

If you need to set the archiving mode to **ARCHIVELOG**, start the database in **Mount** status (and not **Open** status), and use the following command at the SQL*Plus command prompt:

```
alter database archivelog;
```

Confirm that the **db_recovery_file_dest** parameter points to +RECO, and that the **log_archive_dest_1** parameter is set to **USE_DB_RECOVERY_FILE_DEST**.

For RAC databases, one instance must have the **Mount** status when enabling archivelog mode. To enable archivelog mode for a RAC database, perform the following steps:

1. Shut down all database instances:

   ```
srvctl stop database -d
```

2. Start one of the database instances in mount state:

   ```
srvctl start instance -d <db_unique_name> -i <instance_name> -o mount
```

3. Access the SQL*Plus command prompt:

   ```
sqlplus / as sysdba
```

4. Enable archive log mode:

   ```
alter database archivelog;
```

   ```
exit;
```
5. Stop the database:

```bash
srvctl stop instance -d <db_unique_name> -i <instance_name>
```

6. Restart all database instances:

```bash
srvctl start database -d <db_unique_name>
```

7. At the SQL*Plus command prompt, confirm the archiving mode is set to ARCHIVELOG:

```sql
select log_mode from v$database;
```

**Stuck Database Archiver Process and Backup Failures**

Backups can fail when the database instance has a stuck archiver process. For example, this can happen when the flash recovery area (FRA) is full. You can check for this condition using the `srvctl status database -db <db_unique_name> -v` command. If the command returns the following output, you must resolve the stuck archiver process issue before backups can succeed:

```
Instance <instance_identifier> is running on node *<node_identifier>.
Instance status: Stuck Archiver
```

Refer to ORA-00257:Archiver Error (Doc ID 2014425.1) for information on resolving a stuck archiver process.

After resolving the stuck process, the command should return the following output:

```
Instance <instance_identifier> is running on node *<node_identifier>.
Instance status: Open
```

If the instance status does not change after you resolve the underlying issue with the device or resource being full or unavailable, try restarting the database using the `srvctl` command to update the status of the database in the clusterware.

**RMAN Configuration and Backup Failures**

Editing certain RMAN configuration parameters can lead to backup failures in Oracle Cloud Infrastructure. To check your RMAN configuration, use the `show all` command at the RMAN command line prompt.

See the following list of parameters for details about RMAN the configuration settings that should not be altered for databases in Oracle Cloud Infrastructure.

RMAN configuration settings that should not be altered:

```sql
CONFIGURE RETENTION POLICY TO RECOVERY WINDOW OF 30 DAYS;
CONFIGURE CONTROLFILE AUTOBACKUP ON;
CONFIGURE DEVICE TYPE 'SBT_TAPE' PARALLELISM 5 BACKUP TYPE TO COMPRESSED BACKUPSET;
CONFIGURE CHANNEL DEVICE TYPE DISK MAXPIECESIZE 2 G;
CONFIGURE CHANNEL DEVICE TYPE 'SBT_TAPE' PARMS 'SBT_LIBRARY=/var/opt/oracle/dbaas_acfs/<db_name>/opc/libopc.so, ENV=(OPC_PFILE=/var/opt/oracle/dbaas_acfs/<db_name>/opc/opc<db_name>.ora)';
CONFIGURE ARCHIVELOG DELETION POLICY TO BACKED UP 1 TIMES TO 'SBT_TAPE';
CONFIGURE CHANNEL DEVICE TYPE DISK MAXPIECESIZE 2 G;
```
**Loss of Object Store Wallet File and Backup Failures**

RMAN backups fail when an object store wallet file is lost. The wallet file is necessary to enable connectivity to the object store.

To confirm that the object store wallet file exists and has the correct permissions

1. Get the name of the database with the backup failure:

   ```
   SQL> show parameter db_name
   ```

2. Determine the file path of the backup config parameter file that contains the RMAN wallet information:

   ```
   locate opc_<database_name>.ora
   ```

   The default location is `/var/opt/oracle/dbaas_acfs/<database_name>/opc/opc<database_name>.ora`.

   For example:

   ```
   [root@khdyygw-mpjxb1Example /]# find / -name "opctestdb30.ora" -print
   /var/opt/oracle/dbaas_acfs/testdb30/opc/opctestdb30.ora
   ```

3. Find the file path to the wallet file in the backup config parameter file by inspecting the value stored in the `OPC_WALLET` parameter. To do this, navigate to the directory containing the backup config parameter file and use the following `cat` command:

   ```
   cat opc<database_name>.ora
   ```

   For example:

   ```
   [root@khdyygw-mpjxb1Example ]# ls -ltr /var/opt/oracle/dbaas_acfs/testdb30/opc/    
   [root@khdyygw-mpjxb1Example ]# ls -ltr *.ora
   opcptestdb30.ora
   [root@khdyygw-mpjxb1Example ]# cat opptestdb30.ora
   OPC_HOST=https://swiftobjectstorage.us-phoenix-1.oraclecloud.com/v1/dbbackupphx
   OPC_WALLET='LOCATION=file:/var/opt/oracle/dbaas_acfs/testdb30/opc/opc_wallet
   OPC_CONTAINER=bUG3TFsSi8QzjWfuTxxqExample
   _OPC_DEFERRED_DELETE=false
   ```

4. Confirm that the `cwallet.sso` file exists in the directory specified in the `OPC_WALLET` parameter, and confirm that the file has the correct permissions. The file permissions should have the octal value of "600" (`-rw-------`). Use the following command:

   ```
   ls -ltr /var/opt/oracle/dbaas_acfs/<database_name>/opc/opc_wallet
   ```

   For example:

   ```
   [root@khdyygw-mpjxb1Example]# ls -ltr /var/opt/oracle/dbaas_acfs/    
   testdb30/opc/opc_wallet
   -rw------- 1 oracle oinstall 0 Oct 29 01:59 cwallet.sso.lck
   -rw------- 1 oracle oinstall 111231 Oct 29 01:59 cwallet.sso
   ```
TDE Wallet and Backup Failures

Incorrect TDE Wallet Location Specification

For backup operations to work, the $ORACLE_HOME/network/admin/sqlnet.ora file must contain the ENCRYPTION_WALLET_LOCATION parameter formatted exactly as follows:

```
ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)(METHOD_DATA=(DIRECTORY=/var/opt/oracle/dbaas_acfs/<database_name>/tde_wallet))
```

To check the TDE wallet location specification

Use the `cat` command to check the TDE wallet location specification. For example:

```
[oracle@orcl tde]$ cat $ORACLE_HOME/network/admin/sqlnet.ora
ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)(METHOD_DATA=(DIRECTORY=/var/opt/oracle/dbaas_acfs/<database_name>/tde_wallet))
```

Incorrect State of the TDE Wallet

Database backups fail if the TDE wallet is not in the proper state. The following scenarios can cause this problem:

The `ORACLE_UNQNAME` environment variable was not set when the database was started using SQL*Plus

If the database was started using SQL*Plus, and the `ORACLE_UNQNAME` environment variable was not set, the wallet is not opened correctly.

To fix the problem, start the database using the `srvctl` utility:

```
srvctl start database -d <db_unique_name>
```

A pluggable database was added with an incorrectly configured master encryption key

In a multitenant environment for Oracle Database versions that support PDB-level keystore, each PDB has its own master encryption key. For Oracle 18c databases, this encryption key is stored in a single keystore used by all containers. (Oracle Database 19c does not support a keystore at the PDB level.) After you create or plug in a new PDB, you must create and activate a master encryption key for it. If you do not do so, the `STATUS` column in the `v$encryption_wallet` view shows the value `OPEN_NO_MASTER_KEY`.

To check the master encryption key status and create a master key, do the following:

1. Review the the `STATUS` column in the `v$encryption_wallet` view, as shown in the following example:

```
SQL> alter session set container=pdb2;
Session altered.

SQL> select WRL_TYPE,WRL_PARAMETER,STATUS,WALLET_TYPE from v$encryption_wallet;
```

```
WRL_TYPE   WRL_PARAMETER                                   STATUS        WALLET_TYPE
---------- ----------------------------------------------- ----------- --------------------
FILE       /var/opt/oracle/dbaas_acfs/testdb30/tde_wallet/    OPEN_NO_MASTER_KEY AUTOLOGIN
```
2. Confirm that the PDB is in READ WRITE open mode and is not restricted, as shown in the following example:

```
SQL> show pdbs
+-----------------+------------------+----------------++--------------+
<table>
<thead>
<tr>
<th>CON_ID</th>
<th>CON_NAME</th>
<th>OPEN MODE</th>
<th>RESTRICTED</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>PDB$SEED</td>
<td>READ ONLY</td>
<td>NO</td>
</tr>
<tr>
<td>3</td>
<td>PDB1</td>
<td>READ WRITE</td>
<td>NO</td>
</tr>
<tr>
<td>4</td>
<td>PDB2</td>
<td>READ WRITE</td>
<td>NO</td>
</tr>
</tbody>
</table>
```

The PDB cannot be open in restricted mode (the `RESTRICTED` column must show `NO`). If the PDB is currently in restricted mode, review the information in the PDB_PLUG_IN_VIOLATIONS view and resolve the issue before continuing. For more information on the PDB_PLUG_IN_VIOLATIONS view and the restricted status, review the documentation on pluggable database for your Oracle database version.

3. Create and activate a master encryption key for the PDB:
   - Set the container to the PDB:
     ```
     SQL> ALTER SESSION SET CONTAINER = pdb;
     ```
   - Create and activate a master encryption key in the PDB by executing the following command:
     ```
     SQL> ADMINISTER KEY MANAGEMENT SET KEY USING TAG '<tag>' FORCE
          KEYSTORE IDENTIFIED BY <keystore-password> WITH BACKUP USING
          '<backup_identifier>';
     ```

Note the following:
   - The USING TAG clause is optional and can be used to associate a tag with the new master encryption key.
   - The WITH BACKUP clause is optional and can be used to create a backup of the keystore before the new master encryption key is created.

You can also use the dbaascli commands `dbaascli tde status` and `dbaascli tde rotate masterkey` to investigate and manage your keys.

4. Confirm that the status of the wallet has changed from OPEN_NO_MASTER_KEY to OPEN by querying the `v$encryption_wallet` view as shown in step 1.

Incorrect Configuration Related to the TDE Wallet

Configuration parameters related to the TDE wallet can cause backups to fail.

To check configuration related to the TDE wallet

Confirm that the wallet status is `open` and the wallet type is `auto login` by checking the `v$encryption_wallet` view. For example:

```
SQL> select status, wrl_parameter, wallet_type from v$encryption_wallet;
```

```
STATUS  WRL_PARAMETER WALTLET_TYPE
-------- ---------------------------------------------- --------------
OPEN    /var/opt/oracle/dbaas_acfs/testdb30/tde_wallet/ AUTOLOGIN
```
For pluggable databases (PDBs), ensure that you switch to the appropriate container before querying `v$encryption_wallet` view. For example:

```
[oracle@paulo ~]$ sqlplus / as sysdba
SQL> alter session set container=pdb1;
Session altered.
SQL> select WRL_TYPE,WRL_PARAMETER,STATUS,WALLET_TYPE from v$encryption_wallet;
```

<table>
<thead>
<tr>
<th>WRL_TYPE</th>
<th>WRL_PARAMETER</th>
<th>STATUS</th>
<th>WALLET_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE</td>
<td>/var/opt/oracle/dbaas_acfs/testdb30/tde_wallet/</td>
<td>OPEN</td>
<td>AUTOLOGIN</td>
</tr>
</tbody>
</table>

**Missing TDE Wallet File**

The TDE wallet file (`ewallet.p12`) can cause backups to fail if it is missing, or if it has incompatible file system permissions or ownership. Check the file as shown in the following example:

```
[root@khdyygw-mpjxb1example /]# ls -altr /var/opt/oracle/dbaas_acfs/<database_name>/tde_wallet/ewallet.p12
total 76
-rw------ 1 oracle oinstall 5467 Oct 1 20:17 ewallet.p12
```

The TDE wallet file should have file permissions with the octal value "600" ("-rw------"), and the owner of this file should be a part of the `oinstall` operating system group.

**Missing Auto Login Wallet File**

The auto login wallet file (`cwallet.sso`) can cause backups to fail if it is missing, or if it has incompatible file system permissions or ownership. Check the file as shown in the following example:

```
[root@khdyygw-mpjxb1example /]# ls -altr /var/opt/oracle/dbaas_acfs/<database_name>/tde_wallet/cwallet.sso
total 76
-rw------ 1 oracle oinstall 5512 Oct 1 20:18 cwallet.sso
```

The auto login wallet file should have file permissions with the octal value "600" ("-rw------"), and the owner of this file should be a part of the `oinstall` operating system group.

**Obtaining Further Assistance**

If you were unable to resolve the problem using the information in this topic, follow the instructions in [Diagnostic Data Collection For Oracle Database Cloud Service Instances (OCI-C)](https://docs.oracle.com/en/database/oracle-cloud-infrastructure/database-cloud-service/oci-c/2219712.1.html) to collect relevant database and diagnostic information. After you have collected this information, contact Oracle Support.

**DBAAS Tooling: Using dbaascli to Collect Cloud Tooling Logs and Perform a Cloud Tooling Health Check**

Using the `dbaascli diag` command allows you to collect domU dbaas tooling logs for Exadata Cloud Service and Exadata Cloud@Customer systems. You can use these logs to troubleshoot issues related to dbaas tooling.
Starting with DBaaS Tools Cloud Tooling RPM 21.2.1, you can use the `diag` command to collect dbaastools logs and perform a health check on all nodes in an Exadata cluster.

**Note:**
- dbaascli diag commands must be run as the root user
- Running the `dbaascli diag collect` command on a single node will collect log data for all nodes
- We recommend running the commands documented in this topic using the `nohup` option for long-running commands. Redirect the command output to a location you can monitor.

For information on updating Exadata Cloud Tooling, see [How to upgrade DBAAS Cloud Tooling using dbaascli](https://docs.oracle.com/en-us/dbaas/21.2.1/uc-2350471.1.html) (Doc ID 2350471.1).

### Syntax for Collecting Tooling Log Data

The `dbaascli diag collect` command uses the syntax shown below to collect tooling log data:

```
dbaascli diag collect [parameters]
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Default Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>--help</td>
<td>Access help for the command.</td>
<td>No</td>
<td><code>not applicable</code></td>
<td>none</td>
</tr>
<tr>
<td>--destLocation</td>
<td>The domU directory location to store collected logs.</td>
<td>No</td>
<td>A valid full path location present on all nodes in the cluster.</td>
<td>If parameter is not specified, system collects log files as follows: System collects logs at <code>/var/opt/oracle/dbaas_acfs</code>. If that location cannot be used, system collects logs at <code>/u02</code>. Command output displays which directory location is being used to collect logs.</td>
</tr>
<tr>
<td>--dbName</td>
<td>The dbName value of the database for which you want to collect logs.</td>
<td>No</td>
<td>A valid dbName value for the system.</td>
<td>none</td>
</tr>
</tbody>
</table>

Oracle Cloud Infrastructure User Guide 2438
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Default Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>--startTime</td>
<td>The start time for log collection. Requires the use of the --endTime parameter.</td>
<td>No</td>
<td>Format: YYYY-MM-DDTHH24:MM:SS. Must be used together with the --endTime parameter.</td>
<td>If parameter is not specified, system sets start time as 24 hours prior to the current system time.</td>
</tr>
<tr>
<td>--endTime</td>
<td>The start time for log collection. Requires the use of the --startTime parameter.</td>
<td>No</td>
<td>Format: YYYY-MM-DDTHH24:MM:SS. Must be used together with the --startTime parameter.</td>
<td>If parameter is not specified, system sets end time as current system time.</td>
</tr>
<tr>
<td>--nodes</td>
<td>A comma-separated list of nodes to collect logs.</td>
<td>No</td>
<td>Format: node1,node2</td>
<td>If parameter is not specified, system collects logs for all nodes in the cluster.</td>
</tr>
<tr>
<td>--components</td>
<td>A list of components for log collection.</td>
<td>No</td>
<td>One of: db</td>
<td>g</td>
</tr>
<tr>
<td>--objectStoreBucketUri</td>
<td>An Object Storage service pre-authenticated request (PAR) URL used to upload collected logs. Logs are collected from domU. See Using Pre-Authenticated Requests on page 5041 for more information.</td>
<td>No</td>
<td>URL that has been pre-authenticated.</td>
<td>none</td>
</tr>
</tbody>
</table>

**Example: Log collection for all databases**

```
[root@exampleOracleDB ~]# dbaascli diag collect
DBAAS CLI version MAIN
Executing command diag collect
dbaascli diag collect called without component
INFO: Starting diag collect
INFO: Collected diag logs at: /var/opt/oracle/dbaas_acfs/diag_cloudlogs_20210322-2130.tar.gz
```

**Example: Log collection for a specified database**

```
[root@exampleOracleDB ~]# dbaascli diag collect --dbNames myOracleDatabase19cName
DBAAS CLI version MAIN
Executing command diag collect --dbNames myOracleDatabase19cName
dbaascli diag collect called without component
INFO: Starting diag collect
```
INFO: Collected diag logs at: /var/opt/oracle/dbaas_acfs/diag_cloudlogs_20210322-2128.tar.gz

Example: Log collection to a specified domU directory

```
[root@exampleOracleDB ~]# dbaascli diag collect --destLocation /tmp/test/
DBAAS CLI version MAIN
Executing command diag collect --destLocation /tmp/test
dbaascli diag collect called without component
INFO: Starting diag collect
INFO: Collected diag logs at: /tmp/test/diag_cloudlogs_20210322-1731.tar.gz
```

Example: Log collection for a specified timeframe

```
[root@exampleOracleDB ~]# dbaascli diag collect --startTime 2021-03-19T10:00:00 --endTime 2021-03-20T10:00:00
DBAAS CLI version MAIN
Executing command diag collect --startTime 2021-03-19T10:00:00 --endTime 2021-03-20T10:00:00
dbaascli diag collect called without component
INFO: Starting diag collect
INFO: Collected diag logs at: /var/opt/oracle/dbaas_acfs/diag_cloudlogs_20210322-2245.tar.gz
```

Example: Log collection for specific nodes

```
[root@exampleOracleDB ~]# dbaascli diag collect --nodes rbcl1,rbcl2
DBAAS CLI version MAIN
Executing command diag collect --nodes rbcl1,rbcl2
dbaascli diag collect called without component
INFO: Starting diag collect
INFO: Collected diag logs at: /var/opt/oracle/dbaas_acfs/diag_cloudlogs_20210421-1848.tar.gz
```

Example: Log collection for specific components

```
[root@exampleOracleDB ~]# dbaascli diag collect --components dbaastools
DBAAS CLI version MAIN
Executing command diag collect --components dbaastools
dbaascli diag collect called with component dbaastools
INFO: Starting diag collect
INFO: Collected diag logs at: /var/opt/oracle/dbaas_acfs/diag_cloudlogs_20210421-1851.tar.gz
```

Example: Saving collected logs to Object Storage using a PAR URL

```
[root@exampleOracleDB ~]# dbaascli diag collect --objectStoreBucketUri https://objectstorage.us-phoenix-1.oraclecloud.com/p/t0Z-kRV5pSmFzqnf-y5XhaAbM4LS82epeBnulKnCr31IeHVjxI9t0kntLF2kq7fP/n/MyNamespace/b/MyParBucket/o/
DBAAS CLI version MAIN
Executing command diag collect --objectStoreBucketUri https://objectstorage.us-phoenix-1.oraclecloud.com/p/t0Z-kRV5pSmFzqnf-y5XhaAbM4LS82epeBnulKnCr31IeHVjxI9t0kntLF2kq7fP/n/MyNamespace/b/MyParBucket/o/
dbaascli diag collect called without component
INFO: Starting diag collect
```
INFO: Collected diag logs at: https://objectstorage.us-phoenix-1.oraclecloud.com/p/t0Z-kRV5pSmFzqnf-y5XhaAbM4LS82epeBnu1KnCr3IeHVjxI9t0kntLF2Q7fP/n/MyNamespace/b/MyNamespace/o/diag_cloudlogs_20210421-1839.tar.gz

Example: Log collection using nohup mode

[root@exampleOracleDB ~]# nohup dbaascli diag collect > /tmp/nohup.out 2>&1 &

After running the command, monitor /tmp/nohup.out for completion.

Example: Using --help to access inline documentation for the collection of tooling log data

[root@exampleOracleDB ~]# dbaascli diag collect --help
DBAAS CLI version MAIN
Executing command diag collect --help
    diag collect - collect.
        [--destLocation - Location on domU to collect logs. Default : /var/opt/oracle/dbaas_acfs ]
        [--dbName - dbName for which to collect logs. Only one dbName can be specified]
        [--endTime - endTime for log collection. Ex : YYYY-MM-DDTHH24:MM:SS]

Syntax for Performing a Health Check

The dbaascli dbaascli diag healthcheck command uses the syntax shown below to perform a health check on all system nodes:

dbaascli diag healthcheck [parameters]

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Required</th>
<th>Accepted Values</th>
<th>Default Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>--help</td>
<td>Access help for the command.</td>
<td>No</td>
<td>not applicable</td>
<td>none</td>
</tr>
<tr>
<td>--destLocation</td>
<td>The domU directory location to store collected log information.</td>
<td>No</td>
<td>A valid full path location present on all nodes in the cluster.</td>
<td>If parameter is not specified, system collects log files as follows: System collects logs at /var/opt/oracle/dbaas_acfs. If that location cannot be used, system collects logs at /u02. Command output displays which directory location is being used to collect logs.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Required</td>
<td>Accepted Values</td>
<td>Default Values</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------</td>
<td>--------------------------------------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>--nodes</code></td>
<td>A comma-separated list of nodes to collect logs.</td>
<td>No</td>
<td>Format: node1,node2</td>
<td>If parameter is not specified, system collects logs for all nodes in the cluster.</td>
</tr>
<tr>
<td><code>--objectStoreBucketUri</code></td>
<td>An Object Storage service pre-authenticated request (PAR) URL used to upload collected logs. Logs are collected from domU. See Using Pre-Authenticated Requests on page 5041 for more information.</td>
<td>No</td>
<td>URL must be pre-authenticated.</td>
<td><code>none</code></td>
</tr>
</tbody>
</table>

**Example: Health check information**

```
[root@exampleOracleDB ~]# dbaascli diag healthcheck
DBAAS CLI version MAIN
Executing command diag healthcheck
INFO: Starting diag healthcheck
INFO: Collected diag logs at: /var/opt/oracle/dbaas_acfs/diag_cloudlogs_20210322-2246.tar.gz
```

**Example: Saving health check information to a specified domU directory**

```
[root@exampleOracleDB ~]# dbaascli diag healthcheck --destLocation /tmp/test
DBAAS CLI version MAIN
Executing command diag healthcheck --destLocation /tmp/test
INFO: Starting diag healthcheck
INFO: Collected diag logs at: /tmp/test/diag_cloudlogs_20210322-2250.tar.gz
```

**Example: Health check information for specific nodes**

```
[root@exampleOracleDB ~]# dbaascli diag healthcheck --nodes rbcl1,rbcl2
DBAAS CLI version MAIN
Executing command diag healthcheck --nodes rbcl1,rbcl2
INFO: Starting diag healthcheck
INFO: Collected diag logs at: /var/opt/oracle/dbaas_acfs/diag_cloudlogs_20210421-1915.tar.gz
```

**Example: Saving health check information to Object Storage using a PAR URL**

```
[root@exampleOracleDB ~]# dbaascli diag healthcheck --objectStoreBucketUri https://objectstorage.us-phoenix-1.oraclecloud.com/p/t0Z-kRV5pSmFzqnf-y5XhaAbM4LS82epeBnu1KnCr31IeHVjxI9tOkntLF2kq7FP/n/MyNamespace/b/MyParBucket/o
DBAAS CLI version MAIN
Executing command diag healthcheck --objectStoreBucketUri https://objectstorage.us-phoenix-1.oraclecloud.com/p/t0Z-kRV5pSmFzqnf-
```
Example: Using --help to access inline documentation for the health check command

[root@exampleOracleDB ~]# dbaascli diag healthcheck --help
DBAAS CLI version MAIN
Executing command diag healthcheck --help
  diag healthcheck - healthcheck.
      [--destLocation - Location on domU to collect logs. Default : /var/opt/oracle/dbaas_acfs ]

External Database

This section covers troubleshooting common issues for the External Database service.

Registration Fails Due to MACS Agent Connectivity

If you experience a "Connection timed out to OCI agent" error when trying to register an external database, verify your agent installation. See the following topics for instructions and details:

- Verify the Management Agent Installation
- Troubleshoot Management Agent Installation Issues

Deprecated Database Service APIs

For details on deprecated Database service APIs, see Database in the Service Change Announcements documentation.
This chapter explains how to use DevOps.

DevOps is a continuous integration/continuous delivery (CI/CD) service that automates the delivery and deployment of software to Oracle Cloud Infrastructure (OCI) compute platforms.
DevOps Overview

The Oracle Cloud Infrastructure (OCI) DevOps service is an end-to-end, continuous integration and continuous delivery (CI/CD) platform for developers.

Use this service to easily build, test, and deploy software and applications on Oracle Cloud. The DevOps build and deployment pipelines reduce change-driven errors and decreases the time customers spend on building and deploying releases. The service also provides private Git repositories to store your code and supports connections to external code repositories.

With the DevOps service you can do the following:

- Create private code repositories to store and manage source code.
- Mirror external Git repositories from GitHub and GitLab to OCI code repositories.
- Build and test your latest changes in a build pipeline with a service-managed build runner.
- Set up a trigger to automatically run your build pipeline from a source code commit or pull request. Optionally run a deployment pipeline on the successful build run for a complete CI/CD automation.
- Orchestrate your software deployment across regions to OCI platforms such as Container Engine for Kubernetes (OKE), Compute instances, and Functions.
- Avoid downtime during deployments and automate the complexity of updating applications.
- Enhance security and reduce risk in delivery. Automation reduces the chance of human error that might introduce a security vulnerability. As DevOps enables faster software delivery, security bugs can be resolved quickly by rolling out a fix.

Whether you’re migrating workloads to OCI (from on-premises or other clouds) or developing new applications on OCI, you can use the DevOps service to simplify your software delivery lifecycle.

You can build, test, deliver and deploy with DevOps by using the Oracle Cloud Console, REST API, and CLI. See Accessing DevOps.

To get started with the DevOps service, see Getting Started with DevOps.

DevOps Concepts

Review key terms to understand the DevOps service.

DevOps project

A logical grouping of DevOps resources needed to implement a CI/CD workflow. DevOps resources can be artifacts, build pipelines, deployment pipelines, external connections, triggers, and environments.

environment

A reference to the compute resources to which artifacts are deployed. An environment can be a reference to a Function application, a group of Compute instances, or a Container Engine for Kubernetes (OKE) cluster.

instance group

A group of compute hosts. Each instance group can have compute hosts only from one region at a time.

artifact

A collection of binaries and deployment manifests that are delivered to the target deployment environment. DevOps artifacts can be a container image, an instance group deployment configuration, a Kubernetes manifest, or a generic artifact. Artifacts can be hosted on OCI repositories: Container Registry and Artifact Registry.

deployment configuration artifact

Defines the artifacts to be downloaded to the instance and the location where the artifacts have to be copied. The configuration file also specifies the sequence of commands for deployment.
code repository

Private Git repositories hosted by the DevOps service. You can store, manage, and develop source code with the DevOps code repositories.

external connection

Defines the authorization needed to connect to external repositories. DevOps supports connections to GitHub and GitLab external repositories.

stage

A single step in the pipeline. The DevOps service includes predefined stages, which are used in a build or deployment pipeline.

build pipeline

Defines a set of stages for the build process: building, testing and compiling software artifacts, delivering artifacts to OCI repositories, and optionally triggering a deployment.

build specification

Contains build steps and instructions that are run by the service managed build runner.

deployment pipeline

A sequence of steps for deploying a set of artifacts to a target environment. A deployment pipeline contains stages that run sequentially or in parallel.

rollback

A way to manage issues identified with the deployment, including releasing a previous successfully deployed version of the software.

trigger

A DevOps resource to filter incoming events from a source code repository and trigger an action to start a build run on a matching incoming commit.

Trigger also refers to the deployment pipeline stage to trigger the start of a deployment.

deployment

A single run of a deployment pipeline. A deployment contains the state of all the stages running in a deployment pipeline.

work request

A way to track an asynchronous running task for a DevOps project.

Accessing DevOps

You can access DevOps by using the Console (a browser-based interface), Oracle Cloud Infrastructure CLI, or REST APIs.

Instructions for all three access methods are provided throughout this documentation.

- To use the Oracle Cloud Console, you must have an Oracle Cloud Infrastructure (OCI) account (user, password, and tenancy). You must also use a supported browser. For information, see Security Credentials.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Console, API, or CLI. This applies when creating or editing project resources such as environments and pipelines.</td>
</tr>
</tbody>
</table>
• To use the OCI CLI or REST APIs, you can set up your environment, or use Oracle Cloud Infrastructure Cloud Shell.
  • To use the CLI or REST APIs in Cloud Shell, sign in to the Console. See Using Cloud Shell and the OCI CLI Reference.
  • To install the OCI CLI in your environment, follow the steps in the Install CLI quickstart. See also an overview of the CLI.
  • When using REST APIs, refer to REST API documentation and API Reference and Endpoints.

If you perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access that you were granted.

To get started with the DevOps service, see Getting Started with DevOps.

Authentication and Authorization
Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, and which resources, and the type of access they have. For example, policies control who can create users, groups, and compartments, or who can create and manage repositories and artifacts.

• If you're a new administrator, see Getting Started with Policies.
• For details about writing policies for DevOps, see DevOps IAM Policies.
• For details about writing policies for other services, see Policy Reference.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you must be using.

Regions and Availability Domains
DevOps is available in all Oracle Cloud Infrastructure commercial regions. See About Regions and Availability Domains for the list of available regions for Oracle Cloud Infrastructure, along with associated locations, region identifiers, region keys, and availability domains.

Resource Identifiers
DevOps resources, like most types of resources in Oracle Cloud Infrastructure, have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID).

For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Limits
Know the DevOps service limits for your region.

A service limit is the quota or allowance set on a resource.

</tbody>
</table>

To check your limits for **DevOps**:

1. In the Console, open the navigation menu, and click **Governance & Administration**. Under **Governance**, click **Limits, Quotas, and Usage**.
2. Filter on the following values:
   - **Service:** DevOps
   - **Scope:** <your-region>
   - **Resource:**
     - Maximum Number of Concurrent Deployments
     - Maximum Number of Deployment Pipelines
     - Maximum Number of Stages Per Deployment Pipeline
     - Maximum Number of Deployment Artifacts
     - Maximum Number of Environments
     - Maximum Number of DevOps Projects
     - Maximum Number of Build Pipelines
     - Maximum Number of Stages per Build Pipeline
     - Maximum Number of Concurrent Build Runs
     - Maximum Number of Concurrent Service Provided Build Runners
     - Maximum Number of Triggers
     - Maximum Number of External Connections
     - Total Number of Repositories Allowed Per Region Per Tenancy
     - Total Size of a Repository in MB
     - Total Size of a Pack File in MB
   - **Compartment:** <your-tenancy-namespace > (root)

To increase your service limits:

1. In the Console, open the navigation menu, and click Governance & Administration. Under Governance, click Limits, Quotas, and Usage.
2. Click the request a service limit increase link. Only administrators can make the request.

For more information, see Service Limits.

**Getting Started with DevOps**

Learn how to get started with the DevOps service, and the prerequisites for using it.

**Prerequisites**

Before you begin using the DevOps service, you must meet the following prerequisites:

- You must have access to an Oracle Cloud Infrastructure tenancy.
- Each service in Oracle Cloud Infrastructure (OCI) integrates with Identity and Access Management (IAM) for authentication and authorization, for all interfaces (the Console, SDK and CLI, and REST API). Access permissions are provided to users within a particular compartment. You can create a compartment or reuse an existing one. See Managing Compartments.
- An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, and which resources, and the type of access they have. See Authentication and Authorization.

**Setting up Groups and Users**

1. Create a group or use an existing group in your tenancy.
   
   Users of this group are allowed to manage the DevOps service.
2. Create users and add them to the group, or add existing users to the group.
3. **Generate an auth token** for each user using Git to interact with your code repositories. You can also use API signing keys.

Auth tokens are a form of user credentials. They are Oracle-generated token strings, which you can use to authenticate with third-party APIs that do not support OCI's signature-based authentication. The auth token is used for authenticating to OCI on the command line when performing Git operations. Administrators can create and distribute auth tokens to other users. Auth tokens do not expire. Each user can have up to two auth tokens at a time. For more information, see Managing User Credentials.

**Setting up Access for DevOps Resources**

To grant users permission to access the various DevOps resources such as build pipelines, deployment pipelines, artifacts, and code repositories you have to create dynamic groups and IAM policies. See Managing Dynamic Groups and Getting Started with Policies.

For creating dynamic groups and policies, refer the following examples:

- For build pipelines, see Build Pipeline Policies.
- For code repositories, see Code Repository Policies.
- For deployment pipelines, see Deployment Pipeline Policies.

For more details, see DevOps IAM Policies.

**Integrating OCI Code Repository with GitHub or GitLab**

To integrate with third-party code repositories like GitHub and GitLab, you have to retrieve a personal access token (PAT) from those providers and store your PAT securely in an OCI vault. For instructions, see Build Source Integration.

**Note:**

This process is required only for integrating with third-party code repositories and not with the OCI DevOps code repository.

**Setting up Notifications and Topics**

Project notifications keep you apprised of important events and the latest DevOps project status. They also alert you if you need to take any necessary action such as approving a workflow. You must create a topic and add a subscription to the topic. For creating a topic, see Managing Topics and Subscriptions. The topic is required when creating your DevOps project.

**Setting up Repository**

The DevOps service uses an OCI Container Registry repository or an Artifact Registry repository for containing the completed build artifacts. You can create either of these repositories.

**Creating an Auth Token**

Auth tokens are a form of user credentials. They are Oracle-generated token strings, which you can use to authenticate with third-party APIs that do not support Oracle Cloud Infrastructure's signature-based authentication. Auth token is required for using Git to interact with your code repositories.

Learn how to create an auth token by using the Oracle Cloud Console.

1. If you’re creating an auth token for yourself:
   - Sign in to the Console.
   - In the top-right corner of the Console, open the Profile menu and click User Settings.
2. If you're an administrator creating an auth token for another user:
   - Open the navigation menu and click **Identity & Security**.
   - Under **Identity**, click **Users**.
   - Locate the user in the list, and then click the user's name to view their details.
3. Under **Resources**, click **Auth Tokens**.
4. Click **Generate Token**.
5. Enter a description that indicates what this token is for, for example, *Anne's auth token for use with DevOps code repository*. Avoid entering confidential information.
6. Click **Generate Token**.
   - The new token string is displayed. For example, `Dm_____________6MqX`.
7. Copy the auth token immediately to a secure location from which you can retrieve it later, because you won't see the auth token again in the Console.
8. Close the Generate Token dialog box.

For more information, see **Working with Auth Tokens**.

**Build Source Integration**

Learn how to integrate your OCI code repositories with third-party code repositories like GitHub and GitLab.

1. Retrieve a personal access token (PAT) from the hosting service of the third-party code repository.
   - To generate a PAT from GitHub, see **Generating a GitHub PAT**. For GitLab, see **Generating a GitLab PAT**.
2. Store the retrieved PAT securely in an OCI vault.
   - You can reuse existing vaults in your tenancy, or create a vault, master encryption key, and secret.

   **Note:**
   
   Each tenancy has a limit of 10 vaults and each vault can store multiple secrets.

   Vault variables cannot be dynamically replaced. Only Oracle Cloud IDs (OCIDs) of the vault secret is supported.
3. Create a vault secret policy in the root compartment to allow the dynamic group to manage secrets. See **Overview of Vault** and **Managing Secrets**. For example:

   ```
   Allow dynamic-group <dynamic_group_name> to manage secret-family in tenancy
   ```

   **Note:**
   
   This process is required only for integrating with third-party code repositories and not with the OCI DevOps code repository.

**Generating a GitHub PAT**

1. In your GitHub home page, click your profile picture in the top-right corner and then click **Settings**.
2. In the left-side menu, click **Developer settings**.
3. In the left-side menu, click **Personal access tokens** and then click **Generate new token**.
4. Note the reason for generating the token.
5. Select expiration period for the token from the given options.
6. For scopes, to enable the DevOps service to read code from your private repositories, select **Full control of private repositories**.
   - If you want to allow access to code from only public repositories, then you can select **public_repo** scope.
7. Click **Generate token**.

Copy the token immediately to a secure location, because you cannot retrieve the token again after you navigate away from the page.

**Generating a GitLab PAT**

1. In your GitLab home page, click your profile picture in the top-right corner and then click **Edit profile**.
2. In the left-side menu, click **Access Tokens**.
3. Enter a name and optional expiry date for the token.
4. For scopes, select **read_api**.
5. Click **Create personal access token**.

Copy the token immediately to a secure location, because you cannot retrieve the token again after you navigate away from the page.

**Using the DevOps Service**

After you complete the prerequisites, perform the following steps to use the DevOps service for continuous integration, delivery, and deployment of your software to OCI compute platforms:

1. Create a **DevOps project** for grouping the resources needed to implement your continuous integration and deployment (CI/CD) application.
2. Create an OCI **code repository** or integrate with external code repositories such as GitHub and GitLab. See **Mirroring a Repository**.
3. Create a **build pipeline** that contains the stages that define the build process for successfully compiling, testing, and running software applications before deployment.
4. Add a **Managed Build stage** to your build pipeline to test your software application.
   
   Select either OCI code repository or an external code repository (GitHub or GitLab) as the primary code repository for the build.
5. To store the Managed Build stage output, you need an OCI **Container Registry repository** or an **Artifact Registry repository**.
   
   DevOps supports applications stored in OCI Container Registry and Artifact Registry repositories. In **Container Registry** repository Docker images are stored and in **Artifact Registry** repository you can store generic software packages.
6. Create a **DevOps artifact** to point to the repository location containing the build output.
   
   A **parameter** in the artifact URI defines the software application version that is delivered to the OCI code repository.
7. Add a **Deliver Artifacts stage** to your build pipeline after adding the Managed Build stage.
   
   The Deliver Artifacts stage maps the build outputs from the Managed Build stage with the version to deliver to a DevOps artifact resource, and then to the OCI code repository.
8. Start the build process by manually **running a DevOps build pipeline**.
   
   Manual run uses the latest commit to the code repository that was added to the build. You can run the build based on specific commit by noting the commit details.
   
   You can also automatically **trigger a build run** when you commit your changes to the code repository.
9. Create a target environment supported by DevOps, if it doesn’t exist in the **Oracle Cloud Console**. Supported environments are **Container Engine for Kubernetes clusters**, **compute instances** (Oracle Linux and CentOS only), and **Function applications**.
10. Create reference to the **target environment** for deployment.

11. Create a **deployment pipeline** to deliver the build output to the target environment.
   
   DevOps supports deployment to **Kubernetes clusters**, **instance groups**, and **Functions**.
12. Add a **Trigger Deployment stage** to automatically trigger a deployment from the build pipeline or **run the deployment pipeline**.
Managing DevOps Projects

To successfully build and deploy applications by using the DevOps service, first create a DevOps project. A project logically groups the DevOps resources needed to implement a CI/CD workflow. DevOps resources are:

- **Code repositories**: In the DevOps service, you can create your own private code repositories.
- **External connections**: You can create a connection to external repositories such as GitHub and GitLab.
- **Build pipelines**: A build pipeline contains the stages that define the build process for successfully compiling, testing, and running software applications before deployment.
- **Artifacts**: Artifacts are referenced in a pipeline stage for automated deployment to the target environment. They are used to specify software package versions for deployment.
- **Triggers**: A build run can be automatically triggered when you commit your changes to a code repository.
- **Environments**: An environment is the target platform for your software.
- **Deployment pipelines**: A deployment pipeline holds the requirements that must be satisfied to deliver a set of artifacts to the target environment.

To create a DevOps project, see Creating a Project.

Creating a Project

Learn how to create a DevOps project.

Required IAM Policy

Each service in Oracle Cloud Infrastructure (OCI) integrates with Identity and Access Management (IAM) for authentication and authorization, for all interfaces (the Console, SDK and CLI, and REST API). Before you begin using the DevOps service, you must create policies to control who has access to DevOps, and the type of access for each group of users.

For details about writing policies for the DevOps service and policy examples, see DevOps IAM Policies.

You must create a *topic* for project notification. See Managing Topics and Subscriptions.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

Using the Console

1. In the Console, open the navigation menu, and then under Developer Services, click DevOps.
2. In the left-side menu, choose a compartment that you have permission to work in.
   - For more information, see Authentication and Authorization.
3. On the DevOps Projects - Overview page, click Create DevOps project.
4. Enter a name for the project.
5. (Optional) Enter a description.
6. To set up project notifications, click Select Topic.

   **Note:**

   Project notifications keep you apprised of important events and the latest project status. They also alert you if you need to take any necessary action such as approving a workflow. You must create a topic and add subscription to the topic. See Managing Topics and Subscriptions.

   - For selecting topic using topic name, select a Compartment and an associated Topic.
   - For selecting topic using OCID, enter OCID of the topic.
7. (Optional) To add tags to the project, click **Show tagging options**. Tagging is a metadata system that lets you organize and track the resources in your tenancy.

   If you have permissions to create a resource, you also have permissions to add free-form tags to it.

   To add a defined tag, you must have permissions to use the tag namespace.

   For more information, see Resource Tags.

8. Click **Create DevOps project**.

   The DevOps project is created successfully. You can configure required resources such as code repositories, build pipelines, artifact references, target environments, and deployment pipelines.

**Using the API**

To create a DevOps project, use the `CreateProject` operation.

**Using the CLI**

To create a DevOps project, run the `create` command:

```
oci devops project create
```

Required parameters for the `create` command:

- `--compartment-id`
- `--name`
- `--notification-config`

To get all the commands for `project`:

```
oci devops project -h
```

To get help for the `create` command:

```
oci devops project create -h
```

**Editing a Project**

Learn how to edit a DevOps project.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click **Developer Services**. Under **DevOps**, click **Projects**.
2. Click the Actions menu for the project you want to edit, and select **Edit**.
3. Make necessary updates to the project information, and save the changes.

**Using the API**

To edit a DevOps project, use the `UpdateProject` operation.

**Using the CLI**

To edit a DevOps project, run the `update` command:

```
oci devops project update --project-id
```

To get all the commands for `project`:

```
oci devops project -h
```
To get help for the `update` command:

```
oci devops project update -h
```

**Moving a Project**

Learn how to move projects from one compartment to another.

You can move a project and its associated resources, such as environments and artifacts from the existing compartment to a new compartment in the same region.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click Move.
3. Select the new compartment to move the project to.
4. Click Move.

The project and its associated resources are moved to the new compartment.

**Using the API**

To move a DevOps project to another compartment, use the `ChangeProjectCompartment` operation.

**Using the CLI**

To move a DevOps project to another compartment, run the `change-compartment` command:

```
oci devops project change-compartment
```

Required parameters for the `change-compartment` command:

- `--compartment-id | -c`
- `--project-id`

To get all the commands for `project`:

```
oci devops project -h
```

To get help for the `change-compartment` command:

```
oci devops project change-compartment -h
```

**Deleting a Project**

Learn how to delete a DevOps project. The project that you want to delete must not have any resources, such as environments, artifacts, and deployment pipelines.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select the project that you want to delete, and then click Delete.
3. Confirm that you want to delete the project. If the project has no associated resources, the project is permanently deleted.

**Using the API**

To delete a DevOps project, use the `DeleteProject` operation.
Using the CLI

To delete a DevOps project, run the `delete` command:

```
oci devops project delete --project-id
```

To get all the commands for project:

```
oci devops project -h
```

To get help for the `delete` command:

```
oci devops project delete -h
```

Managing Environments

An environment is the target platform for your software. You create references to different destination environments for DevOps deployment.

Before you create references to a target environment, you must perform the following tasks:

- Create a target environment supported by DevOps, if it doesn’t exist in the Oracle Cloud Console. Supported environments are Container Engine for Kubernetes clusters, compute instances (Oracle Linux and CentOS only), and Function applications.
- Create a DevOps project.

The DevOps service creates references based on the selected target environment. For instructions, see the following topics:

- Creating a Kubernetes Cluster Environment
- Creating a Compute Instance Group Environment
- Creating a Functions Environment

Required IAM Policy

Each service in Oracle Cloud Infrastructure (OCI) integrates with Identity and Access Management (IAM) for authentication and authorization, for all interfaces (the Console, SDK and CLI, and REST API). Before you begin using the DevOps service, you must create policies to control who has access to DevOps, and the type of access for each group of users.

For details about writing policies for the DevOps service and policy examples, see DevOps IAM Policies.

Creating a Kubernetes Cluster Environment

Learn how to create a reference to Container Engine for Kubernetes cluster target environment.

Before you begin, you must create a Container Engine for Kubernetes cluster.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

Using the Console

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select an existing project, or create a DevOps project.
3. Click Create environment.
4. For Environment type, select Oracle Kubernetes Engine.

Note:

DevOps currently supports deployments to only public Kubernetes API endpoint and not private. The worker nodes can be on either private or public subnets.
5. Enter a name and optional description for the environment.
6. (Optional) To add tags to the environment, click **Show tagging options**. Tagging is a metadata system that lets you organize and track the resources in your tenancy.

   If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.

   To add a defined tag, you must have permissions to use the tag namespace.

   For more information, see [Resource Tags](#).

7. Click **Next**.
8. Select the region where the cluster is located.
9. Select the compartment in which the cluster is located.
10. Select the cluster and click **Create environment**.

The reference to the Kubernetes cluster environment is created. You can create a deployment pipeline to deploy artifacts to a Container Engine for Kubernetes (OKE) cluster.

**Using the API**

To create a reference to a Kubernetes cluster environment, use the **CreateDeployEnvironment** operation. For the `deployEnvironmentType` attribute, specify the `OKE_CLUSTER` value.

**Using the CLI**

To create a reference to a Kubernetes cluster environment, run the `create-oke-cluster-environment` command:

```
oci devops deploy-environment create-oke-cluster-environment
```

Required parameters for the `create-oke-cluster-environment` command:

- `--cluster-id`
- `--project-id`

To get all the commands for `deploy-environment`:

```
oci devops deploy-environment -h
```

To get help for the `create-oke-cluster-environment` command:

```
oci devops deploy-environment create-oke-cluster-environment -h
```

**Creating a Compute Instance Group Environment**

Learn how to create a reference to an instance group environment.

**Prerequisites**

Before you begin, you need these things:

- Create a compute instance.

If you are creating an instance through a private network, then Network Address Translation (NAT) gateway must be set up. For more information, see [NAT Gateway](#).

**Note:**

DevOps only supports instance group deployments to Oracle Linux and CentOS.
• If any of your commands in the instance group deployment configuration artifact require sudo privileges, then you
have to grant ocarun user with sudo privileges. Follow these steps:
  1. Follow the steps for creating an instance.
  2. To configure advanced settings, click **Show Advanced Options**.
  3. For **Initialization Script**, enter the following cloud-init script to grant the sudo privilege:

```
#cloud-config
users:
- default
- name: ocarun
  sudo: ALL=(ALL) NOPASSWD:ALL
```

  4. When you finish configuring the instance, click **Create**.

For more information, see **Running Commands on an Instance**.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click **Developer Services**. Under **DevOps**, click **Projects**.
2. Select an existing project, or create a **DevOps project**.
3. Click **Create environment**.
4. For **Environment type**, select **Instance Group**.
5. Enter a name and optional description for the environment.
6. (Optional) To add tags to the environment, click **Show tagging options**. Tagging is a metadata system that lets
you organize and track the resources in your tenancy.
   - If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.
   - To add a defined tag, you must have permissions to use the tag namespace.
   - For more information, see **Resource Tags**.
7. Click **Next**.
8. To select the compute hosts to include in the instance group, click **Add instances**.
9. Use the **Region** and **Compartment** fields to select compute hosts from a specific region and compartment.

```
<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Each instance group can have compute hosts only from one region at a time.</td>
</tr>
</tbody>
</table>
```

10. Use the **Filter by state**, **Filter by shape**, and **Filter by text** fields to further narrow down the search for compute
hosts.
11. Select instances from the displayed list to create an instance group, and click **Add instance**.
12. Select the instance group to reference, and then click **Create environment**.

A reference to the selected instance group environment is created. You can create a deployment pipeline to deploy
artifacts to instance groups.

**Using the API**

To create a reference to an instance group environment, use the **CreateDeployEnvironment** operation. For the
deployEnvironmentType attribute, specify the **COMPUTE_INSTANCE_GROUP** value.

**Using the CLI**

To create a reference to an instance group environment, run the **create-compute-instance-environment**
command:

```
oci devops deploy-environment create-compute-instance-environment
```
Required parameters for the `create-compute-instance-environment` command:

- `--compute-instance-group-selectors`
- `--project-id`

To get all the commands for `deploy-environment`:

```
oci devops deploy-environment -h
```

To get help for the `create-compute-instance-environment` command:

```
oci devops deploy-environment create-compute-instance-environment -h
```

**Creating a Functions Environment**

Learn how to create a reference to a Functions environment.

Before you begin, you must create a Function.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click **Developer Services**. Under DevOps, click **Projects**.
2. Select an existing project, or create a DevOps project.
3. Click **Create environment**.
4. For **Environment type**, select **Functions**.
5. Enter a name and optional description for the environment.
6. (Optional) To add tags to the environment, click **Show tagging options**. Tagging is a metadata system that lets you organize and track the resources in your tenancy.
   - If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.
   - To add a defined tag, you must have permissions to use the tag namespace.
   - For more information, see Resource Tags.
7. Click **Next**.
8. Select the region where the Functions resource is located.
9. Select the compartment in which the Functions application is located.
10. Select the application and function to be referenced for deployment.
11. Click **Create environment**.

A reference to the Functions environment is created. You can create a deployment pipeline to deploy artifacts to Oracle Functions.

**Using the API**

To create a reference to Functions environment, use the `CreateDeployEnvironment` operation. For the `deployEnvironmentType` attribute, specify the FUNCTION value.

**Using the CLI**

To create a reference to Functions environment, run the `create-function-environment` command:

```
oci devops deploy-environment create-function-environment
```

Required parameters for the `create-function-environment` command:

- `--function-id`
- `--project-id`
To get all the commands for `deploy-environment`:
```
oci devops deploy-environment -h
```

To get help for the `create-function-environment` command:
```
oci devops deploy-environment create-function-environment -h
```

**Editing an Environment**
Learn how to update environment details. You can only change the environment name and description.

For accessing DevOps using the [Oracle Cloud Console](https://console.oracle.com), REST API, and CLI, see [Accessing DevOps](https://console.oracle.com).

**Using the Console**
1. Open the navigation menu and click **Developer Services**. Under **DevOps**, click **Projects**.
2. Select a project and an environment associated with that project.
3. Click **Edit**.
4. Update the environment name, description, or both, and save the changes.

**Using the API**
To update a deployment environment, use the `UpdateDeployEnvironment` operation.

**Using the CLI**
To update a deployment environment, run the `update` command:
```
oci devops deploy-environment update --environment-id
```

To update a Kubernetes cluster deployment environment, run the `update-oke-cluster-environment` command:
```
oci devops deploy-environment update-oke-cluster-environment --environment-id
```

To update an instance group deployment environment, run the `update-compute-instance-environment` command:
```
oci devops deploy-environment update-compute-instance-environment --environment-id
```

To update a Functions deployment environment, run the `update-function-environment` command:
```
oci devops deploy-environment update-function-environment --environment-id
```

To get all the commands for `deploy-environment`:
```
oci devops deploy-environment -h
```

To get help for the `update` command:
```
oci devops deploy-environment update -h
```

**Deleting an Environment**
Learn how to delete an environment.

For accessing DevOps using the [Oracle Cloud Console](https://console.oracle.com), REST API, and CLI, see [Accessing DevOps](https://console.oracle.com).
Using the Console
1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and an environment associated with that project.
3. Click Delete.
4. Confirm that you want to permanently delete the environment reference.

Using the API
To delete a deployment environment, use the DeleteDeployEnvironment operation.

Using the CLI
To delete a deployment environment, run the delete command:

```
oci devops deploy-environment delete --environment-id
```

To get all the commands for deploy-environment:

```
oci devops deploy-environment -h
```

To get help for the delete command:

```
oci devops deploy-environment delete -h
```

Managing Artifacts
Artifacts are referenced in a pipeline stage for automated deployment to the target environment. They are used to specify software package versions for deployment.

DevOps artifacts can be a container image, a generic artifact, or they can be defined inline. The artifact source varies depending on the type of artifact. In DevOps, you can create references to the following types of artifacts.

- **Container image repository**: Refers to the Oracle Cloud Infrastructure Container Registry repository in which Docker images are stored. See Adding a Container Image Repository Artifact.
- **Instance group deployment configuration**: Refers to the YAML formatted file that is used to manage instance group deployment. See Adding an Artifact in Artifact Registry and Adding an Inline Artifact.
- **Kubernetes manifest**: Refers to the Artifact Registry path, or is defined inline. See Adding an Artifact in Artifact Registry and Adding an Inline Artifact.
- **General artifact**: Refers to any generic software packages to be deployed. See Adding an Artifact in Artifact Registry and Adding an Inline Artifact.

Required IAM Policy
Each service in Oracle Cloud Infrastructure (OCI) integrates with Identity and Access Management (IAM) for authentication and authorization, for all interfaces (the Console, SDK and CLI, and REST API). Before you begin using the DevOps service, you must create policies to control who has access to DevOps, and the type of access for each group of users.

For details about writing policies for the DevOps service and policy examples, see DevOps IAM Policies and Accessing Artifact Registry.

Adding a Container Image Repository Artifact
Learn how to create a reference to a container image repository type of artifact.

In the build pipeline, to store the Managed Build stage output, you need an OCI Container Registry repository or an Artifact Registry repository.

You must create an artifact reference to point to the repository location containing the build output. Before you create an artifact reference, you must have a DevOps project.
For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select an existing project, or create a DevOps project.
3. Click Add artifact.
4. Enter a name for the artifact.
5. For Type, select Container image repository.
6. Enter the path of the Container Registry repository. For example, `<region-key>.ocir.io/<tenancy-namespace>/<repo-name>` is the fully qualified path to a repository in Oracle Cloud Infrastructure Container Registry.
7. Select Yes, substitute placeholders if you want to replace the placeholders in the artifact content by argument values provided during the deployment. Otherwise, select No. See Configuring Parameters.
8. (Optional) To add tags to the artifact, click Show tagging options. Tagging is a metadata system that lets you organize and track the resources in your tenancy.
   - If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.
   - To add a defined tag, you must have permissions to use the tag namespace.
   - For more information, see Resource Tags.
9. Click Add.

A reference to the container image repository is created.

In the build pipeline, the Deliver Artifacts stage maps the build outputs from the Managed Build stage with the version to deliver to the DevOps artifact resource, and then to the OCI code repository.

**Using the API**

To create a container image repository artifact, use the CreateDeployArtifact operation. For the deployArtifactType attribute, specify the DOCKER_IMAGE value.

**Using the CLI**

To create a container image repository artifact, Run the create-ocir-artifact command:

```bash
oci devops deploy-artifact create-ocir-artifact
```

Required Parameters for the create-ocir-artifact command:

- --argument-substitution-mode
- --source-image-uri
- --artifact-type
- --project-id

To get all the commands for deploy-artifact:

```bash
oci devops deploy-artifact -h
```

To get help for the create-ocir-artifact command:

```bash
oci devops deploy-artifact create-ocir-artifact -h
```

**Adding an Inline Artifact**

Learn how to create a reference to artifacts defined inline.

In the build pipeline, to store the Managed Build stage output, you need an OCI Container Registry repository or an Artifact Registry repository.
You must create an artifact reference to point to the repository location containing the build output. Before you create an artifact reference, you must have a DevOps project.

You can create an inline artifact reference for the following types of artifact sources: instance group deployment configurations, general artifacts, and Kubernetes manifests.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select an existing project, or create a DevOps project.
3. Click Add artifact.
4. Enter a name for the artifact.
5. For Type, select Instance group deployment configuration, General artifact, or Kubernetes manifest. See Deployment Configuration File.
6. For Artifact source, select Inline.
7. For Value, enter the contents of the artifact that you want to deploy.
8. Select Yes, substitute placeholders if you want to replace the placeholders in the artifact content by argument values provided during the deployment. Otherwise, select No. See Configuring Parameters.
9. (Optional) To add tags to the artifact, click Show tagging options. Tagging is a metadata system that lets you organize and track the resources in your tenancy.
   - If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.
   - To add a defined tag, you must have permissions to use the tag namespace.
   - For more information, see Resource Tags.
10. Click Add.

In the build pipeline, the Deliver Artifacts stage maps the build outputs from the Managed Build stage with the version to deliver to the DevOps artifact resource, and then to the OCI code repository.

**Using the API**

To create an inline artifact, use the CreateDeployArtifact operation. For the deployArtifactType attribute, select one of the following values:

- DEPLOYMENT_SPEC
- KUBERNETES_MANIFEST
- GENERIC_FILE

**Using the CLI**

To create an inline artifact, run the create-inline-artifact command:

```bash
tabular
oci devops deploy-artifact create-inline-artifact
```

Required parameters for the create-inline-artifact command:

- --argument-substitution-mode
- --base64-encoded-content
- --artifact-type
- --project-id

To get all the commands for deploy-artifact:

```bash
tabular
oci devops deploy-artifact -h
```

To get help for the create-inline-artifact command:

```bash
tabular
oci devops deploy-artifact create-inline-artifact -h
```
Adding an Artifact Registry Artifact
Learn how to create a reference to artifacts located in an Artifact Registry repository.

In the build pipeline, to store the Managed Build stage output, you need an OCI Container Registry repository or an Artifact Registry repository.

You must create an artifact reference to point to the repository location containing the build output. Before you create an artifact reference, you must have a DevOps project, and have access to the Artifact Registry repository. See Accessing Artifact Registry.

Oracle Cloud Infrastructure Artifact Registry is a repository service to store, share, and manage software development packages.

You can create a reference to three types of artifacts in Artifact Registry: instance group deployment configurations, general artifacts, and Kubernetes manifests.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

Using the Console
1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select an existing project, or create a DevOps project.
3. Click Add artifact.
4. Enter a name for the artifact.
5. For Type, select Instance group deployment configuration, General artifact, or Kubernetes manifest. See Deployment Configuration File.
6. For Artifact source, select Artifact Registry repository.
7. Select the region and compartment in which the artifact is located.
8. Enter the repository OCID and repository path of the Artifact Registry repository that you want to add. For more information, see Artifact Registry.
9. Select a version of the artifact.
   You can associate deployments with the artifact versions, and roll back to previous versions. Examples: 1.1.0 or 1.2-beta-2
10. Select Yes, substitute placeholders if you want to replace the placeholders in the artifact content by argument values provided during the deployment. Otherwise, select No. See Configuring Parameters.
11. (Optional) To add tags to the artifact, click Show tagging options. Tagging is a metadata system that lets you organize and track the resources in your tenancy.
    If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.
    To add a defined tag, you must have permissions to use the tag namespace.
    For more information, see Resource Tags.
12. Click Add.
    A reference to the artifact in the Artifact Registry repository is created.

Using the API
To create an Artifact Registry artifact, use the CreateDeployArtifact operation. For the deployArtifactType attribute, select one of the following values:

- DEPLOYMENT_SPEC
- KUBERNETES_MANIFEST
- GENERIC_FILE
Using the CLI

To create an Artifact Registry artifact, run the `create-generic-artifact` command:

```
oci devops deploy-artifact create-generic-artifact
```

Required parameters for the `create-generic-artifact` command:

- `--argument-substitution-mode`
- `--artifact-path`
- `--artifact-version`
- `--repository-id`
- `--artifact-type`
- `--project-id`

To get all the commands for `deploy-artifact`:

```
oci devops deploy-artifact -h
```

To get help for the `create-generic-artifact` command:

```
oci devops deploy-artifact create-generic-artifact -h
```

Editing an Artifact

Learn how to update artifact reference information.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

Using the Console

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and an artifact associated with that project.
3. Click Edit.
4. You can modify artifact name and change artifact type and source. Save the changes.

Using the API

To edit an artifact, use the `UpdateDeployArtifact` operation.

Using the CLI

To edit an artifact, run the `update` command:

```
oci devops deploy-artifact update --artifact-id
```

To edit a container image repository artifact, run the `update-ocir-artifact` command:

```
oci devops deploy-artifact update-ocir-artifact --artifact-id
```

To edit an inline artifact, run the `update-inline-artifact` command:

```
oci devops deploy-artifact update-inline-artifact --artifact-id
```

To edit an Artifact Registry artifact, run the `update-generic-artifact` command:

```
oci devops deploy-artifact update-generic-artifact --artifact-id
```
To get all the commands for deploy-artifact:

```
oci devops deploy-artifact -h
```

To get help for the update command:

```
oci devops deploy-artifact update -h
```

**Deleting an Artifact**

Learn how to delete an artifact reference.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and an artifact associated with that project.
3. Click Delete.
4. Confirm to permanently delete the reference to the artifact.

**Using the API**

To delete a reference to an artifact, use the `DeleteDeployArtifact` operation.

**Using the CLI**

To delete a reference to an artifact, run the `delete` command:

```
oci devops deploy-artifact delete --artifact-id
```

To get all the commands for deploy-artifact:

```
oci devops deploy-artifact -h
```

To get help for the `delete` command:

```
oci devops deploy-artifact delete -h
```

**Managing Code Repositories**

In the DevOps service, you can create your own private code repositories or connect to external code repositories such as GitHub and GitLab.

For creating an OCI code repository, see Creating a Repository.

To mirror a code repository from GitHub or GitLab, see Mirroring a Repository.

To clone a code repository, see Cloning a Repository.

**Creating a Repository**

Learn how to create a code repository in the DevOps service.

**Required IAM Policy**

Each service in Oracle Cloud Infrastructure (OCI) integrates with Identity and Access Management (IAM) for authentication and authorization. To grant users permission to access the DevOps code repositories and other resources, you have to create dynamic groups and IAM policies.

For creating dynamic groups and policies for code repositories, see Code Repository Policies. For more details, see DevOps IAM Policies.
An authentication (auth) token is required for each user who uses Git to interact with the code repositories in Oracle Cloud.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

Before you create a code repository, you must have a DevOps project.

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click Code Repositories on the left-side menu.
3. Click Create Repository.
4. Enter a name and optional description for the repository.
5. (Optional) Enter a default branch name.
   - If the value is not provided, then the branch is named as "main".
6. (Optional) To add tags to the repository, click Show tagging options.
   - Tagging is a metadata system that lets you organize and track the resources in your tenancy.
   - If you have permissions to create a resource, you also have permissions to add free-form tags to it.
   - To add a defined tag, you must have permissions to use the tag namespace.
   - For more information, see Resource Tags.
7. Click Create Repository.
   - An empty code repository is created on the main branch.

**To access your code repository:**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click Code Repositories on the left-side menu.
3. Select a code repository.
4. You can perform the following actions on the repository, as needed. These options are available in the left-side menu of the repository details page:
   - To view and access all the files and folders in your repository, click Files. Last commit and update details are also available.
   - To view and access all the commits pertaining to the code repository, click Commit. Details such as commit date and author are provided. You can filter the commits by author and date. Each commit is assigned a unique ID, which you can use to track the changes.
   - To compare file changes and commit changes between any two branches in your repository, click Compare. Choose a source and target branch to compare.
   - To view and access all the available branches in your repository, click Branches.
   - To view the various tags that point to specific points in the commits, click Git Tags.
   - To monitor the status of all the operations in progress, click Work Requests.

To clone your code repository, see Cloning a Repository.

**Using the API**

To create a code repository, use the CreateRepository operation.

To view a list of commits to the repository, use the ListCommits operation.

To view a list of repositories, use the ListRepositories operation.

**Using the CLI**

To create a code repository, run the `create` command:

```bash
oci devops repository create --name --project-id
```
To view a list of repositories, run the `list` command:

```shell
oci devops repository list --compartment-id or --project-id
```

To view a list of commits, run the `list-commits` command:

```shell
oci devops repository list-commits --repository-id
```

To get all the commands for `repository`:

```shell
oci devops repository -h
```

**Creating an External Connection**

Learn how to create a connection to external repositories such as GitHub and GitLab.

To integrate with third-party code repositories like GitHub and GitLab, you have to create a personal access token (PAT) in GitHub or GitLab and store the PAT in an Oracle Cloud Infrastructure (OCI) vault. For more information, see Build Source Integration on page 2451.

**Required IAM Policy**

Each service in OCI integrates with Identity and Access Management (IAM) for authentication and authorization. For creating dynamic groups and policies for code repositories and external connections, see Code Repository Policies. For more details, see DevOps IAM Policies.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click External Connections on the left-side menu.
3. Click Create External Connection.
4. Enter a name and optional description for the connection.
5. Select the type of external connection, GitHub or GitLab.
6. Select the vault and secret value that contains the personal access token (PAT) to connect to GitHub or GitLab.
7. (Optional) To add tags to the connection, click Show tagging options.
   - Tagging is a metadata system that lets you organize and track the resources in your tenancy.
   - If you have permissions to create a resource, you also have permissions to add free-form tags to it.
   - To add a defined tag, you must have permissions to use the tag namespace.
   - For more information, see Resource Tags.
8. Click Create.
   - The connection to the selected external repository is successfully created.

You can now mirror a code repository from GitHub or GitLab. See Mirroring a Repository.

**Using the API**

To create an external connection, use the `CreateConnection` operation.

**Using the CLI**

To create a GitHub connection, run the `create-github-connection` command:

```shell
oci devops connection create-github-connection --personal-access-token, --project-id
```
To create a GitLab connection, run the `create-gitlab-connection` command:

```
oci devops connection create-gitlab-connection --personal-access-token, --project-id
```

To view list of connections, run the `list` command:

```
oci devops connection list
```

To get all the commands for `connection`:

```
oci devops connection -h
```

### Editing an External Connection

Learn how to update the details of an external connection to a third-party code repository.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click External Connections on the left-side menu.
3. Click the Actions menu for the connection that you want to edit and select Edit.
4. Update the connection details, such as name, description, and vault secret, as needed.
5. Save the changes.

**Using the API**

To edit an external connection, use the `UpdateConnection` operation.

**Using the CLI**

To update a GitHub connection, run the `update-github-connection` command:

```
oci devops connection update-github-connection --connection-id
```

To update a GitLab connection, run the `update-gitlab-connection` command:

```
oci devops connection update-gitlab-connection --connection-id
```

To get all the commands for `connection`:

```
oci devops connection -h
```

### Deleting an External Connection

Learn how to delete external connections.

Before deleting an external connection, all the build stages using the connection must be deleted.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click External Connections on the left-side menu.
3. Click the Actions menu for the connection that you want to delete and select Delete.
4. To confirm the deletion, click Yes, remove external connection.
**Using the API**

To delete an external connection, use the `DeleteConnection` operation.

**Using the CLI**

To delete an external connection, run the `delete` command:

```
oci devops connection delete --connection-id
```

To get all the commands for `connection`:

```
oci devops connection -h
```

**Mirroring a Repository**

In DevOps, you can mirror a code repository from GitHub or GitLab.

Mirroring allows you to mirror repositories to and from external sources. You can mirror branches and commits between repositories.

Before using an external repository in DevOps, you must create a connection to the repository. DevOps supports connection to GitHub and GitLab. To integrate with these third-party code repositories, you have to create a personal access token (PAT) in GitHub or GitLab and store the PAT in an Oracle Cloud Infrastructure (OCI) vault. For more information, see Build Source Integration on page 2451.

An authentication (auth) token is required for each user who uses Git to interact with the code repositories in Oracle Cloud.

**Required IAM Policy**

Each service in OCI integrates with Identity and Access Management (IAM) for authentication and authorization. For creating dynamic groups and policies for code repositories and external connections, see Code Repository Policies. For more details, see DevOps IAM Policies.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

Before you mirror a repository, you must have a DevOps project.

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click Code Repositories on the left-side menu.
3. Click Mirror Repository.
4. Select a connection to an external repository.
5. Select a repository.
6. Select a schedule for synchronizing the repositories. Available options:
   - **Once**: The repository is synchronized once after the mirrored repository is created.
   - **Default**: The repositories are automatically synchronized every 15 minutes after the mirrored repository is created.
   - **Custom**: Select how often the repositories are synchronized after the mirrored repository is created.
7. To complete the mirroring process, click Mirror Repository.

To access your mirrored repository:

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click Code Repositories on the left-side menu.
3. Select a mirrored repository.
4. You can perform the following actions on the repository, as needed. These options are available in the left-side menu of the repository details page:

- To view and access all the files and folders in your repository, click **Files**. Last commit and update details are also available.
- To view and access all the commits pertaining to the code repository, click **Commit**. Details such as commit date and author are provided. You can filter the commits by author and date. Each commit is assigned a unique ID, which you can use to track the changes.
- To compare file changes and commit changes between any two branches in your repository, click **Compare**. Choose a source and target branch to compare.
- To view and access all the available branches in your repository, click **Branches**.
- To view the various tags that point to specific points in the commits, click **Git Tags**.
- To monitor the status of all the operations in progress, click **Work Requests**.

To clone your code repository, see Cloning a Repository.

**Using the API**

To mirror a repository, use the **MirrorRepository** operation.

**Using the CLI**

To mirror a repository, run the **mirror** command:

```
oci devops repository mirror --repository-id
```

To get all the commands for **repository**:

```
oci devops repository -h
```

To get all the commands for **mirror**:

```
oci devops repository mirror -h
```

**Synchronizing a Repository**

The mirrored repository can be synchronized as needed or based on a defined time interval.

1. Open the navigation menu and click **Developer Services**. Under **DevOps**, click **Projects**.
2. Select a project and click **Code Repositories** on the left-side menu.
3. Click the Actions menu for a mirrored repository that you want to synchronize and select **Synchronize now**.
   
   The request to synchronize the repository is successfully submitted. You can check the progress in the work request.
4. To edit the mirroring interval for scheduled synchronization, click the Actions menu for a mirrored repository and select **Edit mirroring interval**.
5. Select a scheduling type. Available options:
   - **None**: The repository is not automatically synchronized unless performed manually.
   - **Default**: The repository is automatically synchronized every 15 minutes.
   - **Custom**: Select how often the repository has to be synchronized.
6. Save the changes.
7. (Optional) To add tags to a repository, click the Actions menu and select **Add Tags**.
   
   Tagging is a metadata system that lets you organize and track the resources in your tenancy.
   
   If you have permissions to create a resource, you also have permissions to add free-form tags to it.
   
   To add a defined tag, you must have permissions to use the tag namespace.

   For more information, see Resource Tags.
**Cloning a Repository**

You can clone the code repository to create a local copy on your computer, add or remove files, commit changes, and work on different branches by using Git operations.

Before you clone a code repository, you must have a code repository or a mirrored repository associated with a DevOps project.

You can use two methods to clone and use your repository: HTTPS and SSH keys.

If you have set up an OCI API signing key, you can use SSH authentication to clone your code repository. For details on how to create and manage the keys associated with a user, see the documentation on API signing keys.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click Code Repositories on the left-side menu.
3. Click the Actions menu for the repository that you want to clone and select Clone.
4. Use one of the following methods:
   - **SSH** - To clone the repository by using SSH, see SSH Authorization.
   - **HTTPS** - To clone the repository by using HTTPS, see HTTPS Authorization.

   The repository is cloned and your credentials are stored for future use.

**SSH Authorization**

To clone the repository using an SSH key, copy the displayed URL.

### Note:

You must generate an SSH key pair for using SSH keys.

You must edit your SSH configuration file to specify the user and key to use for the **git clone** operation. The format for the host entry in your configuration file is:

```
Host <CodeRepositoryHost>
  User <userName>@<tenancyName>
  IdentityFile  <PathToYourSSHPrivateKey>
```

The SSH user is a combination of your login username and tenancy name. For example, if you are using a federated user, https://docs.oracle.com/en-us/iaas/Content/Identity/Concepts/federation.htm, then your code repository's SSH user for Git is, Federation/userName@tenancyName. In the user string:

- **Federation** is optional and is the federated identity provider.
- **userName** is the user who signs in to the OCI Console.
- **tenancyName** is the name of your tenancy, which you can find in the OCI Console.

Example, oracleidentitycloudservice/the-product-manager-user@my-tenancy

The SSH user string need not be URL encoded or escaped. For example, for a code repository in the Ashburn region, the host configuration entry is:

```
Host devops.scmservice.us-ashburn-1.oci.oraclecloud.com
  User the-product-manager-user@my-tenancy
  IdentityFile ~/.ssh/id_rsa
```

For all OCI regions, you can use a wildcard for the host, for example, Host devops.scmservice.*.oci.oraclecloud.com.

**After you save your SSH configuration changes, you can clone your code repository:**
On your local machine's command line, change the working directory location to where you want to clone the repository, and run the `git clone` command with the SSH URL that you copied.

For example, `git clone ssh://devops.scmservice.us-ashburn-1.oci.oraclecloud.com/namespaces/MY-TENANCY/projects/PROJECT-NAME/repositories/REPO-NAME`

**HTTPS Authorization**

To clone the repository by using HTTPS, copy the displayed URL.

**Note:**

You need an auth token to clone the repository using HTTPS.

On your local machine's command line, change the working directory location to where you want to clone the repository, and run the `git clone` command with the HTTPS URL you copied.

For example, `git clone https://devops.scmservice.us-ashburn-1.oci.oraclecloud.com/namespaces/MY-TENANCY/projects/PROJECT-NAME/repositories/REPO-NAME`

You must provide your username (with tenancy, optional federated identity and username) and password (auth token) when prompted.

For a federated user (single sign-on with an identity provider), enter the username in the following format: TenancyName/Federation/UserName. For example, if you use OCI's identity provider, your login would be, Acme/oracleidentitycloudservice/alice.jones@acme.com.

If you are using OCI's direct sign-in, enter the username in the following format: TenancyName/YourUserName. For example, Acme/alice_jones. Your password is the auth token you created previously.

**Editing a Repository**

Learn how to update code repository details.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click Code Repositories on the left-side menu.
3. Click the Actions menu for the repository that you want to edit and select Edit.
4. Update repository name, description, and default branch, as needed.
5. Save the changes.

**Using the API**

To edit a repository, use the `UpdateRepository` operation.

**Using the CLI**

To edit a repository, run the `update` command:

```
oci devops repository update --repository-id
```

To get all the commands for repository:

```
oci devops repository -h
```

**Deleting a Repository**

Learn how to delete code repositories.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.
Using the Console

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click Code Repositories on the left-side menu.
3. Click the Actions menu for the repository that you want to delete and select Delete.
4. Note the repository name that you want to delete to confirm the Delete action and click Delete.

   The Delete action deletes the repository including all branches, triggers, comments, pull requests, and history. Deleting the repository can't be undone, and you can't connect to a deleted repository.

Using the API

To delete a repository, use the DeleteRepository operation.

Using the CLI

To delete a repository, run the delete command:

```
oci devops repository delete --repository-id
```

To get all the commands for repository:

```
oci devops repository -h
```

Managing Build Pipelines

A build pipeline contains the stages that define the build process for successfully compiling, testing, and running software applications before deployment.

A stage is an action in the build pipeline. The DevOps service includes the following pre-defined stages that you can use in a build pipeline:

- Managed Build
- Deliver Artifacts
- Trigger Deployment
- Wait

You can add multiple stages to a pipeline. Stages can be added in a sequence or in parallel. You can remove any stage from the pipeline. When you do, the stage and its associated resources are deleted.

Creating a Build Pipeline

Learn how to create a build pipeline.

Required IAM Policy

Each service in Oracle Cloud Infrastructure (OCI) integrates with Identity and Access Management (IAM) for authentication and authorization. To grant users permission to access the DevOps build pipelines and other resources, you have to create dynamic groups and IAM policies.

For creating dynamic groups and policies for build pipelines, see Build Pipeline Policies. For more details, see DevOps IAM Policies.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

Using the Console

Before you create a build pipeline, you must have a DevOps project.

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project, and click Create build pipeline.
3. Enter a name and optional description for the pipeline.
4. Click Create.
   The build pipeline is successfully created.

You can add the following stages to the pipeline:

- **Managed Build**: Build and test your software applications.
- **Deliver Artifacts**: Store your software applications created from the Managed Build stage in the Oracle Cloud Infrastructure (OCI) Artifact Registry or OCI Container Registry repositories.
- **Trigger Deployment**: Start a deployment pipeline to deploy the output from the build pipeline.
- **Wait**: Pause a specific duration for testing the build pipeline.

**Using the API**

To create a build pipeline, use the `CreateBuildPipeline` operation.

**Using the CLI**

To create a build pipeline, run the `create` command:

```
oci devops build-pipeline create --project-id
```

To get all the commands for `build-pipeline`:

```
oci devops build-pipeline -h
```

**Adding a Managed Build Stage**

Learn how to add a Managed Build stage in the build pipeline.

You have to add code repositories in this stage for the build. In the DevOps service, you can create your own private code repositories or connect to external code repositories such as GitHub and GitLab. The repositories must be configured before adding the Managed Build stage. For creating repositories, see Managing Code Repositories.

Before you add a stage, you must have a build pipeline.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and a build pipeline.
3. To add a stage to the pipeline, click the + icon and select Add stage.
4. For the stage type, select Managed Build, and then click Next.
5. Enter a name and optional description for the stage.
6. The default compute shape (OCPU and memory) is displayed for OCI Build Agent Compute Shape.
   The Managed Build stage runs build instructions on a service managed build runner. You are charged for using the compute shape (OCPU and memory) during the build run.
7. Select Oracle Linux 7 as the base container image.
8. (Optional) Enter the path for the build specification file.
   The build specification contains build steps and settings that the build pipeline uses to run a build.
   This step is required only if the build specification file, `build_spec.yaml` is not located in the root directory of your primary code repository.
9. Select the primary code repository for the build.
   - Select the connection type for the repository. Supported connection types are:
     - OCI Code Repository
     - GitHub
     - GitLab
   
   Only the repositories that you have already configured are available for selection.
   - Select a branch for the selected code repository.
   - For Build Source Name, enter a unique name for the folder where the source code is downloaded on the build runner. Examples: Source1, Source2.
   - Save the changes.
10. To add more code repositories, click Add Build Source and select the repositories.
11. (Optional) Enter a timeout value (in seconds) for the stage.
12. (Optional) To add tags to the stage, click Show tagging options. Tagging is a metadata system that lets you organize and track the resources in your tenancy.
   
   If you have permissions to create a resource, you also have permissions to add free-form tags to it.
   
   To add a defined tag, you must have permissions to use the tag namespace.
   
   For more information, see Resource Tags.
13. To add the stage to the pipeline, click Add.
   
   A stage preview provides a snapshot of the configuration.
14. Add more stages sequentially or in parallel to the pipeline, as needed.

You can add the following stages to the pipeline:
   
   - Deliver Artifacts: Store your software applications created from the Managed Build stage in the Oracle Cloud Infrastructure (OCI) Artifact Registry or OCI Container Registry repositories.
   - Trigger Deployment: Start a deployment pipeline to deploy the output from the build pipeline.
   - Wait: Pause a specific duration for testing the build pipeline.

You can manually run the build or automatically trigger a build run when you commit your changes to the code repository. Manual run uses the latest commit to your code repository. You can run the build based on specific commit by noting the commit details.

Using the API

To create a build pipeline, use the CreateBuildPipeline operation.

To add a Build stage for the pipeline, use the CreateBuildPipelineStage operation. For the buildPipelineStageType attribute, specify the value as BUILD.

Using the CLI

To create a build pipeline, run the create command:

```
oci devops build-pipeline create --project-id
```

To add a Build stage for the pipeline, run the create-build-stage command:

```
oci devops build-pipeline-stage create-build-stage
```

Required parameters are:
   
   - --build-pipeline-id
   - --build-source-collection
   - --image
   - --stage-predecessor-collection
DevOps

To get all the commands for build-pipeline and build-pipeline-stage:

```
oci devops build-pipeline -h
oci devops build-pipeline-stage -h
```

To get help for the create-build-stage command:

```
oci devops build-pipeline-stage create-build-stage -h
```

Adding a Deliver Artifacts Stage
Learn how to add a Deliver Artifacts stage in the build pipeline.

The Deliver Artifacts stage maps the build outputs from the Managed Build stage with the version to deliver to a DevOps artifact resource, and then to the Oracle Cloud Infrastructure (OCI) code repository.

Before you add a stage, you must have a build pipeline.

The Deliver Artifacts stage can't be added as the first stage to a build pipeline. The pipeline must have at least one Managed Build stage first.

The build process generates artifacts, which are software applications or packages that you deploy to target deployment environments. The artifact produced by the Managed Build stage has to be stored in an artifact repository for deployment. DevOps supports artifacts stored in OCI Container Registry and OCI Artifact Registry repositories. The artifacts can be either container images (OCIR) or generic (universal) file types.

To store the Managed Build stage output, create either a Container Registry repository or an Artifact Registry repository. In Container Registry repository Docker images are stored and in Artifact Registry repository you can store generic software packages.

Required IAM Policy
Each service in Oracle Cloud Infrastructure (OCI) integrates with Identity and Access Management (IAM) for authentication and authorization. For creating dynamic groups and policies for adding a Deliver Artifacts stage to the build pipeline, see Artifact Policies. For more details, see DevOps IAM Policies.

Configuring Delivered Artifact Version
You have to create a DevOps artifact to point to the repository location containing the build output.

The version of the software package that is delivered to the OCI code repository is defined by a parameter in the artifact uniform resource identifier (URI). This parameter matches the build specification exported variable or the build pipeline parameter name.

After you create a DevOps artifact referencing either the Container Registry repository or the Artifact Registry repository location, note the artifact location as given in the following example:

```
• Name: node-express-getting-started container
• Type: Container image repository
• Path: iad.ocir.io/TENANCY-NAMESPACE/node-express-getting-started
• Replace parameters: Yes
```

Parameters are replaced at runtime with the values provided during the build.

For the artifact version that is delivered during the build run, assign the Managed Build stage exportedVariables: value to the artifact (image or package) tag. For example, in the build_spec.yaml file, if the exportedVariables: value is BUILDRUN_HASH, then you have to edit the DevOps artifact path to add the tag value as a parameter name as follows:

```
Path: iad.ocir.io/TENANCY-NAMESPACE/node-express-getting-started:${BUILDRUN_HASH}
```
Using the Console

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and a build pipeline.
3. Click the + icon below the Build stage.
4. To add the stage sequentially, select Add stage, or select Add parallel stage.
5. For the stage type, select Deliver Artifacts, and then click Next.
6. Enter a name and optional description for the stage.
7. Click Select Artifact, and then select one or more artifacts associated with your DevOps project.
8. To add new artifact sources, click Create Artifact. See Managing Artifacts.
9. For Build config/result Artifact name under Associate Artifacts with Build Result, enter the value of outputArtifact given in your build specification file.
10. (Optional) To add tags to the stage, click Show tagging options. Tagging is a metadata system that lets you organize and track the resources in your tenancy.

   If you have permissions to create a resource, you also have permissions to add free-form tags to it.

   To add a defined tag, you must have permissions to use the tag namespace.

   For more information, see Resource Tags.
11. To add the stage to the pipeline, click Add.

   A stage preview provides a snapshot of the configuration.
12. Add more stages sequentially or in parallel to the pipeline, as needed.

You can add the following stages to the pipeline:

- Trigger Deployment: Start a deployment pipeline to deploy the output from the build pipeline.
- Wait: Pause a specific duration for testing the build pipeline.

You can manually run the build or automatically trigger a build run when you commit your changes to the code repository.

Using the API

To create a build pipeline, use the CreateBuildPipeline operation.

To add a Deliver Artifacts stage for the pipeline, use the CreateBuildPipelineStage operation. For the buildPipelineStageType attribute, specify the value as DELIVER_ARTIFACT.

Using the CLI

To create a build pipeline, run the create command:

```bash
oci devops build-pipeline create --project-id
```

To add a Deliver Artifacts stage for the pipeline, run the create-deliver-artifact-stage command:

```bash
oci devops build-pipeline-stage create-deliver-artifact-stage
```

Required parameters are:

- --build-pipeline-id
- --deliver-artifact-collection
- --stage-predecessor-collection
To get all the commands for `build-pipeline` and `build-pipeline-stage`:

```
oci devops build-pipeline -h
oci devops build-pipeline-stage -h
```

To get help for the `create-deliver-artifact-stage` command:

```
oci devops build-pipeline-stage create-deliver-artifact-stage -h
```

**Adding a Trigger Deployment Stage**

Learn how to add a Trigger Deployment stage in the build pipeline.

The Trigger Deployment stage automatically triggers a deployment from the build pipeline. DevOps supports deployment to Kubernetes clusters, instance groups, and Functions.

Before you add the Trigger Deployment stage, you must have a build pipeline and a deployment pipeline associated with your DevOps project. The Trigger Deployment stage can't be added as the first stage to a build pipeline. The pipeline must have at least one Build stage first.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and a build pipeline.
3. Click the + icon below the Build stage.
4. To add the stage sequentially, select Add stage, or select Add parallel stage.
5. For the stage type, select Trigger Deployment, and then click Next.
6. Enter a name and optional description for the stage.
7. Click Select Deployment Pipeline, select a deployment pipeline associated with your DevOps project, and then save.

   The **Send Build Pipelines Parameters** check box is selected by default.

   You can modify the parameters before running the build. See Configuring Parameters.

8. (Optional) To add tags to the stage, click Show tagging options. Tagging is a metadata system that lets you organize and track the resources in your tenancy.

   If you have permissions to create a resource, you also have permissions to add free-form tags to it.

   To add a defined tag, you must have permissions to use the tag namespace.

   For more information, see Resource Tags.

9. To add the stage to the pipeline, click Add.

   A stage preview provides a snapshot of the configuration.

   You can manually run the build or automatically trigger a build run when you commit your changes to the code repository.

**Using the API**

To create a build pipeline, use the `CreateBuildPipeline` operation.

To add a Trigger Deployment stage for the pipeline, use the `CreateBuildPipelineStage` operation. For the `buildPipelineStageType` attribute, specify the value as TRIGGER_DEPLOYMENT_PIPELINE.
Using the CLI

To create a build pipeline, run the `create` command:

```
oci devops build-pipeline create --project-id
```

To add a Trigger Deployment stage for the pipeline, run the `create-trigger-deployment-stage` command:

```
oci devops build-pipeline-stage create-trigger-deployment-stage
```

Required parameters:
- `--build-pipeline-id`
- `--deploy-pipeline-id`
- `--is-pass-all-parameters-enabled`
- `--stage-predecessor-collection`

To get all the commands for `build-pipeline` and `build-pipeline-stage`:

```
oci devops build-pipeline -h
oci devops build-pipeline-stage -h
```

To get help for the `create-trigger-deployment-stage` command:

```
oci devops build-pipeline-stage create-trigger-deployment-stage -h
```

Adding a Wait Stage

Learn how to add a Wait stage to any build pipeline to test the pipeline.

Before you add a stage, you must have a build pipeline.

The Wait stage can't be added as the first stage to a build pipeline. The pipeline must have at least one Build stage first.

This stage adds a specified duration of delay in the build pipeline. Duration is given in seconds, for example, 300 seconds. During this duration, the build process is paused.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

Using the Console

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and a build pipeline.
3. To add a stage to the pipeline, click the + icon.
4. Select Add stage to add the stage sequentially or select Add parallel stage.
5. For the stage type, select Wait, and then click Next.
6. Enter a name and optional description for the stage.
7. Enter the wait time in seconds.
8. To add the stage to the pipeline, click Add.

Using the API

To create a build pipeline, use the `CreateBuildPipeline` operation.

To add a Wait stage for the pipeline, use the `CreateBuildPipelineStage` operation. For the `buildPipelineStageType` attribute, specify the value as WAIT.
Using the CLI

To create a build pipeline, run the `create` command:

```bash
oci devops build-pipeline create --project-id
```

To add a wait stage for the pipeline, run the `create-wait-stage` command:

```bash
oci devops build-pipeline-stage create-wait-stage
```

Required parameters:

- `--build-pipeline-id`
- `--wait-criteria`
- `--stage-predecessor-collection`

To get all the commands for `build-pipeline` and `build-pipeline-stage`:

```bash
oci devops build-pipeline -h
oci devops build-pipeline-stage -h
```

To get help for the `create-wait-stage` command:

```bash
oci devops build-pipeline-stage create-wait-stage -h
```

Editing a Build Pipeline

Learn how to update build pipeline information, and the associated stage details.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

Using the Console

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and then click the View all Build Pipelines link.
3. To edit the information for a pipeline:
   a) Click the Actions menu for the pipeline and select Edit.
   b) Update the pipeline name, description, or both, and save the changes.
4. To edit a stage in the pipeline:
   a) Click the Actions menu in the top-right corner of the stage that you want to edit, and select View details.
   b) Click Edit Stage, make the necessary changes to the stage details, and save the changes.

Using the API

To edit a build pipeline, use the `UpdateBuildPipeline` operation.

To update a build pipeline stage, use the `UpdateBuildPipelineStage` operation.

Using the CLI

To edit a build pipeline, run the `update` command:

```bash
oci devops build-pipeline update --build-pipeline-id
```

To update a Build stage, run the `update-build-stage` command:

```bash
oci devops build-pipeline-stage update-build-stage --stage-id
```
To update a Deliver Artifacts stage, run the `update-deliver-artifact-stage` command:

```bash
oci devops build-pipeline-stage update-deliver-artifact-stage --stage-id
```

To update a Trigger Deployment stage, run the `update-trigger-deployment-stage` command:

```bash
oci devops build-pipeline-stage update-trigger-deployment-stage --stage-id
```

To update a Wait stage, run the `update-wait-stage` command:

```bash
oci devops build-pipeline-stage update-wait-stage --stage-id
```

To get all the commands for `build-pipeline` and `build-pipeline-stage`:

```bash
oci devops build-pipeline -h
oci devops build-pipeline-stage -h
```

### Deleting a Build Pipeline

Learn how to delete a build pipeline and its associated stages.

Before you can delete a build pipeline, you must delete all the stages associated with the pipeline.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

#### Using the Console

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click the View all Build Pipelines link.
3. To delete a stage from a pipeline:
   a) Select the pipeline.
   b) Click the Actions menu in the top-right corner of the stage that you want to delete.
   c) Select Delete and confirm to permanently delete the stage from the pipeline.
4. To permanently delete a pipeline along with all its resources, click the Menu icon for the pipeline and select Delete.
5. Confirm the deletion.

#### Using the API

To delete a build pipeline, use the `DeleteBuildPipeline` operation.

To delete a build pipeline stage, use the `DeleteBuildPipelineStage` operation.

#### Using the CLI

To delete a build pipeline, run the `delete` command:

```bash
oci devops build-pipeline delete --build-pipeline-id
```

To delete a build pipeline stage, run the `delete` command:

```bash
oci devops build-pipeline-stage delete --stage-id
```

To get all the commands for `build-pipeline` and `build-pipeline-stage`:

```bash
oci devops build-pipeline -h
oci devops build-pipeline-stage -h
```
Running a Build
Learn how to trigger the build process by manually running a DevOps build pipeline.
You can also automatically trigger a build run when you commit your changes to the code repository.
Before you start the run, you must have a build pipeline defined.
For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

Using the Console
1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and a build pipeline associated with that project.
4. Accept the default name entered for the build run, or change it.
5. Review the defined parameters for the build pipeline. If necessary, you can update the parameter values. For more information, see Configuring Parameters.
6. (Optional) To select a specific commit that can be used to trigger the build run, click Show advanced options. Select a repository based on the source connection type and select required branch and commit.
   By default, manual run uses the latest commit to the code repository that was added to the build.
The progress and status of the run are displayed in the Build Run tab. You can stop an in-progress run before it completes, by clicking Stop run. Note the reason for stopping the run. To view build run details including the build output, click the Menu icon at the top-right corner.

Using the API
To run a build pipeline, use the CreateBuildRun operation.
To update a build run, use the UpdateBuildRun operation.
To cancel a build run, use the CancelBuildRun operation.

Using the CLI
To run a build pipeline, run the create command:

```bash
oci devops build-run create --build-pipeline-id
```
To update a build run, use the update command:

```bash
oci devops build-run update --build-run-id
```
To cancel a build run, use the cancel command:

```bash
oci devops build-run cancel --build-run-id --reason
```
To get all the commands for build-run:

```bash
oci devops build-run -h
```

Build Run Workflow
When a build run starts, a directed acyclic graph (DAG) is provided along with the build run progress and log details. This graph of all the linked stages in the pipeline gives a preview of all the stages that are eligible to run. During the build run, each stage that is running is highlighted in the graph. A build run is successful if all the stages in the pipeline complete successfully.

While the build is running, the progress is tracked; after completion, a history of the actions taken is maintained. When the build run completes, you can view the run status and run progress of each build pipeline stage.
Triggering a Build Run

In OCI DevOps, a build run can be automatically triggered when you commit your changes to a code repository.

Before creating a trigger in DevOps, you must have a DevOps project, a build pipeline, and a code repository associated with the project.

To run a build manually, see Running a Build.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click Triggers on the left-side menu.
3. Click Create Trigger.
4. Enter a name for the trigger, and select an existing source connection:
   - OCI Code Repository
   - GitHub
   - GitLab

   DevOps supports connections to GitHub and GitLab external repositories. See Creating an External Connection.
5. If you choose OCI Code Repository, then select a code repository to commit the changes to.
6. Click Add Action.
7. Select a build pipeline to trigger for the commit operation.
8. (Optional) Select an event that triggers the build run:
   - Push
   - Pull Request Created
   - Pull Request Updated
   - Pull Request Merged
   - Pull Request Reopened

   **Note:**
   Event availability varies based on the type of code repository.
9. Select the source repository branch on which the selected event triggers the build run.
   If you select one of the Pull Request events, then you can also select the target code repository branch.
10. Save the changes.
11. Click Create to create the trigger.
12. Copy the trigger URL and trigger secret because you can't retrieve them again in the Console.

   **Note:**
   The trigger secret is applicable only for external code repositories such as GitHub and GitLab. To access the DevOps service from GitHub and GitLab, you must set up a webhook and secret in the external code repositories.

   For GitHub, see Creating Webhooks and for GitLab, see Webhooks.

**Using the API**

To create a trigger, use the CreateTrigger operation.

**Using the CLI**

To create an OCI code repository trigger, run the create-devops-code-repo-trigger command:

```
oCI devops trigger create-devops-code-repo-trigger --actions, --project-id
```
To create a GitHub trigger, run the `create-github-trigger` command:

```
oci devops trigger create-github-trigger --actions, --project-id
```

To create a GitLab trigger, run the `create-gitlab-trigger` command:

```
oci devops trigger create-gitlab-trigger --actions, --project-id
```

To get all the commands for `trigger`:

```
oci devops trigger -h
```

**Editing a Trigger**

Learn how to update trigger details.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click Triggers on the left-side menu.
3. Click the Actions menu for the trigger that you want to edit and select Edit.
4. Update name and trigger action, as needed. You can't modify the source connection.
5. Save the changes.

**Using the API**

To edit a trigger, use the `UpdateTrigger` operation.

**Using the CLI**

To update an OCI code repository trigger, run the `update-devops-code-repo-trigger` command:

```
oci devops trigger update-devops-code-repo-trigger --trigger-id
```

To update a GitHub trigger, run the `update-github-trigger` command:

```
oci devops trigger update-github-trigger --trigger-id
```

To update a GitLab trigger, run the `update-gitlab-trigger` command:

```
oci devops trigger update-gitlab-trigger --trigger-id
```

To get all the commands for `trigger`:

```
oci devops trigger -h
```

**Deleting a Trigger**

Learn how to delete triggers.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click Triggers on the left-side menu.
3. Click the Actions menu for the trigger that you want to edit and select Delete.
4. Click Yes, remove trigger to confirm the deletion.
Using the API
To delete a trigger, use the **DeleteTrigger** operation.

Using the CLI
To delete a trigger, run the **delete** command:

```bash
oci devops trigger delete --trigger-id
```

To get all the commands for **trigger**:

```bash
oci devops trigger -h
```

Viewing the Build History
Learn how to review the run status of all the build runs associated with a project.

In the DevOps service, you can view run status, duration, and other details for all build runs.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

Using the Console
1. Open the navigation menu and click **Developer Services**. Under **DevOps**, click **Projects**.
2. Select a project, and click **Build History** in the left-side menu.
   
   A list of all build runs associated with the project is displayed with details.
   
   You can filter the list based on any keyword, start date, and end date. To view the list based on build run status, select the required status in the **State** filter.
3. Select a build run to view complete run details, including a snapshot of the pipeline graph and log details.

To view all the selected project's work requests, click **Work Requests** in the left-side menu. The list displays the status of all the operations in progress.

Using the API
To list all build runs, use the **ListBuildRuns** operation.

To list all work requests, use the **ListWorkRequests** operation.

Using the CLI
To view all the build runs, use the **list** command:

```bash
oci devops build-run list
```

To get all the commands for **build-run**:

```bash
oci devops build-run -h
```

Managing Deployment Pipelines
A deployment pipeline holds the requirements that must be satisfied to deliver a set of artifacts to the target environment.

Deployment pipelines contain different stages for automated deployment. Each stage is associated with certain actions in the pipeline. Deployment is executed using the rolling release strategy where a new version is deployed incrementally to the target environment by updating a set of hosts at a time. The update is validated before updating the next set of hosts. This process is repeated until rollout of the new version is complete.

A **Stage** is an action in the deployment pipeline. DevOps service includes pre-defined stages, which could be readily used in a deployment pipeline. They are as follows:
• **Deploy to a Kubernetes cluster**: Uses the built-in Kubernetes rolling update strategy.
• **Deploy to an instance group**: Release update incrementally to the instance group. You can specify the maximum instances that can be offline at one time. This type supports automatic rollbacks.
• **Deploy to Functions**: Uses the built-in Functions update strategy.
• **Control**:
  • **Approval**: Pause the deployment and wait for a manual decision.
  • **Traffic Shift**: Route the traffic between two environments.
  • **Pause**: Pause the deployment for a given duration.
  • **Integrations**: Invokes a function to run custom logic.

You can add multiple stages to a pipeline. Stages can be added in a sequence or in parallel. You can remove any stage from the pipeline. When you do, the stage and its associated resources are deleted.

**Deploying to a Kubernetes Cluster**

Learn how to create a pipeline to deploy artifacts to a Container Engine for Kubernetes (OKE) cluster.

Before you create the pipeline, you must have a [DevOps project](#), [Kubernetes cluster environment](#) to deploy to, and artifacts. Artifacts can be defined inline or located in the [Artifact Registry](#).

**Note:**
DevOps currently supports deployments to only public Kubernetes API endpoint and not private. The worker nodes can be on either private or public subnets.

**Note:**
DevOps deployment pipelines currently do not support deployment to OKE clusters with Helm.

**Required IAM Policy**

Each service in Oracle Cloud Infrastructure (OCI) integrates with Identity and Access Management (IAM) for authentication and authorization. To grant users permission to access the DevOps deployment pipelines and other resources, you have to create dynamic groups and IAM policies.

For creating dynamic groups and policies for deployment pipelines, see [Deployment Pipeline Policies](#). For more details, see [DevOps IAM Policies](#).

For accessing DevOps using the [Oracle Cloud Console](#), [REST API](#), and [CLI](#), see [Accessing DevOps](#).

**Using the Console**

1. Open the navigation menu and click **Developer Services**. Under **DevOps**, click **Projects**.
2. Select a project, and click **Create pipeline**.
3. Enter a name and optional description for the pipeline.
4. For **Pipeline type**, select **Create a deployment pipeline**.
5. Click **Create pipeline**.
6. To add a stage to the new pipeline, click the + icon and select **Add stage**.
7. For stage type, select **Deploy - OKE**, and then click **Next**.
8. Enter a name and optional description for the stage.
9. For **Environment**, select an existing cluster environment.
10. Click **Select Artifact**, and then select one or more artifact resources from your DevOps project.

   The DevOps service performs a Kubernetes server-side apply of the Kubernetes manifest artifacts in the order that they appear in the Console. You can also remove artifacts to select another one or reorder the artifacts list. Removing an artifact in the pipeline stage does not delete the artifact resource from your project. For more information on Kubernetes server-side apply, see [Server-Side Apply](#).
11. (Optional) To override the default environment namespace, enter value for **Override Kubernetes namespace**.

12. To automatically roll back the release stage if the validation fails, select **Yes** for automatic rollback. If the stage fails, automatic rollback deploys the last successful release version. For more information, see [Rolling Back a Deployment](#).

13. (Optional) To add tags to the pipeline, click **Show tagging options**. Tagging is a metadata system that lets you organize and track the resources in your tenancy.

   - If you have permissions to create a resource, you also have permissions to add free-form tags to it.
   - To add a defined tag, you must have permissions to use the tag namespace.

   For more information, see [Resource Tags](#).

14. To add the stage to the pipeline, click **Add**.

   A stage preview provides a snapshot of the configuration.

15. Add more stages sequentially or in parallel to the pipeline, as needed.

To deploy the build output to the target environment, run the **deployment pipeline**. To automatically trigger a deployment from the **build pipeline**, you can add a **Trigger Deployment stage** to the build pipeline.

### Using the API

To create a deployment pipeline, use the `CreateDeployPipeline` operation.

To create a Kubernetes cluster stage for the pipeline, use the `CreateDeployStage` operation. For the `deployStageType` attribute, specify the `OKE_DEPLOYMENT` and `RUN_OKE_JOB` values.

### Using the CLI

To create a deployment pipeline, run the `create` command:

```
oci devops deploy-pipeline create --project-id
```

To create a Kubernetes cluster stage for the pipeline, run the `create-deploy-oke-stage` command:

```
oci devops deploy-stage create-deploy-oke-stage
```

Required parameters for the `create-deploy-oke-stage` command:

- `--kubernetes-manifest-artifact-ids`
- `--oke-cluster-environment-id`
- `--pipeline-id`
- `--stage-predecessor-collection`

To get all the commands for `deploy-pipeline` and `deploy-stage`:

```
oci devops deploy-pipeline -h
oci devops deploy-stage -h
```

To get help for the `create-deploy-oke-stage` command:

```
oci devops deploy-stage create-deploy-oke-stage -h
```

### Changing the Predecessor and Successor of a Stage

As you add stages to build the pipeline, a directed acyclic graph (DAG) of the stages is displayed. The graph shows all the linked stages in the pipeline that are eligible to run. At least one of the stages of the pipeline must be declared as a predecessor, which indicates that the stage is eligible to run immediately when the deployment begins. A pipeline
DevOps can also be specified as the predecessor of a stage when it does not have a preceding stage. Furthermore, stages can have successors.

To modify the predecessor of a stage, follow these steps:

1. In the graph, click the Menu icon in the top-right corner of the stage that you want to edit.
2. Select **Modify Predecessors**.
3. Select the stage that you want to mark as the predecessor, and click **Save**.

To modify the successor of a stage, follow these steps:

1. In the graph, click the Menu icon in the top-right corner of the stage that you want to edit.
2. Select **Modify Successors**.
3. Select the stage that you want to mark as the successor, and click **Save**.

### Deploying to an Instance Group

Learn how to create a pipeline to deploy artifacts to instance groups.

**Prerequisites**

Before you create the pipeline, you need these things:

- Have a [DevOps project](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/devops/), an instance group environment to deploy to, and artifacts. Artifacts can be defined inline or located in the [Artifact Registry](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/devops/).

DevOps deployment supports deploying multiple artifacts in a stage. For instance group deployment, a deployment configuration file defines the commands and runs steps to download application package artifact from the specified artifact registry and place in the target compute instance file system. See [Deployment Configuration File](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/devops/).

- The Compute Instance Run Command plugin must be enabled on the instance, and plugin must be running. To enable the plugin, follow these steps:
  1. In the Console, open the navigation menu, and click **Compute**. Under Compute, click **Instances**.
  2. Select an instance from the instance group to deploy to.
  3. Click the **Oracle Cloud Agent** tab.
  4. For the **Compute Instance Run Command** plugin, toggle the **Enabled Plugin** switch to **Enabled**.

It takes up to 10 minutes for the change to take effect.

**Caution:**

Functionality that depends on the plugin, such as monitoring, autoscaling, deployment, or OS management does not work when the plugin is disabled.

**Caution:**

To deploy applications using the Compute Instance Run Command plugin, you must appropriately configure and maintain least privilege policies. For more information, see [Running Commands on an Instance](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/devops/).

For information about managing plugins, see [Managing Plugins with Oracle Cloud Agent](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/devops/). For troubleshooting, see [Troubleshooting Oracle Cloud Agent](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/devops/).

- Have permission to run commands on the instance. See the required [Identity and Access Management (IAM) policy](https://docs.oracle.com/en/cloud/oracle-cloud-infrastructure/devops/).
**Required IAM Policy**

Each service in Oracle Cloud Infrastructure (OCI) integrates with IAM for authentication and authorization. To grant users permission to access the DevOps deployment pipelines and other resources, you have to create dynamic groups and IAM policies.

For creating dynamic groups and policies for deployment pipelines, see Deployment Pipeline Policies. For more details, see DevOps IAM Policies.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project, and click Create pipeline.
3. Enter a name and optional description for the pipeline.
4. For Pipeline type, select Create a deployment pipeline.
5. Click Create pipeline.
6. To add a stage to the new pipeline, click the + icon and select Add stage.
7. For stage type, select Deploy - Instance Group, and then click Next.
8. Enter a name and optional description for the stage.
9. For Environment, select an existing instance group.
10. Click Select Artifact, and then select available instance group deployment configuration artifacts to deploy.
    The deployment configuration file defines the artifacts to be downloaded to the instance and the location where the artifacts must be copied. For more information, see Deployment Configuration File.
11. (Optional) Click Select Artifact to add more artifacts that are downloaded to the compute instances during the deployment.
    These additional artifacts must not be defined inline.
12. (Optional) Click Select load balancer. The load balancer must be available in the Console.
    a. Select the load balancer region and compartment.
    b. Search for an available load balancer, and select it.
    c. To add a listener to the load balancer, click Select Listener.
    Load balancer distributes production traffic during deployment. Listeners check for incoming traffic on the load balancer's IP address. For more information, see Load Balancer Management and Listener Management.
13. To automatically roll back the release stage if the validation fails, select Yes for automatic rollback. If the stage fails, automatic rollback deploys the last successful release version. For more information, see Rolling Back a Deployment.
14. For Rollout policy, select either Rollout by percentage or Rollout by count. The rollout policy controls the rate and behavior of the instance rollout across the target environment.
    - For Rollout by percentage, enter the percentage value between 1 and 100. This value controls the maximum percentage of instances that are deployed, or are not running, at a time.
    - For Rollout by count, enter the count value. This value controls the maximum number of instances that are deployed, or are not running, at a time.
15. (Optional) For Delay between batches, enter a duration in seconds.
16. (Optional) For Failure policy, select None, Fail by percentage, or Fail by count. The failure policy defines the failure criteria for a stage. It can be defined based on the number of compute hosts failing in an instance group.
    - For Fail by percentage, enter the percentage value between 1 and 100. This value defines the percentage of compute hosts that fail after which the stage fails.
    - For Fail by count, enter the count value. This value defines the number of compute hosts that fail after which the stage fails.
17. (Optional) To add tags to the pipeline, click **Show tagging options**. Tagging is a metadata system that lets you organize and track the resources in your tenancy.

If you have permissions to create a resource, you also have permissions to add free-form tags to it.

To add a defined tag, you must have permissions to use the tag namespace.

For more information, see [Resource Tags](#).

18. To add the stage to the pipeline, click **Add**.

A stage preview provides a snapshot of the configuration.

19. Add more stages sequentially or in parallel to the pipeline, as needed.

To deploy the build output to the target environment, run the [deployment pipeline](#).

To automatically trigger a deployment from the build pipeline, you can add a [Trigger Deployment stage](#) to the build pipeline.

**Using the API**

To create a deployment pipeline, use the [CreateDeployPipeline](#) operation.

To create an instance group deployment stage for the pipeline, use the [CreateDeployStage](#) operation. For the `deployStageType` attribute, specify the `COMPUTE_INSTANCE_GROUP_ROLLING_DEPLOYMENT` value.

**Using the CLI**

To create a deployment pipeline, run the `create` command:

```
oci devops deploy-pipeline create --project-id
```

To create an instance group stage, run the `create-deploy-compute-instance-group-stage` command:

```
oci devops deploy-stage create-deploy-compute-instance-group-stage
```

Required parameters for the `create-deploy-compute-instance-group-stage` command:

- `--compute-instance-group-environment-id`
- `--deployment-spec-artifact-id`
- `--rollout-policy`
- `--pipeline-id`
- `--stage-predecessor-collection`

To get all the commands for `deploy-pipeline` and `deploy-stage`:

```
oci devops deploy-pipeline -h
oci devops deploy-stage -h
```

To get help for the `create-deploy-compute-instance-group-stage` command:

```
oci devops deploy-stage create-deploy-compute-instance-group-stage -h
```

**Changing the Predecessor and Successor of a Stage**

As you add stages to build the pipeline, a directed acyclic graph (DAG) of the stages is displayed. The graph shows all the linked stages in the pipeline that are eligible to run. At least one of the stages of the pipeline must be declared as a predecessor, which indicates that the stage is eligible to run immediately when the deployment begins. A pipeline can also be specified as the predecessor of a stage when it does not have a preceding stage. Furthermore, stages can have successors.

To modify the predecessor of a stage, follow these steps:
1. In the graph, click the Menu icon in the top-right corner of the stage that you want to edit.
2. Select Modify Predecessors.
3. Select the stage that you want to mark as the predecessor, and click Save.

To modify the successor of a stage, follow these steps:
1. In the graph, click the Menu icon in the top-right corner of the stage that you want to edit.
2. Select Modify Successors.
3. Select the stage that you want to mark as the successor, and click Save.

**Deploying to Functions**
Learn how to create a pipeline to deploy artifacts to Oracle Functions.

Before you create the pipeline, you must have a DevOps project, a Functions environment to deploy to, and a container image repository artifact.

**Required IAM Policy**
Each service in Oracle Cloud Infrastructure (OCI) integrates with Identity and Access Management (IAM) for authentication and authorization. To grant users permission to access the DevOps deployment pipelines and other resources, you have to create dynamic groups and IAM policies.

For creating dynamic groups and policies for deployment pipelines, see Deployment Pipeline Policies. For more details, see DevOps IAM Policies.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click Create pipeline.
3. Enter a name and optional description for the pipeline.
4. For Pipeline type, select Create a deployment pipeline.
5. Click Create pipeline.
6. To add a stage to the new pipeline, click the + icon and select Add stage.
7. For stage type, select Deploy - Function, and then click Next.
8. Enter a name and optional description for the stage.
9. For Environment, select an existing function.
   - The read-only Function name field displays the default Functions strategy that is used for the deployment.
10. Click Select Artifact, and then select an existing artifact resource from your DevOps project.
    - Click Remove Artifact to remove one or more artifacts and select another one. Removing an artifact in the pipeline stage does not delete the artifact resource from your project.
11. (Optional) To add tags to the pipeline, click Show tagging options. Tagging is a metadata system that lets you organize and track the resources in your tenancy.
    - If you have permissions to create a resource, you also have permissions to add free-form tags to it.
    - To add a defined tag, you must have permissions to use the tag namespace.
    - For more information, see Resource Tags.
12. To add the Functions stage to the pipeline, click Add.
    - A stage preview provides a snapshot of the configuration.
13. Add more stages sequentially or in parallel to the pipeline, as needed.

To deploy the build output to the target environment, run the deployment pipeline.

To automatically trigger a deployment from the build pipeline, you can add a Trigger Deployment stage to the build pipeline.
**Using the API**

To create a deployment pipeline, use the `CreateDeployPipeline` operation.

To create a Functions deployment stage for the pipeline, use the `CreateDeployStage` operation. For `deployStageType` attribute, specify the `DEPLOY_FUNCTION` and `INVOKE_FUNCTION` values.

**Using the CLI**

To create a deployment pipeline, run the `create` command:

```bash
oci devops deploy-pipeline create --project-id
```

To create a Functions deployment stage for the pipeline, run the `create-deploy-function-stage` command:

```bash
oci devops deploy-stage create-deploy-function-stage
```

**Required parameters for the create-deploy-function-stage command:**

- `--docker-image-artifact-id`
- `--function-environment-id`
- `--pipeline-id`
- `--stage-predecessor-collection`

To get all the commands for `deploy-pipeline` and `deploy-stage`:

```bash
oci devops deploy-pipeline -h
```  
```bash
oci devops deploy-stage -h
```

To get help for the `create-function-stage` command:

```bash
oci devops deploy-stage create-deploy-function-stage -h
```

**Changing the Predecessor and Successor of a Stage**

As you add stages to build the pipeline, a directed acyclic graph (DAG) of the stages is displayed. The graph shows all the linked stages in the pipeline that are eligible to run. At least one of the stages of the pipeline must be declared as a predecessor, which indicates that the stage is eligible to run immediately when the deployment begins. A pipeline can also be specified as the predecessor of a stage when it does not have a preceding stage. Furthermore, stages can have successors.

To modify the predecessor of a stage, follow these steps:

1. In the graph, click the Menu icon in the top-right corner of the stage that you want to edit.
2. Select Modify Predecessors.
3. Select the stage that you want to mark as the predecessor, and click Save.

To modify the successor of a stage, follow these steps:

1. In the graph, click the Menu icon in the top-right corner of the stage that you want to edit.
2. Select Modify Successors.
3. Select the stage that you want to mark as the successor, and click Save.

**Adding a Control Stage**

Learn how to add a control stage to any deployment pipeline.

You can add the following types of control stages to a pipeline:

- Approval
- Traffic Shift
Before you add a control stage, you must have a deployment pipeline defined.

**Required IAM Policy**

Each service in Oracle Cloud Infrastructure (OCI) integrates with Identity and Access Management (IAM) for authentication and authorization. To grant users permission to access the DevOps deployment pipelines and other resources, you have to create dynamic groups and IAM policies.

For creating dynamic groups and policies for deployment pipelines, see Deployment Pipeline Policies. For more details, see DevOps IAM Policies.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Adding an Approval Stage**

Approval stage pauses the deployment for a specified duration for manual decision from the approver. Approvers are notified of deployments that are pending manual approval. You can configure the manual approval stage to require more than one approval. Approvers can approve or reject deployments.

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and a pipeline associated with that project.
3. To add the Approval stage sequentially or in parallel, click the + icon and select Add stage.
4. Select Control - Approval, and then click Next.
5. Enter stage name and optional description.
6. Enter the number of approvers.
7. To add the Approval stage to the pipeline, click Add.

**Adding a Traffic Shift Stage**

Traffic Shift stage routes the traffic between two sets of backend IPs. You can specify the IPs in each group and also configure the batch count and batch delay based on which the traffic is distributed.

Before adding this stage, you must have a load balancer and listener configured in the Oracle Cloud Console. When you create a load balancer resource, you must specify the backend servers. See Load Balancer Management.

The essential components for load balancing include:

- A load balancer with pre-provisioned bandwidth.
- A backend set with a health check policy. See Backend Set Management for more information.
- Backend servers for your backend set. See Backend Server Management for more information.
- One or more listeners. See Listener Management for more information.
- Load balancer subnet security rules to allow the intended traffic. See Security Rules.

To add the Traffic Shift stage using the Console:

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and a pipeline associated with that project.
3. To add the Traffic Shift stage sequentially or in parallel, click the + icon and select Add stage.
4. Select Control - Traffic Shift, and then click Next.
5. Enter stage name and optional description.
6. Click Select load balancer.
   a) Select the load balancer region and compartment.
   b) Select a load balancer from the available list.
7. Select a listener from the available list.
   After you select a listener, the IP addresses of the servers in the backend set are listed under two groups: group A and group B. You can select an IP address to be in one of the two groups.
8. To shift the traffic to one of the target groups, select the Traffic Target.
   The Traffic Shift stage shifts the traffic to the selected IP addresses in the target group.

9. Enter a Batch Count to define the total number of batches that are used to shift the traffic.
   For example, if the batch count is 5, then the traffic shift occurs in 5 batches.

10. Enter a Batch Delay in seconds to define the delay between each batch.

11. (Optional) Enter Ramp Limit to specify the maximum traffic to be shifted.
   For example, if the ramp limit is 50 and batch count is 5, then each batch shifts an additional 10% (50/5) of the traffic to the selected target group. The default ramp limit is 100 implying 100% traffic shift to the target group.
   The service adjusts the weight of the backend set to achieve the preferred traffic shift configuration.

12. To add the Traffic Shift stage to the pipeline, click Add.

Adding a Pause Stage
Pause stage adds a specified duration of delay in the pipeline. Duration is given in seconds, for example, 200 seconds. During this duration, the deployment is paused.

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and a pipeline associated with that project.
3. To add the Pause stage sequentially or in parallel, click the + icon and select Add stage.
4. Select Control - Pause, and then click Next.
5. Enter a name and optional description for the stage.
6. Enter wait time in seconds.
7. To add the Pause stage to the pipeline, click Add.

Using the API
To add an approval stage to the pipeline, use the CreateDeployStage operation. For deployStageType attribute, specify the MANUAL_APPROVAL value.

To add a traffic shift stage to the pipeline, use the CreateDeployStage operation. For deployStageType attribute, specify the LOAD_BALANCER_TRAFFIC_SHIFT value.

To add a pause stage to the pipeline, use the CreateDeployStage operation. For deployStageType attribute, specify the WAIT value.

Using the CLI
To add an approval stage to the pipeline, run the create-manual-approval-stage command:

```
oci devops deploy-stage create-manual-approval-stage
```

Required parameters for the create-manual-approval-stage command:
- --approval-policy
- --pipeline-id
- --stage-predecessor-collection

To add a traffic shift stage to the pipeline, run the create-load-balancer-traffic-shift-stage command:

```
oci devops deploy-stage create-load-balancer-traffic-shift-stage
```

Required parameters for the create-load-balancer-traffic-shift-stage command:
- --blue-backend-ips
- --green-backend-ips
- --load-balancer-config
- --pipeline-id
- --rollout-policy
To add a pause stage to the pipeline, run the `create-wait-stage` command:

```
oci devops deploy-stage create-wait-stage
```

Required parameters for the `create-wait-stage` command:

- `--wait-criteria`
- `--pipeline-id`
- `--stage-predecessor-collection`

To get all the commands for `deploy-pipeline` and `deploy-stage`:

```
oci devops deploy-pipeline -h
oci devops deploy-stage -h
```

To get help for the `create-manual-approval-stage` command:

```
oci devops deploy-stage create-manual-approval-stage -h
```

To get help for the `create-load-balancer-traffic-shift-stage` command:

```
oci devops deploy-stage create-load-balancer-traffic-shift-stage -h
```

To get help for the `create-wait-stage` command:

```
oci devops deploy-stage create-wait-stage -h
```

### Adding an Integrations Stage

An Integrations stage invokes an Oracle Cloud Infrastructure (OCI) function. This stage can be used to run code or custom logic in a serverless manner. For example, you can write a function that validates your application in the staging environment and if successful, deploy the application to the production environment.

Before you begin, you must have a deployment pipeline defined and you must create a function that is invoked when the pipeline is run.

### Required IAM Policy

Each service in OCI integrates with Identity and Access Management (IAM) for authentication and authorization. To grant users permission to access the DevOps deployment pipelines and other resources, you have to create dynamic groups and IAM policies.

For creating dynamic groups and policies for deployment pipelines, see Deployment Pipeline Policies. For more details, see DevOps IAM Policies.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

### Using the Console

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and a pipeline associated with that project.
3. To add the Integrations stage sequentially or in parallel, click the + icon and select Add stage.
4. Select Integrations - Invoke Function, and then click Next.
5. Enter a name and optional description for the stage.
6. For Environment, select an existing function to invoke.

   The read-only Function name field displays the function that is called in the pipeline.

7. (Optional) To select and add artifacts to the stage, click Select Artifact.

   Select an existing artifact resource from your DevOps project. The artifact must be generic (universal) file type. Parameters in the artifact must be in JSON format and can have placeholders. You must select the "Yes, substitute placeholders" option when configuring the DevOps artifact resource to substitute the placeholders with the argument value during deployment. For more information, see Configuring Parameters.

   Here's an example of the generic artifact content to pass two user-defined parameters and their values:

   • Parameters: test_name, app_version
   • Values: {"test_name":"verify_production", "app_version":"${app_version}"}

8. For Stage run mode, select to run asynchronously or synchronously.

   If you select Run asynchronously, the service invokes the function but does not wait for the function to complete. On selecting Run synchronously, the service invokes the function and waits for the function to complete.

9. Select to disable or enable validation.

   If the validation is enabled, then the service verifies the return value of the function. The return value is a UTF-8 string literal, true or false. If the return value is true, then the stage is marked as Succeeded, otherwise the stage is marked as Failed.

   If the validation is disabled, then the service does not verify the return value.

   Validation occurs only if you have selected the option “Run synchronously” for stage run mode.

10. (Optional) To add tags to the pipeline, click Show tagging options. Tagging is a metadata system that lets you organize and track the resources in your tenancy.

   If you have permissions to create a resource, you also have permissions to add free-form tags to that resource.

   To add a defined tag, you must have permissions to use the tag namespace.

   For more information, see Resource Tags.

11. To add the Integrations stage to the pipeline, click Add.

   To deploy the build output to the target environment, run the deployment pipeline.

   To automatically trigger a deployment from the build pipeline, you can add a Trigger Deployment stage to the build pipeline.

   **Using the API**

   To invoke a function in the pipeline, use the CreateDeployStage operation. For deployStageType attribute, specify the INVOKE_FUNCTION value.

   **Using the CLI**

   To invoke a function in the pipeline, run the create-invoke-function-stage command:

   ```shell
   oci devops deploy-stage create-invoke-function-stage
   ```

   Required parameters for the create-invoke-function-stage command:

   • --function-environment-id
   • --is-async
   • --is-validation-enabled
   • --pipeline-id
   • --stage-predecessor-collection
To get all the commands for deploy-pipeline and deploy-stage:

```
oci devops deploy-pipeline -h
oci devops deploy-stage -h
```

To get help for the create-invoke-function-stage command:

```
oci devops deploy-stage create-invoke-function-stage -h
```

Editing a Pipeline
Learn how to update deployment pipeline information, and the associated stage details.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

Using the Console

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click the View all Deployment Pipelines link.
3. To edit the information for a pipeline, click the Menu icon for the pipeline and select Edit pipeline.
4. Update the pipeline name, description, or both, and save the changes.

To edit a stage in the pipeline:

1. Click the Actions menu in the top-right corner of the stage that you want to edit, and select View details.
2. Click Edit Stage, make the necessary changes to the stage details, and click Save.

Using the API
To edit a deployment pipeline, use the UpdateDeployPipeline operation.
To update a pipeline stage, use the UpdateDeployStage operation.

Using the CLI
To edit a deployment pipeline, run the update command:

```
oci devops deploy-pipeline update --pipeline-id
```

To update a pipeline stage, run the update command:

```
oci devops deploy-stage update --stage-id
```

To update a Kubernetes cluster stage, run the update-deploy-oke-stage command:

```
oci devops deploy-stage update-deploy-oke-stage --stage-id
```

To update an instance group stage, run the update-deploy-compute-instance-stage command:

```
oci devops deploy-stage update-deploy-compute-instance-stage --stage-id
```

To update a Functions stage, run the update-deploy-function-stage command:

```
oci devops deploy-stage update-deploy-function-stage --stage-id
```
To get all the commands for deploy-pipeline and deploy-stage:

```bash
oci devops deploy-pipeline -h
oci devops deploy-stage -h
```

**Deleting a Pipeline**

Learn how to delete a deployment pipeline and its associated stages.

Before deleting a deployment pipeline, all the stages associated with the pipeline must be deleted.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

**Using the Console**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and click the View all Deployment Pipelines link.
3. To delete a stage from a pipeline:
   a) Select the pipeline.
   b) Click the Actions menu in the top-right corner of the stage that you want to delete.
   c) Select Delete and confirm to permanently delete the stage from the pipeline.
4. To permanently delete a pipeline along with all its resources, click the Menu icon for the pipeline and select Delete.
5. Confirm the deletion.

**Using the API**

To delete a deployment pipeline, use the `DeleteDeployPipeline` operation.

To delete a pipeline stage, use the `DeleteDeployStage` operation.

**Using the CLI**

To delete a deployment pipeline, run the `delete` command:

```bash
oci devops deploy-pipeline delete --pipeline-id
```

To delete a pipeline stage, run the `delete` command:

```bash
oci devops deploy-stage delete --stage-id
```

To get all the commands for deploy-pipeline and deploy-stage:

```bash
oci devops deploy-pipeline -h
oci devops deploy-stage -h
```

**Deploying Applications**

Learn how to deploy applications by running a DevOps deployment pipeline.

Before you run a pipeline, you must have a deployment pipeline defined.

**Required IAM Policy**

Each service in Oracle Cloud Infrastructure (OCI) integrates with Identity and Access Management (IAM) for authentication and authorization. To grant users permission to access the DevOps deployment pipelines and other resources, you have to create dynamic groups and IAM policies.
For creating dynamic groups and policies for deployment pipelines, see Deployment Pipeline Policies. For more details, see DevOps IAM Policies.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

Using the Console

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and a pipeline associated with that project.
3. Click Run pipeline.
4. Accept the default name entered for the deployment, or change it.
5. Review the defined parameters for the pipeline. If necessary, you can update the parameter values. For more information, see Configuring Parameters.

Deployment progress and status are displayed in the Deployments tab. You can stop a deployment in progress before it completes, by clicking Stop Run. Note the reason for canceling the deployment. Only one deployment can run at a time for a pipeline.

If the deployment pipeline has an Approval stage, then the deployment waits for the manual approval before completion. Approver can approve or reject the deployment. Reason for approval or rejection must be mentioned. After the deployment completes, you can manually roll back failed stages in the pipeline. For more information, see Rolling Back a Deployment.

Deployment Rerun

You can rerun previously completed deployments.

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project, and click Deployments in the left menu.
3. Click the Actions menu for the deployment that you want to rerun and select Re-run.
4. You can update deployment name, parameters, and artifacts used if applicable.
5. Click Start Re-Run.

Using the API

To run a deployment pipeline, use the CreateDeployment operation.

To approve a deployment, use the ApproveDeployment operation.

To update a deployment, use the UpdateDeployment operation.

To cancel a deployment, use the CancelDeployment operation.

Using the CLI

To run a deployment pipeline, run the create-pipeline-deployment command:

```
oci devops deployment create-pipeline-deployment --pipeline-id
```

To redeploy a pipeline, run the create-pipeline-redeployment command:

```
oci devops deployment create-pipeline-redeployment --deployment-id
```

To update a deployment, run the update-pipeline-deployment command:

```
oci devops deployment update-pipeline-deployment --deployment-id
```

To cancel a deployment, run the cancel command:

```
oci devops deployment cancel --deployment-id --reason
```
To approve a deployment, run the `approve` command:

```bash
oci devops deployment approve
```

Required parameters to provide for the `approve` command:
- `--deployment-id`
- `--action`
- `--stage-id`

To get all the commands for deployment:

```bash
oci devops deployment -h
```

**Deployment Workflow**

When deployment starts, a directed acyclic graph (DAG) is provided along with the deployment progress status and log details. This graph of all the linked stages in the pipeline gives a preview of all the stages that are eligible to run. The graph can have multiple sinks (stages that are final and do not lead to other stages). A deployment is successful if all the sink stages complete successfully.

A snapshot of the pipeline is shown throughout the deployment process. While it’s running, the progress is tracked; after completion, a history of the actions taken is maintained. When deployment completes, you can view status of the deployment, including a snapshot of the graph.

During deployment, environments can be shared between pipelines. If two deployments are running in parallel deploying to the same environment, then the environment is locked. After one stage completes its deployment, the environment is unlocked for the other stage to deploy.

**Rolling Back a Deployment**

In DevOps, deployments can be rolled back manually or automatically.

After a deployment is completed, you can roll back a failed stage in the deployment pipeline to the previous successful release version.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

### Manually Roll Back a Deployment

1. Open the navigation menu and click **Developer Services**. Under **DevOps**, click **Projects**.
2. Select a project, and click **Deployments** in the left menu.
3. Select a deployment that has failed.
4. Click the Actions menu in the top-right corner of the failed stage that you want to roll back, and select **Manual Rollback**.
5. Click **Select Deployment**, and then select the deployment ID to roll back based on the deployment timestamp.
6. Update parameters if applicable, and click **Rollback Stage**.

The deployment is successfully rolled back for the selected stage in the pipeline. Rollback of a single stage in the pipeline is considered a new deployment, and a snapshot is provided only for that particular stage during the deployment.

Rollback failure depends on the stage type. For example, rollback of an instance group deployment stage might fail if many hosts in the group fail. The failure also depends on the rollout policy defined when creating the instance group deployment pipeline.

### Automatic Rollback

When creating a deployment pipeline for a cluster or an instance group, you can select the **Automatic Rollback** option. If the validation fails, the release is automatically rolled back. If the stage fails, the last successful release version is deployed. During automatic rollback, other *in-progress* stage continues running, but new stages cannot run, and the deployment completes as **Failed**.
Viewing Deployments
Learn how to review the deployment status of all the deployments associated with a project.

In the DevOps service, all deployments are systematically tracked. You can view status, duration, and other details of all your deployments.

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

Using the Console
1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project, and click Deployments in the left-side menu.
3. A list of all deployments associated with the project is displayed with deployment details.
4. You can filter the list based on deployment name, start date, and end date. To view the list based on deployment status, select the required status in the State filter.
5. (Optional) To view or add tags to a deployment, click the Menu icon for a deployment, and select Add Tags.
   Tagging is a metadata system that allows you to organize and track resources within your tenancy. If you have permissions to create a resource, you also have permissions to add free-form tags to that resource. To add a defined tag, you must have permissions to use the Tag Namespace. For more information, see Resource Tags.
6. Select a deployment name to view complete deployment details, including a snapshot of the pipeline graph and log details.

To view all the selected project’s work requests, click Work Requests in the left-side menu. The list displays the status of all the operations in progress.

Using the API
To list all deployments, use the ListDeployments operation.
To list all work requests, use the ListWorkRequests operation.

Configuring Parameters
Parameters are names of placeholders that exist in DevOps resources. They are available to all resources within the pipeline.

To configure a pipeline parameter, you must have a build pipeline or a deployment pipeline.

All parameters used in the pipeline must have a value before the pipeline is run. When the pipeline is run, you have the option to override the default value of the parameter with an argument value for that particular run. If a parameter has both argument and default value, then the argument value takes precedence.

A pipeline parameter name can be used in a placeholder that exists in DevOps resources and certain API fields. Placeholders are special strings with a unique format, ${parameterName}. When a pipeline is run, the placeholder is substituted with the value of the corresponding pipeline parameter.

Placeholders can be used as input in DevOps resources such as pipeline, stage, or artifact resource. For example, a placeholder can be used while adding a DevOps artifact resource such as in the artifact version or a Container Registry tag. Any placeholders in the artifacts are substituted by the corresponding parameter values by choosing "Yes, substitute parameter" in the artifact configuration. For more details, see Managing Artifacts.

Placeholders can also be used in the content of an artifact, such as instance group deployment specification or a Kubernetes manifest. Consider the following two examples where you can use placeholders:

- In Kubernetes manifest, you can define the replicas as replicas: ${nginxReplicaCount}.
- In instance group deployment specification, you can set an environment variable version as version: ${appVersion}. For more details, see deployment configuration file.

Here’s how you can define pipeline parameters using the Console:

For accessing DevOps using the Oracle Cloud Console, REST API, and CLI, see Accessing DevOps.

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select a project and a pipeline associated with that project.
3. Click the Parameters tab.
4. Enter a name for the parameter.

Parameter names are case-sensitive, and can consist of letters, numbers, or underscores. Example: appVersion
5. (Optional) Enter a default value for the parameter. Example: 1.2
6. Enter a description of the parameter. Example: This is the version of application hello_world.
7. To save the parameter, click the + icon.

Before starting the pipeline run, use the default value of the parameter or override with an argument value.

**DevOps Logs**

DevOps logs emit all the DevOps project resources logs. Learn how to manage logs using the console.

The DevOps service uses the Oracle Cloud Infrastructure (OCI) Logging service to manage logging. See [Logging Overview](#) for general information on logging, including how to name log files and create log groups.

For information on understanding the DevOps log entries, see [Details for DevOps Logging](#).

Before you create logs using the [Oracle Cloud Console](#), you must have a DevOps project.

**Creating Logs**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select an existing project for which you want to create the log.
4. Click the Enable Log switch to enable logging.

Alternatively, click the Menu icon and select Enable Log.

The Enable Log dialog box appears.

5. Enter the following:

- **Compartment**: Select the compartment within which the log file resides from the list.
- **Log Group**: Select an existing log group from the list or click [Create New Group](#) where you can enter the name and description of a new logging group within which your log resides.
- **Log Name**: Enter the name of the log.
- **Log Retention**: Select the time period in months for the logging entry to be retained.

For information on log and log groups, including naming syntax guidelines, see [Managing Logs and Log Groups](#).

6. Click Enable Log.

The Logs list is updated to show the DevOps log that you created.

**Enabling Logging**

Enable disabled log for a DevOps project.

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select an existing project for which you want to enable logging.
4. Click the Enable Log switch to enable logging. Alternatively, click the Menu icon and select Enable Log.
5. Confirm the enabling when prompted.

**Editing Logs**

1. Open the navigation menu and click Developer Services. Under DevOps, click Projects.
2. Select an existing project for which you want to edit the log details.
3. Under **DevOps Project Resources**, click **Logs**.
4. Click the Actions menu and select **Edit Log**. The Log Details dialog box appears.
5. Click **Edit** to modify the log name and save the changes.
6. Click **Change Log Group** to move the logs to a different log group.

**Disabling Logging**

1. Open the navigation menu and click **Developer Services**. Under **DevOps**, click **Projects**.
2. Select an existing project for which you want to disable logging.
3. Under **DevOps Project Resources**, click **Logs**.
4. Click the **Enable Log** switch to disable logging. Alternatively, click the Actions menu and select **Disable Log**.
5. Confirm the disabling when prompted.

**Deleting Logs**

1. Open the navigation menu and click **Developer Services**. Under **DevOps**, click **Projects**.
2. Select an existing project for which you want to delete the log entry.
3. Under **DevOps Project Resources**, click **Logs**.
4. Click the Actions menu and select **Delete Log**.
5. Confirm the deletion when prompted.

**DevOps Events**

Oracle Cloud Infrastructure Events are JSON files that are emitted with some service operations and carry information about that operation.

You can define rules that trigger a specific action when an event occurs. For more information, see **Overview of Events** and **Get Started with Events**. DevOps emits an event for the following actions:

- A DevOps project is created, updated, or deleted.
- A deployment artifact is created, updated, or deleted.
- A code repository is created, mirrored, updated, deleted, or listed.
- A connection is created, updated, or deleted.
- A deployment environment is created, updated, or deleted.
- A build pipeline is created, updated, or deleted.
- A build pipeline stage is created, updated, or deleted.
- A build run is created, updated, or deleted.
- A trigger is created, updated, or deleted.
- A deployment pipeline is created, updated, or deleted.
- A deployment pipeline stage is created, updated, or deleted.
- A deployment is created or updated.
# DevOps Project Events

<table>
<thead>
<tr>
<th>Event Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Project Begin</td>
<td><code>com.oraclecloud.devopsproject.createproject.begin</code></td>
</tr>
<tr>
<td>Create Project End</td>
<td><code>com.oraclecloud.devopsproject.createproject.end</code></td>
</tr>
<tr>
<td>Update Project Begin</td>
<td><code>com.oraclecloud.devopsproject.updateproject.begin</code></td>
</tr>
<tr>
<td>Update Project End</td>
<td><code>com.oraclecloud.devopsproject.updateproject.end</code></td>
</tr>
<tr>
<td>Delete Project Begin</td>
<td><code>com.oraclecloud.devopsproject.deleteproject.begin</code></td>
</tr>
<tr>
<td>Delete Project End</td>
<td><code>com.oraclecloud.devopsproject.deleteproject.end</code></td>
</tr>
</tbody>
</table>

## Example event for creating a DevOps project:

```json
{
    "eventType": "com.oraclecloud.devopsproject.createproject.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "devopsproject",
    "eventTime": "2021-04-16T20:24:35Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..unique_ID",
        "compartmentName": "example_compartment",
        "resourceName": "My test resource",
        "resourceId": "ocid1.example_regional_resource.oc1.phx.unique_ID",
        "availabilityDomain": "availability_domain"
    },
    "eventID": "unique_ID",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..unique_ID"
    }
}
```
# Artifact Events

<table>
<thead>
<tr>
<th>Event Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Deploy Artifact Begin</td>
<td>com.oraclecloud.devopsdeploy.createdeployartifact.begin</td>
</tr>
<tr>
<td>Create Deploy Artifact End</td>
<td>com.oraclecloud.devopsdeploy.createdeployartifact.end</td>
</tr>
<tr>
<td>Update Deploy Artifact Begin</td>
<td>com.oraclecloud.devopsdeploy.updatedeployartifact.begin</td>
</tr>
<tr>
<td>Update Deploy Artifact End</td>
<td>com.oraclecloud.devopsdeploy.updatedeployartifact.end</td>
</tr>
<tr>
<td>Delete Deploy Artifact Begin</td>
<td>com.oraclecloud.devopsdeploy.deletedeployartifact.begin</td>
</tr>
<tr>
<td>Delete Deploy Artifact End</td>
<td>com.oraclecloud.devopsdeploy.deletedeployartifact.end</td>
</tr>
</tbody>
</table>

**Example event for creating an artifact:**

```json
{
  "eventType": "com.oraclecloud.devopsdeploy.createdeployartifact.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "devopsdeploy",
  "eventTime": "2021-04-15T21:32:04Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..unique_ID",
    "compartmentName": "example_compartment",
    "resourceName": "example_resource",
    "resourceId": "ocid1.devopsdeployartifact.oc1.phx.unique_ID",
    "availabilityDomain": "availability_domain"
  },
  "eventID": "unique_ID",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..unique_ID"
  }
}
```
## Code Repository Events

<table>
<thead>
<tr>
<th>Event Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Repository Begin</td>
<td>com.oraclecloud.scm-service-api.CreateRepository.begin</td>
</tr>
<tr>
<td>Update Repository</td>
<td>com.oraclecloud.scm-service-api.UpdateRepository</td>
</tr>
<tr>
<td>Delete Repository Begin</td>
<td>com.oraclecloud.scm-service-api.DeleteRepository.begin</td>
</tr>
<tr>
<td>Mirror Repository</td>
<td>com.oraclecloud.scm-service-api.MirrorRepository</td>
</tr>
<tr>
<td>List Repositories</td>
<td>com.oraclecloud.scm-service-api.ListRepositories</td>
</tr>
</tbody>
</table>

**Example event for creating a code repository:**

```json
{
  "eventType":"com.oraclecloud.scm-service-api.CreateRepository.begin",
  "cloudEventsVersion":"0.1",
  "eventTypeVersion":"2.0",
  "source":"scm-service-api",
  "eventId":"d6b8a809-027c-486e-996d-a0a4fa802407",
  "eventTime":"2021-10-14T00:38:11.353Z",
  "contentType":"application/json",
  "data":{
    "eventGroupingId":"ocid1.devopsworkrequest.oc1..unique_ID",
    "eventName":"CreateRepository",
    "compartmentId":"ocid1.compartment.oc1..unique_ID",
    "compartmentName":"integration_tests",
    "resourceName":"My test resource",
    "resourceId":"ocid1.devopsprepository.oc1..unique_ID",
    "availabilityDomain":"AD2"
  }
}
```
## Connection Events

<table>
<thead>
<tr>
<th>Event Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Connection Begin</td>
<td>com.oraclecloud.devopsbuild.createconnection.begin</td>
</tr>
<tr>
<td>Create Connection End</td>
<td>com.oraclecloud.devopsbuild.createconnection.end</td>
</tr>
<tr>
<td>Update Connection Begin</td>
<td>com.oraclecloud.devopsbuild.updateconnection.begin</td>
</tr>
<tr>
<td>Update Connection End</td>
<td>com.oraclecloud.devopsbuild.updateconnection.end</td>
</tr>
<tr>
<td>Delete Connection Begin</td>
<td>com.oraclecloud.devopsbuild.deleteconnection.begin</td>
</tr>
<tr>
<td>Delete Connection End</td>
<td>com.oraclecloud.devopsbuild.deleteconnection.end</td>
</tr>
</tbody>
</table>

### Example event for `createconnection.begin`:

```json
{
  "eventType":"com.oraclecloud.devopsbuild.createconnection.begin",
  "cloudEventsVersion":"0.1",
  "eventTypeVersion":"2.0",
  "source":"devopsbuild",
  "eventTime":"2021-08-17T15:19:21Z",
  "contentType":"application/json",
  "data":{
    "eventName":"CreateConnection",
    "compartmentId":"ocid1.compartment.oc1..unique_ID",
    "compartmentName":"example_compartment",
    "resourceName":"My test resource",
    "availabilityDomain":"availability_domain"
  },
  "eventID":"unique_ID",
  "extensions":{
    "compartmentId":"ocid1.compartment.oc1..unique_ID"
  }
}
```

### Example event for `createconnection.end`:

```json
{
  "eventType":"com.oraclecloud.devopsbuild.createconnection.end",
  "cloudEventsVersion":"0.1",
  "eventTypeVersion":"2.0",
  "source":"devopsbuild",
  "eventTime":"2021-08-17T15:19:31Z",
  "contentType":"application/json",
  "data":{
    "eventName":"CreateConnection",
    "compartmentId":"ocid1.compartment.oc1..unique_ID",
    "compartmentName":"example_compartment",
    "resourceName":"My test resource",
    "availabilityDomain":"availability_domain",
    "resourceId": "ocid1.devopsconnection.oc1.phx.unique_ID"
  }
}
```
Environment Events

<table>
<thead>
<tr>
<th>Event Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Deploy Environment Begin</td>
<td>com.oraclecloud.devopsdeploy.createdeployenvironment.begin</td>
</tr>
<tr>
<td>Create Deploy Environment End</td>
<td>com.oraclecloud.devopsdeploy.createdeployenvironment.end</td>
</tr>
<tr>
<td>Update Deploy Environment Begin</td>
<td>com.oraclecloud.devopsdeploy.updatedeployenvironment.begin</td>
</tr>
<tr>
<td>Update Deploy Environment End</td>
<td>com.oraclecloud.devopsdeploy.updatedeployenvironment.end</td>
</tr>
<tr>
<td>Delete Deploy Environment Begin</td>
<td>com.oraclecloud.devopsdeploy.deletedeployenvironment.begin</td>
</tr>
<tr>
<td>Delete Deploy Environment End</td>
<td>com.oraclecloud.devopsdeploy.deletedeployenvironment.end</td>
</tr>
</tbody>
</table>

Example event for creating an environment:

```json
{
    "eventType": "com.oraclecloud.devopsdeploy.createdeployenvironment.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "devopsdeploy",
    "eventTime": "2021-04-15T21:32:04Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..unique_ID",
        "compartmentName": "example_compartment",
        "resourceName": "example_resource",
        "resourceId": "ocid1.devopsdeployenvironment.oc1.phx.unique_ID",
        "availabilityDomain": "availability_domain"
    },
    "eventID": "unique_ID",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..unique_ID"
    }
}
```
## Build Pipeline Events

<table>
<thead>
<tr>
<th>Event Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Build Pipeline Begin</td>
<td>com.oraclecloud.devopsbuild.createbuildpipeline.begin</td>
</tr>
<tr>
<td>Create Build Pipeline End</td>
<td>com.oraclecloud.devopsbuild.createbuildpipeline.end</td>
</tr>
<tr>
<td>Update Build Pipeline Begin</td>
<td>com.oraclecloud.devopsbuild.updatebuildpipeline.begin</td>
</tr>
<tr>
<td>Update Build Pipeline End</td>
<td>com.oraclecloud.devopsbuild.updatebuildpipeline.end</td>
</tr>
<tr>
<td>Delete Build Pipeline Begin</td>
<td>com.oraclecloud.devopsbuild.deletebuildpipeline.begin</td>
</tr>
<tr>
<td>Delete Build Pipeline End</td>
<td>com.oraclecloud.devopsbuild.deletebuildpipeline.end</td>
</tr>
</tbody>
</table>

**Example event for `createbuildpipeline.begin`:**

```json
{
  "eventType": "com.oraclecloud.devopsbuild.createbuildpipeline.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "devopsbuild",
  "eventTime": "2021-08-17T15:20:55Z",
  "contentType": "application/json",
  "data": {
    "eventName": "CreateBuildPipeline",
    "compartmentId": "ocid1.compartment.oc1..unique_ID",
    "compartmentName": "example_compartment",
    "resourceName": "My test resource",
    "availabilityDomain": "availability_domain"
  },
  "eventID": "unique_ID",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..unique_ID"
  }
}
```

**Example event for `createbuildpipeline.end`:**

```json
{
  "eventType": "com.oraclecloud.devopsbuild.createbuildpipeline.end",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "devopsbuild",
  "eventTime": "2021-08-17T15:21:10Z",
  "contentType": "application/json",
  "data": {
    "eventName": "CreateBuildPipeline",
    "compartmentId": "ocid1.compartment.oc1..unique_ID",
    "compartmentName": "example_compartment",
    "resourceName": "My test resource",
    "availabilityDomain": "availability_domain",
    "resourceId": "ocid1.devopsbuildpipeline.oc1.phx.unique_ID"
  }

<tr>
<td>Update Deploy Stage End</td>
<td>com.oraclecloud.devopsdeploy.updatedeploystage.end</td>
</tr>
<tr>
<td>Delete Deploy Stage Begin</td>
<td>com.oraclecloud.devopsdeploy.deletedeploystage.begin</td>
</tr>
<tr>
<td>Delete Deploy Stage End</td>
<td>com.oraclecloud.devopsdeploy.deletedeploystage.end</td>
</tr>
</tbody>
</table>

**Example event for creating a stage:**

```json
{
  "eventType": "com.oraclecloud.devopsdeploy.createdeploystage.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "devopsdeploy",
  "eventTime": "2021-04-15T21:32:04Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..unique_ID",
    "compartmentName": "example_compartment",
    "resourceName": "example_resource",
    "resourceId": "ocid1.devopsdeploystage.oc1.phx.unique_ID",
    "availabilityDomain": "availability_domain"
  },
  "eventID": "unique_ID",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..unique_ID"
  }
}
```

### Deployment Events

<table>
<thead>
<tr>
<th>Event Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Deployment</td>
<td>com.oraclecloud.devopsdeploy.createdeployment</td>
</tr>
<tr>
<td>Update Deployment</td>
<td>com.oraclecloud.devopsdeploy.updatedeployment</td>
</tr>
</tbody>
</table>

**Example event for creating a deployment:**

```json
{
  "eventType": "com.oraclecloud.devopsdeploy.createdeployment",
  "cloudEventsVersion": "0.1",
```
DevOps Metrics

Metrics enable you to monitor your cloud resources actively and passively.

You can monitor the performance of your resources by using metrics. This topic describes the metrics emitted by the following metric namespaces:

- **oci_devops_code_repos** (code repository)
- **oci_devops_build** (build)
- **oci_devops_deployment** (deployment)

DevOps metrics help you track the following:

- Time spent for each build run.
- Number of times builds have succeeded and failed.
- Time spent for each deployment.
- Number of times a deployment has failed.
- Number of code repositories.
- Number of pushes and pulls done on code repositories.
- Total size of the code repository.

Resources monitored:

- Build pipelines
- Build runs
- Deployment pipelines
- Deployments
- Code repositories

Prerequisites

To monitor resources, you must be given the required type of access in an IAM policy written by an administrator. Policies are required for using the Console, REST API, or SDK and CLI. The policy must give you access to the monitoring services and the resources being monitored. When you try to perform an action, you might get a message that you don’t have permission or are unauthorized. Confirm with your administrator the type of access that you have been granted and which compartment you must work in. For more information about user authorizations for monitoring, see the Authentication and Authorization section in Overview of Monitoring.

The metrics listed on this page are automatically available for any DevOps instances that you create. You don't need to enable monitoring on the resource to get these metrics.

Available Metrics

DevOps metrics include the following dimensions:
- **projectId**: Project identifier
- **projectName**: Name of the DevOps project
- **buildPipelineId**: Build pipeline identifier
- **stageId**: Build stage identifier
- **lifecycleState**: Current state of the build pipeline
- **stageType**: Type of build stage
- **repositoryType**: Mirrored or Non mirrored (hosted)
- **repositoryId**: Code repository identifier
- **repositoryName**: Code repository name
- **pushType**: HTTP or SSH
- **pullType**: HTTP or SSH
- **deployPipelineId**: Pipeline identifier
- **displayName**: Name of the pipeline
- **deployStageId**: Stage identifier
- **deployStageName**: Stage name

</tbody>
</table>

### Using the Console

Here's how you view the metric charts:

1. In the Console, open the navigation menu. Under **Observability & Management**, go to **Monitoring** and click **Service Metrics**.
2. Select the compartment that contains the DevOps deployments and pipelines whose performance you want to monitor.
3. For **Metric namespace**, select `oci_devops_build`, `oci_devops_deployment`, or `oci_devops_code_repos`.

The **Service Metrics** page dynamically updates the page to show charts for each metric that the selected metric namespace emits.

### Using the API

To monitor the metrics, use the **Monitoring API**.

For information about using the API and signing requests, see REST APIs and Security Credentials.

### DevOps IAM Policies

Create IAM policies to control who has access to DevOps resources, and to control the type of access for each group of users.

Before you can control access to DevOps resources such as code repositories, build pipelines, and deployment pipelines, you must create users and place them in appropriate groups (see Managing Users and Managing Groups). You can then create policies and policy statements to control the access (see Managing Policies).

By default, users in the **Administrators** group have access to all the DevOps resources. If you are new to IAM policies, see Getting Started with Policies.

For a complete list of all policies in Oracle Cloud Infrastructure, see the Policy Reference and Common Policies.

This section explains the following topics:

- Resource Types and Permissions
DevOps

- Supported Variables
- Details for Verb + Resource Type Combination
- Creating a Policy
- Policy Examples

**Resource Types and Permissions**

List of DevOps resource types and associated permissions.

To assign permissions to all DevOps resources, use the `devops-family` aggregate type. For more information, see Permissions.

A policy that uses `<verb> devops-family` is equivalent to writing a policy with a separate `<verb> <resource-type>` statement for each of the individual resource types.

</tbody>
</table>
**Supported Variables**

Variables are used when adding conditions to a policy.

DevOps supports the following variables:

- **Entity**: Oracle Cloud Identifier (OCID)
- **String**: Free-form text.
- **Number**: Numeric value (arbitrary precision)
- **List**: List of Entity, String, or Number
- **Boolean**: True or False

See [General Variables for All Requests](#).

Variables are lowercase and hyphen-separated. For example, `target.tag-namespace.name`, `target.display-name`. Here `name` must be unique, and `display-name` is the description.

Required variables are supplied by the DevOps service for every request. Automatic variables are supplied by the authorization engine (either service-local with the SDK for a thick client, or on the Identity data plane for a thin client).

<table>
<thead>
<tr>
<th>Required Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>target.compartment.id</code> : ENTITY</td>
<td>The OCID of the primary resource for the request</td>
</tr>
<tr>
<td><code>request.operation</code> : STRING</td>
<td>The operation ID (for example, <code>GetUser</code>) for the request</td>
</tr>
<tr>
<td><code>target.resource.kind</code> : STRING</td>
<td>The resource kind name of the primary resource for the request</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Automatic Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>request.user.id</code> : ENTITY</td>
<td>(For user-initiated requests) The OCID of the calling user</td>
</tr>
<tr>
<td><code>request.groups.id</code> : LIST(ENTITY)</td>
<td>(For user-initiated requests) The OCIDs of the groups of <code>request.user.id</code></td>
</tr>
<tr>
<td><code>target.compartment.name</code> : STRING</td>
<td>The name of the compartment specified in <code>target.compartment.id</code></td>
</tr>
<tr>
<td><code>target.tenant.id</code> : ENTITY</td>
<td>The OCID of the target tenant ID</td>
</tr>
</tbody>
</table>

Here's a list of available sources for the variables:

- **Request**: Comes from the request input.
- **Derived**: Comes from the request.
- **Stored**: Comes from the service, retained input.
- **Computed**: Computed from service data.

<td>Available for Get, Update, Delete, and Cancel operations on the Build Run resource.</td>
</tr>
</tbody>
</table>

## Details for Verb + Resource Type Combinations

Identify the permissions and API operations covered by each verb for DevOps resources.

The level of access is cumulative as you go from inspect to read to use to manage. A plus sign (+) in a table cell indicates incremental access when compared to the preceding cell.

For information about granting access, see Permissions.

### devops-project

This table lists the permissions and the APIs that are fully covered by the permissions, for the devops-project resource.

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Covered</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>DEVOPS_PROJECT_INSPECT</td>
<td>ListProjects</td>
<td>List all the project resources in a compartment.</td>
</tr>
<tr>
<td>read</td>
<td>inspect+ DEVOPS_PROJECT_READ</td>
<td>inspect+ GetProject</td>
<td>Get a specific project by ID.</td>
</tr>
<tr>
<td>use</td>
<td>read+ DEVOPS_PROJECT_UPDATE</td>
<td>read+ UpdateProject</td>
<td>Update a specific project.</td>
</tr>
<tr>
<td>manage</td>
<td>use+ DEVOPS_PROJECT_CREATE</td>
<td>use+ CreateProject</td>
<td>Create a project resource.</td>
</tr>
<tr>
<td>manage</td>
<td>use+ DEVOPS_PROJECT_DELETE</td>
<td>use+ DeleteProject</td>
<td>Delete a specific project.</td>
</tr>
<tr>
<td>manage</td>
<td>use+ DEVOPS_PROJECT_MOVE</td>
<td>use+ ChangeProjectCompartment</td>
<td>Move a project to a different compartment.</td>
</tr>
</tbody>
</table>

### devops-deploy-artifact

This table lists the permissions and the APIs that are fully covered by the permissions, for the devops-deploy-artifact resource.
<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Covered</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>DEVOPS_DEPLOY_ARTIFACT_INSPECT</td>
<td>ListDeployArtifacts</td>
<td>List all the artifacts in a project or compartment.</td>
</tr>
<tr>
<td>read</td>
<td>inspect+</td>
<td>inspect+</td>
<td>Get a specific artifact by ID.</td>

<tr>
<td>manage</td>
<td>use+</td>
<td>use+</td>
<td>Create a stage in a build pipeline.</td>
</tr>
<tr>
<td>manage</td>
<td>use+</td>
<td>use+</td>
<td>Delete specific build pipeline stage by ID.</td>
</tr>
</tbody>
</table>

### devops-build-run

This table lists the permissions and the APIs that are fully covered by the permissions, for the devops-build-run resource.

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Permissions</th>
<th>APIs Covered</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>DEVOPS_BUILD_RUN_INSPECT</td>
<td>ListBuildRuns</td>
<td>List the build runs in a project or compartment.</td>
</tr>
<tr>
<td>read</td>
<td>inspect+</td>
<td>inspect+</td>
<td>Gets a specific build run by ID.</td>
</tr>
<tr>
<td>use</td>
<td>read+</td>
<td>read+</td>
<td>Update an existing build run.</td>
</tr>
<tr>
<td>use</td>
<td>read+</td>
<td>read+</td>
<td>Cancel a running build run.</td>
</tr>
<tr>
<td>manage</td>
<td>use+</td>
<td>use+</td>
<td>Start a build run for a given build pipeline.</td>
</tr>
<tr>
<td>manage</td>
<td>use+</td>
<td>use+</td>
<td>Delete an existing build run.</td>
</tr>
</tbody>
</table>

### Creating a Policy

Here's how you create a policy in the Oracle Cloud Console:

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Policies**.
2. Click Create Policy.
3. Enter a name and description for the policy.
4. Under Policy Builder, click the Show manual editor switch to enable the editor.

   Enter a policy rule in the following format:

   ```
   allow service devops to <verb> <resource_type> in <compartment or tenancy details>
   ```

5. Click Create.

   For more information about creating policies, see How Policies Work and Policy Reference.

**Policy Examples**

DevOps policies required for using various DevOps resources such as code repositories, build pipelines and deployment pipelines.

Following policy examples are provided:

- Code repository policies
- Build pipeline policies
- Deployment pipeline policies
- Artifact policies

**Code Repository Policies**

Policy examples for creating your own private code repositories and connecting to external code repositories such as GitHub and GitLab.

See the instructions for creating policies using the console.

- Create dynamic groups for your code repository. You can name the dynamic group as, for example, CoderepoDynamicGroup and replace compartmentOCID with the OCID of your compartment:

  ```
  ALL {resource.type = 'devopsrepository', resource.compartment.id = 'compartmentOCID'}
  ```

  For more information about dynamic groups, including the permissions required to create them, see Managing Dynamic Groups and Writing Policies for Dynamic Groups.

- Create following IAM policies:
  - Allow the dynamic group to manage the DevOps resources in the compartment:

    ```
    Allow dynamic-group CoderepoDynamicGroup to manage devops-family in compartment <compartment_name>
    ```
  
  - Allow the code repositories to access all your tenancy resources:

    ```
    Allow dynamic-group CoderepoDynamicGroup to manage all-resources in tenancy
    ```
  
  - To integrate with external code repositories such as GitHub and GitLab, create a policy in the root compartment. For example, to allow the dynamic group to read secrets:

    ```
    ALL {resource.type = 'devopsconnection', resource.compartment.id = 'compartmentOCID'}
    ```

    ```
    Allow dynamic-group <DynamicGroupName> to read secret-family in tenancy
    ```
Build Pipeline Policies
Policy examples for creating build pipelines and adding stages to the pipeline.

See the instructions for creating policies using the console.

- Create dynamic groups for your build pipeline. You can name the dynamic group as, for example, BuildDynamicGroup and replace compartmentOCID with the OCID of your compartment:

  ```
  ALL {resource.type = 'devopsbuildpipeline', resource.compartment.id = 'compartmentOCID'}
  ```

  For more information about dynamic groups, including the permissions required to create them, see Managing Dynamic Groups and Writing Policies for Dynamic Groups.

- Create IAM policies to allow the dynamic group to access OCI resources in the compartment:

  - To deliver artifacts, provide access to the Container Registry (OCIR):

    ```
    Allow dynamic-group BuildDynamicGroup to manage repos in compartment <compartment_name>
    ```

  - To access vault for personal access token (PAT), provide access to secret-family. This policy is required in the Managed Build stage for accessing PAT to download the source code:

    ```
    Allow dynamic-group BuildDynamicGroup to read secret-family in compartment <compartment_name>
    ```

  - Provide access to read deployment artifacts in the Deliver Artifacts stage, read DevOps code repository in the Managed Build stage, and trigger deployment pipeline in the Trigger Deploy stage:

    ```
    Allow dynamic-group BuildDynamicGroup to manage devops-family in compartment <compartment_name>
    ```

  - To deliver artifacts, provide access to the Artifact Registry:

    ```
    Allow dynamic-group BuildDynamicGroup to manage generic-artifacts in compartment <compartment_name>
    ```

  - To send notifications, provide access to the build pipeline:

    ```
    Allow dynamic-group BuildDynamicGroup to use ons-topics in compartment <compartment_name>
    ```

Deployment Pipeline Policies
Policy examples for creating deployment pipelines and adding stages to the pipeline.

See the instructions for creating policies using the console.

- Create dynamic groups for your deployment pipeline. You can name the dynamic group as, DeployDynamicGroup and replace compartmentOCID with the OCID of your compartment:

  ```
  All {resource.type = 'devopsdeploypipeline', resource.compartment.id = 'compartmentOCID'}
  ```

  For more information about dynamic groups, including the permissions required to create them, see Managing Dynamic Groups and Writing Policies for Dynamic Groups.
DevOps

- Create IAM policies to give permissions to access tenancy resources:
  - Allow the deployment pipeline dynamic group to access your tenancy resources:
    ```
    Allow dynamic-group DeployDynamicGroup to manage all-resources in tenancy
    ```

    This policy gives access to all Oracle Cloud Infrastructure resource types in your tenancy, but you can create IAM policies to give access to specific resource types or compartments. For more information, see Policy Reference.

- For an instance group deployment, you also need to create a dynamic group for these instances and give the dynamic group certain permissions:
  - Create a dynamic group for your instances. For example, you can name the dynamic group as, DeployComputeDynamicGroup and replace compartmentOCID with the OCID of your compartment:
    ```
    All {instance.compartment.id = 'compartmentOCID'}
    ```
  - Create IAM policies to give required access to the deployment instances:
    ```
    Allow dynamic-group DeployComputeDynamicGroup to use instance-agent-command-execution-family in compartment <compartment_name>
    ```
    ```
    Allow dynamic-group DeployComputeDynamicGroup to read generic-artifacts in compartment <compartment_name>
    ```

Artifact Policies

Policy examples for adding the Deliver Artifacts stage to the build pipeline.

The Deliver Artifacts stage maps the build outputs from the Managed Build stage with the version to deliver to a DevOps artifact resource, and then to the Oracle Cloud Infrastructure (OCI) code repository. DevOps supports artifacts stored in OCI Container Registry and Artifact Registry repositories. See Adding a Deliver Artifacts Stage.

See the instructions for creating policies using the console.

- Create dynamic groups for your build pipeline. You can name the dynamic group as, for example, BuildDynamicGroup and replace compartmentOCID with the OCID of your compartment:
  ```
  ALL {resource.type = 'devopsbuildpipeline', resource.compartment.id = 'compartmentOCID'}
  ```

For more information about dynamic groups, including the permissions required to create them, see Managing Dynamic Groups and Writing Policies for Dynamic Groups.
Create following IAM policies:

- Ability to see a list of all repositories in Container Registry belonging to the tenancy or to a particular compartment:
  
  ```
  Allow dynamic-group BuildDynamicGroup to inspect repos in tenancy
  ```

  ```
  Allow dynamic-group BuildDynamicGroup to inspect repos in compartment <compartment_name>
  ```

- Allow artifacts to be pushed to the Container Registry (OCIR) that belongs to the tenancy or to a particular compartment:

  ```
  Allow dynamic-group BuildDynamicGroup to use repos in tenancy
  ```

  ```
  Allow dynamic-group BuildDynamicGroup to use repos in compartment <compartment_name>
  ```

See Policies to Control Repository Access.

- Ability to see a list of generic artifacts in Artifact Registry belonging to the tenancy or to a particular compartment:

  ```
  Allow dynamic-group BuildDynamicGroup to inspect generic-artifacts in tenancy
  ```

  ```
  Allow dynamic-group BuildDynamicGroup to inspect generic-artifacts in compartment <compartment_name>
  ```

- Allow generic artifacts to be pushed to the Artifact Registry that belongs to the tenancy or to a particular compartment:

  ```
  Allow dynamic-group BuildDynamicGroup to use generic-artifacts in tenancy
  ```

  ```
  Allow dynamic-group BuildDynamicGroup to use generic-artifacts in compartment <compartment_name>
  ```

See Artifact Registry IAM Policies.

### Accessing Artifact Registry

Oracle Cloud Infrastructure Artifact Registry is a repository service for storing, sharing, and managing software development packages.

You can access the artifacts that you store in Artifact Registry from the DevOps service. Your administrator must grant the `read all-artifacts` permission to the pipeline resources.

The `read all-artifacts` permission allows the DevOps service to get information and download the following resources:

- Artifact Registry: `artifact-repositories`
- Artifact Registry: `generic-artifacts`
- Compute instances: `instance-images`
- Container Registry: `repos`

To access the artifacts from the deployment pipeline, perform these actions:
• Create dynamic groups for your deployment pipeline. You can name the dynamic group as, DeployDynamicGroup and replace compartmentOCID with the OCID of your compartment:

```
All {resource.type = 'devopsdeploypipeline', resource.compartment.id = 'compartmentOCID'}
```

For more information about dynamic groups, including the permissions required to create them, see Managing Dynamic Groups and Writing Policies for Dynamic Groups.

• Create IAM policies to allow the dynamic groups to access the artifacts from a specific compartment:

```
Allow dynamic-group DeployDynamicGroup to read all-artifacts in compartment <compartment_name>
```

```
Allow dynamic-group DeployDynamicGroup to read instance-images in compartment <compartment_name>
```

For more information, see Artifact Registry IAM Policies.

**Troubleshooting DevOps**

Identify the causes and fixes for common problems with the DevOps service.

**Deploying Applications to OKE**

Fix problems that can occur when you attempt to deploy applications to a Container Engine for Kubernetes (OKE) cluster.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Error message</th>
<th>Cause</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apply Kubernetes manifest step fails because of authorization error.</td>
<td>Authorization failed or requested resource not found.</td>
<td>Either cluster does not exist or dynamic group and policy is missing to provide the pipeline resource access to other Oracle Cloud Infrastructure (OCI) resources in the compartment.</td>
<td>Check if relevant OCI resources exist and a dynamic group is created for the OCI DevOps deploy pipeline resource along with a policy for allowing this dynamic group to access relevant OCI resources. For example, create a dynamic group for your deployment pipeline. You can name the dynamic group as, DeployDynamicGroup and replace compartmentOCID with the OCID of your compartment: All {resource.type = 'devopsdeploypipeline', resource.compartment.id = 'compartmentOCID'} Create an IAM policy to allow the dynamic group to access all the resources: Allow dynamic-group DeployDynamicGroup to manage all-resources in compartment &lt;compartment_name&gt; See DevOps IAM Policies.</td>

DevOps Plug-in for Jenkins

This topic provides information about installing, configuring, and using the Oracle Cloud Infrastructure (OCI) DevOps plug-in for Jenkins.

You can use the DevOps plug-in to upload artifacts, and run deployments on OCI from Jenkins. A Jenkins controller instance with the DevOps plug-in can upload artifacts to the Artifacts Registry repository and trigger the deployment pipeline for deploying those artifacts.

- **Licensing:** The DevOps plug-in is Universal Permissive License (UPL) licensed; third-party content is separately licensed as described in the code.
- **Download:** GitHub
- **Documentation:** OCI DevOps Plug-in for Jenkins

Contributions

Do you have a fix for a bug, or a new feature you'd like to contribute? The DevOps plug-in is open source and accepting pull requests on GitHub.

Notifications

To be notified when a new version of the DevOps plug-in for Jenkins is released, subscribe to the Atom feed.

Questions or Feedback

- **GitHub:** To file bugs and feature requests only.
- **Stack Overflow:** Use the oracle-cloud-infrastructure tag in your post.
- **My Oracle Support**

Build Specification

The build specification contains build steps and settings that the build pipeline uses to run a build.

The build specification is written in YAML. By default, the build specification is located in the root of your primary build source directory and is used when you run a build pipeline. The file is named as build_spec.yml or build_spec.yaml. If the build spec is not present in the root directory, then you have to provide relative path of the file when adding the Managed Build stage.

The build specification is organized into following sections:

- Configuration of the build runner.
- Setup of environment variables.
- Steps to run in sequence.
- Output artifacts.

Build Specification Syntax

```yaml
version: 0.1
component: build
timeoutInSeconds: 10000
shell: bash
```
DevOps

env:
  variables:
    key: "value"
    key: "value"

  vaultVariables:
    key: "secret-id"

exportedVariables:
  - variable
  - variable

inputArtifacts:
  - name: artifact-name
    location: target-location
  - name: artifact-name
    url: downloadable link
    location: target-location

steps:
  - type: Command
    name: step-name
    shell: shellType
    timeoutInSeconds: 650
    command: command
    onFailure:
      - type: Command
        command: |
        command
        command
        timeoutInSeconds: 400

      - type: Command
        name: step-name
        command: |
        command
        command
        command
        onFailure:
          - type: Command
            command: |
            command
            timeoutInSeconds: 400

outputArtifacts:
  - name: artifact-name
    type: artifact-type
    location: source-location

Note:

sudo is not available on the build runner host. If you need superuser permissions, then run your build step as the root user.

Build Specification Parameters

Following are the build specification parameters and their details:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>Mandatory. Indicates the build specification version. A missing or invalid version causes Build stage failure.</td>
</tr>
<tr>
<td></td>
<td>Supported value is 0.1.</td>
</tr>
<tr>
<td>component</td>
<td>Mandatory. Indicates a particular component in DevOps. A missing or invalid value causes build failure.</td>
</tr>
<tr>
<td></td>
<td>Supported value is build.</td>
</tr>
<tr>
<td>timeoutInSeconds</td>
<td>Optional. Specifies the timeout for the whole build specification file. Each 'step' can also optionally have its own timeout value.</td>
</tr>
<tr>
<td></td>
<td>If a value is not specified, then the default value of 8 hours is used. The maximum allowed value is 8 hours.</td>
</tr>
<tr>
<td>shell</td>
<td>Optional. Specifies the shell to be used at the build specification global level. The value can be optionally overridden at the 'step' level.</td>
</tr>
<tr>
<td></td>
<td>Allowed values are /bin/sh and bash. If not specified, then the default value of bash is used.</td>
</tr>
<tr>
<td>env</td>
<td>Optional. You can define custom variables. Three types of variables are supported:</td>
</tr>
<tr>
<td></td>
<td>• <strong>env/variables</strong>: Optional. The key must be a string and POSIX environment variable compliant. The value can be any string. The scope of this variable is the execution of the build specification file. Any change to the value of the variable is visible in the subsequent steps. These variables are available as environment variables for all the steps inside the build specification file. If the value of the variable contains new line(\n) or carriage return(\r) character, then they are replaced with space in the subsequent steps.</td>
</tr>
<tr>
<td></td>
<td>• <strong>env/vaultVariables</strong>: Optional. The key must be a string and POSIX environment variable compliant. The value must be an OCID of the secret from the vault. The vault and build pipeline must be of the same tenancy. The tenancy must have appropriate policy to allow build pipeline resources to access the secret. The scope of this variable is the execution of the build specification file and is available to all the steps in the file. The value for these variables is retrieved from the vault and made available as environment variables for all the steps inside the build specification file.</td>
</tr>
<tr>
<td></td>
<td>• <strong>env/exportedVariables</strong>: Optional. A list of variables can be declared here. The name of the variable must be a string and POSIX environment variable compliant. The value can be assigned in any of the steps inside the build specification file. The scope of this variable is the build pipeline. Any exported variable is available in subsequent stages of the same pipeline.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>inputArtifacts</td>
<td>Optional. Used to define list of input artifacts that are required for running the current Build stage. Supports two types of input artifacts:</td>
</tr>
<tr>
<td></td>
<td>- Artifacts from any of the previous Build stages.</td>
</tr>
<tr>
<td></td>
<td>- Artifacts from any external downloadable HTTP URL.</td>
</tr>
<tr>
<td></td>
<td>The parameters are as follows:</td>
</tr>
<tr>
<td></td>
<td>- <strong>inputArtifacts/*/url</strong>: Optional. The input artifact external downloadable HTTP URL must be provided. The URL must be publicly available. Currently authentication/authorization is not supported.</td>
</tr>
<tr>
<td></td>
<td>- <strong>inputArtifacts/*/name</strong>: Mandatory. If the URL is not present, then this name is used to search for the artifacts produced by the previous Build stages in the same pipeline. Hence, the outputArtifacts/name and inputArtifacts/name must match to consume a specific artifact produced by the previous Build stage in the pipeline.</td>
</tr>
<tr>
<td></td>
<td>- <strong>inputArtifacts/*/location</strong>: Mandatory. A destination path of the local file system where the input artifact needs to be downloaded. The path can be specified in one of these methods:</td>
</tr>
<tr>
<td></td>
<td>- <code>${OCI_PRIMARY_SOURCE_DIR}/pom.xml</code></td>
</tr>
<tr>
<td></td>
<td>- <code>${OCI_WORKSPACE_DIR}/[source-name]/pom.xml</code></td>
</tr>
<tr>
<td></td>
<td>- <code>/workspace/[source-name]/pom.xml</code></td>
</tr>
<tr>
<td></td>
<td>Relative path from project home, pom.xml</td>
</tr>
<tr>
<td></td>
<td>With any one of the values, the input artifact is downloaded to the primary source home directory with a file name, pom.xml. Location does not support exportedVariables or pipeline variables.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>steps</td>
<td>Mandatory. This section defines a list of steps that need to be run.</td>
</tr>
<tr>
<td></td>
<td>• steps/*/type: Mandatory. Specifies the type of the step. Supports only one value, Command.</td>
</tr>
<tr>
<td></td>
<td>• steps/<em>/command: Mandatory field for the Command step type. Both single line and multiple line commands are supported. All the commands specified in one step are run in the same shell session. Based on the steps/</em>/shell value, commands can either be shell or bash.</td>
</tr>
<tr>
<td></td>
<td>Fail fast is not enabled. For the step to be successful, output of the last command in a step is considered. If the last command exit code is 0, then the step is considered as successful.</td>
</tr>
<tr>
<td></td>
<td>• steps/*/name: Optional. A user-friendly name for the step.</td>
</tr>
<tr>
<td></td>
<td>• steps/*/timeoutInSeconds: Optional. Specifies the timeout for the step. If not provided, then the value is inherited from the global timeoutInSeconds parameter. The maximum allowed value is 8 hours.</td>
</tr>
<tr>
<td></td>
<td>• steps/*/shell: Optional. Specifies the shell type of the current step. If not specified, then the value is inherited from the global shell parameter. Allowed values are /bin/sh and shell.</td>
</tr>
<tr>
<td></td>
<td>• steps/*/onFailure: Optional. A list of steps that must be run on failure to gracefully exit the build stage. Run if the corresponding step fails, and after execution the build specification is exited.</td>
</tr>
<tr>
<td></td>
<td>Handling the failure does not affect the status of the build stage. If any one of the steps fails, then the build stage status remains failed, although handled using onFailure block.</td>
</tr>
<tr>
<td></td>
<td>Fail fast is not enabled. Hence, output of the last command in a step is considered for the step to be successful. If the last command exit code is 0, then the step is considered as successful.</td>
</tr>
</tbody>
</table>
## Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>outputArtifacts</td>
<td>Optional. Specifies the artifacts produced by the Build stage. The artifacts produced as output in this section are saved for the lifetime of the current build run. They can be used in the subsequent stages in the build pipeline.</td>
</tr>
<tr>
<td></td>
<td>• <strong>outputArtifacts/*/name</strong>: Mandatory. The name can contain lowercase letters (a-z), uppercase letters (A-Z), underscore (_), and hyphens (-). The name is the unique identifier for the output artifact. In the subsequent stages of the build pipeline, name is used to identify an artifact.</td>
</tr>
<tr>
<td></td>
<td>• <strong>outputArtifacts/*/type</strong>: Mandatory. Allowed values are BINARY and DOCKER_IMAGE.</td>
</tr>
<tr>
<td></td>
<td><strong>BINARY</strong>: Specifies binary files as output artifacts.</td>
</tr>
<tr>
<td></td>
<td><strong>outputArtifacts/*/location</strong>: A source path of the local file system where the output artifact can be found. The path can be specified in either of these methods (assume that the pom.xml file is present in the primary source home directory):</td>
</tr>
<tr>
<td></td>
<td>• <code>$OCI_PRIMARY_SOURCE_DIR&gt;/pom.xml</code></td>
</tr>
<tr>
<td></td>
<td>• <code>$OCI_WORKSPACE_DIR/,[source-name]/pom.xml</code></td>
</tr>
<tr>
<td></td>
<td>• <code>/workspace/[source-name]/pom.xml</code></td>
</tr>
<tr>
<td></td>
<td>• Relative path from project home, pom.xml</td>
</tr>
<tr>
<td></td>
<td>If the file is not found in the provided location, then the Build stage fails.</td>
</tr>
<tr>
<td></td>
<td><strong>DOCKER_IMAGE</strong>: Specifies a Docker image as the output artifact.</td>
</tr>
<tr>
<td></td>
<td><strong>outputArtifacts/*/location</strong>: A built Docker image tag that is built on one of the steps in the build specification file.</td>
</tr>
<tr>
<td></td>
<td>For example, if in any one of the steps in the build specification file, a Docker image is built as, <code>docker build -t iad.ocir.io/ id204we8d65n/hello-world:1.0</code>, then the location field must contain <code>iad.ocir.io/id204we8d65n/hello-world:1.0</code> for producing this artifact.</td>
</tr>
<tr>
<td></td>
<td>The image must be built or pulled, and made available in one of the build specification steps. Otherwise, the outputArtifact step fails and eventually the Build stage also fails.</td>
</tr>
<tr>
<td></td>
<td>Location does not support exportedVariables or pipeline variables.</td>
</tr>
</tbody>
</table>

## Predefined System Variables

DevOps provides a set of predefined system variables with default values that you can use like environment variables in the build specification.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OCI_STAGE_ID</td>
<td>The OCID of the current stage.</td>
</tr>
<tr>
<td>OCI_PIPELINE_ID</td>
<td>The OCID of the current build pipeline.</td>
</tr>
<tr>
<td>OCI_BUILD_RUN_ID</td>
<td>The OCID of the current build run.</td>
</tr>
<tr>
<td>OCI_TRIGGER_COMMIT_HASH</td>
<td>Commit hash of the current trigger.</td>
</tr>
<tr>
<td>OCI_TRIGGER_SOURCE_BRANCH_NAME</td>
<td>Branch that triggers the build.</td>
</tr>
<tr>
<td>OCI_TRIGGER_SOURCE_URL</td>
<td>Repository URL that triggered the build</td>
</tr>
<tr>
<td>OCI_TRIGGER_EVENT_TYPE</td>
<td>Trigger that started the event.</td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>OCI_PRIMARY_SOURCE_DIR</td>
<td>Default working directory of the build (primary source working directory).</td>
</tr>
<tr>
<td>OCI_WORKSPACE_DIR</td>
<td>Working directory value. Contains /workspace as the default value.</td>
</tr>
<tr>
<td>${OCI_WORKSPACE_DIR}/&lt;source-name&gt;</td>
<td>Build source directory path.</td>
</tr>
<tr>
<td></td>
<td>source-name is the name of the build source given by the user while creating the Build stage.</td>
</tr>
<tr>
<td>OCI_BUILD_STAGE_NAME</td>
<td>Build stage name.</td>
</tr>
<tr>
<td>OCI_PRIMARY_SOURCE_NAME</td>
<td>Primary build source name.</td>
</tr>
</tbody>
</table>

**Build Specification Examples**

**Example 1:**

```yaml
version: 0.1
component: build
timeoutInSeconds: 1000
shell: bash

steps:
- type: Command
  name: "Install Maven"
  command: |
  mvn clean install
```

**Example 2:**

```yaml
version: 0.1
component: build
timeoutInSeconds: 6000
shell: bash
env:
  exportedVariables:
    - BuildServiceDemoVersion

steps:
- type: Command
  name: "Build Source"
  timeoutInSeconds: 4000
  command: |
    echo $PATH
    mvn clean install
- type: Command
  timeoutInSeconds: 400
  name: "Dockerizer"
  command: |
    BuildServiceDemoVersion=`echo ${OCI_BUILD_RUN_ID} | rev | cut -c 1-7`
    echo $BuildServiceDemoVersion
    docker build -t build-service-demo .

outputArtifacts:
- name: build-service-demo
  type: DOCKER_IMAGE
  location: build-service-demo
- name: build-service-demo-kube-manifest
  type: BINARY
```
Example 3:

```yaml
version: 0.1
component: build
timeoutInSeconds: 6000
shell: bash

# Variables
ev:
  variables:
    "testEnv" : "testValue1"
  vaultVariables:
    docker_registry_password : <secret-ocid>
  exportedVariables:
    - patch_number
    - build_Result

inputArtifacts:
  - name: hello-dev-jar # There should be a build stage producing this artifact before this stage
    location: /workspace/Source/hello123.class
  - name: public-artifact
    url: https://raw.githubusercontent.com/apache/kafka/trunk/README.md # url should be publicly accessible
    location: /workspace/Source/readme.md

steps:
  - type: Command
    name: "Build Source"
    timeoutInSeconds: 4000
    shell: /bin/sh
    command: |
      # oci cli pre configured with build pipeline resource principal
      oci os ns get
      javac HelloWorld.java
    onFailure:
      - type: Command
        timeoutInSeconds: 400
        shell: /bin/sh
        command: |
          echo "Handling Failure"
          build_result=FAILURE
          echo "Failure successfully handled"
        timeoutInSeconds: 400
  - type: Command
    name: "Dockerizer & Test"
    timeoutInSeconds: 400
    command: |
      docker build -t test-image .
    onFailure:
      - type: Command
        command: |
          echo "Handling Failure"
          build_result=FAILURE
          echo "Failure successfully handled"
        timeoutInSeconds: 400
  - type: Command
    name: "Dockerizer & Test"
    command: |
      build_result=SUCCESS
```

Oracle Cloud Infrastructure User Guide
DevOps

```bash
patch_number==`echo $(OCI_BUILD_RUN_ID) | rev | cut -c 1-7`

outputArtifacts:
  - name: kube-manifest
    type: BINARY
    location: ${OCI_WORKSPACE_DIR}/Source/app.yml
  - name: hello-dev-image
    type: DOCKER_IMAGE
    location: test-image
```

**Deployment Configuration File**

The deployment configuration file defines the artifacts to be downloaded to the instance and the location where the artifacts must be copied. The configuration file also specifies the sequence of commands for deployment.

The configuration file is written in YAML. The file can be defined inline or provided as a generic artifact reference during instance group deployment.

DevOps admins can use the deployment configuration file for the following actions:

- Specify application packages and their locations for storing in the target compute instance.
- Specify the steps required to deploy an application.
- Specify user-defined or built-in environment variables required for deployment.

**Deployment Configuration File Structure**

Following is the basic structure of the deployment configuration file:

```yaml
{
  version:
  component:
  env:
    variables:
  timeoutInSeconds:
  files:
    - source:
      destination:
  steps:
    - stepType: Command
      name:
      command:
      runAs:
      timeoutInSeconds:
    - stepType: Command
}
```

Following are the deployment configuration parameters and their details:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>Version number of the specification file. Value must be 1.0.</td>
</tr>
<tr>
<td>component</td>
<td>Component value. The only supported value is deployment.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>env: variables</td>
<td>User-defined environment variables that are available to the executables or the bash command that run as a part of the deployment.</td>
</tr>
<tr>
<td></td>
<td>Examples: key1: static-value, key2: $(PASSED_FROM_PIPELINE)</td>
</tr>
<tr>
<td></td>
<td>Built-in variables can also be used. To avoid conflict, built-in variables are prefixed with OCI_DEVOPS.</td>
</tr>
<tr>
<td></td>
<td>Built-in variables are:</td>
</tr>
<tr>
<td></td>
<td>• OCI_DEVOPS_PIPELINE_ID</td>
</tr>
<tr>
<td></td>
<td>• OCI_DEVOPS_STAGE_ID</td>
</tr>
<tr>
<td></td>
<td>• OCI_DEVOPS_DEPLOYMENT_ID</td>
</tr>
<tr>
<td></td>
<td>env is an optional parameter.</td>
</tr>
<tr>
<td>files</td>
<td>Specifies the artifacts defined in the deployment pipeline that must be copied and the target compute instance location to copy them to. This parameter is optional.</td>
</tr>
<tr>
<td></td>
<td>A deployment requires the user to have write and execute permissions (chmod o+wx) for the destination's parent directory where you deploy the artifacts. Every ancestor directory of the destination's parent directory requires execute permission (chmod o+x). If the destination folder doesn't exist, then DevOps deployment creates it.</td>
</tr>
<tr>
<td></td>
<td>For example, if you assign the destination directory in the deployment configuration file as /var/services/accountService, then you have to provide write and execute permissions for /var/services, and execute permission for /var.</td>
</tr>
<tr>
<td>files: source</td>
<td>Specifies the source location of the artifacts. The source can refer to a file or folder. If the source is a file, then that file is copied to the folder defined in the destination. If a folder, then all the contents of that folder are copied to the destination. The source uses relative path, whose root is the root folder of one or more artifacts.</td>
</tr>
<tr>
<td></td>
<td>For example, if the general artifact specifies a single file, run.sh, then this file is downloaded to the root (/) folder in the source. If the general artifact is an archive, for example, app_pkg.zip, then the root of the archive content is the root folder.</td>
</tr>
<tr>
<td>files: destination</td>
<td>Specifies the target folder where the source file or folder must be copied.</td>
</tr>
<tr>
<td>steps</td>
<td>Specifies the list of steps that are run sequentially during the deployment. Each step runs as a different process on the instance. All the specified built-in and user-defined environment variables are passed to the process.</td>
</tr>
<tr>
<td>steps: name</td>
<td>User-defined name for the step.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>steps: command</td>
<td>Shell command or shell executable.</td>
</tr>
<tr>
<td></td>
<td>If the files parameter is specified in the configuration file, then the location path for the executable is an absolute path, for example /tmp/genericArtifactDemo/start.sh. If the files parameter is not specified, then relative path is used to specify the location of the executable. The relative path refers to the working folder of the deployment. The artifacts are downloaded and extracted to the current working folder of the deployment.</td>
</tr>
<tr>
<td>steps: runAs</td>
<td>Run the step as the specified user. By default all steps are run as the ocarun user.</td>
</tr>
<tr>
<td>steps: timeoutInSeconds</td>
<td>Specifies the timeout period to finish a step.</td>
</tr>
</tbody>
</table>

Following is an example of a deployment configuration file:

```json
version: 1.0
component: deployment
runAs: root
env:
  variables:
    version: ${appVersion}
files:
  # This section is to define how the files in the artifact shall be put on the compute instance
  - source: /
destination: /tmp/genericArtifactDemo
steps:
  # This section is to define the scripts that each step shall run on the instance after file copy.
  - stepType: Command
    name: Install Apache Web Server
    command: /tmp/genericArtifactDemo/install_dependencies.sh
    runAs: root
    timeoutInSeconds: 600
  - stepType: Command
    name: Stop Web Server
    command: /tmp/genericArtifactDemo/stop.sh
    runAs: root
    timeoutInSeconds: 60
  - stepType: Command
    name: Install New Version of Software
    command: /tmp/genericArtifactDemo/install.sh
    runAs: root
    timeoutInSeconds: 60
  - stepType: Command
    name: Start Web Server
    command: /tmp/genericArtifactDemo/start.sh
    runAs: root
    timeoutInSeconds: 60
```

**Running the Deployment Configuration File**

The DevOps service uses the RunCommand agent to run the commands specified in the configuration file on the target compute instance. For more information about enabling the RunCommand plug-in, see the “Prerequisites” section in Deploying to an Instance Group. If the deployment configuration file contains placeholders, then they are replaced with the values defined in the parameter list of the deployment. See Configuring Parameters.
This chapter explains how to create and manage your DNS zones and guide traffic to your endpoints based on various conditions.

The DNS service helps you create and manage your DNS zones. Traffic Management helps you guide traffic to your endpoints based on various conditions, including endpoint health and the geographic origins of DNS requests.

### Get Started

**Overview of the DNS Service**

The Oracle Cloud Infrastructure Domain Name System (DNS) service lets you create and manage your DNS zones. You can create zones, add records to zones, and allow Oracle Cloud Infrastructure's edge network to handle your domain's DNS queries.

See Supported Resource Records on page 2562 for additional information.
DNS Service Components

The following list describes the components used to build a DNS zone and make it accessible from the internet.

DOMAIN

Domain names identify a specific location or group of locations on the Internet as a whole. A common definition of "domain" is the complete portion of the DNS tree that has been delegated to a user's control. For example, example.com or oracle.com.

ZONE

A zone is a portion of the DNS namespace. A Start of Authority record (SOA) defines a zone. A zone contains all labels underneath itself in the tree, unless otherwise specified.

LABEL

Labels are prepended to the zone name, separated by a period, to form the name of a subdomain. For example, the "www" section of www.example.com or the "docs" and "us-ashburn-1" sections of docs.us-ashburn-1.oraclecloud.com are labels. Records are associated with these domains.

CHILD ZONE

Child zones are independent subdomains with their own Start of Authority and Name Server (NS) records. The parent zone of a child zone must contain NS records that refer DNS queries to the name servers responsible for the child zone. Each subsequent child zone creates another link in the delegation chain.

RESOURCE RECORDS

A record contains specific domain information for a zone. Each record type contains information called record data (RDATA). For example, the RDATA of an A or AAAA record contains an IP address for a domain name, while MX records contain information about the mail server for a domain. OCI normalizes all RDATA into the most machine readable format. The returned presentation of your RDATA may differ from its initial input. For more information about RDATA, please see Supported DNS Resource Record Types.

DELEGATION

The name servers where your DNS is hosted and managed.

Ways to Access the DNS Service

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference on page 3347.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.
**Monitoring Resources**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 4078 and Notifications on page 4900.

For information about available DNS service metrics and how to view them, see DNS Metrics on page 2581.

**DNS Service Capabilities and Limits**

The Oracle Cloud Infrastructure DNS service is limited to 1000 zones per account and 25,000 records per zone. Customers with zone and record size needs exceeding these values are encouraged to contact support at support.oracle.com. Zone file uploads are limited to 1 megabyte (MB) in size per zone file. If your zone file is larger than 1 MB, you will need to split the zone file into smaller batches to upload all of the zone information.

**Required IAM Service Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for DNS, see Details for the DNS Service.

Permissions are required for managing DNS. The level of access is cumulative as you go from inspect > read > use > manage. For example, the read verb covers permissions to read and inspect. The manage verb covers permissions for inspect, read, update, create, delete, and move.

**Policy examples:**

- To enable all operations on zones for a specific user group:

  ```
  Allow group <GroupName> to manage dns in tenancy <TenancyName>
  ```

- To enable a specific group to read zones:

  ```
  Allow group <GroupName> to read zones in tenancy <TenancyName>
  ```

- To create a read only DNS management group:

  ```
  Allow group <GroupName> to read dns in tenancy <TenancyName>
  ```

**Using the DNS Management Overview to Manage DNS Services**

This topic describes the Overview page in the DNS Management section of the Oracle Cloud Infrastructure Console. The Overview provides information on all of the available DNS services.

**Manage DNS Services Section**

The Manage DNS Services section provides you with details on Zones and Traffic Management Steering Policies and links to set them up.

Public DNS Zones hold the trusted DNS records that will reside on Oracle Cloud Infrastructure's nameservers. You can create public zones with publicly available domain names. Private DNS zones contain domain names that resolve DNS queries for private IP addresses within a VCN. You can create private zones to define your own domain name for private address resolution.

**Traffic Management Steering Policies** help you guide traffic to your endpoints based on various conditions, including endpoint health and the geographic origins of DNS requests.
Service Health and Documentation Section

The Service Health tile displays the availability status of all DNS zone management systems in the selected region, and allows you to easily navigate to the Console’s Oracle Cloud Infrastructure status page to check the availability status of all Oracle Cloud Infrastructure services, by region.

The Documentation list provides quick access to information about DNS offerings.

Supporting Services Section

The Supporting Services section provides links to additional DNS Management services available in the Console.

- Private Views allows you to logically group a set of private DNS zones.
- HTTP Redirects allows you to redirect HTTP traffic to another URL.
- TSIG Keys ensures that DNS packets originate from an authorized sender.

Getting Started Section

To make it easier to set up DNS Management, the Console has the following quickstart links to set up DNS services.

- Set Up a Zone creates and publishes a zone, complete with the necessary records.
- Private DNS allows you to define your own domain name for private endpoints.
- Set Up Steering Policies allows you to define the traffic management behavior for your zones.

Getting Started with DNS

If you’re new to Oracle Cloud Infrastructure DNS, this topic gives guidance on how to proceed.

What is DNS?

The Domain Name System (DNS) translates human-readable domain names to machine-readable IP addresses. A DNS nameserver stores the DNS records for a zone, and responds with answers to queries against its database. When you type a domain name into your browser, your operating system queries several DNS nameservers until it finds the authoritative nameserver for that domain. The authoritative nameserver then responds with an IP address or other requested record data. The answer is then relayed back to your browser and the DNS record is resolved to the web page.

Creating a Zone

In this step, you will create a zone. A zone holds the trusted DNS records that will reside on Oracle Cloud Infrastructure’s nameservers.

To add a zone

1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click Create Zone.
3. In the Create Zone dialog box, choose one of the following methods:
   - **Manual** - Enter the following:
     - **Zone Name**: Enter the name of a zone you want to create. Avoid entering confidential information.
     - **Zone Type**: If you want to control the zone contents directly within Oracle Cloud Infrastructure, select Primary. If you want Oracle Cloud Infrastructure to pull zone contents from an external server, select Secondary and enter your Zone Master Server IP address.
     - **Import** - Drag and drop, select, or paste a valid zone file into the Import Zone File window. The zone is imported as a primary zone. For information about formatting a zone file, see Formatting a Zone File.
4. Click Submit.

The system creates and publishes the zone, complete with the necessary SOA and NS records. For more information on adding a record to your zone, see To add a zone record.
Delegating Your Zone

In this step, you will delegate your domain with your registrar. Delegating your domain with your domain's registrar makes your Oracle Cloud Infrastructure hosted zone accessible through the internet.

To delegate a zone

1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click the Zone Name for the zone you want to delegate. Zone details and a list of records appear.
3. Use the Type sort filter to locate the NS records for your zone.
4. Note the name servers in the RDATA field within each NS record.
5. You can use the noted name servers to change your domain's DNS delegation. Refer to your registrar's documentation for instructions.

**Note:**

Once delegation has completed, allow 24 hours for your delegation to propagate across the internet.

To add a zone record

**Tip:**

There are many record types you can add to your zone, depending on your goals for the zone and its DNS management.

1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click the Zone Name in which you want to add a record. Zone details and a list of records appear.

**Tip:**

You can use the Zone Name sort filter to list zone names alphanumerically in ascending or descending order.

3. Click Add Record.
4. In the Add Record dialog box, select a record type from the drop-down list, and then enter the information for the record. Avoid entering confidential information. For more information about record types, see Supported Resource Records on page 2562.
5. (Optional) Click the Add Another Record check box to add multiple records in succession.
6. Click Submit.
7. Once your records have been added, click Publish Changes.
8. In the confirmation dialog box, click Publish Changes.

Common DNS Zone Record Types

For a complete list of records supported by Oracle Cloud Infrastructure DNS, see Supported Resource Records on page 2562.

**A**

An address record used to point a hostname to an IPv4 address. For more information about A records, see RFC 1035.

**AAAA**

An address record used point a hostname at an IPv6 address. For more information about AAAA records, see RFC 3596.

**CNAME**

A Canonical Name record identifies the canonical name for a domain. For more information about CNAME records, see RFC 1035.
MX

A Mail Exchanger record defines the mail server accepting mail for a domain. MX records must point to a hostname. MX records must not point to a CNAME or IP address. For more information about MX records, see RFC 1035.

TXT

A Text record holds descriptive, human readable text, and can also include non-human readable content for specific uses. It is commonly used for SPF records and DKIM records that require non-human readable text items. For more information about TXT records, see RFC 1035.

Testing DNS Using BIND's dig Tool

Using the Domain Information Groper (dig) command line tool, you can test against the delegation where your domain is hosted, and you will immediately see whether the change took place without accounting for the cache or TTL (Time to Live) that you have configured.

For more information on using dig to test your DNS, see Testing DNS Using BIND'S dig Tool on page 2572.

Managing DNS Service Zones

The Oracle Cloud Infrastructure DNS service enables you to manage zones within the Console.

Using the Console

Managing Zones and Zone Records

For information on creating private DNS zone, see Private DNS on page 2574.

To add a zone

1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click Create Zone.
3. In the Create Public Zone dialog box, choose one of the following methods:
   - Manual - Enter the following:
     - Zone Name: Enter the name of a zone you want to create. Avoid entering confidential information.
     - Zone Type:
       - Primary - Select this option if you want to control the zone contents directly within Oracle Cloud Infrastructure.
       - Secondary - Select this option if you want Oracle Cloud Infrastructure to pull zone contents from an external server. Enter your Master Server IP address. Optionally, you can select an existing TSIG key in a specified compartment that is associated with the master server. For more information, see Managing TSIG Keys on page 2571.
   - Import - Drag and drop, select, or paste a valid zone file into the Import Zone File window. The zone is imported as a primary zone. For information about formatting a zone file or how to amend a zone file exported from GoDaddy.com, see Formatting a Zone File.
4. Click Create.

The system creates and publishes the zone, complete with the necessary SOA and NS records. For more information on adding a record to your zone, see To add a zone record.

To update a secondary zone

1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click the secondary **Zone Name** you want to update.

   **Tip:**
   You can use the Zone Type sort filter to sort zone type alphanumerically in ascending or descending order.

3. Click **Master Server IPs**.

4. Select the checkbox for the Master Server IP you want to update, and then select **Edit** from the **Actions** drop-down menu.

5. Make the needed changes, and then click **Submit**.

6. (Optional) Click **Add Master Server** to add another Master Server IP address.

7. Click **Publish Changes**.

8. In the confirmation dialog box, click **Publish Changes**.

   **Tip:**
   For OCI to transfer data from your zone, your nameservers must be able to accept a transfer request from the following IP addresses: 208.78.68.65, 204.13.249.65, 2600:2001:0:1::65, 2600:2003:0:1::65

---

### To delete a zone

**Caution:**
Deletion permanently removes a zone from your DNS service.

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Overview**.
2. Select the checkbox for the zone you want to delete.
3. Click **Delete**. The zone is staged for deletion.
4. Click **Publish Changes** to delete the zone.
5. In the confirmation dialog box, click **Publish Changes**.

### To add a zone record

**Tip:**
There are many record types you can add to your zone, depending on your goals for the zone and its DNS management.

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Overview**.
2. Click the **Zone Name** in which you want to add a record. If you are adding a record to a private zone, click the **Private Zones** tab and then click the zone name. Zone details and a list of records appear.

   **Tip:**
   To locate zones in the Private Zones tab, you can use filters to sort by zones that are protected (system generated) or by associated private view names.

3. Click **Add Record**.
4. In the **Add Record** dialog box, select a record type from the drop-down list, and then enter the information for the record. Avoid entering confidential information. For more information about record types, see Supported **Resource Records** on page 2562.
5. (Optional) Click the **Add Another Record** check box to add multiple records in succession.
6. Click **Submit**.

   **Note:**
   When records are added, they are staged to allow for multiple records to be combined into a set. Before records take effect, they must be published.
7. Once your records have been added, click **Publish Changes**.
8. In the confirmation dialog box, click **Publish Changes**.

**To update a zone record**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Protected Records</strong></td>
</tr>
<tr>
<td>You can change various components of the records within your zones, such as time-to-live (TTL) and relevant RDATA. However, some records contain information that cannot be changed. You can attempt changes to such records through the <strong>Actions</strong> menu, but the system might not permit updates to some fields.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Overview**.
2. Click the **Zone Name** in which you want to update a record. If you are updating a record in a private zone, click the **Private Zones** tab and then click the zone name. Zone details and a list of records appear.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To locate zones in the Private Zones tab, you can use filters to sort by zones that are protected (system generated) or by associated private view names.</td>
</tr>
</tbody>
</table>

3. To help find a record, you can use the following filter options:
   - Enter the name of the record's domain in the **Search** field.
   - To find unpublished records, select the **Staged** check box.
   - To find published records, select the **Unstaged** check box.
   - Use the **Is Protected** sort filter to sort by records that are protected.
   - Use the **Record Type** sort filter to sort records.
4. Select the check box for the record you want to update, and select **Edit** from the **Actions** drop-down menu.
5. In the **Edit Record** dialog box, make the needed changes, and then click **Submit**.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When records are added, they are staged to allow for multiple records to be combined into a set. Before records take effect, they must be published.</td>
</tr>
</tbody>
</table>

6. Click **Publish Changes**.
7. In the confirmation dialog box, click **Publish Changes**.

**Reverting Changes Before Publishing**

You can revert records to their current published state before you publish changes. Once a record has been published, it cannot be reverted. Select the check box for the record you want to revert, and then select **Revert** from the **Actions** drop-down menu.

**To delete a zone record**

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Overview**.
2. Click the **Zone Name** in which you want to delete a record. If you are deleting a record in a private zone, click the **Private Zones** tab and then click the zone name. Zone details and a list of records appear.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To locate zones in the Private Zones tab, you can use filters to sort by zones that are protected (system generated) or by associated private view names.</td>
</tr>
</tbody>
</table>

3. Select the check box for the record you want to delete, and then select **Delete** from the **Actions** drop-down menu.
4. Click **Publish Changes**.
5. In the confirmation dialog box, click **Publish Changes**.

**To delegate a zone**

To make your Oracle Cloud Infrastructure hosted zone accessible through the internet, you must delegate your domain with your domain's registrar.

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Overview**.
2. Click the Zone Name for the zone you want to delegate. Zone details and a list of records appear.
3. Use the **Type** sort filter to locate the NS records for your zone.
4. Note the name servers in the RDATA field within each NS record.
5. You can use the noted name servers to change your domain's DNS delegation. Refer to your registrar's documentation for instructions.

**To move a zone to a different compartment**

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Overview**.
2. In the **List Scope** section, select a compartment.
3. Find the zone in the list, click the the Actions menu, and then click **Choose New Compartment**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

For more information, see [Managing Compartments](#).

**To add a TSIG key**

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Overview**.
2. Click the secondary Zone Name you want to update. Zone details and a list of master server IPs appear.
3. Under Zone Information, click **Add** beside the TSIG field.
4. In the Add TSIG Key dialog box, select one of the following options:
   - **Create New TSIG Key** - Enter the following information:
     - **Name**: The name of the key used in domain name syntax. The name should reflect the names of the hosts and uniquely identify the key among a set of keys these two hosts may share at any given time.
     - **Algorithm**: Select the public key's algorithm used to encrypt or decrypt data. Applicable algorithms include hmac-md5, hmac-sha1, hmac-sha224, hmac-sha256, hmac-h384, and hmac-sha512.
     - **Secret**: The base64 string encoding the binary shared secret that corresponds to the key. A maximum value of 255 characters is allowed.
     - **Tags**: Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
   - **Select Existing TSIG Key** - Select a TSIG Key from the drop-down menu.
5. Click **Add**.
6. Click **Publish**.
7. In the confirmation dialog box, click **Publish Changes**.

For more information, see [Managing TSIG Keys](#) on page 2571.

**To remove a TSIG key from a zone**

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Overview**.
2. Click the secondary Zone Name you want to update. Zone details and a list of master server IPs appear.
3. Under Zone Information, click **Remove** beside the TSIG key name.
4. Click **Publish**.
5. In the confirmation dialog box, click **Publish Changes**. Changes cannot be made to this zone while it is updating. Updating a secondary zone locks it for a short time while our servers sync with your external master servers.

For more information, see [Managing TSIG Keys](#) on page 2571.
DNS and Traffic Management

Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use the following operations to manage your DNS zones:

- GetZone
- ListZones
- CreateZone
- UpdateZone
- DeleteZone
- PatchZoneRecords (add or delete records)
- UpdateZoneRecords

Setting Up Reverse DNS Zones

Reverse DNS, or rDNS, maps an IP address to a hostname. Reverse DNS serves a number of different purposes from email to network troubleshooting. Some of the benefits include:

- Adding a label for network troubleshooting tools such as traceroute.
- Populating the “Received:” header field in an SMTP email.
- Checking for generic reverse DNS such as 1-2-3-4.example.com to identify spammers.
- Verifying a relationship between the owner of a domain name and the owner of the server (IP address).
- Writing a human readable hostname to the log files for system monitoring tools.
- Determining which hostname is affected when maintenance is performed on an IP address.

Before getting started with setting up reverse DNS within your Oracle Cloud Infrastructure account, contact your IP provider and confirm that they allow delegation of your reverse DNS zone. If they do not allow delegation, typically they can host your pointer record (PTR) for you and no reverse DNS configurations are required within your Oracle Cloud Infrastructure account. If they do allow delegation, confirm the exact syntax of the reverse DNS hostname with them, as some providers use slashes and some use dashes. Additionally, if you are delegating a reverse DNS zone, confirm that this zone matches exactly what you configure in your Oracle Cloud Infrastructure account as this is necessary in order for delegation to work properly.

After you create and publish your reverse DNS zone and PTR records, you can update your reverse DNS zone delegation with your IP provider. Delegation changes are not required with your domain registrar with a reverse DNS zone.

Setting up a reverse DNS zone is different for the two types of IP address blocks. Use the following procedures to set up a reverse DNS zone for your IP address block type.

Setting Up Reverse DNS for Classless Address Block (Partial Range of IP Addresses)

To find your reverse DNS zone name using classless address block

1. Make a note of your network IP address. For example, 192.168.15.224/27.
2. Remove the netmask portion of the address. This is the number after the slash (/). For example, remove the '27' after your IP address, 192.168.15.224/27.
3. Reverse the order of the remaining octets. For example, 224.15.168.192.
4. Append ‘in-addr.arpa’ to the end of the IP address. For example, 224.15.168.192.in-addr.arpa.

   Note:
   Some assigning authorities require you to use a slash (/) instead of a dash (-) in the reverse address. Ask which character to use when you contact your assigning authority to delegate the reverse address.

5. Add the netmask back into the address. For example, 224-27.15.168.192.in-addr.arpa.

In this example, 224-27.15.168.192.in-addr.arpa is your reverse DNS zone name.
To create your DNS zone

1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click Create Zone.
3. In the Create Zone dialog box, choose one of the following methods:
   - **Manual** - Enter the following:
     a. **Zone Name**: Enter the name of a zone you want to create. Avoid entering confidential information.
     b. **Zone Type**: If you want to control the zone contents directly within OCI, select Primary. If you want OCI to pull zone contents from an external server, select Secondary and enter your Zone Master Server IP address.
   - **Import** - Drag and drop, select, or paste a valid zone file into the Import Zone File window. The zone is imported as a primary zone. For information about formatting a zone file or how to amend a zone file exported from GoDaddy.com, see Formatting a Zone File on page 2565.
4. Click Submit.

The system creates and publishes the zone, complete with the necessary SOA and NS records.

To create a pointer record (PTR) for each host address

As part of the process of setting up a reverse DNS zone, you need to add a PTR record for each host address. This is done specifically for reverse DNS zones to ensure requests are properly routed for resolution.

1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click the Zone Name in which you want to add the PTR record. Zone details and a list of records appear.
   - **Tip**: You can use the Zone Name sort filter to list to sort zone names alphanumerically in ascending or descending order.
3. Click Add Record.
4. In the Add Record dialog box, select the **PTR – Pointer** record type from the drop-down list. Enter the following information:
   - **Name**: Optional. Name of the subdomain.
   - **TTL**: Click the lock icon to unlock this field. All PTR records in the zone will be updated to reflect the last changes to TTL. This value indicates how long you want to allow external nameservers to cache the information about a given DNS record.
   - **TTL Unit**: Select the unit of time used for the TTL value.
   - **RData Mode**: Select Basic or Advanced format. If you select Advanced, enter the canonical hostname (for example, example.com) that the record is going to point to in the RDATA field.
   - **Hostname**: The web address of your zone.

   For more information about the PTR record type, see Supported Resource Records on page 2562.
5. Click Submit.
6. Once your record has been added, click Publish Changes.
7. In the confirmation dialog box, click Publish Changes.

To add CNAME records for each host at your ISP

If your IP provider does not automatically configure the CNAME record on your behalf, you will need to add a CNAME record for each host at your ISP. This is done specifically for reverse DNS zones to ensure requests are properly routed for resolution.

1. Make a note of the IP address and your desired CNAME for each host in your new reverse DNS zone.
2. Contact your ISP and request that they append a CNAME record for each host in your Oracle Cloud Infrastructure DNS zone to your account with them.
3. Test the reverse DNS path by running the following command:

```
dig -x <insert any regular forward-formatted IP address from the zone> +trace
```

See Testing DNS Using BIND'S dig Tool on page 2572 for more information.

The returned information should show that your reverse domain is now being resolved.

**To update your zone delegation**

To make your Oracle Cloud Infrastructure hosted zone accessible through the internet, you must delegate your domain with your domain's registrar (usually the website where you purchased your domain, such as GoDaddy.com or Bluehost.com).

1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click the Zone Name for the zone you want to delegate. Zone details and a list of records appear.
3. Use the Type sort filter to locate the NS records for your zone.
4. Note the name servers in the RDATA field within each NS record.

You can use the noted name servers to change your domain's DNS delegation. Refer to your registrar's documentation for instructions.

**Setting Up Reverse DNS for Full Address Block**

**To find your reverse DNS zone name using full address block**

1. Make a note of your network IP address. For example, 192.168.15.0.
2. Remove the netmask portion of the address (the last number in the set of 4). For example, 192.168.15.
3. Reverse the order of the remaining three octets. For example, 15.168.192.
4. Append 'in-addr.arpa' to the end. For example, 15.168.192.in-addr.arpa

In this example, 15.168.192.in-addr.arpa is your reverse DNS zone name.

**To create your DNS zone**

1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click Create Zone.
3. In the Create Zone dialog box, choose one of the following methods:
   - **Manual** - Enter the following:
     a. **Zone Name**: Enter the name of a zone you want to create. Avoid entering confidential information.
     b. **Zone Type**: If you want to control the zone contents directly within OCI, select Primary. If you want OCI to pull zone contents from an external server, select Secondary and enter your Zone Master Server IP address.
   - **Import** - Drag and drop, select, or paste a valid zone file into the Import Zone File window. The zone is imported as a primary zone. For information about formatting a zone file or how to amend a zone file exported from GoDaddy.com, see Formatting a Zone File on page 2565.
4. Click Submit.

The system creates and publishes the zone, complete with the necessary SOA and NS records.

**To create a pointer record (PTR) for each host address**

As part of the process of setting up a reverse DNS zone, you need to add a PTR record for each host address. This is done specifically for reverse DNS zones to ensure requests are properly routed for resolution.

1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click the Zone Name in which you want to add the PTR record. Zone details and a list of records appear.

   | Tip: |
   | You can use the Zone Name sort filter to list to sort zone names alphanumerically in ascending or descending order. |

3. Click Add Record.

4. In the Add Record dialog box, select the PTR – Pointer record type from the drop-down list. Enter the following information:
   a. Name: Optional. Name of the subdomain.
   b. TTL: Click the lock icon to unlock this field. All PTR records in the zone will be updated to reflect the last changes to TTL. This value indicates how long you want to allow external nameservers to cache the information about a given DNS record.
   c. TTL Unit: Select the unit of time used for the TTL value.
   d. RData Mode: Select Basic or Advanced format. If you select Advanced, enter the canonical hostname (for example, example.com) that the record is going to point to in the RDATA field.
   e. Hostname: The web address of your zone.

   For more information about the PTR record type, see Supported Resource Records on page 2562.

5. Click Submit.

6. Once your record has been added, click Publish Changes.

7. In the confirmation dialog box, click Publish Changes.

To update your zone delegation

To make your Oracle Cloud Infrastructure hosted zone accessible through the internet, you must delegate your domain with your domain's registrar.

1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click the Zone Name for the zone you want to delegate. Zone details and a list of records appear.
3. Use the Type sort filter to locate the NS records for your zone.
4. Note the name servers in the RDATA field within each NS record.

You can use the noted name servers to change your domain's DNS delegation. Refer to your registrar's documentation for instructions.

Supported Resource Records

The Oracle Cloud Infrastructure DNS service supports many resource record types. The following list provides a brief explanation of the purpose of each supported record type for public DNS. For private DNS, see Private DNS Supported Resource Records. Avoid entering confidential information when entering record data. The RFC links direct you to further information about the record types and data structure.

Note About RDATA

Oracle Cloud Infrastructure normalizes all RDATA into the most machine readable format. The returned presentation of your RDATA may differ from its initial input.

Example:

The RDATA for the ALIAS, CNAME, DNAME, MX, and NS record types may contain one or more absolute domain names. If the specified RDATA for one of these record types does not end in a dot or period to represent the root, the period will be added.

You can use various DNS libraries to normalize your RDATA before input.

**Public DNS Resource Record Types**

**A**

An address record used to point a hostname to an IPv4 address. For more information about A records, see [RFC 1035](https://tools.ietf.org/html/rfc1035).

**AAAA**

An address record used point a hostname at an IPv6 address. For more information about AAAA records, see [RFC 3596](https://tools.ietf.org/html/rfc3596).

**ALIAS**

A private pseudo-record that allows CNAME functionality at the apex of a zone.

**CAA**

A Certification Authority Authorization record allows a domain name holder to specify one or more Certification Authorities authorized to issue certificates for that domain. For more information about CAA records, see [RFC 6844](https://tools.ietf.org/html/rfc6844).

**CDNSKEY**

A Child DNSKEY moves a CDNSSEC key from a child zone to a parent zone. The information provided in this record must match the CDNSKEY information for your domain at your other DNS provider. This record is automatically created if you enable DNSSEC on a primary zone in Oracle Cloud Infrastructure DNS. For more information about CDNSKEY, see [RFC 7344](https://tools.ietf.org/html/rfc7344).

**CDS**

A Child Delegation Signer record is a child copy of a DS record, for transfer to a parent zone. For more information about CDS records, see [RFC 7344](https://tools.ietf.org/html/rfc7344).

**CERT**

**CNAME**

A Canonical Name record identifies the canonical name for a domain. For more information about CNAME records, see [RFC 1035](https://tools.ietf.org/html/rfc1035).

**CSYNC**

A Child-to-Parent Synchronization record syncs records from a child zone to a parent zone. For more information about CNAME records, see [RFC 7477](https://tools.ietf.org/html/rfc7477).

**DHCID**

A DHCP identifier record provides a way to store DHCP client identifiers in the DNS to eliminate potential hostname conflicts within a zone. For more information about DHCID, see [RFC 4701](https://tools.ietf.org/html/rfc4701).

**DNAME**

A Delegation Name record has similar behavior to a CNAME record, but allows you to map an entire subtree beneath a label to another domain. For more information about DNAME records, see [RFC 6672](https://tools.ietf.org/html/rfc6672).
DNSKEY
A DNS Key record documents public keys used for DNSSEC. The information in this record must match the
DNSKEY information for your domain at your other DNS provider. For more information about DNSKEY
records, see RFC 4034.

DS
A Delegation Signer record resides at the top-level domain and points to a child zone’s DNSKEY record. DS
records are created when DNSSEC security authentication is added to the zone. For more information about
DS records, see RFC 4034.

IPSECKEY
An IPSec Key record stores public keys for a host, network, or application to connect to IP security (IPSec)
systems. For more information on IPSECKEY records, see RFC 4025.

KEY
A Key record stores a public key that is associated with a domain name. Currently only used by SIG and
TKEY records. IPSECKEY and DNSKEY have replaced key for use in IPSec and DNSSEC, respectively.
For more information about KEY records, see RFC 4025.

KX
A Key Exchanger record identifies a key management agent for the associated domain name with some
cryptographic systems (not including DNSSEC). For more information about KX records, see RFC 2230.

LOC
A Location record stores geographic location data of computers, subnets, and networks within the DNS. For
more information about LOC records, see RFC 1876.

MX
A Mail Exchanger record defines the mail server accepting mail for a domain. MX records must point to a
hostname. MX records must not point to a CNAME or IP address. For more information about MX records,
see RFC 1035.

NAPTR
A Naming Authority Pointer record stores information used by ENUM (Telephone Number Mapping) to map
E.164 numbers to URIs. For more information about NAPTR records, see RFC 3403.

NS
A Nameserver record lists the authoritative nameservers for a zone. Oracle Cloud Infrastructure DNS
automatically generates NS records at the apex of each new primary zone. For more information about NS
records, see RFC 1035.

NSAP
A Network Service Access Point record maps a domain name to an NSAP address. For more information
about NSAP records, see RFC 1637.

PTR
A Pointer record reverse maps an IP address to a hostname. This behavior is the opposite of an A Record,
which forward maps a hostname to an IP address. PTR records are commonly found in reverse DNS zones.
For more information about PTR records, see RFC 1035.

PX
A resource record used in X.400 mapping protocols. For more information about PX records, see RFC 822
and RFC 2163.
RP
A Responsible Person record contains information on how to contact the designated responsible parties for a domain. For more information about RP records, see RFC 1183.

SOA
A Start of Authority record specifies authoritative information about a DNS zone, including:
- The primary nameserver.
- The email of the domain administrator.
- The domain serial number.
- Several timers relating to refreshing the zone.

The Oracle Cloud Infrastructure DNS automatically generates an SOA record when a zone is created. For more information about SOA records, see RFC 1035.

SPF
A Sender Policy Framework record is a special TXT record used to store data designed to detect email spoofing. For more information about SPF records, see RFC 4408.

SRV
A Service Locator record allows administrators to use several servers for a single domain. For more information about SRV records, see RFC 2782.

SSHFP
An SSH Public Key Fingerprint record publishes SSH public host key fingerprints using the DNS. For more information about SSHFP records, see RFC 6594.

TLSA
A Transport Layer Security Authentication record associates a TLS server certificate, or public key, with the domain name where the record is found. This relationship is called a TLSA certificate association. For more information about TLSA records, see RFC 6698.

TXT
A Text record holds descriptive, human readable text, and can also include non-human readable content for specific uses. It is commonly used for SPF records and DKIM records that require non-human readable text items. For more information about TXT records, see RFC 1035.

Formatting a Zone File
A zone file is a text file that describes a DNS zone. The BIND file format is the industry preferred zone file format and has been widely adopted by DNS server software. The format is defined in RFC 1035.

Example of a Zone File
This is an example of a zone file downloaded from Oracle Cloud Infrastructure DNS.

```
$ORIGIN example.com.
@                    3600 SOA   ns1.p30.oraclecloud.net. (zone-admin.dyndns.com. ; address of responsible party
  2016072701 ; serial number
  3600 ; refresh period
  600 ; retry period
  604800 ; expire time
  1800 ) ; minimum ttl
86400 NS   ns1.p68.dns.oraclecloud.net.
86400 NS   ns2.p68.dns.oraclecloud.net.
86400 NS   ns3.p68.dns.oraclecloud.net.
86400 NS   ns4.p68.dns.oraclecloud.net.
3600 MX    10 mail.example.com.
```

<td>example.com.</td>
</tr>
</tbody>
</table>

**Note:**

**Record Classes**

In the example zone file above, no record classes are displayed. Oracle Cloud Infrastructure DNS only works with Internet (IN) class records but omits the class information in zone files for efficiency purposes.

**Anatomy of a Zone File**

$ORIGIN indicates a DNS node tree and will typically start a DNS zone file. Any host labels below the origin will append the origin hostname to assemble a fully qualified hostname. Any host label within a record that uses a fully qualified domain terminating with an ending period will not append the origin hostname.

**Example:** With $ORIGIN example.com., any record where the host label field is not followed by a period, example.com. will be appended to them.

The “@” symbol is a special label that indicates the $ORIGIN should replace the “@” symbol. This is typically used for the apex of a zone.

**SOA Record** – The $ORIGIN is followed by the zone’s Start Of Authority (SOA) record. An SOA record is required for each zone. It contains the name of the zone, the e-mail address of the party responsible for administering the domain’s zone file, the current serial number of the zone, the primary nameserver of the zone, and various timing elements (measured in seconds).

**SOA Record Format**

```plaintext
@ IN SOA {primary-name-server} {hostmaster-email} {
    {serial-number}
    {time-to-refresh}
    {time-to-retry}
    {time-to-expire}
    {minimum-TTL} }
```

- **Primary Name Server** – The nameserver that contains the original zone file and not an AXFR transferred copy.
- **Hostmaster Email** – Address of the party responsible for the zone. A period “.” is used in place of an “@” symbol. For email addresses that contain periods, replace the periods with a slash “/”.
- **Serial Number** – Version number of the zone. The serial number will increase with each subsequent update to your zone.
- **Time To Refresh** – How long a nameserver should wait prior to checking for a serial number increase within the primary zone file, in seconds. An increased serial number detected by a secondary DNS nameserver means a transfer is needed to sync your records. Only applies to zones using secondary DNS.
- **Time To Retry** – How long a nameserver should wait prior to retrying to update a zone after a failed attempt, in seconds. Only applies to zones using secondary DNS.
- **Time To Expire** – How long a nameserver should wait prior to considering data from a secondary zone invalid and stop answering queries for that zone, in seconds. Only applies to zones using secondary DNS.
- **Minimum TTL** – Minimum Time To Live (TTL). How long a nameserver or resolver should cache a negative response, in seconds.
Anatomy of a Record Within a Zone File

A zone file is a collection of resource records with each record entry described in the following sequence:

<table>
<thead>
<tr>
<th>Format:</th>
<th>Host Label</th>
<th>TTL</th>
<th>Record Class</th>
<th>Record Type</th>
<th>Record Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>example.com.</td>
<td>60</td>
<td>IN</td>
<td>A</td>
<td>104.255.228.125</td>
</tr>
</tbody>
</table>

- **Host Label** – A host label helps to define the hostname of a record and whether the $ORIGIN hostname will be appended to the label. Fully qualified hostnames terminated by a period will not append the origin.
- **TTL** – The Time To Live (TTL) is the amount of time that a DNS record will be cached by an outside DNS server or resolver, in seconds.
- **Record Class** – There are three classes of DNS records: IN (Internet), CH (Chaosnet), and HS (Hesiod). Oracle Cloud Infrastructure DNS only uses the IN class of records.
- **Record Type** – The type of a record, such as CNAME, AAAA, or TXT.
- **Record Data** – The data within a DNS answer, such as an IP address, hostname, or other information. Different record types will contain different types of record data.

Amending Zone Files Exported from GoDaddy.com for Import

GoDaddy.com exports zone files in a proprietary format. To get the Oracle Cloud Infrastructure DNS service to correctly import a zone file exported from GoDaddy.com, you must directly alter the file. Follow these instructions to update the zone file.

1. Export your zone file from GoDaddy.com. Reference GoDaddy.com's documentation to see how this is done.
2. Open the file in your preferred text editor.
3. Prepend a new line to the file before the SOA record with the following information, including the trailing period: $ORIGIN [yourdomain].
4. Once the file has been amended, save the changes to the file and use the zone import function to import the file into your DNS configuration. For more information about zone import, see Managing DNS Zones.

Note: If your zone file includes includes dynamic A records, such as @ 600 IN A GoCentral Published Site, you will need to amend these records with the correct IP addresses of your website. Please contact GoDaddy.com for information about how to obtain this information. Example: @ 600 IN A 192.0.2.255

Tip: Placing a semi-colon at the beginning of a line is valid comment syntax for a zone file, per RFC 1035, but for ease of use and formatting it is recommended to remove the large section of comments from the beginning of the zone file provided by GoDaddy.com, as shown below.

```
Domain: example.com
; Exported (y-m-d hh:mm:ss): 2019-01-10 13:05:04
; This file is intended for use for informational and archival purposes ONLY and MUST be edited before use on a production DNS server.
; In particular, you must update the SOA record with the correct authoritative name server and contact e-mail address information, and add the correct NS records for the name servers which will
```
DNS and Traffic Management

; be authoritative for this domain.
;
; For further information, please consult the BIND documentation
; located on the following website:
;
; http://www.isc.org/
;
; And RFC 1035:
;
; http://www.ietf.org/rfc/rfc1035.txt
;
; Please note that we do NOT offer technical support for any use
; of this zone data, the BIND name server, or any other third-
; party DNS software.
;
; Use at your own risk.
;
; SOA Record

Oracle Cloud Infrastructure User Guide 2568
Managing HTTP Redirects

The HTTP Redirect service allows you to redirect HTTP traffic to another URL. You can use HTTP Redirect to:

- Redirect all HTTP traffic for an entire zone to another zone. For example, if a company owns example.net and example.com, HTTP Redirect lets the company redirect all HTTP traffic for example.net to example.com. This is a one-to-one mapping; wildcards are not supported.
- Redirect a specific subdomain to an HTTP URL. For example, test.example.com can be redirected to http://example.net/test/test.php.
- Redirect a subdomain to a URL with a port number. For example, camera.example.com can be redirected to http://office.example.com:8080 so a user can view their camera system without typing in the port number each time.
- Permanently redirect a domain name that has been deprecated by displaying a 301 response code. Permanently redirecting a domain name informs search engines and browsers what to do with the information.

Required IAM Policies

To work with HTTP Redirects, you need to have a user login to the Console, and your user needs sufficient authority (by way of an IAM policy) to perform all the instructions that follow. If your user is in the Administrators group, you have the required authority.

If your user is not, then a policy like this would allow a specific group to manage HTTP Redirects:

```
Allow group <GroupName> to manage http-redirects in compartment <CompartmentName>
```

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for HTTP Redirect, see Details for the WAF Service.

Using the Console

To create an HTTP redirect

1. Open the navigation menu and click Networking. Under DNS Management, click HTTP Redirects.
2. Select a zone.
3. Click Create HTTP Redirect.
4. In the Create Redirect dialog box, enter the following information:

• **Name**: (Optional) Enter the name of the redirect zone you want to create. Avoid entering confidential information.

• **Select a Zone**: (Optional) Select a zone from a list of configured zones. If the **Create DNS Record** check box is selected, the zone will be used to build an alias record for the redirect.

• **Domain**: Enter the domain name from which traffic is redirected.

• **Target** - Enter the following information for the endpoint where the traffic will be redirected:
  
  • **Protocol**: The network protocol used to interact with the target.
  
  • **Host**: The hostname of the target.
  
  • **Port**: (Optional) The port used to connect to the endpoint. The default is 80 for HTTP and 443 for HTTPS.
  
  • **Path**: (Optional) The specific path on the target for the redirect. A value of {path} will copy the path from the incoming request.
  
  • **Query**: (Optional) The query component of the target URL (for example, "?redirected" in "https://target.example.com/path/to/resource?redirected"). Use of the "\" character is not permitted except to escape a following "\", ",", or "). An empty value results in a redirection target URL with no query component. A static value must begin with a leading ",", optionally followed by other query characters. A request-copying value must exactly match ",{query}\", and will be replaced with the query component of the request URL (including a leading "\" if the request URL includes a query component).

• **Response Code**: The response code that is returned with the redirect. If your website was permanently moved to the redirection URL and you want it to be indexed by search engines, select **301 - Moved Permanently**. If you want to indicate that the URL has been temporarily changed to a different address, select **302 - Found**.

• **Create DNS Record**: Select this check box to create an associated ALIAS record for the redirect in the specified zone. If a record for the zone specified already exists, the DNS record will not be created.

• **ALIAS TTL in Seconds** - The Time to Live for the ALIAS record before a new ALIAS record is retrieved. The default value is 300.

• **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**. The redirect zone is added to the redirects list.

*To edit an HTTP redirect*

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **HTTP Redirects**.
2. Click the name of a redirect zone.
3. Click **Edit**.
4. In the Edit Redirect dialog box, make the needed changes and then click **Save Changes**.

*To delete an HTTP redirect*

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **HTTP Redirects**.
2. Select a redirect zone.
3. Click **Delete**.
4. In the Delete Resource dialog box, click **Delete HTTP Redirect**. Any attached records will need to be managed in **DNS Zone Management**.

*To move an HTTP redirect to another compartment*

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **HTTP Redirects**.
2. Click the name of a redirect zone.
3. Click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.
Using the API

Use the following operations to manage your HTTP redirect zones:

- GetHttpRedirect
- ListHttpRedirects
- CreateHttpRedirect
- UpdateHttpRedirect
- DeleteHttpRedirect
- ChangeHttpRedirectCompartment

Managing TSIG Keys

TSIG (Transaction Signature), also referred to as Secret Key Transaction Authentication, ensures that DNS packets originate from an authorized sender by using shared secret keys and one-way hashing to add a cryptographic signature to the DNS packets. TSIG keys are used to enable DNS to authenticate updates to secondary zones. TSIG keys provide an added layer of security for IXFR and AXFR transactions. A TSIG key consists of a key name, a signing algorithm, and a secret. See RFC 2845 for more information. TSIG keys can also be managed in DNS Zone Management. See Managing DNS Service Zones on page 2555 for more information.

Using the Console

To create a TSIG key

1. Open the navigation menu and click Networking. Under DNS Management, click TSIG Keys.
2. Click Create TSIG key.
3. In the Create TSIG Key dialog box, enter the following:
   - Name: The name of the key used in domain name syntax. The name should reflect the names of the hosts and uniquely identify the key among a set of keys these two hosts may share at any given time.
   - Algorithm: Select the public key's algorithm used to encrypt or decrypt data. Applicable algorithms include hmac-md5, hmac-sha1, hmac-sha224, hmac-sha256, hmac-h384, and hmac-sha512.
   - Secret: The base64 string encoding the binary shared secret that corresponds to the key. A maximum value of 255 characters is allowed.
   - Tags: Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
4. Click Create TSIG Key. The TSIG key details appear.

To view the details of a TSIG key

1. Open the navigation menu and click Networking. Under DNS Management, click TSIG Keys.
2. Click the name of the TSIG key you want to view. TSIG key details and a list of associated zones appear.
3. To view the Secret assigned to the key, click Show beside the Secret field.
4. In the View Secret dialog box, click Close.

To delete a TSIG key

Note:
A TSIG key attached to a zone must be removed from the zone in DNS Zone Management. See Managing DNS Service Zones on page 2555 for more information.

1. Open the navigation menu and click Networking. Under DNS Management, click TSIG Keys.
2. Find the TSIG key in the list, click the Actions icon (three dots), and then click Delete.
3. In the confirmation dialog box, click Delete.

To move a TSIG key to another compartment

1. Open the navigation menu and click Networking. Under DNS Management, click TSIG Keys.
2. In the Scope section, select a compartment.
3. Find the TSIG key in the list, click the Actions icon (three dots), and then click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

For more information, see [Managing Compartments](#).

### Using the API

Use the following operations to manage TSIG keys:

- ListTsigKeys
- CreateTsigKey
- GetTsigKey
- UpdateTsigKey
- DeleteTsigKey
- ChangeTsigKeyCompartment

### Testing DNS Using BIND'S dig Tool

Using the Domain Information Groper (dig) command line tool, you can test against the delegation where your domain is hosted, and you will immediately see whether the change took place without accounting for the cache or TTL (Time to Live) that you have configured.

![Note: Windows users can download the tool from BIND’s website. Use Terminal to access dig on Linux and Macintosh systems.](#)

#### Using dig

Before using BIND’s dig tool, you must access or install dig on your system. Once you have access to dig, you can use dig to test your DNS.

**To access dig (Mac)**

1. From your Applications folder, open the Utilities folder, and then select **Terminal**.
2. When Terminal is open, type a dig command using a hostname you want to look up.

**To install dig (Windows)**

1. Go to BIND’s website and download the most current, stable version of BIND.

![Note: BIND supports both 32 and 64 bit Windows systems. Confirm which version of Windows you are using and download the correct version of BIND. View Microsoft’s documentation to determine which version of Windows you are using.](#)

2. Extract the downloaded file and install BIND in the following directory: `C:\Program Files\ISC BIND 9`. Select the **Tools Only** check box.
3. Once BIND is installed, on the Windows menu open the Control Panel, and then open your System properties.
4. On the **Advanced** tab, click **Environment Variables**.
5. Under **System Variables**, select **Path**, and then click **Edit**.
6. At the end of the path in the Edit System Variable window, add `C:\Program Files\ISC BIND 9\bin`, and then click **OK**.
7. In the Edit Variables window, click **OK**. In the System properties window, click **OK**.

**To open the Command Prompt**

For Windows versions 8 -10:
1. Click the Windows menu icon.
2. In the Search field, type CMD.
3. Click Command Prompt.

For Windows version 7:
1. On the Start menu click Run.
2. Enter CMD, and then click OK.

To use dig to test your DNS
1. Open Terminal (Mac and Linux) or Command Prompt (Windows).
2. Type `dig <any hostname>`, and then press Enter.

The following information is returned:

```
$ dig oracle.com
; <<>> DiG 9.10.6 <<>> oracle.com
;; global options: +cmd
;; got answer:
;; ;<HEADER><< opcode: QUERY, status: NOERROR, id: 45615

```

- **Question section**: The query made to the DNS. In this example, we asked for the first available A record for the hostname, oracle.com.
- **Answer section**: The first available answer for the query made to the DNS. In this example, we received the A record for the IP address 137.254.16.101.
- **Authority section**: The authoritative nameservers from which the answer to the query was received. These nameservers house the zones for a domain.
- **Additional section**: Additional information the resolver may need but not the answer to the query.
dig Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>dig [hostname]</td>
<td>Returns any A record found within the queried hostname's zone.</td>
<td>dig oracle.com</td>
</tr>
<tr>
<td>dig [hostname] [record type]</td>
<td>Returns the records of that type found within the queried hostname's zone.</td>
<td>dig oracle.com MX</td>
</tr>
<tr>
<td>dig [hostname] +short</td>
<td>Provides a brief answer, usually just an IP address.</td>
<td>dig oracle.com +short</td>
</tr>
<tr>
<td>dig @[nameserver address] [hostname]</td>
<td>Queries the nameserver directly instead of your ISP's resolver.</td>
<td>dig @dnsmaster6.oracle.com</td>
</tr>
<tr>
<td>dig [hostname] +trace</td>
<td>Adding +trace instructs dig to resolve the query from the root nameserver downwards and to report the results from each query step.</td>
<td>dig dyn.com +trace</td>
</tr>
<tr>
<td>dig -X [IP address]</td>
<td>Reverse lookup for IP addresses.</td>
<td>dig -X 137.254.16.101</td>
</tr>
<tr>
<td>dig [hostname] any</td>
<td>Returns all records for a hostname.</td>
<td>dig oracle.com any</td>
</tr>
</tbody>
</table>

Private DNS

This topic describes how to create and manage private DNS zones. Private DNS allows you to use your own private DNS domain names and fully manage the associated zones and records to provide hostname resolution for your applications running within and between VCNs, as well as your on-premises or other private network. Private DNS also provides DNS resolution across networks (for example, another VCN within the same region, cross region, or external network). Private DNS can be managed in the OCI DNS API and Console.

Overview of Private DNS

- **Private DNS Zones**: Private DNS zones contain DNS data only accessible from within a VCN, such as private IP addresses. A private DNS zone has similar capabilities to an internet DNS zone, but provides responses only for clients that can reach it through a VCN. Private DNS allows you to duplicate zones across multiple VCNs. A full or partial domain tree can be created. It also supports split-horizon DNS which allows you to use the same domain name for public and private zones. Different answers can be served for public queries versus private queries from within your VCN.

- **Private DNS Views**: A private DNS view is a collection of private zones. You can reference private views from a resolver to manage how DNS queries are answered. A zone can only belong to a single view. The same zone name can be used in multiple views, but the zones will have unique OCIDs to differentiate. You can use those views to create DNS resolvers configured to handle DNS queries from your VCNs. Any given view can be used by an arbitrary number of resolvers, allowing you to share private DNS data across VCNs.

- **Private DNS Resolver**: A private DNS resolver provides responses to DNS queries. It provides responses by checking each customer-referenced view in order, then the default view, then each rule in order, and finally by using internet DNS. The first item in that sequence able to provide an answer does so, and later items are not checked. This is true even for a negative answer. For example, if a query name is covered by a zone in a private view and the name does not exist in the zone, the zone will return an authoritative NXDOMAIN response. Rules allow you to define the logic for how queries should be answered. The resolver listens on 169.254.169.254 by default, but also allows you to define endpoints for listening for queries and forwarding them to other resolvers in other VCNs, a customer's on-premises network, or other private network. IPv6 is not supported for listening or forwarding endpoints. Multiple views can be resolved within a VCN. You can specify an ordered list of views within a resolver. For more information, see Private DNS resolvers on page 4414.
**Supported Resource Records**

The Oracle Cloud Infrastructure DNS service supports many resource record types. The following list provides a brief explanation of the purpose of each supported record type for private DNS. For public DNS, see Public DNS Supported Resource Records. Avoid entering confidential information when entering record data. The RFC links direct you to further information about the record types and data structure.

**Note About RDATA**

Oracle Cloud Infrastructure normalizes all RDATA into the most machine readable format. The returned presentation of your RDATA may differ from its initial input.

**Example:**

The RDATA for the CNAME, DNAME, and MX record types may contain one or more absolute domain names. If the specified RDATA for one of these record types does not end in a dot or period to represent the root, the period will be added.

You can use various DNS libraries to normalize your RDATA before input.

<table>
<thead>
<tr>
<th>Programming Language</th>
<th>Library</th>

<tr>
<td>Python</td>
<td>dnspython</td>
</tr>
</tbody>
</table>

**Private DNS Resource Record Types**

**A**

An address record used to point a hostname to an IPv4 address. For more information about A records, see RFC 1035.

**AAAA**

An address record used point a hostname at an IPv6 address. For more information about AAAA records, see RFC 3596.

**CAA**

A Certification Authority Authorization record allows a domain name holder to specify one or more Certification Authorities authorized to issue certificates for that domain. For more information about CAA records, see RFC 6844.

**CNAME**

A Canonical Name record identifies the canonical name for a domain. For more information about CNAME records, see RFC 1035.

**DNAME**

A Delegation Name record has similar behavior to a CNAME record, but allows you to map an entire subtree beneath a label to another domain. For more information about DNAME records, see RFC 6672.

**MX**

A Mail Exchanger record defines the mail server accepting mail for a domain. MX records must point to a hostname. MX records must not point to a CNAME or IP address. For more information about MX records, see RFC 1035.
PTR
A Pointer record reverse maps an IP address to a hostname. This behavior is the opposite of an A Record, which forward maps a hostname to an IP address. PTR records are commonly found in reverse DNS zones. For more information about PTR records, see RFC 1035.

SRV
A Service Locator record allows administrators to use several servers for a single domain. For more information about SRV records, see RFC 2782.

TXT
A Text record holds descriptive, human readable text, and can also include non-human readable content for specific uses. It is commonly used for SPF records and DKIM records that require non-human readable text items. For more information about TXT records, see RFC 1035.

Required IAM Policies
To work with private DNS, a user needs sufficient authority (by way of an IAM policy). If your user is in the Administrators group, you have the required authority. If your user is not in the Administrators group, then a policy like this will allow a specific group to manage private DNS:

```
Allow group <GroupName> to manage dns in tenancy where target.dns.scope = 'private'
```

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for private DNS, see Details for the DNS Service.

Using the Console
To create a private zone with a private view

Note:
- Private zones can only be viewed in the region in which they are created.
- Creating a private zone at or under "oraclevcn.com" within the default protected view of a VCN-dedicated resolver is not permitted.

1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click the Private Zones tab.
3. Click Create Zone.
4. In the Create Private Zone dialog box, enter the following information:
   - **Zone Name**: Enter the name of the zone you want to create. Avoid entering confidential information. A domain name identifies a particular space within a zone for the purposes of naming systems and/or associating DNS records.
   - **Create in Compartment**: Select the compartment where you want to create the zone.
   - **Zone Type**: This field is read-only. The zone contents will be controlled directly within Oracle Cloud Infrastructure.
   - **DNS Private View**: A private zone must be created within a private view, which cannot be changed. When a private zone is attached to a private view, the private zone cannot be moved to a new private view.
     - **Select Existing Private DNS View**: To select an existing private view in the current compartment, select a private view from the drop-down menu. You can click Change Compartment to change the compartment where the private view exists.
     - **Create New Private DNS View**: Enter a name for the private view. Avoid entering confidential information. This resource is created in the compartment selected previously.
   - **Tags**: Optionally, you can apply tags. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click Create.

The system creates and publishes the zone, complete with the necessary SOA and NS records. The details for the zone appear. You can view the private view associated with this zone by clicking the Private View name in the Zone Information section. For information on adding a record to your zone, see To add a zone record on page 2556.

To create a private view

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Private views can only be viewed in the region in which they are created.</td>
</tr>
</tbody>
</table>

1. Open the navigation menu and click Networking. Under DNS Management, click Private Views.
2. Click Create Private View.
3. In the Create Private View dialog box, enter the following:
   - **Name**: Enter the name of the private view you want to create. Avoid entering confidential information.
   - **Create in Compartment**: Select the compartment where you want to create the private view.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
4. Click Create.

To create a private view with a new private zone

1. Open the navigation menu and click Networking. Under DNS Management, click Private Views.
2. Click Create Private View.
3. In the Create Private Zone dialog box, enter the following information:
   - **Name**: Enter the name of the private view you want to create. Avoid entering confidential information.
   - **Create in Compartment**: Select the compartment where you want to create the private view.
   - **Tags**: Optionally, you can apply tags. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
4. Click Create.

The details for the private view appear.

5. Click Create Zone.
6. In the Create Private Zone dialog box, enter the following:
   - **Zone Name**: Enter the name of the zone you want to create. Avoid entering confidential information. A domain name identifies a particular space within a zone for the purposes of naming systems and/or associating DNS records.
   - **Create in Compartment**: Select the compartment where you want to create the zone.
   - **Zone Type**: This field is read-only. The zone contents will be controlled directly within Oracle Cloud Infrastructure.
   - **Tags**: Optionally, you can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
7. Click Create.

The new zone appears in the zone list associated with the private view you created.
To add a zone record

**Tip:**
There are many record types you can add to your zone, depending on your goals for the zone and its DNS management.

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Overview**.
2. Click the **Zone Name** in which you want to add a record. If you are adding a record to a private zone, click the **Private Zones** tab and then click the zone name. Zone details and a list of records appear.

**Tip:**
To locate zones in the Private Zones tab, you can use filters to sort by zones that are protected (system generated) or by associated private view names.

3. Click **Add Record**.
4. In the **Add Record** dialog box, select a record type from the drop-down list, and then enter the information for the record. Avoid entering confidential information. For more information about record types, see **Supported Resource Records** on page 2562.
5. (Optional) Click the **Add Another Record** check box to add multiple records in succession.
6. Click **Submit**.

**Note:**
When records are added, they are staged to allow for multiple records to be combined into a set. Before records take effect, they must be published.

7. Once your records have been added, click **Publish Changes**.
8. In the confirmation dialog box, click **Publish Changes**.

To update a zone record

**Note:**
Protected Records
You can change various components of the records within your zones, such as time-to-live (TTL) and relevant RDATA. However, some records contain information that cannot be changed. You can attempt changes to such records through the **Actions** menu, but the system might not permit updates to some fields.

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Overview**.
2. Click the **Zone Name** in which you want to update a record. If you are updating a record in a private zone, click the **Private Zones** tab and then click the zone name. Zone details and a list of records appear.

**Tip:**
To locate zones in the Private Zones tab, you can use filters to sort by zones that are protected (system generated) or by associated private view names.

3. To help find a record, you can use the following filter options:
   - Enter the name of the record's domain in the **Search** field.
   - To find unpublished records, select the **Staged** check box.
   - To find published records, select the **Unstaged** check box.
   - Use the **Is Protected** sort filter to sort by records that are protected.
   - Use the **Record Type** sort filter to sort records.
4. Select the check box for the record you want to update, and select **Edit** from the **Actions** drop-down menu.
5. In the Edit Record dialog box, make the needed changes, and then click Submit.

**Note:**
When records are added, they are staged to allow for multiple records to be combined into a set. Before records take effect, they must be published.

6. Click Publish Changes.
7. In the confirmation dialog box, click Publish Changes.

**Reverting Changes Before Publishing**
You can revert records to their current published state before you publish changes. Once a record has been published, it cannot be reverted. Select the check box for the record you want to revert, and then select Revert from the Actions drop-down menu.

To delete a zone record
1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click the Zone Name in which you want to delete a record. If you are deleting a record in a private zone, click the Private Zones tab and then click the zone name. Zone details and a list of records appear.

**Tip:**
To locate zones in the Private Zones tab, you can use filters to sort by zones that are protected (system generated) or by associated private view names.

3. Select the check box for the record you want to delete, and then select Delete from the Actions drop-down menu.
4. Click Publish Changes.
5. In the confirmation dialog box, click Publish Changes.

To edit a private view
1. Open the navigation menu and click Networking. Under DNS Management, click Private Views.
2. Click the name of the private view you want to update.

**Tip:**
You can use the Protected filter to sort private views by views that are protected (system generated).

3. Click Edit.
4. In the Edit Private DNS View dialog box, make the needed changes and then click Save Changes.

To edit a private zone

**Note:**
Private zones are only viewable in the region they are created.

1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click the Private Zones tab.
3. Click the name of the zone you want to update.

**Tip:**
You can use filters to sort private zones by zones that are protected (system generated) or by associated private view names.

4. Click Edit.
5. In the Edit Zone dialog box, make the needed changes and then click Save Changes.

To delete a private zone
1. Open the navigation menu and click Networking. Under DNS Management, click Overview.
2. Click the **Private Zones** tab.
3. Click the Actions icon (three dots) for the zone you want to delete, and then click **Delete**.
4. In the Delete Private Zone dialog box, click **Delete**.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deletion removes associated resources.</td>
</tr>
</tbody>
</table>

**To delete a private view**

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Private Views**.
2. Click the name of the private view that you want to delete.
3. Click **Delete**.
4. In the Delete DNS Private View dialog box, click **Delete**.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deletion removes any associated private zones.</td>
</tr>
</tbody>
</table>

**To delete a private zone from a private view**

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Private Views**.
2. Click the private view that contains the zone you want to delete.
3. Click the Actions menu for the zone you want to delete, and then click **Delete**.
4. In the Delete Private Zone dialog box, click **Delete**.

**To move a private zone to another compartment**

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Overview**.
2. Click the **Private Zones** tab.
3. Click the name of the zone you want to move.
4. Find the zone in the list, click the the Actions menu, and then click **Move Resource**.
5. Choose the destination compartment from the list.
6. Click **Move Resource**.

**To move a private view to another compartment**

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Private Views**.
2. Click the name of the view you want to move.
3. Click **Move Resource**.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**To create a VCN with a dedicated DNS resolver**

See [To create a VCN](#) on page 4325 and [DNS in Your Virtual Cloud Network](#) on page 4409 for more information.

**Using the API**

Use the following operations to manage private zones and records:

- ChangeZoneCompartment
- CreateZone
- DeleteZone
- GetZone
- ListZones
- UpdateZone
- DeleteDomainRecords
- GetDomainRecords
- PatchDomainRecords
- UpdateDomainRecords
- GetZoneRecords
- PatchZoneRecords (add or delete records)
- UpdateZoneRecords
- DeleteRRSet
- GetRRSet
- PatchRRSet
- UpdateRRSet

Use the following operations to manage private views:

- ChangeViewCompartment
- CreateView
- DeleteView
- GetView
- ListViews
- UpdateView

Use the following operations to manage resolvers and resolver endpoints:

- ChangeResolverCompartment
- GetResolver
- ListResolvers
- UpdateResolver
- CreateResolverEndpoint
- DeleteResolverEndpoint
- GetResolverEndpoint
- ListResolverEndpoints
- UpdateResolverEndpoint

**Troubleshooting**

This topic covers some common Private DNS issues and how to address them.

**Querying for a private zone after creation returns an NXDOMAIN error message or Public IP address**

- If a query is sent before the private zone is published, the query recurses to the internet. An error message stating that the domain doesn’t exist or a public name response will be returned for the query.
- Wait until the Time To Live (TTL) expires before querying.

**Network connectivity issues when configuring DNS resolution between VCNs or between a VCN and your on-premises network**

- Ensure that the local peering gateway is set up correctly between VCNs, and the remote peering connection, IPSec tunnel, or FastConnect network connectivity is set up correctly between resolvers.
- Ensure that DHCP is enabled as a protocol over the local peering gateway, remote peering connection, FastConnect or VPN and that the IP addresses of the endpoints are allowed. For more information, see [DHCP Options](#) on page 4417.

**DNS Metrics**

You can monitor the health, capacity, and performance of your DNS services by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_dns` (the DNS service).
Overview of DNS Service Metrics

The DNS service metrics help you measure the number of queries for DNS zones and DNS zones with traffic management policies attached.

Prerequisites

- IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_dns

The metrics listed in the following table are automatically available. You do not need to enable monitoring on the resource to get these metrics.

Each metric includes the following dimensions:

<table>
<thead>
<tr>
<th>RESOURCEID</th>
</tr>
</thead>
<tbody>
<tr>
<td>The OCID of the zone to which the metric applies.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNSQueryCount</td>
<td>DNSQueryCount</td>
<td>count</td>
<td>The number of queries for a DNS zone.</td>
<td>resourceID</td>
</tr>
<tr>
<td>TrafficManagementQueryCount</td>
<td>TrafficManagementQueryCount</td>
<td>count</td>
<td>The number of queries for a zone with Traffic Management policies attached.</td>
<td>resourceID</td>
</tr>
</tbody>
</table>

Using the Console

DNS service metrics are available using the Metrics Explorer feature in the Console. For more information about metrics, see Viewing Metric Charts.

To view DNS metric charts

   For Metric Namespace, select oci_dns.

2. Select a metric to view from the Metric Name field.

3. Select a qualifier specified in the Dimension Name field. For example, the dimension resourceId is specified in the metric definition for DNSQueryCount.

4. Select the value you want to use for the specified dimension in the Dimension Value field. For example, the resource identifier for your instance of interest.

5. Click Update Chart.

   The chart will be updated with the metrics that have been requested.

For more information about monitoring metrics and using alarms, see Monitoring on page 4078. For information about notifications for alarms, see Notifications on page 4900.

Using the API

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)
Overview of the Traffic Management Steering Policies Service

The Oracle Cloud Infrastructure Traffic Management Steering Policies service is a critical component of DNS. Traffic Management Steering Policies enables you to configure policies to serve intelligent responses to DNS queries, meaning different answers (endpoints) may be served for the query depending on the logic the customer defines in the policy. Traffic Management Steering Policies can account for health of answers to provide failover capabilities, provide the ability to load balance traffic across multiple resources, and account for the location where the query was initiated to provide a simple, flexible and powerful mechanism to efficiently steer DNS traffic.

Traffic Management Steering Policies Service Components

The following list describes the components used to build a traffic management steering policy.

STEERING POLICIES

A framework to define the traffic management behavior for your zones. Steering policies contain rules that help to intelligently serve DNS answers.

ATTACHMENTS

Allows you to link a steering policy to your zones. An attachment of a steering policy to a zone occludes all records at its domain that are of a covered record type, constructing DNS responses from its steering policy rather than from those domain's records. A domain can have at most one attachment covering any given record type.

RULES

The guidelines steering policies use to filter answers based on the properties of a DNS request, such as the requests geo-location or the health of your endpoints.

ANSWERS

Answers contain the DNS record data and metadata to be processed in a steering policy.

Ways to Access the Traffic Management Steering Policies Service

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference on page 3347.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Traffic Management Steering Policies Service Capabilities and Limits

The Oracle Cloud Infrastructure Traffic Management Steering Policies service is limited to 100 policies and 1,000 attachments per tenant. See Service Limits on page 247 for a list of applicable limits and instructions for requesting a limit increase.
Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for Traffic Management Steering Policies, see Details for the Traffic Management Steering Policies Service.

Managing Traffic Management Steering Policies

Policy Types

FAILOVER

Failover policies allow you to prioritize the order in which you want answers served in a policy (for example, Primary and Secondary). Oracle Cloud Infrastructure Health Checks are leveraged to determine the health of answers in the policy. If the Primary Answer is determined to be unhealthy, DNS traffic will automatically be steered to the Secondary Answer.

LOAD BALANCER

Load Balancer policies allow distribution of traffic across multiple endpoints. Endpoints can be assigned equal weights to distribute traffic evenly across the endpoints or custom weights may be assigned for ratio load balancing. Oracle Cloud Infrastructure Health Checks are leveraged to determine the health of the endpoint. DNS traffic will be automatically distributed to the other endpoints, if an endpoint is determined to be unhealthy.

GEOLOCATION STEERING

Geolocation steering policies distribute DNS traffic to different endpoints based on the location of the end user. Customers can define geographic regions composed of originating continent, countries or states/provinces (North America) and define a separate endpoint or set of endpoints for each region.

ASN STEERING

ASN steering policies enable you to steer DNS traffic based on Autonomous System Numbers (ASN). DNS queries originating from a specific ASN or set of ASNs can be steered to a specified endpoint.

IP PREFIX STEERING

IP Prefix steering policies enable customers to steer DNS traffic based on the IP Prefix of the originating query.

Typical Traffic Steering Scenarios

This section describes several typical scenarios for using Traffic Management Steering Policies.

Basic Failover

You can leverage Traffic Management Steering Policies to provide automated failover between primary and secondary servers.

Cloud Migration

Weighted load balancing supports controlled migration from your data center to Oracle Cloud Infrastructure servers. You can steer a small amount of traffic (1%) to your new resources in the cloud to verify everything is working as expected. You can then increase the ratios until you are comfortable with fully migrating all DNS traffic to the cloud.
Load Balancing Across Multiple Servers for Scale
You can configure load balancing pools of multiple servers. Traffic Management Steering Policies can automatically distribute DNS traffic across the set of servers. Health Checks may also be used and traffic will be automatically redirected to healthy servers, if a server is determined to be unhealthy.

Hybrid Environments
Since Traffic Management Steering Policies is an agnostic service, it may be used to not only steer traffic to Oracle Cloud Infrastructure resources, but can also be used to steer traffic to any publicly exposed (internet resolvable) resources, including other cloud providers and enterprise data centers.

Worldwide Geolocation Treatment
You can divide your global users into geographically defined regions (for example, state/province level in NA, country level for rest of world) and steer customers to specified resources based on their location. This helps to ensure global, high performing internet resolution, and supports functions such as ring fencing. For example, keeping traffic from China in China and block traffic outside of China into China.

Canary Testing
Leveraging IP Prefix steering, you can configure policies to serve different responses for your internal users versus external users.

Zero-Rating Services
ASN steering conditional steering based on the originating enterprise, mobile operator or other communications provider in support of various commercial agreements that may be in place. Essentially, preferred ASNs can be directed to free resources, while all other traffic can be directed to paid resources.

Using the Console
Managing Traffic Management Steering Policies
To create a Load Balancer policy
2. Click Create Traffic Management Steering Policy.
3. In the Create Traffic Management Steering Policy dialog box, select Load Balancer.
4. Enter the following information:
   • **Policy Name**: The unique name that identifies policy.
   • **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
   • **Maximum Answer Count**: The maximum number of answers returned for the policy.
   • **Answer(s)**: Answer pools contain the group of answers that will be served in response to DNS queries.
     • **Name**: A unique name to identify the answer. Avoid entering confidential information.
     • **Type**: The record type that will be provided as the answer.
     • **RDATA**: A valid domain name or IP address to add as an answer.
     • **Weight**: A number between 0 and 255 used to determine how often an answer is served in relation to other answers. Answers with higher values are more likely to be served.
     • **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select **Mark pool answers eligible** or **Mark pool answers ineligible** from the Actions drop-down menu.
   • **Attach Health Check**: Select an existing Health Check to be included as part of the policy, add a new one, or select **None**.
   • **Attach Domain(s)**: (Optional) The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.

5. Click **Create Policy**.

The system creates and publishes the policy.

**To create a Failover policy**

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Traffic Management Steering Policies**.
2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **Failover**.
4. Enter the following information:
   • **Policy Name**: The unique name that identifies policy. Avoid entering confidential information.
   • **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
   • **Maximum Answer Count**: The maximum number of answers returned for the policy. For priority-based policies, the first valid answer is returned.
   • **Answer Pool(s)**: Answer pools contain the group of answers that will be served in response to DNS queries.
   • **Answer Pool Name**: A user-friendly name for the answer pool, unique within the steering policy. Avoid entering confidential information.
   • **Name**: A unique name to identify the answer. Avoid entering confidential information.
   • **Type**: The record type that will be provided as the answer.
   • **RDATA**: A valid domain name or IP address to add as an answer.
   • **Weight**: A number between 0 and 255 used to determine how often an answer is served in relation to other answers. Answers with higher values are more likely to be served.
   • **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select **Mark pool answers eligible** or **Mark pool answers ineligible** from the Actions drop-down menu.
   • **Pool Priority**: Failover priority rules specify the priority of answers that are served in a policy. If the primary answer is unavailable, traffic is steered to the next answer in the list.
   • **Pool**: Select the priority in which the answers are served.
   • **Attach Health Check**: Select an existing Health Check to be included as part of the policy, add a new one, or select **None**.
   • **Attach Domain(s)**: The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.
5. Click **Create Policy**.

The system creates and publishes the policy.

*To create a Geolocation Steering policy*

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Traffic Management Steering Policies**.
2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **Geolocation Steering**.
4. Enter the following information:
   - **Policy Name**: The unique name that identifies policy. Avoid entering confidential information.
   - **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
   - **Maximum Answer Count**: The maximum number of answers returned for the policy. For priority-based policies, the first valid answer is returned.
   - **Answer Pool(s)**: Answer pools contain the group of answers that will be served in response to DNS queries.
     - **Answer Pool Name**: A user-friendly name for the answer pool, unique within the steering policy. Avoid entering confidential information.
     - **Name**: A unique name to identify the answer. Avoid entering confidential information.
     - **Type**: The record type that will be provided as the answer.
     - **RDATA**: A valid domain name or IP address to add as an answer.
     - **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select **Mark pool answers eligible** or **Mark pool answers ineligible** from the **Actions** drop-down menu.
   - **Geolocation Steering Rules**: Geolocation steering rules specify the priority of answers that are served in a policy. If the primary answer is unavailable, traffic is steered to the next answer in the list. Additional rules and priorities can be added in this section.
     - **Geolocation**: Select a location that will be used to distribute DNS traffic.
     - **Pool Priority**: Select the priority in which the answers are served.
     - **Global Catch-all**: Adding a global catch-all allows you to specify answer pools for queries that do not match any of the specified rules you have added. Click **Add Global Catch-all** and select the pool priorities.
   - **Attach Health Check**: Select an existing Health Check to be included as part of the policy, add a new one, or select **None**.
   - **Attach Domain(s)**: The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.
5. Click **Create Policy**.

The system creates and publishes the policy.

*To create an ASN Steering policy*

1. Open the navigation menu and click **Networking**. Under **DNS Management**, click **Traffic Management Steering Policies**.
2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **ASN Steering**.
4. Enter the following information:
   - **Policy Name:** The unique name that identifies policy. Avoid entering confidential information.
   - **Policy TTL:** The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
   - **Maximum Answer Count:** The maximum number of answers returned for the policy. For priority-based policies, the first valid answer is returned.
   - **Answer Pool(s):** Answer pools contain the group of answers that will be served in response to DNS queries.
     - **Answer Pool Name:** A user-friendly name for the answer pool, unique within the steering policy. Avoid entering confidential information.
     - **Name:** A unique name to identify the answer. Avoid entering confidential information.
     - **Type:** The record type that will be provided as the answer.
     - **RDATA:** A valid domain name or IP address to add as an answer.
     - **Eligible:** Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select Mark pool answers eligible or Mark pool answers ineligible from the Actions drop-down menu.
   - **ASN Steering Rules:** ASN steering rules specify the priority of answers that are served in a policy. If the primary answer is unavailable, traffic is steered to the next answer in the list.
     - **ASN:** Enter an Autonomous System Number (ASN) that will be used to distribute DNS traffic.
     - **Pool Priority:** Select the priority in which the answers are served.
     - **Global Catch-all:** Adding a global catch-all allows you to specify answer pools for queries that do not match any of the specified rules you have added. Click Add Global Catch-all and select the pool priorities.
   - **Attach Health Check:** Select an existing Health Check to be included as part of the policy, add a new one, or select None.
   - **Attach Domain(s):** The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.

5. Click **Create Policy**.

The system creates and publishes the policy.

To create an IP Prefix Steering policy

2. Click **Create Traffic Management Steering Policy**.
3. In the **Create Traffic Management Steering Policy** dialog box, select **IP Prefix Steering**.
4. Enter the following information:
   - **Policy Name**: The unique name that identifies policy. Avoid entering confidential information.
   - **Policy TTL**: The Time to Live for responses from the steering policy. If not specified, the system will set this value on the steering policy.
   - **Maximum Answer Count**: The maximum number of answers returned for the policy. For priority-based policies, the first valid answer is returned.
   - **Answer Pool(s)**: Answer pools contain the group of answers that will be served in response to DNS queries.
     - **Answer Pool Name**: A user-friendly name for the answer pool, unique within the steering policy. Avoid entering confidential information.
     - **Name**: A unique name to identify the answer. Avoid entering confidential information.
     - **Type**: The record type that will be provided as the answer.
     - **RDATA**: A valid domain name or IP address to add as an answer.
     - **Eligible**: Select the check box to indicate that the answer is available within the pool to be used in response to queries. Alternatively, select *Mark pool answers eligible* or *Mark pool answers ineligible* from the Actions drop-down menu.
   - **IP Prefix Steering Rules**: IP prefix steering rules specify the priority of answers that are served in a policy. If the primary answer is unavailable, traffic is steered to the next answer in the list.
     - **Subnet Address**: Enter a subnet address that will be used to distribute DNS traffic.
     - **Pool Priority**: Select the priority in which the answers are served.
     - **Global Catch-all**: Adding a global catch-all allows you to specify answer pools for queries that do not match any of the specified rules you have added. Click *Add Global Catch-all* and select the pool priorities.
   - **Attach Health Check**: Select an existing Health Check to be included as part of the policy, add a new one, or select *None*.
   - **Attach Domain(s)**: The domain name and domain OCID you want to attach to the policy. Additional domains can be added in this section.

5. Click Create Policy.

The system creates and publishes the policy.

*To update a policy*

2. Click the Policy Name you want to update. Policy information and a list of attached domains appear.
   
   **Tip:**
   
   You can use search for a policy by name in the Search field. You can also use the Time Created sort filter to sort the policies chronologically in ascending or descending order.

3. Click Edit.
4. Make the needed changes, and then click Save.

*To attach a domain to an existing policy*

2. Click the Policy Name you want to update. Policy information and a list of attached domains appear.

   **Tip:**

   You can use search for a policy by name in the Search field. You can also use the Time Created sort filter to sort the policies chronologically in ascending or descending order.

3. Click Add Attached Domain(s).
4. In the Add Attached Domain(s) dialog box, enter the domain and select a zone.
5. Click Submit.

**To edit an attached domain**

2. Click the Policy Name you want to update. Policy information and a list of attached domains appear.

   **Tip:**
   
   You can use search for a policy by name in the Search field. You can also use the Time Created sort filter to sort the policies chronologically in ascending or descending order.

3. For the attached domain you want to edit, click the Actions menu, and then click Edit Attached Domain.
4. In the Attached Domain(s) dialog box, enter the domain and select a zone.
5. Click Save.

**To delete a policy**

2. Select the check box for the policy you want to delete.
3. Click Delete. The policy is staged for deletion.
4. Click Publish Changes to delete the policy.
5. In the confirmation dialog box, click Publish Changes.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

For more information about managing steering policies using the API, see Traffic Management Steering Policies API Guide.

Use the following operations to manage your steering policies:

- CreateSteeringPolicy
- ListSteeringPolicies
- GetSteeringPolicy
- UpdateSteeringPolicy
- DeleteSteeringPolicy

Use the following operations to manage your steering policy attachments:

- CreateSteeringPolicyAttachment
- ListSteeringPolicyAttachments
- GetSteeringPolicyAttachment
- UpdateSteeringPolicyAttachment
- DeleteSteeringPolicyAttachment

**Traffic Management Steering Policies API Guide**

Traffic Management Steering Policies allows you to build and configure traffic management policies using the Oracle Cloud Infrastructure DNS REST API. Use the following guide to learn how policies are constructed using the REST API.

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).
An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference on page 3347.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Traffic Management Steering Policy Components

The following list describes the components used to build a Traffic Management Steering Policy.

STEERING POLICIES

An overall framework to define the traffic management behavior for your zones. Steering policies contain rules that help to intelligently serve DNS answers.

ATTACHMENTS

Allows you to link a steering policy to your zones. An attachment of a steering policy to a zone occludes all records at its domain that are of a covered record type, constructing DNS responses from its steering policy rather than from those domain's records. A domain can have at most one attachment covering any given record type.

RULES

The guidelines steering policies use to filter answers based on the properties of a DNS request, such as the requests geo-location or the health of your endpoints.

ANSWERS

Answers contain the DNS record data and metadata to be processed in a steering policy.

TEMPLATES

Templates are predefined rule sequences that create a policy type and its intended behavior. Example: The FAILOVER template determines answers by checking DNS query against a FILTER rule first, then the following rules in succession: HEALTH, PRIORITY, and LIMIT. This gives the domain dynamic failover capability. Policies that define the template field with any policy other than CUSTOM, must follow the rule sequence outlined for that policy type, otherwise, a 400 status code error will be returned upon policy creation.

CASES

A rule may optionally include a sequence of cases defining alternate configurations for how it should behave during processing for any given DNS query. When a rule has no sequence of cases, it is always evaluated with the same configuration during processing. When a rule has an empty sequence of cases, it is always ignored during processing. When a rule has a non-empty sequence of cases, its behavior during processing is configured by the first matching case in the sequence. A rule case with no caseCondition always matches. A rule case with a caseCondition matches only when that expression evaluates to true for the given query.

Create Steering Policies Using Templates

The following section explains the rule configuration for each type of steering policy template followed by an example POST request (CreateSteeringPolicy) displaying how to configure each template.

FAILOVER

Failover policies allow you to prioritize the order in which you want answers served in a policy (for example, Primary and Secondary). Oracle Cloud Infrastructure Health Checks are leveraged to determine the health of answers in the policy. If the Primary Answer is determined to be unhealthy, DNS traffic will automatically be steered to the
Secondary Answer. Each of the following rules must be defined in the order specified below in the `rules` field of your request body when using a FAILOVER template:

<table>
<thead>
<tr>
<th>Order</th>
<th>Rule</th>
<th>Restrictions</th>
<th>Comments</th>
</tr>
</thead>
</table>
| 1     | FILTER  | • No cases are allowed.  
• Answer data must be defined in `defaultAnswerData` using the following JSON:  
```json
{
  "answerCondition": "answer.isDisabled != true",
  "shouldKeep": true
}
``` |                                                                                           |
| 2     | HEALTH  | • No cases are allowed.  
Only included if `healthCheckMonitorId` is defined for the policy. |                                                                                           |
| 3     | PRIORITY| • No cases are allowed.  
• Answer data must be defined in the `defaultAnswerData` property for the rule.  
• Every answer must have a pool property.  
• `defaultAnswerData` restrictions:  
  • Answers cannot be referenced by their name property in `answerCondition` expressions, they must be referenced by their pool property.  
  • Every answer pool must be referenced once and only once.  
  • Every answer pool must have a unique value property.  
  • Each answer pool reference must match the pool property on one or more answers defined in the answer list for the policy. |                                                                                           |
| 4     | LIMIT   | • No cases are allowed. |                                                                                           |

Example of a POST `/steeringPolicies` policy using the FAILOVER template:

```json
{
  "compartmentId": "ocid1...",
  "displayName": "failover between endpoints",
  "ttl": 30,
  "healthCheckMonitorId": "ocid1...",
  "template": "FAILOVER",
  "answers": [
    {
      "name": "server-primary",
      "rtype": "A",
      "rdata": "192.168.0.2",
      "pool": "primary"
    },
    {
      "name": "server-secondary",
      "rtype": "A",
      "rdata": "192.168.0.3",
      "pool": "secondary"
    }
  ]
}
```
LOAD_BALANCE

Load Balancer policies allow distribution of traffic across multiple endpoints. Endpoints can be assigned equal weights to distribute traffic evenly across the endpoints or custom weights may be assigned for ratio load balancing. Oracle Cloud Infrastructure Health Checks are leveraged to determine the health of the endpoint. DNS traffic will be automatically distributed to the other endpoints, if an endpoint is determined to be unhealthy. Each of the following rules must be defined in the order specified below in the rules field of your request body when using a LOAD_BALANCE template:

<table>
<thead>
<tr>
<th>Order</th>
<th>Rule</th>
<th>Restrictions</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>FILTER</td>
<td>• No cases are allowed.</td>
<td>• Answer data must be defined in defaultAnswerData using the following JSON:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Answer data must be defined in defaultAnswerData using the following JSON:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>{</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;answerCondition&quot;: &quot;answer.isDisabled != true&quot;,</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;shouldKeep&quot;: true</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
<td></td>
</tr>
</tbody>
</table>
### DNS and Traffic Management

<table>
<thead>
<tr>
<th>Order</th>
<th>Rule</th>
<th>Restrictions</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>HEALTH</td>
<td>• No cases are allowed.</td>
<td>Only included if healthCheckMonitorId is defined for the policy.</td>
</tr>
<tr>
<td>3</td>
<td>WEIGHTED</td>
<td>• No cases are allowed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Answer data must be defined in the defaultAnswerData property for the rule.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Answers cannot be referenced by their pool property in answerCondition expressions, they must be referenced by their name property.</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>LIMIT</td>
<td>• No cases are allowed.</td>
<td></td>
</tr>
</tbody>
</table>

Example of a POST /steeringPolicies policy using the LOAD_BALANCE template:

```json
{
  "compartmentId": "ocid1...",
  "displayName": "Weighted load balance for a set of answers with health checks",
  "ttl": 30,
  "healthCheckMonitorId": "ocid1...",
  "template": "LOAD_BALANCE",
  "answers": [
    {
      "name": "server1",
      "rtype": "A",
      "rdata": "192.168.0.2"
    },
    {
      "name": "server2",
      "rtype": "A",
      "rdata": "192.168.0.3"
    }
  ],
  "rules": [
    {
      "ruleType": "FILTER",
      "defaultAnswerData": [
        {
          "answerCondition": "answer.isDisabled != true",
          "shouldKeep": true
        }
      ]
    },
    {
      "ruleType": "HEALTH"
    },
    {
      "ruleType": "WEIGHTED",
      "defaultAnswerData": [
        {
          "answerCondition": "answer.name == 'server1'",
          "value": 99
        },
        {
          "answerCondition": "answer.name == 'server2'",
          "value": 1
        }
      ]
    }
  ]
}
```
ROUTE_BY_GEO

Geolocation-based steering policies distribute DNS traffic to different endpoints based on the location of the end user. Customers can define geographic regions composed of originating continent, countries or states/provinces (North America) and define a separate endpoint or set of endpoints for each region. Each of the following rules must be defined in the order specified below in the rules field of your request body when using a ROUTE_BY_GEO template:

<table>
<thead>
<tr>
<th>Order</th>
<th>Rule</th>
<th>Restrictions</th>
<th>Comments</th>
</tr>
</thead>
</table>
| 1     | FILTER | • No cases are allowed.  
• Answer data must be defined in defaultAnswerData using the following JSON: |

```json
{
    "answerCondition": "answer.isDisabled != true",
    "shouldKeep": true
}
```

<table>
<thead>
<tr>
<th>2</th>
<th>HEALTH</th>
<th>• No cases are allowed.</th>
<th>Only included if healthCheckMonitorId is defined for the policy.</th>
</tr>
</thead>
</table>
| 3     | PRIORITY | • The defaultAnswerData property cannot be used on this rule.  
• At least one case must be defined. If there are multiple cases, the final case can provide a "catch-all" case.  
• The caseCondition property on cases can only use query.client.geoKey in the conditional expression.  
• Answers cannot be referenced by their name property in answerCondition expressions, they must be referenced by their pool property.  
• Every answer must have a pool property.  
• For each case's answerData:  
  • Every answer pool must be referenced once and only once.  
  • Every answer pool must have a unique value property (within the case).  
  • Each answer pool reference must match the pool property on one or more answers defined in the answer list for the policy. |}

| 4     | LIMIT  | • No cases are allowed. |
Example of a POST /steeringPolicies request body using the ROUTE_BY_GEO template:

```json
{
    "compartmentId": "ocid1...",
    "displayName": "Geolocations mapped to answer pools",
    "ttl": 30,
    "healthCheckMonitorId": "ocid1...",
    "template": "ROUTE_BY_GEO",
    "answers": [
        {
            "name": "US Server 1",
            "rtype": "A",
            "rdata": "192.168.0.2",
            "pool": "US"
        },
        {
            "name": "US Server 2",
            "rtype": "A",
            "rdata": "192.168.0.3",
            "pool": "US"
        },
        {
            "name": "EU Server 1",
            "rtype": "A",
            "rdata": "192.168.0.4",
            "pool": "EU"
        },
        {
            "name": "EU Server 2",
            "rtype": "A",
            "rdata": "192.168.0.5",
            "pool": "EU"
        },
        {
            "name": "rest of world 1",
            "rtype": "A",
            "rdata": "203.0.113.2",
            "pool": "Global"
        },
        {
            "name": "rest of world 2",
            "rtype": "A",
            "rdata": "203.0.113.3",
            "pool": "Global"
        }
    ],
    "rules": [
        {
            "ruleType": "FILTER",
            "defaultAnswerData": [
                {
                    "answerCondition": "answer.isDisabled != true",
                    "shouldKeep": true
                }
            ]
        },
        {
            "ruleType": "HEALTH"
        },
        {
            "ruleType": "PRIORITY",
            "cases": [
```
ROUTE_BY_ASN

ASN-based steering policies enable you to steer DNS traffic based on Autonomous System Numbers (ASN). DNS queries originating from a specific ASN or set of ASNs can be steered to a specified endpoint. Each of the
DNS and Traffic Management

The following rules must be defined in the order specified below in the `rules` field of your request body when using a `ROUTE_BY_ASN` template:

<table>
<thead>
<tr>
<th>Order</th>
<th>Rule</th>
<th>Restrictions</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>FILTER</td>
<td>- No cases are allowed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Answer data must be defined in <code>defaultAnswerData</code> using the following JSON:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>```json</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;answerCondition&quot;: &quot;answer.isDisabled != true&quot;,</td>
<td></td>
</tr>
<tr>

ROUTE_BY_IP

IP Prefix-based steering policies enable customers to steer DNS traffic based on the IP Prefix of the originating query. Each of the following rules must be defined in the order specified below in the rules field of your request body when using a ROUTE_BY_IP template:

<table>
<thead>
<tr>
<th>Order</th>
<th>Rule</th>
<th>Restrictions</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>FILTER</td>
<td>• No cases are allowed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Answer data must be defined in defaultAnswerData using the following JSON:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>{</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;answerCondition&quot;:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;answer.isDisabled != true&quot;,</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;shouldKeep&quot;: true</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>HEALTH</td>
<td>• No cases are allowed.</td>
<td>Only included if healthCheckMonitorId is defined for the policy.</td>
</tr>
</tbody>
</table>
**DNS and Traffic Management**

<table>
<thead>
<tr>
<th>Order</th>
<th>Rule</th>
<th>Restrictions</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>PRIORITY</td>
<td>- The <code>defaultAnswerData</code> property cannot be used on this rule.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- At least one case must be defined. If there are multiple cases, the final case can provide a &quot;catch-all&quot; case.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The <code>caseCondition</code> property on cases can only use <code>query.client.address</code> in the conditional expression.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Answers cannot be referenced by their name property in <code>answerCondition</code> expressions, they must be referenced by their pool property.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Every answer must have a pool property.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- For each case's <code>answerData</code>:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Every answer pool must be referenced once and only once.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Every answer pool must have a unique value property (within the case).</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Each answer pool reference must match the pool property on one or more answers defined in the answer list for the policy.</td>

        },
        {
          "answerCondition": "answer.pool == 'ABC'",
          "value": 2
        },
        {
          "answerCondition": "answer.pool == 'Other'",
          "value": 3
        }
      ]
    },
    {
      "answerData": [
        {
          "answerCondition": "answer.pool == 'Other'",
          "value": 1
        },
        {
          "answerCondition": "answer.pool == 'ABC'",
          "value": 2
        },
        {
          "answerCondition": "answer.pool == 'DEF'",
          "value": 3
        }
      ]
    }
  ]
},
{
  "ruleType": "LIMIT",
  "defaultCount": 1
}
]
CUSTOM

Custom policies allow you to create complex policies combining the capabilities of failover, load balancing, geolocation, ASN and IP prefix steering. Custom templates do not require a regimented sequence of rules and it is recommended to contact Oracle Cloud Infrastructure support before creating a custom policy.

Rule Types

FILTER

Uses boolean data associated with answers, keeping answers only if the rule's `shouldKeep` value is `true`.

HEALTH

Utilizes Oracle Cloud Health Check monitors to determine the health of your endpoints and add and remove answers from your policy as needed. A health check monitor must be referenced in a health rule to have an effect on the policy. For more information about Health Checks, see Health Checks.

WEIGHTED

Uses a number between 0 and 255 used to determine how often an answer will be served in relation to other answers. Answers with higher values are more likely to be returned.

PRIORITY

Uses an integer associated with each answer to sort answers from lowest to highest value. Example: An answer with a priority value of 1 would be returned before an answer with a priority value of 10 in the list of answers. Answers that do not have a priority value assigned to them will be moved to the end of the list of answers.

LIMIT

Uses a count property to filter away all but the first answers in the list.

Traffic Management Steering Policy geokeys

Use these keys as values for the `geokey` fields of `caseConditions` in `ROUTE_BY_GEO` steering policies.

Continent geokeys

<table>
<thead>
<tr>
<th>Continent Name</th>

**DDoS Protection**

DDoS Protection is an always-on detection and mitigation platform for common DDoS volumetric attacks. The service protects against common layer 3 and 4 attacks like SYN floods, UDP floods, ICMP floods, and NTP Amplification attacks. DDoS Protection is included with all Oracle Cloud Infrastructure accounts and no configuration or monitoring is required.
Email Delivery

This chapter explains how to send large volume email.

Oracle Cloud Infrastructure (OCI) Email Delivery is an email sending service and SMTP relay that provides a fast and reliable managed solution for sending both high volume bulk and transactional emails that need to reach the inbox.

Overview of the Email Delivery Service

Oracle Cloud Infrastructure Email Delivery is an email sending service that provides a fast and reliable managed solution for sending high-volume emails that need to reach your recipients' inbox. Email Delivery provides the tools necessary to send application-generated email for mission-critical communications such as receipts, fraud detection alerts, multi-factor identity verification, and password resets.
Oracle Cloud Infrastructure's Email Deliverability team manages the platform using key deliverability metrics to ensure the best sending reputation possible for your emails.

The following items are provided to you when you send email using the Email Delivery service:

- Unique mailbox provider SMTP configurations on our Mail Transfer Agents (MTA)
- Bounce collection
- User complaint collection
- Email authentication standards
- Deliverability performance

**Email Delivery Service Components**

Email Delivery uses the components described in this section.

**APPROVED SENDERS**

An Approved Sender is a resource that equates to the "From" address. An approved sender is associated with a compartment and only exists in the region where the approved sender was configured. If you need to have the same approved sender in another region, it must be created in the other region. For example, if you create an approved sender in the US West (Phoenix) region, you cannot send email through the US East (Ashburn) region.

**SUPPRESSION LIST**

The Suppression List is included on your Email Delivery console user interface and from the API. Email Delivery automatically adds email addresses with bounce codes showing permanent failures or user complaints to the suppression list to protect your sender reputation. Email Delivery will not send any messages to these recipients in the future.

Reasons for suppression currently include:

- Complaints
- Hard bounces
- Repetitive soft bounces
- Manual entries
- List-unsubscribe requests

**SPF AUTHENTICATION**

Sender Policy Framework (SPF) is used by email receivers to detect email spoofing. Using SPF, an email receiver can check if the Internet Protocol (IP) is explicitly authorized to send for that domain. SPF is implemented by publishing a special TXT record to a domain's DNS records. The TXT record declares which hosts are allowed to send mail on behalf of this domain. Receiving mail servers check the SPF records of sending domains to verify that the email's source IP address is authorized to send from that domain. Without SPF, a spam or phishing email can be “spoofed” to appear that the email comes from a legitimate domain. Domains that implement SPF are much more likely to block emails attempting to spoof your domain. For an overview of how SPF works, see [Sender Policy Framework](#). For details on SPF record syntax, see [SPF Record Syntax](#).

**Regions and Availability Domains**

SMTP credentials can be used for any region, as identities are global assets. However, approved senders (your "From" address) must be configured within each region you plan to use for Email Delivery. To configure approved senders within each region, select a region from the Region menu in the Console and create an approved sender. Configure your application to send email to the endpoint of that region where you created the approved sender, using the global SMTP credentials. The sending application is not required to be located in the region where email is sent from, however, we recommend that it is local or as close as possible for performance reasons.

For more information, see [Regions and Availability Domains](#) on page 210.
Configuring a New Region

If you want to start sending email from a new region, keep the following in mind:

• An approved sender must be created in the new region.
• SMTP credentials are global, however, it is recommended that you generate SMTP credentials for a new user (without console access) in the new region so that the credentials are not shared with other regions. Ensure that the user has the correct privileges.
• Email must be sent to the new regional SMTP connection endpoint.
• The suppression list and approved senders are regional Email Delivery assets.

For example, if an email sent from the US West (Phoenix) region bounces, the recipient email address will be added to the US West (Phoenix) region suppression list. This recipient would not be added to other region suppression lists. If you are sending email from different regions, approved senders must be created in each region.

• SPF must be set up on each subdomain. For example, in your DNS setup, create a TXT record for notification.eu-frankfurt-1.oraclecloud.com and paste the following information from the dialog box into the record: v=spf1 include:eu.rp.oracleemaildelivery.com ~all

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see SDKs and Other Tools.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. You are prompted to enter your cloud tenant, your user name, and your password. For general information about using the API, see About the API.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference on page 3347.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Email Delivery supports the following authentication types for control plane operations (management endpoint):

• **Instance Authorization**: The IAM service feature that enables instances to be authorized actors (or principals) to perform actions on service resources. Each compute instance has its own identity, and it authenticates using the certificates that are added to it. These certificates are automatically created, assigned to instances and rotated, preventing the need for you to distribute credentials to your hosts and rotate them.

• **Cross-Tenancy**: Cross-tenancy authorization allows customers to share resources between tenancies. To authorize a cross-tenancy request, the request must be endorsed by the requester's tenancy and permitted by the target tenancy.

• **Federated**: Federated authentication enables an administrator to configure a relationship between an identity provider and a service provider. When you federate Oracle Cloud Infrastructure with an identity provider, you
manage users and groups in the identity provider. You manage authorization in Oracle Cloud Infrastructure's IAM service. Oracle Cloud Infrastructure tenancies are federated with Oracle Identity Cloud Service by default.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instance authorization, cross-tenancy, and federated authentication types do not apply to SMTP email sending. An approved sender and SMTP credentials are required and must be associated with the same tenancy for SMTP email sending.</td>
</tr>
</tbody>
</table>

## SMTP Authentication and Connection Endpoints

Email Delivery only supports the AUTH PLAIN command when using SMTP authentication. If the sending application is not flexible with the AUTH command, an SMTP proxy/relay can be used. For more information about the AUTH command, see AUTH Command and its Mechanisms.

Use the following regional endpoints for establishing SMTP connections for sending.

- South Korea North (Chuncheon): smtp.email.ap-chuncheon-1.oci.oraclecloud.com
- India South (Hyderabad): smtp.email.ap-hyderabad-1.oci.oraclecloud.com
- Australia Southeast (Melbourne): smtp.email.ap-melbourne-1.oci.oraclecloud.com
- India West (Mumbai): smtp.email.ap-mumbai-1.oci.oraclecloud.com
- Japan Central (Osaka): smtp.email.ap-osaka-1.oci.oraclecloud.com
- Singapore (Singapore): smtp.email.ap-singapore-1.oci.oraclecloud.com
- South Korea Central (Seoul): smtp.email.ap-seoul-1.oci.oraclecloud.com
- Australia East (Sydney): smtp.email.ap-sydney-1.oci.oraclecloud.com
- Japan East (Tokyo): smtp.email.ap-tokyo-1.oci.oraclecloud.com
- Canada Southeast (Montreal): smtp.email.ca-montreal-1.oci.oraclecloud.com
- Canada Southeast (Toronto): smtp.email.ca-toronto-1.oci.oraclecloud.com
- Netherlands Northwest (Amsterdam): smtp.email.eu-amsterdam-1.oci.oraclecloud.com
- Germany Central (Frankfurt): smtp.email.eu-frankfurt-1.oci.oraclecloud.com
- France South (Marseille): smtp.email.eu-marseille-1.oci.oraclecloud.com
- Italy Northwest (Milan): smtp.email.eu-milan-1.oci.oraclecloud.com
- Switzerland North (Zurich): smtp.email.eu-zurich-1.oci.oraclecloud.com
- Israel Central (Jerusalem): smtp.email.il-jerusalem-1.oci.oraclecloud.com
- UAE Central (Abu Dhabi): smtp.email.me-abudhabi-1.oci.oraclecloud.com
- UAE East (Dubai): smtp.email.me-dubai-1.oci.oraclecloud.com
- Saudi Arabia West (Jeddah): smtp.email.me-jeddah-1.oci.oraclecloud.com
- Chile (Santiago): smtp.email.sa-santiago-1.oci.oraclecloud.com
- Brazil East (Sao Paulo): smtp.email.sa-saopaulo-1.oci.oraclecloud.com
- Brazil Southeast (Vinhedo): smtp.email.sa-vinhedo-1.oci.oraclecloud.com
- UK West (Newport): smtp.email.uk-cardiff-1.oci.oraclecloud.com
- UK South (London): smtp.email.uk-london-1.oci.oraclecloud.com
- US East (Ashburn): smtp.email.us-ashburn-1.oci.oraclecloud.com
- US West (Phoenix): smtp.email.us-phoenix-1.oci.oraclecloud.com
- US West (San Jose): smtp.email.us-sanjose-1.oci.oraclecloud.com

## Monitoring Resources

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 4078 and Notifications on page 4900.

For information about available Email Delivery service metrics and how to view them, see Email Delivery Metrics on page 2641.
Email Delivery

Email Delivery Service Capabilities and Limits

See Service Limits on page 247 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Customers that sign up for a free Oracle Cloud trial are limited to:

- A volume of 200 emails per day where an email is defined as either a single recipient in the TO:, CC:, or BCC: fields, or a 2 MB chunk of data.

  Email examples:
  - A single request with 10 recipients (TO:, CC:, or BCC:) equals 10 emails.
  - A 10 MB email sent to a single recipient is equal to 10 MB divided by 2 MB per email. This equals 5 emails.
  - A single email request with a message size of 10 MB sent to 10 recipients is equal to 10 MB divided by 2 MB per email multiplied by 10 recipients. This equals 50 emails.

- 2,000 approved senders.
- Each user is limited to a maximum of two SMTP credentials.
- Sending rates are limited to 10 emails per minute.
- Inline attachments.
- 2 MB maximum message size including base64 encoding and headers.

Enterprise accounts are limited to:

- A volume of 50,000 emails per day where an email is defined as either a single recipient in the TO:, CC:, or BCC: fields, or a 2 MB chunk of data.

  Email examples:
  - A single request with 10 recipients (TO:, CC:, or BCC:) equals 10 emails.
  - A 10 MB email sent to a single recipient is equal to 10 MB divided by 2 MB per email. This equals 5 emails.
  - A single email request with a message size of 10 MB sent to 10 recipients is equal to 10 MB divided by 2 MB per email multiplied by 10 recipients. This equals 50 emails.

  This limit applies to unique recipients among all emails sent. For example, a single email sent to 100 recipients would count the same as 100 individual emails each sent to a single recipient.

- 10,000 approved senders.
- Sending rates are limited to 18,000 emails per minute.
- Inline attachments.
- 2 MB maximum message size including base64 encoding and headers.

Email Delivery, by default, supports messages up to 2 MB, inclusive of message headers, body, and attachments. Each 2 MB of data counts towards your daily sending volume and sending rate limits. For example, a 10 MB counts as five emails.

Based on requirement, you can request a limit increase up to a maximum of 60 MB if you have SPF and DKIM set up for your sending domain. To open a service request to increase the limit, see Requesting a Service Limit Increase on page 249. Your increase request is evaluated by the following information you provide:

- What are your current sending domains?
- Do your sending practices meet the requirements of CAN-SPAM and CASL?
- Briefly describe the type of email you will be sending. For example, are the emails marketing/bulk/newsletters, transactional, notifications, and so on?
- Do you send emails related to payday loans or credit card offers?
- Do you send email on behalf of other companies?
- How do the recipients sign up to receive these emails? Specify any domains they might sign up on.
- Are there any other methods that are used to collect email addresses?
- How many emails do you want to send per month?
- Which ESP supplier are you currently using to send your emails?
- What is the maximum number of messages you need to send in a burst capacity (within a specific timeframe)?
• What is the maximum size of your messages?
• What is the number of emails sent per day that is over 2 MB?
• Are your recipients Oracle email addresses (for example, test.user@oracle.com)?
• Which email delivery region do you intend to use to send email through?

Note:
The Email Delivery platform supports higher volumes. Limits are set as a safeguard for our customers' reputation. To open a service request to increase the email sending limit, see Requesting a Service Limit Increase on page 249.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for Email Delivery, see Details for the Email Service.

Permissions are required for managing and using approved senders and the suppression list. For example:

• To enable all operations on approved senders for a specific user group:

  Allow group <Your Group Name> to manage approved-senders in tenancy

• To enable all operations on suppressions for a specific user group:

  Allow group <Your Group Name> to manage suppressions in tenancy

Dedicated IP Addresses

When you create an Email Delivery service account, by default, your emails are sent from IP addresses shared with other Oracle customers.

Email Delivery supports IPs addresses dedicated to you, for complete control over your reputation. Both a shared IP or dedicated IP strategy can provide excellent delivery depending on your needs and mail stream characteristics.

When using a dedicated pool of Oracle owned IP addresses, only your mail is sent from them.

Note:
Our deliverability experts review all dedicated IP requests to ensure the best deliverability for your situation. Dedicated IP addresses may not be advised for lower volume or more sporadic email sending, as this does not support a good sending reputation and therefore can cause an impact to your email deliverability.

Dedicated IP addresses are ideal for senders who:

• Send large volumes of mail on a consistent basis to sustain their own IP reputation. Sending a large volume of mail consistently is what Internet Service Providers (ISPs) automated filters use to assign a reputation to your IP address. This is one of the key inputs into whether your messages are delivered into the inbox, spam folder, or temporarily rejected.

• Want complete control of their sending reputation AND understand email delivery best practices. When you are the only sender on an IP, it insulates your reputation from other senders. This can be good or bad depending on your sending practices and consistent hygiene.

• Have large volumes, different mail streams, and want to build unique reputations for each. Dedicated IPs enable you to build separate IP reputations based on different types of mail streams like transactional messages
versus bulk marketing mail. If you have the volume to support it, isolating these mail streams can reduce the risk of delivery challenges for more critical message types.

Dedicated IP addresses are likely not a good fit for senders who:

- **Send mail inconsistently at low volumes preventing an ISP reputation from being assigned.** To build an IP reputation, ISPs prefer a predictable mail cadence with enough email volume to assign a reputation. Failing to meet this requirement could lead to delivery challenges. Sending in a shared IP pool with many smaller senders will provide the ISP with a large volume of consistent mail.

- **Do not understand email best practices, which could lead to poor-reputation delivery challenges.** Sending in a shared IP pool with other customers that is managed by Oracle can be less risky for an email novice.

Your mail characteristics (volume, burst rates, reputation, and so on) will vary your dedicated IP strategy. Our teams are trained on dedicated IP strategies and ready to support your needs. If you need help with your configuration, you can go to My Oracle Support and create a service request.

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 243.

Email Delivery supports applying tags to approved senders.

**Integration with Oracle Cloud Infrastructure Services**

Email Delivery audits the following events:

- Creating a sender (CreateSender)
- Deleting a sender (DeleteSender)
- Retrieving details about a sender (ListSenders)

To view logs for events in the Email Delivery service, your user must be in a group with the ability to view all of the Audit event logs in the tenancy. For more information, see Viewing Audit Log Events on page 625.

**Getting Started with Email Delivery**

You can set up the Email Delivery service within the Console. To begin sending email with Email Delivery, complete the following steps:

1. Generate SMTP credentials for a user.
2. Set up permissions.
3. Create an approved sender.
4. Configure SPF on the approved sender domain.
5. Configure the SMTP connection.

For more information, see Getting Started with Email Delivery on page 2620.

**Getting Started with Email Delivery**

Email Delivery provides a highly scalable, cost effective, and reliable way to send email from your applications. Email Delivery includes developer-friendly tools to quickly send application-generated email for mission-critical communications such as receipts, programmatic notifications, or password reset emails.
Email Delivery Basics

When you use Email Delivery, we become your outbound email server. If you have an existing email server, you can keep it and configure it to send through Email Delivery. The Email Delivery service will take care of the feedback loops and platform reputation automatically.

Getting Started

This topic gives guidance on how to get started with Email Delivery. For complete details about the service and its components, see Overview of the Email Delivery Service on page 2614.

Email Configuration Options

You can configure Oracle Cloud Infrastructure using the Console (a browser-based interface), REST API, SDKs, CLI or Terraform.

Using the Email Delivery SDK

The Email Delivery SDK is available in several programming languages. For information on installing and configuring the Oracle Cloud Infrastructure SDKs, see Developer Resources on page 6102.

Examples of SDK usage can be found on GitHub, including:

- Example: Email Delivery SDK for Java
- Example: Email Delivery SDK for Python
- Example: Email Delivery SDK for Ruby
- Example: Email Delivery SDK for Go

Configuring Third-Party Applications

The following information describes how you can configure third-party applications to send email through Email Delivery:

- Integrating Oracle Application Express with Email Delivery on page 2643
- Integrating Postfix with Email Delivery on page 2644
- Integrating Oracle Enterprise Manager with Email Delivery on page 2646
- Integrating Mailx with Email Delivery on page 2647
- Integrating Swaks with Email Delivery on page 2649
Deliverability Best Practices

Email Deliverability is commonly known as the ability to deliver bulk and transactional emails to opt-in recipient inboxes. Refer to Email Deliverability for information on best practices, troubleshooting undelivered emails, and other options to improve inbox placement. For more best practice guidelines, see Best Practices on page 2628.

Sending Email

To begin sending email with Email Delivery, complete the following steps:

**Generate SMTP credentials for a user.**

Simple Mail Transfer Protocol (SMTP) credentials are necessary to send email through Email Delivery. Each user is limited to a maximum of two SMTP credentials. If more than two are required, SMTP credentials must be generated that are associated with another existing user or more users must be created.

**Best Practice:** A security best practice is to generate SMTP credentials for a new user instead of your Console user that already has permissions assigned to it. For detailed instructions on creating a user, see Adding Users.

To generate SMTP credentials for a user

1. View the user's details:
   - If you're generating SMTP credentials for **yourself**:
     Open the Profile menu () and click User Settings.
   - If you're an administrator generating SMTP credentials for **another user**:
     Open the navigation menu and click Identity & Security. Under Identity, click Users. Locate the user in the list, and then click the user's name to view the details.

2. Click SMTP Credentials.
3. Click Generate SMTP Credentials.
4. Enter a Description of the SMTP Credentials in the dialog box.
5. Click Generate SMTP Credentials. A user name and password is displayed.
6. Copy the user name and password for your records and click Close. Copy the credentials immediately, because you can't retrieve the password again after closing the dialog box for security reasons.

   If you're an administrator creating the credential set for another user, you need to securely deliver it to the user by providing it verbally, printing it out, or sending it through a secure email service.

**Set up permissions.**

The new user must be assigned to a group with permissions to manage the email-family resources.

To create a policy to allow a group to manage email-family resources

1. Open the navigation menu and click Identity & Security. Under Identity, click Policies. A list of the policies in the compartment you're viewing is displayed.
2. If you want to attach the policy to a compartment other than the one you're viewing, select the compartment from the list on the left. Where the policy is attached controls who can later modify or delete it (see Overview of Policies).
3. Click Create Policy.
4. Enter the following:

- **Name:** A unique name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later.

- **Description:** A friendly description. You can change this later if you want to.

- **Policy Versioning:** Select *Keep Policy Current* if you'd like the policy to stay current with any future changes to the service's definitions of verbs and resources. Or if you'd prefer to limit access according to the definitions that were current on a specific date, select *Use Version Date* and enter that date in format YYYY-MM-DD format. For more information, see **Advanced Policy Features**.

- **Statement:** Enter the following policy statement:

  ```
  Allow group <group name> to use email-family in compartment <compartment name>
  ```

  For more information about policies and policy syntax, see **Policy Basics**.

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**.

The new policy goes into effect typically within 10 seconds.

See **Managing Approved Senders** on page 2629 and **Generate SMTP Credentials for a User** on page 2628 for more details on Email sending related policy setup requirements.

Suppressions policy must be set at the tenancy level. For more information, see **Managing the Suppression List** on page 2634.

### To add the new user to the group

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. A list of the users in your tenancy is displayed.
2. Locate the user in the list.
3. Click the user. Its details are displayed.
4. Click **Groups**.
5. Click **Add User to Group**.
6. Select the group from the drop-down list, and then click **Add**.

Make sure to let the user know which compartment(s) they have access to.

### Set up an email domain with DKIM.

Here's the general process for setting up a sending domain with DKIM:

1. **Create the email domain:** An email domain lets you set up important authentication measures for sending email, essential to ensure good email delivery reputation.
2. **Configure DKIM:** Configure DKIM for this email domain. This is an important step to help ensure email is delivered and reaches the inbox. Create at least one DKIM.
3. **Add the DKIM record to your DNS setup:** The system generated CNAME record and value can be used in the DNS setup for your email domain. You must add the record to your DNS setup and allow it to propagate throughout the internet before you can activate the DKIM record.
4. **Activate the DKIM record:** Activate the DKIM record to enable signing and authentication of your emails.

   For more information, see **Managing DKIM** on page 2636.

### Create an approved sender.

An approved sender must be set up for all “From:” addresses sending mail through Oracle Cloud Infrastructure, or mail is rejected. An approved sender is associated with a compartment and only exists in the region where the
approved sender was configured. That is, if you create an approved sender in the US West (Phoenix) region, you cannot send email through the US East (Ashburn) region with that sender.

**Best Practices:** Approved senders should not be created in the root compartment. If approved senders exist in the root compartment, you are required to create a policy to manage approved senders in the entire tenant. Creating approved senders in a compartment other than the root allows the policy to be specific to that compartment.

Use of multiple addresses in the email From header is discouraged. If you use multiple addresses, it increases the possibility that your mail is placed in a spam folder or discarded (because of DMARC From alignment rules). The performance of your emails is reduced because all addresses have to be authorized as approved senders. A best practice for the SMTP envelope From address is to match the header From address when you submit mail to Email Delivery. If you use mismatched addresses, it reduces the performance of your emails because both addresses need to be authorized as approved senders. Certain future platform features will not be available if you use mismatched addresses.

**To create an approved sender using the Console**

1. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Email Delivery**.
   In the **Resources** menu, click **Approved Senders**. Ensure that you are in the correct compartment. Your user must be in a group with permissions to manage approved-senders in this compartment.
2. Click **Create Approved Sender** within the **Approved Senders** view.
3. Enter the email address you want to list as an approved sender in the **Add Sender** dialog box.
4. Click **Add**. The email address is added to your Approved Senders list.

**Tip:**
Approved senders are unique to tenancies. If an attempt is made to create a duplicate approved sender within a tenancy, the service will return a 409 Conflict error.

**To create an approved sender using the API**

The following example shows how to create an approved sender. For more information about creating an approved sender, see **CreateSender**.

```
POST /20170907/senders
{
  "compartmentId": "ocid1.compartment.oc1..aaaaaaaat7uqcb6zoxvzoga4d4vh4dtweciaqaced3skz56atf3qp73d7fx",
  "emailAddress": "user@example.com",
}
```

**Configure SPF on the approved sender domain.**

Sender Policy Framework (SPF) is used by email receivers to detect email spoofing. Using SPF, an email receiver can check if the Internet Protocol (IP) is explicitly authorized to send for that domain. SPF is implemented by publishing a special TXT record to a domain's DNS records. The TXT record declares which hosts are allowed to send mail on behalf of this domain. Receiving mail servers check the SPF records of sending domains to verify that the email's source IP address is authorized to send from that domain. Without SPF, a spam or phishing email can be “spoofed” to appear that the email comes from a legitimate domain. Domains that implement SPF are much more likely to block emails attempting to spoof your domain. For an overview of how SPF works, see **Sender Policy Framework**. For details on SPF record syntax, see **SPF Record Syntax**.

The Approved Senders section within the Console provides validation of an SPF record for each of your approved senders.

**To configure SPF**

1. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Email Delivery**.
   In the **Resources** menu, click **Approved Senders**.
2. Select the checkbox for the approved sender you want to view SPF details for and click View SPF.

Tip:
You can search for an approved sender by using the Search field. Addresses can be sorted alphanumerically or by creation date in ascending or descending order.

3. The Manage SPF dialog box appears indicating whether an SPF record for the approved sender exists.
   - If your domain does not currently have an SPF record, the information necessary to add an SPF record in your DNS setup is displayed. See Managing DNS Service Zones for instructions on adding a zone record in Oracle Cloud Infrastructure. If your DNS setup resides with another provider, please reference their documentation for adding a TXT record to your domain.
   - In your DNS setup, create a TXT record and paste the following information into the record based on the sending location:

<table>
<thead>
<tr>
<th>Sending Location</th>
<th>SPF Record</th>
</tr>
</thead>
<tbody>
<tr>
<td>Americas</td>
<td>v=spf1 include:rp.oracleemaildelivery.com~all</td>
</tr>
<tr>
<td>Asia/Pacific</td>
<td>v=spf1 include:ap.jp.oracleemaildelivery.com~all</td>
</tr>
<tr>
<td>Europe</td>
<td>v=spf1 include:eu.jp.oracleemaildelivery.com~all</td>
</tr>
<tr>
<td>All Commercial Regions</td>
<td>v=spf1 include:rp.oracleemaildelivery.com include:ap.jp.oracleemaildelivery.com include:eu.jp.oracleemaildelivery.com~all</td>
</tr>
</tbody>
</table>

Configure the SMTP connection.

Set up and test your SMTP connection using an SMTP library or product such, as Postfix or Sendmail, to send email through Oracle Cloud Infrastructure Email Delivery.

SMTP Connection Endpoints

Use the following regional endpoints for establishing SMTP connections for sending.

<table>
<thead>
<tr>
<th>Sending Region</th>
<th>SMTP Endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>South Korea North (Chuncheon)</td>
<td>smtp.email.ap-chuncheon-1.oci.oraclecloud.com</td>
</tr>
<tr>
<td>India South (Hyderabad)</td>
<td>smtp.email.ap-hyderabad-1.oci.oraclecloud.com</td>
</tr>
<tr>
<td>Australia Southeast (Melbourne)</td>
<td>smtp.email.ap-melbourne-1.oci.oraclecloud.com</td>
</tr>
<tr>
<td>India West (Mumbai)</td>
<td>smtp.email.ap-mumbai-1.oci.oraclecloud.com</td>
</tr>
<tr>
<td>Japan Central (Osaka)</td>
<td>smtp.email.ap-osaka-1.oci.oraclecloud.com</td>
</tr>
<tr>
<td>South Korea Central (Seoul)</td>

</tr>
<tr>
<td>US West (San Jose)</td>
<td>smtp.email.us-sanjose-1.oci.oraclecloud.com</td>
</tr>
</tbody>
</table>

**TLS Requirements**

Oracle maintains strict security policies and only accepts email traffic using Transport Layer Security (TLS). Use of TLS 1.2 is mandatory to send email using Oracle Cloud Infrastructure.

The approved TLS 1.2 ciphers are:

- TLS_DHE_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_DSS_WITH_AES_256_CBC_SHA256
- TLS_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_DSS_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256

**To access SMTP sending information to configure the connection in your system**

Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Email Delivery**. In the **Resources** menu, click **Email Configuration**. The following information is displayed:

- **Public Endpoint**: The public endpoint used to send email to for this region.
- **SMTP Ports**: The SMTP ports used to accept email. Email Delivery supports TLS on port 25 or 587.
**Security**: This field indicates if TLS, the standard means of performing encryption in transit for email, is being used. Customers must encrypt email while it is in transit to the Oracle Cloud Infrastructure Email Delivery service. Encrypted emails are protected from being read during transit.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Java applications (including JavaMail) must be updated to the latest version to ensure the latest protocols, ciphers, and security patches are in compliance with Oracle’s supported security policies and ciphers.</td>
</tr>
</tbody>
</table>

**Begin sending email.**

Use Email Delivery to begin sending email.

**Suppression List**

As you begin to send email, Email Delivery automatically adds email addresses with bounce codes showing permanent failures or user complaints to the suppression list to protect your sender reputation. Email Delivery will not send any messages to these recipients in the future. Reasons for suppression currently include:

- Complaints
- Hard bounces
- Repetitive soft bounces
- Manual entries
- List-unsubscribe requests

**To manually add an email address to the suppression list using the Console**

1. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Email Delivery**. In the **Resources** menu, click **Email Suppression List**.
2. Click **Add Suppression**.
3. In the Add Suppression dialog box, enter the email address.
4. Click **Add**. The email address is added to the suppression list.

For more information, see [Managing the Suppression List](#) on page 2634.

**To manually add an email address to the suppression list using the API**

The following example shows how to add an email address to the suppression list. For more information about managing the suppressions list, see **GetSuppression** and **DeleteSuppression**.

```
POST /20170907/suppressions
{
   "compartmentId": "ocid1.compartment.oc1..aaaaaaaat7uqcb6zoxzoga4d4vh4dtweciapeac3skz56atf3qp73d7fx",
   "emailAddress": "user@example.com",
}
```

**Using the API**

You can access Oracle Cloud Infrastructure using the REST API. Instructions for the API are included in topics throughout this guide. For a list of available SDKs, see [SDKs and Other Tools](#).

**Regions**

See [Regions and Availability Domains](#) on page 2615 for more information.

**Limits**

See [Email Delivery Service Capabilities and Limits](#) for information on new account and enterprise account limits.
**Best Practices**

This section describes best practices for using Email Delivery.

**Volume Testing** - In order to maintain our sender reputation and yours, testing at volume needs to be done using the following best practice.

- Use a recipient address at the email-blackhole.com domain, such as example@email-blackhole.com. Email Delivery will accept the mail but will not deliver it to an inbox.
- If large volume emails are sent to valid email addresses, these will get rejected by receivers and will result in a large amount of hard bounces. This will negatively affect IP reputation. For testing bounce processing, send small amounts of emails to a domain that does not have an MX record, in other words, the domain does not exist.

**Deliverability** - To help you learn and manage the habits that affect your sending reputation, see Email Deliverability on page 2667.

**Sending to Email Aliases** - When sending email to an alias, the alias is considered one recipient. When sending email to a distribution group or list set up in an email client such as Apple Mail or Outlook, a separate email is sent for each recipient in the group.

---

### Generate SMTP Credentials for a User

Simple Mail Transfer Protocol (SMTP) credentials are necessary to send email through Email Delivery. Each user is limited to a maximum of two SMTP credentials. If more than two are required, SMTP credentials must be generated on other existing users or more users must be created.

A security best practice is to generate SMTP credentials for a new user instead of your Console user that already has permissions assigned to it. For detailed instructions on creating a user, see Adding Users. The new user must be assigned to a group with permissions to manage the email-family resources. For example:

```
Allow group <senders group name> to use email-family in compartment <compartment name>
```

Where `<senders group name>` is the group this new user has been assigned to and `<compartment name>` is the name of the compartment which contains the approved senders that will use these credentials for sending. The policy to use email-family ensures that the user has the necessary access to all Email resources and not just approved senders. When attempting to send email, the SMTP error "535 Authorization failed: Envelope From address <approved-sender> not authorized" indicates that either the approved sender does not exist, the "use email-family" policy does not specify the compartment containing the approved sender, or the user with the SMTP credentials is not in a group with the "use email-family" policy.

---

### Using the Console

**To generate SMTP credentials for a user**

1. View the user's details:
   - If you're generating SMTP credentials for *yourself*:
     - Open the **Profile** menu ( çünkü ) and click **User Settings**.
   - If you're an administrator generating SMTP credentials for *another user*:
     - Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. Locate the user in the list, and then click the user's name to view the details.

2. Click **SMTP Credentials**.
3. Click **Generate SMTP Credentials**.
4. Enter a **Description** of the SMTP Credentials in the dialog box.
5. Click **Generate SMTP Credentials**. A user name and password is displayed.
6. Copy the user name and password for your records and click Close. Copy the credentials immediately, because you can't retrieve the password again after closing the dialog box for security reasons.

If you're an administrator creating the credential set for another user, you need to securely deliver it to the user by providing it verbally, printing it out, or sending it through a secure email service.

Managing Approved Senders

An approved sender must be set up for all “From:” addresses sending mail through Oracle Cloud Infrastructure, or mail is rejected. An approved sender is associated with a compartment and only exists in the region where the approved sender was configured. That is, if you create an approved sender in the US West (Phoenix) region, you cannot send email through the US East (Ashburn) region with that sender.

Use of multiple addresses in the email From header is discouraged. If you use multiple addresses, it increases the possibility that your mail is placed in a spam folder or discarded (because of DMARC From alignment rules). The performance of your emails is reduced because all addresses have to be authorized as approved senders. A best practice for the SMTP envelope From address is to match the header From address when you submit mail to Email Delivery. If you use mismatched addresses, it reduces the performance of your emails because both addresses need to be authorized as approved senders. Certain future platform features will not be available if you use mismatched addresses.

The approved senders that you add must use a domain name that you own and control. The following sending domains cannot be used to create approved senders:

- @oracle.com - This sending domain name is reserved for Oracle employee and corporate system use.
- @*.oraclevcn.com - This domain name is reserved for private use within an Oracle Cloud Infrastructure VCN. Email sending domains must have SPF and DKIM records that can be resolved on the public internet, and oraclevcn.com is only reachable within private Oracle Cloud Infrastructure networks. Use of this sending domain results in delivery delays, failures, and a possible blocklist addition.
- @gmail.com, @hotmail.com, @yahoo.com, and other public mailbox service providers - You cannot use a sending domain from a public mailbox service provider such as gmail, hotmail, icloud, yahoo, and so on. These providers tend to have restrictive DMARC records and will not delegate permission to third-party Email Delivery services (through SPF and DKIM records). Use of these sending domains results in delivery delays, failures, and a possible blocklist addition.

The following sending domain is problematic for use as an approved sender:

- @oraclecloud.com - This sending domain name is reserved for Oracle Cloud system use.

Approved senders should not be created in the root compartment. If approved senders exist in the root compartment, you are required to create a policy to manage approved senders in the entire tenant. Creating approved senders in a compartment other than the root allows the policy to be specific to that compartment.

Required IAM Policy

Permissions are required for managing approved senders. For example, to manage approved senders, use the following policy:

```
Allow group <sender admins group> to manage email-family in tenancy
```

Using the `email-family` policy ensures that the user has the necessary access to all Email Delivery resources and not just approved senders. In addition, the user whose credentials will be used to send email from the approved sender must have the right policies. For more information, see Generate SMTP Credentials for a User on page 2628.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for Email Delivery, see Details for the Email Delivery Service.
Moving Approved Senders to a Different Compartment

You can move approved senders from one compartment to another. To manage approved senders and use approved senders to send mail, user groups must have an associated identity policy in the new compartment. For more information, see Managing Compartments.

Using the Console

To create an approved sender

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Resources menu, click Approved Senders. Ensure that you are in the correct compartment. Your user must be in a group with permissions to manage approved-senders in this compartment.
2. Click Create Approved Sender within the Approved Senders view.
3. Enter the email address you want to list as an approved sender in the Create Approved Sender dialog box.
4. Click Create Approved Sender. The email address is added to your Approved Senders list.

Tip:
Approved senders are unique to tenancies. If an attempt is made to create a duplicate approved sender within a tenancy, the service will return a 409 Conflict error.

To delete an approved sender

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Resources menu, click Approved Senders.
2. Find the approved sender you're interested in, click the Actions icon (three dots), and then click Delete.
3. In the confirmation dialog box, click Confirm. The email address is removed from the Approved Senders list.

To move an approved sender to a different compartment

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Resources menu, click Approved Senders.
2. In the List Scope section, select a compartment.
3. Find the approved sender in the list, click the the Actions menu, and then click Choose New Compartment.
4. Choose the destination compartment from the list.
5. Click Move Approved Sender.

For more information, see Managing Compartments.

To manage tags for an approved sender

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Resources menu, click Approved Senders.
2. Find the approved sender you're interested in, click the Actions icon (three dots), and then click View Tags to view or edit existing tags. Or click Apply tag(s) to add new ones.

For more information, see Resource Tags on page 243.

Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152. Use the following operations to manage your approved senders:

• CreateSender
Configure SPF

Sender Policy Framework (SPF) is used by email receivers to detect email spoofing. Using SPF, an email receiver can check if the Internet Protocol (IP) is explicitly authorized to send for that domain. SPF is implemented by publishing a special TXT record to a domain's DNS records. The TXT record declares which hosts are allowed to send mail on behalf of this domain. Receiving mail servers check the SPF records of sending domains to verify that the email's source IP address is authorized to send from that domain. Without SPF, a spam or phishing email can be “spoofed” to appear that the email comes from a legitimate domain. Domains that implement SPF are much more likely to block emails attempting to spoof your domain. For an overview of how SPF works, see Sender Policy Framework. For details on SPF record syntax, see SPF Record Syntax.

The Approved Senders section within the Console provides validation of an SPF record for each of your approved senders. SPF is required for subdomains of oraclegovcloud.com and recommended in other cases.

Using the Console

To configure SPF:

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Resources menu, click Approved Senders.

2. Select the checkbox for the approved sender you want to view SPF details for and click View SPF.

   Tip:
   
   You can search for an approved sender by using the Search field. Addresses can be sorted alphanumerically or by creation date in ascending or descending order.

3. The Manage SPF dialog box appears indicating whether an SPF record for the approved sender exists.

   If your domain does not currently have an SPF record, the information necessary to add an SPF record in your DNS setup is displayed. See Managing DNS Service Zones for instructions on adding a zone record in Oracle Cloud Infrastructure. If your DNS setup resides with another provider, please reference their documentation for adding a TXT record to your domain.

   • In your DNS setup, create a TXT record and paste the following information into the record based on the sending region:

<table>
<thead>
<tr>
<th>Sending Region</th>
<th>SPF Record</th>
</tr>
</thead>
</table>
   | Americas       | v=spf1
                   include:rp.oracleemaildelivery.com
                   -all |
   | Asia/Pacific   | v=spf1
                   include:ap.rp.oracleemaildelivery.com
                   -all |
   | Europe         | v=spf1
                   include:eu.rp.oracleemaildelivery.com
                   -all |
**Email Delivery**

### Sending Region

<table>
<thead>
<tr>
<th>Sending Region</th>
<th>SPF Record</th>
</tr>
</thead>
</table>
| All Commercial Regions         | v=spf1
include:rp.oracleemaildelivery.com
include:ap.rp.oracleemaildelivery.com
include:eu.rp.oracleemaildelivery.com
~all |
| Government Regions             | • For US Government Cloud with FedRAMP Authorization, see SPF Record Syntax on page 191.  
|                                | • For US Federal Cloud with DISA Impact Level 5, see SPF Record Syntax on page 198.  
|                                | • For United Kingdom Government Cloud, see SPF Record Syntax on page 207.  |

- If your domain currently has an SPF DNS record, you must update your record in order to successfully use Email Delivery.
- The following is an example of a command used to view an SPF record:

  ```plaintext
dig -t TXT +short syd1.rp.oracleemaildelivery.com
```

  **Example output:**

  
  "v=spf1 ip4:192.168.0.2/25 -all"

- If you're using other email providers in addition to Email Delivery, you'll need to combine the include statements from your other providers with Email Delivery.

### Configure SMTP Connection

Set up and test your SMTP connection using an SMTP library or product, such as Postfix or Sendmail, to send email through Oracle Cloud Infrastructure Email Delivery.

Open Email Configuration to access SMTP sending information to configure the connection in your system. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Email Delivery**. In the **Resources** menu, click **Email Configuration**. The following information is displayed:

- **Public Endpoint**: The public endpoint used to send email to for this region.
- **SMTP Ports**: The SMTP ports used to accept email. Email Delivery supports TLS on port 25 or 587.
- **Security**: This field indicates if TLS, the standard means of performing encryption in transit for email, is being used. Customers must encrypt email while it is in transit to the Oracle Cloud Infrastructure Email Delivery service. Encrypted emails are protected from being read during transit.

**Important:**

Java applications (including JavaMail) must be updated to the latest version to ensure the latest protocols, ciphers, and security patches are in compliance with Oracle’s supported security policies and ciphers.

### SMTP Connection Endpoints

Use the following regional endpoints for establishing SMTP connections for sending.

<table>
<thead>
<tr>
<th>Sending Region</th>
<th>SMTP Endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>South Korea North (Chuncheon)</td>
<td>smtp.email.ap-chuncheon-1.oci.oraclecloud.com</td>

<td>smtp.email.sa-saopaulo-1.oci.oraclecloud.com</td>
</tr>
<tr>
<td>Brazil Southeast (Vinhedo)</td>
<td>smtp.email.sa-vinhedo-1.oci.oraclecloud.com</td>
</tr>
<tr>
<td>UK West (Newport)</td>
<td>smtp.email.uk-cardiff-1.oci.oraclecloud.com</td>
</tr>
<tr>
<td>UK South (London)</td>
<td>smtp.email.uk-london-1.oci.oraclecloud.com</td>
</tr>
<tr>
<td>US East (Ashburn)</td>
<td>smtp.email.us-ashburn-1.oci.oraclecloud.com</td>
</tr>
<tr>
<td>US West (Phoenix)</td>
<td>smtp.email.us-phoenix-1.oci.oraclecloud.com</td>
</tr>
<tr>
<td>US West (San Jose)</td>
<td>smtp.email.us-sanjose-1.oci.oraclecloud.com</td>
</tr>
</tbody>
</table>

### TLS Requirements

Oracle maintains strict security policies and only accepts email traffic using Transport Layer Security (TLS). Use of TLS 1.2 is mandatory to send email using Oracle Cloud Infrastructure.

The approved TLS 1.2 ciphers are:

- TLS_DHE_RSA_WITH_AES_256_CBC_SHA
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_DSS_WITH_AES_256_CBC_SHA256
- TLS_RSA_WITH_AES_256_CBC_SHA
- TLS_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA
Email Delivery

- TLS_DHE_DSS_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256

Managing the Suppression List

Manually add an email address to the suppression list to prevent it from being part of your sending list.

Users are required to have correct permissions to manage the suppression list. Currently, identity policies for suppression must be at the tenant level (not at the compartment level). The following is an example of the permission policy statement.

```
Allow group <sender admins group> to manage suppressions in tenancy
```

Suppressions are stored at the tenant level. Therefore any request requiring a `compartmentId` must provide the `tenancyId` as the `compartmentId`. For example:

```
Allow group <ordinary users group> to inspect suppressions in tenancy
Allow group <power users group> to read suppressions in tenancy
Allow group <sender admins group> to manage suppressions in tenancy
```

For other policies required for Email sending, see Managing Approved Senders on page 2629 and Generate SMTP Credentials for a User on page 2628. Also, for advanced policies, see Advanced Policy Features.

Using the Console

To manually add an email address to the suppression list

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Resources menu, click Email Suppression List.
2. Click Add Suppression.
3. In the Add Suppression dialog box, enter the email address.
4. Click Add. The email address is added to the Suppression List.

To delete an email address from the suppression list

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Resources menu, click Email Suppression List.
2. Select the checkbox for the email address you want to delete and then click Delete.
3. In the confirmation dialog box, click OK. The email address is removed from the Suppression List.

Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152. Use the following operations to manage your suppressions:

- CreateSuppression
- GetSuppression
- ListSuppressions
• DeleteSuppression

Managing Email Domains

An email domain lets you set up important authentication measures for sending email, essential to ensure good email delivery reputation. An email domain also lets you set up logging for visibility into your email traffic. Your email domain should be a domain you own or control in DNS, since measures used to establish verification and authentication require a DNS record or similar actions. It should be the domain you plan to use for your approved sender email address for sending, and cannot be a public mailbox provider domain such as gmail.com or hotmail.com. After setting up email domains, it is recommended that you create approved senders and configure SPF.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for Email Delivery, see Details for the Email Delivery Service.

To enable all operations on all email resources for a specific user group, use the following policy:

Allow group <Your Group Name> to manage email-family in tenancy <Your Tenancy>

Using the Console

To create an email domain

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Email Delivery menu, click Email Domains.
2. Click Create Email Domain.
3. Enter your email domain name. This should be a domain you own or control in DNS, since measures used to establish verification and authentication require a DNS record or similar actions. It should be the domain you plan to use for your "From" email address for sending, and cannot be a public mailbox provider domain such as gmail.com or hotmail.com.

Tags: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
4. Click Create.

To delete an email domain

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Email Delivery menu, click Email Domains.
2. Find the email domain in the list, click the the Actions icon (three dots), and then click Delete.

To move an email domain to another compartment

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Email Delivery menu, click Email Domains.
2. Find the email domain in the list, click the the Actions icon (three dots), and then click Change Compartment.

Using the API
For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use the following operations to manage email domains:

- CreateEmailDomain
- GetEmailDomain
- ListEmailDomains
- UpdateEmailDomain
- DeleteEmailDomain
- ChangeEmailDomainCompartment

Managing DKIM

DomainKeys Identified Mail (DKIM) is an authentication framework that allows verification of the source and contents of messages by Mail Transfer Agents (MTAs). With DKIM, a signer can cryptographically sign an email message for a domain, claiming responsibility for its authenticity. The recipient verifies the signature by querying the signing domain for the public key to confirm that the signature was created with the matching private key.

DKIM-Signature is an email header field that contains all of the signature and key-fetching data. This header value contains tags with specific details about the email message, such as the signing domain where the verifier can find the public key (“d”) and the specific header fields as of signing (“h”). These tags protect the integrity of the email message, proving that it is from a legitimate source and that the signed contents have not been tampered with. Thus, DKIM can protect a domain from being spoofed for the proliferation of spam or in a phishing attempt.

The following is an example of a DKIM-Signature:

```
DKIM-Signature: v=1; a=rsa-sha256; c=relaxed/relaxed; s=prod-fra-20191115;
  d=fral_rp.oracleemaildelivery.com;
  h=Date:To:From:Subject:Message-Id:MIME-Version:Sender;
  bh=Rskt6Q/nZKmxgXkWUYP6cCBSDJhtkVT0PSrUEVGVgp4=;
  b=Waqhf3halToZeAlJzo4FwhQ3ypTfu/Ngo75g9nHEez8zMvumoyQq+
+GaynJvxlksvKtUpWyhOmlIfW
  YN008po/u6P7w2hrWKVK3J5PbeYjRTrtAUEHGX6LYBI182fUgMwgL8doAlWS/
  0Lb19qF8Leo2dB3
  LMK1P+BhWApLdZQfyzC15rnKyXpyLmlKNMeeVrHJirY2Tgv56s2UT5pncNAh91/0LL7dd9z/
  UhgU
  ET+pGnmdTRxt626+ecNxPRpAeoI+ym+Bgt1iaNJKNUE8aq04Iuf/
  mpsBjwlLr7FrGfHOLEAKe9
  FjB7JTNvrUulauMAwZz3OTPVUvq4wrN8XK7h+g==
```

One DKIM key can be active for your email domain at a time. You can set up DKIM keys in the Console and denote one record to be the active DKIM key to sign your emails with.

For more information about DKIM, see:

- DKIM.org
- RFC 6376 – DomainKeys Identified Mail Signatures

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for Email Delivery, see Details for the Email Delivery Service.
To enable all operations on all email resources for a specific user group, use the following policy:

```
Allow group <Your Group Name> to manage email-family in tenancy <Your Tenancy>
```

You can also use the Policy Builder "Email Management" use case to add a few policy statements that include using the email Public Logging feature.

**Setting Up An Email Domain with DKIM**

Here's the general process for setting up a sending domain with DKIM:

1. **Create the email domain, if it doesn’t exist already:** An email domain lets you set up important authentication measures for sending email, essential to ensure good email delivery reputation.
2. **Configure DKIM:** Configure DKIM for this email domain. This is an important step to help ensure email is delivered and reaches the inbox.
3. **Add the DKIM record to your DNS setup:** The system generated CNAME record and value can be used in the DNS setup for your email domain.

   The following diagram illustrates how a sender domain DNS server can be used to store the CNAME record that contains the DKIM key that points back to OCI DNS. This setup is preferred.
Email Delivery

as it makes key rotation easier. However, if needed, you can request the key and directly store the

The following diagram illustrates how a DKIM key can be stored directly in a DNS setup.
4. **Set up approved senders**: Approved senders must be set up for all “From:” addresses sending mail through Oracle Cloud Infrastructure, or mail is rejected. Setting up approved senders is essential to ensure good email delivery reputation. The DKIM key set up for the domain is automatically associated with ALL approved senders in that domain. See Managing Approved Senders on page 2629 for more information. Only approved senders with the exact domain including subdomain will be signed by your new key. For example, noreply@sample.com will not gain the dkim key associated with mysubdomain.sample.com.

**Task A: Create the email domain**

1. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Email Delivery**. In the **Email Delivery** menu, click **Email Domains**.
2. Click **Create Email Domain**.
3. Enter your email domain name. This should be a domain you own or control in DNS, since measures used to establish verification and authentication require a DNS record update or similar actions. It should be the domain you plan to use for your approved senders, and cannot be a public mailbox provider domain such as gmail.com or hotmail.com.

   **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
4. Click **Create**.

**Task B: Configure DKIM**

DKIM lets the receiving email provider verify that an email was sent and authorized by the owner of the sender's domain. DKIM is set up within DNS records to facilitate verification of digital signing of emails.

1. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Email Delivery**. In the **Email Delivery** menu, click **Email Domains**.
2. Click the name of the email domain where you want to configure DKIM.
3. Click **Add DKIM**.
4. In the DKIM Selector field, enter a selector to be used for this particular DKIM key. All selectors need to be globally unique for your domain. We suggest using a regional indicator and date portion as part of the selector, such as `prefix-region-YYYYMMDD`. The date portion is useful for future key rotation. The DKIM selector can contain only up to 63 lowercase alphanumeric characters (a-z, 0-9) with dashes, and needs to start with a lowercase letter.
5. Click **Generate DKIM Record** to generate the DKIM record. The system generates a CNAME record and value that can be used in your DNS set up for your email domain.
6. Copy the CNAME record and CNAME value for your DNS set up.
7. Click **Done**.

   Email Delivery supports a maximum of two DKIM keys per email domain, however, only one DKIM record will be used for signing for your domain at a time. It is recommended that you rotate your keys every six months.

**Task C: Add the DKIM record to your DNS setup**

See Managing DNS Service Zones on page 2555 for instructions on adding a zone record in Oracle Cloud Infrastructure. If your DNS setup resides with another provider, please reference their documentation for adding records to your domain. Refer to the following documentation links for several common providers:

- Cloudflare
- Dreamhost
- GoDaddy
- HostGator
- Namecheap
- Names.co.uk
- Wix

**Task D: Set up approved senders**
Approved senders can use a DKIM-configured sending domain to become verified. See Managing Approved Senders on page 2629 for information on how to add an approved sender.

Non-commercial realms

In the following government realms, the DKIM TXT record needs to be added to DNS instead of the CNAME pointing to OCI Email Delivery's DNS where the TXT records reside for other realms. The TXT Record value is available through API or in the Console on the left bottom of the DKIM Details page for that DKIM key.

- Oracle Cloud Infrastructure US Government Cloud with FedRAMP High Joint Authorization Board (OC2)
- Oracle Cloud Infrastructure US Federal Cloud with DISA Impact Level 5 authorization (OC3)
- Oracle Cloud Infrastructure United Kingdom Government Cloud (OC4)

Using the Console

To create an email domain

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Email Delivery menu, click Email Domains.
2. Click Create Email Domain.
3. Enter your email domain name. This should be a domain you own or control in DNS, since measures used to establish verification and authentication require a DNS record or similar actions. It should be the domain you plan to use for your “From” email address for sending, and cannot be a public mailbox provider domain such as gmail.com or hotmail.com.
   
   **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
4. Click Create.

To delete an email domain

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Email Delivery menu, click Email Domains.
2. Find the email domain in the list, click the the Actions icon (three dots), and then click Delete.

To move an email domain to another compartment

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Email Delivery menu, click Email Domains.
2. Find the email domain in the list, click the the Actions icon (three dots), and then click Change Compartment.

To create a DKIM record

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Email Delivery menu, click Email Domains.
2. Click the name of the email domain where you want to configure DKIM.
3. Click Add DKIM.
4. In the DKIM Selector field, enter the prefix to be used in generating the DKIM selector for this particular DKIM key. Replacement keys will each have their own unique selector and should include a date component to easily identify when the key should be rotated. The DKIM selector can contain only up to 63 lowercase, alphanumeric characters (a-z, 0-9) with dashes.
5. Click Generate DKIM Record to generate the DKIM record. The system generates a CNAME record and value that can be used in your DNS set up for your email domain.
6. Copy the CNAME record and CNAME value for your DNS set up.
7. Click Done.

   Email Delivery supports a maximum of two DKIM keys per email domain, however, only one DKIM record can be active for your domain at a time. It is recommended that you rotate your keys every six months.
To check for DKIM in DNS

Wait for the system to check the status of the DKIM in your DNS and update the status accordingly.

To delete a DKIM record

1. Open the navigation menu and click Developer Services. Under Application Integration, click Email Delivery. In the Email Delivery menu, click Email Domains.
2. Click the name of the email domain where you want to delete a DKIM record.
3. Find the DKIM selector in the list, click the the Actions icon (three dots), and then click Delete.

Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use the following operations to manage email domains:

• CreateEmailDomain
• GetEmailDomain
• ListEmailDomains
• UpdateEmailDomain
• DeleteEmailDomain
• ChangeEmailDomainCompartment
• CreateDkim
• GetDkim
• ListDkims
• UpdateDkim
• DeleteDkim

Email Delivery Metrics

You can monitor the health, capacity, and performance of your Email Delivery by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_emaildelivery (the Email Delivery service).

Overview of the Email Delivery Service Metrics

Oracle Cloud Infrastructure Email Delivery (Email Delivery) is an email sending service that provides a fast and reliable managed solution for sending high-volume emails that need to reach your recipients' inbox. Email Delivery service metrics help you measure counts for accepted mail, email complaints, emails hard bounced, and emails soft bounced.

• Accepted Mail: Accepted mail consists of the unique emails accepted by the Email Delivery service to send. Emails are defined by the number of unique emails and the number of unique recipients per message attempted to be delivered, resulting in successful delivery and blocked email. For example, sending an email with 10 recipients means 10 emails accepted.
• Email Complaints: Email complaints consists of the number of email complaints for a sender by the Email Delivery service.
• Emails Hard Bounced: Hard bounces occur when a mailbox provider provides a signal that the email address you have tried to send to is not valid. Most often, this happens because the email address does not exist. You should not try to email this address again in the future. The emails hard bounced metric consists of the number of emails hard bounced (permanent failure) for a sender by the recipient domain's email service.
• Emails Soft Bounced: Soft bounces are messages from a mailbox provider that provide a signal that the email address you have tried to send to is not valid for the time being. Usually, a message soft bounces when the inbox is full or cannot be reached. You can try to email this address again in the future. The emails soft bounced metric
Email Delivery consists of the number of emails soft bounced (persistent transient failure) by the recipient domain's email service or because of an inability to reach that service.

- **Emails Relayed:** Emails relayed consists of the number of emails that the Email Delivery service has successfully transferred to a recipient domain. The recipient domain has accepted responsibility and will typically deliver these emails, but can still choose to discard, quarantine, or bounce. A single email may be both relayed and bounced.

**Note:**
Email Delivery is billed for every 1,000 emails accepted.

**Prerequisites**
IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

**Available Metrics: oci_emaildelivery**
The metrics listed in the following table are automatically available for any policies you create. You do not need to enable monitoring on the resource to get these metrics. However, your tenancy must have Email Delivery configured and must send mail to make the oci_emaildelivery metric space available in the Metrics Explorer feature.

Each metric includes the following dimensions:

**RESOURCEID**
The OCID of the policy to which the metric applies.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>EmailsAccepted</td>
<td>Emails Accepted</td>
<td>count</td>
<td>The number of unique emails accepted by the Email Delivery service.</td>
<td>resourceID (The OCID of the approved sender to which the metric applies.)</td>
</tr>
<tr>
<td>EmailComplaints</td>
<td>Email Complaints</td>
<td>count</td>
<td>The number of email complaints for a sender by the Email Delivery service.</td>
<td>resourceDomain (The domain name of the approved sender email address to which the metric applies.)</td>
</tr>
<tr>
<td>EmailsHardBounced</td>
<td>Emails Hard Bounced</td>
<td>count</td>
<td>The number of emails hard bounced (permanent failure) for a sender by the recipient domain's email service.</td>
<td>resourceDomain (The domain name of the approved sender email address to which the metric applies.)</td>
</tr>
<tr>
<td>EmailsSoftBounced</td>
<td>Emails Soft Bounced</td>
<td>count</td>
<td>The number of emails soft bounced (persistent transient failure) by the recipient domain's email service or due to an inability to reach that service.</td>
<td></td>
</tr>
</tbody>
</table>
Using the Console

Email Delivery service metrics are currently only available using the Metrics Explorer feature in the Console. For more information about metrics, see Viewing Metric Charts.

To view Email Delivery metric charts

   For Metric Namespace, select oci_emaildelivery.

2. Select a metric to view from the Metric Name field.

3. Select a qualifier specified in the Dimension Name field. For example, the dimension resourceId is specified in the metric definition for EmailsAccepted.

4. Select the value you want to use for the specified dimension in the Dimension Value field. For example, the resource identifier for your instance of interest.

5. Click Update Chart.

   The chart will be updated with the metrics that have been requested.

For more information about monitoring metrics and using alarms, see Monitoring on page 4078. For information about notifications for alarms, see Notifications on page 4900.

Using the API

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Integrating Oracle Application Express with Email Delivery

Configure Oracle Application Express to Send Email Through Email Delivery

You can use the APEX_MAIL package to send emails from Oracle Application Express applications deployed in Autonomous Transaction Processing. See Creating an Autonomous Database on Shared Exadata Infrastructure on page 1889 and Autonomous Transaction Processing for more information.

Important:

These instructions contain sample code for your convenience and should be used as a reference. For client support, you must contact Oracle Application Express customer support. These steps were tested on an Oracle Linux Server release 7.9 compute instance.

Before you use APEX_MAIL you must configure Oracle Cloud Infrastructure Email Delivery in your Application Express instance.

To enable APEX_MAIL functionality in your Application Express instance in Autonomous Transaction Processing:

1. Identify the SMTP connection endpoint for Email Delivery. You configure the endpoint as the SMTP Host in your Application Express instance in Step 4. See Configure SMTP Connection on page 2632 for more information.
2. Generate SMTP credentials for Email Delivery. Your Application Express instance uses credentials to authenticate with Email Delivery servers when you send email. See Generate SMTP Credentials for a User on page 2628 for more information.

3. Create an approved sender for Email Delivery. You need to complete this step for all email addresses you use as the "From" with APEX_MAIL.SEND calls, as the Application Email From Address in your apps, or in the SMTP_FROM instance parameter. See Managing Approved Senders on page 2629 for more information.

4. Connect to your Autonomous Transaction Processing as ADMIN user using a SQL client and configure the following SMTP parameters using APEX_INSTANCE_ADMIN.SET_PARAMETER:
   - **SMTP_HOST_ADDRESS**: Specifies the SMTP connection endpoint from Step 1.
   - **SMTP_USERNAME**: Specifies the SMTP credential user name from Step 2.
   - **SMTP_PASSWORD**: Specifies the SMTP credential password from Step 2.

   For example:

   ```sql
   BEGIN
   APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_HOST_ADDRESS', 'smtp.us-phoenix-1.oraclecloud.com');
   APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_USERNAME', 'ocid1.user.oc1.username');
   APEX_INSTANCE_ADMIN.SET_PARAMETER('SMTP_PASSWORD', 'password');
   COMMIT;
   END;
   /
   
   5. Send a test email using APEX SQL Workshop. SQL Commands specifying one of the approved senders from Step 3 as "From". For example:

   ```sql
   BEGIN
   APEX_MAIL.SEND(p_from => 'alice@example.com',
                   p_to => 'bob@example.com',
                   p_subj => 'Email from Oracle Autonomous Database',
                   p_body => 'Sent using APEX_MAIL');
   END;
   /
   
   6. To monitor email delivery in your Application Express instance:
   a. Sign in to APEX Administration Services.
   b. Open the Manage Instance page.
   c. Click the Mail Queue link in the Manage Meta Data section.

   Alternatively, query APEX_MAIL_QUEUE and APEX_MAIL_LOG views using a SQL client.

   **More Information**
   - Creating Applications with Oracle Application Express in Autonomous Database
   - APEX_MAIL in Oracle Application Express API Reference
   - APEX_INSTANCE_ADMIN in Oracle Application Express API Reference

   **Integrating Postfix with Email Delivery**

   **Configure Postfix to Send Email Through Email Delivery**

   Postfix is a free and open-source mail transfer agent that routes and delivers electronic mail. It is released under the IBM Public License 1.0 which is a free software license. To learn more about Postfix, see the Postfix website. You can use Postfix to send emails through Email Delivery. Before you use Postfix you must configure Oracle Cloud Infrastructure Email Delivery in your Postfix application.
Important:

These instructions contain sample code for your convenience and should be used as a reference. For client support, you must contact Postfix customer support. These steps were tested on an Oracle Linux Server release 7.9 compute instance and Postfix version 2.10.1.

Note:

The paths and commands used below for specifying file locations are specific to Ubuntu/Debian; your file paths or editing commands may differ depending on the operating system you are using. The changes to the configuration files are the same.

To enable Postfix to integrate with Email Delivery:

1. Make sure Email Delivery is configured to send email. See Getting Started with Email Delivery on page 2620.

    Note:

    The SMTP credentials are required to configure Postfix to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. To open the main.cf file, run the following command:

   ```bash
   sudo vi /etc/postfix/main.cf
   ```

   Add the following information to the end of the file:

   ```conf
   smtp_tls_security_level = may
   smtp_sasl_auth_enable = yes
   smtp_sasl_password_maps = hash:/etc/postfix/sasl_passwd
   smtp_sasl_security_options =
   ```

3. If the following line is present, either remove the line or turn it off:

   ```conf
   smtpd_use_tls = yes
   ```

   Note:

   By default, the Postfix client assumes the maximum allowed message size is that received in the initial Extended HELO (EHLO) response. This will always be our deployment default of 2MB. If you have a higher maximum message size limit, you must configure the Postfix client to ignore this default value. Edit the /etc/postfix/main.cf file and add the following:

   ```conf
   smtp_discard_ehlo_keywords = size
   ```

4. Update relayhost to include your SMTP connection endpoint and port and then save or update the file. For example:

   ```conf
   relayhost = smtp.us-ashburn-1.oraclecloud.com:587
   ```

5. Create the sasl_passwd file in the same directory as main.cf.

   Run the following command:

   ```bash
   sudo vi /etc/postfix/sasl_passwd
   ```
6. Add your relay host and port by entering:

```
server:port user:pass
```

where:

- **server** is your relay host and **port** is 25 or 587.
- **user** is the user name and **pass** is the password you received when you generated your SMTP credentials.

7. Give the permissions in the password file.

Run the following command:

```
sudo chown root:root /etc/postfix/sasl_passwd && sudo chmod 600 /etc/postfix/sasl_passwd
```

8. Generate the password hash.

Run the following command:

```
sudo postmap hash:/etc/postfix/sasl_passwd
```

Run the following command:

```
sudo postfix reload
```

10. Test the configuration by sending a test email.

Run the following command:

```
echo "This is a test message" | mail -s "Test" -r <approved sender email address> <recipient email address>
```

A `status=sent (250 Ok)` message in the log indicates the email was sent successfully.

**Note:**

If you are using SASL authentication, you must use the following RPM package: `cyrus-sasl-plain`. See the Postfix website for further documentation on configuring SASL authentication.

**More Information**

- See the [Postfix website](#) for more information on Postfix configuration.
- See [TLS errors when integrating with Postfix](#) on page 2663 for troubleshooting techniques related to Email Delivery.

**Integrating Oracle Enterprise Manager with Email Delivery**

**Configure Oracle Enterprise Manager to Send Email Through Email Delivery**

You can use Oracle Enterprise Manager to send emails through Email Delivery. Before you use Oracle Enterprise Manager, you must configure Oracle Cloud Infrastructure Email Delivery in your Oracle Enterprise Manager application.

**Important:**

These instructions contain sample code for your convenience and should be used as a reference. For client support, you must contact Oracle Enterprise Manager customer support. These steps were tested on an Oracle Linux Server release 7.9 compute instance.
To enable Oracle Enterprise Manager to integrate with Email Delivery:

1. Make sure Email Delivery is configured to send email. See Getting Started with Email Delivery on page 2620.

2. In Oracle Enterprise Manager, go to the Setup menu and click Initial Setup Console.

3. In the Initial Setup Console section, click Configure Mail Servers in the navigation pane.

4. In the Sender Identify section, click Edit.

5. Enter the name of the administrator or system that should send the email notifications and the email address from which the notifications should be sent, and then click OK.

6. In the Outgoing Mail (SMTP) Servers section, click Create.

7. Enter the mail server host name, the mail server credentials, and the encryption method to be used, and then click OK.

8. Select the outgoing mail server you wish to test and select Test Mail Server. Note the confirmation message in the console and verify that you received the test email in your inbox.

Integrating Mailx with Email Delivery

Configure Mailx to Send Email Through Email Delivery

Mailx is a Unix utility program for sending and receiving mail, also known as a Mail User Agent program. You can use Mailx to send emails through Email Delivery. Before you use Mailx, you must configure Oracle Cloud Infrastructure Email Delivery in your Mailx application.

Use these instructions only if no mail transfer agent (MTA), such as Postfix or Sendmail, is in use on the system. If you are configuring an MTA, follow the configuration instructions for that program and leave the Mailx settings at their defaults. This makes Mailx use the local MTA program to send outbound mail.

To enable Mailx to integrate with Email Delivery:
1. Ensure that Email Delivery is configured to send email. See Getting Started with Email Delivery on page 2620.

**Note:**
The SMTP credentials are required to configure Mailx to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Update the Mailx mail.rc file.

To open the mail.rc file, run the following command:

```
sudo vi ~/.mail.rc
```

Add the following information to the end of the file:

```plaintext
# smtp config
set nss-config-dir=/etc/pki/nssdb/
set smtp-use-starttls
set smtp-auth=plain
set smtp=<SMTP connection endpoint>:25
set from=<from_email_address>
set smtp-auth-user=<OCID from smtp credentials>
set smtp-auth-password=<password from smtp credentials>
```

3. Test the configuration by sending a test email.

Run the following command:

```
echo "Test Email" | mail -v -s "Send an email via mailx" -r "from_name<from_email_address>" -S replyto="from_name<from_email_address>" -S smtp="SMTP connection endpoint:25" -S smtp-use-starttls -S smtp-auth=plain -S smtp-auth-user='ocid from smtp credentials' -S smtp-auth-password='password from smtp credentials' -S ssl-verify=ignore <recipient_email_address> -S nss-config-dir="/etc/pki/nssdb/
```

**Troubleshooting**

"Error in certificate: Peer's certificate issuer has been marked as not trusted" occurs when sending email.

To troubleshoot this issue, complete the following steps:

1. Run the following command to view the certificate chain:

```
echo | openssl s_client -starttls smtp -crlf -connect <SMTP-endpoint>:587 -showcerts
```

Example output:

```
[root@ociuvddatg01 ~]# echo | openssl s_client -starttls smtp -crlf -connect smtp.email.us-ashburn-1.oci.oraclecloud.com:587 -showcerts
CONNECTED(00000003)
depth=2 C = US, O = DigiCert Inc, OU = www.digicert.com, CN = DigiCert Global Root G2
verify return:1
depth=1 C = US, O = DigiCert Inc, CN = DigiCert Global CA G2
verify return:1
depth=0 C = US, ST = California, L = Redwood City, O = Oracle Corporation, OU = Oracle OCI-PROD ASHBURN, CN = smtp.email.us-ashburn-1.oci.oraclecloud.com
verify return:1
```
2. Extract the certificate that signed your domain. In this example, this is the last certificate (2 s:/C=US/O=DigiCert Inc/OU=www.digicert.com/CN=DigiCert Global Root G2). Copy and paste the certificate into a separate DigiCert.pem file, including the BEGIN CERTIFICATE and END CERTIFICATE fields.

3. Install the certificate into the Centos NSSDB database. Replace "DigiCert Global Root G2" in the following example with your certificate:

```
sudo certutil -A -t "C,,," -n "DigiCert Global Root G2" -d /etc/pki/nssdb/ -i DigiCert.pem
```

To view the certificate, use the following command:

```
sudo certutil -L -d /etc/pki/nssdb/
```

**More Information**

- For network security services, see the Mailx documentation.

**Integrating Swaks with Email Delivery**

Swaks (Swiss Army Knife SMTP) is a transaction-based tool you can use to test SMTP configurations in Email Delivery. Before you use Swaks, you must configure Email Delivery and take note of your SMTP sending information and SMTP credentials.

**Important:**

These instructions contain sample code for your convenience and should be used as a reference. For client support, you must contact Swaks customer support. These steps were tested on an Oracle Linux Server release 7.9 compute instance and Swaks version 20201014.0.

**Note:**

Many options and parameters can be used to test various scenarios with Swaks. When Swaks evaluates an option (that is, a flag with parameters), it does so in three steps:

- First, it looks for a configuration file (default location or specified with --config).
- Next, it looks for options in environment variables.
- Finally, it looks at command line options. At each step, any options set earlier are overridden.
Assumptions

The following procedures assume the following:

- The following example supplies options to Swaks via the command line in long form, for example, --server as opposed to the short form, -s.
- The following example assumes the default behavior to connect through network sockets.
- A local certificate is not required for a TLS connection to be negotiated. The following example assumes the default behavior where Swaks does not attempt certificate verification.
- Swaks is primarily intended for use on UNIX-like operating systems with functionality based on known standards so it should work on most modern mail servers.

Configure Swaks to Send Email Through Email Delivery

To enable Swaks to test the configuration of Email Delivery:

1. Ensure Email Delivery is configured to send email. See Getting Started with Email Delivery on page 2620.

   Note:
   The SMTP credentials are required to configure Swaks to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Ensure Swaks is installed. The installation process differs depending on which operating system you are using. For example, run the following command to install Swaks on Oracle Linux:

   ```
   sudo yum install swaks -y
   ```

3. To send a test email with Swaks, run the following command:

   ```
   swaks --pipeline -tls --server <smtp.region.oraclecloud.com> --port <587 or 25> --auth-user '<username OCID from SMTP credentials>' --auth-pass '<password>' --from '<sender email address>' --to '<recipient email address>' --data '<email message>'
   ```

   For example:

   ```
   swaks --pipeline -tls --server smtp.us-ashburn-1.oraclecloud.com --port 25 --auth-user 'ocid1.user.oc1..<unique_ID>' --auth-pass '<password>' --from 'sender@example.com' --to 'recipient@example.com' --data 'From: sender@example.com
   Date: Thu, 13 Sep 2019
   Subject: Test Send
   Test email'
   ```

   Note the following when sending email with Swaks:

   - The -tls parameter is required.
   - The --pipeline parameter is supported to make use of SMTP pipelining.
   - The --port <number> parameter or :<port number> syntax can be used to specify the port.

More Information

- See the Swaks documentation for more information.

Integrating JavaMail with Email Delivery

JavaMail provides a platform-independent and protocol-independent framework to build mail and messaging applications. Before you use JavaMail, you must configure Email Delivery and take note of your SMTP sending information and SMTP credentials. This guide uses the Eclipse IDE and the JavaMail API to send email through Email Delivery.
Important:

These instructions contain sample code for your convenience and should be used as a reference. For client support, you must contact JavaMail customer support. These steps were tested on an Oracle Linux Server release 7.9 compute instance and Java 8 and 11. Java applications (including JavaMail) must be updated to the latest version to ensure that the latest protocols, ciphers, and security patches are in compliance with Oracle's supported security policies and ciphers.

Configure JavaMail to Send Email Through Email Delivery

To enable JavaMail to test the configuration of Email Delivery:

1. Ensure Email Delivery is configured to send email. See Getting Started with Email Delivery on page 2620.

   Note:
   The SMTP credentials are required to configure JavaMail to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

   2. Open a browser and go to https://github.com/javaee/javamail/releases.
   3. Under Downloads, select javax.mail.jar to download the latest version of JavaMail.
   4. Create a project in Eclipse by performing the following steps:
      a. In Eclipse, open the File menu. Select New, and then click Java Project.
      b. In the Create a Java Project dialog box, enter a project name, and then click Next.
      c. In the Java Settings dialog box, select the Libraries tab.
      d. Click Add External JARs.
      e. In the JAR Selection dialog box, browse to the folder in which you downloaded JavaMail. Select the javax.mail.jar file, and then click Open.
      f. In the Java Settings dialog box, click Finish.
   5. In Eclipse, in the Package Explorer window, expand your project.
   6. Under your project, right-click the src directory, select New, and then click Class.
   7. In the New Java Class dialog box, enter “OCIemail” in the Name field and then click Finish.
   8. Enter the following code in OCIemail.java to send a test email with JavaMail:

```java
import java.util.Properties;
import javax.mail.Message;
import javax.mail.Session;
import javax.mail.Transport;
import javax.mail.internet.InternetAddress;
import javax.mail.internet.MimeMessage;

public class OCIemail {
    // Replace FROM with your "From" address.
    // This address must be added to Approved Senders in the console.
    static final String FROM = "<sender email address>";
    static final String FROMNAME = "<sender name>";

    // Replace TO with a recipient address.
    static final String TO = "<recipient email address>";

    // Replace smtp_username with your Oracle Cloud Infrastructure SMTP username generated in console.
    static final String SMTP_USERNAME = "<username OCID from SMTP credentials>";

    public static void main(String[] args) {
        Properties props = new Properties();
        Session session = Session.getDefaultInstance(props, null);
        InternetAddress from = new InternetAddress(FROM);
        InternetAddress to = new InternetAddress(TO);

        MimeMessage msg = new MimeMessage(session);
        msg.setFrom(from);
        msg.setRecipients(Message.RecipientType.TO, to);
        msg.setSubject("Test Email from OCI email");
        String body = "This is a test email from OCI email.

        Contact: <sender name>
        Email: <sender email address>
        
        Thank you.");
        msg.setText(body);

        Transport.send(msg);
    }
}
```
// Replace smtp_password with your Oracle Cloud Infrastructure SMTP password generated in console.
static final String SMTP_PASSWORD = "<SMTP password>";

// Oracle Cloud Infrastructure Email Delivery hostname.
static final String HOST = "<SMTP endpoint>";

// The port you will connect to on the SMTP endpoint. Port 25 or 587 is allowed.
static final int PORT = 587;

static final String SUBJECT = "<subject of your email>";
static final String BODY = String.join(
    System.getProperty("line.separator"),
    "<h1>OCI Email Delivery test</h1>",
    "<p>This email was sent with OCI Email Delivery using the ",
    "<a href='javamail'>https://github.com/javaee/javamail</a>',
    " for <a href='Javahttps://www.java.com'>Java</a>.</p>");

public static void main(String[] args) throws Exception {
    // Create a Properties object to contain connection configuration information.
    Properties props = System.getProperties();
    props.put("mail.transport.protocol", "smtp");
    props.put("mail.smtp.port", PORT);
    props.put("mail.smtp.auth", "true");
    props.put("mail.smtp.auth.login.disable", "true");  //the default authorization order is "LOGIN PLAIN DIGEST-MD5 NTLM". 'LOGIN' must be disabled since Email Delivery authorizes as 'PLAIN'
    props.put("mail.smtp.starttls.enable", "true");   //TLSv1.2 is required
    props.put("mail.smtp.starttls.required", "true");  //Oracle Cloud Infrastructure required

    // Create a Session object to represent a mail session with the specified properties.
    Session session = Session.getDefaultInstance(props);

    // Create a message with the specified information.
    MimeMessage msg = new MimeMessage(session);
    msg.setFrom(new InternetAddress(FROM, FROMNAME));
    msg.setRecipient(Message.RecipientType.TO, new InternetAddress(TO));
    msg.setSubject(SUBJECT);
    msg.setContent(BODY, "text/html");

    // Create a transport.
    Transport transport = session.getTransport();

    // Send the message.
    try {
    

System.out.println("Sending Email now...standby...");

// Connect to OCI Email Delivery using the SMTP credentials specified.
transport.connect(HOST, SMTP_USERNAME, SMTP_PASSWORD);

// Send email.
transport.sendMessage(msg, msg.getAllRecipients());
System.out.println("Email sent!");
}

} catch (Exception ex) {
System.out.println("The email was not sent.");
System.out.println("Error message: " + ex.getMessage());
}

} finally {

// Close & terminate the connection.
transport.close();
}

} 9. In the OCIemail.java file, replace the following with your own values:

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email addresses are case-sensitive. Ensure that the addresses are the same as the ones you entered in Approved Senders in the console.</td>
</tr>
</tbody>
</table>

- **FROM** - Replace with your sender email address. This email address must be added to the Approved Senders list in Email Delivery first.
- **TO** - Replace with your recipient email address.
- **SMTP credentials** - Replace smtp_username and smtp_password with your Oracle Cloud Infrastructure SMTP username and password generated in the console.
- **HOST** - Replace with the Email Delivery SMTP endpoint. For example, smtp.us-ashburn-1.oraclecloud.com.

10. Refer to the requirements for configuring an SMTP connection with Email Delivery. TLSv1.2 is required for Email Delivery. Some default settings of Javamail need to be disabled. For example, JavaMail authorizes in a certain order. The default authorization order is "LOGIN PLAIN DIGEST-MD5 NTLM". Since Email Delivery authorizes as "PLAIN", "LOGIN" needs to be disabled. For example, the following code is entered in OCIemail.java file to configure the SMTP connection:

```java
props.put("mail.smtp.auth", "true");
props.put("mail.smtp.auth.login.disable", "true");
props.put("mail.smtp.starttls.enable", "true");
props.put("mail.smtp.starttls.required", "true");
```

11. Open the File menu and click Save.

12. To build the project, open the Project menu and then select Build Project. If this option is disabled, you may have automatic building enabled.

13. To start the program and send the email, open the Run menu and then click Run.
14. Review the output. If the email was successfully sent, the console displays "Email sent successfully!" Otherwise, it displays an error message.

15. Log into the recipient inbox to verify receipt of the email.

**More Information**

- See the JavaMail documentation for more information.
- There is a known issue that can cause an error. See JavaMail issues occur when multiple recipients are set in an email and one or more of the email addresses are suppressed.

**Integrating Sendmail with Email Delivery**

**Configure Sendmail to Send Email Through Email Delivery**

Sendmail is a general purpose internetwork email routing facility that supports many kinds of mail-transfer and delivery methods, including the Simple Mail Transfer Protocol used for email transport over the Internet. You can use Sendmail to send emails through Email Delivery. Before you use Sendmail you must configure Oracle Cloud Infrastructure Email Delivery in your Sendmail application.

**Important:**

These instructions contain sample code for your convenience and should be used as a reference. For client support, you must contact Sendmail customer support.

**Note:**

The steps below are for configuring Sendmail to send email through Oracle Cloud Infrastructure Email Delivery. These steps were tested on an Oracle Linux Server release 7.9 compute instance and Sendmail-8.14.7-6.el7.x86_64.

To enable Sendmail to integrate with Email Delivery:

1. Make sure Email Delivery is configured to send email. See Getting Started with Email Delivery on page 2620.

   **Note:**

   SMTP credentials are required to configure Sendmail to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Run the following update and install commands:

   ```
   sudo yum update
   sudo yum install sendmail sendmail-cf m4 cyrus-sasl-plain
   ```

3. Update `/etc/mail/authinfo`. Run the following command:

   ```
   sudo vi /etc/mail/authinfo
   ```

   **Note:**

   If `/etc/mail/authinfo` doesn't exist, you can create it by running the command `sudo vi /etc/mail/authinfo`.

   Add the following line:

   ```
   AuthInfo:<SMTP connection endpoint> "U:root" "I:<username from smtp credentials>" "P:<password from smtp credentials>" "M:PLAIN"
   ```
4. Generate the /etc/mail/authinfo.db file.
   Run the following command:
   ```sh
   sudo sh -c 'makemap hash /etc/mail/authinfo.db < /etc/mail/authinfo'
   ```

5. Add support for relaying to the Oracle Cloud Infrastructure Email Delivery SMTP endpoint.
   Run the following command:
   ```sh
   sudo sh -c 'echo "Connect:<SMTP connection endpoint> RELAY" >> /etc/mail/access'
   ```

6. Regenerate /etc/mail/access.db.
   Run the following command:
   ```sh
   sudo sh -c 'makemap hash /etc/mail/access.db < /etc/mail/access'
   ```

7. Create a backup of the sendmail.cf and sendmail.mc files.
   Run the following command:
   ```sh
   sudo sh -c 'cp /etc/mail/sendmail.cf /etc/mail/sendmail_cf.backup && cp /etc/mail/sendmail.mc /etc/mail/sendmail_mc.backup'
   ```

8. Update the /etc/mail/sendmail.mc file.
   Run the following command:
   ```sh
   sudo vi /etc/mail/sendmail.mc
   ```
   Find the MAILER() definitions.
   Type `/MAILER` and press ENTER.
   In Insert mode, add the following settings before any MAILER() definitions:
   ```sh
   define(`SMART_HOST', `<SMTP connection endpoint>')dnl
   define(`RELAY_MAILER_ARGS', `TCP $h 25')dnl
   define(`confAUTH_MECHANISMS', `LOGIN PLAIN')dnl
   FEATURE(`authinfo', `hash -o /etc/mail/authinfo.db')dnl
   MASQUERADE_AS(`<sending_domain>')dnl
   FEATURE(masquerade_envelope)dnl
   FEATURE(masquerade_entire_domain)dnl
   ```
   Disable Insert mode.

   Run the following command:
   ```sh
   sudo chmod 666 /etc/mail/sendmail.cf
   ```

10. Regenerate sendmail.cf.
    Run the following command:
    ```sh
    sudo sh -c 'm4 /etc/mail/sendmail.mc > /etc/mail/sendmail.cf'
    ```

   **Note:**
   If you receive an error, such as "Command not found" or "No such file or directory," confirm that the m4 and sendmail packages are installed on your system.
11. Reset permissions for sendmail.cf to read only.
   Run the following command:
   ```
sudo chmod 644 /etc/mail/sendmail.cf
   ```

12. Restart Sendmail.
   Run the following command:
   ```
sudo /etc/init.d/sendmail restart
   ```

13. Test the configuration by sending a test email.
   Run the following command:
   ```
/usr/sbin/sendmail -vf <from_email_address> <recipient_email_address>
   ```

   Enter the details of the email. After each line press Enter.
   For example:
   ```
   From: <from_email_address>
   To: <recipient_email_address>
   Subject: OCI Email Delivery test email
   This is a test message sent from OCI Email Delivery using Sendmail.
   ```
   Press Ctrl + D to send the email.

14. Verify receipt of the test email.

   **Note:**
   You can troubleshoot an issue by reviewing the Sendmail log on your mail server, located at /var/log/mail.log.

   **More Information**
   - For more information, see the Sendmail Installation and Operation Guide.

**Integrating PeopleSoft with Email Delivery**

**Configure PeopleSoft to Send Email Through Email Delivery**

You can use PeopleSoft to send emails through Email Delivery. Before you use PeopleSoft, you must configure Oracle Cloud Infrastructure Email Delivery in your PeopleSoft application.

**Important:**
These instructions contain sample code for your convenience and should be used as a reference. For client support, you must contact Oracle PeopleSoft customer support.

**Note:**
The following steps require familiarity with PeopleSoft documentation. These steps were tested on an Oracle Linux Server release 7.9 compute instance and PeopleTools version 8.53.06. Please refer to the documentation for your specific PeopleTools version.

To enable PeopleSoft to integrate with Email Delivery:
1. Make sure Email Delivery is configured to send email. See Getting Started with Email Delivery on page 2620.

   **Note:**

   SMTP credentials are required to configure PeopleSoft to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Run the following command to view the certificate chain:

   ```bash
   echo | openssl s_client -showcerts -starttls smtp -crlf -connect <SMTP-endpoint>:587
   ```

   Example output:

   ```
   [root@ociuvddatg01 ~]# echo | openssl s_client -showcerts -starttls smtp -crlf -connect smtp.email.us-ashburn-1.oci.oraclecloud.com:587
   CONNECTED(00000003)
   depth=2 C = US, O = DigiCert Inc, OU = www.digicert.com, CN = DigiCert Global Root G2
   verify return:1
   depth=1 C = US, O = DigiCert Inc, CN = DigiCert Global CA G2
   verify return:1
   depth=0 C = US, ST = California, L = Redwood City, O = Oracle Corporation, OU = Oracle OCI-PROD ASHBURN, CN = smtp.email.us-ashburn-1.oci.oraclecloud.com
   verify return:1
   ---
   Certificate chain
   0 s:/C=US/ST=California/L=Redwood City/O=Oracle Corporation/OU=Oracle OCI-PROD ASHBURN/CN=smtp.email.us-ashburn-1.oci.oraclecloud.com
   i:/C=US/O=DigiCert Inc/OU=www.digicert.com/CN=DigiCert Global Root G2
   1 s:/C=US/O=DigiCert Inc/OU=www.digicert.com/CN=DigiCert Global Root G2
   i:/C=US/O=DigiCert Inc/CN=DigiCert Global CA G2
   2 s:/C=US/O=DigiCert Inc/OU=www.digicert.com/CN=DigiCert Global Root G2
   i:/C=US/O=DigiCert Inc/CN=DigiCert Global CA G2
   ---
   Server certificate
   -----BEGIN CERTIFICATE-----
   ......
   -------END CERTIFICATE-----
   ```

3. Extract the certificate that signed your domain. In this example, this is the last certificate (2 s:/C=US/O=DigiCert Inc/OU=www.digicert.com/CN=DigiCert Global Root G2). Copy and paste the certificate into a separate DigiCert.pem file, including the BEGIN CERTIFICATE and END CERTIFICATE fields.

   For example:

   ```
   -----BEGIN CERTIFICATE-----
   s:/C=US/O=DigiCert Inc/OU=www.digicert.com/CN=DigiCert Global Root G2
   i:/C=US/O=DigiCert Inc/CN=DigiCert Global Root G2
   -------END CERTIFICATE-----
   ```

4. Add the certificates to the PeopleSoft application.

   Log into the Pure Internet Architecture (PIA) as user "PS" and import the certificates into the target environment. See Installing Application Server-Based Digital Certificates and refer to the Adding CA Authorities and Installing Root Certificates section.
5. Encrypt the SMTP password in the config file.

You can encrypt the SMTP password using the PIA or the PSCipher utility.

**Using the PIA**

a. Open the navigation menu on the PeopleSoft dashboard. Go to **PeopleTools**, and then select **Integration Broker**.
b. Select **Configuration**, and then click **Gateways**. Select the default LOCAL gateway.
c. Click **Gateway Setup Properties**. The default user ID is administrator and the default password is the password selected during setup.
d. Click the **Advanced Properties Page** link.
e. Click **Password Encryption** at the bottom of the page. This is where you will encrypt your password.

**Using PSCipher**

The PSCipher utility can be found under $PS_CFG_HOME/webserv/<DOMAIN>/piabin where <DOMAIN> is your web server domain.

Run the following command:

```
./PSCipher.sh <password>
```

**Note:**

The password can have special characters so you will need to enclose the password in single quotes. For example: ```./PSCipher.sh '#rpassword$){'

6. Update the SMTP settings on the PeopleSoft Application server. For more information, see **SMTP Settings** in the PeopleSoft documentation.

Establish an ssh connection to the PeopleSoft Application server machine (as username "opc") and do the following:

a. Switch user to psadm2 (for example, ```sudo su - psadm2```).

**Note:**

`psadm2` is the PeopleTools domain user who creates and configures the Application Server domain.

b. Navigate to the Appserver configuration directory.

Run the following command:

```
$ cd $PS_CFG_HOME/appserv/APPDOM
```

c. Back up the original `psappsrv.cfg` file.
d. Add the following information to the `psappsrv.cfg` file:

```properties
SMTPServer=<SMTP connection endpoint>
SMTPUserName=<username from SMTP credentials>
SMTPUserPassword=<encrypted SMTP password>
SMTPPort=587
SMTPUseSSL=N
SMTPSSLPort=587
SMTPTLSEnable=true
```
7. Add the primary email address for the PeopleSoft application user who is trying to send notification from within the application. In this example, the user is "PS".

Log in as "PS" and do the following:

   a. Open the navigation menu on the PeopleSoft dashboard. Go to PeopleTools, and then select Security.
   b. Select User Profiles, and then click user Profiles. Find the profile for "PS".
   c. On the General tab, click Edit Email Addresses.
   d. Enter the approved sender email address as the primary email address.

8. Log out of the PeopleSoft application.

9. Reboot the application server using the PSADMIN utility. See Using the Application Server Administration Menu.

10. Test the email notification delivery.

Log into the PIA as "PS", and select Notify anywhere in the console. For example, you can do the following:

   a. Go to Peopletools, and then select Web Profile.
   b. Select Web Profile Configuration.
   c. Click Search, and then click PROD in the search results.
   d. Click Notify, enter the notification details, and then click OK.

Confirm receipt of the test email.

To debug SMTP errors (optional):

1. You can add the following parameter to help with SMTP debugging: SMPTTrace=1

LogFence should be set to 5 to use this parameter. The system writes the log information to SMTP<DDMM>.log in $PS_SERVDIR%/LOGS by default, or the custom value set for Log Directory.

For example:

   $PS_CFG_HOME\APPSERV\domain\LOGS\SMTP6_27.log

2. After you set this parameter, you will need to reboot the Application server. Once this parameter is set, you can monitor the SMTP log.

3. Type ls and find the SMTP file for the date you sent the email.

4. Run the following command:

   tail -f <smtp log file and date>

For example,

   tail -f SMTP9_17.log

Search for any errors in the output.

**Troubleshooting**

**535 authentication required error occurs when sending email**

To troubleshoot this issue, complete the following steps:
1. Use the following method to re-encrypt the SMTP user password, and enter it in the PeopleSoft application server or process scheduler configuration file's SMTP settings.
   a. Open any Integration Broker node by navigating to PeopleTools, Integration Broker, Integration Setup, and then click Nodes.
   b. Click on the Connectors tab. Ensure it is using the HTTPTARGET Connector.
   c. Expand the encryption section and encrypt the SMTP user password again.
   d. Enter the new encrypted password in the SMTPUserPassword settings.

2. Verify that the optional parameters below are set in the SMTP settings section of the configuration file even if they are not being used.

   SMTPUseSSL1=N
   SMTPSSLPort1=587
   SMTPTLSEnable1=true
   SMTPTLSRequired1=true
   SMTPClientCertAlias1=

- My Oracle Support: Is There a Way to Both Authenticate And Secure Emails From PeopleSoft?

Integrating Python with Email Delivery

You can use Python to send emails through Email Delivery. Before you can send email you must configure Email Delivery in Python.

Important:

These instructions contain sample code for your convenience and should be used as a reference. For client support, you must contact Python. These steps were tested on an Oracle Linux Server release 7.9 compute instance and Python 3.6. These steps assume you are logged into an Oracle Linux instance. Other distributions of Linux may have different commands and file locations. Java applications (including JavaMail) must be updated to the latest version to ensure that the latest protocols, ciphers, and security patches are in compliance with Oracle’s supported security policies and ciphers.

Configure Python to Send Email Through Email Delivery

To enable Python to test the configuration of Email Delivery:

1. Ensure Email Delivery is configured to send email. See Getting Started with Email Delivery on page 2620.

   Note:

   The SMTP credentials are required to configure Python to use Email Delivery. Be sure to note the user name and password when you generate the SMTP credentials.

2. Ensure Python is installed. The installation process differs depending on which operating system you are using. For example, run the following command to install Python on Oracle Linux:

   sudo yum install python3 -y
3. In a file editor such as vi, create a python script to test Email Delivery.

   Run the following command:

   ```bash
   sudo vi ociemail.py
   ```

4. In the `ociemail.py` file, replace the variables with your own values.

   For example:

   ```python
   # python script for sending SMTP configuration with Oracle Cloud Infrastructure Email Delivery
   import smtplib
   import email.utils
   from email.message import EmailMessage
   import ssl

   # Replace sender@example.com with your "From" address.
   # This address must be verified.
   # this is the approved sender email
   SENDER = 'sender@example.com'
   SENDERNAME = 'Sender Name'

   # Replace recipient@example.com with a "To" address. If your account
   # is still in the sandbox, this address must be verified.
   RECIPIENT = 'recipient@example.com'

   # Replace the USERNAME_SMTP value with your Email Delivery SMTP username.
   USERNAME_SMTP = '
ocid1.user.oc1..<unique_ID>@ocid1.tenancy.oc1..<unique_ID>.vf.com'

   # Put the PASSWORD value from your Email Delivery SMTP password into the
   # following file.
   PASSWORD_SMTP_FILE = 'ociemail.config'

   # If you're using Email Delivery in a different region, replace the HOST
   # value with an appropriate SMTP endpoint.
   # Use port 25 or 587 to connect to the SMTP endpoint.
   HOST = 'smtp.us-ashburn-1.oraclecloud.com'
   PORT = 587

   # The subject line of the email.
   SUBJECT = 'Email Delivery Test (Python smtplib)'

   # The email body for recipients with non-HTML email clients.
   BODY_TEXT = ('Email Delivery Test \n
   This email was sent through the Email Delivery SMTP 
   Interface using the Python smtplib library.'
   }

   # The HTML body of the email.
   BODY_HTML = ''
   <head>
   <body>
   <h1>Email Delivery SMTP Email Test</h1>
   <p>This email was sent with Email Delivery using the
   <a href='https://www.python.org/'>Python</a>
   <a href='https://docs.python.org/3/library/smtplib.html'>smtplib</a> library.</p>
   </body>
   </head>
   </html>

   # get the password from a named config file ociemail.config
   with open(PASSWORD_SMTP_FILE) as f:
   ```
password_smtp = f.readline().strip()

# create message container
msg = EmailMessage()
msg['Subject'] = SUBJECT
msg['From'] = email.utils.formataddr((SENDERNAME, SENDER))
msg['To'] = RECIPIENT

# make the message multi-part alternative, making the content the first part
msg.add_alternative(BODY_TEXT, subtype='text')
# this adds the additional part to the message
# According to RFC 2046, the last part of a multipart message, in this case
# the HTML message, is best and preferred.
msg.add_alternative(BODY_HTML, subtype='html')

# Try to send the message.
try:
    server = smtplib.SMTP(HOST, PORT)
    server.ehlo()
    # most python runtimes default to a set of trusted public CAs that
    # will include the CA used by OCI Email Delivery.
    # However, on platforms lacking that default (or with an outdated set
    # of CAs), customers may need to provide a capath that includes our public
    # CA.
    server.starttls(context=ssl.create_default_context(purpose=ssl.Purpose.SERVER_AUTH,
                                                        cafile=None, capath=None))
    # smtplib docs recommend calling ehlo() before & after starttls()
    server.ehlo()
    server.login(USERNAME_SMTP, password_smtp)
    # our requirement is that SENDER is the same as From address set
    previously
    server.sendmail(SENDER, RECIPIENT, msg.as_string())
    server.close()
except Exception as e:
    print(f"Error: {e}")
else:
    print("Email successfully sent!")

---

**Note:**

Python 2 and legacy email APIs should not be used with Email Delivery.

5. In a file editor such as vi, create a file that contains the SMTP password. Run the following command and replace the contents with your SMTP password:

```
sudo vi ociemail.config
```

6. To send a test email with Python, run the following command from the directory the script is located in:

```
python3 ociemail.py
```

**More Information**

- More Python script examples can be found on [GitHub](https://github).

**Troubleshooting Email Delivery**

This topic provides troubleshooting solutions for problems you might encounter using Email Delivery.
TLS errors when integrating with Postfix

- If you are encountering TLS errors when attempting to integrate Postfix with Email Delivery, ensure that the following setting is removed from the Postfix main.cf file, as it has been deprecated:
  
  ```
  smtp_use_tls = yes
  ```

- Use the following setting instead to turn on TLS:
  
  ```
  smtp_tls_security_level = may
  ```

  Using this setting, the Postfix SMTP server announces STARTTLS support to remote SMTP clients, but does not require that clients use TLS encryption.

- If you want to enforce the use of TLS, so that the Postfix SMTP server announces STARTTLS and accepts no mail without TLS encryption, use the following setting:
  
  ```
  smtp_tls_security_level = encrypt
  ```

For more information, see Postfix TLS Support.

Connectivity Issues

**Note:**

Email Delivery does not prohibit connectivity from any source IP range. Any IP that attempts to connect to Email Delivery will be accepted.

Refer to Configure SMTP Connection on page 2632 for a list of regional endpoints to establish SMTP connections for sending.

**To troubleshoot a problem connecting to endpoint network ports**

- Ensure that you have the correct endpoint DNS name or IP address for the region and that you have been allowed to use the endpoint.
- Test connectivity to the endpoint using port 25 or 587. Use a utility such as Telnet or netcat to attempt to connect to the port manually.

  1. Open a command prompt.
  2. Use the following command to test the network connection.

     ```
     telnet <SMTP endpoint> <port>
     ```

     For example:

     ```
     telnet smtp.email.us-ashburn-1.oci.oraclecloud.com 25
     ```

     The port is open and the test is successful if you see a "Connected to" message. If you are unable to connect to the ports using telnet, you are experiencing a network connectivity issue.

**To troubleshoot a problem connecting to an external mail transfer agent (MTA)**

Use the following steps to determine whether you are able to communicate with an external service on the required ports 25 or 587. If you are unable to connect successfully, you are experiencing a network connectivity issue. If you are able to connect to an external MTA, the network connectivity issue is within Oracle Cloud Infrastructure.
• Connect to an external MTA such as Google's mail exchangers.

1. Open a command prompt.
2. Use the following command to retrieve one of Google's MX server records.

   ```
   dig MX google.com
   ```

3. Use the following command to test connectivity to the endpoint port 25 or 587 against Google's MX servers.

   ```
   telnet <IP address> <port>
   ```

If you are unable to connect to Google's MX servers, this confirms that you are having issues connecting to mail servers (port 25 or 587). It is possible that your egress rules are filtering traffic at the VCN.

If you can connect to an external MTA (that is, you are able to communicate with a public SMTP endpoint on the correct ports) but you cannot connect to Email Delivery public SMTP endpoints on those ports, create a service request with My Oracle Support with this information.

### Common Errors Returned by Email Delivery

#### API Errors

For a complete list of common errors returned by all the services for Oracle Cloud Infrastructure, see [API Errors](#).

#### Common SMTP Errors Returned by Email Delivery

The following table lists the common errors returned by the Email Delivery SMTP service.

<table>
<thead>
<tr>
<th>SMTP Status Code</th>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>254</td>
<td>4.7.1</td>
<td>Message has been accepted but a status code was returned indicating suppression. Enhanced Status Code 4.7.1 indicated a persistent transient failure (<a href="#">RFC3463</a>).</td>
</tr>
<tr>
<td>421</td>
<td>Timeout</td>
<td>Timeout waiting for data from client</td>
</tr>
<tr>
<td>421</td>
<td>4.4.0</td>
<td>Problem attempting to execute commands. Please try again later</td>
</tr>
<tr>
<td>421</td>
<td>Too many connections, try again later</td>
<td></td>
</tr>
<tr>
<td>421</td>
<td>Too many auth failures, try again later</td>
<td>IP based throttle; triggered by repetitive use of invalid SMTP credentials or non-approved sender.</td>
</tr>
<tr>
<td>SMTP Status Code</td>
<td>Error Code</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>421</td>
<td>4.3.0 Mail system failure, closing transmission channel</td>
<td>4.3.0 Mail system failure, closing transmission channel</td>
</tr>
<tr>
<td>451</td>
<td>Server error</td>
<td>An unexpected error has occurred during the SMTP conversation.</td>
</tr>
<tr>
<td>451</td>
<td>Error in Processing</td>
<td>An unexpected error has occurred during the SMTP conversation.</td>
</tr>
<tr>
<td>452</td>
<td>System storage error</td>
<td>The server is unable to persist the message in its delivery queue.</td>
</tr>
<tr>
<td>455</td>
<td>Maximum messages sent per minute reached: limit is &lt;limit&gt;</td>
<td>The SMTP send burst rate (of messages accepted per minute period) has been exceeded.</td>
</tr>
<tr>
<td>455</td>
<td>Maximum messages sent per day reached: limit is &lt;limit&gt;</td>
<td>The SMTP daily send rate (of messages accepted per 24 hour period) has been exceeded.</td>
</tr>
<tr>
<td>501</td>
<td>Invalid command argument, not a valid Base64 string</td>
<td>The base64 encoded AUTH (PLAIN) secret is invalid.</td>
</tr>
<tr>
<td>501</td>
<td>Invalid command argument, does not contain NUL</td>
<td>The base64 encoded AUTH (PLAIN) secret does not contain NUL field separator(s).</td>
</tr>
<tr>
<td>501</td>
<td>Invalid command argument, does not contain the second NUL</td>
<td>The base64 encoded AUTH (PLAIN) secret does not contain second NUL field separator(s).</td>
</tr>
<tr>
<td>503</td>
<td>Need RCPT command</td>
<td>The SMTP client tried to start sending the body of an email message without identifying any email recipients through the required SMTP RCPT command (RFC 5321).</td>
</tr>
<tr>
<td>504</td>
<td>Method not supported</td>
<td>The client has attempted to use an unsupported AUTH mechanism with our service.</td>
</tr>
<tr>
<td>SMTP Status Code</td>
<td>Error Code</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>504</td>
<td>AUTH mechanism mismatch</td>
<td>The client has sent an invalid AUTH command to our service.</td>
</tr>
<tr>
<td>552</td>
<td>Exceeds byte limit</td>
<td>The message has exceeded the size limit enforced by the service (see server response to EHLO for size restriction).</td>
</tr>
<tr>
<td>535</td>
<td>Authentication credentials invalid</td>
<td>Authentication of the SMTP user has failed.</td>
</tr>
<tr>
<td>535</td>
<td>Authentication required</td>
<td>The client has sent commands that require SMTP authentication succeeded before the service is able to process (that is, commands are being sent out of order).</td>
</tr>
<tr>
<td>535</td>
<td>Authorization failed: address &lt;address&gt; not authorized</td>
<td>Authorization of the address (either in the envelope or message) has failed for the SMTP user. The approved sender does not exist, the use email-family policy does not specify the compartment containing the approved sender, or the user with the SMTP credentials is not in a group with the use email-family policy. See Generate SMTP Credentials for a User on page 2628 for more information.</td>
</tr>
<tr>
<td>553</td>
<td>&lt;address&gt; Invalid email address</td>
<td>The RFC-822 Internet Address sent by the client is invalid.</td>
</tr>
<tr>
<td>554</td>
<td>Message parse error</td>
<td>The RFC-2822 Internet Message is invalid (and unable to be parsed by the server). Message without any headers or header is larger than 256 KB.</td>
</tr>
</tbody>
</table>

### Service Limits

For Email Delivery limits issues, see Email Delivery Service Capabilities and Limits and Service Limits on page 247 for a list of applicable limits and instructions for requesting a limit increase.

### Troubleshooting Undelivered Emails

The following issues can cause an email to be undelivered:

- The recipient is on the Suppression List.
- An authentication failure or an issue with the format of the email message occurred. For example, if the SMTP "From" address is not the same as the "From" address in the email body, the email is rejected. The addresses must match and be an Approved Sender. Refer to your sending application’s logs to review any issues.
- Use of multiple addresses in the email From header is discouraged. If you use multiple addresses, it increases the possibility that your mail is placed in a spam folder or discarded (because of Domain-based Message Authentication, Reporting, and Conformance (DMARC) From alignment rules). The performance of your emails is reduced because all addresses have to be authorized as approved senders. Certain future platform features will not be available if you use mismatched addresses.
- Lack of DomainKeys Identified Mail (DKIM).
- View the "dkimSelector" applied to your mail via the Public Logging feature.
DKIM and DMARC can help authenticate your email to help ensure that your emails get delivered to your recipients' inboxes. For more information, see Additional Options to Increase Deliverability on page 2669.

Refer to Deliverability Best Practices to learn about recommendations that can help lower your email bounce rate, stay off blocklists, lower your complaint rate, and improve your email sender reputation.

If you are unable to resolve the issue, you can go to My Oracle Support and create a service request. See Open a support service request for more information.

Troubleshooting an Inactive DKIM Key

To activate your DKIM key, you must provision a DNS CNAME record at this location in your Email Domain's DNS:

<selector>._domainkey.<email-domain>

However, different DNS providers have different user interfaces to specify the location of a DNS record. Some user interfaces accept the full DNS path by default and these will work well. Some user interfaces are relative to the zone by default, so if you paste in the entire string without the trailing period, the user interface will provision the wrong location and that will leave your DKIM key in a "Needs Attention" state. Avoid entries like this:

<selector>._domainkey.<email-domain>.<zone-name>

If your Email Domain is the same as your DNS zone name and if your provider only accepts a zone-relative name, use this DNS CNAME location:

<selector>._domainkey

If your Email Domain is in a subdomain of your zone and if your provider only accepts a zone-relative name, use this DNS CNAME location:

<selector>._domainkey.<subdomain>

Email Deliverability

Email Deliverability is commonly known as the science behind delivering both bulk/marketing and transactional emails to opt-in recipients.

This topic provides information on best practices, troubleshooting undelivered emails, and other ways that senders can improve inbox placement.

Deliverability Best Practices

These email deliverability best practices help you both learn and manage the habits that affect your sending reputation which, in turn, can help more email get delivered.

By following these recommendations, senders can lower both bounce and complaint rates, stay off blocklists, and improve your company’s sending reputation.

Implement an Opt-in Process

The opt-in process is how recipients subscribe to your bulk/marketing lists which gives you permission to send them email. Only send messages to subscribers who have opted-in to your mailing list, avoiding buying or renting lists at all costs.

There are two types of opt-in methods. Note that these methods apply to bulk/marketing email as transactional emails are sent based on an action that requires proof:

- **Single opt-in (unconfirmed):** A user provides their email address and gives the sender permission to receive relevant messages. After the address is provided, messages can be sent without confirming the email address...
Email Delivery

belongs to the user who provided it. The risks in using single opt-in are exposure to list bombing through a targeted attack on a signup form, and by those signing up email addresses that don’t belong to them.

- **Double opt-in (confirmed):** A user provides their email address, but before the first campaign is sent, they receive a confirmation email to the address that signed up. That email requires action from the account owner to confirm that future messages are wanted, most frequently done with a verification click. The double opt-in method ensures that the address was not added without consent and keeps electronic proof if future data privacy inquiries or audits arise.

**Purge Unengaged Users**

One of the easiest and best ways to help keep your marketing lists clean is to remove unengaged users: those addresses which haven’t opened or clicked within an email in a certain amount of time. Unengagement is a strong indication that the recipient is no longer interested in your content or that the account has been abandoned.

Remove recipients who have not engaged with your email in a timeframe defined by your business model but no longer than two years. By doing so, you show major inbox providers that you are keeping an updated database which helps boost your sending reputation. You also avoid the potential of hitting spam traps as some mailbox providers convert inactive inboxes to help prevent scraping of email addresses.

**Database Cleanliness**

Keeping an overall clean and up-to-date database is important in addition to removing unengaged users. The best way to keep a clean database is to sync with Email Delivery using API calls so any hard bounces, unsubscribes, and suppressions are marked as such.

That constant sync helps lessen processing time when sending emails, ensures that your database is always updated, and minimizes the chance you send to an address that you should no longer be sending to.

**Evaluate Your Sending Frequency**

Sending too many emails in a short time might aggravate your recipients, causing them to either unsubscribe or mark your campaigns as spam. By regularly reviewing your strategies, open rates, and other key metrics, you can reduce list fatigue and better learn how they want to engage with you.

Offer the ability to reduce the amount of emails they receive (for example, yearly, quarterly, or monthly), giving you a better chance at retention rather than them unsubscribing altogether. Recipient tastes and wants for email changes over time. Ensure that you’re changing with it.

**Provide an Easily Accessible Unsubscribe URL**

Don’t attempt to hide your unsubscribe link as by doing so, you only further encourage your recipients to click the spam button, further hurting your reputation. Some providers will also hold it against you in their algorithm if you use a light color for your unsubscribe link and language.

If someone wants to be removed from your list, make the link easy to find and include it in both the header and footer. Offer a single-click unsubscribe option in addition to a preference center where they can reduce the frequency of emails, opt in to a different list, and so on.

**CAN-SPAM, GDPR, CASL, and Privacy Laws**

Knowing how to handle, process and market to consumer data in a legally permissible way is a must.

There are several regulatory measures and laws that help protect consumers around the world. One of the oldest is the **CAN-SPAM Act**, a piece of U.S. legislation that established requirements for “commercial” email.

Not using deceptive subject lines, honoring unsubscribes quickly, and having a physical address in the footer of emails are just some of the requirements outlined with violations resulting in fines.

Similarly, there is also **CASL**, a Canadian-based anti-spam set of laws that was heavily based on CAN-SPAM. While based in Canada, the law applies to those who email Canadian residents.
Data privacy has become a hot topic in the last few years which is why knowing about the General Data Privacy Regulation (GDPR) is key. Active in 2018, the law regulates data privacy and protection in the European Union and has become a model for other countries’ privacy laws.

**Oracle Cloud Hosting and Delivery Policy**

Often, the Oracle Cloud Hosting and Delivery Policy is more stringent than some of these industry requirements. It is important that you review Oracle policies before using the service.

Discussing your approach to data privacy and regulation with the appropriate personnel within your company is highly recommended.

**Troubleshooting Undelivered Emails**

The following issues can cause an email to be undelivered:

- The recipient is on the Suppression List.
- An authentication failure or an issue with the format of the email message occurred. For example, if the SMTP "From" address is not the same as the "From" address in the email body, the email is rejected. The addresses must match and be an Approved Sender. Refer to your sending application's logs to review any issues.
- Use of multiple addresses in the email From header is discouraged. If you use multiple addresses, it increases the possibility that your mail is placed in a spam folder or discarded (because of DMARC From alignment rules). The performance of your emails is reduced because all addresses have to be authorized as approved senders. A best practice for the SMTP envelope From address is to match the header From address when you submit mail to Email Delivery. If you use mismatched addresses, it reduces the performance of your emails because both addresses need to be authorized as approved senders. Certain future platform features will not be available if you use mismatched addresses.
- Lack of SPF or DomainKeys Identified Mail (DKIM) on page 2669.

If you are unable to resolve the issue, you can go to My Oracle Support and create a service request. See Open a support service request for more information.

**Additional Options to Increase Deliverability**

**DomainKeys Identified Mail (DKIM)**

DKIM is an authentication framework you can set up to help ensure good email delivery reputation. See Managing DKIM on page 2636 for instructions on setting up DKIM.

**SPF**

A Sender Policy Framework (SPF) lets domain owners identify servers they have approved to send emails on behalf of their domain. In Oracle integration's case, domain owners need to approve OCI as an approved sender and to add a record for it in their domain. See Configure SPF on page 2631 for more information.

**Domain-based Message Authentication, Reporting, and Conformance (DMARC)**

DMARC is a technical specification created by a group of organizations that want to help reduce the potential for email-based abuse by solving long-standing operational, deployment, and reporting issues related to email authentication protocols. DMARC standardizes how email recipients perform email authentication using SPF and DKIM. This gives the sender the ability to have control of mail that does not pass authentication and tell the email recipients what to do with non authenticated mail.

DMARC checks both SPF and DKIM and requires one to pass in order to send and deliver email. When you start using DMARC, it is a best practice to put a `p=none` policy in place and ensure that every legitimate sending application is aligned and authenticated correctly before considering a more aggressive policy. During any transition period where a new email-related service for the sending domain is evaluated, using a DMARC `p=none` policy and following this advice is recommended.
A **DMARC record** is a DNS TXT record in the domain `_dmarc.<sending-domain>` with content similar to the following:

```
"v=DMARC1\;p=none\;rua@mailto:dmarc_rua@example.com\;ruf@mailto:dmarc_ruf@example.com\;fo=1"
```

You must have an administrative INBOX service to receive DMARC reports (in the preceding example, `example.com` is your INBOX provider). Currently Email Delivery does not offer INBOX service or automated DMARC report processing. If you don’t want to manage and process DMARC reports, do not create a DMARC record.

### Create a Custom Return Path

**Note:**

Setting up DKIM is more likely to improve your deliverability than a custom return path. As a result, it is recommended you set up DKIM before or at the same time you set up a custom return path.

Email Delivery is required to process bounces to protect the reputation of our IP addresses and domain. Therefore, by default the Return Path is set to be that of our Bounce servers. Email Delivery offers a custom return path feature to improve inbox placement. To use this feature, you need to set up DNS records for your custom return path domain. The custom return path domain must either match the domain of your approved sender or be a subdomain of that domain. Our suggested naming convention for a custom return path subdomain is `<REGIONKEY>.rp.<sending-domain>`. To prepare for use of this feature, provision SPF and MX records on the custom domain as follows:

### MX Record for Custom Domain

The following record syntax applies to commercial regions only:

10 bmta.email.<REGION IDENTIFIER>.oci.oraclecloud.com

Custom return path is regional. Adding REGION IDENTIFIER to the entry is imperative to avoid confusion. For more information about regions, see [Regions and Availability Domains](#) on page 210.

### SPF Record for Custom Return Path Domain

<table>
<thead>
<tr>
<th>Sending Region</th>
<th>SPF Record</th>
</tr>
</thead>
<tbody>
<tr>
<td>Americas</td>
<td><code>v=spf1 include:rp.oracleemaildelivery.com ~all</code></td>
</tr>
<tr>
<td>Asia/Pacific</td>
<td><code>v=spf1 include:apRp.oracleemaildelivery.com ~all</code></td>
</tr>
<tr>
<td>Europe</td>
<td><code>v=spf1 include:euRp.oracleemaildelivery.com ~all</code></td>
</tr>
<tr>
<td>All Commercial Regions</td>
<td><code>v=spf1 include:rp.oracleemaildelivery.com include:apRp.oracleemaildelivery.com include:euRp.oracleemaildelivery.com ~all</code></td>
</tr>
</tbody>
</table>
### Sending Region

<table>
<thead>
<tr>
<th>Government Regions</th>
<th>SPF Record</th>
</tr>
</thead>
</table>
|                    | • For US Government Cloud with FedRAMP Authorization, see SPF Record Syntax on page 191.  
|                    | • For US Federal Cloud with DISA Impact Level 5, see SPF Record Syntax on page 198.  
|                    | • For United Kingdom Government Cloud, see SPF Record Syntax on page 207. |

**Note:**

You must complete the DNS updates on your domain before the setup can be completed by Oracle Cloud Infrastructure.

After DNS changes are complete, create a service request to request the setup by Oracle Cloud Infrastructure. See [Open a support service request](#) for more information.

The following information is needed to complete this configuration after you have made your DNS changes:

- Tenant OCID
- SMTP endpoint used to submit mail
- Approved sender email address and OCID
- Custom return path domain
Chapter 24

Events

This chapter explains how to create automation in your tenancy.

Events

The Events service helps to create automation in your tenancy.

Overview of Events

Oracle Cloud Infrastructure Events enables you to create automation based on the state changes of resources throughout your tenancy. Use Events to allow your development teams to automatically respond when a resource changes its state.

Here are some examples of how you might use Events:

- Send a notification to a DevOps team when a database backup completes.
- Convert files of one format to another when files are uploaded to an Object Storage bucket.

Create a service request
### How Events Works

Oracle Cloud Infrastructure services emit *events*, which are structured messages that indicate changes in resources. Events (the messages, not the service) follow the CloudEvents industry standard format hosted by the Cloud Native Computing Foundation (CNCF). This standard allows for interoperability between various cloud providers or on-premises systems and cloud providers. An event could be a create, read, update, or delete (CRUD) operation, a resource lifecycle state change, or a system event impacting a resource. For example, an event can be emitted when a backup completes or fails, or a file in an Object Storage bucket is added, updated, or deleted.

Services emit events for resources or data. For example, Object Storage emits events for buckets and objects. Services emit different types of events for resources, which are distinguished as *event types*. Buckets and objects have event types of create, update, and delete, for example. Event types are the changes that produce events by a given resource. For a list of services that produce events and the event types that those services track, see [Services that Produce Events](#) on page 2705.

You work with events by creating *rules*. Rules include a filter you define to specify events produced by the resources in your tenancy. The filter is flexible:

- You can define filters that match only certain events or all events.
- You can define filters based on the way resources are tagged or the presence of specific values in attributes from the event itself.

Rules must also specify an *action* to trigger when the filter finds a matching event. Actions are responses you define for event matches. You set up select Oracle Cloud Infrastructure services that the Events service has established as actions (more on these select services follows). The resources for these services act as destinations for matching events. When the filter in the rule finds a match, the Events service delivers the matching event to one or more of the destinations you identified in the rule. The destination service that receives the event then processes the event in whatever manner you defined. This delivery provides the automation in your environment.

You can only deliver events to certain Oracle Cloud Infrastructure services with a rule. Use the following services to create actions:

- Notifications
- Streaming
- Functions
Events Concepts

The following concepts are essential to working with Events.

EVENTS

An automatic notification of a state change as reported by an event-emitting Oracle Cloud Infrastructure resource. For example, an database resource emits a `backup.begin` event when a backup begins.

EVENT TYPES

A distinction between the different types of events. For more information, see Services that Produce Events on page 2705.

RULES

A JSON object you create to subscribe to an event type and trigger an action should that event occur. For example, a rule might specify that `backup.end` event types from databases trigger the Notifications service to send an email to a particular DevOps engineer. For more information, see Matching Events with Filters on page 2685.

ACTIONS

Rules must also specify an `action` to trigger when the filter finds a matching event. Actions are responses you define for event matches. You set up select Oracle Cloud Infrastructure services that the Events service has established as actions. The resources for these services act as destinations for matching events. When the filter in the rule finds a match, the Events service delivers the matching event to one or more of the destinations you identified in the rule. The destination service that receives the event then processes the event in whatever manner you defined. This delivery provides the automation in your environment.

You can only deliver events to certain Oracle Cloud Infrastructure services with a rule. Use the following services to create actions:

- Notifications
- Streaming
- Functions

Region Availability

Events is currently available in all regions of the commercial realm. See the Oracle Cloud Infrastructure Government Cloud on page 176 section for information about availability in Government Cloud regions.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 6152.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up `groups`, `compartments`, and `policies` that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more
information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference on page 3347.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Administrators: You must write IAM policy that authorize users to work with rules. For more information, see Events and IAM Policies on page 2689.

Limits on Events Resources
The Events service has a limitation of 50 rules per tenancy.

See Service Limits on page 247 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Service Gateway and Events
The Events service also supports private access from Oracle Cloud Infrastructure resources in a VCN through a service gateway. A service gateway allows connectivity to the Events public endpoints from private IP addresses in private subnets. For example, you can manage rules over the Oracle Cloud Infrastructure backbone instead of over the internet. You can optionally use IAM policies to control which VCNs or ranges of IP addresses can access Events. See Access to Oracle Services: Service Gateway on page 4776 for details.

Getting Started with Events
This topic introduces you to creating automation with Events. You create a simple rule that sends a notification whenever someone creates a bucket in a particular compartment in your tenancy.

Setting Up for Events
To try out the Events service for this tutorial, you must have these things set up first:

- Create IAM policy for Events
- Create a topic and subscription to use as an action

| Important:
| A tenancy administrator must configure your tenancy for Events. These configurations give you access to an Oracle Cloud Infrastructure tenancy with the necessary IAM policy and a resource to use as an action.

Create Users, Groups, and Compartments
You can use existing users, groups, and compartments or make new ones.

To create groups and users
If suitable users and groups for assigning users permissions to work with rules don't already exist, log in to the Console as a tenancy administrator and create them.

1. Log in to the Console as a tenancy administrator.
2. If you need a group for Events, perform these steps:
   a. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Groups**. A list of the groups in your tenancy is displayed.
   b. Click **Create Group** and create a new group (see To create a group). Give the group a meaningful name and description. Avoid entering confidential information.

3. If you need user accounts for Events, perform these steps:
   a. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Users**. A list of the users in your tenancy is displayed.
   b. Click **Create User** and create one or more new users (see To create a user).
4. If users haven't been added to groups already, perform these steps:
   a. Open the navigation menu and click Identity & Security. Under Identity, click Groups. A list of the groups in your tenancy is displayed.
   b. Click the group you want to use for Events.
   c. Click Add User to Group.
   d. Select the users from the drop-down list, and then click Add.

To create a compartment

If suitable compartment for rules and the resources that emit events doesn't already exist, log in to the Console as a tenancy administrator and create it.

1. Log in to the Console as a tenancy administrator.
2. Open the navigation menu and click Identity & Security. Under Identity, click Compartments. A list of the compartments in your tenancy is displayed.
3. Click Create Compartment and create a new compartment (see To create a compartment). Give the compartment a meaningful name and description. Avoid entering confidential information.

Create IAM Policy for Events

Before users can start using Events to create automation, as a tenancy administrator you must create IAM policy:
To create a policy that allows users to create and manage rules

1. Log in to the Console as a tenancy administrator.
2. In the Console, open the navigation menu and click Identity & Security. Under Identity, click Policies. A list of the policies in the compartment you're viewing is displayed.
3. Select the root compartment.
4. Click Create Policy.
5. Enter the following:
   - **Name**: A meaningful name for the policy. The name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
   - **Description**: A meaningful description. You can change this later if you want to.
   - **Statement**: Enter the following policy statements to give users in the group the ability to manage and create rules:
     - This line gives the user inspect access to resources in compartments to select actions.
       ```
       allow group <RuleAdmins> to inspect compartments in tenancy
       ```
     - This line gives the user access to defined tags to apply filter tags to rules.
       ```
       allow group <RuleAdmins> to use tag-namespaces in tenancy
       ```
     - These lines give the user access to Streaming resources for actions
       ```
       allow group <RuleAdmins> to inspect streams in tenancy
       allow group <RuleAdmins> to use stream-push in tenancy
       allow group <RuleAdmins> to use stream-pull in tenancy
       ```
     - These lines give the user access to Functions resources for actions.
       ```
       allow group <RuleAdmins> to use virtual-network-family in tenancy
       allow group <RuleAdmins> to manage function-family in tenancy
       ```
     - This line give the user access to Notifications topics for actions.
       ```
       allow group <RuleAdmins> to use ons-topic in tenancy
       ```
     - This line gives the user manage access to rules for Events.
       ```
       allow group <RuleAdmins> to manage cloudevents-rules in tenancy
       ```
6. Click Create.

Create Notifications Topic and Subscription

If a suitable Notifications topic doesn't already exist, then you must log in to the Console as a tenancy administrator and create it. Whether you use an existing topic or create a new one, add an email address as a subscription so that you can monitor that email account for notifications.

To create a topic

1. Open the navigation menu and click Developer Services. Under Application Integration, click Notifications.
2. Click **Create Topic** at the top of the topic list.

3. In the **Create Topic** dialog box, configure your topic.
   - **Name**: Required. Specify a friendly name for the topic. It must be unique; validation is case-sensitive. Avoid entering confidential information.
   - **Description**: Optional. Enter a description for the topic.

4. Click **Create**.

**To create a subscription**

1. Open the navigation menu and click **Developer Services**. Under **Application Integration**, click **Notifications**.
2. Click the name of the topic that you created in the previous step or the topic you intend to use for this tutorial.
3. On the topic detail page, click **Create Subscription**.
4. In the **Create Subscription** dialog box, select **Email**, and then type an email address.

5. Click **Create**.

   The subscription has been created and a subscription confirmation URL will be sent. The subscription remains in "Pending" status until it has been confirmed.

**To confirm a subscription**

- In the confirmation email sent to the address you specified in the previous procedure, click the confirmation URL.

**Using the Console to Create a Rule**

Use the Console to create a rule with a pattern that matches bucket creation events emitted by Object Storage. Specify the Notifications topic you created as an action to deliver matching events. To test your rule, create a bucket. Object Storage emits an event which triggers the action. Check the email specified in the subscription to receive your notification.

**To create a rule**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.

2. Choose a **Compartment** you have permission to work in, and then click **Create Rule**.

   Events compares the rules you create in this compartment to event messages emitted from resources in this compartment and any child compartments.

3. Enter the following.
   - **Display Name**: Specify a friendly name for the rule. You can change this name later. Avoid entering confidential information.
   - **Description**: Specify a description of what the rule does. You can change this description later.

4. In **Event Matching**, select **Event Type**.
   a. In **Service Name**, select **Object Storage**.
   b. In **Event Type**, select **Object Storage - Create Bucket**.

5. In **Actions**, specify the actions to trigger when the filter finds a match:
   a. In **Action Type**, select **Notifications**.
   b. In **Notifications Compartment**, select the compartment that contains the topic.
   c. In **Topic**, select the topic.

6. Click **Create Rule**.

**To create a bucket**

1. Open the navigation menu and click **Storage**. Under **Object Storage**, click **Buckets**.
2. Select the compartment where you created your rule (or any of its subordinate compartments).
3. Click **Create Bucket**.

4. In the **Create Bucket** dialog, specify the attributes of the bucket:
   - **Name**: Required. A user-friendly name or description. Avoid entering confidential information.
   - **Storage Tier**: Select the tier in which you want to store your data. Available tiers include:
     - **Standard** is the primary default Object Storage tier for storing data that is accessed frequently and requires fast and immediate access.
     - **Archive** is a special tier for storing data that is accessed infrequently and requires long retention periods. Access to data in the **Archive** tier is not immediate. You must restore archived data before it’s accessible.

5. Click **Create Bucket**.
To receive your notification

- Log in to the email account you specified in the previous procedure to receive the notification about the bucket being created.

Tip:
You will receive notifications each time a bucket is created in the compartment (or any of its sub compartments) until you disable the rule.

Using the CLI to Create a Rule

When you use the CLI to create a rule, you work a little differently than using the Console.

- To specify the actions for your rule, use a JSON formatted file. You create this file before you create the rule, and the file simplifies the amount of information you must type at the command line.
- To specify an event to match, use a JSON formatted string. You type this right into the console as you create the rule.

To create an action file

1. Create a file and add the following content.
Tip: You can specify functions, streams, or topics as an action.

Example action file template

```
{
  "actions": [
    {
      "actionType": "FAAS",
      "description": "string",
      "functionId": "<function_OCID>",
      "isEnabled": true
    },
    {
      "actionType": "ONS",
      "description": "string",
      "isEnabled": true,
      "topicId": "<topic_OCID>"
    },
    {
      "actionType": "OSS",
      "description": "string",
      "isEnabled": true,
      "streamId": "<stream_OCID>"
    }
  ]
}
```

2. Fill in `<topic_OCID>` with actual topic OCID value from your tenancy.
3. Add a description.
4. Save the file with `action.json` as the file name.

To create a rule

Open a command prompt and run `oci events rule create` to create a rule.

Use the following options:

- `display-name` indicates the name of the rule in the Console
- `is-enabled` indicates whether the rule is evaluated.
- `condition` a JSON formatted string used to indicate a pattern for event matching (see the example command below for usage).
- `compartment-id` indicates the compartment where the rule applies. Events evaluates messages from resources in this compartment and any child compartments.
- `actions` indicates the location in the local file system of the JSON formatted file you created to specify the actions for a rule.
- `wait-for-state=` when used with ACTIVE indicates that the CLI should wait for the service to create the rule, do another GET operation, and then display the rule in the active state. Without the option, the CLI displays the rule immediately in the creating state.

For example:

```
oci events rule create --display-name CLI-created_rule
   --is-enabled true --condition "{"eventType": ["com.oraclecloud.objectstorage.createbucket"]}"
   --compartment-id <compartment_OCID> --actions <path_to_json_formatted_actions_file> --wait-for-state=ACTIVE
```
When you run the preceding command, the CLI prompts you about the rule and its display:

```
Action completed. Waiting until the resource has entered state: ACTIVE
{
  "data": {
    "actions": {
      "actions": [
        {
          "action-type": "ONS",
          "description": "Notifications action",
          "id": "ocid1.eventaction.oc1.phx.<unique_ID>",
          "lifecycle-message": null,
          "lifecycle-state": "ACTIVE",
          "topic-id": "ocid1.onstopic.oc1.phx.<unique_ID>"
        }
      ],
      "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
      "condition": "{"eventType": ["com.oraclecloud.objectstorage.createbucket"]}",
      "defined-tags": {},
      "description": null,
      "display-name": "CLI-created_rule",
      "freeform-tags": {},
      "id": "ocid1.eventrule.oc1.phx.<unique_ID>",
      "is-enabled": true,
      "lifecycle-message": null,
      "lifecycle-state": "ACTIVE",
      "time-created": "2019-04-25T01:32:56.855000+00:00"
    },
    "etag": "<unique_ID>--gzip"
  }
}
```

To create a bucket

1. Open the navigation menu and click Storage. Under Object Storage, click Buckets.
2. Select the compartment where you created your rule (or any of its subordinate compartments).
3. Click Create Bucket.
4. In the Create Bucket dialog, specify the attributes of the bucket:
   - **Name**: Required. A user-friendly name or description. Avoid entering confidential information.
   - **Storage Tier**: Select the tier in which you want to store your data. Available tiers include:
     - **Standard** is the primary default Object Storage tier for storing data that is accessed frequently and requires fast and immediate access.
     - **Archive** is a special tier for storing data that is accessed infrequently and requires long retention periods. Access to data in the Archive tier is not immediate. You must restore archived data before it’s accessible.
5. Click Create Bucket.
**To receive your notification**

- Log in to the email account you specified in the previous procedure to receive the notification about the bucket being created.

| Tip: |
| You receive notifications each time a bucket is created in the compartment (or any of its sub compartments) until you disable the rule. |

**Matching Events with Filters**

This topic describes how to match events with pattern filters in rules to build automation.

**Background**

To understand filtering, it's helpful to review the structure of an actual event message. Events uses JSON objects to represent events. This is an event:

```json
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": "com.oraclecloud.objectstorage.deletebucket",
    "source": "objectstorage",
    "eventTypeVersion": "1.0",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_bucket",
        "resourceId": "ocid1.compartment.oc1..<unique_ID>",
        "availabilityDomain": "NfHZ:PHX-AD-2",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "additionalDetails": {
            "namespace": "example_namespace",
            "publicAccessType": "NoPublicAccess",
            "eTag": "f8ffbe9-ef624e0a6c0-00b5abfa24c7"
        }
    }
}
```

Two key points to remember about all events:

- Events all have the same set of top-level attributes, which are known as the event envelope. With one exception, most of these top-level attributes are not that useful for creating filters. The exception is `eventType`, which identifies the type of event included in the payload.
- The payload of the event appears within the `data` attribute. The information in this field depends on which service produced the event and the event type requested. The information in the payload is useful for isolating one event from another with a filter.

For more information about the envelope, see [Contents of an Event Message](#) on page 2703. For a list of all the services that produce events, see [Services that Produce Events](#) on page 2705.
**Event Matching with Filters**

Rules use filters to select events and route them for delivery to action resources. A rule is represented as a JSON object, similar to an event. The filter is an attribute of the rule, and the attribute is named `condition`. A filter either matches an event or it does not.

A few important things to remember about filters:

- Fields not mentioned in a filter are ignored. You can create a valid filter that matches all event messages with two curly brackets.
- For a filter to match an event, the event must contain all the field names listed in the filter. Field names must appear in the filter with the same nesting structure used in the event.
- Rules apply to events in the compartment in which you create them and any child compartments. This means that a filter specified by a rule only matches events emitted from resources in the same compartment or any child compartments.
- Wildcard matching is supported with the asterisk (*) character. See Examples of Wildcard Matching in Filters on page 2688.

**Examples of Simple Filters**

The following filter matches every event in the compartment and any child compartments where you create the rule.

```json
{
  ...
  "condition": "{}"
}
```

When you add fields to the filter, you limit the events that the filter can match. For example, the following filter matches only `deletebucket` events.

```json
{
  ...
  "condition": "{ "eventType": "com.oraclecloud.objectstorage.deletebucket" }"}
```

To create a filter for more than one event type, use an array in `eventType`. The following filter matches `deletebucket` and `createbucket` events.

```json
{
  ...
  "condition": "{ "eventType": [ "com.oraclecloud.objectstorage.deletebucket", "com.oraclecloud.objectstorage.createbucket" ] }"}
```

**Examples of Filters with Event Payload Attributes**

Both of the following filters would match the event at the top of the page. The first because filter specifies two fields and both fields appear in the event, the second because the "NoPublicAccess" type appears in the event.

The important thing to note is how the field names in the filter match the nesting structure of the event.

```json
{
  ...
  "condition": "{
    "eventType": "com.oraclecloud.objectstorage.deletebucket",
    "NoPublicAccess": "true"
  }"
}
```
Neither of the following filters would match the event at the top of this page. The first because the filter specifies a PublicAccessType not found in the event. The second because the event specifies a name for different bucket.

Examples of Arrays in Filters

Arrays in filters match events if any of the values in the filter match a value in an event. The following filter would match the event at the top of the page because the name of the bucket in the event is included in an array in the filter.
You can use an array in `eventType` (or any of the top-level fields), the event payload as shown in the preceding example, or both the event payload and a top-level field.

```json
{
...

  "condition": "{
    "eventType": [
      "com.oraclecloud.objectstorage.deletebucket",
      "com.oraclecloud.objectstorage.createbucket"
    ],
    "data": {
      "resourceName": [
        "my_bucket_2",
        "my_bucket_1",
        "my_bucket"
      ],
      "additionalDetails": {
        "namespace": "example_namespace",
        "publicAccessType": "NoPublicAccess"
      }
    }
  }
}
```

**Examples of Wildcard Matching in Filters**

The following are a few things to consider about wildcard matching with filters.

- Use the wildcard only in attribute values. You cannot use the asterisk for matching in keys.
- An attribute value with only an asterisk matches all values for the associated attribute name, but *not* null.
- The period character has no special meaning in a filter.

You can add the asterisk at the start of a string, in the middle, or at the end. All of the filters that follow match the event at the top of the page.

- The first matches because the wildcard in `displayName` matches the bucket naming pattern.
- The second one matches because the `publicAccessType` uses a wildcard. Because of the use of the wildcard, these first two filters would also match events from buckets with a similar naming pattern and would include events from buckets with or without public access.
- The third one matches because the event type includes all types of bucket events.

```json
{
...

  "condition": "{
    "data": {
      "resourceName": "my_bucket*",
      
      
    }
  }
}
Events and IAM Policies

This topic describes how an administrator must write IAM policy for the Events service. If you're new to policies, see Getting Started with Policies and Common Policies. For more details about how to write IAM policy for Events, see Details for the Events Service.

Allow Users to Work with Rules

These IAM policies allow users to manage or list rules.

*Let users list rules in a compartment*

**Type of access:** Ability to list Events rules.
**Where to create the policy:** In the tenancy.

| Allow group RuleReaders to read cloudevents-rules in tenancy |

The preceding policy allows RuleReaders to list rules in the tenancy.

*Let admins manage rules in a compartment*

**Type of access:** Ability to manage Events rules, including creating, deleting, updating or moving rules to a different compartment.

**Where to create the policy:** In the tenancy.

This line gives the user inspect access to resources in compartments to select actions.

| allow group <RuleAdmins> to inspect compartments in tenancy |

This line gives the user access to defined tags to apply filter tags to rules.

| allow group <RuleAdmins> to use tag-namespaces in tenancy |

These lines give the user access to Streaming resources for actions.

| allow group <RuleAdmins> to inspect streams in tenancy |
| allow group <RuleAdmins> to use stream-push in tenancy |
| allow group <RuleAdmins> to use stream-pull in tenancy |

These lines give the user access to Functions resources for actions.

| allow group <RuleAdmins> to use virtual-network-family in tenancy |
| allow group <RuleAdmins> to manage function-family in tenancy |

This line give the user access to Notifications topics for actions.

| allow group <RuleAdmins> to use ons-topic in tenancy |

This line gives the user manage access to rules for Events.

| allow group <RuleAdmins> to manage cloudevents-rules in tenancy |

**Managing Rules for Events**

This topic describes how to manage rules for the Events service. For more information about Events, see *Overview of Events* on page 2672.

**Prerequisites for Creating Rules**

- **Action resources:** You must have resources already set up to specify as an action. The Events service invokes the action specified in the rule by delivering the event message to action resources, which can include *topics*, streams, or functions. Every rule must have at least one action. The Events service can invoke any of the following services by delivering an event message for processing:
  - Notifications
  - Streaming
  - Functions
- **IAM policies:** To manage or list rules, you must be given the required type of access in a *policy* written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform a task and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which *compartment* you should work in. For more information, see *Events and IAM Policies* on page 2689.
• Event messages: To create rules, the resources you want to monitor with the rule must emit events. For more information, see Services that Produce Events on page 2705.

**Working with Rules**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Each rule can have a maximum of 10 actions.</td>
</tr>
</tbody>
</table>

A typical workflow for setting up a rule might follow this pattern:

1. **Identify action resources**
   
   Set up or identify whatever action resources you intend to use with the rule. For example, you might set up a Notifications topic and create subscriptions for the DevOps team so that they are notified when backups complete. If a topic already exists, you can use it instead of creating a topic. The resources you specify for actions do not have to be in the same compartment as the rule.

2. **Plan filtering**
   
   Ensure the resources that you want to monitor emit events to the Events service and plan your pattern matching strategy. For example, you might want to monitor backups on Autonomous Data Warehouse instances in the ABC compartment. Ensure Autonomous Data Warehouse instances emit an event type you can use to create the automation you require. Review the example JSON event to determine the best way to identify those resources in filters. See Matching Events with Filters on page 2685 and Services that Produce Events on page 2705.

3. **Create the rule**
   
   Rules apply to events in the compartment in which you create them and any child compartments. Create a rule in the compartment with the resource you want to monitor and specify where to deliver matching events. For example, in the ABC compartment, you might create a rule that filters for Autonomous Data Warehouse backup events. Since Events has no requirement about the location of action resources, you could specify a topic in the XYZ compartment as the resource to deliver any matching events.

**Managing Tags for Rules**

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 243.

**Tags and Event Filtering**

With Events, you can also use tags to target resources in your tenancy. You target resources by adding the tag to a filter in a rule. A filter tag helps you hone automation by targeting only resources that contain a particular tag. For example, let’s say you have dozens of Database instances in your tenancy, but only a few of the most critical of these instances have the tag "Operations." You could create a rule that triggers a particular action for resources that only contain the "Operations" tag.

Policy for working with filter tags is no different from policy for working with tags.

**To manage filter tags**

2. Choose a Compartment you have permission to work in, and then click rule's name.
3. In the Resources menu, click Event Matching.
4. In the Filter Tags section, you can view or edit existing filter tags, or click Add Filter Tag to add new ones.

**To manage tags for rules**

2. Choose a Compartment you have permission to work in, and then click rule's name.
3. Click the Tags tab to view or edit existing tags, or click Add Tags to add new ones.

For more information, see Resource Tags on page 243.
**Move Rules to a Different Compartment**

You can move rules from one compartment to another. When you move a rule to a new compartment, you stop monitoring events from resources in the current compartment and begin monitoring events in the new compartment (and any child compartments). After you move the rule to the new compartment, inherent policies apply immediately and affect access to the rules through the Console. Moving rules doesn't affect access by the Events service to actions defined in rules. For more information, see [Working with Compartments](page:working-with-compartments).

**Monitoring Rules**

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see [Monitoring](page:monitoring) on page 4078 and [Notifications](page:notifications) on page 4900.

For more information about monitoring the rules you create, see [Events Metrics](page:events-metrics) on page 2820.

**Object Events and the Events Service**

Events for objects are handled differently than other resources. Objects do not emit events by default. Use the [Console](page:console), [CLI](page:cli), or [API](page:api) to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.

**Using the Console**

*To create a rule*

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click **Create Rule**.
   
   Events compares the rules you create in this compartment to event messages emitted from resources in this compartment and any child compartments.
3. Enter the following.
   
   - **Display Name**: Specify a friendly name for the rule. You can change this name later. Avoid entering confidential information.
   - **Description**: Specify a description of what the rule does. You can change this description later.
4. In **Rule Conditions**, create a filter:

   **To add an event type**
   a. Select **Event Type**.
   b. Select a **Service Name**.
   c. In **Event type**, select one or more event types for this service.
   d. Click **+ Another Condition** and select **Event Type** to add event types for a different service.

   This filter will match events of the event types you specify.

   **To add an attribute**
   You must first select an event type to add an attribute.
   a. Select **Attribute**.
   b. Select an **Attribute Name**. Attribute values are optional.
   c. Enter an **Attribute Value**. Attribute values are optional.
   d. Click **+ Another Condition** and select **Attribute** to add another attribute.

   This filter will match events of the event types with the attributes you specify.

   **To add a filter tag**
   a. Select **Filter Tag**
   b. Select a **Tag Namespace**.
   c. To specify a free-form tag, select **None (apply a free-form tag)**.
   d. Select a **Tag Key**.
   e. Enter a **Tag Value**. Tag values are optional.
   f. Click **+ Another Condition** and select **Filter Tag** to add another filter tag.

   This filter will match events with the tags you specify.

Filter tags help you to hone automation by targeting only resources that contain a particular tag. If you want to use tags to organize your rules, use resource tags instead. For more information, see Managing Tags for Rules on page 2691.

   **Tip:**
   You can leave this field entirely blank to match all events. See Matching Events with Filters on page 2685.

   **To validate this rule**
   You can only evaluate a rule against one event type at a time. To test different event types, repeat these steps as necessary.
   a. Click **Validate Rule**. The **Test Rule** panel opens.
   b. In **Service Name**, select a service if necessary.
   c. In **Event Type**, select an event type, if necessary. A example event appears based on the selections you made. Edit the values in the event to match the values for any attributes and tags you added to your rule. For more information, see Contents of an Event Message on page 2703.
   d. Click **Check if Example Event Matches Rule**. If the rule doesn't match, use the rule editor to modify any of the following:
      - Add or remove event types
      - Add or remove values or attributes
      - Add or remove tags
      - Insert wildcards
   
   For more information, see Matching Events with Filters on page 2685.
   e. Click **Close**.
To view reference events

a. Click View example events (JSON). The View Example Events panel opens.
b. In Service Name, select a service if necessary.
c. In Event Type, select an event type, if necessary. An example event appears based on the selections you made. Use the events viewer to browse reference events.
d. Click Done.

For more information, see Contents of an Event Message on page 2703 and Matching Events with Filters on page 2685.

To add an attribute

5. In Actions, specify the actions resources to trigger when the filter finds a match:

To select a topic

a. Select Notifications.
b. Select the Notifications Compartment.
c. Select the Topic.
d. Click + Another Action and select Notifications to add another topic.

To select a stream

a. Select Streaming.
b. Select the Stream Compartment.
c. Select the Stream.
d. Click + Another Action and select Streaming to add another stream.

To select a function

a. Select Functions.
b. Select the Function Compartment.
c. Select a Function Application.
d. Select the Function.
e. Click + Another Action and select Functions to add another function.

6. Click Create Rule.

To edit a rule

2. Choose a Compartment that has the rule you want to edit.
3. For the rule you want to edit, click the Actions menu, and then click Edit.
4. Make your changes and click Save Changes.

To disable or enable a rule

2. Choose a Compartment that has the rule you want to work with.
3. For the rule, you want change, click the Actions menu, and then take one of the following actions:
   a. Click Disable
   b. Click Enable
4. Confirm when prompted.

To move a rule to a different compartment

2. In the Scope section, select a compartment.
3. Find the rule in the list, click the the Actions menu, and then click Move Resource.
4. Choose the destination compartment from the list.
5. Click **Move Resource**.

**To validate a rule**

You can only evaluate a rule against one event type at a time. Repeat as necessary to test different event types.

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to test.
3. Click **Validate Rule**.
4. Take one or more of the following actions:
   - If there are no event types in the rule, select the service and event type you want to test.
   - If you want to test a different event type than the one selected by default, select the service and event type you want to test.
   - If you added attribute values or filter tags to the rule, edit the example data in the event to match the values in your rule.
5. Click **Check if Example Event Matches Rule**.

For more information, see [Matching Events with Filters](#) on page 2685 and [Contents of an Event Message](#) on page 2703.

**To delete a rule**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose the **Compartment** that has rule you want to delete.
3. For the rule you want to delete, click the Actions menu, and then click **Delete**.
4. Confirm when prompted.

**To add an action to a rule**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Actions**.
4. Click **Add**.
   - The **Add Action** box appears. Configure the action resources:
     - **To select a topic**
       a. Select **Notifications**.
       b. Select the **Notifications Compartment**.
       c. Select the **Topic**.
     - **To select a stream**
       a. Select **Streaming**.
       b. Select the **Stream Compartment**.
       c. Select the **Stream**.
     - **To select a function**
       a. Select **Functions**.
       b. Select the **Function Compartment**.
       c. Select a **Function Application**.
       d. Select the **Function**.
     - **Action State**: Select to enable the action. Clear to disable.
5. Click **Add Action**.

**To edit an action**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Actions**.
4. Select an action.
5. Go to **Actions** and click **Edit**. The **Edit Action** box appears.
6. Make your changes and click **Save Changes**.

*To enable or disable an action*

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Actions**.
4. Select an action.
5. Go to **Actions** and specify **Enable** or **Disable**.
6. Confirm when prompted.

*To remove an action*

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Actions**.
4. Select an action.
5. Go to **Actions** and click **Remove**.
6. Confirm when prompted.

    Each rule must have one action.

*To add event types to a rule*

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Click **Add Event Type**.
5. In **Service Name**, select a service.
6. In **Event Type**, select an event type for this service.
7. Click **Add Event Type**.

*To edit event types for a rule*

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select an event type.
5. Click **Edit**. The **Edit Event Type** box appears.
6. Make your changes and click **Save Changes**.

*To remove event types for a rule*

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select the check box next to the event types you want to remove.

    **Tip:**

    To select the entire list, select the check box in the header row.

5. Click **Remove**.
6. Confirm when prompted.

*To add attributes to a rule*

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Click **Add Attribute**. The **Add Attribute** box appears. Configure the attribute:
   - **Attribute Name**: Specify an attribute or tag to narrow matching results.
     - Select an attribute name. The list of attribute names is based on the event types you selected. If you select no event types, you cannot add an attribute.
     - If you specify an attribute here, you limit the events that match this rule.
   - **Attribute Values**: Specify one or more values for the attribute name.
     a. Enter a value. As you type, the value appears under the field with (New) appended. Select the value with (New) appended to add the value to **Attribute Values**.
     b. Enter more values for attribute name in the same manner as before.
     ![ATTRIBUTE VALUES](image)
   Here are some things to consider about attribute values:
   - Use an asterisk to create a wildcard. See [Examples of Wildcard Matching in Filters](#) on page 2688.
   - Multiple values for an attribute name broaden your results. If any of the values you enter here match a value in an event, the rule matches. See [Examples of Arrays in Filters](#) on page 2687.
5. Click **Add attribute**.

### To edit attributes for a rule

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select an attribute.
5. Click **Edit**. The **Edit Attribute** box appears.
6. Make your changes and click **Save Changes**.

### To remove attributes for a rule

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select the check box next to the attributes you want to remove.

---

Tip:
To select the entire list, select the check box in the header row.

5. Click Remove.
6. Confirm when prompted.

**To add filter tags to a rule**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Click **Add Filter Tag**.
5. In **Tag Namespace**, do one of the following:
   - Select a namespace to add a defined tag as a filter.
   - Select **None (apply a free-form tag)** to add a free-form tag as a filter.
6. In **Tag Key**, do one of the following:
   - Select the tag key for the defined tag.
   - Enter the tag key for the free-form tag.
7. Enter a **Value**.
8. Click **Add Filter Tag**.

**To edit filter tags for a rule**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select a filter tag.
5. Click **Edit**. The **Edit Attribute** box appears.
6. Make your changes and click **Save Changes**.

**To remove filter tags for a rule**

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose a **Compartment** you have permission to work in, and then click the **Name** of the rule you want to update.
3. In the **Resources** menu, click **Event Matching**.
4. Select the check box next to the filter tags you want to remove.

---

Tip:
To select the entire list, select the check box in the header row.

5. Click **Remove**.
6. Confirm when prompted.

**Using the Command Line Interface (CLI)**

When you use the CLI to create a rule, you work a little differently than using the Console.

- To specify the actions for your rule, use a JSON formatted file. You create this file before you create the rule, and the file simplifies the amount of information you must type at the command line.
- To specify an event to match, use a JSON formatted string. You type this right into the console as you create the rule.

For information about using the CLI, see **Command Line Interface (CLI)**. For a complete list of flags and options available for CLI commands, see **CLI Help**.
To create an action JSON file

To specify the actions for your rule, use a JSON formatted file. For more information, see Advanced JSON Options on page 6141.

1. Create a file and add the following content. This content doesn't have to be escaped or on a single line, it just has to contain valid JSON.

```json
{
   "actions": [
      {
         "actionType": "FAAS",
         "description": "string",
         "functionId": "<function_OCID>",
         "isEnabled": true
      },
      {
         "actionType": "ONS",
         "description": "string",
         "isEnabled": true,
         "topicId": "<topic_OCID>"
      },
      {
         "actionType": "OSS",
         "description": "string",
         "isEnabled": true,
         "streamId": "<stream_OCID>"
      }
   ]
}
```

2. Edit the file and remove any objects you don't want to use as an action. For example, if you wanted to only use Notifications as an action, then you would delete all the other objects.

```json
{
   "actions": [
      {
         "actionType": "ONS",
         "description": "string",
         "isEnabled": true,
         "topicId": "<topic_OCID>"
      }
   ]
}
```

3. Edit the file and fill in any variables with actual values from your tenancy, as shown in the following example.

```json
{
   "actions": [
      {
         "actionType": "ONS",
         "description": "string",
         "isEnabled": true,
         "topicId": "<topic_OCID>"
      }
   ]
}
```

4. Add a description.

5. Save the file as action.json
To create a rule and specify Notifications as an action, run the following command.

```bash
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{}" --compartment-id <compartment_OCID> --actions file://action.json
```

To create a rule

Open a command prompt and run `oci events rule create` to create a rule.

Use the following options:

- `display-name` indicates the name of the rule in the Console
- `is-enabled` indicates whether Events should evaluate the rule.
- `condition` a JSON formatted string used to indicate a pattern for event matching (see Examples for usage).

**Examples**

The following example shows how to pass a simple condition that matches all events. Everything between the double quotes (" ") is a string, while the brackets { } indicate JSON:

```bash
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{}" --compartment-id <compartment_OCID> --actions file://action.json --wait-for-state=ACTIVE
```

To pass complex input to the CLI as a JSON string, you must enclose the entire block in double quotes. Inside the block, each double quote for the key and value strings must be escaped with a backslash (\) character. For example:

```bash
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{\"eventType\":[\"com.oraclecloud.objectstorage.createobject\"]}\" --compartment-id <compartment_OCID> --actions file://action.json --wait-for-state=ACTIVE
```

In PowerShell, to escape double quotes, you must use two characters: The backslash (\) and the back tick (`). For example, in Windows PowerShell:

```bash
oci events rule create --display-name <friendly_name> --is-enabled true --condition "{\"eventType\":[\"com.oraclecloud.objectstorage.createobject\"]}\" --compartment-id <compartment_OCID> --actions file://action.json --wait-for-state=ACTIVE
```

**Tip:**

The `condition` option does not support using a file to pass the JSON formatted string.

For information on creating filters, see [Matching Events with Filters](#) on page 2685.

- `compartment-id` indicates the compartment where the rule applies. Events evaluates messages from resources in this compartment and any subordinate compartments.
- `actions` indicates the location in the local file system of the JSON formatted file you created to specify the actions for a rule.
- `wait-for-state=` when used with ACTIVE indicates that the CLI should wait for the service to create the rule, do another GET operation, and then display the rule in the active state. Without the option, the CLI displays the rule immediately in the creating state.

For example:

```bash
oci events rule create --display-name <friendly_name> --is-enabled true
```
Events

```bash
--condition <json_formatted_string> --compartment-id <compartment_OCID>
--actions <json_formatted_file> --wait-for-state=ACTIVE
```

**Note:**
Replace the values in `<compartment_OCID>` and `<json_formatted_file>` with the actual values from your tenancy and the local file system.

**To delete a rule**

Open a command prompt and run `oci events rule delete` to delete a single rule. For example:

```bash
oci events rule delete --rule-id <rule_OCID>
```

The command returns a prompt, asking for confirmation. Type `y` to delete the rule.

**To get rule metadata**

You can get rule metadata using the CLI. The Console displays this metadata in the **Rule Details** tab.

Open a command prompt and run `oci events rule get` to get information about a single rule. For example:

```bash
oci events rule get --rule-id <rule_OCID>
```

The command returns the following information:

```json
{
    "data": {
        "actions": {
            "actions": [
                {
                    "action-type": "ONS",
                    "description": null,
                    "id": "ocid1.eventaction.oc1.phx.<unique_ID>",
                    "lifecycle-message": null,
                    "lifecycle-state": "ACTIVE",
                    "topic-id": "ocid1.onstopic.oc1.phx.<unique_ID>
                }
            ],
            "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
            "condition": ",
            "defined-tags": null,
            "description": null,
            "display-name": "rule_name",
            "freeform-tags": null,
            "id": "ocid1.eventrule.oc1.phx.<unique_ID>",
            "is-enabled": true,
            "lifecycle-message": null,
            "lifecycle-state": "ACTIVE",
            "time-created": "2019-01-23T00:48:20.155000+00:00"
        },
        "etag": "<unique_ID>--gzip"
    }
}
```

**To get a list of rules**

Open a command prompt and run `oci events rule list` to list the rules in a compartment. For example:

```bash
oci events rule list --compartment-id <compartment_OCID>
```
The command returns the following information:

```json
{
  "data": [
    {
      "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
      "condition": "{}",
      "description": "Example_Rule",
      "display-name": "rule_1",
      "id": "ocid1.eventrule.oc1.phx..<unique_ID>",
      "is-enabled": true,
      "lifecycle-state": "ACTIVE",
      "time-created": "2019-01-22T20:10:53.562000+00:00"
    },
    {
      "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
      "condition": "{}",
      "description": null,
      "display-name": "rule_2",
      "id": "ocid1.eventrule.oc1.phx..<unique_ID>",
      "is-enabled": true,
      "lifecycle-state": "ACTIVE",
      "time-created": "2019-01-22T20:27:25.099000+00:00"
    },
    ...
    {
      "compartment-id": "ocid1.compartment.oc1..<unique_ID>",
      "condition": "{"eventType": ["com.oraclecloud.objectstorage.createobject"]}",
      "description": null,
      "display-name": "rule_75",
      "id": "ocid1.eventrule.oc1.phx..<unique_ID>",
      "is-enabled": true,
      "lifecycle-state": "ACTIVE",
      "time-created": "2019-01-22T23:08:12.379000+00:00"
    }
  ]
}
```

**To update a rule**

Open a command prompt and run `oci events rule update` to update a rule.

To update the condition for a rule:

```
oci events rule update --rule-id <rule_OCID> --condition <json_formatted_string>
```

For example:

```
oci events rule update --rule-id ocid1.eventrule.oc1.phx.<unique_ID> --condition "{}" --wait-for-state=ACTIVE
```

The previous command would update the condition of the rule to use an empty JSON string. The CLI updates the rule, waits for the rule to update and change to the active state (only if you used the `--wait-for-state` option), then displays the updated rule.

Use the following options to update a rule:

- `display-name`
Events

- description
- is-enabled
- condition
- actions
- freeform-tags
- defined-tags

Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use the following operations to manage rules:

- ChangeRuleCompartment
- CreateRule
- DeleteRule
- GetRule
- UpdateRule
- ListRules

Contents of an Event Message

This topic describes the contents of an event message. Every event message includes two main parts:

- Envelope: a container for all event messages
- Payload: the data from the resource emitting the event message

Event Envelope

These attributes for an event envelope are the same for all events. The structure of the envelope follows the CloudEvents industry standard format hosted by the Cloud Native Computing Foundation (CNCF).

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cloudEventsVersion</td>
<td>The version of the CloudEvents specification.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong></td>
</tr>
<tr>
<td></td>
<td>Events uses version 0.1 specification of the CloudEvents event envelope.</td>
</tr>
<tr>
<td>contentType</td>
<td>Set to application/json. The content type of the data contained in the data attribute.</td>
</tr>
<tr>
<td>data</td>
<td>The payload of the event. All of the information within data comes from the resource emitting the event. See the following table for more detail on the structure of the payload.</td>
</tr>
<tr>
<td>eventID</td>
<td>The UUID of the event. This identifier is not an OCID, but just a unique ID for the event.</td>
</tr>
<tr>
<td>eventTime</td>
<td>The time of the event, expressed in RFC 3339 timestamp format.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>eventType</td>
<td>The type of event that happened. For a list of all services that produce events and the even types that those services track, see Services that Produce Events on page 2705.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The service that produces the event can also add, remove, or change the meaning of a field by publishing a new version of an eventType and revising the eventTypeVersion field.</td>
</tr>
<tr>
<td>eventTypeVersion</td>
<td>The version of the event type.</td>
</tr>
<tr>
<td>extensions</td>
<td>The OCID of the compartment from which the event originates. If the event originates from the root compartment of the tenancy, then this attribute specifies a tenancy OCID. This attribute is mandatory in the Oracle Cloud Infrastructure implementation of the CloudEvents specification.</td>
</tr>
<tr>
<td>source</td>
<td>The resource that produced the event. For example, an Autonomous Database or an Object Storage bucket.</td>
</tr>
</tbody>
</table>

### Payload

The data in these fields depends on which service produced the event and the event type it defines.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>compartmentId</td>
<td>The OCID of the compartment of the resource emitting the event.</td>
</tr>
<tr>
<td>compartmentName</td>
<td>The name of the compartment of the resource emitting the event.</td>
</tr>
<tr>
<td>resourceName</td>
<td>The name of the resource emitting the event.</td>
</tr>
<tr>
<td>resourceId</td>
<td>An OCID or an ID for the resource emitting the event.</td>
</tr>
<tr>
<td>availabilityDomain</td>
<td>The availability domain of the resource emitting the event.</td>
</tr>
<tr>
<td>freeFormTags</td>
<td>Free-form tags added to the resource emitting the event.</td>
</tr>
<tr>
<td>definedTags</td>
<td>Defined tags added to the resource emitting the event.</td>
</tr>
<tr>
<td>additionalDetails</td>
<td>A container for attributes unique to the resource emitting the event.</td>
</tr>
<tr>
<td></td>
<td>In the example bucket event that follows, the payload includes three Object Storage attributes:</td>
</tr>
<tr>
<td></td>
<td>• namespace</td>
</tr>
<tr>
<td></td>
<td>• publicAccessType</td>
</tr>
<tr>
<td></td>
<td>• eTag</td>
</tr>
<tr>
<td></td>
<td>To determine what attributes are included for other resources, retrieve an event or consult the reference samples listed on Services that Produce Events on page 2705.</td>
</tr>
</tbody>
</table>
Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 228.

An Example Event

The following is an example bucket event emitted by Object Storage.

```
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.objectstorage.deletebucket",
  "source": "objectstorage",
  "eventTypeVersion": "1.0",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_bucket",
    "resourceId": "ocid1.compartment.oc1..<unique_ID>",
    "availabilityDomain": "NfHZ:PHX-AD-2",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "namespace": "example_namespace",
      "publicAccessType": "NoPublicAccess",
      "eTag": "f8ffb6e9-f602-460f-a6c0-00b5abfa24c7"
    }
  }
}
```

Services that Produce Events

This topic lists the Oracle Cloud Infrastructure services that emit events:

- Analytics Cloud
- API Gateway
- Classic Migration Service
- Bastion
- Big Data
- Block Volume
- Blockchain Platform
- Budgets
- Cloud Guard on page 2719
- Compute
- Container Engine for Kubernetes
- Content Management
- Data Catalog on page 2736
About Event Types and Example Reference Events

Services emit event messages by resource type. Event messages use a combination of an event type and a data payload (from the resource) to identify state changes.

In this section:
- Event types are organized by service, then by resource type
- There is one reference example per resource type if the payload contains the same attributes for all event types

See Matching Events with Filters on page 2685 and Contents of an Event Message on page 2703.

Analytics Cloud

For details about events emitted by Analytics Cloud, see Service Events.

API Gateway

API Gateway resources that emit events:
- API Gateway Certificate Event Types on page 2707
- API Deployment Event Types on page 2708
- API Gateway Event Types on page 2709
- API Event Types on page 2710
API Gateway Certificate Event Types

These are the event types that API Gateway certificates emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Certificate Compartment Begin</td>
<td>com.oraclecloud.apigateway.changegatewaycertificate.begin</td>
</tr>
<tr>
<td>Change Certificate Compartment End</td>
<td>com.oraclecloud.apigateway.changegatewaycertificate.end</td>
</tr>
<tr>
<td>Create Certificate Begin</td>
<td>com.oraclecloud.apigateway.creategatewaycertificate.begin</td>
</tr>
<tr>
<td>Create Certificate End</td>
<td>com.oraclecloud.apigateway.creategatewaycertificate.end</td>
</tr>
<tr>
<td>Delete Certificate Begin</td>
<td>com.oraclecloud.apigateway.deletegatewaycertificate.begin</td>
</tr>
<tr>
<td>Delete Certificate End</td>
<td>com.oraclecloud.apigateway.deletegatewaycertificate.end</td>
</tr>
<tr>
<td>Update Certificate Begin</td>
<td>com.oraclecloud.apigateway.updategatewaycertificate.begin</td>
</tr>
<tr>
<td>Update Certificate End</td>
<td>com.oraclecloud.apigateway.updategatewaycertificate.end</td>
</tr>
</tbody>
</table>

API Gateway Certificate Example

This is an example event for API Gateway certificates:

```json
{
    "eventType": "com.oraclecloud.apigateway.creategatewaycertificate.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "apigateway",
    "eventTime": "2019-08-16T15:09:04.550Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "My_Certificate",
        "resourceId": "ocid1.apigatewaycertificate.oc1.phx.<unique_ID>",
        "availabilityDomain": "availability_domain"
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```
**API Deployment Event Types**

These are the event types that API deployments emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Deployment Compartment Begin</td>
<td>com.oraclecloud.apigateway.changedeploymentcompartment.begin</td>
</tr>
<tr>
<td>Change Deployment Compartment End</td>
<td>com.oraclecloud.apigateway.changedeploymentcompartment.end</td>
</tr>
<tr>
<td>Create Deployment Begin</td>
<td>com.oraclecloud.apigateway.createdeployment.begin</td>
</tr>
<tr>
<td>Create Deployment End</td>
<td>com.oraclecloud.apigateway.createdeployment.end</td>
</tr>
<tr>
<td>Delete Deployment Begin</td>
<td>com.oraclecloud.apigateway.deletedeployment.begin</td>
</tr>
<tr>
<td>Delete Deployment End</td>
<td>com.oraclecloud.apigateway.deletedeployment.end</td>
</tr>
<tr>
<td>Update Deployment Begin</td>
<td>com.oraclecloud.apigateway.updatedeployment.begin</td>
</tr>
<tr>
<td>Update Deployment End</td>
<td>com.oraclecloud.apigateway.updatedeployment.end</td>
</tr>
</tbody>
</table>

**API Deployment Example**

This is an example event for API deployments:

```json
{
  "eventType": "com.oraclecloud.apigateway.createdeployment.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "apigateway",
  "eventTime": "2019-08-16T15:09:04.550Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "My_Deployment",
    "resourceId": "ocid1.apideployment.oc1.phx.<unique_ID>",
    "availabilityDomain": "availability_domain"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```
## API Gateway Event Types

These are the event types that API gateways emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Gateway Compartment Begin</td>
<td>com.oraclecloud.apigateway.changegatewaycompartment.begin</td>
</tr>
<tr>
<td>Change Gateway Compartment End</td>
<td>com.oraclecloud.apigateway.changegatewaycompartment.end</td>
</tr>
<tr>
<td>Create Gateway Begin</td>
<td>com.oraclecloud.apigateway.creategateway.begin</td>
</tr>
<tr>
<td>Create Gateway End</td>
<td>com.oraclecloud.apigateway.creategateway.end</td>
</tr>
<tr>
<td>Delete Gateway Begin</td>
<td>com.oraclecloud.apigateway.deletegateway.begin</td>
</tr>
<tr>
<td>Delete Gateway End</td>
<td>com.oraclecloud.apigateway.deletegateway.end</td>
</tr>
<tr>
<td>Update Gateway Begin</td>
<td>com.oraclecloud.apigateway.updategateway.begin</td>
</tr>
<tr>
<td>Update Gateway End</td>
<td>com.oraclecloud.apigateway.updategateway.end</td>
</tr>
</tbody>
</table>

### Gateway Example

This is an example event for API gateways:

```json
{
  "eventType": "com.oraclecloud.apigateway.creategateway.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "apigateway",
  "eventTime": "2019-08-16T15:09:04.550Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "My_Gateway",
    "resourceId": "ocid1.apigateway.oc1.phx.<unique_ID>",
    "availabilityDomain": "availability_domain"
  },
  "eventId": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```
API Event Types

These are the event types that API resources emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change API Compartment Begin</td>
<td>com.oraclecloud.apigateway.changeapicompartment.begin</td>
</tr>
<tr>
<td>Change API Compartment End</td>
<td>com.oraclecloud.apigateway.changeapicompartment.end</td>
</tr>
<tr>
<td>Create API Begin</td>
<td>com.oraclecloud.apigateway.createapi.begin</td>
</tr>
<tr>
<td>Create API End</td>
<td>com.oraclecloud.apigateway.createapi.end</td>
</tr>
<tr>
<td>Delete API Begin</td>
<td>com.oraclecloud.apigateway.deleteapi.begin</td>
</tr>
<tr>
<td>Delete API End</td>
<td>com.oraclecloud.apigateway.deleteapi.end</td>
</tr>
<tr>
<td>Update API Begin</td>
<td>com.oraclecloud.apigateway.updateapi.begin</td>
</tr>
<tr>
<td>Update API End</td>
<td>com.oraclecloud.apigateway.updateapi.end</td>
</tr>
</tbody>
</table>

API Example

This is an example event for API resources:

```json
{
  "eventType": "com.oraclecloud.apigateway.createapi.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "apigateway",
  "eventTime": "2020-09-09T12:00:00.000Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Application Migration

For details about events emitted by Classic Migration Service, see Service Events.

Bastion

For details about events emitted by Bastion, see Bastion Events.
Big Data
For details about events emitted by Big Data, see Service Events.

Block Volume
Block Volume resources that emit events:

- Block Volume Event Types on page 2711 and Block Volume Backup Event Types on page 2712
- Boot Volume Event Types on page 2714 and Boot Volume Backup Event Types on page 2715
- Volume Groups and Volume Group Backups on page 2716

Block Volume Event Types
These are the event types that block volumes emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Volume Compartment Begin</td>
<td>com.oraclecloud.blockvolumes.changevolumecompartment.begin</td>
</tr>
<tr>
<td>Change Volume Compartment End</td>
<td>com.oraclecloud.blockvolumes.changevolumecompartment.end</td>
</tr>
<tr>
<td>Create Volume Begin</td>
<td>com.oraclecloud.blockvolumes.createvolume.begin</td>
</tr>
<tr>
<td>Create Volume End</td>
<td>com.oraclecloud.blockvolumes.createvolume.end</td>
</tr>
<tr>
<td>Delete Volume Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolume.begin</td>
</tr>
<tr>
<td>Delete Volume End</td>
<td>com.oraclecloud.blockvolumes.deletevolume.end</td>
</tr>
<tr>
<td>Delete Volume Kms Key Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolumekmskey.begin</td>
</tr>
<tr>
<td>Update Volume</td>
<td>com.oraclecloud.blockvolumes.updatevolume</td>
</tr>
<tr>
<td>Update Volume Begin</td>
<td>com.oraclecloud.blockvolumes.updatevolume.begin</td>
</tr>
<tr>
<td>Update Volume End</td>
<td>com.oraclecloud.blockvolumes.updatevolume.end</td>
</tr>
<tr>
<td>Update Volume Kms Key Begin</td>
<td>com.oraclecloud.blockvolumes.updatevolumekmskey.begin</td>
</tr>
<tr>
<td>Update Volume Kms Key End</td>
<td>com.oraclecloud.blockvolumes.updatevolumekmskey.end</td>
</tr>
</tbody>
</table>

Block Volume Example
This is a reference event for block volumes:

```
**Block Volume Backup Event Types**

These are the event types that block volume backups emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Volume Backup Compartment</td>
<td>com.oraclecloud.blockvolumes.changevolumebackupcompartment</td>
</tr>
<tr>
<td>Copy Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.copyvolumebackup.begin</td>
</tr>
<tr>
<td>Copy Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.copyvolumebackup.end</td>
</tr>
<tr>
<td>Create Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.createvolumebackup.begin</td>
</tr>
<tr>
<td>Create Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.createvolumebackup.end</td>
</tr>
<tr>
<td>Create Volume Backup Policy Assignment</td>
<td>com.oraclecloud.blockvolumes.createvolumebackuppolicyassignment</td>
</tr>
<tr>
<td>Delete Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolumebackup.begin</td>
</tr>
<tr>
<td>Delete Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.deletevolumebackup.end</td>
</tr>
<tr>
<td>Delete Volume Backup Policy Assignment</td>
<td>com.oraclecloud.blockvolumes.deletevolumebackuppolicyassignment</td>
</tr>
<tr>
<td>Update Volume Backup</td>
<td>com.oraclecloud.blockvolumes.updatevolumebackup</td>
</tr>
<tr>
<td>Update Volume Backup Policy</td>
<td>com.oraclecloud.blockvolumes.updatevolumebackuppolicy</td>
</tr>
</tbody>
</table>
**Block Volume Backup Example**

This is a reference event for block volume backups:

```json
{
  "eventType": "com.oraclecloud.blockvolumes.createvolumebackup.end",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "BlockVolumes",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_volumebackup via policy:gold",
    "resourceId": "ocid1.volumebackup.oc1..<unique_ID>",
    "additionalDetails": {
      "sourceType": "SCHEDULED",
      "volumeId": "ocid1.volume.oc1..<unique_ID>
    }
  }
}
```

"eventID": "<unique_ID>",
"extensions": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
Events

**Boot Volume Event Types**
These are the event types that boot volumes emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Boot Volume Compartment Begin</td>
<td>com.oraclecloud.blockvolumes.changebootvolumecompartment.begin</td>
</tr>
<tr>
<td>Change Boot Volume Compartment End</td>
<td>com.oraclecloud.blockvolumes.changebootvolumecompartment.end</td>
</tr>
<tr>
<td>Create Boot Volume Begin</td>
<td>com.oraclecloud.blockvolumes.createbootvolume.begin</td>
</tr>
<tr>
<td>Create Boot Volume End</td>
<td>com.oraclecloud.blockvolumes.createbootvolume.end</td>
</tr>
<tr>
<td>Delete Boot Volume Begin</td>
<td>com.oraclecloud.blockvolumes.deletebootvolume.begin</td>
</tr>
<tr>
<td>Delete Boot Volume End</td>
<td>com.oraclecloud.blockvolumes.deletebootvolume.end</td>
</tr>
<tr>
<td>Delete Boot Volume Kms Key Begin</td>
<td>com.oraclecloud.blockvolumes.deletebootvolumekmskey.begin</td>
</tr>
<tr>
<td>Update Boot Volume</td>
<td>com.oraclecloud.blockvolumes.updatebootvolume</td>
</tr>
<tr>
<td>Update Boot Volume Begin</td>
<td>com.oraclecloud.blockvolumes.updatebootvolume.begin</td>
</tr>
<tr>
<td>Update Boot Volume End</td>
<td>com.oraclecloud.blockvolumes.updatebootvolume.end</td>
</tr>
<tr>
<td>Update Boot Volume Kms Key Begin</td>
<td>com.oraclecloud.blockvolumes.updatebootvolumekmskey.begin</td>
</tr>
<tr>
<td>Update Boot Volume Kms Key End</td>
<td>com.oraclecloud.blockvolumes.updatebootvolumekmskey.end</td>
</tr>
</tbody>
</table>

**Boot Volume Example**
This is a reference event for boot volumes:

```json
{
    "eventType": "com.oraclecloud.blockvolumes.createbootvolume.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "BlockVolumes",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_volume",
        "resourceId": "ocid1.volume.oc1..<unique_ID>",
        "availabilityDomain": "<availability_domain>",
```
Boot Volume Backup Event Types

These are the event types that boot volume backups emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Boot Volume Backup Compartment</td>
<td>com.oraclecloud.blockvolumes.changebootvolumebackup</td>
</tr>
<tr>
<td>Copy Boot Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.copybootvolumebackup.begin</td>
</tr>
<tr>
<td>Copy Boot Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.copybootvolumebackup.end</td>
</tr>
<tr>
<td>Create Boot Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.createbootvolumebackup.begin</td>
</tr>
<tr>
<td>Create Boot Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.createbootvolumebackup.end</td>
</tr>
<tr>
<td>Delete Boot Volume Backup Begin</td>
<td>com.oraclecloud.blockvolumes.deletebootvolumebackup.begin</td>
</tr>
<tr>
<td>Delete Boot Volume Backup End</td>
<td>com.oraclecloud.blockvolumes.deletebootvolumebackup.end</td>
</tr>
<tr>
<td>Update Boot Volume Backup</td>
<td>com.oraclecloud.blockvolumes.updatebootvolumebackup</td>
</tr>
</tbody>
</table>

Boot Volume Backup Example

This is a reference event for boot volume backups:

```json
{
    "eventType": "com.oraclecloud.blockvolumes.createbootvolume.end",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "BlockVolumes",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_volumebackup via policy:gold",
        "resourceId": "ocid1.volumebackup.oc1..<unique_ID>",
        "additionalDetails": {
            "sourceType": "SCHEDULED",
            "volumeId": "ocid1.volume.oc1..<unique_ID>
        }
    }
}
```
Volume Groups and Volume Group Backups

These are the event types that volume groups and volume group backups emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Volume Group Compartment</td>
<td>com.oraclecloud.blockvolumes.changevolumegroupcompartment</td>
</tr>
<tr>
<td>Change Volume Group Backup Compartment</td>
<td>com.oraclecloud.blockvolumes.changevolumegroupbackupcompartment</td>
</tr>
<tr>
<td>Create Volume Group</td>
<td>com.oraclecloud.blockvolumes.createvolumegroup</td>
</tr>
<tr>
<td>Create Volume Group Begin</td>
<td>com.oraclecloud.blockvolumes.createvolumegroup.begin</td>
</tr>
<tr>
<td>Create Volume Group End</td>
<td>com.oraclecloud.blockvolumes.createvolumegroup.end</td>
</tr>
<tr>
<td>Create Volume Group Backup Begin</td>
<td>com.oraclecloud.blockvolumes.createvolumegroupbackup.begin</td>
</tr>
<tr>
<td>Create Volume Group Backup End</td>
<td>com.oraclecloud.blockvolumes.createvolumegroupbackup.end</td>
</tr>
<tr>
<td>Delete Volume Group Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolumegroup.begin</td>
</tr>
<tr>
<td>Delete Volume Group End</td>
<td>com.oraclecloud.blockvolumes.deletevolumegroup.end</td>
</tr>
<tr>
<td>Delete Volume Group Backup Begin</td>
<td>com.oraclecloud.blockvolumes.deletevolumegroupbackup.begin</td>
</tr>
<tr>
<td>Delete Volume Group Backup End</td>
<td>com.oraclecloud.blockvolumes.deletevolumegroupbackup.end</td>
</tr>
<tr>
<td>Update Volume Group</td>
<td>com.oraclecloud.blockvolumes.updatevolumegroup</td>
</tr>
<tr>
<td>Update Volume Group Backup</td>
<td>com.oraclecloud.blockvolumes.updatevolumegroupbackup</td>
</tr>
</tbody>
</table>

Volume Group Example

This is a reference event for volume groups:

```json
{
  "eventType": "com.oraclecloud.blockvolumes.createvolumegroup",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "BlockVolumes",
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
```
Events

```json
"eventTime": "2019-01-10T21:19:24Z",
"contentType": "application/json",
"data": {
  "resourceName": "my_volumegroup",
  "resourceId": "ocid1.volumegroup.oc1..<unique_ID>"
}
"eventID": "<unique_ID>",
"extensions": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
```

Blockchain Platform

For details about events emitted by Blockchain Platform, see Service Events.

Budgets

Budgets resources that emit events:

- Alert Rule Event Types on page 2717
- Budget Event Types on page 2718
- Create Triggered Alert Event Types on page 2718

Alert Rule Event Types

These are the event types that alert rule emits:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Alert Rule</td>
<td>com.oraclecloud.budgets.createalertrule</td>
</tr>
<tr>
<td>Update Alert Rule</td>
<td>com.oraclecloud.budgets.updatealertrule</td>
</tr>
<tr>
<td>Delete Alert Rule</td>
<td>com.oraclecloud.budgets.deletealertrule</td>
</tr>
</tbody>
</table>

Alert Rule Example

This is a reference event for creating an alert:

```json
{
  "eventType": "com.oraclecloud.budgets.createalertrule",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "budgets",
  "eventID": "<unique_ID>",
  "eventTime": "2020-02-02T20:20:02.002Z",
  "contentType": "application/json",
  "data": {
    "eventName": "CreateAlertRule",
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "alertrule20200202202002",
    "resourceId": "ocid1.alertrule.oc1.phx.<unique_ID>"
    "availabilityDomain": "availability_domain",
    "additionalDetails": {
      "budgetId": "ocid1.budget.oc1.phx.<unique_ID>"
      "targetType": "COMPARTMENT"
    }
  }
```
Budget Event Types

These are the event types that budget emits:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Budget</td>
<td>com.oraclecloud.budgets.createbudget</td>
</tr>
<tr>
<td>Update Budget</td>
<td>com.oraclecloud.budgets.updatebudget</td>
</tr>
<tr>
<td>Delete Budget</td>
<td>com.oraclecloud.budgets.deletebudget</td>
</tr>
</tbody>
</table>

Budget Example

This is a reference event for updating a budget:

```json
{
    "eventType": "com.oraclecloud.budgets.updatebudget",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "budgets",
    "eventID": "<unique_ID>",
    "eventTime": "2020-02-02T20:20:02.002Z",
    "contentType": "application/json",
    "data": {
        "eventName": "UpdateBudget",
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "My test budget",
        "resourceId": "ocid1.budget.oc1.phx.<unique_ID>",
        "availabilityDomain": "availability_domain",
        "additionalDetails": {
            "targetCompartmentId": "ocid1.tenancy.oc1..<unique_ID>",
            "targetType": "COMPARTMENT"
        }
    },
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>
    }
}
```

Create Triggered Alert Event Types

This is the event type that the create triggered alert emits:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Triggered Alert</td>
<td>com.oraclecloud.budgets.createtriggeredalert</td>
</tr>
</tbody>
</table>
Create Triggered Alert Example

This is a reference event for creating a triggered alert:

```
{
    "eventType": "com.oraclecloud.budgets.createtriggeredalert",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "budgets",
    "eventID": "<unique_ID>",
    "eventTime": "2020-02-02T20:20:02.002Z",
    "contentType": "application/json",
    "data": {
        "eventName": "CreateTriggeredAlert",
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceId": "ocid1.triggeredalert.oc1.phx.<unique_ID>",
        "availabilityDomain": "availability_domain",
        "additionalDetails": {
            "budgetId": "ocid1.budget.oc1.phx.<unique_ID>",
            "alertRuleId": "ocid1.alertrule.oc1.phx.<unique_ID>"
        }
    },
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```

Cloud Guard

Cloud Guard resources that emit events:

- Problems
- Targets

Problem Event Types

These are the event types that problems emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Detected-Problem</td>
<td>com.oraclecloud.cloudguard.problemdetected</td>
</tr>
<tr>
<td>Remediated-Problem</td>
<td>com.oraclecloud.cloudguard.problemremediated</td>
</tr>
</tbody>
</table>

Detected-Problem Example

This is a reference event for detected problems:

```
{
    "eventType": "com.oraclecloud.cloudguard.problemdetected",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "CloudGuardResponderEngine",
    "eventTime": "2020-09-02T18:45:39Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "compartment_name",
        "resourceName": "problem_name",
```
Remediated-Problem Example

This is a reference event for remediated problems:

```json
{
   "eventType" : "com.oraclecloud.cloudguard.problemremediated",
   "cloudEventsVersion" : "0.1",
   "eventTypeVersion" : "2.0",
   "source" : "CloudGuardResponderEngine",
   "eventTime" : "2020-09-02T18:47:00Z",
   "contentType" : "application/json",
   "data" : {
      "compartmentId" : "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName" : "compartment_name",
      "resourceName" : "problem_name",
      "resourceId" : "ocid1.cloudguardproblem.oc1.iad.<unique_ID>",
      "additionalDetails" : {
         "tenantId" : "ocid1.tenancy.oc1...<unique_ID>",
         "problemDescription" : "problem_description",
         "riskLevel" : "CRITICAL",
         "problemRecommendation" : "example_recommendation",
         "status" : "RESOLVED",
         "problemType" : "problem_type",
         "resourceName" : "resource_name",
         "resourceId" : "ocid1.vcn.oc1.iad.<unique_ID>",
         "resourceType" : "resource_type",
         "targetId" : "ocid1.cloudguardtarget.oc1..<unique_ID>",
         "labels" : "label1, label2",
         "firstDetected" : "2020-09-02T18:44:44.145Z",
         "lastDetected" : "2020-09-02T18:44:44.145Z",
         "region" : "us-ashburn-1",
         "responderRuleId" : "responder_rule_id"
      }
   },
   "eventID" : "<unique_ID>",
   "extensions" : {
      "compartmentId" : "ocid1.compartment.oc1..<unique_ID>"
   }
}
```
**Events**

**Target Event Types**

These are the event types that targets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target-Information</td>
<td>com.oraclecloud.cloudguard.targetinformation</td>
</tr>
</tbody>
</table>

**Target-Information Example**

This is a reference event for target information:

```json
{
    "eventType": "com.oraclecloud.cloudguard.targetinformation",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "CloudGuard",
    "eventTime": "2020-02-11T01:29:51.404Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "compartment_name",
        "resourceId": "ocid1.cloudguardtarget.oc1..<unique_ID>",
        "resourceName": "target_name",
        "additionalDetails": {
            "informationName": "information_name",
            "description": "example_description",
            "recommendation": "example_recommendation",
            "tenantId": "ocid1.tenancy.oc1..<unique_ID>",
            "detectorId": "detector_id",
            "detectorRuleId": "detector_rule_id",
            "status": "Open",
            "timeCreated": "2020-02-11T01:29:50.388Z",
            "region": "r2",
            "problemType": "problem_type"
        }
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```

**Compute**

Compute resources that emit events:

- [Autoscaling Event Types](#) on page 2722
- [Capacity Reservation Event Types](#) on page 2723
- [Cluster Network Event Types](#) on page 2724
- [Console History Event Types](#) on page 2725
- [Image Event Types](#) on page 2726
- [Instance Event Types](#) on page 2727
- [Instance Configuration Event Types](#) on page 2730
- [Instance Console Connection Event Types](#) on page 2731
- [Instance Maintenance Event Types](#) on page 2732
- [Instance Pool Event Types](#) on page 2734
## Autoscaling Event Types

These are the event types that autoscaling configurations and autoscaling policies emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Autoscaling Configuration Compartment</td>
<td>com.oraclecloud.autoscaling.changeautoscalingconfigurationcompartment</td>
</tr>
<tr>
<td>Create Autoscaling Configuration</td>
<td>com.oraclecloud.autoscaling.createautoscalingconfiguration</td>
</tr>
<tr>
<td>Delete Autoscaling Configuration</td>
<td>com.oraclecloud.autoscaling.deleteautoscalingconfiguration</td>
</tr>
<tr>
<td>Scaling Action</td>
<td>com.oraclecloud.autoscaling.scalingaction</td>
</tr>
<tr>
<td>Update Autoscaling Configuration</td>
<td>com.oraclecloud.autoscaling.updateautoscalingconfiguration</td>
</tr>
<tr>
<td>Update Autoscaling Policy</td>
<td>com.oraclecloud.autoscaling.updateautoscalingpolicy</td>
</tr>
</tbody>
</table>

### Autoscaling Example

This is a reference event for autoscaling:

```json
{
  "eventType": "com.oraclecloud.autoscaling.scalingaction",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "autoscaling",
  "eventTime": "2019-08-21T04:00:10.046Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    ...
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```
Capacity Reservation Event Types

These are the event types that capacity reservations emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Capacity Reservation Compartment Begin</td>
<td>com.oraclecloud.computeapi.ChangeComputeCapacityReservation.begin</td>
</tr>
<tr>
<td>Change Capacity Reservation Compartment End</td>
<td>com.oraclecloud.computeapi.ChangeComputeCapacityReservation.end</td>
</tr>
<tr>
<td>Create Capacity Reservation Begin</td>
<td>com.oraclecloud.computeapi.CreateComputeCapacityReservation.begin</td>
</tr>
<tr>
<td>Create Capacity Reservation End</td>
<td>com.oraclecloud.computeapi.CreateComputeCapacityReservation.end</td>
</tr>
<tr>
<td>Delete Capacity Reservation Begin</td>
<td>com.oraclecloud.computeapi.DeleteComputeCapacityReservation.begin</td>
</tr>
<tr>
<td>Delete Capacity Reservation End</td>
<td>com.oraclecloud.computeapi.DeleteComputeCapacityReservation.end</td>
</tr>
<tr>
<td>Update Capacity Reservation Begin</td>
<td>com.oraclecloud.computeapi.UpdateComputeCapacityReservation.begin</td>
</tr>
<tr>
<td>Update Capacity Reservation End</td>
<td>com.oraclecloud.computeapi.UpdateComputeCapacityReservation.end</td>
</tr>
</tbody>
</table>

Capacity Reservation Example

This is a reference event for capacity reservations:

```json
{
   "eventType": "com.oraclecloud.computeapi.CreateComputeCapacityReservation.begin",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "ComputeApi",
   "eventTime": "2019-08-20T21:58:13.554Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "resourceName": "example capacity reservation",
      "resourceId": "ocid1.consolehistory.oc1.iad.<unique_ID>",
      "availabilityDomain": "<availability_domain>"
   },
   "eventID": "<unique_ID>"
}
```
Cluster Network Event Types

These are the event types that cluster networks emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Cluster Network Compartment</td>
<td>com.oraclecloud.computemanagement.changeclusternetworkcompartment</td>
</tr>
<tr>
<td>Create Cluster Network Begin</td>
<td>com.oraclecloud.computemanagement.createclusternetwork.begin</td>
</tr>
<tr>
<td>Create Cluster Network End</td>
<td>com.oraclecloud.computemanagement.createclusternetwork.end</td>
</tr>
<tr>
<td>Terminate Cluster Network Begin</td>
<td>com.oraclecloud.computemanagement.terminateclusternetwork.begin</td>
</tr>
<tr>
<td>Terminate Cluster Network End</td>
<td>com.oraclecloud.computemanagement.terminateclusternetwork.end</td>
</tr>
</tbody>
</table>

Cluster Networks Example

This is a reference event for most cluster network events:

```json
{
   "eventType": "com.oraclecloud.computemanagement.createclusternetwork.begin",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "ComputeManagement",
   "eventTime": "2019-09-12T21:45:09.036Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_compartment",
      "resourceName": "my_cluster_network",
      "resourceId": "ocid1.clusternetwork.oc1.uk-london-1.<unique_ID>",
      "availabilityDomain": "<availability_domain>"
   },
   "eventID": "<unique_ID>"
}
```

Create cluster network end and terminate cluster network end don't include the availability domain.
Events

**Console History Event Types**

These are the event types that console histories emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Capture Console History Begin</td>
<td>com.oraclecloud.computeapi.captureconsolehistory</td>
</tr>
<tr>
<td>Capture Console History End</td>
<td>com.oraclecloud.computeapi.captureconsolehistory</td>
</tr>
<tr>
<td>Delete Console History</td>
<td>com.oraclecloud.computeapi.deleteconsolehistory</td>
</tr>
<tr>
<td>Update Console History</td>
<td>com.oraclecloud.computeapi.updateconsolehistory</td>
</tr>
</tbody>
</table>

**Console History Example**

This is a reference event for console histories:

```json
{
    "eventType": "com.oraclecloud.computeapi.captureconsolehistory.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeApi",
    "eventTime": "2019-08-20T21:58:13.554Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceId": "ocid1.consolehistory.oc1.iad.<unique_ID>",
        "availabilityDomain": "<availability_domain>"
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```
## Image Event Types

These are the event types that images emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Image Shape Compatibility</td>
<td>com.oraclecloud.computeapi.addimageshapecompatibility</td>
</tr>
<tr>
<td>Change Image Compartment</td>
<td>com.oraclecloud.computeapi.moveimage</td>
</tr>
<tr>
<td>Create Image Begin</td>
<td>com.oraclecloud.computeapi.createimage.begin</td>
</tr>
<tr>
<td>Create Image End</td>
<td>com.oraclecloud.computeapi.createimage.end</td>
</tr>
<tr>
<td>Delete Image</td>
<td>com.oraclecloud.computeapi.deleteimage</td>
</tr>
<tr>
<td>Export Image Begin</td>
<td>com.oraclecloud.computeapi.exportimage.begin</td>
</tr>
<tr>
<td>Export Image End</td>
<td>com.oraclecloud.computeapi.exportimage.end</td>
</tr>
<tr>
<td>Remove Image Shape Compatibility</td>
<td>com.oraclecloud.computeapi.removeimageshapecompatibility</td>
</tr>
<tr>
<td>Update Image</td>
<td>com.oraclecloud.computeapi.updateimage</td>
</tr>
</tbody>
</table>

### Image Example

This is a reference event for most image events:

```json
{
  "eventType": "com.oraclecloud.computeapi.exportimage.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "eventTime": "2019-08-27T04:12:37.397Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.tenancy.oc1.<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_image",
    "resourceId": "ocid1.image.oc1.iad.<unique_ID>",
    "availabilityDomain": "SoSC:PHX-AD-3"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.tenancy.oc1.<unique_ID>"
  }
}
```

Change image compartment doesn’t include the resource name or availability domain.
### Instance Event Types

These are the event types that Compute instances and instance attachments emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach Boot Volume Begin</td>
<td>com.oraclecloud.computeapi.attachboottvolume.begin</td>
</tr>
<tr>
<td>Attach Boot Volume End</td>
<td>com.oraclecloud.computeapi.attachboottvolume.end</td>
</tr>
<tr>
<td>Attach Secondary VNIC Begin</td>
<td>com.oraclecloud.computeapi.attachvnic.begin</td>
</tr>
<tr>
<td>Attach Secondary VNIC End</td>
<td>com.oraclecloud.computeapi.attachvnic.end</td>
</tr>
<tr>
<td>Attach Volume Begin</td>
<td>com.oraclecloud.computeapi.attachvolume.begin</td>
</tr>
<tr>
<td>Attach Volume End</td>
<td>com.oraclecloud.computeapi.attachvolume.end</td>
</tr>
<tr>
<td>Change Instance Compartment Begin</td>
<td>com.oraclecloud.computeapi.changeinstancecompartment.begin</td>
</tr>
<tr>
<td>Change Instance Compartment End</td>
<td>com.oraclecloud.computeapi.changeinstancecompartment.end</td>
</tr>
<tr>
<td>Detach Boot Volume Begin</td>
<td>com.oraclecloud.computeapi.detachboottvolume.begin</td>
</tr>
<tr>
<td>Detach Boot Volume End</td>
<td>com.oraclecloud.computeapi.detachboottvolume.end</td>
</tr>
<tr>
<td>Detach Secondary VNIC Begin</td>
<td>com.oraclecloud.computeapi.detachvnic.begin</td>
</tr>
<tr>
<td>Detach Secondary VNIC End</td>
<td>com.oraclecloud.computeapi.detachvnic.end</td>
</tr>
<tr>
<td>Detach Volume Begin</td>
<td>com.oraclecloud.computeapi.detachvolume.begin</td>
</tr>
<tr>
<td>Detach Volume End</td>
<td>com.oraclecloud.computeapi.detachvolume.end</td>
</tr>
<tr>
<td>Instance Action Begin</td>
<td>com.oraclecloud.computeapi.instanceaction.begin</td>
</tr>
<tr>
<td>Instance Action End</td>
<td>com.oraclecloud.computeapi.instanceaction.end</td>
</tr>
<tr>
<td>Instance Preemption Action</td>
<td>com.oraclecloud.computeapi.instancepreemptionaction.end</td>
</tr>
<tr>
<td>Launch Instance Begin</td>
<td>com.oraclecloud.computeapi.launchinstance.begin</td>
</tr>
<tr>
<td>Launch Instance End</td>
<td>com.oraclecloud.computeapi.launchinstance.end</td>
</tr>
</tbody>
</table>
**Compute Instance Example**

This is a reference event for most instance events (attach/detach volume and boot volume events don't include additional details):

```
{
    "eventType": "com.oraclecloud.computeapi.launchinstance.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeApi",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "my_instance",
        "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",
        "availabilityDomain": "<availability_domain>",
        "additionalDetails": {
            "imageId": "ocid1.image.oc1.phx.<unique_ID>",
            "shape": "VM.Standard2.1",
            "type": "CustomerVmi"
        }
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>
    }
}
```

This is a reference event for attach/detach VNIC events:

```
{
    "eventType": "com.oraclecloud.computeapi.attachvnic.end",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeApi",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "my_instance",
        "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",
        "availabilityDomain": "<availability_domain>",
        "additionalDetails": {
            "subnetId": "ocid1.subnet.oc1.phx.<unique_ID>",
        }
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>
    }
}
```

This is a reference event for instance action events:

```
{
    "eventType": "com.oraclecloud.computeapi.instanceaction.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeApi",
    "eventTime": "2019-08-16T12:07:14.623Z",
```
This is a reference event for instance preemption events:

```
{
  "eventType": "com.oraclecloud.computeapi.instancepreemptionaction",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "eventTime": "2021-02-16T12:07:14.409Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"",
    "compartmentName": "example_compartment",
    "resourceName": "my_instance",
    "resourceId": "ocid1.instance.oc1.phx.<unique_ID>"",
    "availabilityDomain": "<availability_domain>",
    "additionalDetails": {
      "preemptionAction": "TERMINATE"
    }
  },
  "eventID": "<unique_ID>"",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Oracle Cloud Infrastructure User Guide 2729
### Instance Configuration Event Types

These are the event types that Compute instance configurations emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Instance Configuration Compartment</td>
<td>com.oraclecloud.computemanagement.changeinstanceconfiguration</td>
</tr>
<tr>
<td>Create Instance Configuration</td>
<td>com.oraclecloud.computemanagement.createinstanceconfiguration</td>
</tr>
<tr>
<td>Delete Instance Configuration</td>
<td>com.oraclecloud.computemanagement.deleteinstanceconfiguration</td>
</tr>
<tr>
<td>Launch Instance Configuration Begin</td>
<td>com.oraclecloud.computemanagement.launchinstanceconfiguration.begin</td>
</tr>
<tr>
<td>Launch Instance Configuration End</td>
<td>com.oraclecloud.computemanagement.launchinstanceconfiguration.end</td>
</tr>
<tr>
<td>Update Instance Configuration</td>
<td>com.oraclecloud.computemanagement.updateinstanceconfiguration</td>
</tr>
</tbody>
</table>

### Compute Instance Configuration Example

This is a reference event for most instance configuration events:

```json
{
    "eventType": "com.oraclecloud.computemanagement.createinstanceconfiguration",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeManagement",
    "eventTime": "2019-08-12T22:52:01.062Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "my_instance_configuration",
        "resourceId": "ocid1.instanceconfiguration.oc1.phx..<unique_ID>",
        "availabilityDomain": "<availability_domain>"
    },
    "eventId": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```

Launch instance configuration end doesn't include the availability domain.
**Instance Console Connection Event Types**

These are the event types that Compute instance console connections emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Instance Console Connection Begin</td>
<td>com.oraclecloud.computeapi.createinstanceconsoleconnection.begin</td>
</tr>
<tr>
<td>Create Instance Console Connection End</td>
<td>com.oraclecloud.computeapi.createinstanceconsoleconnection.end</td>
</tr>
<tr>
<td>Delete Instance Console Connection Begin</td>
<td>com.oraclecloud.computeapi.deleteinstanceconsoleconnection.begin</td>
</tr>
<tr>
<td>Delete Instance Console Connection End</td>
<td>com.oraclecloud.computeapi.deleteinstanceconsoleconnection.end</td>
</tr>
<tr>
<td>Update Instance Console Connection Begin</td>
<td>com.oraclecloud.computeapi.updateinstanceconsoleconnection.begin</td>
</tr>
<tr>
<td>Update Instance Console Connection End</td>
<td>com.oraclecloud.computeapi.updateinstanceconsoleconnection.end</td>
</tr>
</tbody>
</table>

**Compute Instance Console Connection Example**

This is a reference event for instance console connections:

```json
{
  "eventType": "com.oraclecloud.computeapi.createinstanceconsoleconnection.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "ComputeApi",
  "eventTime": "2019-08-12T14:47:35.762Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceId": "ocid1.instanceconsoleconnection.oc1.phx.<unique_ID>",
    "availabilityDomain": "<availability_domain>",
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```
Instance Maintenance Event Types

These are the event types that instance maintenance events emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Live Migration Begin</td>
<td>com.oraclecloud.computeapi.livemigrate.begin</td>
</tr>
<tr>
<td>Live Migration End</td>
<td>com.oraclecloud.computeapi.livemigrate.end</td>
</tr>
<tr>
<td>Schedule Maintenance</td>
<td>com.oraclecloud.computeapi.schedulemaintenance</td>
</tr>
</tbody>
</table>

Live Migration Example

This is a reference event for live migration:

```json
{
    "eventType": "com.oraclecloud.computeapi.livemigrate.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeApi",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "my_instance",
        "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",
        "availabilityDomain": "<availability_domain>",
        "additionalDetails": {
            "imageId": "ocid1.image.oc1.phx.<unique_ID>",
            "shape": "VM.Standard2.1",
            "type": "CustomerVmi",
            "volumeId": "ocid1.volume.oc1..<unique_ID>"
        }
    },
    "eventId": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```

Schedule Maintenance Example

This is a reference event for scheduled instance maintenance:

```json
{
    "eventType": "com.oraclecloud.computeapi.schedulemaintenance",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeApi",
```
"contentType": "application/json",
"data": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "compartmentName": "example_compartment",
  "resourceName": "my_instance",
  "resourceId": "ocid1.instance.oc1.phx.<unique_ID>",
  "availabilityDomain": "<availability_domain>",
  "additionalDetails": {
    "imageId": "ocid1.image.oc1.phx.<unique_ID>",
    "shape": "VM.Standard2.1",
    "maintenanceDate": "2019-10-20 22:07:33.0",
    "type": "CustomerVmi",
    "maintenanceType": "Reboot"
  }
},
"eventID": "<unique_ID>",
"extensions": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
}
},
"serviceName": "Compute",
"displayName": "Instance - Schedule Maintenance",
"additionalDetails": [
],
"timeCreated": "2019-08-27T12:00:00.000Z",
}
## Instance Pool Event Types

These are the event types that Compute instance pools emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach Load Balancer Begin</td>
<td>com.oraclecloud.computemanagement.attachloadbalancer.begin</td>
</tr>
<tr>
<td>Attach Load Balancer End</td>
<td>com.oraclecloud.computemanagement.attachloadbalancer.end</td>
</tr>
<tr>
<td>Change Instance Pool Compartment</td>
<td>com.oraclecloud.computemanagement.changeinstancepoolcompartment</td>
</tr>
<tr>
<td>Create Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.createinstancepool.begin</td>
</tr>
<tr>
<td>Create Instance Pool End</td>
<td>com.oraclecloud.computemanagement.createinstancepool.end</td>
</tr>
<tr>
<td>Detach Load Balancer Begin</td>
<td>com.oraclecloud.computemanagement.detachloadbalancer.begin</td>
</tr>
<tr>
<td>Detach Load Balancer End</td>
<td>com.oraclecloud.computemanagement.detachloadbalancer.end</td>
</tr>
<tr>
<td>Reset Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.resetinstancepool.begin</td>
</tr>
<tr>
<td>Reset Instance Pool End</td>
<td>com.oraclecloud.computemanagement.resetinstancepool.end</td>
</tr>
<tr>
<td>Soft Reset Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.softresetinstancepool.begin</td>
</tr>
<tr>
<td>Soft Reset Instance Pool End</td>
<td>com.oraclecloud.computemanagement.softresetinstancepool.end</td>
</tr>
<tr>
<td>Start Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.startinstancepool.begin</td>
</tr>
<tr>
<td>Start Instance Pool End</td>
<td>com.oraclecloud.computemanagement.startinstancepool.end</td>
</tr>
<tr>
<td>Stop Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.stopinstancepool.begin</td>
</tr>
<tr>
<td>Stop Instance Pool End</td>
<td>com.oraclecloud.computemanagement.stopinstancepool.end</td>
</tr>
<tr>
<td>Terminate Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.terminateinstancepool.begin</td>
</tr>
<tr>
<td>Terminate Instance Pool End</td>
<td>com.oraclecloud.computemanagement.terminateinstancepool.end</td>
</tr>
<tr>
<td>Update Instance Pool Begin</td>
<td>com.oraclecloud.computemanagement.updateinstancepool.begin</td>
</tr>
<tr>
<td>Update Instance Pool End</td>
<td>com.oraclecloud.computemanagement.updateinstancepool.end</td>
</tr>
</tbody>
</table>
Compute Instance Pools Example

This is a reference event for most instance pool events:

```json
{
    "eventType": "com.oraclecloud.computemanagement.createinstancepool.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ComputeManagement",
    "eventTime": "2019-08-12T22:52:01.343Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "my_instance_pool",
        "resourceId": "ocid1.instancepool.oc1.phx.<unique_ID>",
        "availabilityDomain": "<availability_domain>"
    },
    "eventID": "<unique_id>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```

These instance pool events don't include the availability domain: create instance pool end, detach load balancer end, reset instance pool end, soft reset instance pool end, start instance pool end, stop instance pool end, and terminate instance pool end.

Container Engine for Kubernetes

Container Engine for Kubernetes resources that emit events:

- Cluster Event Types on page 2735
- Node Pool Event Types on page 2736

Cluster Event Types

These are the event types that clusters emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Cluster Begin</td>
<td>com.oraclecloud.clustersapi.createcluster.begin</td>
</tr>
<tr>
<td>Delete Cluster Begin</td>
<td>com.oraclecloud.clustersapi.deletecluster.begin</td>
</tr>
<tr>
<td>Update Cluster Begin</td>
<td>com.oraclecloud.clustersapi.updatecluster.begin</td>
</tr>
</tbody>
</table>

Cluster Example

This is an example event for clusters:

```json
{
    "eventType": "com.oraclecloud.clustersapi.createcluster.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ClustersAPI",
    "eventID": "<unique_ID>",
    "eventTime": "2020-04-15T16:26:56.848Z",
    "contentType": "application/json",
```
"data": {
    "eventGroupingId": "<unique_ID>",
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "my_cluster",
    "resourceId": "ocid1.cluster.oc1.iad.<unique_ID>",
    "availabilityDomain": "my_availability_domain",
    "freeformTags": null,
    "definedTags": null
  }
}

Node Pool Event Types

These are the event types that node pools emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Node Pool Begin</td>
<td>com.oraclecloud.clustersapi.createnodepool.begin</td>
</tr>
<tr>
<td>Delete Node Pool Begin</td>
<td>com.oraclecloud.clustersapi.deletenodepool.begin</td>
</tr>
<tr>
<td>Update Node Pool Begin</td>
<td>com.oraclecloud.clustersapi.updatenodepool.begin</td>
</tr>
</tbody>
</table>

Node Pool Example

This is an example event for node pools:

```json
{
    "eventType": "com.oraclecloud.clustersapi.createnodepool.begin",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "ClustersAPI",
    "eventId": "<unique_ID>",
    "eventTime": "2020-04-15T16:26:59.418Z",
    "contentType": "application/json",
    "data": {
        "eventGroupingId": "<unique_ID>",
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "my_nodepool",
        "resourceId": "ocid1.nodepool.oc1.iad.<unique_ID>",
        "availabilityDomain": "my_availability_domain",
        "freeformTags": null,
        "definedTags": null
    }
}
```

Content Management

For details about events emitted by Content Management, see Service Events.

Data Catalog

For details about events emitted by Data Catalog, see Data Catalog Events.

Data Integration

For details about events emitted by Data Integration, see Data Integration Events.
Data Labeling

Data Labeling resources that emit events:

- Dataset Event Types on page 2737

Dataset Event Types

These are the event types that datasets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Dataset Begin</td>
<td>com.oraclecloud.dls-prod-&lt;compartmentId&gt;.CreateDataset.begin</td>
</tr>
<tr>
<td>Create Dataset End</td>
<td>com.oraclecloud.data-labeling-service-worker.CreateDataset.end</td>
</tr>
</tbody>
</table>

Dataset Example

This is a reference event for datasets:

```json
{
  "eventType": "com.oraclecloud.dls-prod-<compartmentId>.CreateDataset.begin",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "dls-prod-<compartmentId>",
  "eventId": "<unique_ID>",
  "eventTime": "2021-09-27T09:28:36.500Z",
  "contentType": "application/json",
  "data": {
    "eventGroupingId": "ocid1.datalabelingworkrequest.oc1.<compartmentId>.<unique_ID>",
    "eventName": "CreateDataset",
    "compartmentId": "ocid1.compartment.oc1..<compartmentId>",
    "compartmentName": "example_<compartmentName>",
    "resourceName": "example_<dataset_name>",
    "resourceId": "ocid1.datalabelingdataset.oc1.iad.<unique_ID>",
    "availabilityDomain": "<availability_domain>",
    "definedTags": {
      "Department": "Finance"
    },
    "freeFormTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  }
}
```

Data Safe

For details about events emitted by Data Safe, see Oracle Data Safe Events in Oracle Cloud Infrastructure.

Data Science

For details about events emitted by Data Science, see Creating Automation Using Events.

Data Transfer

Data Transfer resources that emit events:

- Jobs Event Types on page 2738
Events

- Appliances Event Types on page 2739
- Packages Event Types on page 2740
- Devices Event Types on page 2741
- Appliance Entitlements Event Types on page 2742
- Appliance Export Jobs Event Types on page 2743

Jobs Event Types

These are the event types that job events emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Transfer Job</td>
<td>com.oraclecloud.datatransferservice.addtransferjob</td>
</tr>
<tr>
<td>Update Transfer Job</td>
<td>com.oraclecloud.datatransferservice.updatetransferjob</td>
</tr>
<tr>
<td>Delete Transfer Job</td>
<td>com.oraclecloud.datatransferservice.deletetransferjob</td>
</tr>
<tr>
<td>Move Transfer Job</td>
<td>com.oraclecloud.datatransferservice.movetransferjob</td>
</tr>
</tbody>
</table>

Jobs Examples

```json
{
    "eventType": "com.oraclecloud.datatransferservice.addtransferjob",
    "source": "datatransferservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "freeFormTags": {
        "Department": "Finance"
    },
    "definedTags": {
        "Operations": {
            "CostCenter": "42"
        }
    },
    "additionalDetails": {
        "deviceType": "APPLIANCE",
        "uploadBucketName": "example_bucket",
        "lifecycleState": "example_state"
    }
}
```
**Appliances Event Types**

These are the event types that appliances emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Transfer Appliance</td>
<td>com.oraclecloud.datatransferservice.addtransferappliance</td>
</tr>
<tr>
<td>Update Transfer Appliance</td>
<td>com.oraclecloud.datatransferservice.updatetransferappliance</td>
</tr>
<tr>
<td>Delete Transfer Appliance</td>
<td>com.oraclecloud.datatransferservice.deletetransferappliance</td>
</tr>
</tbody>
</table>

**Appliances Example**

```json
{
   "eventType": "com.oraclecloud.datatransferservice.addtransferappliance",
   "source": "datatransferservice",
   "eventTypeVersion": "2.0",
   "eventTime": "2019-01-10T21:19:24Z",
   "contentType": "application/json",
   "extensions": {
       "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   },
   "data": {
       "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
       "compartmentName": "example_compartment",
       "resourceName": "transfer_job",
       "resourceId": "ocid1.datatransferjob.oc1.phx..<unique_ID>",
       "availabilityDomain": "<availability_domain>",
       "freeFormTags": {
           "Department": "Finance"
       },
       "definedTags": {
           "Operations": {
               "CostCenter": "42"
           }
       },
       "additionalDetails": {
           "applianceLabel": "example_label",
           "lifecycleState": "example_state"
       }
   }
}
```
Packages Event Types

These are the event types that packages emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Transfer Package</td>
<td>com.oraclecloud.datatransferservice.addtransferpackage</td>
</tr>
<tr>
<td>Update Transfer Package</td>
<td>com.oraclecloud.datatransferservice.updatetransferpackage</td>
</tr>
<tr>
<td>Delete Transfer Package</td>
<td>com.oraclecloud.datatransferservice.deletetransferpackage</td>
</tr>
<tr>
<td>Attach Devices To Transfer Package</td>
<td>com.oraclecloud.datatransferservice.addtransferpackage</td>
</tr>
<tr>
<td>Detach Devices From Transfer Package</td>
<td>com.oraclecloud.datatransferservice.deletetransferpackage</td>
</tr>
</tbody>
</table>

Packages Example

```json
{
  "eventType": "com.oraclecloud.datatransferservice.addtransferpackage",
  "source": "datatransferservice",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "transfer_job",
    "resourceId": "ocid1.datatransferjob.oc1.phx.<unique_ID>",
    "availabilityDomain": "<availability_domain>"
  },
  "freeFormTags": {
    "Department": "Finance"
  },
  "definedTags": {
    "Operations": {
      "CostCenter": "42"
    }
  },
  "additionalDetails": {
    "packageLabel": "example_label",
    "lifecycleState": "example_state"
  }
}
```
## Devices Event Types

These are the event types that devices emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Transfer Device</td>
<td>com.oraclecloud.datatransferservice.addtransferdevice</td>
</tr>
<tr>
<td>Update Transfer Device</td>
<td>com.oraclecloud.datatransferservice.updatetransferdevice</td>
</tr>
<tr>
<td>Delete Transfer Device</td>
<td>com.oraclecloud.datatransferservice.deletetransferdevice</td>
</tr>
</tbody>
</table>

### Devices Example

```json
{
    "eventType": "com.oraclecloud.datatransferservice.addtransferdevice",
    "source": "datatransferservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_compartment",
        "resourceName": "transfer_job",
        "resourceId": "ocid1.datatransferjob.oc1.phx.<unique_ID>",
        "availabilityDomain": "<availability_domain>",
        "freeFormTags": { "Department": "Finance" },
        "definedTags": { "Operations": { "CostCenter": "42" } },

      "lifecycleStateDetails": "example_details"
    }
  }
}
```

### Database

Database resources that emit events:

- **Autonomous Database events** *(Oracle Cloud)*

  *Note: for Autonomous Database on Exadata Cloud@Customer, see Oracle Exadata Cloud@Customer Events.*

  - Autonomous Database events
  - Autonomous Database critical and information event details
• **Autonomous Database Infrastructure events** *(Oracle Cloud)*
  - Autonomous Container Database events *(applies to dedicated Exadata infrastructure only)*
  - Autonomous Exadata Infrastructure events
  - Autonomous Exadata Infrastructure critical and warning event details
• **Autonomous Data Guard events**
  - Autonomous Data Guard for dedicated Exadata infrastructure
    For Autonomous Database on shared Exadata infrastructure, see **Autonomous Database events**.
• **Database events**
  For Oracle Databases running on Exadata Cloud Service instances, bare metal DB systems, and virtual machine DB systems:
  - Database events
  - Database Critical event details
  - Database Home events
  - Pluggable database events
• **Data Guard association events**
  - Data Guard association events
• **DB system events**
  Used by bare metal DB systems, virtual machine DB systems, and Exadata systems using the DB system resource model.
  - DB system events
  - DB System Critical event details
  - Node (virtual machine) events
  - Node (virtual machine) critical event details
• **Exadata Cloud Service infrastructure events**
  - Cloud Exadata infrastructure resource events
  - Cloud Exadata infrastructure critical events
  - Exadata cloud VM cluster resource events
• **Exadata Cloud@Customer events**: See Oracle Exadata Cloud@Customer Events for full details.
Database Service: Autonomous Database Event Types

These are the event types that Autonomous Databases in the Oracle Cloud emit:

<table>

**Autonomous Database example event**

This is a reference event for Autonomous Databases in the Oracle public cloud:

```json
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": "com.oraclecloud.databaseservice.autonomous.database.backup.begin",
    "source": "databaseservice",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-07-10T14:06:23Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_database",
        "resourceId": "ocid1.autonomousdatabase.oc1.phx.<unique_ID>",
        "availabilityDomain": "SoSC:PHX-AD-3",
        "freeFormTags": {},
        "definedTags": {},
        "additionalDetails": {
            "cpuCoreCount": 1,
            "lifecycleState": "PROVISIONING",
            "dataStorageSizeInTBs": 1,
            "timeCreated": "2019-07-10T14:06:10.905Z",
            "timeUpdated": "2019-07-10T14:06:10.905Z",
            "serviceConsoleUrl": null,
            "licenseType": null,
            "workloadType": "<Data Warehouse | Transaction Processing>",
            "autonomousDatabaseType": "<Dedicated Infrastructure | Shared Infrastructure>"
        }
    }
}
```

**Database Service: Autonomous Database Critical and Information Event Types**

Autonomous Databases emit "critical" and "information" data plane events. **Information events** provide important details about the database lifecycle, such as the time when maintenance begins and maintenance ends, or notifications of connections from a new IP address.

**Critical events** on Autonomous Database are issues that cause disruption to the database.

Both the "information" and "critical" event types use an `additionalDetails` section of the event message to provide specific details about what is happening within the Autonomous Database emitting the event. Details about the conditions and operations that trigger these two event types follow below.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomous Database - Critical</td>
<td><code>com.oraclecloud.databaseservice.autonomous.database.backup.begin</code></td>
</tr>
<tr>
<td>Autonomous Database - Information</td>
<td><code>com.oraclecloud.databaseservice.autonomous.database.backup.begin</code></td>
</tr>
</tbody>
</table>
In the following example of a "critical" event, you can see within the additionalDetails section of the event message that this particular message concerns a "database down" condition that has just ended. The eventName and description fields provide information regarding the critical situation within the "adwfinance" database:

```
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType":
        "com.oraclecloud.databaseservice.autonomous.database.critical",
    "source": "DatabaseService",
    ...
    "additionalDetails": {
        "eventName": "DatabaseDownEnd",
        "dbName": "adwfinance",
        "description": "adwfinance is up and ready for user operations.",
        "workloadType": "Data Warehouse",
        "autonomousDatabaseType": "Shared Infrastructure"
    }
}
```

In the tables below, you can read about the conditions and operations that trigger "critical" and "information" event types. Each condition or operation is identified by a unique eventName value.

<table>
<thead>
<tr>
<th>Critical Event - EventName</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AdminPasswordWarning</td>
<td>Generated when Autonomous Database determines that the ADMIN password will expire after a 30 day grace period is complete. ADMIN passwords should be reset after no more than 360 days. The 30 day grace period begins after a password has been in use for 360 days. If the password is not reset during the grace period, the event is generated a second time, 30 days after the first event notification, to notify you that the password has expired and needs to be reset.</td>
</tr>
</tbody>
</table>
| DatabaseDownBegin                  | The Autonomous Database instance cannot be opened, or the services such as high, low, medium, tp, or tpurgent are not started or available. The following conditions do not trigger DatabaseDownBegin:  
  - Operations performed during the maintenance window  
  - Load balancer, network, or backup related issues  
  - A user stopping the instance  
  This event will not be triggered if you are using Autonomous Data Guard and the standby database is not available due to any of the above conditions. |
## Events

### Critical Event - EventName

**DatabaseDownEnd**

The database is recovered from the down state, meaning the Autonomous Database instance is opened with its services, following a `DatabaseDownBegin` event. `DatabaseDownEnd` is triggered only if there was a preceding `DatabaseDownBegin` event.

The following conditions do not trigger `DatabaseDownEnd`:

- Operations performed during the maintenance window
- A user starting the instance

If you are using Autonomous Data Guard and the primary database goes down, this triggers a `DatabaseDownBegin` event. If the system fails over to the standby database, this triggers a `DatabaseDownEnd` event.

**WalletExpirationWarning**

Generated when Autonomous Database determines that a wallet is due to expire in less than six (6) weeks. This event is reported at most once per week.

### Information Event - EventName

<table>
<thead>
<tr>
<th>EventName</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DatabaseConnection</td>
<td>Generated if a connection is made to the database from a new IP address. A new IP address is defined as an address that has not connected to the database in the last 30 days.</td>
</tr>
<tr>
<td>MaintenanceBegin</td>
<td>Triggered when the maintenance starts and provides the start timestamp (in UTC) for the maintenance. Note: this event does not provide the scheduled start time.</td>
</tr>
<tr>
<td>MaintenanceEnd</td>
<td>Triggered when the maintenance ends and provides the end timestamp (in UTC) for the maintenance. Note: this event does not provide the scheduled end time.</td>
</tr>
<tr>
<td>NewMaintenanceSchedule</td>
<td>Generated when the maintenance date is updated and the new date is shown on the Oracle Cloud Infrastructure Console.</td>
</tr>
<tr>
<td>ScheduledMaintenanceWarning</td>
<td>Generated when the instance is 24 hours from a scheduled maintenance operation, and again when the instance is 1 hour (60 minutes) from the scheduled maintenance.</td>
</tr>
</tbody>
</table>

**Note:**

If you are using Autonomous Data Guard for shared Exadata infrastructure, any of the above listed events that occurs on the standby database does not trigger an Information event.
### Database Service: Autonomous Container Database Event Types

These are the event types that Autonomous Container Databases emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomous Container Database - Change Compartment</td>
<td>com.oraclecloud.databaseservice.changeautonomouscontainerdatabasecompartment.begin</td>

<tr>
<td>Autonomous Exadata Infrastructure - Update End</td>
<td>com.oraclecloud.databaseservice.updateautonomousinfrastructure.end</td>
</tr>
<tr>
<td>Autonomous Exadata Infrastructure - Warning</td>
<td>com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.warning</td>
</tr>
</tbody>
</table>

For details, see Autonomous Exadata Infrastructure Critical and Warning Event Types.

## Autonomous Exadata Infrastructure resource example event

This is a reference event for Autonomous Exadata Infrastructure instances:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.instance.create.begin",
  "source": "databaseservice",
  "tags": [
    ...
  ]
}
```
Database Service: Autonomous Exadata Infrastructure Critical and Warning Event Types

Critical and warning events are generic events for Autonomous Exadata Infrastructure. Critical events deliver information about critical conditions that need immediate attention.

<table>
<thead>
<tr>
<th>Critical Event—EventName</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sslcertificate.expired</td>
<td>This critical event indicates that the SSL certificate has expired. The infrastructure instance remains inaccessible until you renew the certificate.</td>
</tr>
</tbody>
</table>

Warning events deliver information about conditions that may lead to critical events if no action is taken.

<table>
<thead>
<tr>
<th>Warning Event—EventName</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sslcertificateexpiry.reminder</td>
<td>This warning event generates an advisory message that repeats every week beginning six weeks (42 days) before the SSL certificate expires, and decreases the number of days until certificate expiry by 7 with each repetition, until you address the issue or the certificate expires.</td>
</tr>
</tbody>
</table>

In the following example of a critical event, the event message that the SSL certificate for the Autonomous Exadata Infrastructure has expired is located in the additionalDetails section. The description and eventName fields provide information regarding the critical situation within the dedicated Exadata infrastructure.

```
{
    "eventType": "com.oraclecloud.databaseservice.autonomous.exadata.infrastructure.critical",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "databaseservice",
    ...
    "additionalDetails": {
        "cpuCoreCount": 92,
        "lifecycleState": "PROVISIONING",
        "dataStorageSizeInTBs": null,
        "timeCreated": "2019-07-10T23:13:43.136Z",
        "timeUpdated": "2019-07-10T23:28:12.390Z",
        "serviceConsoleUrl": null,
        "licenseType": null,
        "dbName": null
    }
}
```
Database Service: Autonomous Data Guard Event Types for Dedicated Exadata Infrastructure

These are the event types that Autonomous Data Guard associations on dedicated Exadata infrastructure emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomous Data Guard Association - Create Begin</td>
<td>com.oraclecloud.databaseservice.createautonomousdataguardassociation.begin</td>
</tr>
<tr>
<td>Autonomous Data Guard Association - Create End</td>
<td>com.oraclecloud.databaseservice.createautonomousdataguardassociation.end</td>
</tr>
<tr>
<td>Autonomous Data Guard Association - Failover Begin</td>
<td>com.oraclecloud.databaseservice.failoverautonomousdataguardassociation.begin</td>
</tr>
<tr>
<td>Autonomous Data Guard Association - Failover End</td>
<td>com.oraclecloud.databaseservice.failoverautonomousdataguardassociation.end</td>

}```
**Database Service: DB System Critical Event Details**

**Note:**

To receive DB system critical events for bare metal or virtual machine DB systems, you must enable telemetry for the system using the dbcli utility. See [AHF Telemetry Commands](#) on page 2243 for details on enabling telemetry for bare metal and virtual machine DB systems.

The `com.oraclecloud.databaseservice.dbsystem.critical` event delivers information about several types of critical conditions and errors in the `additionalDetails` section of the critical event payload. The following table documents the sub-types of the DB system critical event.

<table>
<thead>
<tr>
<th>EventName (in additionalDetails)</th>
<th>Error or Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVAILABILITY.DG_STATUS</td>
<td>Data Guard error</td>
</tr>
<tr>
<td>ERRORS.ASM.ORA600</td>
<td>ORA-600 internal error</td>
</tr>
<tr>
<td>ERRORS.ASM.ORA7445</td>
<td>ORA-7445 error (unhandled exception in the Oracle source code)</td>
</tr>
</tbody>
</table>

See [Database Critical example event](#) for a JSON example of a critical event.

**Database Service: Node (Virtual Machine) Event Types**

These are the event types that database nodes emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB Node - Update Begin</td>
<td><code>com.oraclecloud.databaseservice.dbnodeaction.end</code></td>
</tr>
<tr>
<td>DB Node - Update End</td>
<td><code>com.oraclecloud.databaseservice.dbnodeaction.end</code></td>
</tr>
<tr>
<td>DB Node - Critical (see DB Node Critical Event Details for more information)</td>
<td><code>com.oraclecloud.databaseservice.dbnode.critical</code></td>
</tr>
</tbody>
</table>

**DB system node example event**

This is a reference event for DB system nodes:

```json
db.system.node.example.event =
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": "com.oraclecloud.databaseservice.db.node.reboot.begin",
    "additionalDetails":
```
Database Service: DB Node Critical Event Details

Note:

To receive DB node critical events for bare metal or virtual machine DB systems, you must enable telemetry for the system using the dbcli utility. See AHF Telemetry Commands on page 2243 for details on enabling telemetry for bare metal and virtual machine DB systems.

The com.oraclecloud.databaseservice.dbnode.critical event delivers information about critical conditions in the additionalDetails section of the DB node critical event payload. The following table documents the sub-types of the DB node critical event.

<table>
<thead>
<tr>
<th>EventName (in additionalDetails)</th>
<th>Error or Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVAILABILITY.CRS_STATUS</td>
<td>Cluster Ready Services clusterware error</td>
</tr>
</tbody>
</table>

See Database Critical example event for a JSON example of a critical event.
Database Service: Oracle Database Home Event Types

These are the event types that Oracle Database Homes emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB Home - Create Begin</td>
<td>com.oraclecloud.databaseservice.createdbhome.begin</td>
</tr>
<tr>
<td>DB Home - Create End</td>
<td>com.oraclecloud.databaseservice.createdbhome.end</td>
</tr>
<tr>
<td>DB Home - Patch Begin</td>
<td>com.oraclecloud.databaseservice.patchdbhome.begin</td>
</tr>
<tr>
<td>DB Home - Patch End</td>
<td>com.oraclecloud.databaseservice.patchdbhome.end</td>
</tr>
<tr>
<td>DB Home - Terminate Begin</td>
<td>com.oraclecloud.databaseservice.deletedbhome.begin</td>
</tr>
<tr>
<td>DB Home - Terminate End</td>
<td>com.oraclecloud.databaseservice.deletedbhome.end</td>
</tr>
<tr>
<td>DB Home - Update Begin</td>
<td>com.oraclecloud.databaseservice.updatedbhome.begin</td>
</tr>
<tr>
<td>DB Home - Update End</td>
<td>com.oraclecloud.databaseservice.updatedbhome.end</td>
</tr>
</tbody>
</table>

```

**Database Service: Database Critical Event Details**

**Note:**

This event type is emitted by Oracle Databases running on Exadata Cloud Service instances, bare metal DB systems, and virtual machine DB systems. To receive database critical events for databases in bare metal or virtual machine DB systems, you must enable telemetry for the system using the dbcli utility. See AHF Telemetry Commands on page 2243 for details on enabling telemetry for bare metal and virtual machine DB systems.
The `com.oraclecloud.databaseservice.database.critical` event delivers information about several types of critical conditions and errors in the `additionalDetails` section of the Database critical event payload. The following table documents the sub-types of the Database Critical event.

<table>
<thead>
<tr>
<th>EventName (in <code>additionalDetails</code>)</th>
<th>Error or Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERRORS.DB.ARCHIVER_STUCK</td>
<td>Archiver stuck error</td>
</tr>
<tr>
<td>AVAILABILITY.DB_STATUS</td>
<td>Database availability error</td>
</tr>
<tr>
<td>ERRORS.DB.HANG</td>
<td>Database hang error</td>
</tr>
<tr>
<td>ERRORS.DB.ORA7445</td>
<td>ORA-7445 error (unhandled exception in the Oracle source code)</td>
</tr>
<tr>
<td>ERRORS.DB.ORA600</td>
<td>ORA-600 internal error</td>
</tr>
</tbody>
</table>

See Database Critical example event for a JSON example of a critical event.

Database Critical example event

The Database Critical, DB Node Critical, and DB System Critical events originate in the data plane and contain details about a critical condition in the `additionalDetails` section of the payload. See the preceding tables for details about these event subtypes.

This is a reference "critical" data plane event for DB systems, DB system nodes, and databases:

```json
{
    "eventType" : "com.oraclecloud.databaseservice.database.critical",
    "cloudEventsVersion" : "0.1",
    "eventTypeVersion" : "2.0",

Database Service: Exadata Cloud Service Infrastructure Critical Event Types

Exadata Cloud Service infrastructure resources emit “critical” data plane events that allow you to receive notifications when your infrastructure resource needs urgent attention.

These events use the **additionalDetails** section of the event message to provide specific details about what is happening within the infrastructure resource emitting the event.

In the following example of a “critical” event, you can see within the **additionalDetails** section of the event message that this particular message concerns an SQL statement that was terminated by Oracle Database Resource Manager because it was consuming excessive CPU or I/O resources. The **eventName** and **description** fields within the **additionalDetails** section provide information regarding the critical situation:

```json
{
    "eventType": "com.oraclecloud.databaseservice.exadatainfrastructure.critical",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "Exadata Storage",
    "eventTime": "2021-07-30T04:53:18Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.tenancy.oc1.<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_exadata_resource",
        "resourceId": "ocid1.dbsystem.oc1.phx.<unique_ID>",
        "availabilityDomain": "phx-ad-2",
        "additionalDetails": {
            "serviceType": "exacs",
            "sqlID": "gnwfm1jgqcfuu",
            "systemId": "ocid1.dbsystem.oc1.eu-frankfurt-1.<unique_ID>",
            "creationTime": "2021-05-14T13:29:28+00:00",
            "dbUniqueID": "1558836122",
            "quarantineType": "SQLID",
            "dbUniqueName": "AB0503_FRA1S6",
            "description": "SQL statement terminated by Oracle Database Resource Manager due to excessive consumption of CPU and/or I/O. The execution plan associated with the terminated SQL stmt is quarantined. Please find the sql identifier in sqlId field of this JSON payload. This feature protects an Oracle database from performance degradation. Please review the SQL statement. You can see the statement using the following commands: \"set serveroutput off\", \"select sql_id, sql_text from v$sqltext where sql_id =<sqlId>\", \"set serveroutput on\",\"quarantineReason": "Manual",
            "asmClusterName": "None",
            "component": "storage",
            "infrastructureType": "exadata",
            "name": "143",

Database Migration

For details about events emitted by Database Migration, see Database Migration Events.

Database Tools

For details about events emitted by Database Tools, see Database Tools Events.
Digital Assistant

For details about events emitted by Digital Assistant, see Events for Digital Assistant Instances.

File Storage

File Storage resources that emit events:

- File System Event Types on page 2772 and Snapshot Event Types on page 2773
- Mount Target Event Types on page 2774
- Export Event Types on page 2775 and Export Set Event Types on page 2775

File System Event Types

These are the event types that file systems emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change File System Compartment</td>
<td>com.oraclecloud.filestorage.changefilesystemcompartment</td>
</tr>
<tr>
<td>Create File System</td>
<td>com.oraclecloud.filestorage.createfilesystem</td>
</tr>
<tr>
<td>Delete File System</td>
<td>com.oraclecloud.filestorage.deletefilesystem</td>
</tr>
<tr>
<td>Update File System</td>
<td>com.oraclecloud.filestorage.updatefilesystem</td>
</tr>
</tbody>
</table>

File System Example

This is a reference event for file systems:

```json
{
  "eventType": "com.oraclecloud.filestorage.createfilesystem",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "filestorage",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..unique_id",
    "compartmentName": "example_name",
    "resourceName": "my_filesystem",
    "resourceId": "ocid1.filesystem.oc1..unique_id",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "eventID": "unique_ID",
    "extensions": {
      "compartmentId": "ocid1.compartment.oc1..unique_id"
    }
  }
}
```
**Snapshot Event Types**

These are the event types that snapshots emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Snapshot</td>
<td>com.oraclecloud.filestorage.createsnapshot</td>
</tr>
<tr>
<td>Delete Snapshot</td>
<td>com.oraclecloud.filestorage.deletesnapshot</td>
</tr>
</tbody>
</table>

**Snapshot Example**

This is a reference event for snapshots:

```json
{
    "eventType": "com.oraclecloud.filestorage.createsnapshot",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "filestorage",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_id>",
        "compartmentName": "example_name",
        "resourceName": "my_snapshot",
        "resourceId": "ocid1.snapshot.oc1..<unique_id>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "unique_ID",

            "compartmentId": "ocid1.compartment.oc1..<unique_id>"
        }
    }
}
```
Mount Target Event Types

These are the event types that mount targets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Mount Target Compartment</td>
<td>com.oraclecloud.filestorage.changemounttargetcompartment</td>
</tr>
<tr>
<td>Create Mount Target</td>
<td>com.oraclecloud.filestorage.createmounttarget</td>
</tr>
<tr>
<td>Delete Mount Target</td>
<td>com.oraclecloud.filestorage.deletemounttarget</td>
</tr>
<tr>
<td>Update Mount Target</td>
<td>com.oraclecloud.filestorage.updatemounttarget</td>
</tr>
</tbody>
</table>

Mount Target Example

This is a reference event for mount targets:

```json
{
    "eventType": "com.oraclecloud.filestorage.createmounttarget",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "filestorage",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_id>",
        "compartmentName": "example_name",
        "resourceName": "my_mounttarget",
        "resourceId": "ocid1.mounttarget.oc1..<unique_id>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "unique_ID",
        "extensions": {
            "compartmentId": "ocid1.compartment.oc1..<unique_id>"
        }
    }
}
```
Export Event Types

These are the event types that exports emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Export</td>
<td>com.oraclecloud.filestorage.createexport</td>
</tr>
<tr>
<td>Delete Export</td>
<td>com.oraclecloud.filestorage.deleteexport</td>
</tr>
<tr>
<td>Update Export</td>
<td>com.oraclecloud.filestorage.updateexport</td>
</tr>
</tbody>
</table>

Export Example

This is a reference event for exports:

```json
{
  "eventType": "com.oraclecloud.filestorage.createexport",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "filestorage",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_id>",
    "compartmentName": "example_name",
    "resourceName": "my_export",
    "resourceId": "ocid1.export.oc1..<unique_id>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {

    }
}
```

## Functions

Functions resources that emit events:

- Application Event Types on page 2776
- Function Event Types on page 2777

### Application Event Types

These are the event types that applications emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Application Compartment</td>
<td>com.oraclecloud.functions.changeapplicationcompartment</td>
</tr>
<tr>
<td>Create Application</td>
<td>com.oraclecloud.functions.createapplication</td>
</tr>
<tr>
<td>Delete Application</td>
<td>com.oraclecloud.functions.deleteapplication</td>
</tr>
<tr>
<td>Update Application</td>
<td>com.oraclecloud.functions.updateapplication</td>
</tr>
</tbody>
</table>

### Application Example

This is an example event for applications:

```json
{
    "eventType": "com.oraclecloud.functions.createapplication",
```
Function Event Types

These are the event types that functions emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Function</td>
<td><code>com.oraclecloud.functions.createfunction</code></td>
</tr>
<tr>
<td>Delete Function</td>
<td><code>com.oraclecloud.functions.deletefunction</code></td>
</tr>
<tr>
<td>Update Function</td>
<td><code>com.oraclecloud.functions.updatefunction</code></td>
</tr>
</tbody>
</table>

Function Example

This is an example event for functions:

```json
{
    "eventType": "com.oraclecloud.functions.createfunction",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "functions",
    "eventTime": "2019-07-22T09:33:44.754Z",
    "contentType": "application/json",
    "data":{
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "my_compartment",
        "resourceName": "my_application",
        "resourceId": "ocid1.fnapp.oc1.phx.<unique_ID>",
        "availabilityDomain": "AD3"
    },
    "eventID": "<unique_ID>",
    "extensions":{
        "compartmentId":":ocid1.compartment.oc1..<unique_ID>"
    }
}
```

GoldenGate

GoldenGate resources that emit events:

- Deployment Event Types on page 2778
Deployment Event Types

These are the event types that deployments emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Deployment Begin</td>
<td>com.oraclecloud.goldengate.CreateDeployment.begin</td>
</tr>
<tr>
<td>Create Deployment End</td>
<td>com.oraclecloud.goldengate.CreateDeployment.end</td>
</tr>
<tr>
<td>Get Deployment</td>
<td>com.oraclecloud.goldengate.GetDeployment</td>
</tr>
<tr>
<td>List Deployments</td>
<td>com.oraclecloud.goldengate.ListDeployment</td>
</tr>
<tr>
<td>Delete Deployment Begin</td>
<td>com.oraclecloud.goldengate.DeleteDeployment.begin</td>
</tr>
<tr>
<td>Delete Deployment End</td>
<td>com.oraclecloud.goldengate.DeleteDeployment.end</td>
</tr>
<tr>
<td>Update Deployment Begin</td>
<td>com.oraclecloud.GoldenGate.UpdateDeployment.begin</td>
</tr>
<tr>
<td>Update Deployment End</td>
<td>com.oraclecloud.GoldenGate.UpdateDeployment.end</td>

<tr>
<td>Delete Database Registration Begin</td>
<td>com.oraclecloud.GoldenGate.DeleteDatabaseRegistration.begin</td>
</tr>
<tr>
<td>Delete Database Registration End</td>
<td>com.oraclecloud.GoldenGate.DeleteDatabaseRegistration.end</td>
</tr>
</tbody>
</table>

**Database Registration Example**

This is a reference event for database registrations:

```
{
  "eventType": "com.oraclecloud.GoldenGate.GetDatabaseRegistration",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "GoldenGate",
  "eventId": "<unique_ID>",
  "eventTime": "2021-03-01T06:58:42.851Z",
  "contentType": "application/json",
  "data": {
    "eventGroupingId": "<unique_ID>",
    "eventName": "GetDatabaseRegistration",
    "compartmentId": "ocid1.compartment.<realm>..<unique_ID>",
    "compartmentName": "example-compartment",
    "resourceName": "",
    "resourceId": "ocid1.goldengatedatabaseregistration.<realm>.<region>...<unique_ID>",
    "availabilityDomain": "AD1",
    "freeformTags": null,
    "definedTags": null,
  }
}
```
**Deployment Backup Event Types**

These are the event types that deployment backups emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>List Deployment Backups</td>
<td>com.oraclecloud.GoldenGate.ListDeploymentBackups</td>
</tr>
<tr>
<td>Get Deployment Backup</td>

</tr>
<tr>
<td>Create Deployment Backup Begin</td>
<td>com.oraclecloud.GoldenGate.CreateDeploymentBackupBegin</td>
</tr>
<tr>
<td>Create Deployment Backup End</td>
<td>com.oraclecloud.GoldenGate.CreateDeploymentBackupEnd</td>
</tr>
<tr>
<td>Delete Deployment Backup Begin</td>
<td>com.oraclecloud.GoldenGate.DeleteDeploymentBackupBegin</td>
</tr>
<tr>
<td>Delete Deployment Backup End</td>
<td>com.oraclecloud.GoldenGate.DeleteDeploymentBackupEnd</td>
</tr>
</tbody>
</table>

**Deployment Backup Example**

This is a reference event for deployment backups:

```json
{
   "eventType": "com.oraclecloud.GoldenGate.GetDeploymentBackup",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "GoldenGate",
   "eventId": "<unique_ID>",
   "eventTime": "2021-03-01T06:51:30.384Z",
   "contentType": "application/json",
   "data": {
      "eventGroupingId": "<unique_ID>",
      "eventName": "GetDeploymentBackup",
      "compartmentId": "ocid1.compartment.<realm>..<unique_ID>",
      "compartmentName": "example-compartment",
      "resourceName": "",
      "resourceId": "ocid1.goldengatedeploymentbackup.<realm>..<region>..<unique_ID>",
      "availabilityDomain": "AD1",
      "freeformTags": {},
      "definedTags": {
         "Oracle-Tags": {
            "CreatedBy": "rahul.n.gupta",
            "CreatedOn": "2021-03-01T06:51:30.006Z"
         }
      }
   }
}
```

**Health Checks**

Health Checks resources that emit events:

- HTTP Monitors Event Types on page 2782
- Ping Monitor Event Types on page 2783
HTTP Monitors Event Types

These are the event types that HTTP monitors emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create HTTP Monitor</td>
<td>com.oraclecloud.healthchecks.createhttpmonitor</td>
</tr>
<tr>
<td>Delete HTTP Monitor</td>
<td>com.oraclecloud.healthchecks.deletehttpmonitor</td>
</tr>
<tr>
<td>Update HTTP Monitor</td>
<td>com.oraclecloud.healthchecks.updatehttpmonitor</td>
</tr>
</tbody>
</table>

HTTP Monitor Example

This is an example event for HTTP monitors:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.healthchecks.createhttpmonitor",
  "source": "healthchecks",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-10-30T12:06:29.451Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

```json
"data": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "compartmentName": "example_name",
  "resourceName": "my_monitor",
  "resourceId": "ocid1.httpmonitor.oc1..<unique_ID>",
  "availabilityDomain": "AD1",
  "freeFormTags": {
    "Department": "Finance"
  },
  "definedTags": {
    "Operations": {
      "CostCenter": "42"
    }
  }
}
```
Ping Monitor Event Types

These are the event types that ping monitors emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Ping Monitor</td>
<td><code>com.oraclecloud.healthchecks.createpingmonitor</code></td>
</tr>
<tr>
<td>Delete Ping Monitor</td>
<td><code>com.oraclecloud.healthchecks.deletepingmonitor</code></td>
</tr>
<tr>
<td>Update Ping Monitor</td>
<td><code>com.oraclecloud.healthchecks.updatepingmonitor</code></td>
</tr>
</tbody>
</table>

Ping Monitor Example

This is an example event for ping monitors:

```json
{
  "cloudEventsVersion": "0.1",
  "eventId": "<unique_ID>",
  "eventType": "com.oraclecloud.healthchecks.createpingmonitor",
  "source": "healthchecks",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-10-30T12:08:11.242Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_monitor",
    "resourceId": "ocid1.pingmonitor.oc1..<unique_ID>",
    "availabilityDomain": "AD1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  }
}
```

IAM

IAM resources that emit events:

- Authentication Policy Event Types on page 2784
- Credentials Event Types on page 2785
- Dynamic Group Event Types on page 2786
- Group Event Types on page 2787
- Identity Provider Event Types on page 2789
- Multi-Factor Authentication TOTP Device Event Types on page 2791
- Policy Event Types on page 2792
- User Event Types on page 2793
**Authentication Policy Event Types**

This is the event type that authentication policies emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update Authentication Policy</td>
<td>com.oraclecloud.identityControlPlane.UpdateAuthenticationPolicy</td>
</tr>
</tbody>
</table>

**Authentication Policy Example**

This is a reference event for authentication policy events:

```json
{
   "eventType": "com.oraclecloud.identityControlPlane.UpdateAuthenticationPolicy",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "identityControlPlane",
   "eventID": "<unique_ID>",
   "eventTime": "2019-10-21T17:23:54.095Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "my_compartment",
      "resourceId": "ocid1.compartment.oc1..<unique_ID>",
      "availabilityDomain": "availability_domain",
      "freeFormTags": {
         "Department": "Finance"
      },
      "definedTags": {
         "Operations": {
            "CostCenter": "42"
         }
      }
   },
   "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
   }
}
```
### Credentials Event Types

These are the event types that credentials emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Auth Token</td>
<td>com.oraclecloud.identityControlPlane.CreateAuthToken</td>
</tr>
<tr>
<td>Create Customer Secret Key</td>
<td>com.oraclecloud.identityControlPlane.CreateCustomerSecretKey</td>
</tr>
<tr>
<td>Create or Reset Password</td>
<td>com.oraclecloud.identityControlPlane.CreateOrResetPassword</td>
</tr>
<tr>
<td>Create SMTP Credential</td>
<td>com.oraclecloud.identityControlPlane.CreateSmtpCredential</td>
</tr>
<tr>
<td>Create Swift Password</td>
<td>com.oraclecloud.identityControlPlane.CreateSwiftPassword</td>
</tr>
<tr>
<td>Delete API Key</td>
<td>com.oraclecloud.identityControlPlane.DeleteApiKey</td>
</tr>
<tr>
<td>Delete Auth Token</td>
<td>com.oraclecloud.identityControlPlane.DeleteAuthToken</td>
</tr>
<tr>
<td>Delete Customer Secret Key</td>
<td>com.oraclecloud.identityControlPlane.DeleteCustomerSecretKey</td>
</tr>
<tr>
<td>Delete SMTP Credential</td>
<td>com.oraclecloud.identityControlPlane.DeleteSmtpCredential</td>
</tr>
<tr>
<td>Delete Swift Password</td>
<td>com.oraclecloud.identityControlPlane.DeleteSwiftPassword</td>
</tr>
<tr>
<td>Update Auth Token</td>
<td>com.oraclecloud.identityControlPlane.UpdateAuthToken</td>
</tr>
<tr>
<td>Update Authentication Policy</td>
<td>com.oraclecloud.identityControlPlane.UpdateAuthenticationPolicy</td>
</tr>
<tr>
<td>Update SMTP Credential</td>
<td>com.oraclecloud.identityControlPlane.UpdateSmtpCredential</td>
</tr>
<tr>
<td>Update Swift Password</td>
<td>com.oraclecloud.identityControlPlane.UpdateSwiftPassword</td>
</tr>
<tr>
<td>Upload API KEY</td>
<td>com.oraclecloud.identityControlPlane.UploadApiKey</td>
</tr>
</tbody>
</table>

### Credentials Example
This is a reference event for most credential events (create or reset password don't include additional details):

```json
{
    "eventType": "com.oraclecloud.identityControlPlane.DeleteApiKey",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "identityControlPlane",
    "eventID": "<unique_ID>",
    "eventTime": "2019-10-21T17:23:54.095Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_user",
        "resourceId": "<unique_ID>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "additionalDetails": {
            "userId": "ocid1.user.oc1..<unique_ID>",
        }
    },
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    }
}
```

### Dynamic Group Event Types

These are the event types that dynamic groups emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Dynamic Group</td>
<td>com.oraclecloud.identityControlPlane.CreateDynamicGroup</td>
</tr>
<tr>
<td>Delete Dynamic Group</td>
<td>com.oraclecloud.identityControlPlane.DeleteDynamicGroup</td>
</tr>
<tr>
<td>Update Dynamic Group</td>
<td>com.oraclecloud.identityControlPlane.UpdateDynamicGroup</td>
</tr>
</tbody>
</table>

### Dynamic Group Example

This is a reference event for dynamic groups:

```json
{
    "eventType": "com.oraclecloud.identityControlPlane.CreateDynamicGroup",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "identityControlPlane",
    "eventID": "<unique_ID>",
    "eventTime": "2019-10-21T17:23:54.095Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_user",
        "resourceId": "<unique_ID>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "additionalDetails": {
            "userId": "ocid1.user.oc1..<unique_ID>",
        }
    },
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    }
}
```
Group Event Types

These are the event types that groups emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add User to Group</td>
<td>com.oraclecloud.identityControlPlane.AddUserToGroup</td>
</tr>
<tr>
<td>Create Group</td>
<td>com.oraclecloud.identityControlPlane.CreateGroup</td>
</tr>
<tr>
<td>Delete Group</td>
<td>com.oraclecloud.identityControlPlane.DeleteGroup</td>
</tr>
<tr>
<td>Remove User From Group</td>
<td>com.oraclecloud.identityControlPlane.RemoveUserFromGroup</td>
</tr>
<tr>
<td>Update Group</td>
<td>com.oraclecloud.identityControlPlane.UpdateGroup</td>
</tr>
</tbody>
</table>

Group Example

This is a reference event for some groups (create, delete, and update events don't include additional details):

```json
{
  "eventType": "com.oraclecloud.identityControlPlane.AddUserToGroup",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_dynamicgroup",
    "resourceId": "ocid1.dynamicgroup.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    }
  }
}
```
```json
"definedTags": {
  "Operations": {
    "CostCenter": "42"
  }
},
"additionalDetails": {
  "userId": "ocid1.user.oc1..<unique_ID>",
  "groupId": "ocid1.group.oc1..<unique_ID>"
},
"extensions": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
```
Identity Provider Event Types

These are the event types that identity providers emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add User to IdP Group</td>
<td>com.oraclecloud.identityControlPlane.AddUserToIdpGroup</td>
</tr>
<tr>
<td>Create Identity Provider</td>
<td>com.oraclecloud.identityControlPlane.CreateIdentityProvider</td>
</tr>
<tr>
<td>Create Identity Provider Group</td>
<td>com.oraclecloud.identityControlPlane.CreateIdentityProviderGroup</td>
</tr>
<tr>
<td>Create IdP Group Mapping</td>
<td>com.oraclecloud.identityControlPlane.CreateIdpGroupMapping</td>
</tr>
<tr>
<td>Create IdP User</td>
<td>com.oraclecloud.identityControlPlane.CreateIdpUser</td>
</tr>
<tr>
<td>Delete Identity Provider</td>
<td>com.oraclecloud.identityControlPlane.DeleteIdentityProvider</td>
</tr>
<tr>
<td>Delete Identity Provider Group</td>
<td>com.oraclecloud.identityControlPlane.DeleteIdentityProviderGroup</td>
</tr>
<tr>
<td>Delete IdP Group Mapping</td>
<td>com.oraclecloud.identityControlPlane.DeleteIdpGroupMapping</td>
</tr>
<tr>
<td>Delete IdP User</td>
<td>com.oraclecloud.identityControlPlane.DeleteIdpUser</td>
</tr>
<tr>
<td>Remove User From IdP Group</td>
<td>com.oraclecloud.identityControlPlane.RemoveUserFromIdpGroup</td>
</tr>
<tr>
<td>Reset IdP SCIM Client</td>
<td>com.oraclecloud.identityControlPlane.ResetIdpScim</td>
</tr>
<tr>
<td>Update Identity Provider</td>
<td>com.oraclecloud.identityControlPlane.UpdateIdentityProvider</td>
</tr>
<tr>
<td>Update IdP Group Mapping</td>
<td>com.oraclecloud.identityControlPlane.UpdateIdpGroupMapping</td>
</tr>
</tbody>
</table>

Identity Provider Example

The following reference events are for identity provider events that include additional details. Some identity providers events do not include additional details. These events are create, delete, and update identity providers, as well as delete identity provider group, delete IdP user, and reset IdP SCIM.

This is a reference event for adding and removing users from IdP groups:

```json
{
    "eventType": "com.oraclecloud.identityControlPlane.AddUserToIdpGroup",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "identityControlPlane",
    "eventID": "<unique_ID>",
```
This is a reference event for create, update, and delete IdP group mapping:

```json
{
    "eventType": "com.oraclecloud.identityControlPlane.CreateIdpGroupMapping",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "identityControlPlane",
    "eventID": "<unique_ID>",
    "eventTime": "2019-10-21T17:23:54.095Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_group",
        "resourceId": "ocid1.idpgroup.oc1..<unique_ID>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "additionalDetails": {
            "userId": "ocid1.user.oc1.<unique_ID>"
        }
    },
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```

This is a reference event for create IdP user and create IdP group:

```json
{
    "eventType": "com.oraclecloud.identityControlPlane.CreateIdpUserAndGroup",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "identityControlPlane",
    "eventID": "<unique_ID>",
    "eventTime": "2019-10-21T17:23:54.095Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_identityprovider",
        "resourceId": "ocid1.idpgroupmapping.oc1..<unique_ID>",
        "availabilityDomain": "availability_domain",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "additionalDetails": {
            "idpGroupName": "my_group",
            "groupId": "ocid1.group.oc1.<unique_ID>"
        }
    },
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```
Multi-Factor Authentication TOTP Device Event Types

These are the event types that MFA TOTP devices emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate MFA TOTP Device</td>
<td>com.oraclecloud.identityControlPlane.ActivateMfaTotpDevice</td>
</tr>
<tr>
<td>Create MFA TOTP Device</td>
<td>com.oraclecloud.identityControlPlane.CreateMfaTotpDevice</td>
</tr>
<tr>
<td>Delete MFA TOTP Device</td>
<td>com.oraclecloud.identityControlPlane.DeleteMfaTotpDevice</td>
</tr>
<tr>
<td>Generate MFA TOTP Device Seed</td>
<td>com.oraclecloud.identityControlPlane.GenerateTotpDeviceSeed</td>
</tr>
</tbody>
</table>

Multi-Factor Authentication TOTP Devices Example

This is a reference event for MFA TOTP Devices:

```json
{
  "eventType": "com.oraclecloud.identityControlPlane.CreateMfaTotpDevice",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_idpgroup",
    "resourceId": "ocid1.idpgroup.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "externalIdentifier": "my_externalidentifier"
    },
    "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    }
  }
}
```
Policy Event Types

These are the event types that policies emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Policy</td>
<td>com.oraclecloud.identityControlPlane.CreatePolicy</td>
</tr>
<tr>
<td>Delete Policy</td>
<td>com.oraclecloud.identityControlPlane.DeletePolicy</td>
</tr>
<tr>
<td>Update Policy</td>
<td>com.oraclecloud.identityControlPlane.UpdatePolicy</td>
</tr>
</tbody>
</table>

Policy Example

This is a reference event for policies:

```json
{
  "eventType": "com.oraclecloud.identityControlPlane.CreatePolicy",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_policy",
    "resourceId": "ocid1.policy.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "userId": "ocid1.user.oc1..<unique_ID>"
    },
    "extensions": {
      "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
  }
}
```
User Event Types
These are the event types that users emit.

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create User</td>
<td>com.oraclecloud.identityControlPlane.CreateUser</td>
</tr>
<tr>
<td>Delete User</td>
<td>com.oraclecloud.identityControlPlane.DeleteUser</td>
</tr>
<tr>
<td>Update User</td>
<td>com.oraclecloud.identityControlPlane.UpdateUser</td>
</tr>
<tr>
<td>Update User Capabilities</td>
<td>com.oraclecloud.identityControlPlane.UpdateUserCapabilities</td>
</tr>
<tr>
<td>Update User State</td>
<td>com.oraclecloud.identityControlPlane.UpdateUserState</td>
</tr>
</tbody>
</table>

User Example
This is a reference event for users:

```json
{
  "eventType": "com.oraclecloud.identityControlPlane.CreateUser",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "identityControlPlane",
  "eventID": "<unique_ID>",
  "eventTime": "2019-10-21T17:23:54.095Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_user",
    "resourceId": "ocid1.user.oc1..<unique_ID>",
    "availabilityDomain": "availability_domain",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  },
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```
Integration
For details about events emitted by Oracle Integration, see Automating with Events.

Java Management
For details about events emitted by the Java Management service, see Service Events.

MySQL Database
For details about events emitted by MySQL Database, see Service Events.

Networking
Networking resources that emit events:
- DHCP Options Event Types on page 2794
- Dynamic Routing Gateway (DRG) Event Types on page 2795
- DRG Attachment Event Types on page 2796
- Internet Gateway Event Types on page 2797
- Local Peering Gateway (LPG) Event Types on page 2798
- NAT Gateway Event Types on page 2799
- Network Security Group (NSG) Event Types on page 2800
- Private IP Event Types on page 2801
- Public IP Event Types on page 2802
- Route Table Event Types on page 2803
- Security List Event Types on page 2804
- Service Gateway Event Types on page 2805
- Subnet Event Types on page 2806
- VCN Event Types on page 2807
- Virtual Network Interface Card (VNIC) Event Types on page 2807
- VLAN Event Types on page 2808

DHCP Options Event Types
These are the event types that sets of DHCP options emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change DHCP Options Compartment</td>
<td>com.oraclecloud.virtualnetwork.changedhcpoptions</td>
</tr>
<tr>
<td>Create DHCP Options</td>
<td>com.oraclecloud.virtualnetwork.createdhcpoptions</td>
</tr>
<tr>
<td>Delete DHCP Options</td>
<td>com.oraclecloud.virtualnetwork.deletedhcpoptions</td>
</tr>
<tr>
<td>Update DHCP Options</td>
<td>com.oraclecloud.virtualnetwork.updatedhcpoptions</td>
</tr>
</tbody>
</table>

DHCP Options Example
This is a reference event for a set of DHCP options:

```json
{
  "eventType": "com.oraclecloud.virtualnetwork.createdhcpoptions",
  "cloudEventsVersion": "0.1",
}
Dynamic Routing Gateway (DRG) Event Types

These are the event types that DRGs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create DRG</td>
<td>com.oraclecloud.virtualnetwork.createdrg</td>
</tr>
<tr>
<td>Delete DRG</td>
<td>com.oraclecloud.virtualnetwork.deletedrg</td>
</tr>
<tr>
<td>Update DRG</td>
<td>com.oraclecloud.virtualnetwork.updatedrg</td>
</tr>
</tbody>
</table>

DRG Example

This is a reference event for a DRG:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createdrg",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.dhcpoptions.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>
        }
    }
}
```
"Operations": {  "CostCenter": "42"
  }
},
"eventID": "<unique_ID>",
"extensions": {  "compartmentId": "ocid1.compartment.oci..<unique_ID>"
  }
}

### DRG Attachment Event Types

These are the event types that DRG attachments emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create DRG Attachment</td>
<td>com.oraclecloud.virtualnetwork.createdrgattachment</td>
</tr>
<tr>
<td>Delete DRG Attachment</td>
<td>com.oraclecloud.virtualnetwork.deletedrgattachment</td>
</tr>
<tr>
<td>Update DRG Attachment</td>
<td>com.oraclecloud.virtualnetwork.updatedrgattachment</td>
</tr>
</tbody>
</table>

### DRG Attachment Example

This is a reference event for a DRG attachment:

```
{
  "eventType": "com.oraclecloud.virtualnetwork.createdrgattachment",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>"
  }
}
```
Internet Gateway Event Types

These are the event types that internet gateways emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Internet Gateway Compartment</td>
<td>com.oraclecloud.virtualnetwork.changeinternetgateway_compartment</td>
</tr>
<tr>
<td>Create Internet Gateway</td>
<td>com.oraclecloud.virtualnetwork.createinternetgateway</td>
</tr>
<tr>
<td>Delete Internet Gateway</td>
<td>com.oraclecloud.virtualnetwork.deleteinternetgateway</td>
</tr>
<tr>
<td>Update Internet Gateway</td>
<td>com.oraclecloud.virtualnetwork.updateinternetgateway</td>
</tr>
</tbody>
</table>

Internet Gateway Example

This is a reference event for an internet gateway:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createinternetgateway",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.internetgateway.oci.phx..<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>"
    },
    "extensions": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>"
    }
}
```
Local Peering Gateway (LPG) Event Types

These are the event types that LPGs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Local Peering Gateway Compartment</td>
<td>com.oraclecloud.virtualnetwork.changelocalpeeringgateway</td>
</tr>
<tr>
<td>Create Local Peering Gateway</td>
<td>com.oraclecloud.virtualnetwork.createlocalpeeringgateway</td>
</tr>
<tr>
<td>Delete Local Peering Gateway</td>
<td>com.oraclecloud.virtualnetwork.deletelocalpeeringgateway</td>
</tr>
<tr>
<td>Update Local Peering Gateway</td>
<td>com.oraclecloud.virtualnetwork.updatelocalpeeringgateway</td>
</tr>
</tbody>
</table>

LPG Example

This is a reference event for an LPG:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createlocalpeeringgateway",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.localpeeringgateway.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        }
    }
}
```
**NAT Gateway Event Types**

These are the event types that NAT gateways emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change NAT Gateway Compartment</td>
<td>com.oraclecloud.natgateway.changenatgatewaycompartment</td>
</tr>
<tr>
<td>Create NAT Gateway</td>
<td>com.oraclecloud.natgateway.createnatgateway</td>
</tr>
<tr>
<td>Delete NAT Gateway</td>
<td>com.oraclecloud.natgateway.deletenatgateway</td>
</tr>
<tr>
<td>Update NAT Gateway</td>
<td>com.oraclecloud.natgateway.updatenatgateway</td>
</tr>
</tbody>
</table>

**NAT Gateway Example**

This is a reference event for NAT gateways:

```json
{
    "eventType": "com.oraclecloud.natgateway.createnatgateway",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "natgateway",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.natgateway.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        }
    }
}
```
Network Security Group (NSG) Event Types

These are the event types that NSGs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Network Security Group Compartment</td>
<td>com.oraclecloud.virtualnetwork.changenetworksecuritygroupcompartment</td>
</tr>
<tr>
<td>Create Network Security Group</td>
<td>com.oraclecloud.virtualnetwork.createnetworksecuritygroup</td>
</tr>
<tr>
<td>Delete Network Security Group</td>
<td>com.oraclecloud.virtualnetwork.deletenetworksecuritygroup</td>
</tr>
<tr>
<td>Update Network Security Group</td>
<td>com.oraclecloud.virtualnetwork.updatenetworksecuritygroup</td>
</tr>
</tbody>
</table>

NSG Example

This is a reference event for an NSG:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createnetworksecuritygroup",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.networksecuritygroup.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventId": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        }
    }
}
```
Private IP Event Types

These are the event types that private IPs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Private IP</td>
<td>com.oraclecloud.virtualnetwork.createprivateip</td>
</tr>
<tr>
<td>Delete Private IP</td>
<td>com.oraclecloud.virtualnetwork.deleteprivateip</td>
</tr>
<tr>
<td>Update Private IP</td>
<td>com.oraclecloud.virtualnetwork.updateprivateip</td>
</tr>
</tbody>
</table>

Private IP Example

This is a reference event for a private IP:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createprivateip",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.privateip.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        }
    }
}
```
Public IP Event Types

These are the event types that public IPs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Public IP Compartment</td>
<td>com.oraclecloud.virtualnetwork.changepublicipcompartment</td>
</tr>
<tr>
<td>Create Public IP</td>
<td>com.oraclecloud.virtualnetwork.createpublicip</td>
</tr>
<tr>
<td>Delete Public IP</td>
<td>com.oraclecloud.virtualnetwork.deletepublicip</td>
</tr>
<tr>
<td>Update Public IP</td>
<td>com.oraclecloud.virtualnetwork.updatepublicip</td>
</tr>
</tbody>
</table>

Public IP Example

This is a reference event for a public IP:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createpublicip",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.publicip.oci.phx..<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
        "eventID": "<unique_ID>",
        "extensions": {
            "compartmentId": "ocid1.compartment.oci..<unique_ID>"
        }
    }
}
```
**Route Table Event Types**

These are the event types that route tables emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Route Table Compartment</td>
<td>com.oraclecloud.virtualnetwork.changeroutetablecompartment</td>
</tr>
<tr>
<td>Create Route Table</td>
<td>com.oraclecloud.virtualnetwork.createroutetable</td>
</tr>
<tr>
<td>Delete Route Table</td>
<td>com.oraclecloud.virtualnetwork.deleteroutetable</td>
</tr>
<tr>
<td>Update Route Table</td>
<td>com.oraclecloud.virtualnetwork.updateroutetable</td>
</tr>
</tbody>
</table>

**Route Table Example**

This is a reference event for route tables:

```json
{
   "eventType": "com.oraclecloud.virtualnetwork.createroutetable",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "virtualNetwork",
   "eventTime": "2019-08-12T17:51:42.789Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oci..<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "example_name",
      "resourceId": "ocid1.routetable.oci.phx.<unique_ID>",
      "availabilityDomain": "XXIT:PHX-AD-1",
      "freeFormTags": {
         "Department": "Finance"
      },
      "definedTags": {
         "Operations": {
            "CostCenter": "42"
         }
      },
      "eventID": "<unique_ID>",
      "extensions": {
         "compartmentId": "ocid1.compartment.oci..<unique_ID>"
      }
   }
}
```
Security List Event Types

These are the event types that security lists emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Security List Compartment</td>
<td>com.oraclecloud.virtualnetwork.changesecuritylistcompartment</td>
</tr>
<tr>
<td>Create Security List</td>
<td>com.oraclecloud.virtualnetwork.createsecuritylist</td>
</tr>
<tr>
<td>Delete Security List</td>
<td>com.oraclecloud.virtualnetwork.deletesecuritylist</td>
</tr>
<tr>
<td>Update Security List</td>
<td>com.oraclecloud.virtualnetwork.updatesecuritylist</td>
</tr>
</tbody>
</table>

Security List Example

This is a reference event for security lists:

```json
{
  "eventType": "com.oraclecloud.virtualnetwork.createsecuritylist",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2019-08-12T17:51:42.789Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oci..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
    "resourceId": "ocid1.securitylist.oci.phx.<unique_ID>",
    "availabilityDomain": "XXIT:PHX-AD-1",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "eventID": "<unique_ID>",
    "extensions": {
      "compartmentId": "ocid1.compartment.oci..<unique_ID>"
    }
  }
}
```
Service Gateway Event Types

These are the event types that service gateways emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach Service</td>
<td>com.oraclecloud.servicegateway.attachserviceid</td>
</tr>
<tr>
<td>Change Service Gateway Compartment</td>
<td>com.oraclecloud.servicegateway.changeservicegatewaycompartment</td>
</tr>
<tr>
<td>Create Service Gateway</td>
<td>com.oraclecloud.servicegateway.createservicegateway</td>
</tr>
<tr>
<td>Delete Service Gateway End</td>
<td>com.oraclecloud.servicegateway.deleteservicegateway.end</td>
</tr>
<tr>
<td>Delete Service Gateway Start</td>
<td>com.oraclecloud.servicegateway.deleteservicegateway.begin</td>
</tr>
<tr>
<td>Detach Service</td>
<td>com.oraclecloud.servicegateway.detachserviceid</td>
</tr>
<tr>
<td>Update Service Gateway</td>
<td>com.oraclecloud.servicegateway.updateservicegateway</td>
</tr>
</tbody>
</table>

Service Gateway Example

This is a reference event for service gateways:

```json
{
   "eventType": "com.oraclecloud.servicegateway.createservicegateway",
   "cloudEventsVersion": "0.1",
   "eventTypeVersion": "2.0",
   "source": "servicegateway",
   "eventTime": "2019-08-12T17:51:42.789Z",
   "contentType": "application/json",
   "data": {
      "compartmentId": "ocid1.compartment.oci..<unique_ID>",
      "compartmentName": "example_name",
      "resourceName": "example_name",
      "resourceId": "ocid1.servicegateway.oci.phx.<unique_ID>",
      "availabilityDomain": "XXIT:PHX-AD-1",
      "freeFormTags": {
         "Department": "Finance"
      },
      "definedTags": {
         "Operations": {
            "CostCenter": "42"
         }
      },
      "eventID": "<unique_ID>",
      "extensions": {
         "compartmentId": "ocid1.compartment.oci..<unique_ID>"
      }
   }
}
```
Subnet Event Types

These are the event types that subnets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Subnet</td>
<td>com.oraclecloud.virtualnetwork.createsubnet</td>
</tr>
<tr>
<td>Delete Subnet</td>
<td>com.oraclecloud.virtualnetwork.deletesubnet</td>
</tr>
<tr>
<td>Update Subnet</td>
<td>com.oraclecloud.virtualnetwork.updatesubnet</td>
</tr>
</tbody>
</table>

Subnet Example

This is a reference event for a subnet:

```json
{
    "eventType": "com.oraclecloud.virtualnetwork.createsubnet",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.subnet.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        },
    }
}
```
**VCN Event Types**

These are the event types that VCNs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create VCN</td>
<td>com.oraclecloud.virtualnetwork.createvcn</td>
</tr>
<tr>
<td>Delete VCN</td>
<td>com.oraclecloud.virtualnetwork.deletevcn</td>
</tr>
<tr>
<td>Update VCN</td>
<td>com.oraclecloud.virtualnetwork.updatevcn</td>
</tr>
</tbody>
</table>

**VCN Example**

This is a reference event for VCNs:

```
{
    "eventType": "com.oraclecloud.virtualnetwork.createvcn",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "virtualNetwork",
    "eventTime": "2019-08-12T17:51:42.789Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oci..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "example_name",
        "resourceId": "ocid1.vcn.oci.phx.<unique_ID>",
        "availabilityDomain": "XXIT:PHX-AD-1",
        "freeFormTags": { "Department": "Finance" },
        "definedTags": { "Operations": { "CostCenter": "42" } }
    },
    "eventID": "<unique_ID>",
    "extensions": { "compartmentId": "ocid1.compartment.oci..<unique_ID>" }
}
```

**Virtual Network Interface Card (VNIC) Event Types**

These are the event types that VNICs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update VNIC</td>
<td>com.oraclecloud.virtualnetwork.updatevnic</td>
</tr>
</tbody>
</table>

**VNIC Example**

This is a reference event for a VNIC:

```
{
```

Oracle Cloud Infrastructure User Guide 2807
Events

```
"eventType": "com.oraclecloud.virtualnetwork.updatevnic",
"cloudEventsVersion": "0.1",
"eventTypeVersion": "2.0",
"source": "virtualNetwork",
"eventTime": "2019-08-12T17:51:42.789Z",
"contentType": "application/json",
"data": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "compartmentName": "example_name",
  "resourceName": "example_name",
  "resourceId": "ocid1.vnic.oci.phx.<unique_ID>",
  "availabilityDomain": "XXIT:PHX-AD-1",
  "freeFormTags": {
    "Department": "Finance"
  },
  "definedTags": {
    "Operations": {
      "CostCenter": "42"
    }
  }
},
"eventID": "<unique_ID>",
"extensions": {
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
}
```

### VLAN Event Types

These are the event types that VLANs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create VLAN</td>
<td>com.oraclecloud.virtualnetwork.createvlan</td>
</tr>
<tr>
<td>Update VLAN</td>
<td>com.oraclecloud.virtualnetwork.updatevlan</td>
</tr>
<tr>
<td>Delete VLAN</td>
<td>com.oraclecloud.virtualnetwork.deletevlan</td>
</tr>
</tbody>
</table>

### VLAN Example

This is a reference event for a VLAN:

```
{
  "eventType": "com.oraclecloud.virtualnetwork.createvlan",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "virtualNetwork",
  "eventTime": "2020-04-16T17:44:31.116Z",
  "contentType": "application/json",
  "eventId": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "example_name",
```
Events

```
"resourceId": "ocid1.vlan.oc1.phx.<unique_ID>",
"availabilityDomain": "XXIT:PHX-AD-1",
"freeFormTags": {
    "Department": "Finance"
},
"definedTags": {
    "Operations": {
        "CostCenter": "42"
    }
},
"additionalDetails": {}
```

NoSQL Database Cloud

For details about events emitted by Oracle NoSQL Database Cloud, see Service Events.

Notifications

Notifications resources that emit events:

- Subscriptions Event Types on page 2809
- Topics Event Types on page 2810

Subscriptions Event Types

These are the event types that subscriptions emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Subscription</td>
<td>com.oraclecloud.notification.createsubscription</td>
</tr>
<tr>
<td>Delete Subscription</td>
<td>com.oraclecloud.notification.deletesubscription</td>
</tr>
<tr>
<td>Move Subscription</td>
<td>com.oraclecloud.notification.movesubscription</td>
</tr>
<tr>
<td>Resend Subscription Confirmation</td>
<td>com.oraclecloud.notification.resendsubscriptionconfirmation</td>
</tr>
<tr>
<td>Update Subscription</td>
<td>com.oraclecloud.notification.updatesubscription</td>
</tr>
</tbody>
</table>

Subscription Example

This is a reference event for subscriptions:

```
{
    "eventType": "com.oraclecloud.notification.createsubscription",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "notification",
    "eventTime": "2019-01-10T21:19:24Z",
    "contentType": "application/json",
    "data":{
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "my_compartment",
        "resourceName": "ons-subscription",
        "resourceId": "ocid1.onssubscription.oc1..<unique_ID>",
    }
}```
Topics Event Types

These are the event types that topics emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Topic</td>
<td><code>com.oraclecloud.notification.createtopic</code></td>
</tr>
<tr>
<td>Delete Topic</td>
<td><code>com.oraclecloud.notification.deletetopic</code></td>
</tr>
<tr>
<td>Move Topic</td>
<td><code>com.oraclecloud.notification.movetopic</code></td>
</tr>
<tr>
<td>Update Topic</td>
<td><code>com.oraclecloud.notification.updateetopic</code></td>
</tr>
</tbody>
</table>

Topic Example

This is a reference event for topics:

```
{
  "eventType": "com.oraclecloud.notification.createtopic",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "notification",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "data":{
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"",
    "compartmentName": "my_compartment",
    "resourceName": "my_topic",
    "resourceId": "ocid1.onstopic.oc1..<unique_ID>"",
    "availabilityDomain": "AD3"
  },
  "eventID": "<unique_ID>",
  "extensions":{
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

Object Storage

Object Storage resources that emit events:

- [Buckets Event Types](#) on page 2811
- [Objects Event Types](#) on page 2811
## Buckets Event Types

These are the event types that buckets emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Bucket</td>
<td>com.oraclecloud.objectstorage.createbucket</td>
</tr>
<tr>
<td>Delete Bucket</td>
<td>com.oraclecloud.objectstorage.deletebucket</td>
</tr>
<tr>
<td>Update Bucket</td>
<td>com.oraclecloud.objectstorage.updatebucket</td>
</tr>
</tbody>
</table>

### Bucket Example

This is an example event for buckets:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.objectstorage.createbucket",
  "source": "objectstorage",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-01-10T21:19:24Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_bucket",
    "resourceId": "ocid1.compartment.oc1..<unique_ID>",
    "availabilityDomain": "all",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "namespace": "example_namespace",
      "publicAccessType": "NoPublicAccess",
      "eTag": "f8ffb6e9-f602-460f-a6c0-00b5abfa24c7"
    }
  }
}
```

## Objects Event Types

Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.
These are the event types that objects emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Object</td>
<td>com.oraclecloud.objectstorage.createobject</td>
</tr>
<tr>
<td>Delete Object</td>
<td>com.oraclecloud.objectstorage.deleteobject</td>
</tr>
<tr>
<td>Update Object</td>
<td>com.oraclecloud.objectstorage.updateobject</td>
</tr>
</tbody>
</table>

**Object Example**

This is an example event for objects:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.objectstorage.createobject",
  "source": "objectstorage",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-07-10T13:37:11Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "Example_Compartment",
    "resourceName": "v1/log/10.0.6.166",
    "resourceId": "",
    "availabilityDomain": "all",
    "additionalDetails": {
      "eTag": "8162db5b-50d7-4947-a576-4401798ed2fa",
      "namespace": "my_namespace",
      "archivalState": null,
      "bucketName": "my_bucket",
      "bucketId": "ocid1.bucket.oc1..<unique_ID>",
    }
  }
}
```

**Operations Insights**

Operations Insights resources that emit events:

- Database insights
**Database Insight Event Types**

These are the event types that database insights emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ingest SQL Text</td>
<td>com.oraclecloud.OperationsInsights.IngestSqlText</td>
</tr>
<tr>
<td>List SQL Searches</td>
<td>com.oraclecloud.OperationsInsights.ListSqlSearches</td>
</tr>
</tbody>
</table>
Database Insight Example 1: Read Event

Following is a reference read event for database insights:

```json
{
    "eventType": "com.oraclecloud.OperationsInsights.SummarizeDatabaseInsightResourceCapacityTrend",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "OperationsInsights",
    "eventID": "<unique_ID>",
    "eventTime": "2020-09-01T00:05:46.370Z",
    "contentType": "application/json",
    "data": {
        "eventGroupingId": "<unique_ID>",
        "eventName": "SummarizeDatabaseInsightResourceCapacityTrend",
        "compartmentId": "ocid1.compartment.<realm>..<unique_ID>",
        "compartmentName": "example_compartment_name",
        "resourceName": "example_resource_name",
        "resourceId": "resourceCapacityTrend",
        "availabilityDomain": "SoSC:PHX-AD-3",
        "freeformTags": null,
        "definedTags": null
    }
}
```

Database Insight Example 2: Ingest Event

Following is a reference ingest event for database insights:

```json
{
    "eventType": "com.oraclecloud.OperationsInsights.IngestSqlText",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "OperationsInsights",
    "eventID": "<unique_ID>",
    "eventTime": "2020-09-01T01:09:00.688Z",
    "contentType": "application/json",
    "data": {
        "eventGroupingId": "<unique_ID>",
        "eventName": "IngestSqlText",
        "compartmentId": "ocid1.compartment.<realm>..<unique_ID>",
        "compartmentName": "example_compartment_name",
        "resourceName": "example_resource_name",
        "resourceId": "actions",
        "availabilityDomain": "AD1",
        "freeformTags": null,
        "definedTags": null
    }
}
```

OS Management

For details about events emitted by OS Management, see Creating Automation with Events.

Resource Manager

Resource Manager resources that emit events:

- [Job Event Types](#) on page 2815
- [Stack Event Types](#) on page 2816
### Job Event Types

These are the event types that jobs emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cancel Job</td>
<td>com.oraclecloud.oracleresourcemanager.canceljob</td>
</tr>
<tr>
<td>Create Job Begin</td>
<td>com.oraclecloud.oracleresourcemanager.createjob</td>
</tr>
<tr>
<td>Create Job End</td>
<td>com.oraclecloud.oracleresourcemanager.createjob</td>
</tr>
<tr>
<td>Update Job</td>
<td>com.oraclecloud.oracleresourcemanager.updatejob</td>
</tr>
</tbody>
</table>

This is a reference event for jobs:

```json
{
    "eventType": "com.oraclecloud.oracleresourcemanager.updateJob",
    "cloudEventsVersion": "0.1",
    "eventTypeVersion": "2.0",
    "source": "OracleResourceManager",
    "eventTime": "2019-07-23T01:46:37.606Z",
    "contentType": "application/json",
    "data": {
        "compartmentId": "ocid1.compartment.oc1..unique_ID",
        "compartmentName": "example_compartment",
        "resourceName": "example_name",
        "resourceId": "ocid1.ormjob.oc1.phx.unique_ID",
        "availabilityDomain": "availability_domain"
    },
    "eventID": "<unique_ID>",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    }
}
```
## Stack Event Types

These are the event types that stacks emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Compartment Begin</td>
<td>com.oraclecloud.oracleresourcemanager.changestackcompartment.begin</td>
</tr>
<tr>
<td>Change Compartment End</td>
<td>com.oraclecloud.oracleresourcemanager.changestackcompartment.end</td>
</tr>
<tr>
<td>Create Stack</td>
<td>com.oraclecloud.oracleresourcemanager.createstack</td>
</tr>
<tr>
<td>Delete Stack</td>
<td>com.oraclecloud.oracleresourcemanager.deletestack</td>
</tr>
<tr>
<td>Update Stack</td>
<td>com.oraclecloud.oracleresourcemanager.updatestack</td>
</tr>
</tbody>
</table>

This is a reference event for stacks:

```json
{
  "eventType": "com.oraclecloud.oracleresourcemanager.createstack",
  "cloudEventsVersion": "0.1",
  "eventTypeVersion": "2.0",
  "source": "OracleResourceManager",
  "eventTime": "2019-07-23T01:32:10.866Z",
  "contentType": "application/json",
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_compartment",
    "resourceName": "example_name",
    "resourceId": "ocid1.ormstack.oc1.phx.<unique_ID>",
    "availabilityDomain": "availability_domain"
  },
  "eventID": "<unique_ID>",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
  }
}
```

## Vulnerability Scanning

For details about events emitted by Vulnerability Scanning, see [Scanning Events](#)

## WAF

WAF resources that emit events:

- [Waas Policy Event Types](#)
- [Address List Event Types](#)
- [Custom Protection Rule Event Types](#)
- [Certificate Event Types](#)
**Waas Policy Event Types**

These are the event types that Waas policies emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Waas Policy Compartment</td>
<td>com.oraclecloud.waf.changewaaspolicycompartment</td>
</tr>
<tr>
<td>Create Waas Policy Begin</td>
<td>com.oraclecloud.waf.createwaaspolicy.begin</td>
</tr>
<tr>
<td>Create Waas Policy End</td>
<td>com.oraclecloud.waf.createwaaspolicy.end</td>
</tr>
<tr>
<td>Delete Waas Policy Begin</td>
<td>com.oraclecloud.waf.deletewaaspolicy.begin</td>
</tr>
<tr>
<td>Delete Waas Policy End</td>
<td>com.oraclecloud.waf.deletewaaspolicy.end</td>
</tr>
<tr>
<td>Update Waas Policy Begin</td>
<td>com.oraclecloud.waf.updatewaaspolicy.begin</td>
</tr>
<tr>
<td>Update Waas Policy End</td>
<td>com.oraclecloud.waf.updatewaaspolicy.end</td>
</tr>
</tbody>
</table>

**Waas Policy Example**

This is an example event for a Waas policy:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.waf.updatewaaspolicy.begin",
  "source": "waf",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-10-11T13:40:54.931962577Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_waas_policy",
    "resourceId": "ocid1.waaspolicy.oc1..<unique_ID>",
    "availabilityDomain": "all",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    },
    "additionalDetails": {
      "domain": "exmaple.com"
    }
  }
}
```
### Address List Event Types

These are the event types that address lists emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Address List Compartment</td>
<td>com.oraclecloud.waf.changeaddresslistcompartment</td>
</tr>
<tr>
<td>Create Address List</td>
<td>com.oraclecloud.waf.createaddresslist</td>
</tr>
<tr>
<td>Delete Address List</td>
<td>com.oraclecloud.waf.deleteaddresslist</td>
</tr>
<tr>
<td>Update Address List</td>
<td>com.oraclecloud.waf.updateaddresslist</td>
</tr>
</tbody>
</table>

### Address List Example

This is an example event for address lists:

```json
{
    "cloudEventsVersion": "0.1",
    "eventID": "<unique_ID>",
    "eventType": "com.oraclecloud.waf.updateaddresslist",
    "source": "waf",
    "eventTypeVersion": "2.0",
    "eventTime": "2019-10-11T13:40:54.931962577Z",
    "contentType": "application/json",
    "extensions": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>"
    },
    "data": {
        "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
        "compartmentName": "example_name",
        "resourceName": "my_waas_address_list",
        "resourceId": "ocid1.waasaddresslist.oc1..<unique_ID>",
        "availabilityDomain": "all",
        "freeFormTags": {
            "Department": "Finance"
        },
        "definedTags": {
            "Operations": {
                "CostCenter": "42"
            }
        }
    }
}
```
**Custom Protection Rule Event Types**

These are the event types that protection rules emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Custom Protection Rule Compartment</td>
<td>com.oraclecloud.waf.changecustomprotectionrulecompartment</td>
</tr>
<tr>
<td>Create Custom Protection Rule</td>
<td>com.oraclecloud.waf.createcustomprotectionrule</td>
</tr>
<tr>
<td>Delete Custom Protection Rule</td>
<td>com.oraclecloud.waf.deletecustomprotectionrule</td>
</tr>
<tr>
<td>Update Custom Protection Rule</td>
<td>com.oraclecloud.waf.updatecustomprotectionrule</td>
</tr>
<tr>
<td>Update Waas Policy Custom Protection Rules</td>
<td>com.oraclecloud.waf.updatewaaspolicycustomprotectionrules</td>
</tr>
</tbody>
</table>

**Protection Rule Example**

This is an example event for custom protection rules:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.waf.updatecustomprotectionrule",
  "source": "waf",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-10-11T13:40:54.931962577Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_waas_custom_protection_rule",
    "resourceId": "ocid1.waascustomprotectionrule.oc1..<unique_ID>",
    "availabilityDomain": "all",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  }
}
```
Certificate Event Types

These are the event types that certificates emit:

<table>
<thead>
<tr>
<th>Friendly Name</th>
<th>Event Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change Certificate Compartment</td>
<td>com.oraclecloud.waf.changecertificatecompartment</td>
</tr>
<tr>
<td>Create Certificate</td>
<td>com.oraclecloud.waf.createcertificate</td>
</tr>
<tr>
<td>Delete Certificate</td>
<td>com.oraclecloud.waf.deletecertificate</td>
</tr>
<tr>
<td>Update Certificate</td>
<td>com.oraclecloud.waf.updatecertificate</td>
</tr>
</tbody>
</table>

Certificate Example

This is an example event for certificates:

```json
{
  "cloudEventsVersion": "0.1",
  "eventID": "<unique_ID>",
  "eventType": "com.oraclecloud.waf.updatecertificate",
  "source": "waf",
  "eventTypeVersion": "2.0",
  "eventTime": "2019-10-11T13:40:54.931962577Z",
  "contentType": "application/json",
  "extensions": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  },
  "data": {
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "compartmentName": "example_name",
    "resourceName": "my_waas_certificate",
    "resourceId": "ocid1.waascertificate.oc1..<unique_ID>",
    "availabilityDomain": "all",
    "freeFormTags": {
      "Department": "Finance"
    },
    "definedTags": {
      "Operations": {
        "CostCenter": "42"
      }
    }
  }
}
```

Events Metrics

You can monitor performance of your rules by using metrics, alarms, and notifications. This topic describes the metrics emitted by the metric namespace `oci_cloudevents` (the Events service).

Resources: rules. Also measures data for events, which are not resources.

Prerequisites

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action
and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

**Overview of the Events Service Metrics**

You create rules that specify which events should be delivered to other services for processing. This delivery creates the automation in your tenancy. A rule identifies an event pattern to match and specifies other services to deliver matching events to. Metrics help you measure the success of the rules you create (in terms of pattern matching and delivery) and the quality and scope of the emitted events in your tenancy. For more information, see Overview of Events on page 2672.

**Available Metrics: oci_cloudevents**

The metrics listed in the following table are automatically available for rules you create. You do not need to enable monitoring to get these metrics.

Each metric includes one or more of the following dimensions:

**RESOURCEID**

The OCID of the rule or compartment to which the metric applies.

**EVENTTYPE**

The type of event emitted by a resource.

**RESOURCEDisplayNAME**

The name of the rule.

**ACTIONTYPE**

One or more of the following types of resources that receives an event from the Events service.

- Notifications
- Streaming
- Functions

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>PublishedEvents</td>
<td>Events Emitted</td>
<td>count</td>
<td>Total number of events emitted by resources in a compartment.</td>
<td>eventType, resourceId</td>
</tr>
<tr>
<td>MatchedEvents</td>
<td>Events Matched</td>
<td>count</td>
<td>If you view the default chart from a rule, this metric provides the total number of events matched for the rule. If you view the chart from the Service Metrics page, this metric gives a total number of matched events for all the rules in a compartment.</td>
<td>resourceDisplayName, resourceId</td>
</tr>
</tbody>
</table>
Using the Console

To view default metric charts for a rule

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose the **Compartment** that contains the rule you want to view, and then click the rule's name.
3. Click **Metrics**. The **Metrics** page displays a default set of charts for the current rule.

For more information about monitoring metrics and using alarms, see Monitoring on page 4078. For information about notifications for alarms, see Notifications on page 4900.

To view default metric charts for a compartment

1. Open the navigation menu and click **Observability & Management**. Under **Events Service**, click **Rules**.
2. Choose the **Compartment** that contains the rules you want to monitor.
3. Click **Metrics**. The **Metrics** page displays a default set of charts for the current compartment.

For more information about monitoring metrics and using alarms, see Monitoring on page 4078. For information about notifications for alarms, see Notifications on page 4900.

Using the API

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)
Chapter 25

File Storage

This chapter explains how to create file systems, how to manage them, and how to mount them to write files.

Use File Storage to create scalable, distributed, enterprise-grade network file systems. File Storage supports NFSv3 with NLM for full POSIX semantics, snapshots capabilities, and data at-rest encryption.

Overview of File Storage

Oracle Cloud Infrastructure File Storage service provides a durable, scalable, secure, enterprise-grade network file system. You can connect to a File Storage service file system from any bare metal, virtual machine, or container instance in your Virtual Cloud Network (VCN). You can also access a file system from outside the VCN using VCN peering, Oracle Cloud Infrastructure FastConnect, and Internet Protocol security (IPSec) virtual private network (VPN).

Large Compute clusters of thousands of instances can use the File Storage service for high-performance shared storage. Storage provisioning is fully managed and automatic as your use scales from a single byte to exabytes without upfront provisioning.

The File Storage service supports the Network File System version 3.0 (NFSv3) protocol. The service supports the Network Lock Manager (NLM) protocol for file locking functionality.

Oracle Cloud Infrastructure File Storage employs 5-way replicated storage, located in different fault domains, to provide redundancy for resilient data protection. Data is protected with erasure encoding.

The File Storage service uses the "eventual overwrite" method of data eradication. Files are created in the file system with a unique encryption key. When you delete a single file, its associated encryption key is eradicated, making the file inaccessible. When you delete an entire file system, the file system is marked as inaccessible. The service systematically traverses deleted files and file systems, frees all the used space, and eradicates all residual files.

Use the File Storage service when your application or workload includes big data and analytics, media processing, or content management, and you require Portable Operating System Interface (POSIX)-compliant file system access semantics and concurrently accessible storage. The File Storage service is designed to meet the needs of applications and users that need an enterprise file system across a wide range of use cases, including the following:

- **General Purpose File Storage**: Access to an unlimited pool of file systems to manage growth of structured and unstructured data.
- **Big Data and Analytics**: Run analytic workloads and use shared file systems to store persistent data.
- **Lift and Shift of Enterprise Applications**: Migrate existing Oracle applications that need NFS storage, such as Oracle E-Business Suite and PeopleSoft.
- **Databases and Transactional Applications**: Run test and development workloads with Oracle, MySQL, or other databases.
- **Backups, Business Continuity, and Disaster Recovery**: Host a secondary copy of relevant file systems from on-premises to the cloud for backup and disaster recovery purposes.
- **MicroServices and Docker**: Deliver stateful persistence for containers. Easily scale as your container-based environments grow.

File Storage Concepts

Using the File Storage service requires an understanding of the following concepts, including some that pertain to Oracle Cloud Infrastructure Networking:

**MOUNT TARGET**

An NFS endpoint that lives in a subnet of your choice and is highly available. The mount target provides the IP address or DNS name that is used in the mount command when connecting NFS clients to a file system.
File systems are exported (made available) through mount targets. When you use the console to create your first file system, the workflow also creates a mount target and export for it.

You can reuse the same mount target to make as many file systems available on the network as you wish. To reuse the same mount target for multiple file systems, create an export in the mount target for each file system.

Mount target limitations:

- Each mount target can accept up to 100,000 NFS client connections.
- If you use in-transit encryption, each mount target can accept up to 64 NFS/SSL client connections. See Using In-transit Encryption on page 2847 for more information.
- By default, you can create two mount targets per account per availability domain. See Service Limits on page 247 for a list of applicable limits and instructions for requesting a limit increase.

See Managing Mount Targets on page 2885 for more information about working with this resource.

**EXPORT**

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. When you use the console to create your first file system, the workflow also creates a mount target and export for it. Thereafter,

- You can create as many exports in a mount target for different file systems as you wish.
- You can create as many exports in a mount target for a single file system as you wish.
- You can delete and re-create exports in a mount target as often as you need to.
- You can add export options to an export to control access to the file system.

For more information, see Managing Mount Targets on page 2885 and Working with NFS Export Options on page 2838.

**EXPORT SET**

Collection of one or more exports that control what file systems the mount target exports using NFSv3 protocol and how those file systems are found using the NFS mount protocol. Each mount target has an export set. Each file system associated with the mount target has at least one export in the export set.

**EXPORT PATH**

A path that is specified when an export is created. It uniquely identifies the file system within the mount target, letting you associate many file systems to a single mount target. This path is unrelated to any path within the file system itself, or the client mount point path.

The File Storage service adds an export that pairs the file system's Oracle Cloud Identifier (OCID) and path. See Paths in File Systems on page 2917 for more information.

**EXPORT OPTIONS**

NFS export options are a set of parameters within the export that specify the level of access granted to NFS clients when they connect to a mount target. An NFS export options entry within an export defines access for a single IP address or CIDR block range. You can have up to 100 options per export. For more information, see Working with NFS Export Options on page 2838.

**VIRTUAL CLOUD NETWORK (VCN)**

A private network that you set up in the Oracle data centers, with firewall rules and specific types of communication gateways that you can choose to use. A VCN covers a single, contiguous IPv4 CIDR block of your choice. For more information about VCNs, see VCNs and Subnets on page 4321 in the Oracle Cloud Infrastructure Networking documentation.

You can set up a service gateway and give your VCN private access to the File Storage service. A service gateway can be used only by resources in the gateway's own VCN. Traffic to the service will not travel
through the internet. When creating the service gateway, enable the service label called **All <region> Services in Oracle Services Network**. It includes the File Storage service. Be sure to update route tables for any subnets that need to access File Storage through the service gateway.

For more information and detailed instructions, see Setting Up a Service Gateway in the Console on page 4780

**SUBNETS**

Subdivisions you define in a VCN (for example, 10.0.0.0/24 and 10.0.1.0/24). Subnets contain virtual network interface cards (VNICs), which attach to instances. A subnet can span a region or exist in a single availability domain. A subnet consists of a contiguous range of IP addresses that do not overlap with other subnets in the VCN. For each subnet, you specify the routing rules and security lists that apply to it. For more information about subnets, see VCNs and Subnets on page 4321 in the Oracle Cloud Infrastructure Networking documentation.

**SECURITY RULES**

Virtual firewall rules for your VCN. Your VCN comes with a default security list, and you can add more. These security lists provide ingress and egress rules that specify the types of traffic allowed in and out of the instances. You can choose whether a given rule is stateful or stateless. Security list rules must be set up so that clients can connect to file system mount targets.

Network security groups (NSGs). Another method for applying security rules is to set them up in a network security group (NSG), and then add the mount target to the NSG. Unlike security list rules that apply to all VNICs in the subnet, NSGs apply only to resource VNICs you add to the NSG.

See Security Rules on page 4338, Security Lists on page 4355, and Network Security Groups on page 4346 for more information, examples, and scenarios about how these features interact in your network.

**SNAPSHOTS**

Snapshots provide a consistent, point-in-time view of your file system, and you can take as many snapshots as you need. You pay only for the storage used by your data and metadata, including storage capacity used by snapshots. Each snapshot reflects only data that changed from the previous snapshot. For more information, see Managing Snapshots on page 2896.

**Encryption**

The File Storage service encrypts all file system and snapshot data at rest. By default all file systems are encrypted using Oracle-managed encryption keys. You have the option to encrypt all of your file systems using the keys that you own and manage using the Vault service.

**Note:**

Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.

For more information, see Overview of Vault on page 5682.

For information about how to use your own key for new file systems, see Creating File Systems on page 2851. See To update the key for a file system on page 2884 for how to assign or change the key for an existing file system.

**Data Transfers**

FastConnect offers you the ability to accelerate data transfers. You can leverage the integration between FastConnect and the File Storage service to perform initial data migration, workflow data transfers for large files, and disaster recovery scenarios between two regions, among other things.
File Storage Space Allocation

The File Storage service allocates space in blocks of variable size in a way that is fine-tuned to minimize total customer cost and optimize performance for modern workloads. The minimum block size used is 8192 bytes. For example, if you create a 1-byte file, we allocate 8192 bytes. We use larger blocks to store larger files. To learn more about file system and snapshot usage, see File System Usage and Metering on page 2918.

How File Storage Permissions Work

File Storage service resources include file systems, mount targets, and export sets. The AUTH_UNIX style of authentication and permission checking is supported for remote NFS client requests. You use Oracle Cloud Infrastructure Identity and Access Management (IAM) policy language to define access to Oracle Cloud Infrastructure resources. You can consider exports and snapshots subsidiary resources of export sets and file systems, respectively. As such, they do not need their own permissions. Related resources include Oracle Cloud Infrastructure Compute instances and Oracle Cloud Infrastructure Networking virtual cloud networks (VCNs).

Oracle Cloud Infrastructure users require resource permissions to create, delete, and manage resources. Without the appropriate IAM permissions, you cannot export a file system through a mount target. Until a file system has been exported, compute instances cannot mount it. For more information about creating an IAM policy, see Let users create, manage, and delete file systems.

If you have successfully exported a file system on a subnet, then you use Networking security lists to control traffic to and from the subnet and, therefore, the mount target. Security lists act as a virtual firewall, allowing only the network traffic you specify to and from the IP addresses and port ranges configured in your ingress and egress rules. The security list you create for the subnet lets hosts send and receive packets and mount the file system. If you have firewalls on individual instances, use FastConnect, or use a virtual private network (VPN), the settings for those might also impact security at the networking layer. For more information about creating a security list for the File Storage service, see Creating File Systems on page 2851. See About Security on page 2830 for more information on how different types of security work together in your file system.

Regions and Availability Domains

You can use the File Storage service in all regions. For a list of supported regions, see Regions and Availability Domains on page 210.

When you create file systems and mount targets, you specify the availability domain they are created in. All file system data is then stored entirely within the availability domain the file system resides in. Within an availability domain, the File Storage service uses synchronous replication and high availability failover to keep your data safe and available.

You cannot move a file system to a different availability domain or region. However, you can take a snapshot of your data and use a tool such as rsync to copy your data to a different availability domain or region. To maximize performance for data protection operations, you can use the File Storage Parallel Tools suite. The Parallel File Tools suite provides parallel versions of tar, rm, and cp. See Managing Snapshots on page 2896 for more information on using snapshots to protect your data.

While it is possible to access mount targets from any availability domain in a region, for optimal performance, place File Storage resources in the same availability domain as the compute instances that access them.

Subnets can be either AD-specific or regional. You can create File Storage resources in either type of subnet. Regional subnets allow compute instances to connect to any mount target in the subnet regardless of AD, with no additional routing configuration. However, to minimize latency, place mount targets in the same AD as compute instances just as you would in an AD-specific subnet. For more information, see Overview of VCNs and Subnets on page 4322.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2672.

The following File Storage resources emit events:
• File systems
• Snapshots
• Mount targets
• Exports
• Export sets

**Resource Identifiers**

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 228.

**Ways to Access Oracle Cloud Infrastructure**

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 6152.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up **groups**, **compartments**, and **policies** that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference on page 3347.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Limits on Your File Storage Components**

See Service Limits on page 247 for a list of applicable limits and instructions for requesting a limit increase.

To set compartment-specific limits on file systems or mount targets, administrators can use compartment quotas.

**Additional Documentation Resources**

The following Oracle Cloud Infrastructure File Storage service solution playbooks and white papers are available:

- **Sharing the Application Tier File System in Oracle E-Business Suite Release 12.2 or 12.1.3 Using the Oracle Cloud Infrastructure File Storage Service**
  Learn best practices for using a File Storage service shared application tier file system for Oracle E-Business Suite.

- **Learn about deploying Oracle E-Business Suite on Oracle Cloud Infrastructure**
  Learn how file storage is part of a multihost, secure, high-availability topology for Oracle E-Business Suite.

- **Design a pilot-light disaster recovery (DR) topology**
  Learn how to use file storage in your disaster recovery topology.
About Security

Access Control

The File Storage service uses four different layers of access control. Each layer has its own authorization entities and methods which are separate from the other layers.

Tip:
Watch a video about security in File Storage.

The Oracle Cloud Infrastructure (OCI) policy layer uses policies to control what users can do within Oracle Cloud Infrastructure, such as creating instances, a VCN and its security rules, mount targets, and file systems.

The Network security layer controls which instance IP addresses or CIDR blocks can connect to a host file system. It uses VCN security list rules to allow or deny traffic to the mount target, and therefore access to any associated file system.

The NFS export option layer is a method of applying access control per-file system export based on source IP address that bridges the Network Security layer and the NFS v.3 Unix Security layer.

The NFS v.3 Unix security layer controls what users can do on the instance, such as installing applications, creating directories, mounting external file systems by a local mount point, and reading and writing files.

</tr>
</tbody>
</table>

Oracle Cloud Infrastructure Identity and Access Management

You can create users and groups in Oracle Cloud Infrastructure. Then, you can use policies to specify which users and groups can create, access, or modify resources such as file systems, mount targets, snapshots, and export options within. See Overview of Oracle Cloud Infrastructure Identity and Access Management to learn more about how to set up access.
Network Security

The network security layer allows you to use VCN network security groups (NSGs) and security rules to block the appropriate ports from specific IP addresses and CIDR blocks and restrict host access. However, it’s on an ‘all or nothing’ basis - the client either can or cannot access the mount target, and therefore all file systems associated with it. See Ways to Secure Your Network on page 4335 for general information about VCN security groups, security lists, and rules. See Configuring VCN Security Rules for File Storage on page 2832 for specific information about the security rules necessary for File Storage.

NFS v.3 Unix security

File Storage service supports the AUTH_UNIX style of authentication and permission checking for remote NFS client requests. When mounting file systems, we recommend that you use the -nosuid option. This option disables set-user-identifier or set-group-identifier bits. Remote users are prevented from gaining higher privileges using a setuid program. For more information, see Mounting File Systems on page 2859.

Remember that users in UNIX aren’t the same as users in Oracle Cloud Infrastructure - they’re not linked or associated in any way. The Oracle Cloud Infrastructure policy layer doesn’t govern anything that happens inside the file system, the UNIX security layer does. Conversely, the UNIX security layer doesn’t govern creating file systems or mount targets in Oracle Cloud Infrastructure.

File Storage does not support file level Access Control Lists (ACLs). Only user, group, and world permissions are supported. File Storage uses the NFSv3 protocol, which doesn't include support for ACLs. setfacl fails on mounted file systems. getfacl returns only standard permissions.

**Note:**

Some implementations might extend the NFSv3 protocol and add support for ACLs as part of a separate rpc program.

**SETFACL error example**

This example shows an example of a setfacl error:

```
[opc@example setfacl_testing]$ ls -ld test
drwxr--r--. 2 opc opc 0 Jul  2 10:31 test
[opc@example setfacl_testing]$ setfacl -m u:applmgr:r test
setfacl: test: Operation not supported
[opc@example setfacl_testing]$[opc@example setfacl_testing]$ getfacl test
# file: test
# owner: opc
# group: opc
user::rwx
group::r--
other::r--
[opc@example setfacl_testing]$
```

**NFS export options**

NFS export options are a method of applying access control at both the network security layer and the NFS v.3 Unix security layer. You can use NFS export options to limit access levels by IP addresses or CIDR blocks connecting to multiple file systems through exports of an associated mount target. Access can be restricted so that each client’s file system is inaccessible and invisible to the other, allowing for managed hosted environment security. Moreover, you can set NFS v.3 Unix security permissions for read-only, read/write, or root-squash for your file systems. See Working with NFS Export Options on page 2838 for more information.
Encryption

Within Oracle Cloud Infrastructure

All data is encrypted at rest. You can leave all encryption-related matters to Oracle, or you can choose to manage your own encryption using the Oracle Cloud Infrastructure Vault (KMS) service. You can use KMS to create master encryption keys and data encryption keys, rotate keys to generate new cryptographic material, enable or disable keys for use in cryptographic operations, assign keys to file systems, and use keys for encryption and decryption.

Note:
Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.

For more information, see Overview of Vault on page 5682.

Between Instances and Mounted File Systems

In-transit encryption provides a way to secure your data between instances and mounted file systems using TLS v. 1.2 (Transport Layer Security) encryption.

In-transit encryption is enabled by installing a client package on your instance. The package creates an NFS endpoint, network namespace, and network interface. A forwarder process receives requests from the NFS client, encrypts them and sends them to the mount target using a TLS tunnel.

For more information, see Using In-transit Encryption on page 2847.

Configuring VCN Security Rules for File Storage

Before you can mount a file system, you must configure security rules to allow traffic to the mount target's VNIC using specific protocols and ports. Security rules enable traffic for the following:

- Open Network Computing Remote Procedure Call (ONC RPC) rpcbind utility protocol
- Network File System (NFS) protocol
- Network File System (MOUNT) protocol
- Network Lock Manager (NLM) protocol

File Storage Security Rule Scenarios

There are three basic scenarios that require different security rules for File Storage:

Scenario A: Mount target and instance in the same subnet

In this scenario, the mount target that exports the file system is in the same subnet as the instance you want to mount the file system to.

- Stateful ingress from ALL ports in source CIDR block to TCP ports 111, 2048, 2049, and 2050.
- Stateful ingress from ALL ports in source CIDR block to UDP ports 111 and 2048.
- Stateful egress from TCP ALL ports to ports 111, 2048, 2049, and 2050 in destination CIDR block.
- Stateful egress from UDP ALL ports to port 111 in destination CIDR block.

Important:

Oracle recommends that NFS clients be limited to reserved ports. To do this, set the Source Port range to 1-1023. You can also set export options for a file system to require clients to connect from a privileged source port. For more information, see Working with NFS Export Options on page 2838.

Here's an example of the rules for Scenario A set up for a single subnet that contains both the mount target and the instance. In this example, both the mount target and the instance are in CIDR block 10.0.0.0/24:
Using a security list

Security lists are associated with subnets. You can set up the required security rules in the default security list for the mount target subnet, or create a new security list. Security list rules apply to all resources in the subnet.

Using a network security group (NSG)

Another method for applying security rules is to set them up in a network security group (NSG), and then add the mount target to the NSG. Unlike security list rules that apply to all VNICs in the subnet, NSGs apply only to the resource VNICs you add to the NSG.

See Ways to Enable Security Rules for File Storage on page 2836 for an overview of these methods and instructions about how to use them to set up security rules.

Scenario B: Mount target and instance in different subnets

In this scenario, the mount target that exports the file system is in a different subnet than the instance you want to mount the file system to. Security rules must be configured for both the mount target and the instance either in a security list for each subnet, or a network security group (NSG) for each resource.

Set up the following the following security rules for the mount target. Specify the instance IP address or CIDR block as the source for ingress rules and the destination for egress rules:

- Stateful ingress from ALL ports in the source instance CIDR block to TCP ports 111, 2048, 2049, and 2050.
- Stateful ingress from ALL ports in the source instance CIDR block to UDP ports 111 and 2048.
- Stateful egress from TCP ports 111, 2048, 2049, and 2050 to ALL ports in the destination instance CIDR block.
- Stateful egress from UDP port 111 ALL ports in the destination instance CIDR block.

**Important:**

Oracle recommends that NFS clients be limited to reserved ports. To do this, set the Source Port range to 1-1023. You can also set export options for a file system to require clients to connect from a privileged source port. For more information, see Working with NFS Export Options on page 2838.

Next, set up the following security rules for the instance. Specify the mount target IP address or CIDR block as the source for ingress rules and the destination for egress rules:

- Stateful ingress from source mount target CIDR block TCP ports 111, 2048, 2049, and 2050 to ALL ports.
- Stateful ingress from source mount target CIDR block UDP port 111 to ALL ports.
- Stateful egress from ALL ports to destination mount target CIDR block TCP ports 111, 2048, 2049, and 2050.
- Stateful egress from ALL ports to destination mount target CIDR block UDP ports 111 and 2048.
Here's an example of the rules for Scenario B set up in security list rules for the instance and mount target. This example shows rules for specific source and destination CIDR blocks.

**Ingress** rules for the **mount target's** NSG or subnet security list. The *instance CIDR block* 10.0.0.0/24 is the source:

Using a Security List

Security lists are associated with subnets. If you use security lists to set up your security rules, you need to set up the mount target rules in the mount target subnet, and the instance rules in the instance subnet. You can add the rules to the default security list for each subnet, or create new security lists.

Using a network security group (NSG)

Another method for applying security rules is to set them up in a network security group (NSG), and then add the mount target and instance to the NSG. Unlike security list rules that apply to all VNICs in the subnet, NSGs apply only to resource VNICs you add to the NSG.

See Ways to Enable Security Rules for File Storage on page 2836 for an overview of these methods and instructions about how to use them to set up security rules.

Scenario C: Mount target and instance use in-transit encryption

In this scenario, in-transit encryption secures your data between instances and mounted file systems using TLS v.1.2 (Transport Layer Security) encryption. See Using In-transit Encryption on page 2847 for more information.

You can limit the source or destination to the IP address or CIDR block of your choice. Alternatively, you can allow traffic from all sources or destinations.

Set up the following security rules for the mount target:

- Stateful ingress from ALL ports in the source CIDR block to TCP port 2051.
- Stateful egress from TCP port 2051 to ALL ports in the destination CIDR block.

Using a security list

Security lists are associated with subnets. You can set up the required security rules in the default security list for the mount target subnet, or create a new security list. Security list rules apply to all resources in the subnet.
Using a network security group (NSG)

Another method for applying security rules is to set them up in a network security group (NSG), and then add the mount target to the NSG. Unlike security list rules that apply to all VNICs in the subnet, NSGs apply only to resource VNICs you add to the NSG.

See Ways to Enable Security Rules for File Storage on page 2836 for an overview of these methods and instructions about how to use them to set up security rules.

Ways to Enable Security Rules for File Storage

The Networking service offers two virtual firewall features that both use security rules to control traffic at the packet level. The two features are:

- **Security lists:** The original virtual firewall feature from the Networking service. When you create a VCN, a default security list is also created. Add the required rules to the security list for the subnet that contains the mount target. (If you're setting up Scenario B: Mount target and instance in different subnets on page 2833, you have to add rules for both subnets.) See Setting Up Required Rules in a Security List on page 2836 for instructions.

- **Network security groups (NSGs):** A subsequent feature designed for application components that have different security postures. Create an NSG that contains the required rules, and then add the mount target to the NSG. Alternatively, you can add the required rules to a previously existing NSG, and add the mount target to the NSG. Each mount target can belong to up to five (5) NSGs. (If you're setting up Scenario B: Mount target and instance in different subnets on page 2833, you have to add both the mount target and instance to an NSG that contains the required security rules.) See Setting Up Required Rules in a Network Security Group (NSG) on page 2837 for instructions.

Important:

You can use security lists alone, network security groups alone, or both together. It depends on your particular security needs.

If you choose to use both security lists and network security groups, the set of rules that applies to a given mount target VNIC is the combination of these items:

- The security rules in the security lists associated with the VNIC's subnet
- The security rules in all NSGs that the VNIC is in

It doesn't matter which method you use to apply security rules to the mount target VNIC, as long as the ports for protocols necessary for File Storage are correctly configured in the rules applied.

See Security Rules on page 4338, Security Lists on page 4355, and Network Security Groups on page 4346 for more information, examples, and scenarios about how these features interact in your network. Networking Overview on page 4232 provides general information about networking. See About Security on page 2830 for information about how security rules work with other types of security in File Storage.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let network admins manage a cloud network covers management of all networking components, including security lists and NSGs. See the Policy Reference on page 3347 for more information.

If you're new to policies, see Getting Started with Policies and Common Policies.

Using the Console

Setting Up Required Rules in a Security List

You can add the required rules to a pre-existing security list associated with a subnet, such as the default security list that is created along with the VCN. See To create a security list on page 4358 for more information.
To add required rules to a security list

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. In the Scope section, select the compartment that contains the VCN the subnet is in.
3. Click the name of the VCN.
4. On the details page for the cloud network, in Resources, and then click Security Lists.
5. Click the name of the security list used by the subnet.
7. Click Add Ingress Rules.
   - Specify that it's a stateful rule by leaving the check box clear. (For more information about stateful and stateless rules, see Stateful Versus Stateless Rules on page 4344). By default, rules are stateful unless you specify otherwise.
   - To allow traffic from the subnet of the cloud network, click Source Type, choose CIDR, and then enter the CIDR block for the subnet. For example, 10.0.0.0/24.
   - Click IP Protocol, and then choose the protocol. For example, TCP.
   - In Source Port Range, specify the range of ports that you want to allow traffic from. Alternatively, accept the default of All to allow traffic from any source port.
   - Click Destination Port Range, and then enter individual ports or a port range. For example, 2048-2050.
8. Click + Additional Ingress Rule to create more ingress rules.
9. When you're done, click Add Ingress Rules.
11. Click Add Egress Rules.
   - Specify that it's a stateful rule by leaving the check box clear.
   - Click Destination Type, choose CIDR, and then enter the CIDR block for the subnet. For example, 10.0.0.0/24.
   - Click IP Protocol, and then choose the protocol. For example, TCP.
   - In Source Port Range, and then enter individual ports or a port range. For example, 2048-2050.
   - In Destination Port Range, accept the default of All to allow traffic to any destination port.
12. Click + Additional Egress Rule to create more egress rules.
13. When you're done, click Add Egress Rules.

Setting Up Required Rules in a Network Security Group (NSG)

The general process for setting up NSGs that work with File Storage is:

1. Create an NSG with the required security rules. (Alternatively, you can add them to a previously existing NSG.)
2. Add the mount target (or more specifically, the mount target's VNIC) to the NSG. You can do this when you create the mount target, or you can update the mount target and add it to one or more NSGs that contain the required security rules.
3. If you're setting up Scenario B: Mount target and instance in different subnets on page 2833, you'll have to add both the mount target and instance to an NSG that contains the required security rules.

To create an NSG with the required security rules

Prerequisite: Become familiar with the parts of security rules.

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Click the VCN you're interested in.
5. Enter the following:
   - **Name**: A descriptive name for the network security group. The name doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   - **Create in Compartment**: The compartment where you want to create the network security group, if different from the compartment you're currently working in.
   - **Show Tagging Options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

6. Click **Next**.

7. Enter ingress rules.
   - Specify that it's a stateful rule by leaving the check box clear. (For more information about stateful and stateless rules, see Stateful Versus Stateless Rules on page 4344). By default, rules are stateful unless you specify otherwise.
   - In **Direction**, choose **Ingress**.
   - To allow traffic from the subnet of the cloud network, click **Source Type**, choose **CIDR**, and then enter the CIDR block for the subnet. For example, `10.0.0.0/24`.
   - Click **IP Protocol**, and then choose the protocol. For example, **TCP**.
   - In **Source Port Range**, specify the range of ports that you want to allow traffic from. Alternatively, accept the default of **All** to allow traffic from any source port.
   - Click **Destination Port Range**, and then enter individual ports or a port range. For example, **2048-2050**.

8. Click **+ Another Rule** to create more ingress rules.

9. Enter egress rules.
   - Specify that it's a stateful rule by leaving the check box clear.
   - In **Direction**, choose **Egress**.
   - Click **Destination Type**, choose **CIDR**, and then enter the CIDR block for the subnet. For example, `10.0.0.0/24`.
   - Click **IP Protocol**, and then choose the protocol. For example, **TCP**.
   - In **Source Port Range**, and then enter individual ports or a port range. For example, **2048-2050**.
   - In **Destination Port Range**, accept the default of **All** to allow traffic to any destination port.

10. Click **+ Another Rule** to create more egress rules.

11. When you're done, click **Create**.

### To add a mount target to an NSG

- When creating a mount target along with a file system: See To create a file system on page 2852.
- When creating only the mount target: See To create a mount target on page 2889.

#### For an existing mount target:

1. Open the navigation menu and click **Storage**. Under File Storage, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target you're interested in, click the Actions menu, and then click **View Mount Target Details**.
4. In the **Mount Target Information** tab, click the **Edit** link next to Network Security Groups.
5. Select a **Compartment** and NSG from the list.
6. Click **Save**.

### To add an instance to an NSG

See To add or remove a resource from an NSG on page 4353 for instructions on how to add an instance to an NSG.

### Working with NFS Export Options

This topic describes the basic features of NFS export options, and how to control client access to your file system.
Overview

NFS export options enable you to create more granular access control than is possible using just security list rules to limit VCN access. You can use NFS export options to specify access levels for IP addresses or CIDR blocks connecting to file systems through exports in a mount target. Access can be restricted so that each client’s file system is inaccessible and invisible to the other, providing better security controls in multi-tenant environments.

Using NFS export option access controls, you can limit clients' ability to connect to the file system and view or write data. For example, if you want to allow clients to consume but not update resources in your file system, you can set access to Read Only. You can also reduce client root access to your file systems and map specified User IDs (UIDs) and Group IDs (GIDs) to an anonymous UID/GID of your choice. For more information about how NFS export options work with other security layers, see About Security on page 2830.

Tip:
Watch a video about working with NFS export options in File Storage.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users create, manage, and delete file systems allows users to manage NFS export options.

If you're new to policies, see Getting Started with Policies and Common Policies.

Exports

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

See To create an export for a file system on page 2878 for more information.

NFS Export Options

NFS export options are a set of parameters within the export that specify the level of access granted to NFS clients when they connect to a mount target. An NFS export options entry within an export defines access for a single IP address or CIDR block range. You can have up to 100 options per export.

Each separate client IP address or CIDR block you want to define access for needs a separate export options entry in the export. For example, if you want to set options for NFS client IP addresses 10.0.0.6, 10.0.0.8, and 10.0.0.10, you need to create three separate entries, one for each IP address.

File Storage service considers the listed order of each export options entry for the export. During an NFS request by a client, File Storage service applies the first set of options that matches the client Source IP address. Only the first set is applied; the rest are ignored.

For example, consider the following two export options entries specifying access for an export:

Entry 1: Source: 10.0.0.0/16, Access: Read Only
Entry 2: Source: 10.0.0.8, Access: Read/Write

In this case, clients who connect to the export from IP address 10.0.0.8 have Read Only access. The request Source IP address is contained in the CIDR block specified in the first entry, and File Storage Service applies the options in the first match.
Important:

File systems can be associated with one or more exports, contained within one or more mount targets. If the client source IP address does not match any entry on the list for a single export, then that export is not visible to the client. However, the file system could be accessed through other exports on the same or other mount targets. **To completely deny client access to a file system, be sure that the client source IP address or CIDR block is not included in any export for any mount target associated with the file system.**

The following options can be set to control export access:

- **Source**: The IP address or CIDR block of a connecting NFS client.
- **Require Privileged Source Port (true/false)**: This setting determines whether the NFS clients specified in source are required to connect from a privileged source port. Privileged ports are any port including 1-1023. On Unix-like systems, only the root user can open privileged ports. Setting this value to true disallows requests from unprivileged ports. The default for this setting is different depending on how the export is created. Creating an export without an explicit ClientOption array sets the requirePrivilegedSourcePort attribute of the client option to false. When you create a ClientOption array explicitly, requirePrivilegedSourcePort defaults to true. For example, creating an export in the Console using the default selections sets requirePrivilegedSourcePort to false. Creating an export in the API along with a ClientOption array sets requirePrivilegedSourcePort to true.

**Important:**

When **Require Privileged Source Port** is set to true, you also have to follow these additional configuration steps:

1. When mounting the file system from a Unix-like system, include the resvport option in your mount command when mounting. For example:

   ```
   sudo mount -o resvport 10.x.x.x:/fs-export-path /mnt/yourmountpoint
   ```

   For more information, see [Mounting File Systems From Unix-Style Instances](#) on page 2861.

2. When mounting the file system from a Windows system, be sure the UseReserverdPorts registry key value is set to 1.

   For more information, see [Mounting File Systems From Windows Instances](#) on page 2870.

- **Access (Read_Only, Read_Write)**: This setting specifies the source NFS client access. If unspecified, defaults to Read_Write.
- **Identity Squash (All, Root, None)**: This setting determines whether the source clients accessing the file system have their User ID (UID) and Group ID (GID) remapped to anonymousUid and anonymousGid. If you choose All, all users and groups are remapped. If Root, only the root user UID/GID combination 0/0 is remapped. If None, no users are remapped. If unspecified, defaults to None.
- **anonymousUid**: This setting is used along with the Identity Squash option. When remapping users, you can use this setting to change the default anonymousUid of 65534 to any user ID of your choice.
- **anonymousGid**: This setting is used along with the Identity Squash option. When remapping groups, you can use this setting to change the default anonymousGid of 65534 to any group ID of your choice.
**Typical Access Control Scenarios**

When you create file system and export, the NFS export options for that file system are set to the following defaults, which allow full access for all NFS client source connections. These defaults must be changed if you want to restrict access:

- **Source**: 0.0.0.0/0 (All)
- **Require Privileged Source Port**: False
- **Access**: Read_Write
- **Identity Squash**: None

**Scenario A: Control Host Based Access**

Provide a managed hosted environment for two clients. The clients share a mount target, but each has their own file system, and cannot access each other's data. For example:

- Client A, who is assigned to CIDR block 10.0.0.0/24, requires Read/Write access to file system A, but not file system B.
- Client B, who is assigned to CIDR block 10.1.1.0/24, requires Read/Write access to file system B, but not file system A.
- Client C, who is assigned to CIDR block 10.2.2.0/24, has no access of any kind to file system A or file system B.
- Both file systems A and B are associated to a single mount target, MT1. Each file system has an export contained in the export set of MT1.

Since Client A and Client B access the mount target from different CIDR blocks, you can set the client options for both file system exports to allow access to only a single CIDR block. Client C is denied access by not including its IP address or CIDR block in the NFS export options for any export of either file system.

**Console Example**

Set the export options for file system A to allow Read/Write access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.

![Edit Export Options](image1)

Set the export options for file system B to allow Read/Write access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.

![Edit Export Options](image2)
CLI Example

Set the export options for file system A to allow Read_Write access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.

```bash
oci fs export update --export-id <File_system_A_export_ID> --
export-options '[["source":"10.0.0.0/24","require-privileged-source-port":"true","access":"READ_WRITE","identity-squash":"NONE","anonymous-uid":65534,"anonymous-gid":65534}]'
```

Set the export options for file system B to allow Read_Write access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.

```bash
oci fs export update --export-id <File_system_B_export_ID> --export-
options '[["source":"10.1.1.0/24 ","require-privileged-source-port":true,"access":"READ_WRITE","identity-squash":"NONE","anonymous-uid":65534","anonymous-gid":65534}]'
```

API Example

Set the export options for file system A to allow READ_WRITE access only to Client A, who is assigned to CIDR block 10.0.0.0/24. Client B and Client C are not included in this CIDR block, and cannot access the file system.

```yaml
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "exportOptions": [
    {
      "source": "10.0.0.0/24",
      "requirePrivilegedSourcePort": true,
      "access": "READ_WRITE",
      "identitySquash": "NONE",
      "anonymousUid": 65534,
      "anonymousGid": 65534
    }
  ]
}
```

Set the export options for file system B to allow READ_WRITE access only to Client B, who is assigned to CIDR block 10.1.1.0/24. Client A and Client C are not included in this CIDR block, and cannot access the file system.

```yaml
PUT/<Current_API_Version>/exports/<File_System_B_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
  "exportOptions": [
    {
      "source": "10.1.1.0/24",
      "requirePrivilegedSourcePort": true,
      "access": "READ_WRITE",
      "identitySquash": "NONE",
      "anonymousUid": 65534,
      "anonymousGid": 65534
    }
  ]
}
```

Scenario B: Limit the Ability to Write Data

Provide data to customers for consumption, but don’t allow them to update the data.
For example, you'd like to publish a set of resources in file system A for an application to consume, but not change. The application connects from IP address 10.0.0.8.

**Console Example**

Set the source IP address 10.0.0.8 to Read Only in the export for file system A:

![Edit Export Options](image)

**CLI Example**

Set the source IP address 10.0.0.8 to READ_ONLY in the export for file system A:

```sh
ci fs export update --export-id <File_System_A_export_OCID> --
export-options '{"source":"10.0.0.8","require-privileged-source-port":true,"access":"READ_ONLY","identitysquash":"NONE","anonymousuid":65534,"anonymousgid":65534}'
```

**API Example**

Set the source IP address 10.0.0.8 to READ_ONLY in the export for file system A:

```json
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>

```exportOptions`: [{
  "source": "10.0.0.8",
  "requirePrivilegedSourcePort": true,
  "access": "READ_ONLY",
  "identitySquash": "NONE",
  "anonymousUid": 65534,
  "anonymousGid": 65534
}]
```

**Scenario C: Improve File System Security**

To increase security, you'd like to limit the root user's privileges when connecting to File System A. Use Identity Squash to remap root users to UID/GID 65534. In Unix-like systems, this UID/GID combination is reserved for 'nobody', a user with no system privileges.
Console Example

**CLI Example**

`oci fs export update --export-id <File_System_A_export_OCID> --export-options '[["source":"0.0.0.0/0","require-privileged-source-port":"true","access":"READ_WRITE","identitysquash":"ROOT","anonymousuid":65534,"anonymousgid":65534]]'`

**API Example**

```
PUT/<Current_API_Version>/exports/<File_System_A_export_OCID>
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
   "exportOptions": [
   {
      "source": "0.0.0.0/0",
      "requirePrivilegedSourcePort": true,
      "access": "READ_WRITE",
      "identitySquash": "ROOT",
      "anonymousUid": 65534,
      "anonymousGid": 65534
   }
   ]
}
```

**Tip:**
If you don't want a file system to be visible to any clients, you can set all of the properties in the `exportOptions` array to empty values. For example,

```json
{
   "exportOptions": [
   {
      "source": "",
      "requirePrivilegedSourcePort": "",
      "access": "",
      "identitySquash": ""
   }
   ]
}
```

**Using the Console**

*To set export options for a file system*

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. In the **List Scope** section, select a compartment. All of the file systems in the selected compartment are displayed.
3. Find the file system you want to set export options for, click the **Actions** menu, and then click **View File System Details**.
4. In the **Exports** list, find the export you want to set export options in, click the Actions menu, and then click **View Export Details**. If there is no export listed for the file system, you can create one. See **To create an export for a file system** on page 2878 for more information.

<table>
<thead>
<tr>
<th>Tip:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To be sure you be sure that you select the correct export, check the following:</td>
</tr>
<tr>
<td>• <strong>The export path:</strong> This path uniquely identifies the file system within the mount target. <strong>No two exports in a mount target can have the same export path, even if the exports are for the same file system.</strong></td>
</tr>
<tr>
<td>• <strong>The mount target name:</strong> File systems can be exported through more than one mount target. Be sure that you’ve selected the export for the correct mount target.</td>
</tr>
</tbody>
</table>

5. Click **Edit Export Options**.

6. Make one or more of these changes:
   - Change an export option entry in the list.
   - Click **Another Option** to create a new export option entry.
   - Click the Actions menu for an entry and move it up or down in the list.

7. When you're done, click **Update**.

**To view exports for a file system**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the file system in the list, click the Actions menu, and then click **View File System Details**.
4. Under **Resources**, click **Exports**.

**To view all exports in a mount target**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target in the list, click the Actions menu, and then click **View Details**.
4. Under **Resources**, click **Exports**.

**Using the CLI**

For information about using the CLI, see **Command Line Interface (CLI)** on page 6117.

**To create an export**

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set. This example creates an export along with its NFS export options.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path "</pathname>" --export-options "{"source":"10.0.0.0/16","requireprivilegedsourceport":"true","access":"READWRITE","identitysquash":"NONE","anonymousuid":0,"anonymousgid":0}"
```

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Export Path Names</strong></td>
</tr>
<tr>
<td>The path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For any two export resources associated with the same export set, the path sequence for the first export resource can’t contain the complete path element sequence of the second export sequence. Paths...</td>
</tr>
</tbody>
</table>
can't end in a slash. No path element can be a period (.) or two periods in sequence (..). Lastly, no path can exceed 255 bytes.

Examples:

Acceptable:
/example and /path
/example1 and /example2

Not Acceptable:
/example and /example/path
/ and /example
/example/
/example/path/..example1

To update export options

Open a command prompt and run `oci fs export update`. To update export options for a specified file system, use `--export-options`.

For example:

```bash
oci fs export update --export-id <export_OCID> --export-options '[["source":"<0.0.0.0/0>","require-privileged-source-port":"true","access":"READ_ONLY","identity-squash":"ROOT","anonymous-uid":"65534","anonymous-gid":"65534"]]'
```

WARNING: Updates to export-options will replace any existing values. Are you sure you want to continue? [y/N]: y

Tip:

If you don't want a file system to be visible to any clients, you can set all of the properties in Client Options to empty values. For example,

```bash
oci fs export update --export-id <export_OCID> --export-options '[["source":"","require-privileged-source-port":"true","access":"READ_ONLY","identity-squash":"ROOT","anonymous-uid":"65534","anonymous-gid":"65534"]]'
```

To list exports

Open a command prompt and run `oci fs export list` to list all exports in a specified compartment.

For example:

```bash
oci fs export list --compartment-id <target_compartment_id>
```

To delete an export

Open a command prompt and run `oci fs export delete` to delete an export.

For example:

```bash
oci fs export delete --export-id <export_OCID>
```
Caution:
When you delete an export, you can no longer mount the file system using the file path specified in the deleted export.

Using the API

- CreateExport
- UpdateExport
- ListExports
- GetExport
- DeleteExport

Using In-transit Encryption

In-transit encryption provides a way to secure your data between instances and mounted file systems using TLS v.1.2 (Transport Layer Security) encryption. Together with other methods of security such as Oracle Cloud Infrastructure Vault (KMS) and File Storage's encryption-at-rest, in-transit encryption provides for end-to-end security.

- For general information about getting started with file systems, see Overview of File Storage on page 2825.
- For more information on the Vault service, see Overview of Vault on page 5682.
- For more information on securing your file system, see About Security on page 2830 and the Securing File Storage on page 5350 reference in the Security Guide.

How In-transit Encryption is Enabled

In-transit encryption doesn't require any updates to your file system's mount target or export configuration. To enable in-transit encryption, you install a package called oci-fss-utils on your instance. The oci-fss-utils package creates a network namespace and virtual network interface on your instance and provides a local NFS endpoint. The oci-fss-utils package also runs a forwarder process in the background called oci-fss-forwarder.

The network namespace isolates the forwarder process from your instance’s networking environment. The virtual network interface provides the forwarder process a unique IP address. The local NFS endpoint provides NFS connection capability.

The file system is mounted using a special command that initiates encryption. After the file system is mounted, the oci-fss-forwarder process connects the local NFS client to the NFS endpoint. The process then receives requests from the NFS client, encrypts them and sends them to the mount target using a TLS tunnel.

Here are the general steps for setting up In-transit encryption:

1. Download the oci-fss-utils package. For instructions, see Task 1: Download the OCI-FSS-UTILS package on page 2848
2. Install the oci-fss-utils package on the instance. For instructions, see Task 2: Install the OCI-FSS-UTILS package on Oracle Linux or CentOS on page 2849
3. Use the in-transit encryption command to mount the file system. For instructions, see Task 3: Mount the file system with the encryption command on page 2849

Limitations and Considerations

- In-transit encryption is only supported for instances running Oracle Enterprise Linux 7 or CentOS7 versions.
- The in-transit encryption installation package is distributed as an RPM for Oracle Linux and CentOS and can be downloaded at cloud-infrastructure-file-storage-downloads.html
- You must install the oci-fss-utils package on every instance that requires encrypted access to a mount target.
- The number of encrypted NFS/TLS connections for a single mount target is limited to 64. This limitation is caused by TLS memory requirements. Unlike NFS connections, TLS connections do not share memory buffers. So, once a TLS connection has been established, the allocated memory stays dedicated to it.
- DNS hostnames are not supported for mounting encrypted file systems with oci-fss-forwarder. Use the mount target IP address to mount encrypted file systems.
Important:

If you are not using the latest version of the `oci-fss-utils` package, you might experience SSL connection failures. SSL connection failures can cause NFSv3 operations to fail.

We recommend that you always upgrade to the latest version of the `oci-fss-utils` package as soon as it's available. See File Storage Release Notes for information about new RPM version releases.

Setting up In-transit Encryption

Prerequisites

- Add the following new rules to the security list for the mount target subnet. Alternatively, you can add the following rules to a Network Security Group (NSG) and then add the mount target to the NSG. For more information and instructions about adding security list rules for File Storage, see Configuring VCN Security Rules for File Storage on page 2832.
  - A stateful **ingress** rule allowing **TCP** traffic to a **Destination Port Range** of **2051**.
  - A stateful **egress** rule allowing **TCP** traffic from a **Source Port Range** of **2051**.

Important:

Standard (unencrypted) access to File Storage mount targets requires access to the following ports:

- Stateful ingress to TCP ports 111, 2048, 2049, and 2050.
- Stateful ingress to UDP ports 111 and 2048.
- Stateful egress from TCP ports 111, 2048, 2049, and 2050.
- Stateful egress from UDP port 111.

If you have previously set up rules for standard access, and you want to enforce encrypted access only, then you can disable the standard access ports.

*Only the rules for TCP port 2051 are required for encrypted access.*

Setup Tasks

**Task 1: Download the OCI-FSS-UTILS package**

Internet access is required to download the RPM installation package. If the destination instance doesn't have internet access, you can download the RPM to a staging instance on your network and then use the `scp` command to securely copy the RPM from the staging instance to the destination instance.

The `scp` command requires an SSH key pair to authenticate a remote user. If your instances are UNIX-style systems, you probably already have the `ssh-keygen` utility installed. To determine if it's installed, open a shell or terminal and type `ssh-keygen` on the command line. If it's not installed, you can obtain OpenSSH for UNIX from [http://www.openssh.com/portable.html](http://www.openssh.com/portable.html).

1. (Optional) Create a directory for the RPM installation package on the destination instance. For example:

   ```bash
   sudo mkdir -p /<rpm_directory_name>
   ```

2. Download the `oci-fss-utils` package from [cloud-infrastructure-file-storage-downloads.html](http://cloud-infrastructure-file-storage-downloads.html) to the directory on the destination instance or to a staging instance on your network.

   If you've downloaded the package directly to the destination instance, skip the next step and proceed directly to **Task 2: Install the OCI-FSS-UTILS package on Oracle Linux or CentOS** on page 2849.

   If you've downloaded the package to a staging instance, proceed to the next step in these instructions.
3. Open a terminal window on the staging instance, and use the `scp` command to securely copy the RPM from the staging instance to the destination instance. For example:

```
scp -i <private_key> <path_to_.rpm> <username>@<destination-public-ip-address>:/<rpm_directory_name>
```

After the RPM package is downloaded to the target instance, proceed to Task 2: Install the OCI-FSS-UTILS package on Oracle Linux or CentOS on page 2849.

**Task 2: Install the OCI-FSS-UTILS package on Oracle Linux or CentOS**

1. Open a terminal window on the destination instance.
2. Install the package using the following command:

```
sudo yum localinstall oci-fss-utils-<version>.rpm
```

The package creates a namespace called `ns1` in your instance, which contains a default network interface for ethernet traffic. A network interface pair is created for each mount target.

After the package has finished installing, proceed to Task 3: Mount the file system with the encryption command on page 2849.

**Task 3: Mount the file system with the encryption command**

1. Open a terminal window in your instance.
2. Create a mount point by typing the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

```
sudo mkdir -p /mnt/yourmountpoint
```
3. Mount the file system using the following command:

```
sudo mount -t oci-fss 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `yourmountpoint`
with the path to the local mount point. The export path is the path to the file system (relative to the mount target IP address).

If you have installed `oci-fss-utils` version 2.0-1 or above, you can mount the file system in FIPS approved mode by including `-o fips` in the mount command. For example:

```bash
sudo mount -t oci-fss -o fips 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

**Important:**

DNS hostnames are not currently supported for mounting file systems with the `mount -t oci-fss` command. You must use the mount target IP address.

Example output from the `mount -t oci-fss` command:

```
```

Each time you mount a file system using this command, a new `oci-fss` service is initiated with an incrementing sequence number between 2 and 255. For example, `oci-fss-2.service`, `oci-fss-3.service`, and so on.

**Tip:**

You can use the `resvport` option to restrict the client to using a specific reserved port. For example:

```bash
sudo mount -t oci-fss -o resvport=900 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

## Managing In-transit Encryption

### To auto-mount a file system

Auto-mount ensures that a file system is automatically re-mounted on an instance if it is rebooted.

1. Open a terminal window on the instance. Mount the file system as described in .
2. Open the `/etc/fstab` file for editing:

   ```bash
cd /etc
   vi fstab
   ```
3. Add the following line to the fstab file:

```
10.x.x.x:/fs-export-path /mnt/yourmountpoint oci-fss x-
  systemd.requires=oci-fss-init.service,defaults,nofail 0 0
```

Replace 10.x.x.x: with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `yourmountpoint` with the path to the local mount point.

If you have installed `oci-fss-utils` version 2.0-1 or above, you can mount the file system in FIPS approved mode by including `-o fips` in the mount command. For example:

```
10.x.x.x:/fs-export-path /mnt/yourmountpoint oci-fss x-
  systemd.requires=oci-fss-init.service,defaults,nofail,fips 0 0
```

**Important:**

DNS hostnames are not currently supported for mounting file systems with the mount `-t oci-fss` command. You must use the mount target IP address.

**Tip:**

You can use the resvport option to restrict the client to using a specific reserved port. For example:

```
10.x.x.x:/fs-export-path /mnt/yourmountpoint
  oci-fss x-systemd.requires=oci-fss-
  init.service,defaults,nofail,resvport=900 0 0
```

**To unmount a file system**

When you unmount a file system, you must use another `oci-fss-utils` command to ensure that the associated local network namespace is removed:

1. Open a terminal window on the instance.
2. Use the following command to unmount the file system:

```
sudo umount -t oci-fss /mnt/yourmountpoint
```

Replace `yourmountpoint` with the path to the local mount point.

**To uninstall the OCI-FSS-UTILS package**

1. First, unmount all mounted file systems. For instructions, see To unmount a file system on page 2851.
2. Open a terminal window on the instance.
3. Type the following command to uninstall the `oci-fss` package:

```
sudo yum remove oci-fss-utils
```

**Creating File Systems**

You can create a shared file system in the cloud using the File Storage service. Network access to your file system is provided through a `mount target`. Exports control how NFS clients access file systems when they connect to a mount target. File systems must have at least one `export` in one mount target for any instance to `mount` and use the file system. When you use the console to create your first file system, the workflow also creates a mount target and export for it.
**Required IAM Service Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users create, manage, and delete file systems allows users to create file systems. Since mount targets are network endpoints, users must also have "use" permissions for VNICs, private IPs, private DNS zones, and subnets to create or delete a mount target. See the Policy Reference on page 3347 for more information.

If you're new to policies, see Getting Started with Policies and Common Policies.

**Prerequisites**

Before you create a file system, you need:

- At least one Virtual Cloud Network (VCN) in a compartment. For more information, see VCNs and Subnets on page 4321.
- Correctly configured security rules for the file system mount target. Security rules can be created in the security list for the mount target subnet, or in a Network Security Group (NSG) that you add the mount target to. See Security Rules on page 4338 for information about how security rules work in Oracle Cloud Infrastructure. Use the instructions in Configuring VCN Security Rules for File Storage on page 2832 to set up security rules correctly for your file systems.

**Using the Console**

**To create a file system**

2. In the left-hand navigation, in the List Scope section, under Compartment, select a compartment.
3. Click Create File System.

   **Note:**

   File systems are encrypted by default. You cannot turn off encryption.

4. You can choose to accept the system defaults, or change them by clicking Edit Details.

   **File System Information:**

   - **Name:** File Storage service creates a default name using "FileSystem-YYMMDD-HHMM". Optionally, change the default name for the file system. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the file system. Avoid entering confidential information.
   - **Availability domain:** The first availability domain selected in the left panel list is used as default.
   - **Encryption:** File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key.

   **Note:**

   Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.

To use Vault for your encryption needs, select Encrypt using customer-managed keys check box. Then, select the Vault compartment and Vault that contain the master encryption key you want to use. Also select the Master encryption key compartment and Master encryption key. For more information about encryption, see Overview of Vault on page 5682.

   **Caution:**

   Be sure to back up your vaults and keys. Deleting a vault and key otherwise means losing the ability to decrypt any resource or data that
the key was used to encrypt. For more information, see Backing Up Vaults and Keys on page 5736.

- **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

- **Export Information**
  Mount targets use exports to manage access to file systems. The path name uniquely identifies the file system within the mount target, and is used by an instance to mount the file system.
  
  - **Export Path**: The File Storage service creates a default export path using the file system name. Optionally, replace the default export path name with a new path name, preceded by a forward slash (/). For example, /fss. This value specifies the mount path to the file system (relative to the mount target IP address or hostname). Avoid entering confidential information.

  **Important:**

  The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

  **Acceptable:**

  /example and /path
  /example and /example2

  **Not Acceptable:**

  /example and /example/path
  / and /example
  /example/
  /example/path/..example1

  **Caution:**

  If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

  **Note:**

  Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

  For more information, see Paths in File Systems on page 2917.

- **Use Secure Export Options**: Select to set the export options to require NFS clients to use a privileged port (1-1023) as its source port. This option enhances security because only a client with root privileges can use
a privileged source port. After the export is created, you can edit the export options to adjust security. See Working with NFS Export Options on page 2838 for more information.

**Caution:**

Leaving the "Use Secure Export Options" setting disabled allows unprivileged users to read and modify any file or directory on the target file system.

- **Mount Target Information:**

  File systems must be associated with a mount target to be mounted by an instance.

  If you have one or more previously created mount targets in the availability domain, the File Storage service automatically chooses the most recently created mount target in the list. If you don't have a mount target in the selected availability domain, the File Storage service creates one using the following defaults.

  - **Mount Target Name:** File Storage service creates a default mount target name using "Mount-YYYYMMDD-HHMM".
  - **Compartment:** The compartment you're currently working in.
  - **Virtual Cloud Network:** The first VCN listed in the current compartment is used as default.
  - **Configure Network Security Groups:** Select this option to add this mount target to an NSG you've created. Choose an NSG from the list. Each mount target can belong to up to five (5) NSGs.

  **Important:**

  Rules for the NSG you select must be configured to allow traffic to the mount target’s VNIC using specific protocols and ports. For more information, see Configuring VCN Security Rules for File Storage on page 2832.

  - **Subnet:** The most recently created subnet listed in the selected availability domain is used as default. Subnets can be either AD-specific or regional (regional ones have “regional” after the name). For more information, see VCNs and Subnets on page 4321.

5. If you want to accept the defaults for the mount target, click **Create**. The file system is created with the information displayed. If you want to choose another mount target or change the default information, click the **Edit Details** link.

6. In the **Mount Target Information** section, specify details for the mount target that is associated with the file system:

   - **Select an Existing Mount Target:** Choose this option if you want to associate the file system with a mount target you already created. Choose the **Mount Target** from the list. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target.

   **Tip:**

   If there aren't any mount targets in the current combination of availability domain and compartment, this option is disabled. You can:

   - Choose a different compartment.
   - Choose a different availability domain in the **File System Information** section.
   - Create a new mount target.

   - **Create a New Mount Target:** Choose this option if you want to create a new mount target associated with this file system. By default, the mount target is created in your current compartment and you can use network resources in that compartment. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target, its VCN, or subnet resources.

   **Important:**

   The mount target is always in the same availability domain as the file system. While it is possible to access mount targets from any AD in
a region, for optimal performance, your mount target and file system should be in the same availability domain as the compute instances that access them. For more information, see Regions and Availability Domains on page 2828.

- **Create in Compartment**: Specify the compartment you want to create the mount target in.
- **New Mount Target Name**: Optionally, replace the default with a friendly name for the mount target. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the mount target. Avoid entering confidential information.

**Note:**
The mount target name is different than the DNS hostname, which is specified in step 7.

- **Virtual Cloud Network Compartment**: The compartment containing the cloud network (VCN) in which to create the mount target.
- **Virtual Cloud Network**: Select the cloud network (VCN) where you want to create the new mount target.
- **Configure Network Security Groups**: Select this option to add this mount target to an NSG you've created. Choose an NSG from the list.

**Important:**
Rules for the NSG you select must be configured to allow traffic to the mount target's VNIC using specific protocols and ports. For more information, see Configuring VCN Security Rules for File Storage on page 2832.

- **Subnet Compartment**: Specify the compartment containing a subnet within the VCN to attach the mount target to.
- **Subnet**: Select a subnet to attach the mount target to. Subnets can be either AD-specific or regional (regional ones have "regional" after the name). For more information, see VCNs and Subnets on page 4321.

**Caution:**
Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

- **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Optionally, click **Show Advanced Options** to configure the mount target's advanced options.

- **IP Address**: You can specify an unused IP address in the subnet you selected for the mount target.
- **Hostname**: You can specify a hostname you want to assign to the mount target.

**Note:**
The File Storage service constructs a fully qualified domain name (FQDN) by combining the hostname with the FQDN of the subnet the mount target is located in.

For example, myhostname.subnet123.dnslabel.oraclevcn.com.

Once created, the hostname may be changed in the mount target's Details page. See Managing Mount Targets on page 2885 for more information.
8. **Click Create.**

The File Storage service typically creates the file system and mount target within seconds. Next, mount the file system from an instance so that you can read and write directories and files in your file system. See [Mounting File Systems](#) on page 2859 for instructions about obtaining mount commands for your operating system type and mounting your file system.

**To clone a file system**

Before you can clone a file system, at least one snapshot must exist for the file system. See [To create a snapshot](#) on page 2897 and [Cloning File Systems](#) on page 2900 for more information.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the file system you want to clone, click the Actions menu, and then click **View File System Details**.
4. In the **Snapshots** list, find the snapshot you want to use as the source of the clone, click the Actions menu, and then click **Clone**.

The clone is a copy of the file system data as it exists at the date and time that the selected snapshot was taken.

5. In the **Create Clone** page, specify the details about the clone that aren't inherited from the parent file system.

You can choose to accept the provided system defaults, or change them by clicking **Edit Details**. For a detailed description of each file system property and its defaults, see [File System Information](#).

6. **Click Create.**

Hydration begins immediately upon instantiation of the clone.

Cloned file systems are managed in the same way that any other file system is managed. See [Managing File Systems](#) on page 2875 for more information.

To view the clone's hydration status, source snapshot, parent file system, and other cloning information, visit the **Details** page of the cloned file system. See [To view file system details](#) on page 2877.

You can mount and use the clone immediately for READ or WRITE operations after you create it. See [Mounting File Systems](#) on page 2859 for more information.

**Using the command line interface (CLI)**

For information about using the CLI, see [Command Line Interface (CLI)](#) on page 6117.

**To create a file system**

Open a command prompt and run `oci fs file-system create` to create a file system. For example:

```bash
oci fs file-system create --availability-domain <target_availability_domain>
--display-name "<My File System>" --compartment-id <target_compartment_id>
```

Avoid entering confidential information.

The file system is created.

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key. For more information, see [Overview of Vault](#) on page 5682.

For example:

```bash
oci fs file-system create --availability-domain AAbC:US-ASHBURN-AD-1 --display-name "My File System" --compartment-id ocid1.compartment.oc1..<unique_id> --kms-key-id --kms-key-id ocid1.key.oc1.phx.<unique_id>
```
To create a file system that is encrypted with a Key Management Key

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key.

**Note:**

Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.

For more information, see Overview of Vault on page 5682.

**Caution:**

Be sure to back up your vaults and keys. Deleting a vault and key otherwise means losing the ability to decrypt any resource or data that the key was used to encrypt. For more information, see Backing Up Vaults and Keys on page 5736.

Open a command prompt and run `oci fs file-system create` to create a file system that is encrypted with a key management key.

```ocl
oci fs file-system create --availability-domain <target_availability_domain> --display-name "<My File System>" --compartment-id <target_compartment_id> --kms-key-id <target_key_id>
```

For example:

```ocl
oci fs file-system create --availability-domain AAbC:US-ASHBURN-AD-1 --display-name "My File System" --compartment-id ocid1.compartment.oc1..<unique_id> --kms-key-id ocid1.key.oc1.iad.<unique_id>
```

To create a mount target

You can create a mount target for file systems in a specified compartment and subnet. A file system can only be associated with a mount target in the same availability domain.

**Caution:**

Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

Open a command prompt and run `oci fs mount-target create` to create a mount target.

For example:

```ocl
oci fs mount-target create --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --subnet-id <subnet_OCID> --display-name "<My Mount Target>"
```

Avoid entering confidential information.

To create an export

An export is a file system together with the path that can be used to mount it. Each export resource belongs to one export set.

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set.
For example:

```bash
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path "</pathname>"
```

**Important:**

The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

Acceptable:

```
/example and /path
/example and /example2
```

Not Acceptable:

```
/example and /example/path
/ and /example
/example/
/example/path/..example1
```

**Caution:**

If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

**Note:**

Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

For more information, see [Paths in File Systems](https://docs.oracle.com/en-us/iaas/Content/FS/Concepts/filesystemspaths.htm) on page 2917.

**To clone a file system**

Before you can clone a file system, at least one snapshot must exist for the file system. See [To create a snapshot](https://docs.oracle.com/en-us/iaas/Content/FS/Concepts/filesystemsnapshots.htm) on page 2897 and [Cloning File Systems](https://docs.oracle.com/en-us/iaas/Content/FS/Concepts/cloningfs.htm) on page 2900 for more information.

To create a file system clone, use the `file-system create` command, and include the OCID of the file system snapshot you want to use as a source for the clone.

For example:

```bash
oci fs file-system create --availability-domain AAbC:US-ASHBURN-AD-1 --display-name "Clone_1" --compartment-id ocid1.compartment.oc1..<unique_id> --kms-key-id --kms-key-id ocid1.key.oc1.phx.<unique_id> --source-snapshot-id ocid1.snapshot.oc1..<unique_id>
```

For more information about clones, see [Cloning File Systems](https://docs.oracle.com/en-us/iaas/Content/FS/Concepts/cloningfs.htm) on page 2900.
Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use the following operations to create file systems:

- CreateFileSystem
- CreateMountTarget
- CreateExport

Mounting File Systems

Users of Unix-style operating systems and Windows Server 2012 R2 and later versions can connect to a file system and write files. Mount targets serve as file system network access points for file systems. After your mount target is assigned an IP address, you can use it together with the file system export path to mount the file system. On the instance from which you want to mount the file system, you need to install an NFS client. For Unix-style operating systems, you create a mount point. When you mount the file system, the mount point effectively represents the root directory of the File Storage file system, allowing you to write files to the file system from the instance. Windows operating systems use a drive letter assignment instead of a mount point to represent root access.

Prerequisites

- The file system must have at least one export in at least one mount target. When you create a new file system, an export for the file system is created at the same time. See Creating File Systems on page 2851 for more information.

Mounting File Systems From an Instance

Mounting File Systems From Unix-Style Instances on page 2861 (Including Oracle Linux DB instances)
Mounting File Systems From Windows Instances on page 2870

Obtaining Mount Command Samples

Mount command samples that include mount information for a specific mount target and file system are available in the Console. Samples are available for the following operating system images:

- Oracle Linux
- CentOS
- Debian
- Red Hat Linux
- Ubuntu

Here's an example of the information contained in a mount command sample. The file system name is used to create directory names:
If you specified a hostname for the mount target, the sample uses the FQDN in the commands. If you didn't specify a hostname, the sample uses the mount target IP address. Using a FQDN to mount your file system is optional; even if you specified a hostname, you can edit the command to use the IP address instead. If you use an FQDN to mount the file system, ensure that the FQDN correctly resolves to the mount target's IP address. For more information, see DNS in Your Virtual Cloud Network on page 4409.

Mount command samples mount the file system at the file system root directory. Mount command samples don't include subdirectory information for the file system. If you want to mount a subdirectory of the file system, you must edit the sample to append the subdirectory path to the export path. For more information on mounting subdirectories in Linux-type instances, see To mount a file system subdirectory (Linux). For more information on mounting subdirectories in Windows instances, see To mount a file system subdirectory (Windows).

**Caution:**

When mounting file systems, the following mount option combination is **not supported** by the File Storage service:

- `soft` when the file system is mounted with the read/write mount option (`-o rw`). **This combination can cause corruption of your data.**

The following mount options or mount option combinations are **not recommended** for use with the File Storage service:

- `soft` when the file system is mounted with the read-only mount option (`-o ro`) and the `timeo` has been specified as less than 300 seconds. **This combination can cause a profusion of I/O error responses.**
- `rsize` or `wsize`. **These options cause issues with performance.**

**Note:**

When mounting file systems, Network Lock Manager (NLM) is enabled for file locking by default. The default requires no specified mount option. Typical NFS workloads function normally using the default.
Some applications might require you to specify the nolock mount option. Refer to your application documentation for best practices regarding this mount option.

**Required IAM Service Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users create, manage, and delete file systems allows users to obtain mount commands.

If you're new to policies, see Getting Started with Policies and Common Policies.

**Using the Console**

*To get mount command samples*

2. In the List Scope section, select a compartment.

   The Console displays a list of file systems that have already been created in the compartment, if any.
3. Find the file system you want to mount, click the Actions menu, and then click View File System Details.
4. In Resources, click Exports.
5. Find the export in the mount target you want to use to mount the file system, click the Actions menu, and then click Mount Commands.

   **Tip:**

   To be sure that you select the correct export, check the following:

   - **The export path:** This path uniquely identifies the file system within the mount target. No two exports in a mount target can have the same export path, even if the exports are for the same file system.
   - **The mount target name:** File systems can be exported through more than one mount target. Be sure that you've selected the export for the correct mount target.

6. In Image, choose the image of the compute instance you want to mount the file system to.
7. Click the Copy link to copy the commands.

Next, mount the file system from a Unix-style or Windows instance.

**Mounting File Systems From Unix-Style Instances**

Users of Ubuntu and Linux operating systems can use the command line to connect to a file system and write files. Mount targets serve as network access points for file systems. After your mount target is assigned an IP address, you can use it together with the export path to mount the file system. On the instance from which you want to mount the file system, you need to install an NFS client and create a mount point. When you mount the file system, the mount point effectively represents the root directory of the File Storage file system, allowing you to write files to the file system from the instance. You can mount to any directory within the file system.

**Prerequisites**

- The file system must have at least one export in at least one mount target. When you create a new file system, an export for the file system is created at the same time. See Creating File Systems on page 2851 for more information.
Mounting File Systems

You can use the following instructions to construct your mount commands, or use the Console to get mount command samples that include all the information for a specific mount target and file system. For more information, see Obtaining Mount Command Samples on page 2859.

Mount command samples mount the file system at the file system root directory. Mount command samples don’t include subdirectory information for the file system. If you want to mount your Linux-type instance at a subdirectory of the file system, you must edit the sample to append the subdirectory path to the export path. For more information, see To mount a file system subdirectory on page 2868.

Caution:

When mounting file systems, the following mount option combination is not supported by the File Storage service:

- soft when the file system is mounted with the read/write mount option (-o rw). This combination can cause corruption of your data.

The following mount options or mount option combinations are not recommended for use with the File Storage service:

- soft when the file system is mounted with the read-only mount option (-o ro) and the timeo has been specified as less than 300 seconds. This combination can cause a profusion of I/O error responses.
- rsize, or wsize. These options cause issues with performance.

Note:

When mounting file systems, Network Lock Manager (NLM) is enabled for file locking by default. The default requires no specified mount option. Typical NFS workloads function normally using the default.

Some applications might require you to specify the nolock mount option.

Refer to your application documentation for best practices regarding this mount option.

To mount a file system from Ubuntu or Debian

1. Open a command window. Then, get the NFS client by copying and pasting the Install Command from the Console or type the following:

   ```
sudo apt-get install nfs-common
   ```

2. Create a mount point by copying and pasting the Create Mount Point Command from the Console or type the following, replacing yourmountpoint with the local directory from which you want to access your file system.

   ```
sudo mkdir -p /mnt/yourmountpoint
   ```
3. Mount the file system by copying and pasting the **Mount Command** from the Console or type the following:

```sh
sudo mount -o nosuid,resvport 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

- Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target.
- Replace `fs-export-path` with the export path you specified when associating the file system with the mount target.
- Replace `yourmountpoint` with the path to the local mount point.

**Tip:**
IP address and export path information is available in the **Details** page of the mount target associated with your file system. See **To view details of a mount target** on page 2890 for more information.

**Caution:**
Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to ‘root’. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

**Note:**
The `-o resvport` option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See **Working with NFS Export Options** on page 2838 for more information.

4. View the file system.

```sh
df -h
```

5. Write a file to the file system by typing the following. Replace `yourmountpoint` with the path to the local mount point and `helloworld` with your file name.

```sh
sudo touch /mnt/yourmountpoint/helloworld
```

6. Verify that you can view the file by typing the following. Replace `yourmountpoint` with the path to the local mount point.

```sh
cd /mnt/yourmountpoint
ls
```

See **Mount Command Fails** on page 2924 in **Troubleshooting Your File System** on page 2922 for more information about common issues you may encounter.

**To mount a file system from Solaris**

1. Open a command window.
2. Create a mount point by typing the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

```sh
sudo mkdir -p /mnt/yourmountpoint
```
3. Mount the file system by typing the following:

```bash
sudo mount -F nfs -o vers=3 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

- Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target.
- Replace `fs-export-path` with the export path you specified when associating the file system with the mount target.
- Replace `yourmountpoint` with the path to the local mount point.

**Tip:**

IP address and export path information is available in the Details page of the mount target associated with your file system. See To view details of a mount target on page 2890 for more information.

4. View the file system.

```bash
df -h
```

5. Write a file to the file system by typing the following. Replace `yourmountpoint` with the path to the local mount point and `helloworld` with your file name.

```bash
sudo touch /mnt/yourmountpoint/helloworld
```

6. Verify that you can view the file by typing the following. Replace `yourmountpoint` with the path to the local mount point.

```bash
cd /mnt/yourmountpoint
ls
```

See Mount Command Fails on page 2924 in Troubleshooting Your File System on page 2922 for more information about common issues you may encounter.

To mount a file system from Linux, Red Hat, or CentOS

1. Open a command window. Then, get the NFS client by copying and pasting the Install Command from the Console or typing the following:

```bash
sudo yum install nfs-utils
```

2. Create a mount point by copying and pasting the Create Mount Point Command from the Console or type the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

```bash
sudo mkdir -p /mnt/yourmountpoint
```
3. Mount the file system by copying and pasting the **Mount Command** from the Console or type the following:

```
sudo mount -o nosuid,resvport 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

- Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target.
- Replace `fs-export-path` with the export path you specified when associating the file system with the mount target.
- Replace `yourmountpoint` with the path to the local mount point.

**Tip:**

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See [To view details of a mount target](#) on page 2890 for more information.

**Caution:**

Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

**Note:**

The `-o resvport` option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See [Working with NFS Export Options](#) on page 2838 for more information.

4. View the file system.

```
df -h
```

5. Write a file to the file system by typing the following. Replace `yourmountpoint` with the path to the local mount point and `helloworld` with your file name.

```
sudo touch /mnt/yourmountpoint/helloworld
```

6. Verify that you can view the file by typing the following. Replace `yourmountpoint` with the path to the local mount point.

```
cd /mnt/yourmountpoint
ls
```

See [Mount Command Fails](#) on page 2924 in [Troubleshooting Your File System](#) on page 2922 for more information about common issues you may encounter. See if you want to mount a subdirectory of the file system.

### To mount a file system from a Database VM instance

Database VM instances are built on Oracle Linux 6.8, unlike Oracle Linux compute instances, which run on version 7.4. The NFS Utilities package is pre-installed on DB instances, but the Open Network Computing Remote Procedure Call (ONC RPC) rpcbind utility is disabled by default. Oracle Linux 6.8 does not have systemd, so DB instances are managed differently than OL compute instances. An Oracle DB instance comes with a set of iptables rules that excludes any non-database ports and need to be updated to allow mount target traffic.

1. SSH to the DB system.

```
ssh -i <private_key_path> opc@<db_system_ip_address>
```
2. Start the rpcbind service by typing the following:

```bash
sudo service rpcbind start
```

3. Use the chkconfig command to enable starting rpcbind service at system startup.

```bash
sudo chkconfig rpcbind on
```

4. Change the default configuration of iptables to include the mount target IP address and allow traffic by typing the following. Replace `10.x.x.x` with the local subnet address assigned to the mount target for the file system. Save the new iptables entries.

```bash
sudo iptables -A INPUT -p tcp -s 10.x.x.x -j ACCEPT

sudo iptables -A OUTPUT -p tcp -s 10.x.x.x -j ACCEPT

sudo service iptables save
```

5. Create a mount point by typing the following, replacing `yourmountpoint` with the local directory from which you want to access your file system.

```bash
sudo mkdir -p /mnt/yourmountpoint
```

6. Mount the file system by copying and pasting the **Mount Command** from the Console or type the following:

```bash
sudo mount -t nfs -o nosuid,resvport,tcp,vers=3 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

- Replace `10.x.x.x` with the local subnet IP address assigned to your mount target.
- Replace `fs-export-path` with the export path you specified when associating the file system with the mount target.
- Replace `yourmountpoint` with the path to the local mount point.

**Tip:**

IP address and export path information is available in the Details page of the mount target associated with your file system. See [To view details of a mount target](#) on page 2890 for more information.

**Caution:**

Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

**Note:**

The `-o resvport` option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See [Working with NFS Export Options](#) on page 2838 for more information.

See [Mount Command Fails](#) on page 2924 in [Troubleshooting Your File System](#) on page 2922 for more information about common issues you may encounter.

**To auto-mount a file system**

Auto-mount ensures that a file system is automatically re-mounted on an instance if it is rebooted.

1. Open a command window. Then, mount the file system using the steps described in the previous section.
2. Type the following command to get the file system entry point:

```
sudo cat /etc/mtab | grep -i nfs
```

3. Copy the file system entry point, and open the `/etc/fstab` file:

```
cd /etc
vi fstab
```

4. Add the following line to the `fstab` file:

```
<file_system_ip_address>:<file_system_path_name> <your_local_mount_point> nfs defaults,nofail,nosuid,resvport 0 0
```

**Caution:**

Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The `nosuid` option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

**Important:**

Be sure to add the `nofail` option to each entry. This option ensures that an unavailable file system does not cause the instance reboot process to fail.

**Note:**

The `-o resvport` option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See [Working with NFS Export Options](#) on page 2838 for more information.

5. Save the `fstab` file.

See [Mount Command Fails](#) on page 2924 in [Troubleshooting Your File System](#) on page 2922 for more information about common issues you may encounter.

**Mounting File System Subdirectories**

If your file system has an existing directory structure, you can mount any file system subdirectory. The subdirectory becomes the effective root directory at the mount point of the instance, and excludes sibling directories.

For example, suppose "FileSystem1" has an export path of `/FileSystem1` and a directory structure like this:
The file system is exported from "MountTarget1" which has an IP address of 10.0.0.16.

The following command mounts directoryA to the instance mount point /mnt/mymountpoint:

```
sudo mount -o nosuid,resvport 10.0.0.16:/FileSystem1/rootdirectory/directoryA /mnt/mymountpoint
```

Neither directoryB or FileB would be accessible from the instance mount point.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mounting a subdirectory to limit access to sibling directories is not sufficient to secure your file system. For information on security methods, see About Security on page 2830.</td>
</tr>
</tbody>
</table>

**To mount a file system subdirectory**

1. Open a command window. Then, get the NFS client by copying and pasting the Install Command from the Console or typing the following:

```
sudo yum install nfs-utils
```

2. Create a mount point by copying and pasting the Create Mount Point Command from the Console or type the following, replacing yourmountpoint with the local directory from which you want to access your file system.

```
sudo mkdir -p /mnt/yourmountpoint
```
3. Mount the file system by copying and editing the **Mount Command** from the Console or type the following:

```bash
sudo mount -o nosuid, resvport 10.x.x.x:/fs-export-path/directory-path /mnt/yourmountpoint
```

- Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target.
- Replace `fs-export-path` with the export path you specified when associating the file system with the mount target.
- Replace `directory-path` with the path from the root directory to subdirectory you want to mount.
- Replace `yourmountpoint` with the path to the local mount point.

**Tip:**

IP address and export path information is available in the **Details** page of the mount target associated with your file system. See **To view details of a mount target** on page 2890 for more information.

**Caution:**

Omitting the `-o nosuid` option may allow unprivileged users to escalate their permissions to 'root'. The **nosuid** option disables set-user-identifier or set-group-identifier bits within the mounted system, which are rarely used.

**Note:**

The `-o resvport` option is required when the “Require Privileged Source Port” export option is used and otherwise optional. It causes the mounting filesystem to connect from a privileged source port (1-1023). See **Working with NFS Export Options** on page 2838 for more information.

4. View the file system.

```bash
df -h
```

5. Write a file to the file system by typing the following. Replace `yourmountpoint` with the path to the local mount point and `helloworld` with your file name.

```bash
sudo touch /mnt/yourmountpoint/helloworld
```

6. Verify that you can view the file by typing the following. Replace `yourmountpoint` with the path to the local mount point.

```bash
cd /mnt/yourmountpoint
ls
```

**To unmount a file system**

1. Open a terminal window on the instance.
2. Use the following command to unmount the file system:

```bash
sudo umount /mnt/yourmountpoint
```

Replace `yourmountpoint` with the path to the local mount point.

**Writing to File Systems**

When a file system is created, its root directory is owned by the `root` user. If you're connecting from an instance that uses a Linux or CentOS platform image, the default user is `opc`. If you're connecting from an instance that uses an Ubuntu platform image, the default user is `ubuntu`. These default users are not root users, so you can't initially write
a file or directory to a new file system with these users. Depending on your security requirements, there are several ways to proceed:

- Connect as the root user. Then, create files or directories in the new file system.
- Connect as the root user. Then, change the ownership or permissions of the file system root directory to allow other users (such as opc or ubuntu) to write to the file system.
- Connect as the root user. Then, create subdirectories with ownership or permissions that allow other users to write to the subdirectory.

Learn more about updating file and directory ownership and permissions.

- Connect as the default user. Then, use the sudo command to write or to change permissions or ownership of files or directories. The sudo command temporarily provides a regular user with root user permissions. Here's an example of using the sudo command to write to the file system:

  ```
  sudo touch /mnt/yourmountpoint/helloworld
  ```

  Learn more about the sudo command.

For more information about accessing instances, see Connecting to an Instance on page 1163.

### Mounting File Systems From Windows Instances

Users of Windows Server 2012 R2 and later versions can mount a file system on any available drive letter using the mount target IP address and the file system export path.

The Windows NFS client must be installed on the instance from which you want to mount the file system.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Installing the Windows NFS client may require a restart of your system.</td>
</tr>
</tbody>
</table>

Access to NFS file systems requires UNIX-style user and group identities, which are not the same as Windows user and group identities. To enable users to access NFS shared resources, Windows client for NFS accesses file systems anonymously, using AnonymousGid and AnonymousUid. On brand new file systems, write permissions are only granted to the root user. The AnonymousGid and AnonymousUid identity values must be configured to allow write access.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Updating the 'AnonymousGid' and 'AnonymousUid' values require registry changes to your system.</td>
</tr>
</tbody>
</table>

After you have installed the NFS client and correctly mapped user identities, you can mount the file system to any available drive letter using the command line or Map network drive. You can access your file system through the chosen drive letter to write files.

**Prerequisites**

- The file system must have at least one export in at least one mount target. When you create a new file system, an export for the file system is created at the same time. See Creating File Systems on page 2851 for more information.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When mounting file systems, the following mount option combination is not supported by the File Storage service:</td>
</tr>
<tr>
<td><code>soft</code> when the file system is mounted with the read/write mount option <code>(-o rw)</code>. This combination can cause corruption of your data.</td>
</tr>
</tbody>
</table>
The following mount options or mount option combinations are **not recommended** for use with the File Storage service:

- **soft** when the file system is mounted with the read-only mount option (-o ro) and the `timeo` has been specified as less than 300 seconds. **This combination can cause a profusion of I/O error responses.**
- **rsize** or **wsize**. **These options cause issues with performance.**

**Note:**

When mounting file systems, Network Lock Manager (NLM) is enabled for file locking by default. The default requires no specified mount option. Typical NFS workloads function normally using the default. Some applications might require you to specify the `nolock` mount option. Refer to your application documentation for best practices regarding this mount option.

### Using Windows Command Prompt

*To mount a file system from Windows Server Command Prompt*

If you are using Windows platform images, the NFS client is already installed, and the correct user identities are mapped. Skip to step 4.

1. Open **Windows PowerShell** and run as **Administrator**:
   a. Go to **Start** and click the **Windows PowerShell** icon.
   b. In Windows PowerShell, type the following to run as Administrator:
      
      ```
      Start-Process powershell -Verb runAs
      ```
   c. In the **User Account Control** window, click **Yes**. A new Administrator: PowerShell window opens. You can close the standard PowerShell window to avoid confusing them.

2. In Administrator: PowerShell, get the NFS client by typing the following:

   ```
   Install-WindowsFeature -Name NFS-Client
   Set-ItemProperty HKLM:\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default -Name AnonymousUid -Value 0
   Set-ItemProperty HKLM:\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default -Name AnonymousGid -Value 0
   Stop-Service -Name NfsClnt
   Restart-Service -Name NfsRdr
   Start-Service -Name NfsClnt
   ```

   **Important:**

   If you've set export options for your file system to require clients to connect from a privileged source port (1-1023), then you must set the **UseReservedPorts** registry key to 1. For example:

   ```
   Set-ItemProperty HKLM:\SOFTWARE\Microsoft \ClientForNFS\CurrentVersion\Default -Name UseReservedPorts -Value 1
   ```

   For more information, see [Working with NFS Export Options](#) on page 2838.

Open a standard Command Prompt Window:

a. Click Start, then click Command Prompt.

**Important:**

NFS file systems mounted as Administrator are not available to standard users.

4. In the standard Windows Command Line (CMD) window, mount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X:` with the drive letter of any available drive you want to map the file system to.

```
mount 10.x.x.x:/fs-export-path X:
```

**Tip:**

IP address and export path information is available in the Details page of the mount target associated with your file system. See To view details of a mount target on page 2890 for more information.

**Important:**

The export path is the path to the file system (relative to the mount target IP address or hostname). If you did not specify a path when you associated the file system and mount target, then "/" represents the full extent of the mount target. In that case, you must use a "!" when mounting the file system. For example: `mount 10.0.0.0:!/ X:`

5. Write a file to the file system by typing the following. Replace `X:` with the drive letter you used in step 10 and `helloworld` with your file name.

```
X:

echo > helloworld.txt
```

6. Verify that you can view the file by typing the following.

```
dir
```

See Troubleshooting Windows NFS Connections on page 2947 for more information about common issues you might encounter.

**Using Windows File Explorer**

To mount a file system from Windows Server File Explorer

If you are using Windows platform images, the NFS client is already installed, and the correct user identities are mapped. Skip to step 9.

1. Open Windows PowerShell and run as Administrator:

   a. Go to Start and click the Windows PowerShell icon.
   b. In Windows PowerShell, type the following to run as Administrator:

```
Start-Process powershell -Verb runAs
```
   c. In the User Account Control window, click Yes. A new Administrator: PowerShell window opens. You can close the standard PowerShell window to avoid confusing them.
2. In Administrator: PowerShell, get the NFS client by typing the following:

```
Install-WindowsFeature -Name NFS-Client
```

3. If necessary, restart your system.

4. Open the registry editor (regedit) to map the AnonymousGid and AnonymousUid to the root user.

   **Caution:**
   
   User identity mapping requires changes to your system registry.

   a. Click **Windows Search**.
   b. Enter **regedit** in the **Search** field and press **Enter**.
   c. Click **Yes** to allow changes to your device.
   d. Click HKEY_LOCAL_MACHINE. Then, browse to: Software\Microsoft\ClientForNFS\CurrentVersion\Default.

5. Add a new DWORD32 registry entry for AnonymousGid:

   a. Click **Edit**, and select **New DWORD (32 bit) Value**.
   b. In the **Name** field, enter AnonymousGid. Leave the value at 0.

6. Repeat step 5 to add a second DWORD32 registry entry named AnonymousUid with a value of 0.

   ![Registry Editor Image]

   **Important:**
   
   If you’ve set export options for your file system to require clients to connect from a privileged source port (1-1023), then you must set the **UseReservedPorts** registry key to 1.

   For more information, see **Working with NFS Export Options** on page 2838.

7. Open Windows Command Line (CMD) and run as Administrator:

   a. Go to **Start** and scroll down to **Apps**.
   b. In the **Windows System** section, press **Ctrl+Shift** and click **Command Prompt**.

8. In the Windows Command Line (CMD) window, restart the NFS Client by typing the following:

```
nfsadmin client stop
nfsadmin client start
```

9. Open **File Explorer** and select **This PC**. In the **Computer** tab, select **Map network drive**.
10. Select the Drive letter that you want to assign to the file system.
11. In the Folder field, enter the following. Replace 10.x.x.x with the local subnet IP address assigned to your mount target, and fs-export-path with the export path you specified when associating the file system with the mount target.

```
\10.x.x.x\fs-export-path
```

**Tip:**
IP address and export path information is available in the Details page of the mount target associated with your file system. See To view details of a mount target on page 2890 for more information.

**Important:**
The export path is the path to the file system (relative to the mount target IP address or hostname). If you did not specify a path when you associated the file system and mount target, then "\\" represents the full extent of the mount target. In that case, you must use a "!" when entering the file system folder path. For example: \10.0.0.0\!

12. Click the Finish button when complete.

See Troubleshooting Windows NFS Connections on page 2947 for more information about common issues you might encounter.

**Mounting File System Subdirectories**
If your file system has an existing directory structure, you can mount any file system subdirectory. The subdirectory becomes the effective root directory at the mount point of the instance, and excludes sibling directories.

For example, suppose "FileSystem1" has an export path of /FileSystem1 and a directory structure like this:

```
(MountTarget1)
10.0.0.16: /FileSystem1
```

![Diagram of file system mounting](image)
The file system is exported from "MountTarget1" which has an IP address of 10.0.0.16.

The following command mounts directoryA to drive letter X:

```
mount 10.0.0.16:/rootdirectory/directoryA X:
```

Neither directoryB or FileB would be accessible from drive X.

**Caution:**

Mounting a subdirectory to limit access to sibling directories is not sufficient to secure your file system. For information on security methods, see About Security on page 2830.

**To mount a file system subdirectory**

1. Choose the method you want to use to mount the file system Using Windows Command Prompt on page 2871 or Using Windows File Explorer on page 2872.
2. Follow the instructions to install the NFS client and add the registry entries for AnonymousGid and AnonymousUid.
3. After the NFS client is installed and registry entries are added, both mounting methods describe how to enter the mount information for the file system. Depending on which method you use, edit the mounting information to append the subdirectory path to the export path:

   a. If you're Using Windows Command Prompt on page 2871, type the following command (step 4):

      ```
      mount 10.x.x.x:/fs-export-path/directory-path X:
      ```

   b. If you're Using Windows File Explorer on page 2872, enter the following in the Folder field of the drive letter you want to map the file system to (step 11):

      ```
      \10.x.x.x\fs-export-path\directory-path
      ```

**Managing File Systems**

In the File Storage service, file systems are associated with a single compartment. When you select a compartment, the Console displays all file systems in the compartment. You can also see exports and snapshots associated with each file system. If there are no file systems in the compartment, see Creating File Systems on page 2851 for instructions about creating one.

The compartment has policies that indicate what actions a user can take to manage file system. UNIX permissions control what actions a user can take on the files stored in the file system. See About Security on page 2830 for more information.

Actions you can take to manage a file system include:

- Viewing file system details
- Editing file system settings
- Viewing associated file system resources
- Creating an export for the file system
• Deleting a file system

You can perform most administrative tasks for your file systems using the Console, Command Line Interface (CLI), or API. You can use the Console to list mount targets exporting a specific file system. Use the API or CLI if you want to list all mount targets in a compartment.

To access a file system, it must have at least one export in one mount target. Next, mount the file system from an instance, and then you can create directories and read and write files. For more information about creating an export for a file system, see To create an export for a file system on page 2878 in this topic. For more information about accessing your file system, see Mounting File Systems.

Limitations and Considerations

• Each tenancy in a region can have 1 CreateFileSystem or ChangeFilesystemCompartment operation in progress at a time. See 409 error occurs when creating or moving a file system or mount target for more information.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users create, manage, and delete file systems allows users to manage file systems.

If you're new to policies, see Getting Started with Policies and Common Policies.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 243.

Moving File Systems to a Different Compartment

You can move file systems from one compartment to another. When you move a file system to a new compartment, its associated snapshots move with it. After you move the file system to the new compartment, inherent policies apply immediately and affect access to the file system and snapshots through the Console. Moving these resources doesn't affect access to file systems and snapshots from mounted instances. For more information, see Managing Compartments.

Details About Your File System

The file system details page provides the following information about your file system:

FILE SYSTEM OCID

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). You need your file system's OCID to use the Command Line Interface (CLI) or the API. You also need the OCID when contacting support. See Resource Identifiers on page 228.

Availability Domain

When you create a file system, you specify the availability domain that it resides in. An availability domain is one or more data centers located within a region. You need your file system's availability domain to use the Command Line Interface (CLI) or the API. For more information, see Regions and Availability Domains on page 210.
CREATED
The date and time that the file system was created.

COMPARTMENT
When you create a file system, you specify the compartment that it resides in. A compartment is a collection of related resources (such as cloud networks, compute instances, or file systems) that are only accessible to those groups that have been given permission by an administrator in your organization. You need your file system's compartment to use the Command Line Interface (CLI) or the API. For more information, see Managing Compartments.

UTILIZATION
Metered size of the file system that gets updated hourly. If the file system is a clone, this value represents only the differentiated data unique to the clone. For more information, see File System Usage and Metering on page 2918.

HYDRATION
Indicates whether the file system is a clone currently copying metadata from its source. See Cloning File Systems on page 2900.

SOURCE SNAPSHOT
If the file system is a clone, a link is provided to the clone's source snapshot. If the source snapshot is deleted, the link is disabled. See Cloning File Systems on page 2900.

PARENT FILE SYSTEM
If the file system is a clone, a link is provided to the clone's parent file system. See Cloning File Systems on page 2900.

ROOT
Indicates whether the file system is the root of a clone tree. See Cloning File Systems on page 2900.

DESCENDANTS
Indicates whether the file system has been cloned. See Cloning File Systems on page 2900.

RESOURCES
Resources such as exports and snapshots that are associated with the file system are listed here. Click the resource type link to see a list of each individual resource. Each export in the list shows the file system's export path and mount target. You need the export path to mount a file system.

Using the Console

To view file system details
The File Storage service displays a list of file systems in each compartment.

2. In the List Scope section, select a compartment.
3. To view information about a file system, find the file system, click the Actions menu, and then click View File System Details.

To change the file system name
You can change the display name of the file system.

2. In the List Scope section, select a compartment.
3. To view information about a file system, find the file system, click the Actions menu, and then click View File System Details.
4. Click Rename.
5. Enter the new file system name. Avoid entering confidential information. Then click **Rename**.

To create an export for a file system

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. In the left-hand navigation, in the **List Scope** section, under **Compartment**, select a compartment.
3. Click the name of the file system you want to create an export for, and click **Create Export**.

   **Note:**
   File systems are encrypted by default. You cannot turn off encryption.

4. You can choose to accept the system defaults, or change them by clicking **Edit Details**.
5. If you want to **accept the defaults** for the mount target, click **Create**. The file system is created with the information displayed. If you want to choose another mount target or change the default information, click the **Edit Details** link.
6. In the **Mount Target Information** section, specify details for the mount target that is associated with the file system:
   - **Select an Existing Mount Target:** Choose this option if you want to associate the file system with a mount target you already created. Choose the **Mount Target** from the list. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target.

   **Tip:**
   If there aren't any mount targets in the current combination of availability domain and compartment, this option is disabled. You can:
   - Choose a different compartment.
   - Create a new mount target.

   - **Create a New Mount Target:** Choose this option if you want to create a new mount target associated with this file system. By default, the mount target is created in your current compartment and you can use network resources in that compartment. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target, its VCN, or subnet resources.

   **Important:**
   The mount target is always in the same availability domain as the file system. While it is possible to access mount targets from any AD in a region, for optimal performance, your mount target and file system should be in the same availability domain as the compute instances.
that access them. For more information, see Regions and Availability Domains on page 2828.

- **Create in Compartment**: Specify the compartment you want to create the mount target in.
- **New Mount Target Name**: Optionally, replace the default with a friendly name for the mount target. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the mount target. Avoid entering confidential information.

**Note:**
The mount target name is different than the DNS hostname, which is specified in step 7.

- **Virtual Cloud Network Compartment**: The compartment containing the cloud network (VCN) in which to create the mount target.
- **Virtual Cloud Network**: Select the cloud network (VCN) where you want to create the new mount target.
- **Configure Network Security Groups**: Select this option to add this mount target to an NSG you've created. Choose an NSG from the list.

**Important:**
Rules for the NSG you select must be configured to allow traffic to the mount target's VNIC using specific protocols and ports. For more information, see Configuring VCN Security Rules for File Storage on page 2832.

- **Subnet Compartment**: Specify the compartment containing a subnet within the VCN to attach the mount target to.
- **Subnet**: Select a subnet to attach the mount target to. Subnets can be either AD-specific or regional (regional ones have "regional" after the name). For more information, see VCNs and Subnets on page 4321.

**Caution:**
Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

- **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

7. Optionally, click **Show Advanced Options** to configure the mount target's advanced options.

- **IP Address**: You can specify an unused IP address in the subnet you selected for the mount target.
- **Hostname**: You can specify a hostname you want to assign to the mount target.

**Note:**
The File Storage service constructs a fully qualified domain name (FQDN) by combining the hostname with the FQDN of the subnet the mount target is located in.

For example, myhostname.subnet123.dnslabel.oraclevcn.com.

Once created, the hostname may be changed in the mount target's Details page. See Managing Mount Targets on page 2885 for more information.

8. Click **Create**.
Next, mount the file system from an instance so that you can read and write directories and files in your file system. See Mounting File Systems on page 2859 for instructions about obtaining mount commands for your operating system type and mounting your file system.

To set the file system reported size

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibiinodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the Reported Size or Reported Inodes value in the file system's mount target. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

| Important: |
| Changing the Reported Size or Reported Inodes for a mount target affects all file systems exported by the mount target. Changing these values does not limit the amount of data you can store. |

2. In the List Scope section, select a compartment.
3. Find the mount target you're interested in, click the Actions menu, and then click View File System Details.
4. In Exports, click on the mount target name.
5. Click the Reported Size (in GiB) Edit or the Reported Inodes (in GiI) icon.
6. Enter the maximum free space in gibibytes or the maximum inodes in gibiinodes you want the File Storage service to report.
7. Click the Save icon.

| Important: |
| There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the df command. For more information, see File System Usage and Metering on page 2918. |

To manage tags for a file system

2. In the List Scope section, select a compartment.
3. Find the file system you're interested in, click the Actions menu, and then click View File System Details.
4. Click the Tags tab to view or edit the existing tags. Or click Apply tag(s) to add new ones.

For more information, see Resource Tags on page 243.

To move a file system to a different compartment

1. Open the Console,
3. In the List Scope section, select a compartment.
4. Find the file system in the list, click the the Actions menu, and then click Change Compartment.
5. Choose the destination compartment from the list.
6. Click Change Compartment.

The file system is moved immediately. Moving a file system doesn't affect mounted instances.

To move a file system to a different subnet

There might be situations where you need to move a file system to a different subnet. For example, since you can't change subnet size, you might need to move the file system to a larger or smaller subnet as your needs change.

1. Create the new subnet. See VCNs and Subnets on page 4321 for instructions.
2. Create a new mount target in the new subnet. See To create a mount target on page 2889 for instructions.
3. Create new export with the same export path in the new mount target to the file system. See To create an export for a file system on page 2878 for instructions.

- Choose Select Existing Mount Target
- Be sure that the export path for the new export is exactly the same as the export path for the original export. The original and new mount target can exist at the same time without issue.

4. Switch over the instance mount point to the new mount target. This can be done at any time convenient to your maintenance schedule:

a. Stop any workload application processes running on the instance mount point.
b. Unmount the file system. See To unmount a file system on page 2869 for instructions.
c. Mount the file system using the new mount target, but the same mount point that was previously used.

For example: If the file system was mounted with the original mount target like this:

```
sudo mount 10.0.0.10:/my-export-path /mnt/MyMountPoint
```

Then the new mount command would look like this:

```
sudo mount 10.1.1.10:/my-export-path /mnt/MyMountPoint
```

See Mounting File Systems on page 2859 for instructions.
d. Update any system configuration files that use the old export path. For example, /etc/fstab.
e. Start workload applications and verify that they can access the file system as expected.
f. After testing and verification is complete, you can delete the original mount target and subnet.

To assign a key to a file system

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Be sure to back up your vaults and keys. Deleting a vault and key otherwise means losing the ability to decrypt any resource or data that the key was used to encrypt. For more information, see Backing Up Vaults and Keys on page 5736.</td>
</tr>
</tbody>
</table>

Prerequisites:

- At least one key vault and key in the Vault service. For more information, see Overview of Vault on page 5682.
- Correctly set permissions that allow the File Storage service to use keys. For example:

```
Allow service FssOclProd to use keys in compartment <compartment_name>
```

For more information, see Common Policies.

2. Under List Scope, in the Compartment list, choose the compartment that contains the file system that you want to encrypt with a Vault master encryption key.
3. From the list of file systems, click the file system name.
4. Next to Encryption Key, click Edit.
5. In Encryption Type, select Encrypt using customer-managed keys.
6. Choose the vault compartment, vault, key compartment, and key.
7. When you are finished, click Save Changes.
To specify Oracle-managed keys for a file system

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. However, if you assign a Vault key to a file system, you can later return the file system to using Oracle-managed keys for encryption. For more information, see Overview of Vault on page 5682.

2. Under List Scope, in the Compartment list, choose the compartment that contains the file system that you want to encrypt with a Vault master encryption key.
3. From the list of file systems, click the file system name.
4. Next to Encryption Key, click Edit.
5. In Encryption Type, select Encrypt using Oracle-managed keys.
6. When you are finished, click Save Changes.

To delete a file system

You can permanently delete a file system.

Caution:
You cannot undo this operation. Any data in a file system is permanently deleted with the file system. Snapshots of the file system are permanently deleted with the file system. You cannot recover a deleted file system or its snapshots.

Note:
Before you can delete the root file system of a clone tree, all of its descendants must first be deleted. See for more information.

2. In the List Scope section, select a compartment.
3. Find the file system you want to delete.
4. Click the Actions menu, and then click View File System Details.
5. Delete all of the file system's exports:
   - In Exports, select the check box for all exports listed, and then click Delete.
6. When all of the exports are deleted, click Delete to delete the file system.

The file system is deleted immediately, along with all of its snapshots.

Using the Command Line Interface (CLI)

For information about using the CLI, see Command Line Interface (CLI) on page 6117.

To list file systems

Open a command prompt and run `oci fs file-system list` to list all the file systems in a specified availability domain and compartment.

For example:

```bash
oci fs file-system list --availability-domain <target_availability_domain> --compartment-id <target_compartment_id>
```

To get a specific file system

Open a command prompt and run `oci fs file-system get` to retrieve information about a specific file system.
For example:

```
oci fs file-system get --file-system-id <file_system_OCID>
```

**To update a file system**

Open a command prompt and run `oci fs file-system update` to update a specific file system's information. For example:

```
oci fs file-system update --file-system-id <file_system_OCID> --display-name "<New File System Name>"
```

Avoid entering confidential information.

**To create an export for a file system**

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path "</pathname>"
```

**Important:**

The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

Acceptable:

```
/example and /path
/example and /example2
```

Not Acceptable:

```
/example and /example/path
/ and /example
/example/
/example/path/../example1
```

**Caution:**

If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.
Note:

Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

For more information, see Paths in File Systems on page 2917.

**To set the file system reported free space**

Some existing application installers perform a capacity check before running an installation process. Sometimes an installation fails because of too much available capacity. The File Storage service currently reports 8 exabytes of available capacity by default for each file system.

Customers can define how much free capacity is reported as available to the operating system.

Open a command prompt and type in the following command:

```bash
oci fs export-set update --export-set-id <export_set_OCID> --max-fs-stat-bytes <number_of_bytes>
```

Important:

The maximum free space setting affects each export in the export set. Setting the maximum free space does not limit the amount of data you can store.

**To move a file system to a different compartment**

```bash
oci fs file-system change-file-system-compartment --file-system-id <file_system_OCID> --compartment-id <destination_compartment_OCID>
```

**To update the key for a file system**

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. Optionally, you can encrypt the data in this file system using your own Vault encryption key.

Note:

Currently, only symmetric Advanced Encryption Standard (AES) keys are supported for file system encryption.

Caution:

*Be sure to back up your vaults and keys.* Deleting a vault and key otherwise means losing the ability to decrypt any resource or data that the key was used to encrypt. For more information, see Backing Up Vaults and Keys on page 5736.

**Prerequisites:**

- At least one key vault and key in the Vault service. For more information, see Overview of Vault on page 5682.
- Correctly set permissions that allow the File Storage service to use keys. For example:

```bash
Allow service FssOci1Prod to use keys in compartment <compartment_name>
```

For more information, see Common Policies.

Open a command prompt and run `oci fs file-system update` to update the file system with a new key.

```bash
oci fs file-system update --file-system-id <file_system_OCID> --kms-key-id <target_key_id>
```
For example:

```
oci fs file-system update --file-system-id
ocid1.filesystem.oc1.phx.<unique_id> --kms-key-id
ocid1.key.oc1.phx.<unique_id>
```

### To specify Oracle-managed keys for a file system

File systems use Oracle-managed keys by default, which leaves all encryption-related matters to Oracle. However, if you assign a Vault key to a file system, you can later return the file system to using Oracle-managed keys for encryption.

Open a command prompt and run `oci fs file-system update`. Leave the `--kms-key-id` value unspecified.

```
oci fs file-system update --file-system-id <file_system_OCID> --kms-key-id ""
```

For example:

```
oci fs file-system update --file-system-id
ocid1.filesystem.oc1.phx.<unique_id> --kms-key-id ""
```

### To delete a file system

You can delete a file system if no non-deleted export resources reference it. Deleting a file system also deletes all its snapshots.

Open a command prompt and run `oci fs file-system delete` to delete a file system.

For example:

```
oci fs file-system delete --file-system-id <file_system_OCID>
```

**Caution:**

You cannot undo this operation. Any data in a file system is permanently deleted with the file system. Snapshots of the file system are permanently deleted with the file system. You cannot recover a deleted file system or its snapshots.

### Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use the following operations to manage file systems:

- ListFileSystems
- GetFileSystem
- UpdateFileSystem
- ChangeFileSystemCompartment
- DeleteFileSystem

### Managing Mount Targets

This topic describes the basics of managing mount targets.

**Overview**

Actions you can take to manage a mount target include:
File Storage

- Viewing mount target details
- Obtaining mount command samples
- Creating a new export and file system
- Editing exports and export options
- Change the reported size of exported file systems
- Deleting a mount target

You can perform most administrative tasks for your mount targets using the Console, Command Line Interface (CLI), or API. You can use the Console to list mount targets exporting a specific file system. Use the API or CLI if you want to list all mount targets in a compartment.

**Mount Target**

A mount target is an NFS endpoint that lives in a VCN subnet of your choice and provides network access for file systems. The mount target provides the IP address or DNS name that is used together with a unique export path to mount the file system. When you use the console to create your first file system, the workflow also creates a mount target and export for it.

You can reuse the same mount target to make as many file systems available on the network as you wish. To reuse the same mount target for multiple file systems, create an export in the mount target for each file system.

**Exports**

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. When you use the console to create your first file system, the workflow also creates a mount target and export for it. Thereafter:

- You can create as many exports in a mount target for different file systems as you wish.
- You can create as many exports in a mount target for a single file system as you wish.
- You can delete and re-create exports in a mount target as often as you need to.
- You can add export options to an export to control access to the file system.

**NFS Export Options**

NFS export options are a set of parameters within the export that specify the level of access granted to NFS clients when they connect to a mount target. An NFS export options entry within an export defines access for a single IP address or CIDR block range. You can have up to 100 options per export.

For more information, see Working with NFS Export Options on page 2838.

**Limitations and Considerations**

- Each availability domain is limited to two mount targets by default.
  See Service Limits on page 247 for a list of applicable limits and instructions for requesting a limit increase.
- Each mount target can accept up to 100,000 NFS client connections. If you use in-transit encryption, each mount target can accept up to 64 NFS/SSL client connections. See Using In-transit Encryption on page 2847 for more information.
- Each tenancy in a region can have 1 CreateMountTarget or ChangeMountTargetCompartment operation in progress at a time. See 409 error occurs when creating or moving a file system or mount target for more information.
• Each mount target requires three internal IP addresses in the subnet to function:
  • Two of the IP addresses are used during mount target creation. The third IP address must remain available for
    the mount target to use for high availability failover.
  • The third IP address is used to create a new VNIC for the mount target during failover. The original primary
    IP address is retained.
  • The File Storage service doesn't "reserve" the third IP address required for high availability failover.
  • Use care to ensure that enough unallocated IP addresses remain available for your mount targets to use during
    failover.
  • Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP
    addresses for mount target creation.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access
is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message
that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and
which compartment to work in.

For administrators: The policy in Let users create, manage, and delete file systems allows users to manage mount
targets. Since mount targets are network endpoints, users must also have "use" permissions for VNICs, private IPs,
private DNS zones, and subnets to create or delete a mount target. See the Policy Reference on page 3347 for more
information.

If you're new to policies, see Getting Started with Policies and Common Policies.

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags
at the time you create a resource, or you can update the resource later with the wanted tags. For general information
about applying tags, see Resource Tags on page 243.

**Moving Mount Targets to a Different Compartment**

You can move mount targets from one compartment to another. When you move a mount target to a new
compartment, its associated export set and exports move with it. After you move the mount target to the new
compartment, inherent policies apply immediately and affect access to the mount target, export set, and exports
through the Console. Moving these resources doesn't affect access to file systems and snapshots from mounted
instances. For more information, see Managing Compartments.

**Details About Your Mount Target**

The mount target details page provides the following information about your mount target:

**MOUNT TARGET OCID**

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud
Identifier (OCID). You need your mount target's OCID to use the Command Line Interface (CLI) or the API.
You also need the OCID when contacting support.

**CREATED**

The date and time that the mount target was created.

**Availability Domain**

When you create a mount target, you specify the availability domain that it resides in. An availability domain
is one or more data centers located within a region. You need your mount target's availability domain to use
the Command Line Interface (CLI) or the API. For more information, see Regions and Availability Domains
on page 210.
COMPARTMENT

When you create a mount target, you specify the compartment that it resides in. A compartment is a collection of related resources (such as cloud networks, compute instances, or file systems) that are accessible only to those groups that have been given permission by an administrator in your organization. You need your mount target's compartment to use the Command Line Interface (CLI) or the API. For more information, see Managing Compartments.

REPORTED SIZE (GiB)

The maximum capacity in gibibytes reported by the file systems exported through this mount target. The File Storage service currently reports 8589934592 gibibytes (GiB) of available capacity by default. If you are installing an application that requires a specific reported size, you can change the reported size. Typically, setting the size to 1024 GiB is sufficient for most applications. This value is updated hourly. See To set the file system reported size on page 2891 for more information.

REPORTED INODES (GiI)

The maximum capacity in gibiinodes reported by the file systems exported through this mount target. The File Storage service currently reports gibiinodes (GiI) of available inodes by default. If you are installing an application that requires specific reported inodes, you can change the reported inodes. Typically, setting the inodes to 1024 GiI is sufficient for most applications. This value is updated hourly. See To set the file system reported size on page 2891 for more information.

NETWORK SECURITY GROUPS

The network security groups that the mount target belongs to. Each mount target can belong to up to five (5) NSGs. See To add a mount target to a network security group on page 2892 for more information.

VIRTUAL CLOUD NETWORK

The VCN that contains the subnet where the mount target VNIC resides.

SUBNET

The subnet within the VCN where the mount target VNIC resides. Subnets can be either AD-specific or regional (regional ones have “regional” after the name). For more information, see VCNs and Subnets on page 4321.

IP ADDRESS

The IP address that was assigned to the mount target when it was created. You need your mount target's IP address to mount associated file systems.

HOSTNAME

The hostname that was assigned to the mount target, if any. For more information about hostnames, see DNS in Your Virtual Cloud Network on page 4409.

FULLY QUALIFIED DOMAIN NAME

The hostname together with the subnet domain name. For more information, see DNS in Your Virtual Cloud Network on page 4409. If you specify a hostname, you can use the FQDN to mount the file system.

EXPORT SET OCID

The OCID of the mount target's export set resource. Each mount target has one export set, which contains all of the exports for the mount target. You need your mount target's export set OCID when you perform export-related tasks in the Command Line Interface (CLI) or the API.

EXPORTS

All of the mount target's exports are listed here. The export path and name of each file system is also listed. You need the export path to mount a file system.
Using the Console
To create a mount target

**Important:**
While it is possible to access mount targets from any AD in a region, for optimal performance, your mount targets should be in the same availability domain as the compute instances that access them. For more information, see Regions and Availability Domains on page 2828.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
   The Console displays a list of mount targets that have already been created in the compartment, if any.
3. Click **Create Mount Target**.
4. Enter the required mount target information. Click the **click here** link in the dialog box if you want to enable compartment selection for the mount target, its VCN, or subnet resources:
   - **New Mount Target Name:** Optionally, replace the default with a friendly name for the mount target. It doesn't have to be unique; an Oracle Cloud Identifier (OCID) uniquely identifies the mount target. Avoid entering confidential information.
     **Note:**
     The mount target name is different than the DNS hostname, which is specified in step 5.
   - **Virtual Cloud Network Compartment:** The compartment containing the cloud network (VCN) in which to create the mount target.
   - **Virtual Cloud Network:** Select the cloud network (VCN) where you want to create the new mount target.
   - **Configure Network Security Groups:** Select this option to add this mount target to an NSG you've created. Choose an NSG from the list.
     **Important:**
     Rules for the NSG you select must be configured to allow traffic to the mount target's VNIC using specific protocols and ports. For more information, see Configuring VCN Security Rules for File Storage on page 2832.
   - **Subnet Compartment:** Specify the compartment containing a subnet within the VCN to attach the mount target to.
   - **Subnet:** Select a subnet to attach the mount target to. Subnets can be either AD-specific or regional (regional ones have "regional" after the name). For more information, see VCNs and Subnets on page 4321.
     **Caution:**
     Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.
5. Optionally, click **Show Advanced Options** to configure the mount target's advanced options.
   - **IP Address**: You can specify an unused IP address in the subnet you selected for the mount target.
   - **Hostname**: You can specify a hostname you want to assign to the mount target.

   **Note:**
   The File Storage service constructs a fully qualified domain name (FQDN) by combining the hostname with the FQDN of the subnet the mount target is located in.

   For example, myhostname.subnet123.dnslabel.oraclevcn.com.

   Once created, the hostname may be changed in the mount target's Details page. See Managing Mount Targets on page 2885 for more information.

6. Click **Create**.

**To view details of a mount target**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.

   The Console displays a list of mount targets that have already been created in the compartment, if any.
3. Find the mount target you're interested in, click the Actions menu, and then click **View Mount Target Details**.

**To change the mount target name**

You can change the display name of the mount target.

   **Note:**
   Changing the display name doesn't affect mounting file systems exported through the mount target.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. To view information about a file system, find the file system, click the Actions menu, and then click **View Mount Target Details**.
4. Click **Rename**.
5. Enter the new mount target name. Avoid entering confidential information. Then click **Rename**.

**To create an export and a new file system**

Exports control how NFS clients access file systems when they connect to a mount target. File systems must have at least one export in at least one mount target in order for instances to mount the file system. The following steps create an export and a new file system. If you want to create an export for an existing file system, see To create an export for a file system on page 2878.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the left-hand navigation, in the **List Scope** section, under **Compartment**, select a compartment.
3. Click the name of the mount target you want to create an export for, and click **Create Export**.

   **Note:**
   File systems are encrypted by default. You cannot turn off encryption.

4. You can choose to accept the system defaults, or change them by clicking **Edit Details**.
5. Click **Create**.

Next, mount the file system from an instance so that you can read and write directories and files in your file system. See Mounting File Systems on page 2859 for instructions about obtaining mount commands for your operating system type and mounting your file system.
To set the file system reported size

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibiinodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the Reported Size or Reported Inodes value in the file system's mount target. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

**Important:**

Changing the Reported Size or Reported Inodes for a mount target affects all file systems exported by the mount target. Changing these values does not limit the amount of data you can store.

1. Open the navigation menu and click Storage. Under File Storage, click Mount Targets.
2. In the List Scope section, select a compartment.
3. Find the mount target you're interested in, click the Actions menu, and then click View Mount target Details.
4. Click the Reported Size (in GiB) Edit or the Reported Inodes (in GiI) icon.
5. Enter the maximum size in gibibytes or the maximum inodes in gibiinodes you want the File Storage service to report.
6. Click the Save icon.

**Important:**

There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the df command. For more information, see File System Usage and Metering on page 2918.

To delete an export

**Note:**

Deleting an export does not impact the data stored in the associated file system. Deleting an export disconnects any instance that mounts the file system with the deleted export path. Mount targets that have no exports still count toward your service limit.

1. Open the navigation menu and click Storage. Under File Storage, click Mount Targets.
2. In the List Scope section, select a compartment.
3. Find the mount target you're interested in, click the Actions menu, and then click View Mount target Details.
4. In Exports, find the export you want to delete.
5. Click the Actions menu, and then click Delete.

To manage tags for a mount target

1. Open the navigation menu and click Storage. Under File Storage, click Mount Targets.
2. In the List Scope section, select a compartment.
3. Find the mount target you're interested in, click the Actions menu, and then click View Mount Target Details.
4. Click the Tags tab to view or edit the existing tags. Or click Apply tag(s) to add new ones.

For more information, see Resource Tags on page 243.

To move a mount target to a different compartment

1. Open the Console.
2. Open the navigation menu and click Storage. Under File Storage, click Mount Targets.
3. In the List Scope section, select a compartment.
4. Find the mount target in the list, click the the Actions menu, and then click Change Compartment.
5. Choose the destination compartment from the list.
6. Click **Change Compartment**.

**To add a mount target to a network security group**

You can add the mount target to one or more Network Security Groups (NSGs). File storage requires specific rules to be configured for NSGs that are associated with mount targets. For more information, see Configuring VCN Security Rules for File Storage on page 2832.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target you're interested in, click the Actions menu, and then click **View Mount Target Details**.
4. In the **Mount Target Information** tab, click the **Edit** link next to **Network Security Groups**.
5. Select a **Compartment** and NSG from the list.
6. Click **Save**.

**To delete a mount target**

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. In the **List Scope** section, select a compartment.
3. Find the mount target you want to delete.
4. Click the Actions menu, and then click **Delete**.

**Caution:**

Deleting the mount target also deletes all of its exports of associated file systems. File systems are no longer available through the deleted mount target.

Deleting a mount target has no effect on file system data or file system snapshots.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI) on page 6117.

**To create a mount target**

You can create a mount target for file systems in a specified compartment and subnet. A file system can only be associated with a mount target in the same availability domain.

**Caution:**

Each mount target requires three internal IP addresses in the subnet to function. Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses. Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.

Open a command prompt and run **oci fs mount-target create** to create a mount target.

For example:

```
oci fs mount-target create --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --subnet-id <subnet_OCID> --display-name "<My Mount Target>"
```

Avoid entering confidential information.

You can create a mount target that is added to a network security group (NSG).
For example:

```bash
oci fs mount-target create --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --subnet-id <subnet_OCID> --display-name "<My Mount Target>" --nsg-ids ["<nsg_OCID_1>", "<nsg_OCID_2>"]
```

**To update a mount target**

Open a command prompt and run `oci fs mount-target update` to update a specific mount target’s information or to add it to a network security group (NSG).

For example:

```bash
oci fs mount-target update --mount-target-id <mount_target_OCID> --display-name "<New Mount Target Name>" --nsg-ids ["<nsg1_OCID>", "<nsg2_OCID>"]
```

Avoid entering confidential information.

**To delete a mount target**

Open a command prompt and run `oci fs mount-target delete` to delete a mount target. Deleting a mount target also deletes the mount target's VNICs.

For example:

```bash
oci fs mount-target delete --mount-target-id <mount_target_OCID>
```

**Caution:**

Deleting a mount target can cause any clients that have mounted an associated file system to hang. Be sure to have all clients unmount the file systems before deleting the mount target.

**To list mount targets**

You cannot use the Console to list mount targets. Use the command line interface or the API from a host machine running a UNIX-style operating system.

Open a command prompt and run `oci fs mount-target list` to list all mount targets in a specified availability domain and compartment.

For example:

```bash
oci fs mount-target list --availability-domain <target_availability_domain> --compartment-id <target_compartment_OCID>
```

**To get a specific mount target**

Open a command prompt and run `oci fs mount-target get` to retrieve information about a specific mount target.

For example:

```bash
oci fs mount-target get --mount-target-id <mount_target_OCID>
```

**To create an export**

Exports control how NFS clients access file systems when they connect to a mount target. File systems are exported (made available) through mount targets. Each mount target maintains an export set which contains one or many exports. A file system may be exported through one or more mount targets. A file system must have at least one export in one mount target in order for instances to mount the file system. The information used by an export includes the file system OCID, mount target OCID, export set OCID, export path, and client export options. Typically, an
export is created in a mount target when the file system is created. Thereafter, you can create additional exports for a file system in any mount target that resides in the same availability domain as the file system.

Open a command prompt and run `oci fs export create` to create an export for a specified file system within a specified export set.

For example:

```
oci fs export create --export-set-id <export_set_OCID> --file-system-id <file_system_OCID> --path "</pathname>"
```

**Important:**

The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

Acceptable:

```
/example and /path
/example and /example2
```

Not Acceptable:

```
/example and /example/path
/ and /example
/example/
/example/path/../../example1
```

**Caution:**

If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

**Note:**

Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

For more information, see [Paths in File Systems](#) on page 2917.

**To list exports**

Open a command prompt and run `oci fs export list` to list all exports in a specified compartment.

For example:

```
oci fs export list --compartment-id <target_compartment_id>
```

**To get a specific export**

Open a command prompt and run `oci fs export get` to retrieve information about a specific export.

For example:

```
oci fs export get --export-id <export_OCID>
```
To delete an export

Open a command prompt and run `oci fs export delete` to delete an export.

For example:

```
oci fs export delete --export-id <export_OCID>
```

**Caution:**
When you delete an export, any file system referenced by the export is no longer accessible through the associated mount target.

To list export sets

Open a command prompt and run `oci fs export-set list` to list all export sets in a specified availability domain and compartment.

For example:

```
oci fs export-set list --availability-domain <target_availability_domain> --compartment-id <target_compartment_OCID>
```

To get a specific export set

Open a command prompt and run `oci fs export-set get` to retrieve information about a specific export set.

For example:

```
oci fs export-set get --export-set-id <export_set_OCID>
```

To update an export set

Open a command prompt and run `oci fs export-set update` to update a specific export set's information.

For example:

```
oci fs export-set update --export-set-id <export_set_OCID> --display-name "<New Export Set Name>"
```

To set the file system reported size

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibiinodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the `Reported Size` or `Reported Inodes` value in the export set of the file system's mount target. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

**Important:**
Changing the `Reported Size` or `Reported Inodes` for a mount target affects all file systems exported by the mount target. Changing these values does not limit the amount of data you can store.

**Important:**
There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the `df` command. For more information, see File System Usage and Metering on page 2918.
Open a command prompt and type in the following command:

```
oci fs export-set update --export-set-id <export_set_OCID> --max-fs-stat-bytes <number_of_bytes>
```

**To move a mount target to a different compartment**

```
oci fs mount-target change-mount-target-compartment --mount-target-id <mount_target_OCID> --compartment-id <destination_compartment_OCID>
```

**Using the API**

- CreateMountTarget
- UpdateMountTarget
- DeleteMountTarget
- GetMountTarget
- ListMountTargets
- ChangeMountTargetCompartment
- CreateExport
- DeleteExport
- GetExport
- ListExports
- UpdateExportSet
- GetExportSet
- ListExportSets

**Managing Snapshots**

The File Storage service supports snapshots for data protection of your file system. Snapshots are a consistent, point-in-time view of your file systems. Snapshots are copy-on-write, and scoped to the entire file system. The File Storage service encrypts all file system and snapshot data at rest. You can take as many snapshots as you need.

Data usage is metered against differentiated snapshot data. If nothing has changed within the file system since the last snapshot was taken, the new snapshot does not consume more storage. For more information, see File System Usage and Metering on page 2918.

Snapshots are accessible under the root directory of the file system at `.snapshot/name`. When you use an NFSv3 client to perform operations such as `ls`, `du`, or `find` on the snapshot directory, the service automatically exports the directory. The client uses `nfs_d_automount()` to detect and mount the directory. After the directory is detected and mounted the first time, the client mounts the directory automatically.

For data protection, you can use a tool that supports NFSv3 to copy your data to a different availability domain, region, file system, object storage, or remote location.

For best performance, we recommend that you use the parallel tar (`partar`) and parallel copy (`parcp`) tools provided in the File Storage Parallel File Toolkit for this purpose. These tools work best with parallel workloads and requests. The Parallel File Toolkit is available for Oracle Linux, Red Hat Enterprise Linux, and CentOS. You can use `rsync` or regular `tar` for other operating system types. See Installing the Parallel File Tools on page 2906 for more information.

**Tip:**

Watch a video about protecting data with snapshots in File Storage.
Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users create, manage, and delete file systems allows users to create and delete snapshots.

If you're new to policies, see Getting Started with Policies and Common Policies.

Details About Your Snapshot

The Details page provides the following information about your snapshot:

SNAPSHOT OCID

Every Oracle Cloud Infrastructure resource has an Oracle-assigned unique ID called an Oracle Cloud Identifier (OCID). You need your snapshot's OCID to use the Command Line Interface (CLI) or the API. You also need the OCID when contacting support. See Resource Identifiers on page 228.

CREATED

The date and time that the snapshot was created.

DESCENDANTS

Indicates whether the this snapshot has been used to create a clone. See Cloning File Systems on page 2900.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 243.

Using the Console

To create a snapshot

2. In the List Scope section, select a compartment.
3. In the File Systems list, locate the file system you want to take a snapshot of. Click the Actions menu, and then click View File System Details.
4. In Resources, click Snapshots.
5. Click Create Snapshot.
6. Fill out the required information:
   - Name: Enter a name for the snapshot. It must be unique among all other snapshots for this file system. The name can't be changed. Avoid entering confidential information.
7. Click Create Snapshot. The snapshot is accessible under the root directory of the file system at .snapshot/name.

To view details of a snapshot

2. In the List Scope section, select a compartment.
3. In the File Systems list, locate the file system you took the snapshot of. Click the Actions menu, and then click View File System Details.
4. In Resources, click Snapshots.
5. In the Snapshots list, locate the snapshot you're interested in. Click the Actions menu, and then click View Snapshot Details.
To create a snapshot from a Unix-style instance

You can create a snapshot from an instance that you've mounted the file system to. Snapshots are created under the root folder of your file system, in a hidden directory named `.snapshot`.

1. Connect to your instance and open a command window.
2. Navigate to your file system's hidden `.snapshot` directory. Type the following, replacing `yourmountpoint` with the name of the directory where you mounted the file system.

```bash
cd /mnt/yourmountpoint/.snapshot
```
3. Use the `mkdir` command to create a directory in the hidden `.snapshot` directory. The directory you create is the snapshot. Give the snapshot a name that will help you identify it. Avoid using confidential information in the snapshot name. For example:

```bash
mkdir snapshot-Jan1
```
4. Use the `ls` command to verify that your snapshot has been created in the `.snapshot` directory.

```bash
ls
```

To restore a snapshot

Snapshots are created under the root folder of your file system, in a hidden directory named `.snapshot`.

You can restore a file within the snapshot, or an entire snapshot using the `cp` command. Use the `-r` option when restoring a snapshot that contains subdirectories.

For example:

```bash
cp -r .snapshot/snapshot_name/* destination_directory_name
```

Optionally, you can use `rsync`, `tar`, or another tool that supports NFSv3 to copy your data to another remote location. For optimal performance, use the Parallel File Tools.

For example:

```bash
parcp .snapshot/snapshot_name/* destination_directory_name
```

To manage tags for a snapshot

2. In the List Scope section, select a compartment.
3. In the File Systems list, locate the file system you took the snapshot of. Click the Actions menu, and then click View File System Details.
4. In Resources, click Snapshots.
5. In the Snapshots list, locate the snapshot you're interested in. Click the Actions menu, and then click View Snapshot Details.
6. Click the Tags tab to view or edit the existing tags. Or click Apply tag(s) to add new ones.

For more information, see Resource Tags on page 243.

To clone a file system from a snapshot

Before you can clone a file system, at least one snapshot must exist for the file system. See To create a snapshot on page 2897 for more information.

2. In the List Scope section, select a compartment.
3. Find the file system you want to clone, click the Actions menu, and then click View File System Details.
4. In the **Snapshots** list, find the snapshot you want to use as the source of the clone, click the Actions menu, and then click **Clone**.

   The clone is a copy of the file system data as it exists at the date and time that the selected snapshot was taken.

5. In the **Create Clone** page, specify the details about the clone that aren't inherited from the parent file system, such as name, export information, and mount target information. You can choose to accept the provided system defaults, or change them by clicking **Edit Details**. For a detailed description of each file system property and its defaults, see To create a file system on page 2852.

6. Click **Create**.

   Hydration begins immediately upon instantiation of the clone.

   Cloned file systems are managed in the same way that any other file system is managed. See Managing File Systems on page 2875 for more information.

   To view the clone's hydration status, source snapshot, parent file system, and other cloning information, visit the **Details** page of the cloned file system. See To view file system details on page 2877.

   You can mount and use the clone immediately for READ or WRITE operations after you create it. See Mounting File Systems on page 2859 for more information.

**To delete a snapshot**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
</table>
If the snapshot is deleted while a clone of it is being hydrated, the source snapshot remains in the DELETING state until hydration is complete. See for more information.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the file system with the snapshot you want to delete.
4. Click the Actions menu, and then click **View File System Details**.
5. In **Resources**, click **Snapshots**.
6. Find the snapshot you want to delete.
7. Click **Delete**.

**Using the Command Line Interface (CLI)**

For information about using the CLI, see Command Line Interface (CLI) on page 6117.

**To create a snapshot**

You can create a snapshot of a file system. A snapshot is a point-in-time view of the file system. The snapshot is accessible at ./shapshot/name.

Open a command prompt and run `oci fs snapshot create` to create a snapshot of a file system.

For example:

```
oci fs snapshot create --file-system-id <file_system_OCID> --name "<January1>"
```

Avoid entering confidential information.

**To list snapshots**

Open a command prompt and run `oci fs snapshot list` to list all snapshots associated with a specific file system.

For example:

```
oci fs snapshot list --file-system-id <file_system_OCID>
```
To get a specific snapshot
Open a command prompt and run `oci fs snapshot get` to retrieve information about a specific snapshot.
For example:

```
oci fs snapshot get --snapshot-id <snapshot_OCID>
```

To delete a snapshot
Open a command prompt and run `oci fs snapshot delete` to delete a snapshot.
For example:

```
oci fs snapshot delete --snapshot-id <snapshot_OCID>
```

Using the API
- CreateSnapshot
- ListSnapshots
- GetSnapshot
- DeleteSnapshot
- CreateFileSystem (To create a file system clone, include the OCID of the file system snapshot you want to use as a source for the clone in the `sourceSnapshotId` parameter.)

If you have issues managing snapshots, see Troubleshooting Snapshot Management on page 2942.

Cloning File Systems
This topic describes how to create a clone of an existing file system.

Overview
A clone is a new file system that is created based on a snapshot of an existing file system. Snapshots preserve the state of the data of a file system at a particular point in time. If you take snapshots of a file system at regular intervals, you can create clones of the file system as it existed at multiple points in its lifetime.

A snapshot provides the initial blueprint for a clone. You can clone a parent file system, or you can clone a clone, as long as there's at least one snapshot available. At the point of creation, the data included in the clone is identical to the data in the snapshot. After creation, data changes in the clone aren't included in the original file system. Conversely, any data changes to the original file system aren't included in the clone. All file systems operate independently of each other, regardless of whether they are parent file systems, clones, or clones of clones.

Clones are space and time efficient because creating a clone doesn't replicate or move any data from the parent file system to the clone. Instead, the clone references the parent file system for any data they share. A file system that is a clone of a clone also references the original parent file system for any shared data.

When you create a clone, initially only the metadata incurs storage costs. Clone data usage is metered only against differentiated data. Data that the clone references from the parent file system isn't metered against the clone, just the parent. For more information, see File System Usage and Metering on page 2918.

**Note:**
Clones count against your tenancy's service limits the same way regular file systems do.

See Service Limits on page 247 for a list of applicable limits and instructions for requesting a limit increase.

You can use clones for testing, patching, and faster application provisioning. If failed testing or patching causes the data to become unrecoverable, create a new clone from the original file system snapshot, delete the old clone, and restart your operation.
Cloning Concepts

PARENT FILE SYSTEM

A parent file system is a file system that contains data referenced by one or many clones. When you create a clone, you must specify which file system snapshot is used as the blueprint for the clone directory hierarchy and file data. The file system that contains this snapshot is the initial parent of the clone. The clone continues to reference the parent file system for any data they share in common.

A clone’s parent file system can change after the clone is created. For example, if you delete a clone’s parent file system, the file system parent’s parent (the clone’s grandparent) becomes the clone’s new parent. The clone's data references are transferred to the new parent.

SOURCE SNAPSHOT

The snapshot used as a blueprint to create a clone. A snapshot is a point-in-time reference of a file system. You can take as many snapshots of a file system as you like, as often as you like. A parent file system can have snapshots available for many points along its lifetime. You can create a clone of your file system as it exists today, or as it existed in the past, as long as snapshots were taken of the file system at those times. For more information, see Managing Snapshots on page 2896.

FILE SYSTEM CLONE

A clone is a new file system that is created based on a snapshot of existing file system. A clone automatically inherits the directory hierarchy and file data of the file system. All snapshots that exist in the parent file system are inherited by the clone, up to and including the snapshot that is used as the source of the clone. The timeCreated field of inherited snapshots are set to the time the clone operation was initiated. You can choose to keep or delete these snapshots.

File system properties such as compartment, tags, display name, keys, and mount target export information are not copied over from the parent. These properties must be specified manually. You can access the clone by creating an export for it and mounting it to an instance in the same manner as any other file system. See To create an export for a file system on page 2878 and Mounting File Systems on page 2859.

When a clone is created, it is assigned a unique OCID. A clone also contains the following information on its Details page to let you track its relationships to other file systems and snapshots:

- **Hydration**: Indicates whether the clone is currently copying metadata from the source.
- **Source snapshot**: A link to the snapshot used to create the clone.
- **Parent File System**: A link to the parent file system of the clone.
- **Root**: Indicates whether this file system is the root of a clone tree.
- **Descendants**: Indicates whether this file system has been cloned.

Cloned file systems are managed in the same way that any other file system is managed. See Managing File Systems on page 2875 for information on how view the clone's Details page, edit its properties, or delete the clone.

CLONE TREE

A clone tree is a group of clones that all descend from the same root file system. There is a transitive relationship between the root and the descendant clones. To delete the root of a clone tree, all its descendants must first be deleted.

In this diagram, B, C, D, E, F, G are all clones. A# B# C#D and A# B# E# F# G are all part of a clone tree. File system A is the root of this clone tree, and it is the parent of file system B.
A clone tree branch is a set of clones whose data diverges from a common ancestor in the clone tree. In the example above, C and D are one branch of the clone tree, and E, F, and G are a second branch of the clone tree.

**Depth** is a term used to describe how many clones are between one file system and another in a clone tree. In the example above, the depth from G to E is 2, and the depth from G to A is 4.

**Size** is a term used to describe how many clones descend from a single parent. In the example above, the size of the clone tree from clone A is 6, but the size of the clone tree from F is only 1.

**HYDRATION**

Hydration is the process of copying metadata from the source to the clone. Hydration is an asynchronous process that starts when the clone is created. The clone is immediately available on creation and can be used for regular operations while hydration is in progress. You can see whether a clone is still in the process of hydration by visiting its **Details** page. See To view file system details on page 2877.

**Limitations and Considerations**

**Logical Organization**

You can only create a clone in the same availability domain as its parent file system. See About Regions and Availability Domains on page 210 for more information.

**Clone Hydration**

**Performance**

Creating a clone is instantaneous and you can immediately access the clone for both READ and WRITE operations. However, there is a minor performance impact on both the parent and clone when accessing shared data while hydration is in progress. Performance impact is more significant on the clone than the parent. The duration of impact depends on the size of the source.

If the clone and parent are concurrently hydrating, hydration can affect the performance of the clone tree root. When creating clones, we recommend that you do not have more than 10 clones hydrating within a clone tree concurrently.

In this diagram, file system A is the root of the clone tree. File systems B, C, D, E, F, and G are all concurrently hydrating, so the performance of file system A might be impacted.
After hydration is complete, there is no further impact to the parent file system or clone tree root. You can see if hydration is in progress on a clone by viewing its Details page. See To view file system details on page 2877.

Clone Tree Size and Depth

The number of clones in a clone tree that can hydrate concurrently is limited based on the following two values:

- **Maximum Size: 10** This value represents the maximum allowed number of clones in a clone tree concurrently hydrating from a single parent file system.
- **Maximum Depth: 5** This value represents the maximum number of unhydrated clones on a clone tree branch between the clone you’re creating and its last hydrated ancestor.

Exceeding these limits causes the cloning operation to fail. Wait until enough clones complete hydration, and then try the operation again.

Deleting Resources

**File Systems**

You can delete a file system if it is not the root of a clone tree. If a file system is the root of a clone tree, all descendant clones must first be deleted.

If a clone parent is deleted while any of its descendants are still hydrating, the parent remains in the DELETING state until hydration is complete. The metered space associated with the clone parent remains in use until all hydration is complete for all descendant clones. While a file system is still in a DELETING state, its parent, children, and siblings cannot be deleted. A file system in a DELETING state cannot be cloned. However, you can still clone its siblings or children.

After deletion is complete, the parent of the deleted file system becomes the new parent of the descendant clones.

**Source Snapshot**

You can delete the source snapshot of a clone. If the source snapshot is deleted while a clone of it is being hydrated, the source snapshot remains in the DELETING state until hydration is complete.

**Parent Snapshots**

A clone inherits all snapshots from the parent. If you delete a snapshot within a parent file system while hydration is in progress, the snapshot remains in the DELETING state until hydration is complete. After hydration is complete, you can delete any snapshot in the parent or clone file system at any time.

See instructions for deleting file systems in Managing File Systems on page 2875

See instructions for deleting snapshots in Managing Snapshots on page 2896.
**Metering and Billing**

A parent file system is metered for all the data shared with its descendant clones. A clone is metered for its metadata and incremental changes made to its data. When a clone is deleted, all blocks that are referenced solely by that clone are reclaimed. If another clone is hydrating from the deleted clone, the referenced blocks are reclaimed after hydration is complete.

If you delete a parent clone, any data blocks shared by descendant clones cannot be released. Allocated blocks referenced by descendant clones are transferred to the new clone parent (the clone parent's parent) for metering purposes. You are not metered more than once for data shared between multiple file systems. For more information, see [File System Usage and Metering](#) on page 2918.

**Required IAM Service Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: Cloning a file system uses the `CreateFileSystem` API operation and requires the `FILE_SYSTEM_CLONE` permission. The policy in [Let users create, manage, and delete file systems](#) allows users to clone file systems. See the [Policy Reference](#) on page 3347 for more information.

If you're new to policies, see [Getting Started with Policies](#) and [Common Policies](#).

**Using the Console**

**To clone a file system**

Before you can clone a file system, at least one snapshot must exist for the file system. See [To create a snapshot](#) on page 2897 for more information.

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. In the **List Scope** section, select a compartment.
3. Find the file system you want to clone, click the Actions menu, and then click **View File System Details**.
4. In the **Snapshots** list, find the snapshot you want to use as the source of the clone, click the Actions menu, and then click **Clone**.

   The clone is a copy of the file system data as it exists at the date and time that the selected snapshot was taken.

5. In the **Create Clone** page, specify the details about the clone that aren't inherited from the parent file system. You can choose to accept the provided system defaults, or change them by clicking **Edit Details**. For a detailed description of each file system property and its defaults, see [File System Information](#).
6. Click **Create**.

Hydration begins immediately upon instantiation of the clone.

Cloned file systems are managed in the same way that any other file system is managed. See [Managing File Systems](#) on page 2875 for more information.

To view the clone's hydration status, source snapshot, parent file system, and other cloning information, visit the **Details** page of the cloned file system. See [To view file system details](#) on page 2877.

**Next Steps:**

You can export, mount, and use the clone immediately for READ or WRITE operations after you create it. See [To create an export for a file system](#) on page 2878 and [Mounting File Systems](#) on page 2859 for more information.
Using the Command Line Interface (CLI)

To create a file system clone
To create a file system clone, use the `file-system create` command, and include the OCID of the file system snapshot you want to use as a source for the clone.

For example:

```
oci fs file-system create --availability-domain AAbC:US-ASHBURN-AD-1 --display-name "Clone_1" --compartment-id ocid1.compartment.oc1..<unique_id> --kms-key-id --kms-key-id ocid1.key.oc1.iad.<unique_id> --source-snapshot-id ocid1.snapshot.oc1..<unique_id>
```

To find all clones created from a specific source snapshot or parent file system
Open a command prompt and run `oci fs file-system list` to list all the file systems in a specified availability domain and compartment. Include either `--source-snapshot-id` or `--parent-file-system-id`.

An example using `--source-snapshot-id`.

```
oci fs file-system list --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --source-snapshot-id <snapshot_id>
```

An example using `--parent-file-system-id`.

```
oci fs file-system list --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --parent-file-system-id <parent_filesystem_id>
```

Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use the following operations to create file system clones:

- CreateFileSystem
- CreateMountTarget
- CreateExport

To create a cloned file system instead of a new file system, the CreateFileSystem operation requires the `sourceSnapshotId` parameter. For example:

```
POST /20171215/fileSystems
Host: filestorage.us-phoenix-1.oraclecloud.com
<authorization and other headers>
{
    "availabilityDomain": "pWEh:PHX-AD-2",
    "compartmentId": "ocid1.compartment.oc1..<unique_id>"",
    "displayName": "Clone_1",
    "freeformTags": {},
    "definedTags": {},
    "kmsKeyId": "ocid1.key.oc1..<unique_ID>",
    "sourceSnapshotId": "ocid1.snapshot.oc1..<unique_ID>
}
```

If you have issues managing clones, see Troubleshooting File System Clones on page 2934.
Using File Storage Parallel Tools

The Parallel File Tools suite provides parallel versions of `tar`, `rm`, and `cp`. These tools can run requests on large file systems in parallel, maximizing performance for data protection operations.

The toolkit includes:

- **partar**: Use this command to create and extract tarballs in parallel.
- **parrm**: You can use this command to recursively remove a directory in parallel.
- **parcp**: Use this command to recursively copy a directory in parallel.

Installing the Parallel File Tools

The tool suite is distributed as an RPM for Oracle Linux, Red Hat Enterprise Linux, and CentOS.

To install Parallel File Tools on Linux

To install Parallel File Tools on an Oracle Linux instance:

1. Open a terminal window on the destination instance.
2. Type the following command:

   ```bash
   sudo yum install -y fss-parallel-tools
   ```

To install Parallel File Tools on CentOS and Red Hat 6.x

To install Parallel File Tools on CentOS and Red Hat 6.x:

1. Open a terminal window on the destination instance.
2. Type the following command:

   ```bash
   sudo wget http://yum.oracle.com/RPM-GPG-KEY-oracle-ol6 -O /etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
   sudo yum --enablerepo=ol6_developer install fss-parallel-tools
   ```

To install Parallel File Tools on CentOS and Red Hat 7.x

1. Open a terminal window on the destination instance.
2. Type the following command:

   ```bash
   sudo wget http://yum.oracle.com/RPM-GPG-KEY-oracle-ol7 -O /etc/pki/rpm-gpg/RPM-GPG-KEY-oracle
   sudo yum --enablerepo=ol7_developer install fss-parallel-tools
   ```

Using the Tools - Simple Examples

Here are some simple examples of how the different tools are commonly used in Oracle Cloud Infrastructure File Storage.

To copy all files and folders from one directory to another

In this example, `parcp` is used to copy the contents of one folder to another. The `-P` option is used to set the number of parallel threads you want to use.

```bash
$parcp -P 16 /source/folder /destination/folder
```
To create a .TAR archive of a directory

The following command will create a .tar archive of the contents of the specified directory, and store it as a tarball in the directory. In the example below, the name of the directory that is being used to create the tarball is example.

```
$partar pcf example.tar example -P 16
```

You can also create a tarball and send it to a different directory. In the example below, the directory being used to create the tarball is example. The tarball is being created in the /test directory.

```
$partar pcf example.tar example -P 16 -C /test
```

Using the Tools - Advanced Examples

Here are some examples of how the different tools are used in more advanced scenarios.

To copy selected files or folders into a .TAR archive and exclude others

You can specify which files and folders are included when you create a .tar archive using partar. Let's say you have a directory that looks like this:

```
[opc@example sourcedir]$ ls -l
total 180
-rw-r-----...  1 opc opc          0 Apr 15 02:55 example2020-04-15_02-55-33_217107549.error
-rw-r-----...  1 opc opc         10 Apr 15 03:18 example2020-04-15_02-55-33_217107549.log
-rw-rw-r---...  1 opc opc         12 Apr 15 03:18 example2020-04-15_03-18-13_267771997.error
-rw-rw-r---...  1 opc opc         10 Apr 15 03:18 example2020-04-15_03-18-13_267771997.log
-rwrxr-xr-x...  1 opc opc         37 Nov 30  2017 File1.txt
-rwrxr-xr-x...  1 opc opc         15 Dec  1  2017 File2.txt
-rwrxr-xr-x...  1 opc opc         39 Nov 30  2017 File3.txt
-rwrxr-xr-x...  1 opc opc         57 Dec  1  2017 File4.txt
```

The following command creates a .tar archive that:

- Excludes all .log and .error files.
- Names the .tar archive mytar
- Sends the .tar ball from /sourcedir to /mnt/destinationdir
- Extracts the .tar archive

```
[opc@example sourcedir]$ partar cf - mytar '*.log*' --exclude '*.err*' | partar xf - -C /mnt/destinationdir
```

Performing ls -l on /mnt/destinationdir/mytar shows that only the desired files have been copied.

```
[opc@example mytar]$ ls -l
```

```
total 148
-rwrxr-xr-x...  1 opc opc         37 Nov 30  2017 File1.txt
-rwrxr-xr-x...  1 opc opc         15 Dec  1  2017 File2.txt
-rwrxr-xr-x...  1 opc opc         39 Nov 30  2017 File3.txt
-rwrxr-xr-x...  1 opc opc         57 Dec  1  2017 File4.txt
```
To copy selected files or folders from one directory to another

You can specify which files and folders are included when you use `parcp` to copy from one directory to another. Let's say you have a directory that looks like this:

```
[opc@example sourcedir]$ ls -l
total 180
-rw-r-----.  1 opc opc          0 Apr 15 02:55 example2020-04-15_02-55-33_217107549.error
-rw-r-----.  1 opc opc         10 Apr 15 03:18 example2020-04-15_02-55-33_217107549.log
-rw-r--r--.  1 opc opc         12 Apr 15 03:18 example2020-04-15_03-18-13_267771997.error
-rw-r--r--.  1 opc opc         10 Apr 15 03:18 example2020-04-15_03-18-13_267771997.log
-rwxr-xr-x.  1 opc opc         37 Nov 30  2017 File1.txt
-rwxr-xr-x.  1 opc opc         15 Dec  1  2017 File2.txt
-rwxr-xr-x.  1 opc opc         39 Nov 30  2017 File3.txt
-rwxr-xr-x.  1 opc opc         57 Dec  1  2017 File4.txt
```

First, create a `.txt` file containing a list of files you want to exclude. In this example, it's `/home/opc/list.txt`.

The following command copies the contents from `sourcedir` to `/mnt/destinationdir` and:

- Excludes `File4.txt` and the `.log` and `.error` files, as listed in `/home/opc/list.txt`.

```
[opc@example ~]$ cat /home/opc/list.txt
File4.txt
*.log*
*.err*
[opc@example ~]$ date; time sudo parcp --exclude-from=/home/opc/list.txt -P 16 --restore /sourcedir /mnt/destinationdir;
date Mon Jun  1 15:58:30 GMT 2020
real 9m55.820s
user 0m3.602s
sys 1m5.441s
Mon Jun  1 16:08:25 GMT 2020
```

Performing `ls -l` on `/mnt/destinationdir` shows that only the desired files have been copied.

```
[opc@example destinationdir]$ ls -l
total 91
-rwxr-xr-x.  1 opc opc         37 Nov 30  2017 File1.txt
-rwxr-xr-x.  1 opc opc         15 Dec  1  2017 File2.txt
-rwxr-xr-x.  1 opc opc         39 Nov 30  2017 File3.txt
```

To use PARCP as an effective alternative for RSYNC in parallel

The `--restore` option in `parcp` is similar to using the `-a` `-r` `-x` and `-H` options in `rsync`. (See `rsync(1)`-Linux Man Page.) The `-P` option is used to set the number of parallel threads you want to use.

The `restore` option includes the following behavior:

- Recurse into directories
- Stop at file system boundaries
• Preserve hard links, symlinks, permissions, modification times, group, owners, and special files such as named sockets and fifo files

$parcp -P 16 --restore /source/folder/ /destination/folder/

You can use parcp with the --restore and --delete options to sync files between a source and target folder. This is a good substitute for using rsync in parallel. As files are added or removed from the source directory, you can run this command at regular intervals to add or remove the same files from the destination directory. You can automate syncing by using this command option in a cron job.

sudo parcp -P 32 --restore --delete /source/folder/ /destination/folder/

File System Metrics

You can monitor the health, capacity, and performance of your file systems and mount targets by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_filestorage (the File Storage service).

Overview of Metrics for oci_filestorage

File Storage service metrics help you measure operations and throughput related to file systems and mount targets. The available metrics help you determine quickly if your file system is accessible, how much data is flowing through its associated mount target, and if operations are producing unexpected errors. You can get visibility into your workload IOPs and latency, and set up alarms to receive notifications if tolerance thresholds are exceeded.

File Storage metrics include these resources:

• **File system**: A high-performance shared storage entity made available to a network by an associated mount target.
• **Mount target**: An NFS endpoint that lives in a VCN subnet of your choice and provides network access for file systems.

Metrics provided for file systems can be filtered or grouped by their associated mount target.

Raw Data Point Frequency

For every 1-minute interval, the File Storage service posts one raw data point to the Monitoring service. The Monitoring service charts show data points at 1-minute, 5-minute, 1-hour (60-minute), and 1-day intervals. Supported values for interval depend on the specified time range in the metric query (not applicable to alarm queries). More interval values are supported for smaller time ranges. For example, if you select one hour for the time range, then all interval values are supported. If you select 90 days for the time range, then only the 1h or 1d interval values are supported. The available statistics are calculated by using the count of 1-minute data points in the select interval. For example, for a given metric:

• The mean for each 5-minute interval is calculated over 5 raw data points.
• The mean for each 60-minute interval is calculated over 60 raw data points.

Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_filestorage

The metrics listed in the following table are automatically available for any file system or mount target. You do not need to enable monitoring on the resource to get these metrics.
You also can use the Monitoring service to create custom queries. Each metric includes one or more of the following dimensions:

**RESOURCEID**

The *OCID* of the file system or mount target.

**MOUNTTARGETID**

The *OCID* of the mount target exporting an associated file system.

**THROUGHPUT**

The type of request throughput:

- ReadThroughput
- WriteThroughput

**SIZE**

The request size range:

- 0–8 KiB
- 8–64 KiB
- 64 KiB – 1 MiB

**HEALTHITEM**

The type of health rate item:

- SuccessRate
- ErrorRate

### File System Metrics

**Tips for Working with File Storage Metrics**

You can use the tables below to help interpret the data you see in File Storage metric charts. You can familiarize yourself with the typical metrics emitted by the File Storage service using the chart defaults.
## File System Charts

<table>
<thead>
<tr>
<th>This chart...</th>
<th>shows this information...</th>
<th>using these defaults...</th>
<th>that you can use to...</th>
</tr>
</thead>
</table>
| Read Throughput/Write Throughput | The read or write throughput of your file system in bytes per second. Read/write throughput is averaged across all mount targets that export the file system. Only the default **mean** statistic is meaningful. | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours  
• y-axis - bytes per second | • Ensure that your workloads have sufficient read/write bandwidth for maximum performance.  
• Identify which file systems have the highest and lowest throughput.  
• Receive notifications when read or write throughput is above or below tolerance, so you can take action. |
| Read Requests/Write Requests | Read or write operation requests processed by your file systems in bytes per second. Each operation is placed in one of these three size groups:  
• 0–8 KiB  
• 8–64 KiB  
• 64 KiB – 1 MiB  
Only the default **mean** statistic is meaningful. | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours  
• Grouped by: size  
• y-axis - bytes per second | • See which file systems might have lower performance than expected.  
• Measure impact of operation size on file system and workload performance.  
• Identify and monitor file systems whose workloads are consistently receiving larger read or write requests and compare performance over time.  
• Receive notifications when operation bytes per second for a larger group size is too high. |
<table>
<thead>
<tr>
<th><strong>This chart...</strong></th>
<th><strong>shows this information...</strong></th>
<th><strong>using these defaults...</strong></th>
<th><strong>that you can use to...</strong></th>
</tr>
</thead>
</table>
| **Read Latency/Write Latency** | Average latency of read or write operation requests processed by your file systems in bytes per second. Each operation is placed in one of these three size groups:  
• 0–8 KiB  
• 8–64 KiB  
• 64 KiB – 1 MiB  
These charts don’t report zero latency, or periods when there are no read/write operations happening. Information is presented in the charts as individual data points. | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours  
• Grouped by: size | • See which file systems might have lower performance than expected due to operation latency.  
• Measure impact of operation latency on file system and workload performance.  
• Troubleshoot possible network or application issues that might increase file system latency.  
• Receive notifications when operation latency exceeds tolerance, so you can take action. |
| **Metadata Latency** | Average latency of read or write metadata operation requests processed by your file systems in bytes per second. CREATE, GETATTR, SETATTR, and REMOVE operations are shown.  
Each operation is placed in one of these three size groups:  
• 0–8 KiB  
• 8–64 KiB  
• 64 KiB – 1 MiB | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours  
• Grouped by: size | • See which metadata operations requested by your workload have the highest and lowest latency.  
• Measure impact of metadata operation latency on file system and workload performance.  
• Receive notifications when a metadata operation exceeds tolerance.  
• Troubleshoot your application workloads. |
| **Metadata IOPs** | IOPs per second of read or write metadata operation requests processed by your file systems. CREATE, GETATTR, SETATTR, and REMOVE operations are shown. | • Statistic - rate  
• Interval - 1 minute  
• Time range - 3 hours  
• Grouped by: operation  
• y-axis - bytes per second | • See which metadata operations requested by your workload have the highest and lowest IOPs.  
• Identify specific operations that might consistently have higher or lower IOPs.  
• Receive notifications when IOPs for a metadata operation are below tolerance.  
• Troubleshoot your application workloads. |
### File Storage

<table>
<thead>
<tr>
<th>This chart...</th>
<th>shows this information...</th>

<tr>
<td>This chart...</td>
<td>shows this information...</td>
<td>using these defaults...</td>
<td>that you can use to...</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------------------</td>
<td>------------------------</td>
<td>-----------------------</td>
</tr>
</tbody>
</table>
| Connections  | The number of active connections for each mount target. Typically, one connection represents one NFS client. | • Statistic - sum  
• Interval - 1 minute  
• Time range - 3 hours | • See how many active connections each mount target has.  
• Measure impact of high connection count on file system and workload performance.  
• Decide if additional mount targets are required for your workload. |
| Health       | The percentage of requests processed successfully by the mount target. | • Statistic - mean  
• Interval - 1 minute  
• Time range - 3 hours | • See which mount targets have the highest and lowest percentage of successfully processed requests.  
• Identify mount targets that are not performing well and troubleshoot possible causes.  
• Receive notifications when mount target health drops below tolerance, so you can take action. |

### Using the Console

#### To view default metric charts for a single file system

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **File Systems**.
2. Click the file system to view its details.
3. Under **Resources**, click **Metrics**.

For more information about monitoring metrics and using alarms, see **Monitoring** on page 4078. For information about notifications for alarms, see **Notifications** on page 4900.

#### To view default metric charts for a single mount target

1. Open the navigation menu and click **Storage**. Under **File Storage**, click **Mount Targets**.
2. Click the mount target to view its details.
3. Under **Resources**, click **Metrics**.

For more information about monitoring metrics and using alarms, see **Monitoring** on page 4078. For information about notifications for alarms, see **Notifications** on page 4900.

#### To view default metric charts for multiple file systems and mount targets

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Service Metrics**.
2. For **Compartment**, select the compartment that contains the file storage resource you're interested in.
3. For Metric Namespace, select `oci_filestorage`.

The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see Monitoring on page 4078. For information about notifications for alarms, see Notifications on page 4900.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

**Paths in File Systems**

The File Storage service uses three kinds of paths:

1. **Export Paths** are part of the information contained in an export that makes a file system available through a mount target. The export path uniquely identifies the file system within the mount target, letting you associate up to 100 file systems behind a single mount target. The export path is used by an instance to mount (logically attach to) the file system. This path is unrelated to any path within the file system or the client instance. It exists solely as a way to distinguish one file system from another within a single mount target.

In this mount command example, `10.0.0.6` is the mount target IP address. `/FileSystem1` is the unique export path that was specified when the file system was associated with a mount target during creation.

```bash
sudo mount 10.0.0.6:/FileSystem1 /mnt/mountpointA
```

**Important:**

The export path must start with a slash (/) followed by a sequence of zero or more slash-separated elements. For multiple file systems associated with a single mount target, the export path sequence for the first file system cannot contain the complete path element sequence of the second file system export path sequence. Export paths cannot end in a slash. No export path element can be a period (.) or two periods in sequence (..). No export path can exceed 1024 bytes. Lastly, no export path element can exceed 255 bytes. For example:

Acceptable:

- `/example` and `/path`
- `/example` and `/example2`

Not Acceptable:

- `/example` and `/example/path`
- `/` and `/example`
- `/example/`
Caution:
If one file system associated to a mount target has '/' specified as an export path, you can't associate another file system with that mount target.

Note:
Export paths cannot be edited after the export is created. If you want to use a different export path, you must create a new export with the desired path. Optionally, you can then delete the export with the old path.

See Managing Mount Targets on page 2885 for more information about mount targets and exports.

2. Mount Point Paths are paths within a client instance to a locally accessible directory to which the remote file system is mounted.

In this mount command example, /mnt/mountpointA is the path to the directory on the client instance on which the external file system is mounted.

```
sudo mount 10.0.0.6:/FileSystem1 /mnt/mountpointA
```

See Mounting File Systems on page 2859 for more information.

3. File System Paths are paths to directories within the file system, and contain the contents of the file system. When the file system is mounted, you can create any directory structure within it you like. Snapshots of the file system can be accessed using the file system path, under the file system's root directory at .snapshot/name.

The following example shows the path to a snapshot called 'January 1' when navigating from the instance:

```
/mountpointA/.snapshot/January1
```

File System Usage and Metering

This topic describes how usage and metering are calculated for your file systems, to help you understand and manage your service costs. This topic also describes different ways to see your file system, clone, and snapshot utilization and the differences in reporting that can occur depending on which method you use.

Overview

File Storage service provisioning is fully managed and automatic as your utilization scales. For more information, see Space Allocation on page 2918.

Here are the methods you can use to view your file system, clone, and snapshot usage:

- The File Storage service reports metered file system utilization and updates hourly. The metered file system utilization comes from the meteredBytes value in the API, and represents the authoritative utilization value that is used to count your service cost. You can access the reported utilization for each of your file systems using the Console, the Command Line Interface (CLI), or the API. For more information, see the following section File System Metered Utilization on page 2919.

- The File Storage service supports Network File System (NFS) protocol, so you can use the df or du command from your instance command line tool to see usage for mounted file systems. However, the usage reported by du can differ from both the meteredBytes value and the df value. For more information, see Using DF and DU Commands on page 2920.

Space Allocation

The File Storage service allocates space in blocks of variable size in a way that minimizes total customer cost and optimizes performance. Other storage systems might allocate blocks differently than Oracle Cloud Infrastructure File Storage. If you copy files from another storage device to your Oracle Cloud Infrastructure file system, you might see minor differences when you compare the physical file size before and after copying.
**Metering and Service Cost**

This section describes aspects of file system usage and how they affect your overall service costs.

**File System Metered Utilization**

The File Storage service reports metered utilization size for each file system. The metered utilization size is updated on an hourly cycle. You can see the metered **Utilization** size in the Console on the **Details** page of the file system. This value comes from the File Storage service API `meteredBytes` property which is the total number of bytes consumed by the file system. If the file system is a clone of another file system, the clone is only metered for the differentiated data unique to the clone.

The `meteredBytes` value is updated asynchronously with respect to updates to the file system. Your usage charges are calculated based on the `meteredBytes` value.

You can also use the CLI or API to obtain this information. See Managing File Systems on page 2875 for instructions about how to view your file system utilization.

**Important:** When you add or remove files from your file system, it can take the File Storage service up to one hour to report the change in metered size.

**Snapshot Metered Utilization**

A snapshot is a point-in-time view of your file system. Snapshots initially consume no additional usage in the file system, because they reference the original data instead of duplicating it, limiting usage cost. A snapshot doesn't change which blocks it references after it's taken.

Snapshot data usage is metered against differentiated data only. If nothing has changed within the file system since the last snapshot was taken, a new snapshot does not consume more storage. The metered size of snapshots is included in the reported `meteredBytes` value of the file system it belongs to.

For example:

1. Let's say you create a file system called "MyFileSystem" and add "File1". The new file system now contains 1 GB including metadata. After the hourly update cycle is complete, the total `meteredBytes` shown by the File Storage service is 1 GB.
2. Next, you create a snapshot of "MyFileSystem" named "Snapshot1". After the hourly update cycle is complete, the total `meteredBytes` shown by the File Storage service remains at 1 GB, because there's no differentiated data yet.
3. You then overwrite the first 0.5 GB of "File1". Now, "MyFileSystem" has a file that is different than the version previously captured in "Snapshot1". The `meteredBytes` value is 1.5 GB, because the differentiated data between the live file system and the snapshot is 0.5 GB.

   1 GB (snapshot) + 0.5 GB (differentiated data) = 1.5 GB
4. If you then delete "File1", "MyFileSystem" now has a `meteredBytes` value of 1 GB, which represents just the usage for "Snapshot1".
5. Finally, delete "Snapshot1". Deleting the snapshot removes its references to the file data. Provided no other snapshots reference the file data, the space is relinquished and utilization returns to zero.

**Clone Metered Utilization**

The initial metered cost of a file system clone is based on its metadata only, because clones reference the parent file system's data instead of duplicating it.

A clone’s parent file system is metered for all the data shared with its descendant clones. A clone is metered for all its metadata and incremental changes made to its data. When a clone is deleted, all blocks that are referenced solely by that clone are reclaimed. If another clone is hydrating from the deleted clone, the referenced metadata blocks are reclaimed after hydration is complete.
If you delete a parent clone, any data blocks shared by descendant clones cannot be released. Allocated blocks referenced by descendant clones are transferred to the new clone parent (the parent's parent) for metering purposes. You are not metered more than once for data shared between multiple file systems.

For example:

1. Let's say you create a clone of "FileSystemA" called "Clone1". At the time of creation, and before any data is altered:
   - "FileSystemA" (parent) is metered for its data and metadata.
   - "Clone1" is metered only for its metadata.

2. Then, you create a new 1GB file in "Clone1" called "File1":
   - "FileSystemA" (parent) is metered for the data it shares with "Clone1" (clone).
   - "Clone1" is metered for its metadata plus the 1GB of changed data incurred by "File1".

3. FileSystemA's parent is "OriginalRoot". It is the root of the clone tree. Let's say you delete "FileSystemA":
   - "OriginalRoot" becomes the new parent of "Clone1".
   - "OriginalRoot" is metered for the data it shares with "Clone1".
   - "Clone1 is metered for its metadata plus the 1GB of changed data incurred by "File1."

Metadata Metered Utilization

Files in the file system require space to be allocated for metadata. 512 bytes are required for each directory entry, and 8192 bytes are required for each symlink. Multiple hardlinks to a file create multiple directory entries for the file, and increases the metadata utilization. This utilization is included in the meteredBytes value of the file system to which it belongs.

Using DF and DU Commands

You can use df or du commands from your instance command-line application to view usage information about your file system. To use these commands to view file system usage, the file system must first be mounted to the instance. See Mounting File Systems on page 2859 for instructions on mounting your file system.

How the Commands Work

- df provides the amount of storage metered for your file system. Results are returned quickly, but can be up to 1 hour out of date.
- du provides the storage used by a directory hierarchy. The du command walks the directory tree, and if your hierarchy is large, it can take a long time to run and return results.

How Results can Differ

DF and DU report snapshot and clone utilization differently

A snapshot is a point-in-time view of a file system. Snapshots reference unchanged file system data instead of duplicating it. The file system blocks that the snapshot references don't count towards the snapshot utilization. Only differentiated data increases the snapshot utilization.

The same behavior is true for file system clones. Clones reference the data they share with their parent file system. The file system blocks that the clone references don't count toward the clone's utilization. Only differentiated data increases clone utilization.

- The df command retrieves information provided by the File Storage service using the NFS FSSTAT call. The NFS FSSTAT call accounts correctly for the way that snapshots and clones reference file system data. Only utilization caused by differentiated data is reported.
- The du command descends the file system tree and uses each file's size attribute to total up the space used. When you create a snapshot or a clone, it copies the original size attribute for each file. So, if you run the du command, the snapshot reports the file system's size at the time the snapshot was taken not necessarily the snapshot's actual
current utilization. Clones initially report the parent file system's size at the time the source snapshot was taken. When changes are made to clone data, du begins to report new size attributes for updated files only.

For example,

1. Let's say you create file system called "MyFileSystem". You then add a 1 GB file called "FileA" to the file system. Here's how each command would report size:

<table>
<thead>
<tr>
<th>For...</th>
<th>du reports...</th>
<th>df reports...</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileA</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>MyFileSystem</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
</tbody>
</table>

2. You then create "Snapshot1". The snapshot is placed in the / .snapshot folder of MyFileSystem. Here's how each command would report size:

<table>
<thead>
<tr>
<th>For...</th>
<th>du reports...</th>
<th>df reports...</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileA</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>snapshot1</td>
<td>1 GB</td>
<td>0 GB</td>
</tr>
<tr>
<td>MyFileSystem</td>
<td>2 GB</td>
<td>1 GB</td>
</tr>
</tbody>
</table>

- df reports 0 GB for Snapshot1 because the data hasn't changed yet, so there is no space allocated for differentiated data.
- du reports 1 GB for Snapshot1 because it reports the copied file size attribute of FileA, which is 1 GB.

3. You then use "Snapshot1" to create a clone called "Clone1". Here's how each command would report size:

<table>
<thead>
<tr>
<th>For...</th>
<th>du reports...</th>
<th>df reports...</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileA</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>Snapshot1</td>
<td>1 GB</td>
<td>0 GB</td>
</tr>
<tr>
<td>MyFileSystem</td>
<td>2 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>Clone1</td>
<td>1 GB</td>
<td>0 GB</td>
</tr>
</tbody>
</table>

- df reports 0 GB for Clone1 because the data hasn't changed yet, so there is no space allocated for differentiated data.
- du reports 1 GB for Clone1 because it reports the copied file size attribute of FileA, which is 1 GB.

4. You add a 1 GB file called "FileB" to the cloned file system. Here's how each command would report size:

<table>
<thead>
<tr>
<th>For...</th>
<th>du reports...</th>
<th>df reports...</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileA</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>Snapshot1</td>
<td>1 GB</td>
<td>0 GB</td>
</tr>
<tr>
<td>MyFileSystem</td>
<td>2 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>Clone1</td>
<td>2 GB</td>
<td>1 GB</td>
</tr>
<tr>
<td>FileB</td>
<td>1 GB</td>
<td>1 GB</td>
</tr>
</tbody>
</table>

- df reports 1 GB for Clone1 for the differentiated data added in FileB.
- du reports 2 GB for Clone1 because it reports the sum of the copied file size attributes of FileA and FileB.
Important:
Charges are calculated using the `meteredBytes` value. The utilization size reported by `du` can be much larger than `meteredBytes` value. `df` reports the same value as `meteredBytes`, so you can use it to accurately view the file system size.

DF and DU count hard links differently
- `df` counts each file only once.
- `du` may count files with hard links more than once.

DF and DU count symlinks and metadata differently
- `df` reports the utilization of bytes required by File Storage for metadata and symlinks, even on empty files.
- `du` reports empty files as using zero bytes. It doesn't accurately report the bytes being used by File Storage for metadata and symlinks.

Troubleshooting Your File System
These topics cover some common issues you may run into and how to address them.

File System Setup

Creating a File System With an Assigned Key Fails

How to resolve problems creating a file system with an assigned Oracle Cloud Infrastructure Vault key.

**Symptom:** Creating a file system with an assigned Oracle Cloud Infrastructure Vault key fails with the following exception:

```java
com.oracle.bmc.model.BmcException: (401, NotAuthenticated, false) The required information to complete authentication was not provided or was incorrect.
```

**Cause:** The File Storage service requires authorization to use keys on your behalf. Additionally, you must also authorize users to delegate key usage to the service in the first place. Authorization is provided to the service and users using specific IAM policies.

**Solution:**

1. Create a policy in the tenancy to let a user group delegate key usage in a compartment. For example:

   ```
   Allow group FileWriters to use key-delegate in compartment ABC where target.key.id = '<key_OCID>'
   ```

2. Assign the user who is creating the file system to the group.

3. Create a policy in the tenancy to let the File Storage service use the key. For example:

   ```
   Allow service FssOc1Prod to use keys in compartment ABC where target.key.id = '<key_OCID>'
   ```

For more information, see Assigning Keys on page 5702.

**File Storage CREATE API Operations Fail**

**Symptom:** API resource create operations such as `createFileSystem` fail to create resources.

**Cause:** High volume can cause API calls to fail. If you haven't specified `retry` in your request, the operation isn't tried again, and the resource isn't created.

**Solution:** Retry the API operation. Use the `opc-retry-token` header in the create resource request. For example:

```
POST /20171215/fileSystems
Host: filestorage.us-phoenix-1.oraclecloud.com
opc-retry-token: 239787fs987
<authorization and other headers>
{
    "availabilityDomain" : "pWEh:PHX-AD-2",
    "compartmentId" : "ocid1.compartment.oc1..<unique_ID>",
    "displayName" : "media-files-1"
}
```

See REST APIs on page 6339 for more information.

**Mount Command Fails**

This topic troubleshoots issues with file system mount commands.

**Symptom:** Mount command fails.

**Cause 1:** Network security rules are incorrectly set up or missing

**Solution 1:** Verify that the network security rules are set up according to the instructions found in Configuring VCN Security Rules for File Storage on page 2832.

**Cause 2:** There is an issue with the peering configuration of the network between the instance and the file system

Examples of network peering include:

- Remote Peering: Same tenancy, different region
• Local Peering: Same-region, cross-tenancy
• On-premises network to Oracle Cloud Infrastructure

**Solution 2:** Verify that your network peering elements are correctly configured to allow traffic. Some example of elements that restrict traffic are:
• Route table source and destination
• Firewall rules

You can confirm that your connection issue is caused by your peering network configuration by verifying that you can mount the file system from an instance within the same VCN or subnet. For more information, see Networking Overview on page 4232.

**Cause 3:** There is no export option specified for the export you're using in the mount command.

**Solution 3:** There must be at least one export option in the export you use to mount the file system. See Working with NFS Export Options on page 2838 for more information.

**Symptom:** Mount command fails with an error such as:

```
-mount.nfs: mount point <mount_point> does not exist_
```

or

```
-mount.nfs: mounting <MountTarget>:<ExportPath> failed, reason given by
server: No such file or directory
```

**Cause:** The information in the mount command is incorrect or there's a typo in it.

**Solution:** Verify the information in your mount command is correct:
• Verify that the mount point directory exists. If not, create it.
• Verify that there's no typo in the mount point in the mount command.
• Verify that the export path in the mount command doesn't contain a typo, and the spelling and case is the same as in the export.

**More Information:**
If there's a typo in the mount point, the system reports that the mount point doesn't exist.

If there's a typo or a case mismatch in the export path, the system reports that the path doesn't exist.

The export path is specified when you create an export for the file system in a mount target. It uniquely identifies the file system within the mount target, letting you associate multiple file systems to a single mount target. The export path is appended to the mount target IP address, and used to mount the file system.

```
sudo mount 10.0.0.6:/example/path /mnt/mountpointA
```

In this example, 10.0.0.6: is the mount target IP address, and /example/path is the export path. /mnt/mountpointA is the path to the directory on the client instance on which the external file system is mounted.

<table>
<thead>
<tr>
<th><strong>Tip:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>You can find all the export paths for a file system in the <strong>Exports</strong> list shown in its <strong>Details page</strong>, together with associated mount target information.</td>
</tr>
</tbody>
</table>

• You can obtain the correct export path by copying mount commands directly from the file system export. These commands minimize the chance of a typing error. See To get mount command samples on page 2861 for more information.

• If one file system associated with a mount target uses an export path of '/', it will prevent you from associating more file systems with that mount target. No two file systems associated with the same mount target can have an export path that contains a complete path of the other.

See Paths in File Systems on page 2917 for more information.
Symptom: Mounting a file system using an FQDN in the mount command fails, but mounting with an IP address succeeds.

Cause: If the mount target has a hostname specified, the File Storage service creates an FQDN for it and includes it in the mount command sample for the file system. Be sure that the FQDN correctly resolves to the mount target's IP address. For more information about DNS resolution, see DNS in Your Virtual Cloud Network on page 4409.

Symptom: Mount command fails. The dmsg operation displays the following message:

```
2249184.121077]
Redirecting File System Framework Version 0.10 <www.redirfs.org> with TrendMicro Patch 1.2779.e4268f8
```

Cause: TrendMicro Deep Security Agent has mount hooks that can interfere with NFS.

Solution: Stop the ds_agent by running the following command:

```
/etc/init.d/ds_agent stop
```

Mount Target Creation Fails

Mount target creation can fail for various reasons:

- **You've exceeded your mount target limit.**

  Each availability domain is limited to two mount targets by default. If you create both a file system and a mount target at the same time, it is possible for the file system to be successfully created but the mount target creation to fail because of this limitation.

  This limitation can be avoided by reusing a previously created mount target for new file systems. You can reuse a single mount target to make as many file systems available on the network as you wish.

  - To reuse a mount target when creating a new file system, select **Select an Existing Mount Target**. The workflow creates a new export for the file system in the existing mount target of your choice.
  
  - To reuse a mount target for an existing file system, you must manually create a new export for the file system in the mount target. For more information, see **To create an export for a file system** on page 2878.

  See **Service Limits** on page 247 for a list of applicable limits and instructions for requesting a limit increase.

- **There aren't enough available IP addresses in your subnet.**

  Each mount target requires three internal IP addresses in the subnet to function:

  - Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.
  
  - The third IP address is used to create a new VNIC for the mount target during failover. The original primary IP address is retained.
  
  - The File Storage service doesn't "reserve" the third IP address required for high availability failover.
  
  - Use care to ensure that enough unallocated IP addresses remain available for your mount targets to use during failover.
  
  - Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses for mount target creation.

Write to File System Fails

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Linux-style instances:</td>
</tr>
<tr>
<td>- Mount the file system. Follow the procedure found in <strong>Mounting File Systems From Unix-Style Instances</strong> on page 2861.</td>
</tr>
<tr>
<td>- Set up security rules to work with File Storage. Follow the procedure found in <strong>Configuring VCN Security Rules for File Storage</strong> on page 2832</td>
</tr>
</tbody>
</table>

Symptom 1: Writing to a file system from a mounted instance fails.
For example, open a terminal window on the instance and use the touch command to write a 'helloworld' file:

```
touch /mnt/yourmountpoint/helloworld
```

The write operation fails with the error:

```
touch: cannot touch '/mnt/yourmountpoint/helloworld': Permission denied
```

**Cause:** When a file system is created, the root user owns the root directory. If you're connecting from an instance that uses a Linux or CentOS platform image, the default user is opc. The default user is ubuntu when you connect from an instance that uses an Ubuntu platform image. These default users are not root users, so you can't initially write a file or directory to a new file system with these users.

**Solution:** You can implement one of the following solutions:

- Connect as the root user. Then, create files or directories in the new file system.
- Connect as the root user. Then, change the ownership or permissions of the file system root directory to allow other users (such as opc or ubuntu) to write to the file system.
- Connect as the root user. Then, create subdirectories with ownership or permissions that allow other users to write to the subdirectory.

  Learn more about updating file and directory ownership and permissions.

- Connect as the default user. Then, use the sudo command to write or to change permissions or ownership of files or directories. The sudo command temporarily provides a regular user with root user permissions. Here's an example of using the sudo command to write to the file system:

  ```
sudo touch /mnt/yourmountpoint/helloworld
  ```

  Learn more about the sudo command.

For more information about accessing instances, see Connecting to an Instance on page 1163.

**Troubleshooting File System Management**

Here are some issues you may run into while managing your file system.

- [Showmount Command Fails](#) on page 2932
- [Symbolic Links (Symlinks) Produce Errors](#) on page 2932
- [Removing File Locks from a Host that is No Longer Available](#) on page 2931
- [Cannot Delete VCN - Mount Target VNIC Still Attached](#)
- [409 Error Occurs When Creating or Moving a File System or Mount Target](#) on page 2933
- [Metadata Operations Are Very Slow or Fail](#) on page 2930
- [Mount Fails With USE -NOLOCK Error After Instance Reboot](#) on page 2927
- [File System Appears Empty After Instance Reboot](#) on page 2928
- [Cannot Unmount a File System: Device is Busy](#) on page 2928
- [DF Operation Reports File System as 100% Used (0% Free)](#) on page 2929
- [DF Operation and Utilization Values Do Not Reflect Recent File Deletions](#) on page 2929
- [Removing Snapshots With RM -RF Fails](#) on page 2943
- [Mounted File System No Longer Accessible](#) on page 2931
- [RSYNC is Slow When Copying Files](#) on page 2932
- [Deleted Snapshots Still Appear in DF Output](#) on page 2942

**Mount Fails With USE -NOLOCK Error After Instance Reboot**

**Symptom:** Cannot re-mount a file system after rebooting the instance. Manual re-mount fails with use -nolock error.

**Cause:** The NFS client services aren't running on the instance.
More Information: The `rpcbind` and `nfslock` services don't automatically start at reboot by default.

Solution:
1. Add the file system to the instance `/etc/fstab` file, so the file system is automatically remounted after reboot.
   a. See To auto-mount a file system on page 2866 for instructions.
2. Set the `rpcbind` and `nfslock` services to start automatically on every reboot.
   a. Use the following commands to start the `rpcbind` and `nfslock` services:

   ```
   $service rpcbind start
   $service nfslock start
   ```
   b. Verify that the `rpcbind` and `nfslock` services are running:

   ```
   $service rpcbind status
   $service nfslock status
   ```
   c. Enable the services to start automatically at reboot:

   ```
   $chkconfig rpcbind on
   $chkconfig nfslock on
   ```

File System Appears Empty After Instance Reboot

Symptom: After a rebooting an instance, the file system appears empty.

Cause: The file system was not automatically remounted after the reboot.

More Information: The `rpcbind` and `nfslock` services don't automatically start at reboot by default.

Solution:
1. Add the file system to the instance `/etc/fstab` file, so the file system is automatically remounted after reboot.
   a. See To auto-mount a file system on page 2866 for instructions.
2. Set the `rpcbind` and `nfslock` services to start automatically on every reboot.
   a. Use the following commands to start the `rpcbind` and `nfslock` services:

   ```
   $service rpcbind start
   $service nfslock start
   ```
   b. Verify that the `rpcbind` and `nfslock` services are running:

   ```
   $service rpcbind status
   $service nfslock status
   ```
   c. Enable the services to start automatically at reboot:

   ```
   $chkconfig rpcbind on
   $chkconfig nfslock on
   ```

Cannot Unmount a File System: Device is Busy

Symptom: Unmounting (`umount`) fails with a message: `device is busy`. For example:

```
sudo umount -f 10.x.x.x:/fs-export-path /mnt/yourmountpoint
device is busy
```

Cause 1: You're attempting to run the `umount` command from within the mountpoint directory.

Solution 1: Move to a directory outside the file system mount point, and retry the `umount` command.

Cause 2: An abrupt disconnect from the file system's mount target occurred.
More Information: An NFS message similar to the example below is displayed:

```
parrm: B cannot remove 'mnt/directory/.nfs <unique_id>':
  Device or resource busy
```

Solution 2:
1. Use the `fuser` or `lsof` operation to find the process that has locked the file and note its ID.

   See `lsof(8)` - Linux Man Page for information about how to use `lsof`.

   See `fuser(1)` - Linux Man Page for information about how to use `fuser`.

2. After you've identified the process that has locked the file, stop the process using the `kill` command. For example:

   ```
   kill <process_id>
   ```

   See `kill(1)` - Linux Man Page for more information.

3. Retry the `umount` command.

DF Operation Reports File System as 100% Used (0% Free)

Symptom: Running the `df` command on a mounted file system unexpectedly reports zero available space (100% used, 0% free), rather than a realistic value.

Cause: The mount target that exports the file system has its **Reported Size** value set incorrectly.

Solution: Reset the mount target's **Reported Size (GiB)** to the default value of 8589934592 GiB. For instructions, see To set the file system reported size on page 2891.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changing the <strong>Reported Size</strong> in the mount target affects all file systems exported through the mount target.</td>
</tr>
</tbody>
</table>

DF Operation and Utilization Values Do Not Reflect Recent File Deletions

Symptom: You recently deleted files from the system to reclaim space. Running the `df` command on a mounted file system does not reflect these updates and report correct usage. The Console reports a **Utilization** value for the file system that is incorrect. Running the `du` command shows the correct usage.

Cause: Snapshots are present on the file system.

Solution: Snapshots contribute to metered usage. Deleted files are still referenced by snapshots. To fully reclaim space, delete the snapshots. See Metering and Service Cost on page 2919 and Using DF and DU Commands on page 2920 for more information.

File System Resources Aren't Visible in the Console

Learn about why a file system resource might not be visible to you.

Symptom: You create a resource, but can't view it after it's created.

Cause: You don't have permission to work in the compartment that the resource resides in. Resources in a compartment that you don't have access to aren't visible to you.

When you create a resource, you can specify the compartment you want to create it in. The resource doesn't have to be in the same compartment as related file system resources. Another user might move the resource from one compartment (that you have access to) to another (that you don't).

Solution 1: Create the resource in a compartment you have permission to work in.

Solution 2: Obtain permission to work in the compartment that the resource resides in. For information about setting up user access, see Overview of Oracle Cloud Infrastructure Identity and Access Management.
File Storage

Metadata Operations Are Very Slow or Fail

**Symptom:** Metadata operations such as `ls -l`, `du`, or `find` are very slow.

**Causes:**

1. `ls`, `find`, and `du` are sequential operations. They create NFS `readdir` and `readdirplus` requests proportional to the number of entries in the directory. The service has high response latency on `readdir` and `readdirplus` requests. The severity of this performance issue can vary because of the directory size, number of files, or how busy the file system is.

2. If a client performs an `ls -l` operation while another client is writing to the file system, an issue with `READDIRPLUS` can cause looping behavior on the client instance.

**Solutions for Cause 1:**

- Use `ls -ld` or `stat` instead of `ls -l`. These operations are much quicker on large directories than `ls -l`.

  For example:

  ```
  [opc@instance01 dd]$ time ls -l|wc -l
  401425
  real 0m39.786s
  user 0m4.389s
  sys 0m5.403s
  [opc@instance01 dd]$ time ls -ld
  drwxrwxr-x. 4 opc opc 401424 Apr 17 14:18 .
  real 0m0.009s
  user 0m0.001s
  sys 0m0.003s
  [opc@instance01 dd]$ time stat .|grep Size
  Size: 401424     Blocks: 785        IO Block: 32768  directory
  real 0m0.010s
  user 0m0.002s
  sys 0m0.003s
  [opc@instance01 dd]$
  ```

- Redistribute your files to sub-directories instead of storing a large volume of files in a single directory.

**Solutions for Cause 2:**

- Disable the `READDIRPLUS` NFS operation on the instance:

  1. Open a terminal window on the instance.
  2. Unmount the file system with the `umount` command. For example:

     ```
     sudo umount 10.x.x.x:/fs-export-path /mnt/yourmountpoint
     ```

  3. Remount the file system, and include the `-o nordinplus` option to disable `READDIRPLUS`. For example:

     ```
     sudo mount -o nordinplus 10.x.x.x:/fs-export-path /mnt/yourmountpoint
     ```
• Apply a Linux kernel patch:

A Linux kernel patch is available that addresses this issue. The patch is available to install with Oracle Ksplice on Oracle Linux 7.x instances only. Oracle Ksplice lets you apply important security updates and other critical kernel updates without a reboot. The patch addressing this behavior was made available on April 17th, 2020.

Oracle Ksplice must be installed on the instance. After you install Ksplice, you can install available Ksplice patches.

See Installing and Running Oracle Ksplice on page 1081 for instructions.

After you install the patch, you can verify the effective kernel version. Ksplice uptrack doesn't change the output of the uname command. uname continues to reflect the version of the kernel the instance was booted into.

Instead, use uptrack-uname to see what effective kernel your instance is running. uptrack-uname has the same format as uname and supports the common uname flags, including -r and -a

For example:

$ uptrack-uname -r
4.14.35-1902.302.2.el7uek.x86_64

Mounted File System No Longer Accessible

**Symptom:** A file system that was previously mounted and available is no longer accessible.

**Cause:** The file system's mount target or export was deleted.

**More Information:** File systems are made available to the network using an associated mount target. An export controls how NFS clients access the file systems when they connect to the mount target. A file system needs at least one export in an associated mount target to be available for mounting. Deleting a mount target or an export of a file system makes the file system unavailable.

Even if the file system is exported through multiple mount targets, any instance that uses the deleted mount target or export information to mount the file system loses access. See Managing Mount Targets on page 2885.

**Solution:** Re-create the mount target and a new export for the file system.

1. Follow these instructions to re-create the mount target and export: To create an export for a file system on page 2878.
2. If the mount target still exists, choose Select an Existing Mount Target. If the mount target has been deleted, choose Create a New Mount Target.
3. If you're re-creating the mount target, you can re-use the same name, IP address, and hostname information as the old mount target. Click on Advanced Options to set the IP address and hostname.

Removing File Locks from a Host that is No Longer Available

The File Storage service supports the removal of file locks from any file system. To request the removal of file locks on a file system:

1. Go to My Oracle Support and sign in.
   If you are not signed in directly to Oracle Cloud Support, click Switch to Cloud Support at the top of the page.
2. Click Create Service Request.
3. Select the following from the displayed menus:
   • **Service Type:** Select Oracle Cloud Infrastructure from the list.
   • **Service Name:** Select the appropriate option for your organization.
   • **Problem Type:** FSS File System Lock Removal Request.
4. Enter your contact information.
5. Enter a **Description**, and then enter the following required fields specific to your issue. For most Oracle Cloud Infrastructure issues you need to include the OCID (Oracle Cloud Identifier) for each resource you need help with. See **Locating Oracle Cloud Infrastructure IDs** on page 154 for instructions on locating these.

- Tenancy OCID
- File System OCID
- Mount Target OCID
- Host IP Address

For help with any of the general fields in the service request or for information on managing your service requests, click **Help** at the top of the Oracle Cloud Support page.

**RSYNC is Slow When Copying Files**

**Symptom:** `rsync` runs very slowly against a file system.

**Cause:** `rsync` is a serial operation, so it is slow when copying a large file system, especially if snapshots are included in the process.

**Solution:** Use one of the following alternatives:

- **GNU Parallel to run rsync in parallel.** For example:

  ```
  time find /mnt/MyFileSystem -mindepth 1 -maxdepth 1 | parallel -P100 rsync --archive --perms --owner --group --xattrs --acls --recursive --delete --compress --exclude=.snapshot --ignore-errors --progress --log-file=$HOME/rsync/logs/test.log1 --quiet -e ssh ({}) root@10.0.3.6:/mnt/rsync_target
  ```

  For more information, see **GNU Parallel - GNU Project**.

- **File Storage Parallel Tools**
  For more information and examples, see **Using File Storage Parallel Tools** on page 2906.

- **The find command in combination with the xargs option.** For example:

  ```
  find ${source_dir} -mindepth 1 -maxdepth 1 | xargs -P 24 -I {} rsync --archive --perms --owner --group --xattrs --acls --recursive --delete --compress --log-file=<logfile_path> -quiet -e ssh () <destination_user>@<destination_instance>:<destination_dir>
  ```

  See **find(1)** - Linux Man Page and **xargs(1)** - Linux Man Page for more information.

**Showmount Command Fails**

The File Storage service supports the `showmount -e` command. You can use the `showmount -e` command to show a list of NFS exports available from a specific mount target IP address.

For example, `$ showmount -e 10.0.0.0`

To enable the command, you must create a security list rule in the subnet containing the mount target. The rule must be a **stateful ingress** rule for **UDP** traffic with a **Destination Port Range** of **111**.

Click here for instructions about **Configuring VCN Security Rules for File Storage** on page 2832.

For more information about this command, see the **Linux manual page about showmount**.

**Important:**

Only `showmount -e` is supported. No other options are supported, and the `-e` option must be included.

**Symbolic Links (Symlinks) Produce Errors**

The File Storage service fully supports the use of symbolic links. However, symbolic links are interpreted by the client and symlinks that point outside of the mounted File Storage system may be interpreted differently by each client and lead to unexpected results, such as broken links or pointing to the wrong file. Symbolic link targets that
work on one client might be broken on another due to differences in file system layout or because clients mounted the file system using different mount targets.

Snapshots can also break symbolic links that point to a target outside the file system’s root directory. This is because when you create a snapshot of a file system, it becomes available as a subdirectory of the .snapshot directory.

To minimize these potential issues, use a relative path as the target path when creating a symbolic link to a file in the network file system. Also, ensure that relative paths do not point to a target path outside the File Storage service root directory except when the target is on the local machine. If you must use a symbolic link that points to a target path outside the file system, use an absolute path starting with the client’s root directory.

For example:

- Pointing to "/user/bin/example" works.
- Pointing to "/yourmountpoint/..." does not work.
- Pointing to "/home/user/yourmountpoint/..." does not work.

### 409 Error Occurs When Creating or Moving a File System or Mount Target

**Symptom:** When creating or moving a file system or mount target from one compartment to another, you encounter a 409 error. For example:

```python
oci.exceptions.ServiceError: {'opc-request-id': '<<OPC REQUEST ID>>', 'code': 'Conflict', 'message': 'Another filesystem is currently being provisioned, try again later', 'status': 409}
```

**Cause:** There are constraints that limit the number of concurrent operations that a tenancy can perform on file system and mount target resources in a region:

- Each tenancy in a region can have 1 CreateFileSystem or ChangeFilesystemCompartment operation in progress at a time.
- Each tenancy in a region can have 1 CreateMountTarget or ChangeMountTargetCompartment operation in progress at a time.

**Solution:** Retry the operation, either manually or programmatically. The default retry strategy for the OCI SDK is to not retry 409 conflicts, so create a custom retry strategy that retries on 409.

For more information, see 409 error occurs when creating or moving a file system or mount target in Known Issues. For more information about retry strategies, see SDK Behaviors - Retries.

Several examples of building a custom retry strategy are provided at https://github.com/oracle/oci-python-sdk/blob/master/examples/retries.py.

### Operations on a File System Fail With Error: 37: No Locks Available

Troubleshoot operations failure on a file system that produces Error: 37: No locks available.

**Symptom:** Operations on the file system sometimes fail with Linux-x86_64 Error: 37: No locks available.

**Cause:** The rpc-statd service and lockd daemon are not running on the client.

**Solution:** Enable and start the rpc-statd service to initialize the lockd service:

1. Open a terminal window on the instance and use the following commands to enable the rpc-statd service:

```bash
$sudo systemctl status rpc-statd
$sudo systemctl enable rpc-statd
$sudo systemctl start rpc-statd
$sudo systemctl status rpc-statd
```
Troubleshooting File System Clones
A list of troubleshooting topics about cloning file systems.

- Cloning a File System Fails on page 2935
- Cloning a File System Doesn't Replicate File System Data on page 2934
- File System Clones Aren't Visible on page 2935
- Cannot Delete a File System on page 2934

Cannot Delete a File System
Troubleshoot issues deleting a file system.

Symptom: Deleting a file system fails.

Cause 1: The file system has exports in one or more mount targets. Before you can delete a file system, all of its exports must first be deleted.

Solution 1: Delete all of the file system's exports, then delete the file system. See To delete a file system on page 2882 for instructions.

Cause 2: The file system is the root of a clone tree. Before you can delete the root of a clone tree, all of its descendant clones must first be deleted.

Solution 2: Locate and delete all of the file system's descendant clones:
1. Visit the file system Details page and note down the file system OCID. See To view file system details on page 2877.
2. Use the Command Line Interface (CLI) to list all of the file system's clones. Use the following command, and replace <parent_filesystem_id> with the file system OCID you obtained in step 1. For more information about using the CLI, see Command Line Interface (CLI) on page 6117.

```bash
oci fs file-system list --availability-domain <target_availability_domain> --compartment-id <target_compartment_id> --parent-filesystem-id <parent_filesystem_id>
```
3. Delete all of the file systems in the resulting output list.
4. Delete the parent file system.

You can also use the API to locate all of the file systems with a specified parent. For more information, see ListFileSystems.

Cause 3: Clones or siblings of the file system are currently being deleted.

Solution 3: Wait until the clones or siblings have all finished deleting, and then try again.

Cause 4: The file system is currently being cloned.

Solution 4: Wait until the clone operation succeeds, and then try again.

For general information, see Cloning File Systems on page 2900 and Managing File Systems on page 2875.

Cloning a File System Doesn't Replicate File System Data
Find out why cloning is not suitable for data replication of file systems for data protection purposes, and what to do instead.

Problem: You want to use the cloning feature to replicate a file system in another location in Oracle Cloud Infrastructure for data protection purposes.

More information: File system clones are not a data protection or replication solution. There are two reasons for this:

- Clones can only be created in the same availability domain as the parent file system. You can't specify a target location for a file system clone.
- Creating a clone doesn't replicate or move any data from the parent to the clone. Instead, the clone references the parent file system for any data they share.

Solution: You can use File Storage Parallel Tools to copy or sync your file system data between locations.
The toolkit includes:

- **partar**: Use this command to create and extract tarballs in parallel.
- **parrm**: You can use this command to recursively remove a directory in parallel.
- **parcp**: Use this command to recursively copy a directory in parallel.

See Using File Storage Parallel Tools on page 2906 for installation instructions and example commands for common data protection operations.

**Cloning a File System Fails**

Troubleshoot problems creating a clone.

**Symptom 1:** Cloning a file system fails with the following error:

"The cloning operation failed because the clone tree has reached the maximum number of clones (10) allowed to concurrently hydrate from a single specified parent. Wait until one or more clones of this parent finish hydrating, and then try again."

**Cause 1:** The clone tree has reached the maximum size of unhydrated clones descending from the parent you're cloning. See Cloning Concepts on page 2901 for a diagram and examples. See Limitations and Considerations on page 2902 for an example of how this value relates to hydrating clones.

Clone tree size can fluctuate while hydration is in progress, causing the cloning operation to fail. For example:

Let’s say a root file system (File System A) has two child clones currently hydrating from it. (Clone 1 and Clone 2). Clone 1 has 10 children currently hydrating from it, which is the maximum allowed clone tree size for Clone 1.

If you delete Clone 1, File System A becomes the new parent of the 10 child clones currently hydrating, in addition to Clone 2. Deleting Clone 1 causes File System A to immediately reach the maximum clone tree size of 11.

If you then try to clone File System A, the operation fails because File System A has reached the maximum allowed clone tree size.

**Solution 1:** Wait until at least one of the parent’s descendant clones has finished hydrating, and then try the operation again.

**Symptom 2:** Cloning a file system fails with the following error:

"The cloning operation failed because the clone tree branch has reached the maximum number of unhydrated clones (5) between the clone and a hydrated ancestor. Wait until a closer ancestor of the clone finishes hydrating, and then try again."

**Cause 2:** There are too many clones currently hydrating in the clone tree branch between the closest fully hydrated ancestor and the clone you're creating. This attribute is also called clone tree **depth**. See Cloning Concepts on page 2901 for a diagram and examples. See Limitations and Considerations on page 2902 for an example of how this value relates to hydrating clones.

**Solution 2:** Wait until at least one closer ancestor of the clone has completed hydrating, and then try the operation again.

**Symptom 3:** Cloning a file system fails with no specific error.

**Cause 3:** The file system you're attempting to clone is currently in a DELETING state.

**Solution 3:** You can't create a clone from a parent file system that's currently being deleted. Clone a child or sibling of the file system instead.

For general information, see Cloning File Systems on page 2900.

**File System Clones Aren't Visible**

Learn about why your clones may not be visible in the Console.

**Symptom:** You use a file system snapshot to create a clone, but can't view the clone after it's created.

**Cause:** You don't have permission to work in the compartment that the clone resides in. Resources in a compartment that you don't have access to aren't visible to you.
When you create a clone, you can specify the compartment you want to create it in. The clone doesn't have to be in the same compartment as the parent file system. Another user might move the clone from one compartment (that you have access to) to another (that you don't).

**Solution 1:** Create the clone in a compartment you have permission to work in.

**Solution 2:** Obtain permission to work in the compartment that the clone resides in. For information about setting up user access, see [Overview of Oracle Cloud Infrastructure Identity and Access Management](#).

For general information, see [Cloning File Systems](#) on page 2900.

### Troubleshooting Mount Target Management

Troubleshooting topics about mount target management.

- [Cannot Delete VCN- Mount Target VNIC Still Attached](#) on page 2936
- [Mount Target is in a Failed State](#) on page 2937
- [Checking Network Connectivity for a Mount Target With RPCINFO](#) on page 2938

#### Cannot Delete VCN- Mount Target VNIC Still Attached

A mount target is an NFS endpoint that lives in a VCN subnet of your choice and provides network access for the file systems that it exports. Each mount target has a VNIC to enable network access. Mount target VNICs that remain in a VCN must be deleted before you can delete the VCN.

Deleting a mount target also deletes all of the exports of associated file systems that exist in its export set. Data in the file systems is not affected, but the file systems are no longer available through the deleted mount target. You can create new exports for the file system in a different mount target and subnet.

For more information, see [Managing Mount Targets](#) on page 2885.

**To resolve this issue using the Console**

1. Note the OCID in the error message you receive when you attempt to delete the VCN. Mount target OCIDs contain the identifier `mounttarget`. For example:
   ```plaintext
   ocid1.mounttarget.oc1.phx.examplemounttargetid
   ```
2. Note the **Compartment** and **Subnet** information of the **VCN** you want to delete, and to assist navigation and choosing the correct mount target to delete.
3. Delete the mount target using the following steps:
   a. Open the navigation menu and click **Storage**, then click **File Storage**, then click **Mount Targets**.
   b. In the **List Scope** section, select a compartment.
   c. Find the mount target you want to delete.
   d. Click the Actions menu, and then click **Delete**.

   **Caution:**
   Deletion of the mount target also deletes all of its exports of associated file systems. File systems are no longer available through the deleted mount target.

   **Tip:**
   In the Console, the mount target OCID can be seen in the mount target details page in the **Mount Target Information** tab. See [Managing Mount Targets](#) on page 2885 for more information about how to view the mount target details page. Be sure the mount target OCID seen on the details page matches the mount target OCID provided by the VCN delete process error message.

4. Delete the VCN.
**To resolve this issue using the API**

1. Note the OCID in the error message you receive when you attempt to delete the VCN. Mount target OCIDs contain the identifier `mounttarget`. For example:

   `ocid1.mounttarget.oc1.phx.examplemounttargetid`

2. Delete the mount target using the following steps:
   a. Use `DeleteMountTarget` to delete the mount target. For example:

      ```
      DELETE /20171215/mountTargets/
      ocid1.mounttarget.oc1.phx.examplemounttargetid
      Host: filestorage.us-phoenix-1.oraclecloud.com
      <authorization and other headers>
      ```

   b. You can use `GetMountTarget` to verify that the mount target has been deleted. For example:

      ```
      GET /20171215/mountTargets/
      ocid1.mounttarget.oc1.phx.examplemounttargetid?
      compartmentId=<compartmentId>
      Host: filestorage.us-phoenix-1.oraclecloud.com
      <authorization and other headers>
      ```

      The API should return Status 404 Not Found.

**To resolve this issue using the CLI**

For general information about using the CLI, see Command Line Interface (CLI) on page 6117.

1. Note the OCID in the error message you receive when you attempt to delete the VCN. Mount target OCIDs contain the identifier `mounttarget`. For example:

   `ocid1.mounttarget.oc1.phx.examplemounttargetid`

2. Delete the mount target using the following steps:
   a. Use `oci fs mount-target delete` to delete the mount target. For example:

      ```
      oci fs mount-target delete --mount-target-id
      ocid1.mounttarget.oc1.phx.examplemounttargetid
      ```

   b. You can use `oci fs export get` to verify that the mount target has been deleted. For example:

      ```
      oci fs export get --export-id
      ocid1.mounttarget.oc1.phx.examplemounttargetid
      ```

      The CLI should return a message indicating the mount target is not found. For example:

      ```
      {
        "code": "NotAuthorizedOrNotFound",
        "message": "Authorization failed or requested resource not found.",
        "opc-request-id": "<requestID>",
        "status": 404
      }
      ```

If you still can't delete the VCN, be sure there are no other resources remaining in the VCN that might prevent it. For more information, see Subnet or VCN Deletion on page 4877.

**Mount Target is in a Failed State**

**Symptom:** A mount target reports a Failed state. File systems are not accessible using the mount target’s IP address.

**Possible Cause:** There are insufficient unallocated IP addresses in the subnet. The mount target cannot fail over successfully.
Each mount target requires three internal IP addresses in the subnet to function:

- Two of the IP addresses are used during mount target creation. The third IP address must remain available for the mount target to use for high availability failover.
- The third IP address is used to create a new VNIC for the mount target during failover. The original primary IP address is retained.
- The File Storage service doesn’t “reserve” the third IP address required for high availability failover.
- Use care to ensure that enough unallocated IP addresses remain available for your mount targets to use during failover.
- Do not use /30 or smaller subnets for mount target creation because they do not have sufficient available IP addresses for mount target creation.

Solution:

1. Delete the failed mount target.
   
   To delete a mount target on page 2892
   
2. Export the file system through an active mount target. You can create a replacement mount target and then create an export for the file system, or create an export for the file system in a pre-existing mount target.
   
   - You can use the same export paths for the associated file systems as the previous mount target. However, the export path must be unique for each file system within the mount target.
   - If you create a replacement mount target, you can use the same IP address as the previous mount target, if available. Be sure to explicitly specify the desired IP address when you create the mount target.

   To create a mount target on page 2889
   
   To create an export for a file system on page 2878
   
3. If necessary, mount the file systems again.
   
   Mounting File Systems on page 2859
   
4. To prevent a recurrence of this issue, ensure that sufficient unallocated IP addresses remain available in the subnet.

Checking Network Connectivity for a Mount Target With RPCINFO

Use the RPCINFO utility to check that your mount target is connected to the network on all required ports.

The rpcinfo utility is a program that retrieves a list of all the remote procedure call (RPC) services currently running, their names and descriptions, and the ports they are using. You can use the rpcinfo utility to verify that a mount target is connected to the network on all required ports.

Mount targets require connectivity to the following ports and protocols:

- TCP connectivity to ports 111, 2048, 2049, and 2050
- UDP connectivity to ports 111 and 2048

Installing the RPCINFO Utility

The utility must be installed on an instance that has network access to the mount target IP address.

Windows Server 2012 R2 and later versions come with rpcinfo already installed.

For other operating systems, such as Linux, CentOS, or Ubuntu, open a terminal and run the rpcinfo command to verify that the utility is installed. If the command isn't recognized, use the following commands to install the utility.

To install RPCINFO on Linux or CentOS

To install rpcinfo on an Oracle Linux or CentOS instance:
1. Open a terminal window on the instance.
2. Type the following command:

```bash
yum install rpcbind
```

**To install RPCINFO on Ubuntu**

To install rpcinfo on an Ubuntu instance:

1. Open a terminal window on the instance.
2. Type the following command:

```bash
apt-get install rpcbind
```

### Using the RPCINFO Utility

1. Identify the IP address of the mount target. You can obtain it from the details page of the mount target. See To view details of a mount target on page 2890.
2. Open a terminal on the instance, and type the following command to retrieve information about the mount target. Replace `mount_target_IP_address` with the mount target IP address:

```bash
$ rpcinfo -p <mount_target_IP_address>
```

For example, if your mount target IP address is `10.0.0.7`, your command and its output would look like this:

```bash
$ rpcinfo -p 10.0.0.7
```

<table>
<thead>
<tr>
<th>program</th>
<th>vers</th>
<th>proto</th>
<th>port</th>
<th>service</th>
</tr>
</thead>
<tbody>
<tr>
<td>100001</td>
<td>2</td>
<td>udp</td>
<td>111</td>
<td>portmapper</td>
</tr>
<tr>
<td>100001</td>
<td>3</td>
<td>udp</td>
<td>111</td>
<td>portmapper</td>
</tr>
<tr>
<td>100001</td>
<td>4</td>
<td>udp</td>
<td>111</td>
<td>portmapper</td>
</tr>
<tr>
<td>100002</td>
<td>2</td>
<td>tcp</td>
<td>2050</td>
<td>nlockmgr</td>
</tr>
</tbody>
</table>

3. For each program listed, use the following commands to make an RPC call to report whether a response was received:

- Make an RPC call using UDP (`-u`)

```bash
$ rpcinfo -u <mount_target_IP_address> <program_number>
```

- Make an RPC call using TCP (`-t`)

```bash
$ rpcinfo -t <mount_target_IP_address> <program_number>
```

If the RPC call is successful, the output should look like this example:

```bash
$ rpcinfo -u 10.0.0.7 100005
```

<table>
<thead>
<tr>
<th>program</th>
<th>vers</th>
<th>proto</th>
<th>port</th>
<th>service</th>
</tr>
</thead>
<tbody>
<tr>
<td>100005</td>
<td>1</td>
<td>udp</td>
<td>2048</td>
<td>mountd</td>
</tr>
<tr>
<td>100005</td>
<td>1</td>
<td>tcp</td>
<td>2048</td>
<td>mountd</td>
</tr>
<tr>
<td>100005</td>
<td>2</td>
<td>udp</td>
<td>2048</td>
<td>mountd</td>
</tr>
<tr>
<td>100005</td>
<td>2</td>
<td>tcp</td>
<td>2048</td>
<td>mountd</td>
</tr>
<tr>
<td>100005</td>
<td>3</td>
<td>udp</td>
<td>2048</td>
<td>mountd</td>
</tr>
<tr>
<td>100005</td>
<td>3</td>
<td>tcp</td>
<td>2048</td>
<td>mountd</td>
</tr>
</tbody>
</table>
For more information on the `rpcinfo` utility, see `rpcinfo(8)-Linux Man Page` and `Windows RPCINFO Documentation`.

**Troubleshooting In-transit Encryption-enabled Mount Targets**

Troubleshooting topics about mount targets using in-transit encryption.

- General Troubleshooting for In-transit Encryption-enabled Mount Targets on page 2940
- Attempts to Mount a File System with In-transit Encryption Do Not Respond or Fail on page 2941
- In-transit Encryption-enabled Mount Targets Stop Responding to OS Commands on page 2942

**General Troubleshooting for In-transit Encryption-enabled Mount Targets**

If you experience issues with in-transit encryption, try the following techniques:

*Verify that you have all the security list rules set up correctly for the mount target subnet.*

In-transit encryption requires the following security list rules:

- A stateful **ingress** rule allowing TCP traffic to a **Destination Port Range** of 2051.
- A stateful **egress** rule allowing TCP traffic from a **Source Port Range** of 2051.

For more information and instructions, see Security Rules on page 4338.

*Verify that the oci-fss service is running for the mounted file system.*

If it is not, restart the service.

**To verify the service is running**

When you mount a file system using the `mount.oci-fss` command, it creates a systemd-managed service called `oci-fss<sequence_number>.service`. `<sequence_number>` is an incrementing value between 2-255. An `oci-fss` service is created for every file system mounted using the command. The exact name of the service is displayed as output when the file system is mounted.

For example:

```
```

1. Open a terminal window on the instance.
2. Verify that the service is running using the following command:

   ```
   systemctl status oci-fss-<sequence_number>
   ```

**To start the service**

1. Open a terminal window on the instance.
2. Use the following command to start the service:

   ```
   systemctl start oci-fss-<sequence_number>
   ```

*Verify that the namespace ns1 has been created and contains a network interface.*

**To verify the network namespace**

1. Open a terminal window on the instance.
2. Use the following command to verify the namespace and see the network interface:

   ```
   sudo ip netns exec ns1 ip link list
   ```

You should see output displaying all the ethernet devices within namespace ns1. For example:

```
1: lo: <LOOPBACK> mtu 65536 qdisc noop state DOWN mode DEFAULT group default qlen 1000
```
Verify that IP forwarding is running on the instance.

Installing `oci-fss-utils` automatically turns on IP forwarding. However, you may have other processes running on the instance that disable it.

**To verify that IP forwarding is running on the instance**

1. Open a terminal window on the instance.
2. Use the following command to view the status of IP forwarding:

   ```
   # sysctl net.ipv4.ip_forward
   net.ipv4.ip_forward = 1
   ```

   An output value of 1 means that IP forwarding is enabled. This value is read from the `/proc/sys/net/ipv4/ip_forward` file.

   If the output value is 0, then IP forwarding is not enabled for the instance. Enable IP forwarding by following the instructions in **To enable IP forwarding on the instance** on page 2941.

**To enable IP forwarding on the instance**

If IP forwarding is not currently enabled on the instance, you must enable it and make the change permanent.

1. Open a terminal window on the instance.
2. Type the following command to open the `/etc/sysctl.conf` file:

   ```
   sudo vi /etc/sysctl.conf
   ```

3. Remove the `#` to uncomment this line: `# net.ipv4.ip_forward=1`. If the value is 0, change it to 1.
4. Type `:wq` to save the file and exit the editor.

Use the `tcpdump` utility to analyze traffic between the `oci-fss` service and the NFS client.

**To obtain information using TCPDUMP**

1. Open a terminal window on the instance.
2. Type the following command:

   ```
   sudo ip netns exec ns1 tcpdump -i v-peer2 "port 2049"
   ```

Use the `journalctl` command to view any messages that may have been logged by systemd regarding the service.

**To obtain information from the SYSTEMD journal**

1. Open a terminal window on the instance.
2. Type the following command:

   ```
   journalctl -f -u oci-fss-<version>
   ```

   `-f` displays the most recent journal entries, and prints new entries as they are appended to the journal.

   `-u` specifies a specific systemd service unit. In this case, `oci-fss-<sequence_number>` is the specified unit. If no unit is specified, `journalctl` returns all systemd entries.

Attempts to Mount a File System with In-transit Encryption Do Not Respond or Fail

**Symptom:** When mounting a file system using in-transit encryption, the process does not respond or fails.

**Cause 1:** Port 2051 is not open to TLS (Transport Layer Security) traffic. In-transit encryption uses TLS v.1.2 encryption.
Solution 1: Add the following rules to the security list for the VCN the mount target resides in, or add them to a network security group (NSG) associated to the mount target:

- **A stateful ingress** rule allowing **TCP** traffic to a **Destination Port Range** of **2051**.
- **A stateful egress** rule allowing **TCP** traffic from a **Source Port Range** of **2051**.

For more information about security rules for in-transit encryption, see In-transit Encryption: Prerequisites.

For general information about security rules, see Configuring VCN Security Rules for File Storage on page 2832.

Cause 2: The version of **oci-fss-utils** is out of date.

Solution 2: Upgrade to the newest version of **oci-fss-utils**:

1. Uninstall the old **oci-fss-utils** package. For instructions, see To uninstall the OCI-FSS-UTILS package on page 2851.
2. Download and install the newest version of the **oci-fss-utils** package. For instructions, see Task 1: Download the OCI-FSS-UTILS package on page 2848 and Task 2: Install the OCI-FSS-UTILS package on Oracle Linux or CentOS on page 2849.
3. Remount the file system. For instructions, see Task 3: Mount the file system with the encryption command on page 2849.

In-transit Encryption-enabled Mount Targets Stop Responding to OS Commands

**Symptom:** Commands issued to a file system using in-transit encryption receive no response.

**Cause:** More than 64 client connections to the in-transit encryption-enabled mount target.

**Solution:** Reduce the number of SSL clients (both instances and processes) concurrently connecting to the mount target to less than 64.

This behavior is because of a known and documented limitation of the number of SSL connections the mount target allows. For more information, see Limitations and Considerations on page 2847.

Troubleshooting Snapshot Management

Troubleshooting topics about snapshot management.

- **Deleted Snapshots Still Appear in DF Output** on page 2942
- **Removing Snapshots With RM -RF Fails** on page 2943

Deleted Snapshots Still Appear in DF Output

Resolve an issue where deleted snapshots still appear in DF output with "stale file handle".

**Symptom:** Previously deleted snapshots still appear in df output with the message **stale file handle**.

**Cause:** When you use an NFSv3 client to perform operations such as **ls**, **du**, or **find** on the snapshot directory, the service automatically exports the directory. The client uses **nfs_d_automount()** to detect and mount the directory. After the directory is detected and mounted the first time, the client mounts the directory automatically.

If you then delete the snapshot, the mount becomes disconnected. The client still holds an active reference to the snapshot, but can no longer access the snapshot itself, so it reports **stale file handle**.

**Solution:** Manually unmount the snapshot. This might require using the **-f** flag in the **umount** command. For example:

```
sudo umount -f 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

**Note:**

If the umount command fails with the message **device busy**, see **Cannot Unmount a File System: Device is Busy** on page 2928 for a solution to this problem.
Removing Snapshots With RM -RF Fails

**Symptom:** Using the `rm -rf .snapshot/<snapshot_folder>` operation to delete a snapshot from a mounted file system fails.

**Cause:** Snapshots are read-only and can't be deleted by running `rm -rf .snapshot/<snapshot_folder>` from a client instance. Snapshots must be deleted using the console, CLI, or API.

**Solution:** Use one of these methods to delete the snapshot:
- Use the Console
- Use the CLI
- Use the API

Troubleshooting Applications

Here are some issues you might run into when installing applications that use your file system.

- **Application Installation Fails Due to Too Much or Too Little Available Capacity** on page 2944
- **Application Performance is Not as Expected** on page 2945
- **Apache Webserver Fails** on page 2944
- **Oracle E-Business Suite Concurrent Processing is Slow** on page 2946
- **Access to File System is Denied Due to Stale File Handle** on page 2943
- **Sharing the Application Tier File System in Oracle E-Business Suite Release 12.2 or 12.1.3 Using the Oracle Cloud Infrastructure File Storage Service**
  Learn best practices for using a File Storage service shared application tier file system for Oracle E-Business Suite.
- **32-Bit Application Stops Reading or Writing to a File System** on page 2946

Access to File System is Denied Due to Stale File Handle

**Symptom:** Access to a file system fails with a message: `stale file handle`. For example:

```
[root@example]# /mnt/MyFileSystem
[root@example]# ls -l
ls: cannot access dbclient: Stale file handle
```

**Cause:** This issue happens when an application opens or creates a file, deletes and closes it, and then attempts to access or delete the same file again.

**Solution 1:** Restart the application.

**Solution 2:** If Solution 1 doesn't solve the issue, unmount and re-mount the file system. This might require using the `-f` flag in the `umount` command. For example:

```
sudo umount -f 10.x.x.x:/fs-export-path /mnt/yourmountpoint
sudo mount 10.x.x.x:/fs-export-path /mnt/yourmountpoint
```

**Note:**

If the unmount command fails with the message `device busy`, see **Cannot Unmount a File System: Device is Busy** on page 2928 for a solution to this problem.

**Solution 3:** If the first two solutions don't solve the issue, reboot the instance.
Apache Webserver Fails

Symptom 1: When Apache webserver is installed on a File Storage file system, login to the web page fails and the Apache error_log contains messages like the following:

```
Permission denied: [client IP:port] AH00529: <FSS_mount_point>/public/.htaccess pcfg_openfile: unable to check htaccess file, ensure it is readable and that <FSS_mount_point>/public is executable
```

```
Permission denied: [client IP:port] AH00035: access to /index.php denied (filesystem path '<FSS_mount_point>/index.php') because search permissions are missing on a component of the path
```

Additional Information:

Permission checks show sufficient read and execute access on the directory and the files. Providing full access (777 permission) to the file storage mount point for testing purposes also fails.

**Caution:**
The '777' permission is used strictly for testing purposes, and might compromise your security policy. **Be sure to revert your file system mount point permissions to their previous state after testing is complete.**

Cause: By default, the Apache webserver installation expects a local drive. You need to explicitly direct the installation to NFS.

Solution: Enable NFS compatibility for Apache.

Open a terminal on the instance and run:

```
$ sudo setsebool httpd_use_nfs on
```

Or:

```
$ sudo setsebool -P httpd_use_nfs 1
```

Application Installation Fails Due To Too Much or Too Little Available Capacity

The File Storage service reports file system capacity as 8589934592 gibibytes (GiB) and 8589934592 gibiinodes (GiI) by default. Sometimes, application installers perform a space requirement check prior to running an installation process but cannot correctly interpret the reported size or reported inodes of the file system. When this occurs, you can define the file system size reported to the operating system by setting the **Reported Size** or **Reported Inodes** value in the export set of the file system's mount target.

**Important:**
Changing the **Reported Size** or **Reported Inodes** for a mount target affects all file systems exported by the mount target. **Changing these values does not limit the amount of data you can store.**

If your application installation is failing because of too little available space, you can expand the reported available free space. If your application installation is failing because of too much reported available free space, you can reduce it. Typically, setting the size to 1024 GiB and the inodes to 1024 GiI permits successful installation.

**Important:**
There can be a delay of up to 1 hour when reporting file system usage, either in the console or by using the `df` command.
To set the reported free space in the API

You can use the UpdateExportSet operation to update the MaxFsStatBytes.

See REST APIs on page 6339 for more information.

Application Performance is Not as Expected

Several factors can impact application performance:

- **Available bandwidth**
  
  We recommend that you use bare metal compute instances because instance bandwidth scales with the number of oCPU’s. Bare metal compute instances provide the greatest bandwidth. Virtual machines (VMs) are bandwidth limited based on the number of CPUs consumed. Single oCPU VM compute instances provide the least bandwidth.

- **Latency**

  Subnets can be either AD-specific or regional. The type of subnet you choose to create your File Storage resources in can affect latency. You can create File Storage resources in either type of subnet.

  Regional subnets allow compute instances to connect to any mount target in the subnet regardless of AD, with no additional routing configuration. However, to minimize latency, place mount targets in the same AD as compute instances just as you would in an AD-specific subnet.

  For more information, see VCNs and Subnets on page 4321.
Mount options

By not providing explicit values for mount options such as rsize and wsize, the client and server can negotiate the window size for read and write operations that provide the best performance.

Oracle E-Business Suite Concurrent Processing is Slow

Symptom: On an Oracle E-business Suite system that uses a shared application tier file system, EBS concurrent processing is slow.

Cause: The APPLLDM environment variable is referenced by AutoConfig and used to control the placement of concurrent processing logs. The placement of these files can have performance implications.

Solution: Set APPLLDM to a value other than single, so that there are multiple log and output directories instead of one large directory. See Sharing the Application Tier File System in Oracle E-Business Suite Release 12.2 or 12.1.3 Using the Oracle Cloud Infrastructure File Storage Service for instructions.

32-Bit Application Stops Reading or Writing to a File System

Symptom: After a period of functioning correctly, a 32-bit application suddenly stops reading or writing to a file system. The read/write operations fail with an error such as:

```
Applications fail to install on FSS mount point: "Value too large for defined data type" - OCI FSS/Mount Target Resources (Doc ID 2672465.1)
```

Cause: The 32-bit application cannot consume larger file IDs. The File Storage service is designed to work with 64-bit applications, so the file IDs generated by File Storage become too large for legacy applications to consume.

More Information:

- If the application uses a signed 32-bit integer to store the file identifier, then the maximum value that the application can handle before overflow is 2147483647 \( (2^{31}-1) \).
- If the application uses an unsigned 32-bit integer to store the file identifier, then the maximum value that the application can handle before overflow is 4294967295 \( (2^{32}-1) \).
- If the application uses a signed 64-bit integer to store the file identifier, then the maximum value that the application can handle before overflow is 9223372036854775807 \( (2^{63}-1) \).

To check the size of new file IDs being generated, open a terminal on a connected instance, and run the following command:

```
touch <File_Storage_mount_point>/test; ls -i <File_Storage_mount_point>/test
```

Solution 1: Upgrade your application to a 64-bit version.

Solution 2: Create a new file system to use with your legacy 32-bit application.
More Information: Removing files from the original file system does not reset the file ID generation back to 0, so you must create a new file system to start again with small file IDs. Remember that after a certain amount of time, file IDs will become too large for the 32-bit application.

Note:
Solution 2 isn't applicable in all cases, depending on the nature of the application and the files it produces. For example, if you are performing a data refresh that copies files from a production file system to a non-production file system, this option would work. However, for applications with organically growing file systems, this option may not work.

Solution 3: Set the kernel parameter enable_ino64=0.

More Information: Setting nfs.enable_ino64=0 instructs the NFS client to return 32-bit inode numbers for readdir() and stat() system calls (instead of the full 64-bit inode numbers).

Important:
This solution requires an instance reboot.

1. Open a terminal window on the instance as the root user and type the following command to verify the current nfs.enable_ino64=0 setting.

   ```
   # cat /sys/module/nfs/parameters/enable_ino64
   ```

   The system should return Y, indicating that 64-bit inodes are enabled.

2. Run the following command to set nfs.enable_ino64=0.

   ```
   echo "options nfs enable_ino64=0" > /etc/modprobe.d/nfs.conf
   ```

3. Reboot the instance.

4. Verify that the setting is updated using the following command:

   ```
   # cat /sys/module/nfs/parameters/enable_ino64
   ```

   The system should return N, indicating that 64-bit inodes are disabled and returned to 32-bit.

5. Verify that the file system is mounted to the instance, or mount the file system. See Mounting File Systems on page 2859.

Troubleshooting Windows NFS Connections

Here are some issues you may run into with Windows NFS Connections to your file system.

- Create and Write to File System Fails using Windows NFS on page 2947
- Mounted Drive is Not Visible in File Explorer on page 2950
- Mounted Drive is Not Visible in PowerShell on page 2951
- Mounting from File Explorer Fails With "An Unexpected Error Occurred." on page 2952
- File Copy or Delete is Stuck at 99% on page 2952
- Transferring Data From a Windows SMB Share to a File System on page 2952
- Accessing a Mounted File System is Slow or Fails After a Few Seconds on page 2953
- File and folder names that use Japanese characters are garbled on page 2954

Create and Write to File System Fails using Windows NFS

Important:
Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:
File Storage

- Install the NFS Client. Follow the installation procedure found in Mounting File Systems From Windows Instances on page 2870.
- Set up security rules to work with File Storage. Follow the procedure found in Configuring VCN Security Rules for File Storage on page 2832.

**Symptom:** After installing Windows NFS client, you can successfully mount the file system from Windows, but any attempt to create or update a file in the file system fails.

**Cause 1:** Registry entries that map the `AnonymousGid` and `AnonymousUid` to the root user are missing or in the wrong place.

Access to NFS file systems requires UNIX-style user and group identities, which are not the same as Windows user and group identities. To enable users to access NFS shared resources, Windows client for NFS accesses file systems anonymously, using `AnonymousGid` and `AnonymousUid`. On brand new file systems, write permissions are only granted to the root user.

**Solution:** Verify that the correct registry entries are located in `HKEY_LOCAL_MACHINE\Software\Microsoft\ClientForNFS\CurrentVersion\Default`. If not, add the `AnonymousGid` and `AnonymousUid` registry entries to map them to the root user, and then remount the file system with the new user privileges.

**Tip:**

You can verify the `AnonymousGid` and `AnonymousUid` are correctly set for a mounted file system by opening a Windows Command Line (CMD) window and typing the `mount` command without any arguments. A list of all mounted file systems and their properties is shown. The `AnonymousGid` (GID) and `AnonymousUid` (UID) values should appear as 0.

For example:

C:\> mount
Local    Remote
Properties

| X:      \10.0.1.0\FileSystem  |
|---------|-----------------------------|
| UID=0, GID=0 |
| rsize=1048576, wsize=1048576 |
| mount=soft, timeout=0.8 |
| retry=1, locking=yes |
| fileaccess=755, lang=ANSI |
| casesensitive=no |
| sec=sys |

If they appear as -2, they have not been correctly set. Proceed to the instructions below.

**To map the `AnonymousGid` and `AnonymousUid` to the root user**

1. In the Windows Command Line (CMD) window, unmount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export...
path you specified when associating the file system with the mount target, and X with the drive letter of any available drive you want to map the file system to.

Tip:

IP address and export path information is available in the Details page of the mount target associated with your file system. See To view details of a mount target on page 2890 for more information.

```
umount 10.x.x.x:/fs-export-path X:
```

2. Open the registry editor (regedit):
   
   • Click Windows Search.
   • Enter regedit in the Search field and press Enter.
   • Click Yes to allow changes to your device.

3. Click HKEY_LOCAL_MACHINE. Then, browse to: Software\Microsoft\ClientForNFS\CurrentVersion\Default.

4. Add a new DWORD32 registry entry for AnonymousGid:
   
   • Click Edit, and select New DWORD (32 bit) Value.
   • In the Name field, enter AnonymousGid. Leave the value at 0.

5. Repeat step 3 to add a second DWORD32 registry entry named AnonymousUid with a value of 0.

6. Open Windows Command Line (CMD) and run as Administrator:
   
   • Go to Start and scroll down to Apps.
   • In the Windows System section, press Ctrl+Shift and click Command Prompt.

7. In the Windows Command Line (CMD) window, restart the NFS Client by typing the following:

   ```
nfsadmin client stop
nfsadmin client start
```
8. Close the Administrator: Windows Command Prompt (CMD) window. Open a standard Command Prompt Window:
   - Click Start, then click Command Prompt.

   **Important:**
   NFS file systems mounted as Administrator are not available to standard users.

9. In the standard Windows Command Line (CMD) window, mount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

   ```
   mount 10.x.x.x:/fs-export-path X:
   ```

**Cause 2:** A standard user is trying to access a file system that was mounted using the Administrator: Command Prompt (CMD). When mounting file systems, it isn't necessary to run the Command Prompt as Administrator.

**Solution:** Unmount the file system and then remount the file system using a standard Command Prompt (CMD)

**To remount a file system with a standard Command Prompt (CMD)**

1. Open Windows Command Line (CMD) and run as Administrator:
   - Go to Start and scroll down to Apps.
   - In the Windows System section, press Ctrl+Shift and click Command Prompt.

2. In the Administrator: Windows Command Line (CMD) window, unmount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

   ```
   umount 10.x.x.x:/fs-export-path X:
   ```

   **Tip:**
   IP address and export path information is available in the Details page of the mount target associated with your file system. See To view details of a mount target on page 2890 for more information.

4. Open a standard Command Prompt Window:
   - Click Start, then click Command Prompt.

5. In the standard Command Line (CMD) window, mount the file system by typing the following. Replace `10.x.x.x:` with the local subnet IP address assigned to your mount target, `fs-export-path` with the export path you specified when associating the file system with the mount target, and `X` with the drive letter of any available drive you want to map the file system to.

   ```
   mount 10.x.x.x:/fs-export-path X:
   ```

**Mounted Drive is Not Visible in File Explorer**

**Important:**
Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:

- Install the NFS Client. Follow the installation procedure found in Mounting File Systems From Windows Instances on page 2870.
- Set up security rules to work with File Storage. Follow the procedure found in Configuring VCN Security Rules for File Storage on page 2832.
Symptom: After installing Windows NFS client, you can successfully mount the file system from Windows, but the file system drive is not visible in File Explorer.

Cause: A standard user is trying to access a file system that was mounted using the Administrator: Command Prompt (CMD). When mounting file systems, it isn't necessary to run the Command Prompt as Administrator.

Solution: Unmount the file system and then remount the file system using a standard Command Prompt. (CMD) See To remount a file system with a standard Command Prompt (CMD) on page 2950.

Mounted Drive is Not Visible in PowerShell

Important:

Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:

- Install the NFS Client. Follow the installation procedure found in Mounting File Systems From Windows Instances on page 2870.
- Set up security rules to work with File Storage. Follow the procedure found in Configuring VCN Security Rules for File Storage on page 2832.

Symptom: After installing Windows NFS client, you can successfully mount the file system from either Windows File Explorer or the Command Prompt (CMD) using mount or net use commands. However, the file system drive is not visible in PowerShell.

Cause: A known issue exists where drives mapped from outside PowerShell aren't visible from within PowerShell.

Solution: Unmount the file system and remount the file system within PowerShell, using options to make it visible in File Explorer and in the CMD application.

To unmount a file system using the CMD prompt

1. Open Windows Command Line (CMD) and run as Administrator:
   - Go to Start and scroll down to Apps.
   - In the Windows System section, press Ctrl+Shift and click Command Prompt.
2. In the Administrator: Windows Command Line (CMD) window, unmount the file system by typing the following. Replace 10.x.x.x: with the local subnet IP address assigned to your mount target, fs-export-path with the export path you specified when associating the file system with the mount target, and X with the drive letter of any available drive you want to map the file system to.

   Tip:
   IP address and export path information is available in the Details page of the mount target associated with your file system. See To view details of a mount target on page 2890 for more information.

   umount 10.x.x.x:/fs-export-path X:

To map a drive in PowerShell and make it visible

You can map a drive in PowerShell and then use options to make it visible from File Explorer and the Windows Command Line (CMD).

1. Open Windows PowerShell and run as Administrator:
   - Go to Start and click the Windows PowerShell icon.
   - In Windows PowerShell, type the following to run as Administrator:

     Start-Process powershell -Verb runAs

   - In the User Account Control window, click Yes. A new Administrator: PowerShell window opens. You can close the standard PowerShell window to avoid confusing them.
2. Type the following cmdlet. Replace 10.x.x.x: with the local subnet IP address assigned to your mount target, *fs-export-path* with the export path you specified when associating the file system with the mount target, and *X* with the drive letter of any available drive you want to map the file system to:

```
New-PSDrive X -PsProvider FileSystem -Root \10.x.x.x:\fs-export-path -Persist
```

### Mounting from File Explorer Fails With "An Unexpected Error Occurred."

**Important:**

Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:

- Install the NFS Client. Follow the installation procedure found in [Mounting File Systems From Windows Instances](#) on page 2870.
- Set up security rules to work with File Storage. Follow the procedure found in [Configuring VCN Security Rules for File Storage](#) on page 2832.

**Symptom:** The IP address and export path are correctly represented in the Folder field. When you click Finish, the system attempts to connect to the file system, but fails with an error: "The mapped network drive could not be created because the following error has occurred: An unexpected error occurred."

**Solution 1:** Reboot the instance, and mount the file system again using File Explorer.

**Solution 2:** Mount the file system using the Command Prompt.

### File Copy or Delete is Stuck at 99%

Troubleshoot an issue where a Windows mounted file system cannot complete a copy or delete operation.

**Symptom:** When you try to copy or delete a file in a file system mounted on a Windows instance, the process gets stuck at 99%.

**Cause:** By default, a Windows instance tries to access a mounted file system using Server Message Block (SMB) ports 139 and 445. Since File Storage file systems use an NFS mount, the process fails.

**Solution:** Reorder the network provider list to place Nfsnp first. Follow the steps in [To change the network provider order on Windows 2012+](#) on page 2953.

**Important:** Reordering of the network provider list requires a system restart.

### Transferring Data From a Windows SMB Share to a File System

Mount the Windows SMB share as a CIFS share and use a copy tool such as PARCP or FPSYNC to transfer data.

This topic describes how to transfer data from a Windows Server Message Block (SMB) share to a File Storage file system. Since the SMB protocol and the NFS protocol used by File Storage are not compatible, an instance that can mount both the NFS file system and the SMB share is used to create a bridge between them.

1. Identify or create a Linux instance in Oracle Cloud Infrastructure that has network access to both the File Storage file system and the Windows SMB share.
2. Open a terminal on the instance.
3. Type the following to install the CIFS utility and verify that it is installed:

```bash
$ sudo yum install -y cifs-utils
$ rpm -qa | grep cifs
```
4. Mount the Windows SMB share as a Common Internet File System (CIFS) share:
   a. Create a mount point directory. For example,
      ```
sudo mkdir /mnt/win_share
      ```
   b. Mount the CIFS share:
      ```
sudo mount -t cifs -o username=<win_share_user> //<win_IP_address/hostname>/<share_name> /mnt/<win_share_dir>
      ```
      For example:
      ```
$sudo mount -t cifs -o username=opc //win2012/c /mnt/win_share
      ```

5. Use the parcp utility from the File Storage Paralell Tools suite or fpsync to copy the files from the CIFS share to the mounted file system. For installation information about parcp, see Using File Storage Parallel Tools on page 2906. For information about fpsync, visit fpsyncManual Page.

For example:
```
parcp -P 32 /mnt/win_share /mnt/MyFilesystem
fpsync -v -n 8 -f 101 -o "-lptgoD -v --numeric-ids -e ssh" /mnt/win_share /mnt/MyFilesystem
```

**Accessing a Mounted File System is Slow or Fails After a Few Seconds**

**Important:**
Before proceeding with troubleshooting, be sure to implement the following prerequisites for connecting to file systems from Windows instances:

• Install the NFS Client. Follow the installation procedure found in Mounting File Systems From Windows Instances on page 2870.
• Set up security rules to work with File Storage. Follow the procedure found in Configuring VCN Security Rules for File Storage on page 2832

**Symptom 1:** Accessing a mounted file system with File Explorer or Universal Naming Convention (UNC) path or Command Prompt/Powershell is significantly delayed or fails. The effect is intermittent.

**Symptom 2:** Mount fails using Windows NFS connection with "Network Error 53 “Network path not found”.

**Cause:** By default, Windows network providers have higher priority than the client for NFS network provider. Initially, the delay as Windows tries each provider in the default order is significant. Subsequent attempts may be faster because the mount information is cached. After the cache times out, the delay increases again. The native Windows file system client called Distributed File System (DFS) is also given default priority over NFS client, increasing the delay.

**Solution:** Change the network provider order and disable the DFS client so that the client for NFS Network provider is tried first.

For reference, see:

• Support for UNC Naming and MUP
• Modify the protocol bindings and network provider order
• MUP and DFS Interactions

To change the network provider order on Windows 2012+

1. Click **Windows Search**.
2. Enter `regedit` in the **Search** field and press **Enter**.
3. Click **Yes** to allow changes to your device.
4. Click HKEY_LOCAL_MACHINE.
5. Browse to: System\CurrentControlSet\Control\NetworkProvider\Order
6. Change the Network Provider order from default to Nfsnp,RDPNP,LanmanWorkstation:
   a. Right-click ProviderOrder, and select Modify.
   b. In the Value Data field, enter Nfsnp,RDPNP,LanmanWorkstation. If there are any further items that exist in this field on your instance, enter them after LanmanWorkstation.
   c. Click OK.
7. Restart the instance.

To disable the DFS Client on Windows 2012+
1. Click Windows Search.
2. Enter regedit in the Search field and press Enter.
3. Click Yes to allow changes to your device.
4. Click HKEY_LOCAL_MACHINE.
5. Browse to: System\CurrentControlSet\Services\Mup.
6. Add a new DWORD32 registry entry for DisableDfs:
   a. Click Edit, and select New DWORD (32 bit) Value.
   b. In the Name field, enter DisableDfs.
   c. Right-click DisableDFS, and select Modify.
   d. In the Value Data field, enter 1.
   e. Click OK.
7. Restart the instance.

File and folder names that use Japanese characters are garbled

Symptom: File and folder names that use Japanese characters are garbled when the file system is mounted in Windows.

Cause: Currently, a limitation exists when viewing non-ANSI characters in Windows NFS client v.3. File Storage uses NFS v.3 with lang=ANSI option by default. So, Japanese characters don't appear correctly.

Solution: Use the following command to mount the file system with lang=EUC-JP:

```bash
C:\> mount -o lang=EUC-JP \IP_address\export drive_letter:
```

Limitations and Considerations for this solution:

1. This solution only works with Windows operating systems. Operating systems such as Linux use UTF-8 encoding.
2. This solution can cause issues with Universal Naming Convention (UNC) paths. For example, \server_name\folder_name\file_name.
Chapter 26

Functions

This chapter explains how to create, deploy, and invoke functions using Oracle Functions.

Functions

Functions is a serverless platform that enables you to create, run, and scale business logic without managing any infrastructure.

What's new

- Get Started
  - QuickStart on Cloud Shell
  - QuickStart on local host
  - Learn about Functions
  - Review key concepts

- Sample Functions
  - Sample functions on GitHub
  - Follow solution playbooks
  - Learn from reference architectures
  - Try Developer tutorials

- Observe Functions
  - Function logs
  - Function tracing
  - Function metrics
  - Troubleshooting

- Control access
  - Control access to functions
  - Container permissions
  - Private network access

- Create Functions
  - Create applications
  - Create functions
  - Use existing Docker images
  - Use custom Dockerfiles

- Invoke Functions
  - Invoke functions
  - Invoke functions from other services

- Integrate Functions
  - Integrate with other products
  - Access file systems
  - Pass parameters

- Functions and Fn Project
  - Upgrade Fn Project CLI
  - Manage FDKs and languages
  - Differences between Functions and Fn Project

- Community

Overview of Functions

Oracle Functions is a fully managed, multi-tenant, highly scalable, on-demand, Functions-as-a-Service platform. It is built on enterprise-grade Oracle Cloud Infrastructure and powered by the Fn Project open source engine. Use Oracle Functions (sometimes abbreviated to just Functions) when you want to focus on writing code to meet business needs.

The serverless and elastic architecture of Oracle Functions means there's no infrastructure administration or software administration for you to perform. You don't provision or maintain compute instances, and operating system software patches and upgrades are applied automatically. Oracle Functions simply ensures your app is highly-available, scalable, secure, and monitored. With Oracle Functions, you can write code in Java, Python, Node, Go, and Ruby (and for advanced use cases, bring your own Dockerfile, and Graal VM). You can then deploy your code, call it directly or trigger it in response to events, and get billed only for the resources consumed during the execution.

Oracle Functions is based on Fn Project. Fn Project is an open source, container native, serverless platform that can be run anywhere - any cloud or on-premises. Fn Project is easy to use, extensible, and performant. You can download and install the open source distribution of Fn Project, develop and test a function locally, and then use the same tooling to deploy that function to Oracle Functions.

You can access Oracle Functions using the Console, a CLI, and a REST API. You can invoke the functions you deploy to Oracle Functions using the CLI or by making signed HTTP requests.

Oracle Functions is integrated with Oracle Cloud Infrastructure Identity and Access Management (IAM), which provides easy authentication with native Oracle Cloud Infrastructure identity functionality. See Overview of Oracle Cloud Infrastructure Identity and Access Management.

To get set up and running quickly with Oracle Functions, see the Functions QuickStart Guides on page 2963. A number of related Developer Tutorials are also available.

Important:

Advance Notice of Mandatory Requirement to Upgrade the Fn Project CLI, April 2021

If you have installed the Fn Project CLI and are using it to initialize, build, and deploy functions, you will have to upgrade the Fn Project CLI on or before 1st May, 2021. For more information see Upgrading the Fn Project CLI on page 3024.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 6152.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the REST API, see REST APIs on page 6339.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2672.

The following Oracle Functions resources emit events:

- applications
- functions
You can also have events in other services invoke functions in Oracle Functions. See Invoking Oracle Functions from Other Oracle Cloud Infrastructure Services on page 3009.

**Resource Identifiers**

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 228.

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference on page 3347.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Oracle Functions Capabilities and Limits**

The number of functions and applications you can create in a region is controlled by Oracle Functions service limits (see Functions Limits on page 267). The default service limits vary according to your payment method. If you need more capacity, you can submit a request to increase the default service limits (see Requesting a Service Limit Increase on page 249).

The maximum amount of data you can send to a function (the function's request payload) is 6MB. The maximum amount of data a function can return in response to a request (the function's response payload) is 6MB. These limits are fixed and cannot be changed.

Some other Oracle Functions capabilities and limits are also fixed. However, there are also a number that you can change. See Changing Default Memory and Timeout Settings on page 2996.

**Required IAM Service Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

For more information about policies for Oracle Functions, see:

- Creating Policies to Control Access to Network and Function-Related Resources on page 3082
- Details for Functions

**Oracle Functions Concepts**

This topic describes key concepts you need to understand when using Oracle Functions.

**Functions Developers**

Oracle Cloud Infrastructure users who use Oracle Functions to create and deploy functions are referred to as 'functions developers'. To use Oracle Functions, functions developers must have Oracle Cloud Infrastructure user accounts. Their user accounts must belong to groups to which appropriate policies grant access to function-related resources.
See Creating Groups and Users to use with Oracle Functions, if they don't exist already on page 3081.

**Applications**

In Oracle Functions, an application is:

- a logical grouping of functions
- a way to allocate and configure resources for all functions in the application
- a common context to store configuration variables that are available to all functions in the application
- a way to ensure function runtime isolation

When you define an application in Oracle Functions, you specify the subnets in which to run the functions in the application. You also specify whether to enable logging for the functions in the application.

When functions from different applications are invoked simultaneously, Oracle Functions ensures these function executions are isolated from each other.

Best practice is to group multiple functions in a single application for better efficiency and performance.

Oracle Functions shows applications and their functions in the Console.

See Creating Applications on page 2983.

**Functions**

In Oracle Functions, functions are:

- small but powerful blocks of code that generally do one simple thing
- grouped into applications
- stored as Docker images in a specified Docker registry
- invoked in response to a CLI command or signed HTTP request

When you deploy a function to Oracle Functions using the Fn Project CLI, the function is built as a Docker image and pushed to a specified Docker registry.

A definition of the function is stored as metadata in the Oracle Functions server. The definition describes how the function is to be executed and includes:

- the Docker image to pull when the function is invoked
- the maximum length of time the function is allowed to execute for
- the maximum amount of memory the function is allowed to consume

Oracle Functions shows functions, and the applications into which they are grouped, in the Console.

See Creating, Deploying, and Invoking a Helloworld Function on page 2981.

**Invocations**

In Oracle Functions, a function's code is run (or executed) when the function is called (or invoked). You can invoke a function that you've deployed to Oracle Functions from:

- The Fn Project CLI.
- The Oracle Cloud Infrastructure SDKs.
- Signed HTTP requests to the function's invoke endpoint. Every function has an invoke endpoint.
- Other Oracle Cloud services (for example, triggered by an event in the Events service) or from external services.

When a function is invoked for the first time, Oracle Functions pulls the function's Docker image from the specified Docker registry, runs it as a Docker container, and executes the function. If there are subsequent requests to the same function, Oracle Functions directs those requests to the same container. After a period being idle, the Docker container is removed.

Oracle Functions shows information about function invocations in metric charts.

See Invoking Functions on page 3005.
Triggers

A trigger is the result of an action elsewhere in the system, that sends a request to invoke a function in Oracle Functions. For example, an event in the Events service might cause a trigger to send a request to Oracle Functions to invoke a function. Alternatively, a trigger might send regular requests to invoke a function on a defined, time-based schedule.

A function might not be associated with any triggers, or it can be associated with one or multiple triggers.

How Oracle Functions Works

This topic describes how Oracle Functions works when you deploy a function, and when you invoke a function.

What Happens When You Deploy a Function to Oracle Functions?

When you have written the code for a function and it's ready to deploy, you can use a single Fn Project CLI command to perform all the deploy operations in sequence:

- building a Docker image from the function
- providing a definition of the function in a func.yaml file that includes:
  - the maximum length of time the function is allowed to execute for
  - the maximum amount of memory the function is allowed to consume
- pushing the image to the specified Docker registry
- uploading function metadata (including the memory and time restrictions, and a link to the image in the Docker registry) to the Fn Server
- adding the function to the list of functions shown in the Console

The above process of deploying a function to Oracle Functions is shown in the diagram.

Note that once the image has been uploaded to the Docker registry, it is your responsibility to update the image. For example, when new language versions are supported (for more information, see Function Development Kits (FDKs) on page 3028).

What Happens When You Invoke a Function?

You can invoke a function that you've deployed to Oracle Functions from:
Functions

- The Fn Project CLI.
- The Oracle Cloud Infrastructure SDKs.
- Signed HTTP requests to the function's invoke endpoint. Every function has an invoke endpoint.
- Other Oracle Cloud services (for example, triggered by an event in the Events service) or from external services.

When a function is invoked for the first time, Oracle Functions first verifies the request with the IAM service. Assuming the request passes authentication and authorization checks, Oracle Functions then passes the request to the Fn Server, which uses the function definition to:

- identify the Docker image of the function to pull from the Docker registry
- execute the function by running the function's image as a container on an instance in a subnet associated with the application to which the function belongs

When the function is executing inside the container, the function can read from and write to other resources and services running in the same subnet (for example, Database as a Service). The function can also read from and write to other shared resources (for example, Object Storage) and other Oracle Cloud Services. You can specify the maximum length of time the function is allowed to execute by setting a timeout in the func.yaml file or in the Console.

Oracle Functions stores the function's logs in Oracle Cloud Infrastructure or in an external logging destination.

When the function has finished executing and after a period being idle, the Docker container is removed. If Oracle Functions receives another call to the same function before the container is removed, the second request is routed to the same running container. If Oracle Functions receives a call to a function that is currently executing inside a running container, Oracle Functions scales horizontally to serve both incoming requests and a second Docker container is started.

Oracle Functions shows information about function invocations in metric charts.

The above process of invoking a function is shown in the diagram.
Oracle Functions Resiliency, Availability, Concurrency, and Scalability

Resiliency and Availability

Resiliency and availability refers to the ability of a system to continue operating, despite the failure or sub-optimal performance of some of its components.

In the case of Oracle Functions:

- The control plane is a set of components that manages function definitions.
- The data plane is a set of components that executes functions in response to invocation requests.

For resiliency and high availability, both the control plane and data plane components are distributed across different availability domains and fault domains in a region. If one of the domains ceases to be available, the components in the remaining domains take over to ensure that function definition management and execution are not disrupted.

When functions are invoked, they run in the subnets specified for the application to which the functions belong. For resiliency and high availability, best practice is to specify a regional subnet for an application (or alternatively, multiple AD-specific subnets in different availability domains). If an availability domain specified for an application ceases to be available, Oracle Functions runs functions in an alternative availability domain.

Concurrency and Scalability

Concurrency refers to the ability of a system to run multiple operations in parallel using shared resources. Scalability refers to the ability of the system to scale capacity (both up and down) to meet demand.

In the case of Functions, when a function is invoked for the first time, the function's image is run as a container on an instance in a subnet associated with the application to which the function belongs. When the function is executing inside the container, the function can read from and write to other shared resources and services running in the same subnet (for example, Database as a Service). The function can also read from and write to other shared resources (for example, Object Storage), and other Oracle Cloud Services.

If Oracle Functions receives multiple calls to a function that is currently executing inside a running container, Oracle Functions automatically and seamlessly scales horizontally to serve all the incoming requests. Oracle Functions starts multiple Docker containers, up to the limit specified for your tenancy. The default limit is 60 GB of RAM reserved for function execution per availability domain, although you can request an increase to this limit. Provided the limit is not exceeded, there is no difference in response time (latency) between functions executing on the different containers.

When functions from different applications are invoked simultaneously, Oracle Functions ensures these function executions are isolated from each other.

Different Options for Function Development Environments

When setting up your Oracle Functions development environment, you have different options:

- **Option 1: Setting up Cloud Shell. (Recommended)** For users trying out Oracle Functions for the first time, this is the recommended way to get started quickly. By copying and pasting a few commands from the Console into the Cloud Shell window, you can set up an Oracle Functions development environment in just a few minutes.

  This option enables you to experiment creating, deploying, and invoking new functions. You can also explore Oracle Functions using the samples on Git Hub (see Oracle Functions Samples).

  Use the Functions QuickStart on Cloud Shell on page 2963 if you want to set up Cloud Shell as your Oracle Functions development environment.
• **Option 2: Setting up a local machine.** For most users (especially Mac and Linux users), this will be the way to work with Oracle Functions. If you set up a local machine, you'll have to specify `--provider oracle` when you create a new Fn Project CLI context.

This option enables Oracle Functions to perform authentication and authorization using Oracle Cloud Infrastructure request signing, private keys, user groups, and policies that grant permissions to those user groups.

Use the [Functions QuickStart on Local Host](#) on page 2968 if you want to set up a local machine as your Oracle Functions development environment.

• **Option 3: Setting up an Oracle Cloud Infrastructure compute instance.** For some users, this will be more convenient than setting up a local machine. If you set up an Oracle Cloud Infrastructure compute instance, you'll have to specify `--provider oracle-ip` when you create a new Fn Project CLI context.

This option enables Oracle Functions to perform authentication and authorization using instance OCIDs, dynamic groups, and policies granting permissions to those dynamic groups. This approach removes the requirement for users to manage private keys. Note that to set up an Oracle Functions development environment on an Oracle Cloud Infrastructure compute instance, you must:

• have permission to create dynamic groups
• create a new dynamic group that includes the compute instance's OCID
• create a policy to give the new dynamic group access to function resources, network resources, and Oracle Cloud Infrastructure Registry
• specify `--provider oracle-ip` when you create a new Fn Project CLI context

Use the [Functions QuickStart on an OCI Compute Instance](#) on page 2975 if you want to set up an Oracle Cloud Infrastructure compute instance as your Oracle Functions development environment.

### Functions QuickStart Guides

Use these QuickStart Guides to get set up and running quickly with Oracle Functions:

• [Functions QuickStart on Cloud Shell](#) on page 2963 (recommended)
• [Functions QuickStart on Local Host](#) on page 2968
• [Functions QuickStart on an OCI Compute Instance](#) on page 2975

If you're not sure which QuickStart Guide to use, see [Different Options for Function Development Environments](#) on page 2962.

### Functions QuickStart on Cloud Shell

**A. Set up your tenancy**

1. **Create groups and users**

If suitable users and groups don't exist already:

1. Sign in to the Console as a tenancy administrator.
2. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Groups**.
3. Create a new group by clicking **Groups** and then **Create Group**.
4. Create a new user by clicking **Users** and then **Create User**.
5. Add a user to a group by clicking **Groups**, then the name of the group, and then **Add User to Group**.

![Add User to Group](image)

See **Configuration Notes** for more information.

2. **Create compartment**

If a suitable compartment in which to create network resources and Oracle Functions resources doesn't exist already:

1. Sign in to the Console as a tenancy administrator.
2. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Compartments**.
3. Click **Create Compartment**.

![Create Compartment](image)

See **Configuration Notes** for more information.

3. **Create VCN and subnets**

If a suitable VCN in which to create network resources doesn't exist already:

1. Sign in to the Console as a tenancy administrator.
2. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
3. Click **Start VCN Wizard** to create a new VCN.
4. In the **Start VCN Wizard** dialog box, select **VCN with Internet Connectivity** and click **Start VCN Wizard**.
5. Enter a name for the new VCN, click **Next**, and then click **Create** to create the VCN along with the related network resources.

See **Configuration Notes** for more information.

4. **Create policy for group and service**

If one or more Oracle Functions users is not a tenancy administrator:

1. Sign in to the Console as a tenancy administrator.
2. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Policies**.
3. Click **Create Policy**, specify a name and description for the new policy, and select the tenancy's root compartment.
4. Use the Policy Builder to create the policy. Select **Functions** from the list of **Policy use cases**, and base the policy on the policy template **Let users create, deploy, and manage functions and applications**.

The policy template includes the following policy statements:

- Allow group `<group-name>` to use cloud-shell in tenancy
- Allow group `<group-name>` to manage repos in tenancy
- Allow group `<group-name>` to read objectstorage-namespaces in tenancy
- Allow group `<group-name>` to manage logging-family in tenancy
- Allow group `<group-name>` to read metrics in tenancy
- Allow group `<group-name>` to manage functions-family in tenancy
- Allow group `<group-name>` to use virtual-network-family in tenancy
- Allow group `<group-name>` to use apm-domains in tenancy
- Allow group `<group-name>` to read vaults in tenancy
- Allow group `<group-name>` to use keys in tenancy
- Allow service faas to use apm-domains in tenancy
- Allow service faas to read repos in tenancy where request.operation='ListContainerImageSignatures'
- Allow service faas to {KEY_READ} in tenancy where request.operation='GetKeyVersion'
- Allow service faas to {KEY_VERIFY} in tenancy where request.operation='Verify'

If necessary, you can restrict these policy statements by compartment.

See **Configuration Notes** for more information.

**B. Create application**

1. **Create your first application**

   1. Sign in to the Console as a functions developer.
   2. In the Console, open the navigation menu and click **Developer Services**. Under **Functions**, click **Applications**.
   3. Select the region you are using with Oracle Functions.
   4. Click **Create Application**.

   ![Create Application](image)

   Click **Create Application**.

   5. Specify:

      - helloworld-app as the name for the new application. You’ll deploy your first function in this application, and specify this application when invoking the function.
      - The VCN and subnet in which to run the function.

   6. Click **Create**.

   See **detailed instructions** for more information.
C. Set up your Cloud Shell dev environment

1. Display the Getting Started page and the Cloud Shell window

On the Applications page in the Console:

1. Click the helloworld-app application you just created to display the application details page.
2. Click the Getting Started link, and then click Cloud Shell Setup.

Tip: The Getting Started page now displays commands tailored specifically for you. You copy and paste these commands to configure your Cloud Shell environment for functions development.

3. Click Launch Cloud Shell to display the Cloud Shell terminal window.

2. Set up Fn Project CLI context

Copy and paste commands from the Getting Started page into the Cloud Shell terminal window to configure your environment, as follows:

1. Find the name of the pre-created Fn Project context for the current region in which you created the application:

   ```
   fn list context
   ```

   At least two Fn Project contexts are returned, a default context and a context for the current region (for example, named us-phoenix-1).

2. Set the Fn Project context to use the region context:

   ```
   fn use context <region-context>
   ```

   where `<region-context>` is the context for the current region. For example:

   ```
   fn use context us-phoenix-1
   ```

3. Configure the Fn Project context with the OCID of the current compartment that will own deployed functions:

   ```
   fn update context oracle.compartment-id <compartment-ocid>
   ```

   For example:

   ```
   fn update context oracle.compartment-id ocid1.compartment.oc1..aaaaaaaarvdfa72n...
   ```

4. Configure the Fn Project context with the Oracle Cloud Infrastructure Registry address in the current region and tenancy that you want to use with Oracle Functions:

   ```
   fn update context registry <region-key>.ocir.io/<tenancy-namespace>/<repo-name-prefix>
   ```

   where `<repo-name-prefix>` is a prefix of your choosing for the Oracle Cloud Infrastructure Registry repository in which to store images for the function. For example:

   ```
   fn update context registry phx.ocir.io/ansh81vrulzp/acme-repo
   ```
See Configuration Notes for more information.

### 3. Generate auth token

On the Getting Started page in the Console:

1. Click Generate an Auth Token to display the Auth Tokens page, and click Generate Token.

2. Enter a meaningful description for the auth token in the Generate Token dialog, and click Generate Token. The new auth token is displayed (for example, 6aN...6MqX).

3. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.

4. Close the Generate Token dialog.

See Configuration Notes for more information.

### 4. Log in to Registry

On the Getting Started page in the Console:

1. Copy the following command:

   ```
   docker login -u '<tenancy-namespace>/<user-name>' <region-key>.ocir.io
   ```

   For example:

   ```
   docker login -u 'ansh81vru1zp/jdoe@acme.com' phx.ocir.io
   ```

   If your tenancy is federated with Oracle Identity Cloud Service, the format will be slightly different. For example:

   ```
   docker login -u 'ansh81vru1zp/oracleidentitycloudservice/jdoe@acme.com' phx.ocir.io
   ```

2. In the terminal window, paste the command you just copied and run it.

3. When prompted for a password, enter the Oracle Cloud Infrastructure auth token that you created and copied earlier. For example, 6aN...6MqX

   You're now ready to start creating, deploying, and invoking functions.

See Configuration Notes for more information.

### D. Create, deploy, and invoke your function

#### 1. Create your first function

In the terminal window:

1. Create a helloworld java function by entering:

   ```
   fn init --runtime java hello-java
   ```

   A directory called hello-java is created, containing:

   - a function definition file called func.yaml
   - a /src directory containing source files and directories for the helloworld function
   - a Maven configuration file called pom.xml that specifies the dependencies required to compile the function

   Java is just one of several supported languages.

   See detailed instructions for more information.
2. Deploy your first function

In the terminal window:

1. Change directory to the hello-java directory created in the previous step:

   ```bash
   cd hello-java
   ```

2. Enter the following single Fn Project command to build the function and its dependencies as a Docker image called hello-java, push the image to the specified Docker registry, and deploy the function to Oracle Functions in the helloworld-app application that you created earlier:

   ```bash
   fn -v deploy --app helloworld-app
   ```

3. (Optional) Confirm that the function has been deployed to Oracle Functions by clicking **Functions** (under **Resources** on the details page for the helloworld-app application) and noting that the hello-java function now appears.

   See detailed instructions for more information.

3. Invoke your first function

In the terminal window:

1. Invoke the hello-java function by entering:

   ```bash
   fn invoke helloworld-app hello-java
   ```

   The 'Hello world!' message is displayed.

2. Invoke the hello-java function with the parameter 'John' by entering:

   ```bash
   echo -n 'John' | fn invoke helloworld-app hello-java
   ```

   The 'Hello John!' message is displayed.

Congratulations! You've just created, deployed, and invoked your first function using Oracle Functions!

See detailed instructions for more information.

4. Next steps

Now that you've created, deployed, and invoked a function, learn how to:

- view function logs in the Oracle Cloud Infrastructure Logging service, or by configuring a syslog URL (see Storing and Viewing Function Logs on page 3039)
- explore Oracle Functions using samples on GitHub (see Oracle Functions Samples)
- invoke a function using SDKs (see Using SDKs to Invoke Functions on page 3007)

You're done!

**Functions QuickStart on Local Host**

A. Set up your tenancy

1. **Create groups and users**

   If suitable users and groups don't exist already:

   1. Sign in to the Console as a tenancy administrator.
   2. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Groups**.
   3. Create a new group by clicking **Groups** and then **Create Group**.
4. Create a new user by clicking Users and then Create User.

5. Add a user to a group by clicking Groups, then the name of the group, and then Add User to Group.

See Configuration Notes for more information.

2. Create compartment

If a suitable compartment in which to create network resources and Oracle Functions resources doesn't exist already:

1. Sign in to the Console as a tenancy administrator.
2. Open the navigation menu and click Identity & Security. Under Identity, click Compartments.
3. Click Create Compartment.

See Configuration Notes for more information.

3. Create VCN and subnets

If a suitable VCN in which to create network resources doesn't exist already:

1. Sign in to the Console as a tenancy administrator.
2. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
3. Click Start VCN Wizard to create a new VCN.
4. In the Start VCN Wizard dialog box, select VCN with Internet Connectivity and click Start VCN Wizard.
5. Enter a name for the new VCN, click Next, and then click Create to create the VCN along with the related network resources.

See Configuration Notes for more information.

4. Create policy for group and service

If one or more Oracle Functions users is not a tenancy administrator:

1. Sign in to the Console as a tenancy administrator.
3. Click Create Policy, specify a name and description for the new policy, and select the tenancy's root compartment.
4. Use the Policy Builder to create the policy. Select Functions from the list of Policy use cases, and base the policy on the policy template Let users create, deploy, and manage functions and applications.

The policy template includes the following policy statements:

- Allow group <group-name> to use cloud-shell in tenancy
- Allow group <group-name> to manage repos in tenancy
- Allow group <group-name> to read objectstorage-namespaces in tenancy
- Allow group <group-name> to manage logging-family in tenancy
- Allow group <group-name> to read metrics in tenancy
- Allow group <group-name> to manage functions-family in tenancy
- Allow group <group-name> to use virtual-network-family in tenancy
- Allow group <group-name> to use apm-domains in tenancy
- Allow group <group-name> to read Vaults in tenancy
- Allow group <group-name> to use keys in tenancy
- Allow service faas to use apm-domains in tenancy
- Allow service faas to read repos in tenancy where request.operation='ListContainerImageSignatures'
- Allow service faas to [KEY_READ] in tenancy where request.operation='GetKeyVersion'
- Allow service faas to [KEY_VERIFY] in tenancy where request.operation='Verify'

If necessary, you can restrict these policy statements by compartment.

See Configuration Notes for more information.

B. Create application

1. Create your first application

   1. Sign in to the Console as a functions developer.
   2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
   3. Select the region you are using with Oracle Functions.
   4.

   Click Create Application.

   5. Specify:

   - helloworld-app as the name for the new application. You'll deploy your first function in this application, and specify this application when invoking the function.
   - The VCN and subnet in which to run the function.

   6. Click Create.

   See detailed instructions for more information.
C. Set up your local host dev environment

1. Install and start Docker

In a terminal window in your development environment:

1. Confirm that Docker is installed by entering:

   docker version

   If you see an error message indicating that Docker is not installed, you have to install Docker before proceeding. See the Docker documentation for your platform (for Oracle Linux, see here).

   Assuming Docker is installed, go to the Prerequisites section of the Fn Project home page on GitHub and confirm that the installed version of Docker is at least the minimum version specified there. If not, re-install Docker before proceeding.

2. Launch the standard hello-world Docker image as a container to confirm that Docker is running by entering:

   docker run hello-world

   If you see an error message indicating that Docker is not running, you have to start the Docker daemon before proceeding. See the Docker documentation.

See Configuration Notes for more information.

2. Set up API signing key and OCI profile

1. Sign in to the Console as a functions developer.

2. Open the Profile menu and click User Settings.

3. Under Resources, click API Keys, and then click Add API Key.

4. Select Generate API Key Pair in the Add API Key dialog.

5. Click Download Private Key and save the private key file (as a .pem file) in the ~/.oci directory. (If the ~/.oci directory doesn't already exist, create it now).

6. Click Add to add the new API signing key to your user settings.

   The Configuration File Preview dialog is displayed, containing a configuration file snippet with basic authentication information for a profile named DEFAULT (including the fingerprint of the API signing key you just created).

7. Copy the configuration file snippet shown in the text box, and close the Configuration File Preview dialog.

8. In a text editor, open the ~/.oci/config file and paste the snippet into the file. (If the ~/.oci/config file doesn't already exist, create it now).

9. In the text editor, change the profile in the snippet you've just pasted, as follows:

   • Change the name of the profile from [DEFAULT] to a name of your choosing (for example, [functions-developer-profile]). Note that the ~/.oci/config file cannot contain two profiles with the same name.

   • Change the value of the key_file parameter of the profile to specify the path of the private key file (the .pem file) you downloaded earlier.

10. In the text editor, save the changes you've made to the ~/.oci/config file, and close the text editor.
11. In a terminal window, change permissions on the private key file (the .pem file) to ensure that only you can read it, by entering:

```
chmod go-rwx ~/.oci/<private-key-file-name>.pem
```

See Configuration Notes for more information about setting up an API signing key and creating a profile.

### 3. Install Fn Project CLI

In a terminal window in your development environment:

1. Install the Fn Project CLI using the appropriate instructions below for your environment:
   - Linux or MacOS: Enter:
     ```bash
curl -LSs https://raw.githubusercontent.com/fnproject/cli/master/install | sh
```
   - MacOS using Homebrew: Enter:
     ```bash
brew update && brew install fn
```
   - Windows: Follow the Install Fn Client instructions on GitHub.
   - Linux, MacOS, or Windows: Download and run the binary from the Fn Project Releases page on GitHub.

2. Confirm that the Fn Project CLI has been installed by entering:

```
fn version
```

See Configuration Notes for more information.

### 4. Set up Fn Project CLI context provider --oracle

In a terminal window in your development environment:

1. Create a new Fn Project CLI context by entering:

```
fn create context <my-context> --provider oracle
```

Note that you specify `--provider oracle` to enable authentication and authorization using Oracle Cloud Infrastructure request signing, private keys, user groups, and policies that grant permissions to those user groups.

2. Specify that the Fn Project CLI is to use the new context by entering:

```
fn use context <my-context>
```

3. Configure the new Fn Project CLI context with the name of the OCI profile you’ve created for use with Oracle Functions (for example, `[functions-developer-profile]`), by entering:

```
fn update context oracle.profile <profile-name>
```

See Configuration Notes for more information.

### 5. Complete Fn Project CLI context configuration

In a terminal window in your development environment:

1. Configure the new Fn Project CLI context with the OCID of the compartment you want to own deployed functions

```
fn update context oracle.compartment-id <compartment-ocid>
```
2. Configure the new context with the api-url endpoint to use when calling the OCI API by entering:

```bash
fn update context api-url <api-endpoint>
```

where `<api-endpoint>` is one of the endpoints in the list of Functions endpoints in Functions API, in the format `https://functions.<region-identifier>.oci.oraclecloud.com`. For example:

```bash
fn update context api-url https://functions.us-phoenix-1.oci.oraclecloud.com
```

3. Configure the Fn Project CLI context with the Oracle Cloud Infrastructure Registry address in the current region and tenancy that you want to use with Oracle Functions:

```bash
fn update context registry <region-key>.ocir.io/<tenancy-namespace>/<repo-name-prefix>
```

where `<repo-name-prefix>` is a prefix of your choosing for the Oracle Cloud Infrastructure Registry repository in which to store images for the function. For example:

```bash
fn update context registry phx.ocir.io/ansh81vru1zp/acme-repo
```

See Configuration Notes for more information.

6. **Generate auth token**

1. Sign in to the Console as a functions developer.
2. Open the User menu and go to User Settings. On the Auth Tokens page, click Generate Token.
3. Enter a meaningful description for the auth token in the Generate Token dialog, and click Generate Token. The new auth token is displayed.
4. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
5. Close the Generate Token dialog.

See Configuration Notes for more information.

7. **Log in to Registry**

On the Getting Started page in the Console:

1. Copy the following command:

```bash
docker login -u '<tenancy-namespace>/<user-name>' <region-key>.ocir.io
```

For example:

```bash
docker login -u 'ansh81vru1zp/jdoe@acme.com' phx.ocir.io
```

If your tenancy is federated with Oracle Identity Cloud Service, the format will be slightly different. For example:

```bash
docker login -u 'ansh81vru1zp/oracleidentitycloudservice/jdoe@acme.com' phx.ocir.io
```

2. In the terminal window, paste the command you just copied and run it.
3. When prompted for a password, enter the Oracle Cloud Infrastructure auth token that you created and copied earlier. For example, 6aN...6MqX

You're now ready to start creating, deploying, and invoking functions.

See Configuration Notes for more information.
D. Create, deploy, and invoke your function

1. Create your first function

In the terminal window:

1. Create a helloworld java function by entering:

   
   ```
   fn init --runtime java hello-java
   ```

   A directory called hello-java is created, containing:
   
   - a function definition file called func.yaml
   - a /src directory containing source files and directories for the helloworld function
   - a Maven configuration file called pom.xml that specifies the dependencies required to compile the function

   Java is just one of several supported languages.

   See detailed instructions for more information.

2. Deploy your first function

In the terminal window:

1. Change directory to the hello-java directory created in the previous step:

   ```
   cd hello-java
   ```

2. Enter the following single Fn Project command to build the function and its dependencies as a Docker image called hello-java, push the image to the specified Docker registry, and deploy the function to Oracle Functions in the helloworld-app application that you created earlier:

   ```
   fn -v deploy --app helloworld-app
   ```

3. (Optional) Confirm that the function has been deployed to Oracle Functions by clicking Functions (under Resources on the details page for the helloworld-app application) and noting that the hello-java function now appears.

   See detailed instructions for more information.

3. Invoke your first function

In the terminal window:

1. Invoke the hello-java function by entering:

   ```
   fn invoke helloworld-app hello-java
   ```

   The 'Hello world!' message is displayed.

2. Invoke the hello-java function with the parameter 'John' by entering:

   ```
   echo -n 'John' | fn invoke helloworld-app hello-java
   ```

   The 'Hello John!' message is displayed.

Congratulations! You've just created, deployed, and invoked your first function using Oracle Functions!

See detailed instructions for more information.

4. Next steps

Now that you've created, deployed, and invoked a function, learn how to:

- view function logs in the Oracle Cloud Infrastructure Logging service, or by configuring a syslog URL (see Storing and Viewing Function Logs on page 3039
- explore Oracle Functions using samples on GitHub (see Oracle Functions Samples)
• invoke a function using SDKs (see Using SDKs to Invoke Functions on page 3007)

You're done!

Functions QuickStart on an OCI Compute Instance

A. Set up your tenancy
   1. Create groups and users

If suitable users and groups don't exist already:
   1. Sign in to the Console as a tenancy administrator.
   3.

Create a new group by clicking Groups and then Create Group.
   4.

Create a new user by clicking Users and then Create User.
   5. Add a user to a group by clicking Groups, then the name of the group, and then Add User to Group.

See Configuration Notes for more information.

2. Create compartment

If a suitable compartment in which to create network resources and Oracle Functions resources doesn't exist already:
   1. Sign in to the Console as a tenancy administrator.
   2. Open the navigation menu and click Identity & Security. Under Identity, click Compartments.
   3.

Click Create Compartment.

See Configuration Notes for more information.

3. Create VCN and subnets

If a suitable VCN in which to create network resources doesn't exist already:
   1. Sign in to the Console as a tenancy administrator.
   2. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
   3. Click Start VCN Wizard to create a new VCN.
4. In the **Start VCN Wizard** dialog box, select **VCN with Internet Connectivity** and click **Start VCN**.

5. Enter a name for the new VCN, click **Next**, and then click **Create** to create the VCN along with the related network resources.

See [Configuration Notes](#) for more information.

### 4. Create policy for group and service

If one or more Oracle Functions users is not a tenancy administrator:

1. Sign in to the Console as a tenancy administrator.
2. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Policies**.
3. Click **Create Policy**, specify a name and description for the new policy, and select the tenancy's root compartment.
4. Use the Policy Builder to create the policy. Select **Functions** from the list of **Policy use cases**, and base the policy on the policy template **Let users create, deploy, and manage functions and applications**.

The policy template includes the following policy statements:

- Allow group <group-name> to use cloud-shell in tenancy
- Allow group <group-name> to manage repos in tenancy
- Allow group <group-name> to read objectstorage-namespaces in tenancy
- Allow group <group-name> to manage logging-family in tenancy
- Allow group <group-name> to read metrics in tenancy
- Allow group <group-name> to manage functions-family in tenancy
- Allow group <group-name> to use virtual-network-family in tenancy
- Allow group <group-name> to use apm-domains in tenancy
- Allow group <group-name> to read vaults in tenancy
- Allow group <group-name> to use keys in tenancy
- Allow service faas to use apm-domains in tenancy
- Allow service faas to read repos in tenancy where request.operation='ListContainerImageSignatures'
- Allow service faas to (KEY_READ) in tenancy where request.operation='GetKeyVersion'
- Allow service faas to (KEY_VERIFY) in tenancy where request.operation='Verify'

If necessary, you can restrict these policy statements by compartment.

See [Configuration Notes](#) for more information.

#### B. Create application

1. **Create your first application**

   1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click **Developer Services**. Under **Functions**, click **Applications**.
3. Select the region you are using with Oracle Functions.
4. Click **Create Application**.
5. Specify:
   - **helloworld-app** as the name for the new application. You'll deploy your first function in this application, and specify this application when invoking the function.
   - The VCN and subnet in which to run the function.
6. Click **Create**.

See [detailed instructions](#) for more information.

**C. Set up an OCI compute instance**

1. **Create instance and obtain OCID**
   1. Sign in to the Console as a tenancy administrator.
   2. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
   3. Select the compartment in which to create network resources and Oracle Functions resources.
   4. If a suitable compute instance doesn't exist in the compartment already, click **Create Instance** and:
      - select the compartment, VCN, and subnets for use with Oracle Functions
      - specify that a public IP address is to be assigned to the new compute instance
      - select the file that contains the SSH key to access the new compute instance
   5. On the **Instance Details** page, copy the OCID and public IP address of the compute instance to use as the development environment.

See [documentation](#) for more information.

2. **Create a dynamic group**

Create a new dynamic group to include the compute instance:

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Dynamic Groups**.
2. Create a new dynamic group.
3. Enter a rule that includes the compute instance's OCID:

```
ANY {instance.id = '<instance-ocid>'}
```

See [documentation](#) for more information.

3. **Create policy for dynamic group**

Create a policy to give the new dynamic group access to function resources, network resources, and Oracle Cloud Infrastructure Registry:

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Policies**.
2. Click **Create Policy** and use the Policy Builder's manual editor to create a new policy with the following policy statements:
   - Allow dynamic-group <dynamic-group-name> to manage functions-family in compartment <compartment-name>
   - Allow dynamic-group <dynamic-group-name> to use virtual-network-family in compartment <compartment-name>
   - Allow dynamic-group <dynamic-group-name> to read repos in tenancy

See [documentation](#) for more information.
D. Set up your OCI compute instance dev environment

1. Install and start Docker

In a terminal window in your development environment:

1. Confirm that Docker is installed by entering:

```bash
docker version
```

If you see an error message indicating that Docker is not installed, you have to install Docker before proceeding. See the Docker documentation for your platform (for Oracle Linux, see here).

Assuming Docker is installed, go to the Prerequisites section of the Fn Project home page on GitHub and confirm that the installed version of Docker is at least the minimum version specified there. If not, re-install Docker before proceeding.

2. Launch the standard hello-world Docker image as a container to confirm that Docker is running by entering:

```bash
docker run hello-world
```

If you see an error message indicating that Docker is not running, you have to start the Docker daemon before proceeding. See the Docker documentation.

See Configuration Notes for more information.

2. Install Fn Project CLI

In a terminal window in your development environment:

1. Install the Fn Project CLI using the appropriate instructions below for your environment:

   - Linux or MacOS: Enter:

   ```bash
curl -LSs https://raw.githubusercontent.com/fnproject/cli/master/install | sh
```

   - MacOS using Homebrew: Enter:

   ```bash
brew update && brew install fn
```

   - Windows: Follow the Install Fn Client instructions on GitHub.

   - Linux, MacOS, or Windows: Download and run the binary from the Fn Project Releases page on GitHub.

2. Confirm that the Fn Project CLI has been installed by entering:

```bash
fn version
```

See Configuration Notes for more information.

3. Set up Fn Project CLI context provider --oracle-ip

In a terminal window in your development environment:

1. Create a new Fn Project CLI context by entering:

```bash
fn create context <my-context> --provider oracle-ip
```

Note that you specify --provider oracle-ip to enable authentication and authorization using instance OCIDs, dynamic groups, and policies granting permissions to those dynamic groups.

2. Specify that the Fn Project CLI is to use the new context by entering:

```bash
fn use context <my-context>
```

See Configuration Notes for more information.
4. Complete Fn Project CLI context configuration

In a terminal window in your development environment:

1. Configure the new Fn Project CLI context with the OCID of the compartment you want to own deployed functions

   ```bash
   fn update context oracle.compartment-id <compartment-ocid>
   ```

2. Configure the new context with the api-url endpoint to use when calling the OCI API by entering:

   ```bash
   fn update context api-url <api-endpoint>
   ```

   where `<api-endpoint>` is one of the endpoints in the list of Functions endpoints in Functions API, in the format `https://functions.<region-identifier>.oci.oraclecloud.com`. For example:

   ```bash
   fn update context api-url https://functions.us-phoenix-1.oci.oraclecloud.com
   ```

3. Configure the Fn Project CLI context with the Oracle Cloud Infrastructure Registry address in the current region and tenancy that you want to use with Oracle Functions:

   ```bash
   fn update context registry <region-key>.ocir.io/<tenancy-namespace>/<repo-name-prefix>
   ```

   where `<repo-name-prefix>` is a prefix of your choosing for the Oracle Cloud Infrastructure Registry repository in which to store images for the function. For example:

   ```bash
   fn update context registry phx.ocir.io/ansh81vrlzp/acme-repo
   ```

See Configuration Notes for more information.

5. Generate auth token

1. Sign in to the Console as a functions developer.
2. Open the User menu and go to User Settings. On the Auth Tokens page, click Generate Token.
3. Enter a meaningful description for the auth token in the Generate Token dialog, and click Generate Token. The new auth token is displayed.
4. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
5. Close the Generate Token dialog.

See Configuration Notes for more information.

6. Log in to Registry

In a terminal window in your development environment:

1. Enter the following command:

   ```bash
   docker login -u '<tenancy-namespace>/<user-name>' <region-key>.ocir.io
   ```

   For example:

   ```bash
   docker login -u 'ansh81vrlzp/jdoe@acme.com' phx.ocir.io
   ```

   If your tenancy is federated with Oracle Identity Cloud Service, the format will be slightly different. For example:

   ```bash
   docker login -u 'ansh81vrlzp/oracleidentitycloudservice/jdoe@acme.com' phx.ocir.io
   ```
2. When prompted for a password, enter the Oracle Cloud Infrastructure auth token that you created and copied earlier. For example, 6aN...6MqX

You're now ready to start creating, deploying, and invoking functions.

See Configuration Notes for more information.

**E. Create, deploy, and invoke your function**

1. **Create your first function**

In the terminal window:

1. Create a helloworld java function by entering:

   ```
   fn init --runtime java hello-java
   ```

   A directory called hello-java is created, containing:
   - a function definition file called func.yaml
   - a /src directory containing source files and directories for the helloworld function
   - a Maven configuration file called pom.xml that specifies the dependencies required to compile the function

   Java is just one of several supported languages.

   See detailed instructions for more information.

2. **Deploy your first function**

In the terminal window:

1. Change directory to the hello-java directory created in the previous step:

   ```
   cd hello-java
   ```

2. Enter the following single Fn Project command to build the function and its dependencies as a Docker image called hello-java, push the image to the specified Docker registry, and deploy the function to Oracle Functions in the helloworld-app application that you created earlier:

   ```
   fn -v deploy --app helloworld-app
   ```

3. (Optional) Confirm that the function has been deployed to Oracle Functions by clicking **Functions** (under **Resources** on the details page for the helloworld-app application) and noting that the hello-java function now appears.

   See detailed instructions for more information.

3. **Invoke your first function**

In the terminal window:

1. Invoke the hello-java function by entering:

   ```
   fn invoke helloworld-app hello-java
   ```

   The 'Hello world!' message is displayed.

2. Invoke the hello-java function with the parameter 'John' by entering:

   ```
   echo -n 'John' | fn invoke helloworld-app hello-java
   ```

   The 'Hello John!' message is displayed.

   Congratulations! You've just created, deployed, and invoked your first function using Oracle Functions!

   See detailed instructions for more information.
4. Next steps

Now that you've created, deployed, and invoked a function, learn how to:

• view function logs in the Oracle Cloud Infrastructure Logging service, or by configuring a syslog URL (see Storing and Viewing Function Logs on page 3039)
• explore Oracle Functions using samples on GitHub (see Oracle Functions Samples)
• invoke a function using SDKs (see Using SDKs to Invoke Functions on page 3007)

You're done!

Preparing for Functions

Before you can deploy functions to Oracle Functions, you have to perform the tasks described in the Functions QuickStart Guides on page 2963 to configure:

• Your Oracle Cloud Infrastructure tenancy for function development.
  
  When your tenancy is configured, you will have access, via a suitable policy and user account, to a compartment that has a VCN with at least one public subnet (and an internet gateway) or at least one private subnet (and a service gateway). For more information about these network components, see Networking on page 4232.

• Your client environment for functions development.
  
  When your client environment is configured, you will have access to the Fn Project CLI, and a Docker registry in which to store images (this documentation assumes you will be using Oracle Cloud Infrastructure Registry as your Docker registry and provides instructions accordingly).

Use the Functions QuickStart Guides on page 2963 to complete these configuration tasks.

For additional information about the configuration tasks, see Appendix: Configuration Notes for Oracle Functions on page 3080.

Availability by Region

Oracle Functions is available in the Oracle Cloud Infrastructure regions listed at Regions and Availability Domains on page 210. Refer to that topic to see region identifiers, region keys, and availability domain names.

Creating Functions

Read about how to create functions and applications with Oracle Functions:

• Creating, Deploying, and Invoking a Helloworld Function on page 2981
• Creating Applications on page 2983
• Creating and Deploying Functions on page 2985
• Using Custom Dockerfiles on page 2986
• Creating Functions from Existing Docker Images on page 2988

Creating, Deploying, and Invoking a Helloworld Function

You can start off using Oracle Functions by using Fn Project CLI commands to:

• create a simple helloworld function written in java
• push the image to the Docker registry that's configured for Oracle Functions
• deploy the function to an application in Oracle Functions
• invoke the function

Tip:

If you aren’t able to successfully complete one of the steps in this topic, review the solutions for common problems (see Troubleshooting Oracle Functions on page 3067).
To get started with Oracle Functions:

1. Confirm that you have completed the steps in the Functions QuickStart Guides on page 2963.
2. Sign in to the Console as a functions developer.
3. Use the Console to create a new application in Oracle Functions:
   a. In the Console, open the navigation menu and click **Developer Services**. Under **Functions**, click **Applications**.
   b. Select the region you intend to use for Oracle Functions. Oracle recommends that you use the same region as the Docker registry specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
   c. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
   The **Applications** page shows the applications already defined in the compartment.
   d. Click **Create Application** and specify:
      - The name for the new application as helloworld-app.
      - The VCN and subnet (or subnets, up to a maximum of three) in which to run the function. For example, a VCN called acme-vcn-01 and a public subnet called Public Subnet IHsY:US-PHOENIX-AD-1). If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, select multiple subnets. Oracle recommends that subnets are in the same region as the Docker registry specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
   e. Click **Create**.
4. Log in to your development environment as a functions developer.
5. In a terminal window, create a helloworld java function by entering:

   ```
   fn init --runtime java helloworld-func
   ```

   A directory called helloworld-func is created, containing:
   - A function definition file called func.yaml, containing the minimum amount of information required to build and run the function. See the Fn Project documentation to find out about the additional parameters you can include in a func.yaml file.
   - A /src directory containing source files and directories for the helloworld function (including /src/main/java/com/example/fn/HelloFunction.java).
   - A Maven configuration file called pom.xml that specifies the project artifacts and dependencies required to compile the function from the source files.
6. Change directory to the newly created helloworld-func directory.
7. Enter the following single Fn Project command to build the function and its dependencies as a Docker image called helloworld-func, push the image to the specified Docker registry, and deploy the function to Oracle Functions in the helloworld-app:

   ```
   fn -v deploy --app helloworld-app
   ```

   The `-v` option simply shows more detail about what Fn Project commands are doing (see Using the Fn Project CLI with Oracle Functions on page 3023).
8. (Optional) Assuming the specified Docker registry is Oracle Cloud Infrastructure Registry, use the Console to confirm that the helloworld-func image has been pushed to Oracle Cloud Infrastructure Registry successfully:

   a. In the Console, open the navigation menu and click Developer Services. Under Containers, click Container Registry.
   
   b. Choose the registry's region.

   You see all the repositories in the registry to which you have access. The image you pushed is in a new repository with a name constructed from:

   • the repository name prefix in the address of the Docker registry in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088)
   
   • the name of the helloworld-func image

   For example, the new repository might be called acme-repo/helloworld-func.
   
   c. Click the name of the new repository. You see details of the helloworld-func image that's been pushed to Oracle Cloud Infrastructure Registry.

9. (Optional) Use the Console to confirm that the function has been deployed to Oracle Functions successfully:

   a. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
   
   b. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).

   The Applications page shows that an application called helloworld-app has been created.
   
   c. Click the helloworld-app application to see the functions within it.

   The Functions page shows that the helloworld-func function has been deployed to Oracle Functions.

10. In a terminal window, invoke the helloworld-func function by entering:

    ```
    fn invoke helloworld-app helloworld-func
    ```

    The 'Hello World !' message is displayed.

Congratulations! You've successfully created and deployed your first function to Oracle Functions!

**Creating Applications**

You can create applications in Oracle Functions in readiness for deploying functions. An application need not contain any functions.

You can create applications using the Console, the Fn Project CLI, and the API.

For more information about applications, see Applications on page 2959.

**Using the Console**

To create a new application in Oracle Functions using the Console:

1. Confirm that you have completed the steps in the Functions QuickStart Guides on page 2963.
2. Sign in to the Console as a functions developer.
3. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
4. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
5. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).

   The Applications page shows the applications already defined in the compartment.
6. Click **Create Application** and specify:
   - A name for the new application (for example, acmeapp). Avoid entering confidential information.
   - The VCN and subnet (or subnets, up to a maximum of three) in which to run functions. For example, a VCN called acme-vcn-01 and a public subnet called Public Subnet IHSY:US-PHOENIX-AD-1). If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, select multiple subnets. Oracle recommends that the subnets are in the same region as the Docker registry that’s specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).

7. Click **Create**.
   The new application appears in the list of applications.

**Using Fn Project CLI Commands**

To create a new application in Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, create a new application by entering:

   ```
   fn create app <app-name> --annotation oracle.com/oci/subnetIds='["<subnet-ocid>"]'
   ```

   where:
   - `<app-name>` is the name of the new application. Avoid entering confidential information.
   - `<subnet-ocid>` is the OCID of the subnet (or subnets, up to a maximum of three) in which to run functions. If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, specify multiple subnets (enclose each OCID in double quotes separated by commas, in the format '[["<subnet-ocid>"],["<subnet-ocid>"]]'). Oracle recommends that the subnets are in the same region as the Docker registry that’s specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).

   For example:

   ```
   fn create app acmeapp --annotation oracle.com/oci/subnetIds='["ocid1.subnet.oc1.phxaaaaaaaaacnh..."]'
   ```

   An application is created in Oracle Functions, in the tenancy and region implied by the subnet OCID and belonging to the compartment specified in the Fn Project CLI context file.

3. Verify that the new application has been created by entering:

   ```
   fn list apps
   ```

   For example:

   ```
   $ fn list apps
   acmeapp
   ```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use these API operations to manage applications:

- **CreateApplication**
- **DeleteApplication**
Functions

- GetApplication
- UpdateApplication

Creating and Deploying Functions

You use Fn Project CLI commands to create and deploy functions to Oracle Functions.

Tip:
If you aren't able to successfully complete one of the steps in this topic, review the solutions for common problems (see Troubleshooting Oracle Functions on page 3067).

Using Fn Project CLI Commands

To create and deploy a function to Oracle Functions using Fn Project CLI commands:

1. Confirm that you have completed the steps in the Functions QuickStart Guides on page 2963.
2. If the application to which you want to add the function doesn't yet exist in Oracle Functions, create it now using the Fn Project CLI or the Console. For example, you might create a new application called acmeapp. See Creating Applications on page 2983.
3. Log in to your development environment as a functions developer.
4. In a terminal window, change directory to the directory containing the function code.
5. Initialize the function by entering:

   ```
   fn init --runtime <runtime-language> <function-name>
   ```

   where:
   - `<runtime-language>` is one of the supported runtime languages (currently go, java, node, python, and ruby are supported)
   - `<function-name>` is the name to use as the function name. If you don't specify a function name, the name of the current directory (in lower case) is used. Avoid entering confidential information.

   For example:

   ```
   fn init --runtime java acme-func
   ```

   A directory is created with the function name you specified, containing:
   - A function definition file called func.yaml, containing the minimum amount of information required to build and run the function. See the Fn Project documentation to find out about the additional parameters you can include in a func.yaml file.
   - A /src directory containing source files and directories.
   - A Maven configuration file called pom.xml that specifies the project artifacts and dependencies required to compile the function from the source files.

   Note that depending on the runtime language you specify, the `fn init` command might create an /example directory containing code for a helloworld application. As a matter of good practice, you'll probably want to delete the /example directory.

6. Change directory to the newly created directory.
7. Enter the following single Fn Project command to build the function and its dependencies as a Docker image, push the image to the specified Docker registry, and deploy the function to Oracle Functions:

```
fn -v deploy --app <app-name>
```

where `<app-name>` is the name of the application in Oracle Functions to which you want to add the function. For example:

```
fn -v deploy --app acmeapp
```

The `-v` option simply shows more detail about what Fn Project commands are doing (see Using the Fn Project CLI with Oracle Functions on page 3023).

Note that you can build, push, and deploy the function using separate Fn Project commands, instead of the single `fn deploy` command.

Also note that if you are adding the function to an application that has a signature verification policy enabled, you have to specify additional options. See Signing Function Images and Enforcing the Use of Signed Images from Registry on page 2998.

8. (Optional) Assuming the specified Docker registry is Oracle Cloud Infrastructure Registry, use the Console to confirm that the image has been pushed to Oracle Cloud Infrastructure Registry successfully:

   a. In the Console, open the navigation menu and click Developer Services. Under Containers, click Container Registry.
   
   b. Choose the registry's region.
   
   You see all the repositories in the registry to which you have access. The image you pushed is in a new private repository with a name constructed from:
   
   - the repository name prefix in the address of the Docker registry in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088)
   - the name of the image you pushed
   
   For example, the new repository might be called `acme-repo/acme-func`.
   
   c. Click the name of the new repository. You see details of the image that's been pushed to Oracle Cloud Infrastructure Registry

9. (Optional) Use the Console to confirm that the function has been deployed to Oracle Functions successfully:

   a. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
   
   b. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
   
   The Applications page shows the applications in the compartment, including the one you specified in the `fn deploy` command.
   
   c. Click the name of the application you specified in the `fn deploy` command to see the functions within it.
   
   The Functions page shows that the function has been deployed to Oracle Functions.

Using Custom Dockerfiles

When you build or deploy a function with Oracle Functions, a Docker image is created and pushed to a Docker registry. As with any Docker image, the instructions to build the image are contained in a Dockerfile.

If the function is written in one of the languages supported by an Fn Project FDK (Functions Development Kit), Oracle Functions uses the `runtime`, `build_image`, and `run_image` settings in a `func.yaml` file to determine the language (and therefore the build-time and run-time dependencies) to include in the Docker image. If you use the `fn init` command to initialize the function, a `func.yaml` file is created for you. For example, a `func.yaml` might look like:

```
schema_version: 20180708
```
When you build or deploy the function, Oracle Functions uses the settings in the func.yaml file to create a temporary Dockerfile containing the instructions from which to build the Docker image. For example, a temporary Dockerfile is shown below.

```yaml
FROM fnproject/fn-java-fdk-build:jdk11-1.0.116 as build-stage
WORKDIR /function
ENV MAVEN_OPTS -Dhttp.proxyHost= -Dhttp.proxyPort= -Dhttps.proxyHost= -Dhttps.proxyPort= -Dhttp.nonProxyHosts= -Dmaven.repo.local=/usr/share/maven/ref/repository
ADD pom.xml /function/pom.xml
ADD src /function/src
RUN ["mvn", "package"]
FROM fnproject/fn-java-fdk:jre11-1.0.116
WORKDIR /function
COPY --from=build-stage /function/target/*.jar /function/app/
CMD ["com.example.fn.HelloFunction::handleRequest"]
```

Having created the Docker image, Oracle Functions deletes the temporary Dockerfile.

If you want more control over the Docker image that is created, you can modify the Dockerfile that Oracle Functions creates. Alternatively, you can create your own Dockerfile entirely from scratch. In both cases, the Dockerfile is referred to as a ‘custom Dockerfile’. This workflow is sometimes referred to as Bring-Your-Own-Dockerfile, or BYOD.

When you build or deploy the function, Oracle Functions uses the instructions in the custom Dockerfile to build the Docker image.

To have Oracle Functions use a custom Dockerfile when building a Docker image:

1. Make a copy of the Dockerfile you want to use as a custom Dockerfile.
2. Save the new file to the directory containing the func.yaml file.
3. Give the new file the name Dockerfile.
   
   Note that you must name the file Dockerfile.
4. Open the file named Dockerfile in an editor of your choice.

   For example, the Dockerfile file might contain the following lines to install the Oracle Instant Client from an oraclelinux:7-slim base image:

```yaml
FROM oraclelinux:7-slim
RUN yum -y install oracle-release-el7 oracle-nodejs-release-el7 && \
    yum-config-manager --disable ol7_developer_EPEL && \
    yum -y install oracle-instantclient19.3-basiclite nodejs && \
    rm -rf /var/cache/yum
WORKDIR /function
ADD . /function/
RUN npm install
CMD exec node func.js
```
5. Include the following lines in the file named Dockerfile (as described in Permissions Granted to Containers Running Functions on page 3021):

```
groupadd --gid 1000 fn && 
adduser --uid 1000 --gid fn fn
```

For example:

```
FROM oraclelinux:7-slim
RUN yum -y install oracle-release-el7 oracle-nodejs-release-el7 && 
yum-config-manager --disable ol7_developer_EPEL && 
yum -y install oracle-instantclient19.3-basiclite nodejs && 
rm -rf /var/cache/yum && 
groupadd --gid 1000 fn && 
adduser --uid 1000 --gid fn fn
```

WORKDIR /function
ADD . /function/
RUN npm install
CMD exec node func.js

6. Save the file named Dockerfile. You can now use the Dockerfile file as a custom Dockerfile.

7. In the func.yaml file, change the value of the runtime: parameter to runtime: docker.

   For example, if the func.yaml file contains runtime: java, change it to runtime: docker.

8. Use the fn build or fn deploy commands to build or deploy the function.

Oracle Functions uses the instructions in the custom Dockerfile (the file named Dockerfile) to build the Docker image for the function, and push it to the Docker registry.

### Creating Functions from Existing Docker Images

You can create a new function definition in the Oracle Functions server in different ways:

- Using the Console or the Fn Project CLI command fn create function to create a new function based on an existing Docker image that has already been pushed to the Docker registry (as described in this topic).
- Using the single Fn Project CLI command fn deploy to build a new Docker image, push the image to the Docker registry, and create a new function based on the image in one step (as described in Creating and Deploying Functions on page 2985).
- Using the API (see CreateFunction).

When using the Console or the fn create function command to create a new function based on an existing Docker image, you specify function metadata to store in the Oracle Functions server. For example, the maximum length of time the function is allowed to execute for.

The existing image on which you base a new function must be suitable for use with Oracle Functions. Typically, to build and push a suitable image, you or somebody else will use Fn Project CLI commands and/or Docker CLI commands. For example, having written your function code and a func.yaml file containing function metadata (perhaps based on the template helloworld function and func.yaml created using fn init), you can:

- Use fn build to build a new Docker image from the function.
- Use docker push to push the image to the Docker registry.

With the image in the Docker registry, you can then use the Console to create a function based on the image, as described in this topic.
Using the Console

To use the Console to create a new function in the Oracle Functions server from an existing Docker image that has already been pushed to the Docker registry:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
4. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).

The Applications page shows the applications defined in the compartment.

5. Click the name of the application in which you want to create the new function.
6. Click Create Function and specify:
   
   - **Name**: A name for the new function. Avoid entering confidential information.
   - **Image**: The existing image in the Oracle Cloud Infrastructure Registry in your currently selected region. You first select the image repository, and then the image version.
   - **Memory**: The maximum amount of memory the function can use during execution.
   - **Timeout**: The maximum amount of time the function will be allowed to run for.
   - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
7. Click Create to create the new function in the Oracle Functions server.

The new function is shown in the Console, in the list of functions in the application you selected.

Using Fn Project CLI Commands

To use the Fn Project CLI to create a new function in the Oracle Functions server from an existing Docker image that has already been pushed to the Docker registry:

1. Log in to your development environment as a functions developer.
2. In a terminal window, create a new function by entering:

   ```
   fn create function <app-name> <function-name> <image-name>
   ```

   where:
   - `<app-name>` is the name of an existing application in which to create the new function.
   - `<function-name>` is the name of the new function you want to create. Avoid entering confidential information.
   - `<image-name>` is the name of the existing image in the Docker registry on which to base the new function.

   For example:

   ```
   fn create function acmeapp acme-func phx.ocir.io/ansh81vrulzp/acme-repo/acme-func:0.0.3
   ```

   A new function is created in Oracle Functions, based on the existing image and with the name you specified

3. Verify that the new function has been created by entering:

   ```
   fn list functions <app-name>
   ```

   For example:

   ```
   $ fn list functions acme-app
   ```
Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use these API operations to manage functions:

- CreateFunction
- DeleteFunction
- GetFunction
- UpdateFunction

Managing Functions

Read about how to manage functions and applications with Oracle Functions:

- Viewing Functions and Applications on page 2990
- Updating Functions on page 2992
- Deleting Applications and Functions on page 2995
- Changing Default Memory and Timeout Settings on page 2996
- Scanning Function Images for Vulnerabilities on page 2997
- Signing Function Images and Enforcing the Use of Signed Images from Registry on page 2998

Viewing Functions and Applications

Having deployed functions to Oracle Functions, you'll typically want to view the functions you've deployed, along with other functions in the same application and different applications. For example, you might want to see:

- all the applications in a compartment
- details of the image for a given function

You can view applications and functions using the Console, the Fn Project CLI, and the API.

Using the Console

To view details of applications and functions deployed to Oracle Functions using the Console:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
4. Select the compartment containing the applications and functions that you want to see information about.
   The Applications page shows all the applications in the compartment you selected.
5. Click the name of an application to see the functions within it.
   The Functions page shows details for all the functions within the application you selected, including:
   - the Docker image created for each function
   - when the function was last updated
6. Click the name of a function on the Functions page to see additional information about that function, including the values of timeout and memory configuration parameters.

Using Fn Project CLI Commands

To view details of applications and functions deployed to Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. If you want to see details about applications, in a terminal window:
   • Enter the following command to see a simple list of applications:

   ```
   fn list apps
   ```

   For example:

   ```
   $ fn list apps
   acme-app
   ```

   • Enter the following command to see more detail about a particular application:

   ```
   fn inspect app <app-name>
   ```

   For example:

   ```
   $ fn inspect app acme-app
   {
     "annotations": {
       "oracle.com/oci/appCode": "fht7ns4mn2q",
       "oracle.com/oci/compartmentId": "ocid1.compartment.ocl..aaaaaaaw_____nyq",
       "oracle.com/oci/subnetIds": [
         "ocid1.subnet.ocl.phx.aaaaaaao..."
       ],
       "oracle.com/oci/tenantId": "ocid1.tenancy.ocl..aaaaapa...keq"
     },
     "created_at": "2018-07-13T17:54:34.000Z",
     "id": "ocid1.fnapp.ocl.phx.aaaaaaaaaf______r3ca",
     "name": "acme-app",
     "updated_at": "2018-07-13T17:54:34.000Z"
   }
   ```

3. If you want to see details about functions, in a terminal window:
   • Enter the following command to see a simple list of functions in a particular application:

   ```
   fn list functions <app-name>
   ```

   For example:

   ```
   $ fn list functions acme-app
   NAME            IMAGE
   acme-func       phx.ocir.io/ansh81vru1zp/acme-repo/acme-func:0.0.3
   acme-func-dev   phx.ocir.io/ansh81vru1zp/acme-repo/acme-func-dev:0.0.7
   acme-func-test  phx.ocir.io/ansh81vru1zp/acme-repo/acme-func-test:0.0.6
   ```

   • Enter the following command to see more detail about a particular function:

   ```
   fn inspect function <app-name> <function-name>
   ```

   For example:

   ```
   $ fn inspect function acme-app acme-func
   {
     "annotations": {
   ```
Functions

Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use these API operations to see details about applications and functions:

- ListApplications
- ListFunctions

Updating Functions

Having previously created a function definition in the Oracle Functions server, you can change some, but not all, of the function's properties. For example, you can change the maximum length of time a function is allowed to execute for, but you cannot change the function's name.

You can change the Docker image on which a function is based. If you do want to change the image, the replacement image must be suitable for use with Oracle Functions, and must have already been pushed to the Docker registry.

With the replacement image in the Docker registry, you can then update a function's definition so that it is based on the replacement image, as described in this topic. If the replacement image has the same name and tag as the image on which the function was originally based, see Notes About Image Digests on page 2994.

You can update functions using the Console, the Fn Project CLI, and the API.

Using the Console to update an existing function

To use the Console to update an existing function in the Oracle Functions server:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
4. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).

The Applications page shows the applications defined in the compartment.
5. Click the name of the application containing the existing function that you want to update.
6. Click the name of the function that you want to update.
7. Click Edit and update some or all of the following properties:

- **Image**: The existing image in the Oracle Cloud Infrastructure Registry in your currently selected region. You first select the image repository, and then the image version. If the image has the same name and tag as the image on which the function was originally based, see Notes About Image Digests on page 2994.
- **Memory**: The maximum amount of memory the function can use during execution.
- **Timeout**: The maximum amount of time the function will be allowed to run for.

8. Click Save to update the function in the Oracle Functions server.

The function's updated properties are shown in the Console.

**Using Fn Project CLI Commands**

To use the Fn Project CLI to update an existing function in the Oracle Functions server:

1. Log in to your development environment as a functions developer.
2. In a terminal window, update properties of an existing function by entering:

```bash
fn update function <app-name> <function-name> --image <image-name> --
<property> <value>
```

where:

- `<app-name>` is the name of an existing application containing the existing function.
- `<function-name>` is the name of the existing function you want to update.
- `--image <image-name>` (optionally) is the name of an existing image in the Docker registry that you now want to base the function on, instead of the previously specified image. If the image has the same name and tag as the image on which the function was originally based, see Notes About Image Digests on page 2994.
- `--<property> <value>` (optionally) is the property you want to update, and the new value you want it to have. Enter `fn update function --help` to see a list of properties and valid values.

For example:

```bash
fn update function acmeapp acme-func --image phx.ocir.io/ansh81vrulzp/
acme-repo/acme-func:0.0.4 --timeout 60

fn update function acmeapp acme-func --memory 256
```

The properties of the existing function are updated with the values you specified.

3. Verify that the function has been updated by entering:

```bash
fn inspect function <app-name> <function-name>
```

For example:

```bash
fn inspect function acme-app acme-func
```

Output:

```
{
   "annotations": {
      "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-
phoenix-1.functions.oci.oraclecloud.com/20181201/functions/
oci1.fnfunc.ocl.phx.aaaa___uxoa/actions/invoke",
      "oracle.com/oci/compartmentId":
      "oci1.compartment.oci..aaaaaaaawaaaa__nyq"
   },
   "app_id": "oci1.fnapp.ocl.phx.aaaaaaaafaaaa__r3ca",
```
Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use the UpdateFunction API operation to update functions.

Notes About Image Digests

Images in a Docker registry are identified by repository, name, and a tag. In addition, Docker gives each version of an image a unique alphanumeric digest. When pushing an updated Docker image, it's recommended best practice to give the updated image a new tag to identify it, rather than reusing an existing tag. However, even if you push an updated image and give it the same name and tag as an earlier version, the newly pushed version will have a different digest to the earlier version.

When you create a function with Oracle Functions, you specify the name and tag of a particular version of an image on which to base the function. To avoid later inconsistencies, Oracle Functions also records the unique digest of that particular version of the image.

By default, if you push an updated version of an image to the Docker registry with the same name and tag as the original version of the image on which a function is based, Oracle Functions continues to use the original digest to pull the original version of the image. This might be the behavior you require. However, if you want Oracle Functions to pull the later version of the image, you can explicitly change the digest that Oracle Functions uses to identify which version of the image to pull in one of the following ways:

- Use the fn update function command and specify the original name and tag of the version of the image on which you want the function to be based. For example:

  ```
  fn update function acmeapp acme-func --image phx.ocir.io/ansh81vrulzp/acme-repo/acme-func:0.0.4 --annotation oracle.com/oci/imageDigest=""
  ```

  Oracle Functions will update the digest recorded for the image on which the function is based to be the digest of the image in the Docker registry that has the name and tag you specify.

- Use the fn update function command and specify the digest of the version of the image on which you want the function to be based. For example:

  ```
  fn update function acmeapp acme-func --annotation oracle.com/oci/imageDigest="sha256:8af7cb8d7______c498c0"
  ```

  Oracle Functions will update the digest recorded for the image on which the function is based to be the digest you specify.

- Use the Console and click Edit Function on the Function Information tab, re-select the original name and tag of the version of the image on which the function is currently based, and click Save Changes. Oracle Functions will update the digest recorded for the image on which the function is based.

- Use the Oracle Cloud Infrastructure API or an Oracle Cloud Infrastructure SDK (for more information, see REST APIs on page 6339 and Software Development Kits and Command Line Interface on page 6152).
Deleting Applications and Functions

You can delete applications and functions in Oracle Functions that you or other functions developers have created, provided you have been granted the necessary permission (FN_APP_DELETE or FN_FUNCTION_DELETE as appropriate).

Note the following:

- Deleting a function does not delete the Docker image on which the function is based. To delete the image, you have to delete it explicitly (see Deleting and Undeleting an Image on page 5100).
- Deleting applications and functions is permanent. You cannot undelete an application or function that you've deleted.
- Deleting a function does not necessarily enable you to immediately delete the subnet and VCN in which the function runs. Expect to wait up to five minutes after the function was last invoked before you can delete the associated network resources.

You can delete applications and functions using the Console, the Fn Project CLI, and the API.

Using the Console

When using the Console to delete applications and functions, note that:

- when you delete an application, all of its functions are also deleted
- you're always prompted to confirm deletion because you cannot undelete an application or function later

To delete applications and functions in Oracle Functions using the Console:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
4. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).

The Applications page shows the applications defined in the compartment.
5. To delete an application, and all of its functions:
   a. Click the name of the application you want to delete.
   b. On the Application Detail page, click Delete and confirm you want to delete the application as follows:
      - If the application does not have functions within it, click Delete to confirm that you want to delete the application.
      - If the application does have functions within it, you are shown a list of the functions in the application. To delete the application, enter DELETE <APPLICATION-NAME> in the text box, and click Delete.

   Note that deleting an application and all of its functions does not delete the Docker images on which the functions are based. To delete the images, you have to delete them explicitly (see Deleting and Undeleting an Image on page 5100).
6. To delete a function:
   a. Click the name of the application containing the function you want to delete.
   b. On the Application Detail page, click the name of the function you want to delete.
   c. On the Function Detail page, click Delete and confirm you want to delete the function.

   Note that deleting a function does not delete the Docker image on which the function is based. To delete the image, you have to delete it explicitly (see Deleting and Undeleting an Image on page 5100).

Using Fn Project CLI Commands

When using the Fn Project CLI to delete applications and functions, note that you cannot delete an application if it contains functions (you must delete the functions first).
To delete applications and functions in Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. To delete an application:
   a. In a terminal window, enter:

   ```
   fn delete app <app-name>
   ```

   where `<app-name>` is the name of the application to delete.
   For example:

   ```
   fn delete app acmeapp
   ```

   b. Verify that the application has been deleted by entering:

   ```
   fn list apps
   ```

3. To delete a function:
   a. In a terminal window, enter:

   ```
   fn delete function <app-name> <function-name>
   ```

   where:
   - `<app-name>` is the name of the application containing the function you want to delete.
   - `<function-name>` is the name of the function you want to delete.
   For example:

   ```
   fn delete function acmeapp acme-func
   ```

   b. Verify that the function has been deleted by entering:

   ```
   fn list functions <app-name>
   ```

   For example:

   ```
   fn list functions acmeapp
   ```

Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use these API operations to delete applications and functions:

- DeleteApplication
- DeleteFunction

Changing Default Memory and Timeout Settings

You can change several aspects of Oracle Functions default behavior using configuration parameters and environment variables.

Depending on the parameter, you can override a default value by specifying an alternative value in the following ways (note the order of precedence):

- by adding an entry to the func.yaml file (which overrides default values)
- by explicitly setting an environment variable (which overrides values set in the func.yaml file)
• by including a command option when you invoke the function using the Fn Project CLI (which overrides values set in environment variables or in the func.yaml file)

The following table indicates the parameters you can set, the default value, and where the default value can be overridden.

<table>
<thead>
<tr>
<th>Parameter Description</th>
<th>Default Value</th>
<th>Units</th>
<th>func.yaml Parameter</th>
<th>Environment Variable</th>
<th>Fn CLI option</th>
<th>Notes</th>
</tr>
</thead>
</table>
| Maximum time a function will be allowed to run | 30 | Seconds | timeout | n/a | n/a | Maximum value: 300
Best practice is to specify a timeout that is close to that likely to be required, rather than significantly more. |
| Maximum memory threshold for a function | 128 | MB | memory | FN_MEMORY | n/a | One of:
• 128
• 256
• 512
• 1024
If this limit is exceeded during execution, the function is stopped and an error message is logged. |

For more information about the above parameters, and other configuration parameters, see Func files in the Fn Project documentation.

**Scanning Function Images for Vulnerabilities**

In Oracle Functions, a function's definition specifies the Docker image to push to, and pull from, a repository in Oracle Cloud Infrastructure Registry.

You can set up Oracle Cloud Infrastructure Registry (also known as Container Registry) to scan function images when they are pushed to a function's repository. The function images are scanned for security vulnerabilities published in the publicly available Common Vulnerabilities and Exposures (CVE) database. See Scanning Images for Vulnerabilities on page 5110.

To perform function image scanning, Container Registry makes use of the Oracle Cloud Infrastructure Vulnerability Scanning service and Vulnerability Scanning REST API (see Scanning Images in the Vulnerability Scanning service documentation). Note that you must give the Vulnerability Scanning service permission to pull images from Container Registry (see Required IAM Policy for Scanning Function Images for Vulnerabilities on page 2998).

You enable function image scanning by adding an image scanner to the function's repository. From then on, any images pushed to that repository are scanned for vulnerabilities by the image scanner. If the repository already contains images, the four most recently pushed images are immediately scanned for vulnerabilities. You can disable
image scanning on a particular repository by removing the image scanner. See Using the Console to Enable and Disable Image Scanning on page 5111.

Whenever new vulnerabilities are added to the CVE database, Container Registry automatically re-scans images in repositories that have scanning enabled.

You can view the results of image scans in the Console (see Using the Console to View Results of Image Scans on page 5111). For every scanned function image, you can view:

- A summary of each scan of the image for the last 13 months, showing the number of vulnerabilities found in each scan, and a single overall risk level for each scan. Image scan results are retained for 13 months to enable you to compare the scan results over time.
- Detailed results of each image scan, to see a description of each vulnerability, along with its risk level, and (where available) a link to the CVE database for more information.

Always use the latest FDK build-time and runtime base images to reduce the number of known vulnerabilities included in an image and reported in the scan results. See How to upgrade an existing function to use the latest FDK build-time and runtime base image version for a supported language on page 3033.

Required IAM Policy for Scanning Function Images for Vulnerabilities

If you enable repositories for image scanning, you must give the Vulnerability Scanning service permission to pull images from Container Registry.

To grant this permission for all images in the entire tenancy:

```text
allow service vulnerability-scanning-service to read repos in tenancy
allow service vulnerability-scanning-service to read compartments in tenancy
```

Signing Function Images and Enforcing the Use of Signed Images from Registry

For compliance and security reasons, system administrators often want to deploy software into a production system only when they are satisfied that:

- the software comes from a trusted source
- the software has not been modified since it was published, compromising its integrity

To meet these requirements, you can sign images stored in Oracle Cloud Infrastructure Registry. Signed images provide a way to verify both the source of an image and its integrity. Oracle Cloud Infrastructure Registry enables users or systems to push images to the registry and then sign them creating an image signature. An image signature associates an image with a master encryption key obtained from Oracle Cloud Infrastructure Vault.

Users or systems pulling a signed image from Oracle Cloud Infrastructure Registry can be confident both that the source of the image is trusted, and that the image's integrity has not been compromised. For more information, see Signing Images for Security on page 5102.

To further enhance security, you can configure Oracle Functions applications to only allow the creation, updating, deployment, and invocation of functions based on images in Oracle Cloud Infrastructure Registry that have been signed by particular master encryption keys. At a high level, these are the steps to follow:

- Obtain the master encryption keys from Oracle Cloud Infrastructure Vault to use to sign the images that are pushed to, and pulled from, Oracle Cloud Infrastructure Registry when creating, updating, deploying, and invoking functions.
- Create an image signature verification policy for the application. The signature verification policy defines the master encryption key that must be used to sign images that are pushed to, and pulled from, Oracle Cloud Infrastructure Registry when creating, updating, deploying, and invoking functions in the application.
- When using the `fn deploy` command to deploy functions in an application that has a signature verification policy, specify the master encryption key from the signature verification policy in the function's `func.yaml` file. When pushing the function's image to Oracle Cloud Infrastructure Registry using the Fn Project CLI, the Fn Project CLI signs the image with the master encryption key. See Using the Fn Project CLI to Sign a Function Image for Deployment in an Application With a Signature Verification Policy on page 3001.
• When using the Console or the `fn create function` command to create a new function in an application with a signature verification policy, base the function on an existing Docker image that has been signed by a master encryption key in the policy. See Creating Functions from Existing Docker Images on page 2988. Similarly, when updating a function, always base the function on an existing image that has been signed by a master encryption key in the policy (see Updating Functions on page 2992). To find out how to sign images in Oracle Cloud Infrastructure Registry, see Signing Images for Security on page 5102.

You invoke a function in an application that has a signature verification policy in exactly the same ways as functions in other applications. When the function is invoked, Oracle Functions first verifies that the function's image in Oracle Cloud Infrastructure Registry has been signed with the encryption key specified in the application's signature verification policy. If encryption key verification is successful, Oracle Functions pulls the image from Oracle Cloud Infrastructure Registry and invokes the function. If encryption key verification is unsuccessful, the error code and message (status 502: message: FunctionImageVerificationFail: Image cannot be verified or no valid signature found) are:

• returned to the caller
• shown in the Function Errors chart on the Metrics page in the Console
• shown in the default invocation span on the Traces page in the Console (when function tracing is enabled)

Note the following:

• You can include up to five functions in an application for which you define a signature verification policy. You cannot add a sixth function to such an application. Also note that you cannot define a signature verification policy for an existing application that already contains six or more functions.

• Before creating a signature verification policy for an existing application, make sure that any existing functions in the application are based on images that have already been signed by the master encryption key that you intend to specify in the policy. Otherwise, you will not be able to create the signature verification policy.

• An image in Oracle Cloud Infrastructure Registry can be signed using multiple signatures, each associated with a different master encryption key. Provided an application's signature verification policy includes one of the master encryption keys, the application allows the image to be pulled from Oracle Cloud Infrastructure Registry.

• If you enable an application to use its signature verification policy but Oracle Functions cannot connect to Oracle Cloud Infrastructure Registry, no images can be pulled from Oracle Cloud Infrastructure Registry.

Required IAM Policies for Enforcing the Use of Signed Images

To enforce a signature verification policy, Oracle Functions must have been granted:

• access to verify master encryption keys in Oracle Cloud Infrastructure Vault with a policy like:

```plaintext
Allow service faas to {KEY_READ} in compartment <compartment-name> where request.operation = 'GetKeyVersion'
```

```plaintext
Allow service faas to {KEY_VERIFY} in compartment <compartment-name> where request.operation = 'Verify'
```

• access to images in Oracle Cloud Infrastructure Registry with a policy like:

```plaintext
Allow service faas to read repos in tenancy where request.operation='ListContainerImageSignatures'
```

To create a signature verification policy, you must have been granted:

• access to master encryption keys in Oracle Cloud Infrastructure Vault with a policy like:

```plaintext
Allow group <groupname> to read vaults in compartment <compartment-name>
```

```plaintext
Allow group <groupname> to use keys in compartment <compartment-name>
```
Functions

- access to images in Oracle Cloud Infrastructure Registry with a policy like:

  ```allow group <groupname> to read repos in tenancy```

You can restrict the master encryption keys that can be used for function image signing, and signature verification by using more restrictive policies (for example, see Policy Statements to Give the Oracle Functions Service and Oracle Functions Users Access to Oracle Vault Resources on page 3085).

**Obtaining Encryption Keys with which to Sign Function Images (if they don't exist already)**

To obtain the master encryption key to include in an application's signature verification policy, and to specify when deploying a function in the application:

1. If you don't already have access to an RSA or ECDSA asymmetric key in Oracle Cloud Infrastructure Vault, either obtain access to an existing RSA or ECDSA asymmetric key or create a new master encryption key as an RSA or ECDSA asymmetric key (see To create a new master encryption key on page 5694).

   Note that the use of AES symmetric keys to sign images is not supported. For more information about different key types, see Overview of Vault on page 5682.

2. Make a note of both the OCID of the master encryption key and the OCID of the key version stored in Oracle Cloud Infrastructure Vault. See To view key details on page 5694.

   You use these OCIDs when deploying the function.

**Creating a Signature Verification Policy for an Application**

To define a signature verification policy for an application and specify a master encryption key that can be used to sign images:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
4. Select the compartment containing the application for which you want to define a signature verification policy.

   The Applications page shows all the applications in the compartment you selected.
5. Click the name of the application for which you want to define a signature verification policy.
6. Under Resources, click Signature Verification.
7. Click Manage Signature Verification.
8. Select Enable signature verification policies for this application to enable the application to use the signature verification policy you define.

   If a policy to grant Oracle Functions access to Oracle Cloud Infrastructure Registry does not already exist, you are prompted to create such a policy. If you're an administrator, create the policy. Otherwise, ask your administrator to create the policy for you. See Required IAM Policies for Enforcing the Use of Signed Images on page 2999.
9. Select a master encryption key in Oracle Cloud Infrastructure Vault that must have been used to sign images.

   If policies to grant Oracle Functions access to the master encryption key in Oracle Cloud Infrastructure Vault do not already exist, you are prompted to create such policies. If you're an administrator, create the policies. Otherwise, ask your administrator to create the policies for you. See Required IAM Policies for Enforcing the Use of Signed Images on page 2999.

   Note that any existing functions in the application must be based on images that have already been signed by the master encryption key that you select. Otherwise, you will not be able to create the signature verification policy.
10. Click Save Changes.

From now on:

- When you deploy a function in this application (for example, using the fn deploy command), you have to set image signing options. These options identify the master encryption key in the application's signature verification
policy, including the OCID of the master encryption key. Assuming you specify a valid master encryption key, the image is pushed to Oracle Cloud Infrastructure Registry and signed with the encryption key.

- When you create a new function (or update an existing function) in this application using the Console or the Fn Project CLI, you have to specify an existing image that has been signed using the master encryption key in the application's signature verification policy.
- When a function in this application is invoked, Oracle Functions first verifies the image in Oracle Cloud Infrastructure Registry. Oracle Functions only pulls the image from Oracle Cloud Infrastructure Registry and invokes the function if encryption key verification is successful.

**Using the Fn Project CLI to Sign a Function Image for Deployment in an Application With a Signature Verification Policy**

You can use the Fn Project CLI command `fn deploy` command to deploy a function in an application that has a signature verification policy, by specifying the master encryption key from the signature verification policy in the function's `func.yaml` file. The function image is then signed during deployment.

To use the Fn Project CLI to deploy a function based on a signed function image in an application that has an enabled signature verification policy:

1. Follow the steps in Creating and Deploying Functions on page 2985 to create a function using the `fn init` command, but do not immediately use the `fn -v deploy` command. Instead, follow the instructions below to first add image signing details to the function's `func.yaml` file, and then use the `fn -v deploy` command.
2. Having used the `fn init` command to initialize the function, change directory to the newly created directory containing the function's `func.yaml` file.
3. Edit the function's `func.yaml` file and add the following section:

   ```yaml
   signing_details:
     image_compartment_id: <root-compartment-ocid>
     kms_key_id: <key-ocid>
     kms_key_version_id: <key-version-ocid>
     signing_algorithm: <signing-algorithm>
   ```

   where:

   - `image_compartment_id: <root-compartment-ocid>` is the OCID of the tenancy's root compartment that owns the repository in Oracle Cloud Infrastructure Registry to which you are going to push the function image. For example, `image_compartment_id: ocid1.tenancy.oc1..aaaaaaaa___ta`.
   - `kms-key-id: <key-ocid>` is the OCID of the master encryption key to use to sign the image. Since you will be deploying a function based on this image in an application with an enabled signature verification policy, you must specify the OCID of a master encryption key that is included in the signature verification
policy (see Creating a Signature Verification Policy for an Application on page 3000). For example, kms-key-id: ocid1.key.oc1.phx.bbqehaq3aadfa.abyh______qlj

- kms-key-version-id: <key-version-ocid> is the OCID of the key version to use to sign the image. For example, kms-key-version-id: ocid1.keyversion.oc1.phx.0.bbqehaq3aadfa.acy6______mbb
- signing-algorithm: <signing-algorithm> is one of the following algorithms to use to sign the image:
  - SHA_224_RSA_PKCS_PSS
  - SHA_256_RSA_PKCS_PSS
  - SHA_384_RSA_PKCS_PSS
  - SHA_512_RSA_PKCS_PSS
  - SHA_224_RSA_PKCS1_V1_5
  - SHA_256_RSA_PKCS1_V1_5
  - SHA_384_RSA_PKCS1_V1_5
  - SHA_512_RSA_PKCS1_V1_5
  - ECDSA_SHA_256
  - ECDSA_SHA_384
  - ECDSA_SHA_512

The algorithm to choose depends on the type of the master encryption key. For RSA keys, supported signature schemes include PKCS #1 and RSASSA-PSS, along with different hashing algorithms. For ECDSA keys, ECDSA is the supported signature scheme with different hashing algorithms. For the latest list of supported algorithms, see Sign and the SignDataDetails resource in the Vault API documentation.

For example, signing-algorithm: SHA_224_RSA_PKCS_PSS

For example:

```yaml
schema_version: 20180708
name: hello-java
version: 0.0.1
runtime: java
build_image: fnproject/fn-java-fdk-build:jdk11-1.0.141
run_image: fnproject/fn-java-fdk:jre11-1.0.141
cmd: com.example.fn.HelloFunction::handleRequest
signing_details:
  image_compartment_id: ocid1.tenancy.oc1..aaaaaaaa___ta
  kms_key_id: ocid1.key.oc1.phx.bbqehaq3aadfa.abyh______qlj
  kms_key_version_id: ocid1.keyversion.oc1.phx.0.bbqehaq3aadfa.acy6______mbb
  signing_algorithm: SHA_224_RSA_PKCS_PSS
```

4. In the directory containing the function's func.yaml file, enter the following single Fn Project command to build and deploy the function and its dependencies as a signed Docker image:

```bash
fn -v deploy --app <app-name>
```

where <app-name> is the name of an application with an enabled image verification policy.

The image is built, pushed to the specified Docker registry, and signed with the master encryption key and key version specified in the func.yaml file. The function based on the signed image is successfully deployed to Oracle Functions in the application with the enabled image verification policy that you specified in the command.

**Using the OCI CLI to Sign a Function Image for Deployment in an Application With a Signature Verification Policy**

You can use the OCI CLI command `oci artifacts container image-signature sign-upload` to sign a function image after you have used the Fn Project CLI command `fn push` to push the image to Oracle.
Cloud Infrastructure Registry. You can then use the OCI CLI commands `oci fn function create` and `oci fn function update` to deploy a function based on the signed image in an application that has a signature verification policy.

To use the OCI CLI to deploy a function based on a signed function image in an application that has an enabled signature verification policy:

1. Follow the steps in Creating and Deploying Functions on page 2985 to create a function, but do not use the `fn -v deploy` command. Instead of using `fn -v deploy`, follow the numbered steps below to:
   - use the `fn -v build` command to build the function and its dependencies as a Docker image
   - use the `fn -v push` command to tag and push the image to Container Registry
   - use the `oci artifacts container image-signature sign-upload` command to sign the image
   - use the `oci fn function create` command to create a function based on the signed image (or use the `oci fn function update` command to base an existing function on the signed image)

2. Build the function and its dependencies as a Docker image using the `fn -v build` command. For example:

```
fn -v build
```

3. Make a note of the image name shown in the output from the previous command.
   For example, the image name might be `phx.ocir.io/ansh81vru1zp/helloworld/helloworld-func:0.0.1`

4. Push the image to Container Registry using the `fn -v push` command. For example:

```
fn -v push
```

5. Obtain the OCID of the image, either using the Console (see Viewing Images and Image Details on page 5099), or using the CLI (use the `oci artifacts container image list --compartment-id <compartment-ocid> --repository-name <repository-name>` command).

6. Sign the image you pushed to Container Registry using the master key and key version in the Vault service, creating an image signature, by entering:

```
oci artifacts container image-signature sign-upload --compartment-id <compartment-ocid> --kms-key-id <key-ocid> --kms-key-version-id <key-version-ocid> --signing-algorithm <signing-algorithm> --image-id <image-ocid> --description <signature-description>
```

where:

- `--compartment-id <compartment-ocid>` is the OCID of the compartment to which the image's repository belongs. For example, `--compartment-id ocid1.compartment.oc1..aaaaaaaa23_____smwa`
- `--kms-key-id <key-ocid>` is the OCID of the master encryption key to use to sign the image. Since you will be creating a function based on this image in an application with an enabled signature verification policy, you must specify the OCID of a master encryption key that is included in the signature verification policy.
Functions

policy (see Creating a Signature Verification Policy for an Application on page 3000). For example, --
kms-key-id ocid1.key.oc1.phx.bbqehaq3aadfa.abyh______qlj

• --kms-key-version-id <key-version-ocid> is the OCID of the
  key version to use to sign the image. For example, --kms-key-version-id
  ocid1.keyversion.oc1.phx.0.bbqehaq3aadfa.acy6______mbb

• --signing-algorithm <signing-algorithm> is one of the following algorithms to use to sign the
  image:

  • SHA_224_RSA_PKCS_PSS
  • SHA_256_RSA_PKCS_PSS
  • SHA_384_RSA_PKCS_PSS
  • SHA_512_RSA_PKCS_PSS
  • SHA_224_RSA_PKCS1_V1_5
  • SHA_256_RSA_PKCS1_V1_5
  • SHA_384_RSA_PKCS1_V1_5
  • SHA_512_RSA_PKCS1_V1_5
  • ECDSA_SHA_256
  • ECDSA_SHA_384
  • ECDSA_SHA_512

The algorithm to choose depends on the type of the master encryption key. For RSA keys, supported signature
schemes include PKCS #1 and RSASSA-PSS, along with different hashing algorithms. For ECDSA keys,
ECDSA is the supported signature scheme with different hashing algorithms. For the latest list of supported
algorithms, see Sign and the SignDataDetails resource in the Vault API documentation.

For example, --signing-algorithm SHA_224_RSA_PKCS_PSS

• --image-id <image-ocid> is the OCID of the image to sign. For example, --image-id
  ocid1.containerimage.oc1.phx.0.ansh81vru1zp.aaaaaaaalqzj______yks

• --description <signature-description> is optional text of your choice to describe the
  image. The description is included as part of the signature, and is shown in the Console. For example, --
  description "Image for UAT testing"

For example:

oci artifacts container image-signature sign-upload --compartment-
id ocid1.compartment.oc1..aaaaaaaa23______smwa --kms-key-id
ocid1.key.oc1.phx.bbqehaq3aadfa.abyh______qlj --kms-key-version-
id ocid1.keyversion.oc1.phx.0.bbqehaq3aadfa.acy6______mbb
--signing-algorithm SHA_224_RSA_PKCS_PSS --image-id
ocid1.containerimage.oc1.phx.0.ansh81vru1zp.aaaaaaaalqzj______yks --
description "Image for UAT testing"

The function image is now signed with the same master encryption key that is specified in the application's
signature verification policy.
7. If you want to create a new function based on the signed image, enter:

```bash
oci fn function create --application-id <app-ocid> --display-name <function-name> --image <image-name> --memory-in-mbs <memory>
```

where:

- `<app-ocid>` is the OCID of the application with the enabled signature verification policy, in which to create the new function.
- `<function-name>` is the name of the new function you want to create. Avoid entering confidential information.
- `<image-name>` is the name of the signed image in the Docker registry on which to base the new function.
- `<memory>` is the maximum usable memory for the new function

For example:

```bash
oci fn function create --application-id ocid1.fnapp.oc1.phx.aaaaaaaaaf______r3ca --display-name helloworld-func --image phx.ocir.io/ansh81vruizp/helloworld/helloworld-func:0.0.1 --memory-in-mbs 128
```

A new function is successfully created in the application that has the signature verification policy. The function is based on the signed image and with the name you specified.

8. If you want to update an existing function so that the function is based on the signed image, update the existing function by entering:

```bash
oci fn function update --function-id <function-ocid> --image <image-name>
```

where:

- `<function-ocid>` is the OCID of the existing function you want to update.
- `<image-name>` is the name of the signed image in the Docker registry on which to base the function.

For example:

```bash
oci fn function update --function-id ocid1.fnfunc.oc1.phx.aaaa____uxoa --image phx.ocir.io/ansh81vruizp/helloworld/helloworld-func:0.0.1
```

### Invoking Functions

Read about how to invoke functions with Oracle Functions:

- [Invoking Functions](#) on page 3005
- [Invoking Oracle Functions from Other Oracle Cloud Infrastructure Services](#) on page 3009

### Invoking Functions

You can invoke a function that you’ve deployed to Oracle Functions in different ways:

- Using the Fn Project CLI.
- Using the Oracle Cloud Infrastructure CLI.
- Using the Oracle Cloud Infrastructure SDKs.
- Making a signed HTTP request to the function's invoke endpoint. Every function has an invoke endpoint.

Each of the above invokes the function via requests to the API. Any request to the API must be authenticated by including a signature and the OCID of the compartment to which the function belongs in the request header. Such a request is referred to as a 'signed' request. The signature includes Oracle Cloud Infrastructure credentials in an encrypted form.
If you use the Fn Project CLI or the Oracle Cloud Infrastructure CLI to invoke a function, authentication is handled for you. See Using the Fn Project CLI to Invoke Functions on page 3006 and Using the Oracle Cloud Infrastructure CLI to Invoke Functions on page 3007.

If you use an Oracle Cloud Infrastructure SDK to invoke a function, you can use the SDK to handle authentication. See Using SDKs to Invoke Functions on page 3007.

If you make a signed HTTP request to a function's invoke endpoint, you'll have to handle authentication yourself by including a signature and the OCID of the compartment to which the function belongs in the request header. You can do this in different ways:

- Using the Oracle Cloud Infrastructure CLI raw-request command. See Sending a Signed Request to a Function's Invoke Endpoint (using the Oracle Cloud Infrastructure CLI raw-request command) on page 3008.
- Writing code to programmatically sign requests. For information about the required credentials and how to sign the requests, see Request Signatures on page 6359.

Tip:
If you aren't able to successfully complete one of the steps in this topic, review the solutions for common problems (see Troubleshooting Oracle Functions on page 3067).

Using the Fn Project CLI to Invoke Functions

To invoke a function deployed to Oracle Functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, enter:

   ```bash
   fn invoke <app-name> <function-name>
   ```

   where:
   - `<app-name>` is the name of the application containing the function you want to invoke
   - `<function-name>` is the name of the function you want to invoke

   For example:

   ```bash
   fn invoke helloworld-app helloworld-func
   ```

   Output:

   ```
   Hello World!
   ```

   Tip:
   If you want to pass arguments and values to a function, prefix the `fn invoke` command with `echo -n '\n<argument>=<value>' |`
   
   If the function is expecting the argument and value as JSON, use a valid JSON format. For example:

   ```bash
   echo -n '\n{"name":"John"}' | fn invoke helloworld-app helloworld-func
   ```

   Output:

   ```
   Hello John!
   ```
Using the Oracle Cloud Infrastructure CLI to Invoke Functions

If you have installed the Oracle Cloud Infrastructure CLI, you can use it to send API requests to invoke functions. Among other things, the Oracle Cloud Infrastructure CLI will facilitate Oracle Cloud Infrastructure authentication. For information about using the Oracle Cloud Infrastructure CLI, see Command Line Interface (CLI) on page 6117.

These instructions assume:

- you have already installed and configured the Oracle Cloud Infrastructure CLI
- you want to invoke a function as the functions developer that's configured for your development environment

To invoke a function using the Oracle Cloud Infrastructure CLI:

1. Log in to your development environment as a functions developer.
2. In a terminal window, enter:

   ```
   oci fn function invoke <function-ocid> --file "<output-filepath>" --body "<request-parameters>
   ```

   where:

- `<function-ocid>` is the OCID of the function you want to invoke. To find out a function's OCID, use the `fn inspect` command to see the value of the function's `id` property (see Viewing Functions and Applications on page 2990).
- `<output-filepath>` is the path and name of a file to write the response to. To write the response to stdout, specify `--file "-"`
- `<request-parameters>` are optionally arguments and values to pass to the function. If the function is expecting arguments and values as JSON, use a valid JSON format. For example, `--body '{"name":"John"}'`. Note that you must include `--body ""` in the request, even if there are no request parameters to pass.

For example:

- 

   ```
   oci fn function invoke --function-id ocid1.fnfunc.oc1.phx.aaaa___uxoa --file "-" --body ""
   ```

   Output:

   ```
   Hello World !
   ```

- 

   ```
   oci fn function invoke --function-id ocid1.fnfunc.oc1.phx.aaaa___uxoa --file "-" --body '{"name":"John"}'
   ```

   Output:

   ```
   Hello John !
   ```

Using SDKs to Invoke Functions

If you're writing a program to invoke a function in a language for which an Oracle Cloud Infrastructure SDK exists, Oracle recommends you use that SDK to send API requests to invoke the function. Among other things, the SDK will facilitate Oracle Cloud Infrastructure authentication.

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use the `InvokeFunction` API operation to invoke functions.

Obtaining a Function's Invoke Endpoint

When invoking a function using the Oracle Cloud Infrastructure CLI `raw-request` command, you have to specify the function's invoke endpoint.
To obtain a function's invoke endpoint:

1. Log in to your development environment as a functions developer.
2. In a terminal window, enter:

   ```
   fn inspect function <app-name> <function-name>
   ```

   where:
   - `<app-name>` is the name of the application containing the function for which you want to obtain the invoke endpoint
   - `<function-name>` is the name of the function for which you want to obtain the invoke endpoint

   For example:

   ```
   fn inspect function helloworld-app helloworld-func
   ```

   Output:

   ```
   {
   "annotations": {
   "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke",
   ...
   }
   }
   ```

   The function's invoke endpoint is the value of "fnproject.io/fn/invokeEndpoint". For example, "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke" (abbreviated for readability).

**Sending a Signed Request to a Function's Invoke Endpoint (using the Oracle Cloud Infrastructure CLI raw-request command)**

If you have installed the Oracle Cloud Infrastructure CLI, you can use it to send API requests to invoke functions. Among other things, the CLI will facilitate Oracle Cloud Infrastructure authentication. For more information about using the Oracle Cloud Infrastructure CLI, see Command Line Interface (CLI) on page 6117.

These instructions assume:

- you have already installed and configured the Oracle Cloud Infrastructure CLI
- you want to invoke a function as the functions developer that's configured for your development environment

To invoke a function deployed to Oracle Functions by sending a signed request to the function's invoke endpoint using the Oracle Cloud Infrastructure CLI `raw-request` command:

1. Log in to your development environment as a functions developer.
2. Obtain the function's invoke endpoint (see Obtaining a Function's Invoke Endpoint on page 3007).

   For example, "fnproject.io/fn/invokeEndpoint": "https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa____uxoa/actions/invoke" (abbreviated for readability).
3. Use the Oracle Cloud Infrastructure CLI `raw-request` command to invoke the function by sending a signed POST request to the function's invoke endpoint by entering:

```
oci raw-request --http-method POST --target-uri <invoke-endpoint> --request-body "<request-parameters>"
```

where:

- `<invoke-endpoint>` is the endpoint you obtained in the earlier step.
- `<request-parameters>` are optionally arguments and values to pass to the function. If the function is expecting arguments and values as JSON, use a valid JSON format. Note that you must include `--request-body ""` in the request, even if there are no request parameters to pass.

For example:

Output:

```
Hello World !
```

Output:

```
Hello John !
```

4. If a passphrase was provided to encrypt the API signing key, enter the passphrase when prompted.

**Invoking Oracle Functions from Other Oracle Cloud Infrastructure Services**

You can invoke functions in Oracle Functions from other Oracle Cloud Infrastructure services. Typically, you'll want an event in another service to trigger a request to invoke a function defined in Oracle Functions.

This functionality is currently available in:

- The Events service. For more information, see Functions on page 2776 in Services that Produce Events on page 2705.
- The Notifications service. For more information, see Notifications on page 4900. For a scenario, see Scenario A: Automatically Resize VMs on page 4917.
- The API Gateway service. For more information, see Adding a Function in Oracle Functions as an API Gateway Back End on page 529.
- The Oracle Integration service, using the OCI Signature Version 1 security policy. For more information, see Configure Oracle Integration to Call Oracle Cloud Infrastructure Functions with the REST Adapter in Using the REST Adapter with Oracle Integration.
- The Service Connector Hub service. You can invoke a function to process data (as the task in a service connector), or to act on the processed data (as the target in a service connector). For more information, see Service Connector Hub on page 5426. For a scenario, see Scenario: Send Log Data to an Autonomous Database on page 5447.
- The Streaming service (via Service Connector Hub). You can synchronously invoke a function to consume and process data from partitions in a stream (as the task in a service connector). For more information, see Streaming on page 5534 and Service Connector Hub on page 5426.
Integrating Functions

Read about how to integrate Oracle Functions with other systems:

- Integrating Oracle Functions with Other Oracle Products on page 3010
- Accessing File Systems from Running Functions on page 3015
- Passing Custom Configuration Parameters to Functions on page 3016

Integrating Oracle Functions with Other Oracle Products

You can integrate functions you've deployed to Oracle Functions with other Oracle products, as described in the following topics:

- Accessing Other Oracle Cloud Infrastructure Resources from Running Functions on page 3010
- Connecting to Oracle Autonomous Database Instances from Running Functions on page 3015

Accessing Other Oracle Cloud Infrastructure Resources from Running Functions

When a function you've deployed to Oracle Functions is running, it can access other Oracle Cloud Infrastructure resources. For example:

- You might want a function to get a list of VCNs from the Networking service.
- You might want a function to read data from an Object Storage bucket, perform some operation on the data, and then write the modified data back to the Object Storage bucket.

To enable a function to access another Oracle Cloud Infrastructure resource, you have to include the function in a dynamic group, and then create a policy to grant the dynamic group access to that resource. For more information about dynamic groups, including the permissions required to create them, see Managing Dynamic Groups.

Having set up the policy and the dynamic group, you can then include a call to a 'resource principal provider' in your function code. The resource principal provider uses a resource provider session token (RPST) that enables the function to authenticate itself with other Oracle Cloud Infrastructure services. The token is only valid for the resources to which the dynamic group has been granted access.

Note also that the token is cached for 15 minutes. So if you change the policy or the dynamic group, you will have to wait for 15 minutes to see the effect of your changes.

Oracle recommends that you use the resource principal provider included in the Oracle Cloud Infrastructure SDK. However, you might be writing a function in a language that the Oracle Cloud Infrastructure SDK does not support. Or you might simply not want to use the Oracle Cloud Infrastructure SDK. In either case, you can write your own custom resource principal provider to enable a function to authenticate itself with other Oracle Cloud Infrastructure services, using files and environment variables in the container in which the function is executing.

Using the Console

To enable a running function to access other Oracle Cloud Infrastructure resources:
1. Log in to the Console and create a new dynamic group:
   a. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Dynamic Groups**.
   b. Follow the instructions in To create a dynamic group, and give the dynamic group a name (for example, `acme-func-dyn-grp`).
   c. When specifying a rule for the dynamic group, consider the following examples:
      - If you want all functions in a compartment to be able to access a resource, enter a rule similar to the following that adds all functions in the compartment with the specified compartment OCID to the dynamic group:
        ```
        ALL {resource.type = 'fnfunc', resource.compartment.id = 'ocid1.compartment.oc1..aaaaaaaa23________smwa'}
        ```
      - If you want a specific function to be able to access a resource, enter a rule similar to the following that adds the function with the specified OCID to the dynamic group:
        ```
        resource.id = 'ocid1.fnfunc.oc1.iad.aaaaaaaaacq________dnya'
        ```
      - If you want all functions with a specific defined tag to be able to access a resource, enter a rule similar to the following that adds all functions with the defined tag to the dynamic group:
        ```
        ALL {resource.type = 'fnfunc', tag.department.operations.value = '45'}
        ```
      
      Note that free-form tags are not supported. For more information about tagging, see Resource Tags on page 243.
   d. Click **Create Dynamic Group**.

   Having created a dynamic group that includes the function, you can now create a policy to give the dynamic group access to the required Oracle Cloud Infrastructure resource.

2. Create a new policy:
   a. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Policies**.
   b. Follow the instructions in To create a policy, and give the policy a name (for example, `acme-func-dyn-grp-policy`).
   c. When specifying a policy statement, consider the following examples:
      - If you want functions in the `acme-func-dyn-grp` to be able to get a list of all the VCNs in the tenancy, enter a rule similar to the following:
        ```
        allow dynamic-group acme-func-dyn-grp to inspect vcns in tenancy
        ```
      - If you want functions in the `acme-func-dyn-grp` to be able to read and write to a particular Object Storage bucket, enter a rule similar to the following:
        ```
        allow dynamic-group acme-func-dyn-grp to manage objects
        in compartment acme-storage-compartment where all
        {target.bucket.name='acme-functions-bucket'}
        ```
      - If you want functions in the `acme-func-dyn-grp` to be able to read and write to all resources in a compartment, enter a rule similar to the following:
        ```
        allow dynamic-group acme-func-dyn-grp to manage all-resources in
        compartment acme-storage-compartment
        ```
   d. Click **Create** to create the new policy.
Functions

3. Include a resource principal provider in the function code to enable the function to authenticate with other Oracle
Cloud Infrastructure services. See:
•
•

Example: Adding the Oracle Resource Principal Provider to a Python Function to Get a List of VCNs from the
Networking Service on page 3012
Example: Adding a Custom Resource Principal Provider to a Function on page 3012

Example: Adding the Oracle Resource Principal Provider to a Python Function to Get a List of VCNs from
the Networking Service
Having added a function to a dynamic group, and created a policy that allows the dynamic group to list the VCNs
in the tenancy, you could include code similar to the following example to get a list of VCNs from the Networking
service. This example uses the Oracle resource principal provider to extract credentials from the RPST token.
import io
import json
from fdk import response
import oci
def handler(ctx, data: io.BytesIO=None):
signer = oci.auth.signers.get_resource_principals_signer()
resp = do(signer)
return response.Response(ctx,
response_data=json.dumps(resp),
headers={"Content-Type": "application/json"} )
def do(signer):
# List VCNs -------------------------------------------------------client = oci.core.VirtualNetworkClient({}, signer=signer)
try:
vcns = client.list_vcns(signer.compartment_id)
vcns = [[v.id, v.display_name] for v in vcns.data]
except Exception as e:
vcns = str(e)
return {"vcns": vcns, }
Example: Adding a Custom Resource Principal Provider to a Function
Oracle recommends that you use the resource principal provider included in the Oracle Cloud Infrastructure SDK.
However, you might be writing a function in a language that the Oracle Cloud Infrastructure SDK does not support.
Or you might simply not want to use the Oracle Cloud Infrastructure SDK. In either case, you can write your own
custom resource principal provider to enable a function to authenticate itself with other Oracle Cloud Infrastructure
services, using files and environment variables in the container in which the function is executing.
The container in which a function executes includes a directory tree that holds Oracle Cloud Infrastructure compatible
credentials, specifically:
•
•

A resource principal session token (RPST) in a file named rpst. The RPST token is formatted as a JWT token, and
includes claims that identify the function's host tenancy and compartment.
A private key for use in making requests to Oracle Cloud Infrastructure services on behalf of the function, in a file
named private.pem.

The following environment variables are set inside the container in which the function executes:
•
•
•
•

OCI_RESOURCE_PRINCIPAL_VERSION, containing the value 2.2.
OCI_RESOURCE_PRINCIPAL_RPST, containing the absolute path to the rpst file (including the filename).
OCI_RESOURCE_PRINCIPAL_PRIVATE_PEM, containing the absolute path to the private.pem file
(including the filename).
OCI_RESOURCE_PRINCIPAL_REGION, containing the region identifier in which the function is deployed (for
example, us-phoenix-1).

Oracle Cloud Infrastructure User Guide

3012


To enable a function to access another Oracle Cloud Infrastructure service, add code to the function so that it can authenticate itself with the other resource:

1. Add code that loads the RPST token from the path in the OCI RESOURCE PRINCIPAL RPST environment variable.
2. Add code that loads the private key from the path in the OCI RESOURCE PRINCIPAL PRIVATE PEM environment variable.
3. Add code that uses the RPST token and the private key to create an Oracle Cloud Infrastructure request signature (see Request Signatures on page 6359).
4. Add code that constructs the request to the other Oracle Cloud Infrastructure resource.

If necessary, you can identify:

- The endpoints of other Oracle Cloud Infrastructure services in the same (local) region as the function, using the region identifier in the OCI RESOURCE PRINCIPAL REGION environment variable.
- The function's host tenancy and compartment, using the res_tenant and res_compartment claims in the RPST token.

For example, the sample Python function below includes a custom resource principal provider that extracts credentials from the RPST token. It then submits a GET request to the IAM API's getTenancy operation to return the OCID of the function's tenancy.

```python
#!/usr/bin/env python3
import base64
import email.utils
import hashlib
import httpsig_cffi.sign
import json
import logging
import os.path
import re
import requests.auth
import urllib.parse

LOG = logging.getLogger(__name__)

# The following class is derived from the Python section in https://docs.cloud.oracle.com/iaas/Content/API/Concepts/signingrequests.htm

class SignedRequestAuth(requests.auth.AuthBase):
    """A requests auth instance that can be reused across requests""
    generic_headers = [
        "date",
        "(request-target)",
        "host"
    ]
    body_headers = [
        "content-length",
        "content-type",
        "x-content-sha256",
    ]
    required_headers = {
        "get": generic_headers,
        "head": generic_headers,
        "delete": generic_headers,
        "put": generic_headers + body_headers,
        "post": generic_headers + body_headers,
    }
```
```python
def __init__(self, key_id, private_key):
    # Build a httpsig_cffi.requests_auth.HTTPSignatureAuth for each
    # HTTP method's required headers
    self.signers = {}
    for method, headers in self.required_headers.items():
        signer = httpsig_cffi.sign.HeaderSigner(
            key_id=key_id, secret=private_key,
            algorithm="rsa-sha256", headers=headers[:])
        use_host = "host" in headers
        self.signers[method] = (signer, use_host)

def inject_missing_headers(self, request, sign_body):
    # Inject date, content-type, and host if missing
    request.headers.setdefault("date", email.utils.formatdate(usegmt=True))
    request.headers.setdefault("content-type", "application/json")
    request.headers.setdefault("host", urllib.parse.urlparse(request.url).netloc)

    # Requests with a body need to send content-type,
    # content-length, and x-content-sha256
    if sign_body:
        body = request.body or ""
        if "x-content-sha256" not in request.headers:
            m = hashlib.sha256(body.encode("utf-8"))
            base64digest = base64.b64encode(m.digest())
            base64string = base64digest.decode("utf-8")
            request.headers["x-content-sha256"] = base64string
        request.headers.setdefault("content-length", len(body))

    def __call__(self, request):
        verb = request.method.lower()
        # nothing to sign for options
        if verb == "options":
            return request
        signer, use_host = self.signers.get(verb, (None, None))
        if signer is None:
            raise ValueError("Don't know how to sign request verb {}".format(verb))

        # Inject body headers for put/post requests, date for all requests
        sign_body = verb in ["put", "post"]
        self.inject_missing_headers(request, sign_body=sign_body)

        use_host:
            host = urllib.parse.urlparse(request.url).netloc
        else:
            host = None

        signed_headers = signer.sign(
            request.headers, host=host,
            method=request.method, path=request.path_url)
        request.headers.update(signed_headers)
        return request

def rp_auther():
    if os.environ['OCI_RESOURCE_PRINCIPAL_VERSION'] != "2.2":
        raise EnvironmentError("{} must be set to the value "2.2".format('OCI_RESOURCE_PRINCIPAL_VERSION'))
    rpst = os.environ['OCI_RESOURCE_PRINCIPAL_RPST']
    if os.path.isabs(rpst):
        with open(rpst) as f:
            rpst = f.read()```
private_key = os.environ['OCI_RESOURCE_PRINCIPAL_PRIVATE_PEM']
if os.path.isabs(private_key):
    with open(private_key) as f:
        private_key = f.read()
return get_claims(rpst), SignedRequestAuth('ST${}'.format(rpst),
private_key)

def get_claims(rpst):
    """Parse an RPST as a JWT; return a dictionary of claims
    The claims that are important are: sub, res_compartment, and res_tenant. These carry the resource OCID together with its location.
    """
    s = rpst.split('.')[1]
    s += '=' * ((4 - len(s) % 4) % 4)  # Pad to a multiple of 4 characters
    return json.loads(base64.b64decode(s).decode('utf-8'))

# Use RP credentials to make a request
region = os.environ['OCI_RESOURCE_PRINCIPAL_REGION']
claims, rp_auth = rp_auther()
response = requests.get("https://identity.{}.oraclecloud.com/20160918/
tenancies/{}").format(region, claims['res_tenant']), auth=rp_auth)
print(response.json())

Connecting to Oracle Autonomous Database Instances from Running Functions
You can deploy a function to Oracle Functions that connects to Oracle Autonomous Database instances.

Note that an Oracle Autonomous Database instance can be protected by an access control list (ACL). If the ACL is enabled, only those IP addresses and VCNs explicitly added to the ACL are allowed to connect to the database.

If you want a function running in a private subnet to connect to an Oracle Autonomous Database instance that has ACL enabled, edit the database's access control list and add the VCN.

If you want a function running in a public subnet to connect to an Oracle Autonomous Database instance that has ACL enabled:

1. Remove the default route rule that routes all outgoing internet traffic through the VCN's internet gateway.
2. Add a NAT gateway to the VCN.
3. Configure the subnet's route table with a rule that sends all outgoing internet traffic to the NAT gateway, and configure the subnet's security lists to allow internet traffic.
4. Review the NAT gateway's properties to obtain its public IP address.
5. Edit the database's access control list and add the NAT gateway's public IP address.

For more information about Oracle Autonomous Databases and ACLs, see Access Control Lists (ACLs) for Databases on Shared Exadata Infrastructure on page 1881.

Accessing File Systems from Running Functions
A function you've deployed to Oracle Functions can access the file system of the container in which it's running as follows:

- the function can read files from all directories
- the function can write files to the /tmp directory

For example, you might want a function to download an Excel file and then read its contents. To meet this requirement, you might create a function that writes the file to the /tmp directory in the container's filesystem, and then subsequently reads the file.
When writing files to the /tmp directory, the /tmp directory is generally always writable. However, the maximum allowable size of the /tmp directory depends on the maximum memory threshold specified for the function:

<table>
<thead>
<tr>
<th>Maximum memory threshold for the function (MB)</th>
<th>Maximum allowed size of /tmp (MB)</th>
<th>Maximum allowed number of files (inodes) in /tmp</th>
</tr>
</thead>
<tbody>
<tr>
<td>128MB</td>
<td>32MB</td>
<td>1024</td>
</tr>
<tr>
<td>256MB</td>
<td>64MB</td>
<td>2048</td>
</tr>
<tr>
<td>512MB</td>
<td>128MB</td>
<td>4096</td>
</tr>
<tr>
<td>1024MB</td>
<td>256MB</td>
<td>8192</td>
</tr>
</tbody>
</table>

Note that the /tmp directory might be shared by successive invocations of the function. A file written by an earlier invocation of a function could still exist when the function is invoked a second time. It is your responsibility to delete any files to avoid unexpected behavior.

### Passing Custom Configuration Parameters to Functions

The code in functions you deploy to Oracle Functions will typically require values for different parameters. Some pre-defined parameters are available to your functions as environment variables. But you'll often want your functions to use parameters that you've defined yourself. For example, you might create a function that reads from and writes to a database. The function will require a database connect string, comprising a username, password, and hostname. You'll probably want to define username, password, and hostname as parameters that are passed to the function when it's invoked.

To pass user-defined parameters to a function deployed in Oracle Functions, you create key-value pairs known as custom configuration parameters. You can create custom configuration parameters that are:

- application-wide, meaning they are passed to every function in an application
- function-specific, meaning they are passed to the particular function for which they are defined (function-specific parameters override application-wide parameters with the same name)

To create custom configuration parameters, you can use:

- the `config:` section of a function's `func.yaml` file, to define function-specific custom configuration parameters
- the Console and the Fn Project CLI, to define both application-wide and function-specific custom configuration parameters

Oracle Functions combines all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb.

### Using the Console

To specify custom configuration parameters to pass to functions using the Console:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click **Developer Services**. Under **Functions**, click **Applications**.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
4. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).

   The **Applications** page shows the applications defined in the compartment.
5. Click the name of the application containing functions to which you want to pass custom configuration parameters:
   - To pass one or more custom configuration parameters to every function in the application, click Configuration to see the Configuration section for the application.
   - To pass one or more custom configuration parameters to a particular function, click the function's name to see the Configuration section for the function.

6. In the Configuration section, specify details for the first custom configuration parameter:
   - **Key**: The name of the custom configuration parameter. The name must only contain alphanumeric characters and underscores, and must not start with a number. For example, `username`
   - **Value**: A value for the custom configuration parameter. The value must only contain printable unicode characters. For example, `jdoe`

7. Click the plus button to save the new custom configuration parameter.

Oracle Functions combines the key-value pairs for all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb. You cannot save the new custom configuration parameter if the size of the serially-encoded configuration object would be greater than 4Kb.

8. (Optional) Enter additional custom configuration parameters as required.

Using Fn Project CLI Commands

To specify custom configuration parameters to pass to functions using the Fn Project CLI:

1. Log in to your development environment as a functions developer and open a terminal window.
2. To specify one or more custom configuration parameters to pass to every function in an existing application, enter:

   ```
   fn config app <app-name> <key> <value>
   ```

   where:
   - `<app-name>` is the name of the application containing the functions to which you want to pass the custom configuration parameter.
   - `<key>` is the name of the custom configuration parameter. The name must only contain alphanumeric characters and underscores, and must not start with a number.
   - `<value>` is the value to give to the custom configuration parameter. The value must only contain printable unicode characters.

   For example:
   ```
   fn config app acmeapp username jdoe
   ```

   Note the following:
   - You can also define application-wide custom configuration parameters when you create a new application using the `fn create app` command.
   - Oracle Functions combines the key-value pairs for all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb.
3. To specify one or more custom configuration parameters to pass to a particular function, enter:

```
fn config function <app-name> <function-name> <key> <value>
```

where:
- `<app-name>` is the name of the application containing the function to which you want to pass the custom configuration parameter.
- `<function-name>` is the name of the function to which to pass the custom configuration parameter.
- `<key>` is the name of the custom configuration parameter. The name must only contain alphanumeric characters and underscores, and must not start with a number.
- `<value>` is the value to give to the custom configuration parameter. The value must only contain printable unicode characters.

For example:

```
fn config function acmeapp acme-func username jdoe
```

Note the following:
- You can also define function-specific custom configuration parameters when you create a new function using the `fn create function` command.
- Oracle Functions combines the key-value pairs for all the custom configuration parameters (both application-wide and function-specific) in the application into a single, serially-encoded configuration object with a maximum allowable size of 4Kb.

### Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use these API operations to define custom configuration parameters:

- CreateFunction
- UpdateFunction
- CreateApplication
- UpdateApplication

### Samples, Playbooks, Architectures, and Tutorials

Refer to other resources to learn more about using Oracle Functions:

- Sample Functions on page 3018
- Solution Playbooks on page 3019
- Reference Architectures on page 3019
- Developer Tutorials on page 3019

### Sample Functions

When you set up your development environment for Oracle Functions, simple helloworld functions are included by default. These sample functions enable you to get up and running quickly with Oracle Functions.

In addition, a number of how-to's, patterns, use cases, and other samples are available in the Oracle Functions samples repository on GitHub. These include:

- examples of how to interact with other Oracle Cloud Infrastructure services
- examples of how to optimally connect to databases
- examples of how to use Cloud Events to trigger functions
- use cases for IT Governance, Data Processing, SaaS Application Extensions, and more
Solution Playbooks

Solution playbooks are targeted, cross-product explanations and architectures showing how to handle or implement a specific scenario on Oracle Cloud Infrastructure. They are available from the Oracle Cloud Infrastructure Architecture Center.

Extend SaaS Applications with a Cloud Native Approach

The Extend SaaS Applications with a Cloud Native Approach solution playbook shows how to design a SaaS extension for Oracle Fusion Applications Cloud Service using a Cloud Native approach.

In this high-level design, Oracle Functions serves as the back-end implementation of a REST API, secured by Oracle Identity Cloud Service. Authentication is handled by Oracle Cloud Infrastructure API Gateway.

Reference Architectures

Reference architectures are architectures, configurations, and best practices for deploying on Oracle Cloud Infrastructure. They are available from the Oracle Cloud Infrastructure Architecture Center.

Automate Loading Data to a Data Warehouse Using a Serverless Application

The Automate Loading Data to a Data Warehouse Using a Serverless Application reference architecture shows how to use a serverless function to automate the process of extracting data from files generated by various databases or applications and loading the data into a data warehouse for analysis.

In this architecture, the Events service is triggered when zipped CSV files are uploaded to a specific bucket in Oracle Cloud Infrastructure Object Storage. The emitted event invokes a function in Oracle Functions, which extracts the data from the uploaded files and loads the data into an Oracle Autonomous Data Warehouse instance. After the data is loaded to the data warehouse, the processed CSV files are moved to a different bucket in Object Storage.

Developer Tutorials

Developer Tutorials show you how to complete development-related tasks with step-by-step instructions. Developer Tutorials for Oracle Functions are available in the Oracle Cloud Infrastructure documentation.

Controlling Access

Read about access control with Oracle Functions:

- Controlling Access to Invoke and Manage Functions on page 3019
- Permissions Granted to Containers Running Functions on page 3021
- Oracle Functions Support for Private Network Access on page 3022

Controlling Access to Invoke and Manage Functions

When configuring a tenancy for function development, you specify the following identity policy statement (as described in Policy Statements to Give Oracle Functions Users Access to Function-Related Resources on page 3083):

```
Allow group <group-name> to manage functions-family in compartment <compartment-name>
```

This identity policy enables authenticated users in the specified group to manage (that is, create, update, and delete) functions and applications in the named compartment, and also enables those users to invoke functions in the compartment. This policy typically meets the requirements of functions developers developing and testing multiple functions in your organization.

However, this identity policy might be too permissive to meet your security requirements to control the invocation and management of functions in production environments. For example, in a production environment you might
want to prevent users from invoking functions completely, or restrict users to invoking just functions in a specific application, or to invoking just a particular function.

To control the functions that users in a group can invoke and manage, set up identity policies:

1. To control the functions that a user can invoke and manage, confirm that they are not in a group that has been given the manage functions-family permission.

2. If you want to enable users in a group to create, update, and delete applications and functions in a compartment, but to be unable to invoke functions, enter the following policy statements:

   Allow group <group-name> to manage fn-app in compartment <compartment-name>

   Allow group <group-name> to manage fn-function in compartment <compartment-name>

3. If you want to allow invocations of particular functions only, or invocations of functions in particular applications only, include the appropriate function and application OCIDs in suitable policy statements. For example:

   • To enable users to invoke all the functions in a specific application, enter a policy statement in the following format:

   Allow group <group-name> to use fn-invocation in compartment <compartment-name> where target.app.id = '<application-OCID>'

   • To enable users to invoke one specific function, enter a policy statement in the following format:

   Allow group <group-name> to use fn-invocation in compartment <compartment-name> where target.function.id = '<function-OCID>'

   • To enable users to invoke all the functions in all applications except for functions in one specific application, enter a policy statement in the following format:

   Allow group <group-name> to use fn-invocation in compartment <compartment-name> where target.app.id != '<application-OCID>'

   • To enable users to invoke all the functions in a compartment except for one specific function, enter a policy statement in the following format:

   Allow group <group-name> to use fn-invocation in compartment <compartment-name> where target.function.id != '<function-OCID>'

   • To enable users to invoke two specific functions, enter a policy statement in the following format:

   Allow group <group-name> to use fn-invocation in compartment <compartment-name> where ANY {target.function.id='<function-OCID>', target.function.id='<function-OCID>'}

   • To enable users to invoke one specific function along with all the functions in a specific application, a policy statement in the following format:

   Allow group <group-name> to use fn-invocation in compartment <compartment-name> where ANY {target.function.id='<function-OCID>', target.app.id='<application-OCID>'}
4. If you want to allow function invocation and management requests only from particular IP addresses:
   a. Create a network source to specify the allowed IP addresses, if a suitable network source doesn't exist already (see Managing Network Sources).
   b. Add a policy statement to enable only those IP addresses in the network source to invoke or manage functions. For example:
      • To only allow function invocation requests from IP addresses defined in a network source named corpnet, enter a policy statement in the following format:
        
        ```
        Allow group <group-name> to use fn-invocation in compartment <compartment-name> where request.networkSource.name='corpnet'
        ```
      • To only allow function management requests from IP addresses defined in a network source named corpnet, enter a policy statement in the following format:
        
        ```
        Allow group <group-name> to manage functions-family in compartment <compartment-name> where request.networkSource.name='corpnet'
        ```

### Permissions Granted to Containers Running Functions

When a function you've deployed to Oracle Functions is invoked, it runs inside a container. The operations that a container can perform are determined by the user ID (UID) and group ID (GID) specified when the container is started. If a UID or GID is not specified, the container runs processes as the root user, with all the default capabilities enabled.

When starting a container to run a function, Oracle Functions always specifies a user named 'fn' with a UID of 1000, and a group name 'fn' with a GID of 1000. No privileges are granted to UID 1000 and GID 1000, so the container (and the function running inside it) does not acquire the default capabilities listed in the Docker documentation. In addition, the container is prevented from gaining privileges.

As a result, do not create and deploy functions that:

- depend on capabilities that are unavailable
- depend on privilege elevation (for example, su, sudo or setuid)

If you are using your own Dockerfile, include the following lines:

```bash
groupadd --gid 1000 fn && adduser --uid 1000 --gid fn fn
```

For example:

```bash
FROM oraclelinux:7-slim

RUN yum -y install oracle-release-el7 oracle-nodejs-release-el7 && yum-config-manager --disable ol7_developer_EPEL &&
    yum -y install oracle-instantclient19.3-basiclite nodejs &&
    rm -rf /var/cache/yum &&
    groupadd --gid 1000 fn &&
    adduser --uid 1000 --gid fn fn

WORKDIR /function
ADD . /function/
RUN npm install

CMD exec node func.js
```
Note that if you do not include the `groupadd` and `adduser` lines in the above example Dockerfile, you will see the following error message:

```
cx_Oracle.DatabaseError: ORA-12560: TNS:protocol adapter error
```

**Oracle Functions Support for Private Network Access**

Oracle Functions supports private communication between a function in a VCN and other Oracle Cloud Infrastructure resources and supported services in the Oracle Services Network without the traffic going over the internet. You can:

- enable a function in the VCN to access other resources and services
- enable other resources and services to invoke functions in the VCN

To provide such private access:

- create and deploy functions in private subnets
- add a service gateway to the VCN

For more information, see Access to Oracle Services: Service Gateway on page 4776.

**Adding Applications to Network Security Groups (NSGs)**

Network security groups (NSGs) enable you to define ingress and egress rules that apply to particular VNICs and other resources in a VCN. Unlike a security list, which is attached to a subnet and which has security rules that apply to all the resources in that entire subnet, you can add individual resources to an NSG. Using NSGs rather than security lists gives you more granular control over the security rules that apply to individual resources. For more information about NSGs, see Network Security Groups on page 4346.

You can add an Oracle Functions application to one or more NSGs (up to a maximum of five). Adding an application to an NSG enables you to define ingress and egress rules that apply to all the functions in that particular application.

Using NSGs is useful when you have specified the same subnet for multiple applications that have different access requirements. You can add the applications to different NSGs, enabling you to apply different security rules to the functions running in those applications. For example, you might want functions in one application to access a database and object storage, and functions in a second application to access the database and make an external call through a NAT gateway to a REST service on the public internet. Using NSGs enables you to have both applications in the same subnet without compromising network security.

You can add or remove an application to or from an NSG using the Console, the OCI CLI, and the API.

**Required IAM Policy for Adding Applications to NSGs**

Before you can add applications to NSGs, the group to which you belong must have permission to use NSGs. See Policy Statement to Give Oracle Functions Users Access to Network Resources on page 3084.

**Using the Console**

To add or remove an existing Oracle Functions application to or from a network security group (NSG) using the Console:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
4. Select the compartment specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).

   The Applications page shows the applications defined in the compartment.
5. Click the name of the application that you want to add to an NSG, or to remove from an NSG.

   The Network Security Groups field on the Application Information tab shows the NSGs to which the application has already been added (if any).
6. To add the application to an NSG:
   a. Click **Edit** beside **Network Security Groups**.
   b. In the **Edit Network Security Groups** dialog, select the NSG to which you want to add the application.
      
      The NSG can be in the same compartment or a different compartment, but must be in the same VCN as the subnets specified for the application.
   c. If you want to add the application to multiple NSGs, click **Another Network Security Group** and select additional NSGs (up to a maximum of five).
   d. Click **Save Changes**.

7. To remove the application from an NSG:
   a. Click **Edit** beside **Network Security Groups**.
   b. In the **Edit Network Security Groups** dialog, click the X button beside the NSG(s) from which you want to remove the application.
      
      The application need not be added to any NSGs.
   c. Click **Save Changes**.
   
   The ingress and egress rules defined for the NSGs shown in the **Network Security Groups** field on the **Application Information** tab now apply to functions in the application.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use these API operations to add or remove an application to or from an NSG:

- CreateApplication
- UpdateApplication

**Functions and Fn Project**

Read about how to use Oracle Functions together with Fn Project:

- Using the Fn Project CLI with Oracle Functions on page 3023
- Upgrading the Fn Project CLI on page 3024
- Differences between Oracle Functions and Fn Project on page 3027

**Using the Fn Project CLI with Oracle Functions**

Oracle Functions is powered by the Fn Project open source engine. As a result, you can use the Fn Project CLI to perform create, read, update, and delete operations on Oracle Functions.

To enable you to use the Fn Project CLI with Oracle Functions, you perform a number of preparatory tasks. See Functions QuickStart Guides on page 2963 and Client Environment Configuration Notes for Oracle Functions on page 3086.

Most Fn Project CLI commands have a similar syntax:

```
fn [global options] <command> [command options] [subcommands] [arguments]
```

For example, to:

- list all the available applications, use the command:

  ```
  fn list apps
  ```
• create an application, use a command like:

```ebnf
cfn create app acmeapp --annotation oracle.com/oci/
subnetIds='["ocid1.subnet.oc1.phx.aaaaaaacnh..."]'
```

• invoke a function, use a command like:

```ebnf
cfn invoke helloworld-app helloworld-func
```

• change the profile that the Fn Project CLI uses for its context, use a command like:

```ebnf
cfn update context oracle.profile john-oci-profile
```

To see a complete list of Fn Project CLI commands, you can:

• Log in to your development environment as a functions developer and enter `fn --help` or `fn -h` in a terminal window.

• In a web browser, go to the Fn Project CLI documentation.

To see detailed information about individual Fn Project CLI commands, you can:

• Log in to your development environment as a functions developer and enter `fn <command> [subcommand] --help` or `fn <command> [subcommand] -h` in a terminal window. For example:

```ebnf
cfn create --help
```

```ebnf
cfn update app -h
```

• In a web browser, go to the Fn Project CLI documentation and select the command from the list.

From time to time, new versions of the Fn Project CLI are released. See Upgrading the Fn Project CLI on page 3024.

### Upgrading the Fn Project CLI

Oracle Functions is powered by the Fn Project open source engine. As a result, you can use the Fn Project CLI to perform create, read, update, and delete operations on Oracle Functions. For more information about the Fn Project CLI, see Using the Fn Project CLI with Oracle Functions on page 3023.

From time to time, new versions of the Fn Project CLI are released. To:

• See which version of the Fn Project CLI is currently installed and whether it is the most recent version, log in to your development environment as a functions developer and enter `fn version` in a terminal window. The Fn Project CLI version number is displayed. If a more recent version of the Fn Project CLI is available, the number of the latest available version is also displayed.

• Upgrade the Fn Project CLI to the most recent version, reinstall the Fn Project CLI. See Functions QuickStart Guides on page 2963 and Installing the Fn Project CLI on page 3087.

### Advance Notice of Mandatory Requirement to Upgrade the Fn Project CLI, April 2021

If you have installed the Fn Project CLI and are using it to initialize, build, and deploy functions, you must upgrade the Fn Project CLI on or before 1st May, 2021. After this date, the initialize, build, and deploy commands might start failing with errors.

By 1st May, 2021:

• The Fn Project Java FDK libraries will no longer be available from the current Jfrog Bintray repository. The Fn Project Java FDK libraries are moving to the new Maven Central repository.

• New versions of the Fn Project Python FDK libraries will have been released.

Both of these changes require you to upgrade the Fn Project CLI to version 0.6.6 (or later).
**Steps to upgrade to Fn Project CLI version 0.6.6 (or later)**

1. In a terminal window in your development environment, confirm that the Fn Project CLI has been installed by entering:

   ```bash
   fn --version
   ```

   If the version shown is not version 0.6.6 (or later), complete the following steps to upgrade the Fn Project CLI.

2. Upgrade to the latest version of the Fn Project CLI in one of the following ways:
   - In a Linux or MacOS environment, enter:
     ```bash
     curl -LSs https://raw.githubusercontent.com/fnproject/cli/master/install | sh
     ```
     If prompted for a password, enter the superuser's password.
   - In a MacOS environment using Homebrew, enter:
     ```bash
     brew update && brew install fn
     ```
   - In all environments, download and install the latest binary from the Releases page.
     For more detailed instructions, see the README.md file in the fnproject/cli repository on GitHub.

3. In a terminal window, confirm that Fn Project CLI version 0.6.6 (or later) has been installed by entering:

   ```bash
   fn --version
   ```

**General FAQs**

**How does this affect me?**

If you have installed the Fn Project CLI and are using it to initialize, build, and deploy functions, you must upgrade the Fn Project CLI on or before 1st May, 2021. After this date, the initialize, build, and deploy commands might start failing with errors.

**Are there any required actions I need to take?**

Yes. Oracle has released a new version of the Fn Project CLI. Follow the steps to upgrade the Fn Project CLI promptly. See Steps to upgrade to Fn Project CLI version 0.6.6 (or later) on page 3025.

**What if I don't upgrade by 1st May, 2021?**

If you do not upgrade the Fn Project CLI by 1st May, 2021, the initialize, build, and deploy commands might start failing with errors. You can fix the errors by upgrading the Fn Project CLI. However, we strongly recommend you upgrade the Fn Project CLI before 1st May, 2021 to avoid any disruption.

**Can I do anything to work around or avoid this change?**

No. Upgrading the Fn Project CLI promptly is the recommended solution.

**I am using the Fn Project CLI pre-installed with Cloud Shell. Do I need to upgrade the Fn Project CLI myself?**

No. If you are using the Fn Project CLI bundled in Cloud Shell, Oracle will automatically upgrade the Fn Project CLI for you before 1st May, 2021.
I am using the Fn Project CLI pre-installed with Visual Builder Studio (previously Developer Cloud). Do I need to upgrade the Fn Project CLI myself?

No. If you are using the Fn Project CLI bundled with Visual Builder Studio (previously Developer Cloud), Oracle will automatically upgrade the Fn Project CLI for you before 1st May, 2021.

Will the functions that I have already deployed stop working after 1st May, 2021?

No. Any functions you have already deployed will continue to work. However, if you need to change the functions and redeploy them, you have to use the latest Fn Project CLI.

Java Function FAQs

I have functions written in Java. What changes, if any, do I need to make?

If you have existing Java functions, you have to:
• Upgrade the Fn Project CLI to version 0.6.6 (or later). See Steps to upgrade to Fn Project CLI version 0.6.6 (or later) on page 3025.
• Remove the definition of the fn-release-repo Jfrog Bintray repository from each function's pom.xml file. In the example below, remove everything between the <repositories> and </repositories> tags, including the tags themselves:

```xml
<repositories>
  <repository>
    <id>fn-release-repo</id>
    <url>https://dl.bintray.com/fnproject/fnproject</url>
    <releases>
      <enabled>true</enabled>
    </releases>
    <snapshots>
      <enabled>false</enabled>
    </snapshots>
  </repository>
</repositories>
```

By upgrading the Fn Project CLI and removing the definition of the fn-release-repo Jfrog Bintray repository, you ensure that subsequent build and deploy operations use the Maven Central repository instead of the Jfrog Bintray repository.

Python Function FAQs

When I run fn init --help using the new CLI, I don't see Python 3.7.1 and Python 3.8.5 anymore. Why not?

Python 3.7.1 has been replaced by Python 3.7, and Python 3.8.5 has been replaced by Python 3.8. This change ensures you get the latest patch version each time you build a function image using the fn build or fn deploy commands.

I have functions written in Python 3.7.1 or Python 3.8.5. What changes should I make to use the latest Python 3.7 or Python 3.8 patch versions?

Make the following change in each function's func.yaml file and redeploy the function:
• replace runtime: python3.7.1 with runtime: python3.7
• replace runtime: python3.8.5 with runtime: python3.8
Other Language FAQs

My functions use Node.js, Golang, Ruby, or my own Dockefile. I do not use Java or Python. Do I need to upgrade the Fn Project CLI?

Yes. We strongly recommend you upgrade the Fn Project CLI before 1st May, 2021.

Differences between Oracle Functions and Fn Project

In general, Oracle Functions and Fn Project are very similar. However there are some differences, as detailed below.

Differences in Authentication When Making API Calls

When you use the Oracle Cloud Infrastructure API with Oracle Functions, in the request header you have to provide:

- the OCID of the compartment to which the function belongs
- Oracle Cloud Infrastructure authentication details

Differences When Invoking Functions

To invoke a function deployed to Oracle Functions, you have to explicitly specify an Oracle Cloud Infrastructure endpoint (unless you’re using the Fn Project CLI).

For example, https://fht7ns4mn2q.us-phoenix-1.functions.oci.oraclecloud.com/20181201/functions/ocid1.fnfunc.oc1.phx.aaaa___uxoa/actions/invoke.

You can obtain the appropriate endpoint by making a call to the API, either directly or by using the Fn Project CLI command:

```
fn inspect function <app-name> <function-name>
```

Additional Context Configuration Parameters in Oracle Functions

As well as supporting Fn Project context configuration parameters, Oracle Functions also has some additional parameters, as shown in the following table.

<table>
<thead>
<tr>
<th>Additional Parameter</th>
<th>Set in</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
</table>
| provider             | A context configuration .yaml file in ~/.fn/contexts | oracle | Enables Oracle Functions rather than Fn Project functionality. When provider is set to oracle, the following parameters are valid:
  - oracle.compartment-id
  - oracle.profile
  See Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088. |
### Use of Annotations

When you're creating and viewing Oracle Functions resources using the Fn Project CLI, annotations enable you to identify and specify associated Oracle Cloud Infrastructure resources.

For example:

- When you're using the Fn Project CLI to create a new application, you use the `--annotation` parameter to specify the OCID of the subnet in which to run the function.
- When you're using the Fn Project CLI to view the properties of a function, the `annotations` element shows the OCID of the compartment that owns the function.

Note that unlike other configuration parameters and environment variables, annotation values cannot be passed as arguments to running Docker containers.

### Function Runtimes

Read about managing Function Development Kits (FDKs) and supported language versions:

- Function Development Kits (FDKs) on page 3028
- Languages Supported by Oracle Functions on page 3034
- FDK Base Images and Linux Distributions on page 3035

### Function Development Kits (FDKs)

Oracle Functions uses Fn Project Function Development Kits (FDKs) to support popular languages - Java, Node.js, Python, Go, and Ruby. An FDK is a set of helper libraries that handle system internals (such as protocols, parsing input and output, and logic for function containers). Each language FDK consists of three components:

- A build-time base image, containing language-specific libraries and tools to build executable functions.
- A runtime base image, to provide a language-specific runtime environment in which to run executable functions.
- An FDK library (in the case of Java, the FDK library is included in the build-time and runtime base images).

FDKs are specific to particular versions of a given language. Oracle regularly publishes new FDK build-time and runtime base images for supported languages (for example, to issue a patch, or to support a newly released version of the language). In the case of Java, an FDK update always includes all three components (the build-time and runtime base images, as well as the FDK library). In the case of other languages, an FDK update might include one or more of the components.

<table>
<thead>
<tr>
<th>Additional Parameter</th>
<th>Set in</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oracle.compartment-id</code></td>
<td>A context configuration .yaml file in <code>~/.fn/contexts</code></td>
<td><code>&lt;compartment-ocid&gt;</code></td>
<td>Specifies the OCID of the Oracle Cloud Infrastructure compartment that owns function-related resources. See Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088.</td>
</tr>
<tr>
<td><code>oracle.profile</code></td>
<td>A context configuration .yaml file in <code>~/.fn/contexts</code></td>
<td><code>&lt;profile-name&gt;</code></td>
<td>Specifies which profile to use from the <code>~/.oci/config</code> file. If not set, the profile named default is used. See Setting the Context for the Fn Project CLI Using the <code>oracle.profile</code> Parameter on page 3090.</td>
</tr>
</tbody>
</table>
When you first create a function using the Fn Project CLI `fn init` command, you specify the language in which the function's source code is written using the `--runtime` command option. As well as specifying a language, you can optionally specify a version of the language. If you don't specify the language version, the Fn Project CLI assumes you want to use the most recent version of the language FDK that's available. The Fn Project CLI records the value of the `--runtime` command option as the value of the `runtime:` parameter in the function's `func.yaml`. The Fn Project CLI also adds values for the `build_image:` and `run_image:` parameters in the `func.yaml` file according to the `--runtime` command option you specify, as follows:

- If you specify simply a language as the value of the `--runtime` command option, the Fn Project CLI adds the most recent versions of that language's FDK build-time and runtime base images as values for the `build_image:` and `run_image:` parameters. For example, if you enter `fn init --runtime python helloworld-func` and Python 3.8 is the most recent version available, the Fn Project CLI adds the following:

  ```
  runtime: python
  build_image: fnproject/python:3.8-dev
  run_image: fnproject/python:3.8
  ```

- If you specify both a language and a version as the value of the `--runtime` command option, the Fn Project CLI adds the corresponding version of the language's FDK build-time and runtime base images as values for the `build_image:` and `run_image:` parameters. For example, if you enter `fn init --runtime python3.7 helloworld-func`, the Fn Project CLI adds the following:

  ```
  runtime: python3.7
  build_image: fnproject/python:3.7-dev
  run_image: fnproject/python:3.7
  ```

When you build a function using using `fn build` or `fn deploy`, the Fn Project CLI creates a Docker image (and in the case of `fn deploy`, pushes the image to a Docker registry). The Docker image contains the function's runtime dependencies. If the function is written in a language for which an FDK is available, the Fn Project CLI:

- Uses the build-time base image specified by the `build_image:` parameter to build an executable version of the function, and includes the executable function in the Docker image.
- Includes the runtime base image specified by the `run_image:` parameter in the Docker image, to provide the runtime environment in which to run the executable function.

The Fn Project CLI uses cached versions of the FDK's build-time and runtime base images, if these are available. If cached versions of the base images are not available, the Fn Project CLI pulls the language FDK's build-time and runtime base images from Docker Hub.

Note that if a new version of a language FDK is released, the values for the `build_image:` and `run_image:` parameters in an existing function's `func.yaml` file are not automatically updated. The initial versions of the language FDK's build-time and runtime base images that were previously specified as values for the `build_image:` and `run_image:` parameters when the function was created are still used to build the function executable, and to provide the runtime environment. Using the initial values of the `build_image:` and `run_image:` parameters helps to ensure the function code remains compatible with the language FDK's build-time and runtime base images.

If you want to re-build an existing function with a different language version, and include a different runtime in the function's Docker image, change the values of the `build_image:` and `run_image:` parameters in the function's `func.yaml` file to reference a different version of the language FDK. For consistency and to avoid confusion, update the value of the `runtime:` parameter to correspond to the `--runtime` command option for the version of the language FDK. In the case of Java functions, you also have to change the FDK version in the function's `pom.xml` file.

**Examples**

The examples in this section assume you are using Fn Project CLI version 0.6.7 (and later), and that Python 3.8 is the most recent version of Python supported by the Python FDK.
Example 1: Create a new function with Python 3.8 using Fn Project CLI version 0.6.7 (or later)

If you want to create a new function with Python 3.8, run either of the following commands:

```
fn init --runtime python helloworld-func
fn init --runtime python3.8 helloworld-func
```

In the case of `fn init --runtime python helloworld-func`, the Fn Project CLI records the value of the `--runtime` command option as the value of the `runtime:` parameter in the function's `func.yaml`, and adds the most recent version numbers of the Python FDK's build-time and runtime base images as values for the `build_image:` and `run_image:` parameters:

```
runtime: python
build_image: fnproject/python:3.8-dev
run_image: fnproject/python:3.8
```

In the case of `fn init --runtime python3.8 helloworld-func`, the Fn Project CLI records the value of the `--runtime` command option as the value of the `runtime:` parameter in the function's `func.yaml`, and adds the Python 3.8 FDK's build-time and runtime base images as values for the `build_image:` and `run_image:` parameters:

```
runtime: python3.8
build_image: fnproject/python:3.8-dev
run_image: fnproject/python:3.8
```

From now on, when you build the function, the Fn Project CLI continues to use those initial versions of the build-time and runtime base images to build the function executable, and to provide the runtime environment.

Example 2: Create a new function with Python 3.7 using Fn Project CLI version 0.6.7 (or later)

If you want to create a new function with Python 3.7, run the following command:

```
fn init --runtime python3.7 helloworld-func
```

The Fn Project CLI records the value of the `--runtime` command option as the value of the `runtime:` parameter in the function's `func.yaml`, and adds the version of the Python FDK's build-time and runtime base images that are appropriate for Python 3.7 as values for the `build_image:` and `run_image:` parameters, as shown:

```
runtime: python3.7
build_image: fnproject/python:3.7-dev
run_image: fnproject/python:3.7
```

From now on, when you build the function, the Fn Project CLI continues to use those initial Python 3.7 versions of the build-time and runtime base images to build the function executable, and to provide the runtime environment.

Example 3: Rebuild an existing function with Python 3.6 using Fn Project CLI version 0.6.7 (or later)

If you want to rebuild an existing function that was initially built with Python 3.6 (using Fn Project CLI version 0.6.7), and you want to continue to build it with Python 3.6, run the following command:

```
fn build helloworld-func
```

The `build_image:` and `run_image:` parameters in the `func.yaml` file were originally set to versions of the Python FDK's build-time and runtime base images appropriate for Python 3.6. When you build the function, the Fn Project CLI continues to use the same Python 3.6 build-time and runtime base images to build the function executable, and to provide the runtime environment.
Example 4: Rebuild an existing Python 3.6 function with Python 3.8 using Fn Project CLI version 0.6.7 (or later)

If you want to rebuild an existing function that was initially built with Python 3.6 (using Fn Project CLI version 0.6.7), and you now want to build it with Python 3.8:

- Change the values of the `build_image:` and `run_image:` parameters in the function's `func.yaml` to reference the latest FDK version for Python 3.8 (see How to find out the latest FDK build-time and runtime base image versions for a particular supported language version on page 3033):

  ```yaml
  runtime: python3.6
  build_image: fnproject/python:3.8-dev
  run_image: fnproject/python:3.8
  ```

- For consistency and to avoid confusion, update the value of the `runtime:` parameter to correspond to the `--runtime` command option for Python 3.8.

  ```yaml
  runtime: python3.8
  build_image: fnproject/python:3.8-dev
  run_image: fnproject/python:3.8
  ```

- Run the following command:

  ```bash
  fn build helloworld-func
  ```

The Fn Project CLI uses the versions of the Python FDK's build-time and runtime base images specified by the `build_image:` and `run_image:` parameters in the `func.yaml` file to build the function executable, and to provide the runtime environment. From now on, when you build the function, the Fn Project CLI uses those versions of the build-time and runtime base images.

Behavior in Earlier Versions of the Fn Project CLI (prior to version 0.6.7)

Using versions of the Fn Project CLI prior to version 0.6.7, every time you built or rebuilt a function written in a language supported by an FDK (with the exception of Java, see below), the Fn Project CLI used cached versions of the language FDK's build-time and runtime base images, if these were available. If cached versions of the base images were not available, the Fn Project CLI pulled the most recent versions of the base images from Docker Hub. As a result, you could not be certain that the function code was compatible with the language FDK's build-time base image used to build the function executable, or with the runtime base image used to provide the runtime environment.

You can continue to build existing functions exactly as before, by not explicitly specifying the version of the language FDK when you build a function. The Fn Project CLI will continue to use cached versions of the FDK's build-time and runtime base images (if available), or pull the most recent versions of the base images from Docker Hub (if cached images are not available).

Starting with Fn Project CLI version 0.6.7:

- If you explicitly specify the version of the language FDK when you create a function, the Fn Project CLI adds that version as the value of the `build_image:` and `run_image:` parameters in the function's `func.yaml` file.
- If you build or deploy a function and the function's `func.yaml` file does not already contain `build_image:` and `run_image:` parameters because it was created with an earlier Fn Project CLI version, the Fn Project CLI adds the parameters to the `func.yaml` file. The values of the `build_image:` and `run_image:` parameters record the versions of the FDK build-time and runtime base images that the Fn Project CLI is currently using.

Unless you explicitly specify a different version when you re-build the function later, the Fn Project CLI continues to use the FDK version specified by the `build_image:` and `run_image:` parameters.

Note that in the case of Java functions, previous versions of the Fn Project CLI did add the `runtime:`, `build_image:`, and `run_image:` parameters to `func.yaml` files, to help ensure the function code remained compatible with the Java FDK's build-time and runtime base images.

If you want to re-build an existing function with a different language version, and include a different runtime in the function's Docker image, change the values of the `build_image:` and `run_image:` parameters in the function's
func.yaml file to reference a different version of the language FDK. For consistency and to avoid confusion, update the value of the runtime: parameter to correspond to the --runtime command option for the version of the language FDK. In the case of Java functions, you also have to change the FDK version in the function’s pom.xml file.

**How to find out the language versions supported by FDKs**

To find out the versions of languages supported by FDKs (Java, Node.js, Python, Go, and Ruby):

1. If it hasn’t already been upgraded, upgrade the Fn Project CLI to the most recent version (version 0.6.7 or later). See Upgrading the Fn Project CLI on page 3024.

2. In a terminal window, enter:

   ```bash
   fn init --help | grep runtime
   ```

   For example:

   ```bash
   fn init --help | grep runtime
   --runtime value Choose an existing runtime - go, go1.15, java, java11, java8, kotlin, node, node11, node14, python, python3.6, python3.7, python3.8, ruby, ruby2.7
   ```

   In the above example, you can see that different FDKs support two versions of Java, three versions of Python, and one version each of Node.js, Go, and Ruby. For more details about the supported versions, see Languages Supported by Oracle Functions on page 3034.

**How to find out the version of the FDK build-time and runtime base images used for an existing function**

To find out the version of the FDK build-time and runtime base images that the Fn Project CLI is currently using to build the function executable, and to provide the runtime environment:

1. If it hasn’t already been upgraded, upgrade the Fn Project CLI to the most recent version (version 0.6.7 or later). See Upgrading the Fn Project CLI on page 3024.

2. In a terminal window, change to the directory containing the function code.

3. Use the `fn build` or `fn deploy` commands to build or deploy the function.

   The `build_image:` and `run_image:` parameters are added to the function’s func.yaml file, if they aren’t already present. The parameter values show the version of the FDK build-time and runtime base images that the Fn Project CLI is currently using to build the function executable, and to provide the runtime environment.

**How to find out the default FDK build-time and runtime base image versions for a given language**

To find out the default FDK build-time and runtime base image versions that the Fn Project CLI is currently using to build function executables, and to provide the runtime environment, for functions written in a given language:

1. If it hasn’t already been upgraded, upgrade the Fn Project CLI to the most recent version (version 0.6.7 or later). See Upgrading the Fn Project CLI on page 3024.

2. In a terminal window, create a new helloworld function by entering:

   ```bash
   fn init --runtime <language> hello-func
   ```

   where `<language>` is the particular language you’re interested in (one of java, python, node, ruby, or go).

   For example:

   ```bash
   fn init --runtime java hello-func
   ```

3. Change to the `/hello-func` directory created for the new function, and open the func.yaml file in a text editor.

   The default FDK build-time and runtime base image versions for the language you specified are shown as values of the `build_image:` and `run_image:` parameters.
How to find out the latest FDK build-time and runtime base image versions for a particular supported language version

To find out the latest FDK build-time and runtime base image versions that the Fn Project CLI is currently using to build executables, and to provide the runtime environment, for functions in a particular version of a given language.

1. If it hasn’t already been upgraded, upgrade the Fn Project CLI to the most recent version (version 0.6.7 or later). See Upgrading the Fn Project CLI on page 3024.
2. To see the supported language versions available, run:

   ```
   fn init --help | grep runtime
   ```

   For example:

   ```
   fn init --help | grep runtime
   --runtime value Choose an existing runtime - go, go1.15, java, javal1, java8, kotlin, node, node11, node14, python, python3.6, python3.7, python3.8, ruby, ruby2.7
   ```

   Note the valid values of the `--runtime` command option for the particular language you're interested in, which include the numbers of supported versions. For example, java11, java8, python3.8, python3.7, python3.6, node14, node11, ruby2.7, go1.15.

3. In a terminal window, create a new helloworld function by entering:

   ```
   fn init --runtime <language-version> hello-func
   ```

   where `<language-version>` is the particular language and version you’re interested in.

   For example:

   ```
   fn init --runtime java8 hello-func
   ```

4. Change to the `/hello-func` directory created for the new function, and open the `func.yaml` file in a text editor.

   The latest supported FDK build-time and runtime base image versions for the language version you specified are shown as values of the `build_image:` and `run_image:` parameters.

How to upgrade an existing function to use the latest FDK build-time and runtime base image version for a supported language

To upgrade an existing function so that the Fn Project CLI uses the latest FDK build-time and runtime base image versions for a supported language to build the function executable, and to provide the runtime environment:

1. If it hasn’t already been upgraded, upgrade the Fn Project CLI to the most recent version (version 0.6.7 or later). See Upgrading the Fn Project CLI on page 3024.
2. In a terminal window, change to the directory containing the function code and open the `func.yaml` file in a text editor.

   The `build_image:` and `run_image:` parameters show the FDK build-time and runtime base image versions currently being used by the Fn Project CLI to build the function executable, and to provide the runtime environment. For example:

   ```
   build_image: fnproject/fn-java-fdk-build:jdk11-1.0.105
   run_image: fnproject/fn-java-fdk:jre11-1.0.105
   ```

   If the `build_image:` and `run_image:` parameters are not present in the `func.yaml` file, use the `fn build` or `fn deploy` commands to build the function. Doing so will add the `build_image:` and `run_image:` parameters to the `func.yaml` file, set to the FDK build image and runtime image versions currently being used by the Fn Project CLI.
3. Find out the FDK build-time image and runtime base image versions for the version of the language you want
the Fn Project CLI to use (see How to find out the latest FDK build-time and runtime base image versions for a
particular supported language version on page 3033).

4. Open the func.yaml file in a text editor (if it’s not already open), and update it as follows:
   a. Change the values of the `build_image:` and `run_image:` parameters to the FDK build-time and runtime
      base image versions you identified in the previous step.
      
      For example, you might change:
      ```yaml
      build_image: fnproject/fn-java-fdk-build:jdk11-1.0.105
      run_image: fnproject/fn-java-fdk:jre11-1.0.105
      ```
      to
      ```yaml
      build_image: fnproject/fn-java-fdk-build:jdk11-1.0.130
      run_image: fnproject/fn-java-fdk:jre11-1.0.130
      ```
   b. For consistency and to avoid confusion, change the value of the `runtime:` parameter to correspond to the
      `--runtime` command option for the version of the language. For example:
      ```yaml
      runtime: java11
      ```

5. For Java functions only, open the pom.xml file in a text editor and update the `<fdk.version>` element to
   correspond to the version specified in the func.yaml.
   
   For example, you might change `<fdk.version>1.0.105</fdk.version>` to
   `<fdk.version>1.0.130</fdk.version>.

6. Deploy the function again and test it to confirm that the function code is compatible with the new FDK build-
   time and runtime base image versions that the Fn Project CLI is now using to build the function executable, and to
   provide the runtime environment.

**Languages Supported by Oracle Functions**

Function Development Kits (FDKs) are specific to particular versions of a given language. FDK updates are regularly
published for supported languages (for example, to issue a patch, or to support a newly released version of the
language).

Existing functions built using old FDK base images will continue to work. However, Oracle recommends you
upgrade functions to a supported language version wherever possible.

The following table shows:

- **FDK Language:** The languages for which FDKs are currently available.
- **Default:** The default language version for an FDK (usually the latest language version).
- **Supported:** The language versions for which FDK updates are regularly published.
- **Deprecated:** Language versions for which FDK updates are no longer published.

Functions

FDK Base Images and Linux Distributions

In earlier releases (before December 15, 2021), the Fn Project FDK (Function Development Kit) build-time and runtime base images for the different supported languages were built on top of Alpine and Debian Linux distributions. These base images are known as the 'Alpine/Debian FDK base images'.

From December 15, 2021, nearly all the FDK build-time and runtime base images for the different supported languages are built on top of the Oracle Linux 8 slim distribution. These base images are known as the 'Oracle Linux 8 FDK base images'. New functions you deploy will use these Oracle Linux 8 FDK base images. The only exceptions are the FDK build-time and runtime base images for Python 3.7, which continue to be built on top of the Debian Linux distribution.

From December 15, 2021, the Alpine/Debian FDK base images are deprecated (with the exception of the Debian FDK base images for Python 3.7). For a limited time, the deprecated Alpine/Debian FDK base images remain available but with different image tags. However, no further updates to the deprecated Alpine/Debian FDK base images are planned. Twelve months after December 15, 2021 (that is, from December 15, 2022), the deprecated Alpine/Debian FDK base images will no longer be available.

Note that the Alpine/Debian Linux distributions and the Oracle Linux 8 slim distribution have different package managers. After the transition to the Oracle Linux 8 FDK base images, the temporary Dockerfile created by Oracle Functions when deploying new functions contains Oracle Linux 8 slim package manager commands.

For existing functions already deployed to Oracle Functions:

- If Oracle Functions uses the settings in a function's func.yaml file to create a temporary Dockerfile containing the instructions from which to build the function's Docker image, the function will build and deploy without errors. The temporary Dockerfile includes the correct Oracle Linux 8 slim package manager commands.
- If you have created a custom Dockerfile for a function (for example, by modifying the Dockerfile that Oracle Functions creates, and setting runtime: docker in the function's func.yaml file), the function might now build and deploy with errors such as missing apt-get .... The errors occur if the custom Dockerfile includes Alpine/Debian package manager commands. In this case, replace the Alpine/Debian package manager commands with Oracle Linux 8 slim package manager commands. (For a short-term workaround, see My functions still require the Alpine and Debian Linux distributions. Is there a temporary workaround? on page 3037.)

For more information about the transition from Alpine/Debian FDK base images to Oracle Linux 8 FDK base images, see Frequently Asked Questions About FDK Base Images and Linux on page 3035.

Frequently Asked Questions About FDK Base Images and Linux

What are the Supported FDK Base Images?

From December 15, 2021, the following FDK base images are supported:

<table>
<thead>
<tr>
<th>FDK Language</th>
<th>Language Version</th>
<th>FDK Base Image Name/Tag/Version</th>
<th>Base Image OS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Java</td>
<td>11</td>
<td>Build-time base image: fnproject/fn-java-fdk-build:jdk11-1.0.143 (or later)</td>
<td>Oracle Linux 8 slim</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Runtime base image: fnproject/fn-java-fdk:jre11-1.0.143 (or later)</td>
<td></td>
</tr>
<tr>
<td>FDK Language</td>
<td>Language Version</td>
<td>FDK Base Image Name/Tag/Version</td>
<td>Base Image OS</td>
</tr>
<tr>
<td>--------------</td>
<td>------------------</td>
<td>--------------------------------</td>
<td>--------------</td>
</tr>
</tbody>
</table>
| Java         | 8                | Build-time base image: fnproject/fn-java-fdk-build:1.0.143 (or later)  
Runtime base image: fnproject/fn-java-fdk:1.0.143 (or later) | Oracle Linux 8 slim |
| Python       | 3.8              | Build-time base image: fnproject/python:3.8-dev  
Runtime base image: fnproject/python:3.8 | Oracle Linux 8 slim |
| Python       | 3.7              | Build-time base image: fnproject/python:3.7-dev  
Runtime base image: fnproject/python:3.7 | Debian |
| Python       | 3.6              | Build-time base image: fnproject/python:3.6-dev  
Runtime base image: fnproject/python:3.6 | Oracle Linux 8 slim |
| Ruby         | 2.7              | Build-time base image: fnproject/ruby:2.7-dev  
Runtime base image: fnproject/ruby:2.7 | Oracle Linux 8 slim |
| Go           | 1.15             | Build-time base image: fnproject/go:1.15-dev  
Runtime base image: fnproject/go:1.15 | Oracle Linux 8 slim |
| Node.js      | 14               | Build-time base image: fnproject/node:14-dev  
Runtime base image: fnproject/node:14 | Oracle Linux 8 slim |
What does it mean to deprecate the Alpine/Debian FDK base images?

From December 15, 2021, the Alpine/Debian FDK base images are deprecated, which means that:

- No further updates to the Alpine/Debian FDK base images are planned.
- Twelve months after December 15, 2021 (that is, from December 15, 2022), the Alpine/Debian FDK base images will no longer be available.

My functions still require the Alpine and Debian Linux distributions. Is there a temporary workaround?

From December 15, 2021, Oracle strongly recommends you use the appropriate Oracle Linux 8 FDK base images for the languages and language versions in which your functions are written.

If you cannot immediately start using the Oracle Linux 8 FDK base images because you have functions that still require the Alpine or Debian Linux distributions, there is a temporary workaround. For a limited time, the Alpine/Debian FDK base images remain available but with modified image tags. You can update custom Dockerfiles to use the deprecated Alpine/Debian FDK base images instead of the Oracle Linux base images by explicitly specifying the modified image tags. See How do I specify deprecated Alpine/Debian FDK base images in custom Dockerfiles after December 15, 2021? on page 3038 for the list of modified image tags.

For example, consider the following custom Dockerfile for a Python function, which specifies fnproject/python:3.6-dev and fnproject/python:3.6 as the FDK build-time and runtime base images respectively:

```dockerfile
FROM fnproject/python:3.6-dev as build-stage
WORKDIR /function
ADD requirements.txt /function/
RUN pip3 install --target /python/ --no-cache --no-cache-dir -r requirements.txt &&
    rm -fr ~/.cache/pip /tmp* requirements.txt func.yaml Dockerfile .venv
ADD . /function/
RUN rm -fr /function/.pip_cache

FROM fnproject/python:3.6
RUN apt-get update && apt-get install -y imagemagick
WORKDIR /function
COPY --from=build-stage /function /function
COPY --from=build-stage /python /python
ENV PYTHONPATH=/python
ENTRYPOINT ["/python/bin/fdk", "/function/func.py", "handler"]
```

Before December 15, 2021, this custom Dockerfile uses the Debian FDK build-time and runtime base images. After December 15, 2021, it uses the Oracle Linux 8 FDK build-time and runtime base images.

To use the deprecated Debian FDK build-time and runtime base images after December 15, 2021, you must explicitly specify the names of the deprecated Debian FDK build-time and runtime base images in the custom Dockerfile (fnproject/python:3.6-debian-dev and fnproject/python:3.6-debian), as shown below:

```dockerfile
FROM fnproject/python:3.6-debian-dev as build-stage
WORKDIR /function
ADD requirements.txt /function/
RUN pip3 install --target /python/ --no-cache --no-cache-dir -r requirements.txt &&
    rm -fr ~/.cache/pip /tmp* requirements.txt func.yaml Dockerfile .venv
ADD . /function/
RUN rm -fr /function/.pip_cache

FROM fnproject/python:3.6-debian
RUN apt-get update && apt-get install -y imagemagick
WORKDIR /function
COPY --from=build-stage /function /function
COPY --from=build-stage /python /python
```
How do I specify deprecated Alpine/Debian FDK base images in custom Dockerfiles after December 15, 2021?

From December 15, 2021, use the following FDK base image names in custom Dockerfiles to specify deprecated Alpine/Debian FDK build-time and runtime base images:

<table>
<thead>
<tr>
<th>FDK Language</th>
<th>Language Version</th>
<th>FDK Base Image Name/Tag/Version</th>
<th>Base Image OS</th>
</tr>
</thead>
</table>
| Java         | 11               | Build-time base image (either of the following):  
• fnproject/fn-java-fdk-build:jdk11-latest-debian  
• fnproject/fn-java-fdk-build:jdk11-1.0.142 (or earlier)  
Runtime base image (either of the following):  
• fnproject/fn-java-fdk:jre11-latest-debian  
• fnproject/fn-java-fdk:jre11-1.0.142 (or earlier) | Debian |
| Java         | 8                | Build-time base image (either of the following):  
• fnproject/fn-java-fdk-build:latest-debian  
• fnproject/fn-java-fdk-build:1.0.142 (or earlier)  
Runtime base image (either of the following):  
• fnproject/fn-java-fdk:latest-debian  
• fnproject/fn-java-fdk:1.0.142 (or earlier) | Debian |
<table>

**Observing Functions**

Read about how to view function logs and use function tracing with Oracle Functions:

- Storing and Viewing Function Logs on page 3039
- Distributed Tracing for Functions on page 3043
- Function Metrics on page 3063

**Storing and Viewing Function Logs**

When a function is invoked, you'll typically want to access the function's logs for troubleshooting. The Oracle Cloud Infrastructure Logging service is the default and recommended option for accessing, searching, and storing function
logs. See Using the Console to Enable and View Function Logs in Oracle Cloud Infrastructure Logging on page 3040. For more information about the contents of function logs, see Details for Functions on page 4005.

Alternatively, there might be occasions when you want to send function logs to an external logging destination like Papertrail. To send logs to an external logging destination instead of the Oracle Cloud Infrastructure Logging service, you use the Fn Project CLI to specify a syslog URL. See Using Fn Project CLI Commands to Specify a syslog URL on page 3041.

Note that to store and view logs for a function, the function must include print statements. For example:

- For node.js: `console.log('Entering Hello Node.js function');`
- For java: `System.err.println("Entering Java Hello World Function");`
- For go: `fmt.Println("Entering Hello Go function")`

### Using the Console to Enable and View Function Logs in Oracle Cloud Infrastructure Logging

To enable and view function logs in the Oracle Cloud Infrastructure Logging service:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click `Developer Services`. Under `Functions`, click `Applications`.
3. Select the region and compartment containing the application with functions for which you want to create, enable, and view logs.

   The `Applications` page shows all the applications in the compartment you selected.

4. Select the application with functions for which you want to create, enable, and view logs.

5. To create and enable a new function log in the Oracle Cloud Infrastructure Logging service:
   
   a. Under `Resources`, click `Logs`, click the Actions icon (three dots), and then click `Enable Log` and specify:
      - **Compartment**: The compartment in which to create the new log. By default, the current compartment.
      - **Log Group**: The log group in which to create the new log. Select an existing log group, or select:
        - **Auto-create a default log group** to create a default log group with a default name (DEFAULT_GROUP), if one doesn't exist already.
        - **Create a new log group** to create a new log group with a name and description that you provide.
      - **Log Name**: The name of the new log. By default, `<application-name>_invoke`.
      - **Log Retention**: The length of time to retain log data.

   b. Click `Enable Log` to create the new log (and the new log group, if you specified one).

   For more information, see Enabling Logging for a Resource on page 3978.

6. To enable an existing function log, under `Resources`, click `Logs`, click the Actions icon (three dots), and then click `Enable Log`.

7. To view the data in an existing function log, under `Resources`, click `Logs`, and then click the name of the log group containing the log you want to view in the `Log Group` column. The log opens in the log group's `Log Details` page, enabling you to view log data, and sort and filter log data by time.

8. Click the down arrow beside a log event to see log data for that event.

9. Click Explore with Log Search to search log data.

   **Tip:**

   When searching log data, you can use the `data.opcRequestId` field to filter logs by request id. If an API deployment in API Gateway invokes a function on an Oracle Functions back end, you can see logs relating to both the API Gateway request and the Oracle Functions request by using the same `data.opcRequestId` field together with a wildcard, as follows:

   a. On the Logging Search page, click the down arrow beside a log event to see log data for that event.
b. Click the "data.opcRequestId" field in the function log and select **Filter matching** from the popup menu.

For example, assume the function log contains the field "data.opcRequestId": 
"/01FJA5VCVM0000000000025M1Z/01FJA5VCVM0000000000025M20".

The field "data.opcRequestId": 
"/01FJA5VCVM0000000000025M1Z/01FJA5VCVM0000000000025M20" is copied into the Log Search (Basic Mode) page as a filter.

c. On the Log Search (Basic Mode) page, click **Show Advanced Mode** and replace the second half of the "data.opcRequestId" field value shown in the Query field with the * (asterisk) wildcard.

For example, so that it reads data.opcRequestId: 
'/01FJA5VCVM0000000000025M1Z/*'

d. Click **Search**.

### Using Fn Project CLI Commands to Specify a syslog URL

The Oracle Cloud Infrastructure Logging service is the default and recommended option for accessing, searching, and storing function logs.

Alternatively, you can send function logs to an external logging destination like Papertrail instead by using the Fn Project CLI to specify a syslog URL. Note that to use an external logging destination, you must have set up a VCN with public subnets and an internet gateway (see Creating the VCN and Subnets to Use with Oracle Functions, if they don't exist already on page 3081).

To send function logs to an external logging destination by setting the syslog URL:

1. Log in to your development environment as a functions developer.
2. To create a new application and specify that all functions in the application send their logs to an external logging destination, enter:

```bash
fn create app <app-name> --syslog-url <logging-service-url> --annotation oracle.com/oci/subnetIds='["<subnet-ocid>"]'
```

where:

- `<app-name>` is the name of the new application. Avoid entering confidential information.
- `<logging-service-url>` is the syslog URL to which to send logs.
- `<subnet-ocid>` is the OCID of the public subnet (or subnets, up to a maximum of six) in which to run functions. If a regional subnet has been defined, best practice is to select that subnet to make failover across availability domains simpler to implement. If a regional subnet has not been defined and you need to meet high availability requirements, select multiple subnets (enclose each OCID in double quotes separated by commas, in the format ' ["<subnet-ocid>","<subnet-ocid>" ] '). Oracle recommends that the public subnets
Functions

are in the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).

For example:

```
fn create app acmeapp --syslog-url tcp://my.papertrail.com:4242 --annotation oracle.com/oci/subnetIds='["ocid1.subnet.oc1.phx.aaaaaaaacnh..."]'
```

Note that if you subsequently set up Oracle Cloud Infrastructure Logging to store logs, the existing syslog URL details are retained. So if you later decide to resume sending function logs to the external logging destination, you simply have to disable Oracle Cloud Infrastructure Logging and logs will be sent to the syslog URL again.

3. To update an existing application and specify that all functions in the application send their logs to an external logging destination, enter:

```
fn update app <app-name> --syslog-url <logging-service-url>
```

where:

- `<app-name>` is the name of the application to update
- `<logging-service-url>` is the syslog URL to which to send logs

For example:

```
fn update app acmeapp --syslog-url tcp://my.papertrail.com:4242
```

4. To update an existing application and remove the external logging destination specified for the syslog URL, enter:

```
fn update app <app-name> --syslog-url ''
```

where:

- `<app-name>` is the name of the application to update

For example:

```
fn update app acmeapp --syslog-url ''
```

### Previously Supported Logging Options

In earlier Oracle Functions releases (prior to the release of the Oracle Cloud Infrastructure Logging service), you could specify where Oracle Functions stores a function's logs by setting up a 'logging policy' for the application containing the function. Previously, you could use the Console to set up a logging policy to:

- Store logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage by selecting the OCI Logging option.

To view function logs in a storage bucket, the group to which you belong must have been granted access with the following identity policy statements:

- Allow group <group-name> to manage object-family in compartment <compartment-name>
- Allow group <group-name> to read objectstorage-namespaces in compartment <compartment-name> (Usually created when configuring your tenancy for function development. See Policy Statements to Give Oracle Functions Users Access to Oracle Cloud Infrastructure Registry Repositories on page 3082.)

- Store logs by sending them to an external logging destination like Papertrail by selecting the Syslog URL option.

For an existing application where you have previously already set up a logging policy, the above functionality is still supported and the existing logging policy is applied. However, note the following:

- You cannot use the Console to set up a new logging policy or edit an existing logging policy.
• If the existing logging policy specified storing function logs as objects in a storage bucket in Oracle Cloud Infrastructure Object Storage:
  • The ability to store logs in Object Storage will be deprecated in a future release.
  • Oracle recommends you switch to storing logs using Oracle Cloud Infrastructure Logging.
  • If you do switch to using Oracle Cloud Infrastructure Logging to store logs, you cannot revert to storing the logs in Object Storage.
  • Logs stored in Object Storage will continue to exist (with each log name including the OCID of the associated function, as before).
• If the existing logging policy specified a syslog URL:
  • If you switch to using Oracle Cloud Infrastructure Logging to store logs, the existing syslog URL details are retained. So if you later decide to resume sending function logs to the external logging destination, you simply have to disable Oracle Cloud Infrastructure Logging and logs will be sent to the syslog URL again.
  • If you want to change the syslog URL in the existing logging policy, you have to use the Fn Project CLI to change it.

Distributed Tracing for Functions

When a function is invoked but doesn't run or perform as expected, you need to investigate the issue at a detailed level. The distributed tracing feature observes the function's execution as it moves through the different components of the system. You can trace and instrument standalone functions to debug execution and performance issues. You can also use function tracing to debug issues with complete serverless applications comprising multiple functions and services, such as:
• a function calling another function
• a function calling other services such as the Object Storage service
• a function that serves as a backend for an API gateway deployed in the API Gateway service
• a function triggered in response to an event by the Events service, Notifications service, or Service Connector Hub

The Oracle Functions tracing capabilities are provided by the Oracle Cloud Infrastructure Application Performance Monitoring service. Features in Application Performance Monitoring (APM) enable you to identify and troubleshoot failures and latency issues in the functions you create and deploy.

In the Application Performance Monitoring service:
• An APM domain contains the systems monitored by Application Performance Monitoring. An APM domain is an instance of a collector of trace and span data which stores, aggregates, displays, and visualizes the data.
• A trace is the complete flow of a request as it passes through all the components of a distributed system in a given time period. It consists of an entire tree of spans all related to the same single overall request flow.
• A span is an operation or a logical unit of work with a name, start time, and duration, within a trace. A span is a time segment associated with the duration of a unit of work within the overall request flow.

The Application Performance Monitoring Trace Explorer enables you to visualize the entire request flow and explore trace and span details for diagnostics. You can view and monitor slow traces and traces with errors. To isolate and identify trace issues, you can drill down into specific spans, such as page loads, AJAX calls, and service requests. For more information about the Application Performance Monitoring service, see Application Performance Monitoring.

To enable tracing for a function, you must:
1. Set up a policy to give the Oracle Functions service permission to access APM domains, if the policy does not exist already (see Policy Statements to Give the Oracle Functions Service and Oracle Functions Users Access to Tracing Resources on page 3084).
2. Set up an APM domain.
3. Enable tracing for the Functions application and select the APM domain you created.
4. Enable tracing for one or more functions.

When you enable tracing for a function, Oracle Functions automatically generates a "default function invocation span." The default span captures information about the function's execution context including the overall time taken to process the request and return a response to the caller. In addition to the default function invocation span, you can
add code to functions to define custom spans. Use custom spans to capture more function-specific information to help with debugging. For example, you might define custom spans to capture the start and end of specific units of work. For example, units of work could include getting the database password from the Vault, opening a database connection, and retrieving records from the database.

Four variables have been added to the Oracle Functions context that provide helpful tracing information. These variables include:

- **FN_APP_NAME**: The function application name.
- **FN_FN_NAME**: The function name.
- **OCI_TRACE_COLLECTOR_URL**: The APM domain URL with data key.
- **OCI_TRACING_ENABLED**: Is tracing enabled?
  - When retrieved from environment variables, returns 0 or 1.
  - When retrieved from the function context, returns true or false as appropriate for the language used.

**Required IAM Policy for Enabling Tracing**

Before you can enable tracing, the group to which you belong must have permission to access existing APM domains or to create APM domains. In addition, Oracle Functions must have permission to access APM domains. See Policy Statements to Give the Oracle Functions Service and Oracle Functions Users Access to Tracing Resources on page 3084.

**Using the Console to Enable Tracing and View Function Traces**

A couple of steps are required to enable tracing and to view function traces for the Oracle Cloud Infrastructure Application Performance Monitoring (APM) service. First, enable tracing for the application containing the function. Then, enable tracing for one or more functions. You can then view function traces in the APM Trace Explorer.

**Using the Console to Enable Tracing**

To enable tracing, follow these steps.

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region and compartment containing the Functions application.
   
   The Applications page shows all the applications in the compartment you selected.
4. Select the Functions application for which you want to enable tracing.
5. To enable tracing for the application:
   
   a. Under Resources, click Traces.
   
   b. Select the Trace Enabled option and specify:
      
      - **Compartment**: The compartment in which to create the trace. By default, the current compartment.
      - **APM Domain**: The APM domain (defined in the Application Performance Monitoring service) in which to create the trace. To use an existing APM Domain, select an existing APM domain from the list. Or, to create a new APM domain, click APM Domain. For more information about APM domains, see Getting Started with Application Performance Monitoring.

   
   **Note:**

   The APM Domain needs to have both public and private data keys for function tracing to work. If the keys do not exist, you can create them through the console interface.

   c. Click Enable Trace to enable tracing for the application.

Having enabled tracing for the Functions application, you can now enable tracing for one or more functions in the application.
6. To enable tracing for specific functions in the application:
   a. Under Resources, click Functions.
   b. Select the Enable Trace option beside one or more function(s) for which you want to enable tracing.

   The Enable Trace option is only shown if you have previously enabled tracing for the application. Note the following:
   - If the Enable Trace option is not shown, you must enable tracing for the application. If you haven't already enabled tracing for the application, see the previous step.
   - If you previously enabled tracing for the application but later disabled it, an Enable application tracing link is shown. Click the Enable application tracing link to re-enable tracing for the application (see the previous step). Having re-enabled tracing for the application, you can then enable tracing for specific functions.

When you have enabled tracing for the application and one or more functions, you can view function traces.

**Using the Console to View Function Traces**

To view the traces for functions that have tracing enabled:

1. Sign in to the Console as a functions developer.
2. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
3. Select the region and compartment containing the Functions application with functions for which you want to view function traces.
   The Applications page shows all the applications in the compartment you selected.
4. Select the application containing the functions for which you want to view traces.
5. To see traces for functions:
   a. To see traces for all the functions that have tracing enabled in the application:
      1. Under Resources, click Traces.
      2. Click the name of the trace.
   
      **Note:**
      
      A trace name is only shown if you have already enabled tracing for the application.
   b. To see the trace for a specific function that has tracing enabled:
      1. Under Resources, click Functions.
      2. Click the Actions icon (three dots) beside the function, and then click View Trace.
   
      **Note:**
      
      The View Trace option is only shown if you have already enabled tracing for the function.

The traces for the functions you selected are shown in the APM Trace Explorer. By default, a trace is shown for the default function invocation span, and any custom spans defined for the function.

6. In the APM Trace Explorer:
   a. Click a trace to see the spans for that trace.
   b. Click a span to see the details captured for that span.

For more information about using the APM Trace Explorer, see Use Trace Explorer.

**Tracing a Chain of Functions**

By default, function tracing provides a trace for an entire function invocation. However, often with modern cloud applications, you need to chain function invocations. OCI Functions tracing provides the ability trace the execution of
a function invoked by another function. This ability means you can examine the execution of each function in a chain 
of calls in a single tree of spans in APM trace explorer.

To trace a chain of functions, you need to propagate the X-B3 headers X-B3-TraceId, X-B3-SpanId, X-B3- 
ParentSpanId, and X-B3-Sampled in the function invocation request from your function code.

After the function has run, the trace data from your functions is collected and available in APM Trace Explorer. For 
more information about using the APM Trace Explorer, see Use Trace Explorer.

Tracing a Chain of Functions with Python

Here's an example of how you can trace a chain of functions. If you want to try this example, you need to create 
two sample functions. Follow these steps to set up your functions.

1. Create your tracing Python function: fn init --runtime python <your-function-name-1>
2. Create your "Hello World!" Python function: fn init --runtime python <your-function-name-2>
3. Deploy both functions: fn -v deploy --app <app-name>
4. Get the second functions OCID and invoke endpoint: fn inspect function your-app-name your-
function-name-2
5. Create JSON file to pass the required information into the first function. For example, your test.json file 
might look like this:

```json
{
    "function_ocid": "ocid1.fnfunc.ocl.iad.aaaaaaaaaaaaaaaaaaaaaa",
    "function_endpoint": "https://xxxxxxxxx.us-
ashburn-1.functions.oci.oraclecloud.com",
    "function_body": "",
    "__comment": "Alternatively, you can set function_body to { "name": 
"Oracle" }"
}
```
6. When the first function is invoked, you can pass the second functions information using test.json: fn 
invoke <app-name> <your-function-name-1> < test.json

Now you are ready to update the first function with the required code updates.

Configure Packages

Update your requirements.txt file to include the following packages:

```
fdk
oci
```

Save the file.

Update your Function Code to Propagate the X-B3 Headers

The Python function calls the handler function and passes in the JSON information from the invoke command. The 
handler function is broken in into several small blocks to simplicity. The complete source file is provided at the 
bottom of this section.

Load the JSON Data

In this first part, the JSON data is loaded from the function invocation.
import io
import json
import logging
import oci
from fdk import response

def handler(ctx, data: io.BytesIO=None):
    app_name = ctx.AppName()
    func_name = ctx.FnName()
    logging.getLogger().info("Inside app: "+app_name+" | function: "+func_name+" | method: handler")

    try:
        body = json.loads(data.getvalue())
        function_endpoint = body.get("function_endpoint")
        function_ocid = body.get("function_ocid")
        function_body = body.get("function_body")
    except (Exception) as ex:
        print('ERROR: Missing key in payload', ex, flush=True)
        raise

Create Invoke Client and Gather Header Information

Create the Functions invoke client using the OCI Python SDK and Functions resource principals. Then, retrieve the tracing_context and extract the required information to create the HTTP headers.

signer = oci.auth.signers.get_resource_principals_signer()
client = oci.functions.FunctionsInvokeClient(config={}, signer=signer,
service_endpoint=function_endpoint)

# Zipkin X-B3- header propagation
#
tracing_context = ctx.TracingContext()
trace_id = tracing_context.trace_id()
span_id = tracing_context.span_id()
parent_span_id = tracing_context.parent_span_id()
is_sampled = tracing_context.is_sampled()

Propagate the X-B3 Headers

The OCI Python SDK lets you set custom headers. Use this technique to pass the X-B3 headers in to the second function invocation. Header information is passed for trace_id, span_id, parent_span_id and is_sampled. Finally, the second function is invoked with client and the response is passed to this function's response.

# if tracing is enabled, is_sampled will be true in the tracing context
if is_sampled:
    # To propagate headers in the OCI SDK in the request to the next function,
    # add the X-B3- headers in the request. This header will be included in ALL
    # subsequent calls made.
    if trace_id is not None:
        client.base_client.session.headers['X-B3-TraceId'] = trace_id
        logging.getLogger().info("Inside app: "+app_name+" | function: "+func_name+" | method: handler | trace_id: "+trace_id)
if span_id is not None:
    client.base_client.session.headers['X-B3-SpanId'] = span_id
logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | span_id: " + span_id)

if parent_span_id is not None:
    client.base_client.session.headers['X-B3-ParentSpanId'] = parent_span_id
logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | parent_span_id: " + parent_span_id)

    client.base_client.session.headers['X-B3-Sampled'] = str(int(is_sampled))
    logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | is_sampled: " + str(int(is_sampled)))
else:
    # function.trace is DISABLED
    logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | function tracing is DISABLED")

    resp = client.invoke_function(function_id=function_ocid,
invoke_function_body=function_body)
logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | Response: " + resp.data.text)

    return response.Response(
        ctx,
        response_data=resp.data.text,
        headers={"Content-Type": "application/json"})

Review Complete Function Source Code

Here is the complete source code for the sample Python function.

```
#  # oci-invoke-function-python version 2.0.
#  # Copyright (c) 2021 Oracle, Inc.
#  # Licensed under the Universal Permissive License v 1.0 as shown at https://oss.oracle.com/licenses/upl.
#
import io
import json
import logging
import oci
from fdk import response

def handler(ctx, data: io.BytesIO=None):
    app_name = ctx.AppName()
    func_name = ctx.FnName()
    logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler")

    try:
        body = json.loads(data.getvalue())
        function_endpoint = body.get("function_endpoint")
        function_ocid = body.get("function_ocid")
        function_body = body.get("function_body")
    except (Exception) as ex:
        print('ERROR: Missing key in payload', ex, flush=True)
Functions

```python
signer = oci.auth.signers.get_resource_principals_signer()
client = oci.functions.FunctionsInvokeClient(config={}, signer=signer,
service_endpoint=function_endpoint)

# Zipkin X-B3- header propagation
#
tracing_context = ctx.TracingContext()
trace_id = tracing_context.trace_id()
span_id = tracing_context.span_id()
parent_span_id = tracing_context.parent_span_id()
is_sampled = tracing_context.is_sampled()

# if tracing is enabled, is_sampled will be true in the tracing context
if is_sampled:
    # To propagate headers in the OCI SDK in the request to the next
    # function, add the X-B3- headers in the request. This header will be included
    # in ALL subsequent calls made.
    if trace_id is not None:
        client.base_client.session.headers['X-B3-TraceId'] = trace_id
        logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | trace_id: " + trace_id)
    if span_id is not None:
        client.base_client.session.headers['X-B3-SpanId'] = span_id
        logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | span_id: " + span_id)
    if parent_span_id is not None:
        client.base_client.session.headers['X-B3-ParentSpanId'] = parent_span_id
        logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | parent_span_id: " + parent_span_id)
        client.base_client.session.headers['X-B3-Sampled'] = str(int(is_sampled))
        logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | is_sampled: " + str(int(is_sampled)))
    else:
        # function.trace is DISABLED
        logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | function tracing is DISABLED")

resp = client.invoke_function(function_id=function_ocid,
invoke_function_body=function_body)
logging.getLogger().info("Inside app: " + app_name + " | function: " + func_name + " | method: handler | Response: " + resp.data.text)

return response.Response(
    ctx,
    response_data=resp.data.text,
    headers={"Content-Type": "application/json"})
```

Adding Custom Spans to Functions

With function tracing enabled, the default function invocation span provides a trace for the entire function invocation. The default span can provide good information, but when investigating your code you might want to dig deeper. Custom spans are added directly to your code and allow you to define spans for a method or a block of code. The resulting data provides a better picture of your function as it runs.
Before you can use custom spans, you must enable tracing for your application and functions using the Oracle Cloud Infrastructure Application Performance Monitoring (APM) service. To set up tracing, you must:

1. Set up a policy to give the Oracle Functions service permission to access APM domains, if the policy does not exist already (see Policy Statements to Give the Oracle Functions Service and Oracle Functions Users Access to Tracing Resources on page 3084).
2. Set up an APM domain.
3. Enable tracing for the Functions application and select the APM domain you created.
4. Enable tracing for one or more functions.

These steps have already been covered. However, a couple more things are required for custom spans:

• Select a distributed tracing client library, for example Zipkin.
• Add client libraries to your function dependencies.
• In your function code, use the OCI_TRACING_ENABLED function context variable to check if tracing is enabled.
• In your function code, use the OCI_TRACE_COLLECTOR_URL function context variable to send your custom spans to your APM domain.
• Add instrumentation to your function code.

**Note:**
To use custom spans, you must have the following minimum versions of the Fn Project FDKs:

- Java FDK: 1.0.129
- Python FDK: 0.1.22
- Node FDK: 0.0.20

### Adding Custom Spans to Java Functions

Here's an example of how to use Zipkin to add custom spans to your Java function. If you want to try this example, you can create a Java "Hello World!" function and add custom span code. To create a sample function:

- Create a Java function: `fn init --runtime java apm-fn-java`
- For simplicity, remove the `src/test` directory.

#### Configure Maven

Add the following dependencies to the `<dependencies>` section of your Maven `pom.xml` file.

```xml
<dependency>
    <groupId>io.zipkin.reporter2</groupId>
    <artifactId>zipkin-sender-urlconnection</artifactId>
    <version>2.16.3</version>
</dependency>
<dependency>
    <groupId>io.zipkin.reporter2</groupId>
    <artifactId>zipkin-reporter-brave</artifactId>
    <version>2.16.3</version>
</dependency>
<dependency>
    <groupId>io.zipkin.brave</groupId>
    <artifactId>brave</artifactId>
    <version>5.13.3</version>
</dependency>
<dependency>
    <groupId>io.zipkin.brave</groupId>
    <artifactId>brave-core</artifactId>
    <version>4.13.6</version>
</dependency>
```
Save the file.

**The HandleRequest Method**

Observations about the method follow the `handleRequest` source code.

```java
package com.example.fn;
import brave.Span;
import brave.Tracer;
import brave.Tracing;
import brave.propagation.*;
import brave.sampler.Sampler;
import com.fnproject.fn.api.tracing.TracingContext;
import com.github.kristofa.brave.IdConversion;
import zipkin2.reporter.Sender;
import zipkin2.reporter.brave.AsyncZipkinSpanHandler;
import zipkin2.reporter.urlconnection.URLConnectionSender;

public class HelloFunction {
    Sender sender;
    AsyncZipkinSpanHandler zipkinSpanHandler;
    Tracing tracing;
    Tracer tracer;
    String apmUrl;
    TraceContext traceContext;

    public String handleRequest(String input, TracingContext tracingContext) {
        try {
            initializeZipkin(tracingContext);
            // Start a new trace or a span within an existing trace
            Span span =
                tracer.newChild(traceContext).name("MainHandle").start();
            System.out.println("Inside Java Hello World function");
            try (Tracer.SpanInScope ws = tracer.withSpanInScope(span)) {
                method1();
                method2();
                method3();
            } catch (RuntimeException | Error e) {
                span.error(e); // Unless you handle exceptions, you might
                not know the operation failed!
                throw e;
            } finally {
                span.finish(); // note the scope is independent of the span.
                Always finish a span.
                tracing.close();
                zipkinSpanHandler.flush();
            }
        } catch (Exception e) {
            return e.getMessage();
        }
        return "Hello, AppName " + tracingContext.getAppName() + " :: fnName " + tracingContext.getFunctionName();
    }

    private void initializeZipkin(TracingContext tracingContext) {
        Sender sender;
        AsyncZipkinSpanHandler zipkinSpanHandler;
        Tracing tracing;
        Tracer tracer;
        String apmUrl;
        TraceContext traceContext;
    }
}
```

- The `TracingContext tracingConext` object passes in all the APM-related information needed to make connections to the APM service.
• The `initializeZipkin` method is called which updates the `tracingContext` and creates a `tracer` object which is used to set up custom spans.

• A span is created for the parent custom span. Then three methods are called in the scope of the parent span.

• Notice in the `finally` block all the tracing objects are closed out.

**The initializeZipkin Method**

Observations about the `initializeZipkin` method follow the source code.

```java
public void initializeZipkin(TracingContext tracingContext) throws Exception {
    System.out.println("Initializing the variables");
    apmUrl = tracingContext.getTraceCollectorURL();
    sender = URLConnectionSender.create(apmUrl);
    zipkinSpanHandler = AsyncZipkinSpanHandler.create(sender);
    tracing = Tracing.newBuilder()
        .localServiceName(tracingContext.getServiceName())
        .sampler(Sampler.NEVER_SAMPLE)
        .addSpanHandler(zipkinSpanHandler)
        .build();
    tracer = tracing.tracer();
    tracing.setNoop(!tracingContext.isTracingEnabled());
    traceContext = TraceContext.newBuilder()
        .traceId(IdConversion.convertToLong(tracingContext.getTraceId()))
        .spanId(IdConversion.convertToLong(tracingContext.getSpanId()))
        .sampled(tracingContext.isSampled()).build();
}
```

• The `traceContext` is passed in to create all the objects used to create custom spans.

• The `apmURL` is retrieved from the `getTraceCollectorURL()` method. The URL is the endpoint to the APM domain and is used to create the `tracer` object which builds the custom spans.

• A builder takes the `zipkinSpanHandler` and the service name to create a `tracer` object. This `tracer` object is used to create custom spans.

**Creating Custom Spans**

With the `tracer` object initialized, custom spans can be created.

```java
public void method1() {
    System.out.println("Inside Method1 function");
    TraceContext traceContext = tracing.currentTraceContext().get();
    Span span = tracer.newChild(traceContext).name("Method1").start();
    try {
        Thread.sleep(200);
    } catch (InterruptedException e) {
        e.printStackTrace();
    } finally {
        span.finish();
    }
}
```

• The `method1` method creates a custom span named "Method1."
Review Complete Function Source Code

Here is the complete source code for the sample Java tracing function.

```java
package com.example.fn;
import brave.Span;
import brave.Tracer;
import brave.Tracing;
import brave.propagation.*;
import brave.sampler.Sampler;
import com.fnproject.fn.api.tracing.TracingContext;
import com.github.kristofa.brave.IdConversion;
import zipkin2.reporter.Sender;
import zipkin2.reporter.brave.AsyncZipkinSpanHandler;
import zipkin2.reporter.urlconnection.URLConnectionSender;

public class HelloFunction {
    Sender sender;
    AsyncZipkinSpanHandler zipkinSpanHandler;
    Tracing tracing;
    Tracer tracer;
    String apmUrl;
    TraceContext traceContext;
    public void initializeZipkin(TracingContext tracingContext) throws Exception {
        System.out.println("Initializing the variables");
        apmUrl = tracingContext.getTraceCollectorURL();
        sender = URLConnectionSender.create(apmUrl);
        zipkinSpanHandler = AsyncZipkinSpanHandler.create(sender);
        tracing = Tracing.newBuilder()
            .localServiceName(tracingContext.getServiceName())
            .sampler(Sampler.NEVER_SAMPLE)
            .addSpanHandler(zipkinSpanHandler)
            .build();
        tracer = tracing.tracer();
        tracing.setNoop(!tracingContext.isTracingEnabled());
        traceContext = TraceContext.newBuilder()
            .traceId(IdConversion.convertToLong(tracingContext.getTraceId()))
            .spanId(IdConversion.convertToLong(tracingContext.getSpanId()))
            .sampled(tracingContext.isSampled()).build();
    }

    public String handleRequest(String input, TracingContext tracingContext) {
        try {
            initializeZipkin(tracingContext);
            // Start a new trace or a span within an existing trace representing an operation
            Span span = tracer.newChild(traceContext).name("MainHandle").start();
            System.out.println("Inside Java Hello World function");
            try (Tracer.SpanInScope ws = tracer.withSpanInScope(span)) {
                method1();
                method2();
                method3();
            } catch (RuntimeException | Error e) {
                span.error(e); // Unless you handle exceptions, you might not know the operation failed!
                throw e;
            }
        } finally {
```

Oracle Cloud Infrastructure User Guide 3053
span.finish(); // note the scope is independent of the span.
Always finish a span.
    tracing.close();
    zipkinSpanHandler.flush();
} catch (Exception e) {
    return e.getMessage();
}
return "Hello, AppName " + tracingContext.getAppName() + " :: fnName " + tracingContext.getFunctionName();
}

public void method1() {
    System.out.println("Inside Method1 function");
    TraceContext traceContext = tracing.currentTraceContext().get();
    Span span = tracer.newChild(traceContext).name("Method1").start();
    try {
        Thread.sleep(200);
    } catch (InterruptedException e) {
        e.printStackTrace();
    } finally {
        span.finish();
    }
}

public void method2() {
    System.out.println("Inside Method2 function");
    TraceContext traceContext = tracing.currentTraceContext().get();
    Span span = tracer.newChild(traceContext).name("Method2").start();
    try {
        Thread.sleep(400);
    } catch (InterruptedException e) {
        e.printStackTrace();
    } finally {
        span.finish();
    }
}

public void method3() {
    System.out.println("Inside Method3 function");
    TraceContext traceContext = tracing.currentTraceContext().get();
    Span span = tracer.newChild(traceContext).name("Method3").start();
    try {
        Thread.sleep(300);
    } catch (InterruptedException e) {
        e.printStackTrace();
    } finally {
        span.finish();
    }
}

Adding Custom Spans to Python Functions

Here's an example of how to use Zipkin to add custom spans to your Python function. If you want to try this example, you can create a Python "Hello World!" function and add custom span code. To create a sample function:

- Create a Python function: fn init --runtime python apm-fn-python
Configure Packages

Update your requirements.txt file to include the following packages:

```python
fdk
requests
py_zipkin
```

Save the file.

Creating Handler Class and Parent Custom Span

The Python function calls the handler function and passes in the function context to create custom spans.

```python
def handler(ctx, data: io.BytesIO = None):
    tracing_context = ctx.TracingContext()
    with zipkin_span(
        service_name=tracing_context.service_name(),
        span_name="Customer Code",
        transport_handler=(
            lambda encoded_span: transport_handler(
                encoded_span, tracing_context
            )
        ),
        zipkin_attrs=tracing_context.zipkin_attrs(),
        encoding=Encoding.V2_JSON,
        binary_annotations=tracing_context.annotations()
    ):
        name = "World"
        try:
            body = json.loads(data.getvalue())
            name = body.get("name")
        except (Exception, ValueError) as ex:
            logging.getLogger().info('error parsing json payload: ' + str(ex))
            logging.getLogger().info("Inside Python Hello World function")
            time.sleep(0.005)
            example(ctx)
        return response.Response(
            ctx, response_data=json.dumps(
                "message": "Hello {0}".format(name)),
            headers={"Content-Type": "application/json"}
        )
```

- The `tracing_context` is passed from the function context and contains all the information needed to create and configure custom spans.

  **Note:**

  If tracing is not enabled, the tracing context is an empty object. With an empty tracing context, the `is_sampled` flag is set to `None` and `py_zipkin` does not emit spans.

- The `with zipkin_span` statement is used to create spans.
  - The information in `tracing_context` is used to get the `service_name`, call the `transport_handler`, and set the `zipking_attrs`.
  - A custom span name is specified just by setting `span_name`.
  - Tracing attributes required for Zipkin are retrieved from the tracing context: `tracing_context.zipkin_attrs()`.
• With the custom span setup, the main block runs boilerplate "Hello World!" code. With the only exception, a call to the example function.

The transport_handler Function

The transport_handler function communicates with the APM domain with messages about span execution.

```python
# transport handler, needed by py_zipkin
def transport_handler(encoded_span, tracing_context):
    return requests.post(
        tracing_context.trace_collector_url(),
        data=encoded_span,
        headers={"Content-Type": "application/json"},
    )
```

• The trace_collector_url is returned from the function context. This URL provides the communication endpoint for your custom spans to the APM domain.

Creating a Custom Span in Example Function

The example function demonstrates the creation of a custom span.

```python
def example(ctx):
    with zipkin_span(
        service_name=ctx.TracingContext().service_name(),
        span_name="Get ADB Password from OCI Vault",
        binary_annotations=ctx.TracingContext().annotations()
    ) as example_span_context:
        try:
            logging.getLogger().debug("Get ADB Password from OCI Vault")
            time.sleep(0.005)
            # throwing an exception to show how to add error messages to spans
            raise Exception('Request failed')
        except (Exception, ValueError) as error:
            example_span_context.update_binary_annotations(
                {"Error": True, "errorMessage": str(error)}
            )
        else:
            FakeResponse = namedtuple("FakeResponse", "status, message")
            fakeResponse = FakeResponse(200, "OK")
            # how to update the span dimensions/annotations
            example_span_context.update_binary_annotations(
                {
                    "responseCode": fakeResponse.status,
                    "responseMessage": fakeResponse.message
                }
            )
```

• The with zipkin_span statement is used to identify the custom span and give it a name.
• The example_span_context block raises an exception and returns an error message.

Review Complete Function Source Code

Here is the complete source code for the sample Python tracing function.

```python
import io
import json
import logging
```
from fdk import response

import requests
import time
from py_zipkin import Encoding
from py_zipkin.zipkin import zipkin_span
from collections import namedtuple

# transport handler, needed by py_zipkin
def transport_handler(encoded_span, tracing_context):
    return requests.post(
        tracing_context.trace_collector_url(),
        data=encoded_span,
        headers={"Content-Type": "application/json"},
    )

def handler(ctx, data: io.BytesIO = None):
    tracing_context = ctx.TracingContext()
    with zipkin_span(
        service_name=tracing_context.service_name(),
        span_name="Customer Code",
        transport_handler=(
            lambda encoded_span: transport_handler(
                encoded_span, tracing_context
            )
        ),
        zipkin_attrs=tracing_context.zipkin_attrs(),
        encoding=Encoding.V2_JSON,
        binary_annotations=tracing_context.annotations()
    ):
        name = "World"
        try:
            body = json.loads(data.getvalue())
            name = body.get("name")
        except (Exception, ValueError) as ex:
            logging.getLogger().info('error parsing json payload: ' + str(ex))
        logging.getLogger().info("Inside Python Hello World function")
        time.sleep(0.005)
        example(ctx)
        return response.Response(
            ctx, response_data=json.dumps(
                {"message": "Hello {0}".format(name)},
                headers={"Content-Type": "application/json"}
            )
        )

def example(ctx):
    with zipkin_span(
        service_name=ctx.TracingContext().service_name(),
        span_name="Get ADB Password from OCI Vault",
        binary_annotations=ctx.TracingContext().annotations()
    ) as example_span_context:
        try:
            logging.getLogger().debug("Get ADB Password from OCI Vault")
            time.sleep(0.005)
            # throwing an exception to show how to add error messages to
            raise Exception('Request failed')
        except (Exception, ValueError) as error:
            example_span_context.update_binary_annotations(Oracle Cloud Infrastructure User Guide
Adding Custom Spans to Node Functions

Here's an example of how to use Zipkin to add custom spans to your Node.js function. If you want to try this example, you can create a Node "Hello World!" function and add custom span code. To create a sample function:

- Create a Node function:
  ```
  fn init --runtime node apm-fn-node
  ```

Configure Node Dependencies

Update your `package.json` file to include the following packages:

```json
{
  "name": "apm-tracing-node-fdk-simple-trace-final",
  "version": "1.0.0",
  "description": "Example APM tracing function",
  "main": "func.js",
  "author": "",
  "license": "Apache-2.0",
  "dependencies": {
    "@fnproject/fdk": ">=0.0.13",
    "node-fetch": "^2.6.1",
    "zipkin": "^0.22.0",
    "zipkin-transport-http": "^0.22.0"
  }
}
```

Save the file.

Update Handle Method

Key observations about the `fdk.handle` method follow the source code.

```javascript
// ZipkinJS core components.
const {
  ExplicitContext,
  Annotation,
  Tracer,
  TraceId,
  BatchRecorder,
  jsonEncoder,
  sampler,
  option
} = require('zipkin');

// An HTTP transport for dispatching Zipkin traces.
const {HttpLogger} = require('zipkin-transport-http');
```
fdk.handle(async function(input, ctx) {
    tracer = createOCITracer(ctx);

    var result;
    // Start a new 'scoped' server handling span.
    await tracer.scoped(async function () {
        // Fetch some resource
        result = await tracer.local('fetchResource', () => {
            return fetchResource();
        });
        // Perform some processing
        result = await tracer.local('processResource', () => {
            return someComputation(result);
        });
        // Update some resource
        result = await tracer.local('updateResource', () => {
            return updateResource(result);
        });
        await flush();
    });
    return result;
});

- The tracer is created and then used to create a parent custom span. Then child spans are created for the

Reviewing the createOCITracer Function

Key observations about the function follow the source code.

/**
 * Creates a basic Zipkin Tracer using values from context of the function
 * invocation.
 *
 * @param {*} ctx The function invocation context.
 * @returns A configured Tracer for automatically tracing calls.
 */
function createOCITracer (ctx) {
    // An OCI APM configured Tracer
    //
    const tracingCxt = ctx.tracingContext
    const tracer = new Tracer({
        ctxImpl: new ExplicitContext(),
        recorder: new BatchRecorder({
            logger: new HttpLogger({
                // The configured OCI APM endpoint is available in the function
                // invocation context.
                endpoint: tracingCxt.traceCollectorUrl,
                jsonEncoder: jsonEncoder.JSON_V2
            })),
            // APM Dimensions that should be included in all traces can be
            // directly on Tracer.
            defaultTags: createOCITags(ctx),
        // A custom sampling strategy can be defined.
        sampler: createOCISampler(ctx),
        localServiceName: tracingCxt.serviceName,
    });
}
The function context (ctx) is passed to this function which provides the information required to connect to the APM domain. If you follow the function calls, you can see how the tracing IDs and fields are built.

**Review Complete Function Source Code**

Here is the complete source code for the sample Node tracing function.

```javascript
const fdk = require('@fnproject/fdk')
// ZipkinJS core components.
const {
    ExplicitContext,
    Tracer,
    TraceId,
    BatchRecorder,
    jsonEncoder,
    sampler,
    option
} = require('zipkin')

// An HTTP transport for dispatching Zipkin traces.
const { HttpLogger } = require('zipkin-transport-http')

fdk.handle(async function (input, ctx) {
    var tracer = createOCITracer(ctx)

    var result
    // Start a new 'scoped' server handling span.
    await tracer.scoped(async function () {
        // Fetch some resource
        result = await tracer.local('fetchResource', () => {
            return fetchResource()
        })
        // Perform some processing
        result = await tracer.local('processResource', () => {
            return someComputation(result)
        })
        // Update some resource
        result = await tracer.local('updateResource', () => {
            return updateResource(result)
        })

        await flush()
    })

    return result
})
```
// App Simulation Functions

/**
 * Simulate fetching some required resource. This could be another OCI service
 * or an external call.
 * @returns A Promise with the success or failure of the operation.
 */
function fetchResource () {
    return simulate(1000, { fetchResource: 'OK' })
}

/**
 * Simulate some work. This could be another OCI service.
 * @returns A Promise with the success or failure of the operation.
 */
async function someComputation (toReturn) {
    var i
    for (i = 0; i < 5; i++) {
        await simulate(1000)
    }
    toReturn.processResource = 'OK'
    return toReturn
}

/**
 * Simulate updating some resource. This could be another OCI service or an
 * external call.
 * @returns A Promise with the success or failure of the operation.
 */
async function updateResource (toReturn) {
    await simulate(500)
    toReturn.updateResource = 'OK'
    return toReturn
}

/**
 * A helper function to simulate an operation that takes a specified amount of time.
 * @param {*} ms The simulated time for the activity in milliseconds.
 * @returns A promise that resolves when the simulated activity finishes.
 */
function simulate (ms, result) {
    return new Promise(resolve => setTimeout(resolve, ms, result))
}

/**
 * Functions service may freeze or terminate the container on completion.
 * This function gives extra time to allow the runtime to flush any pending traces.
 * See: https://github.com/openzipkin/zipkin-js/issues/507
 * @returns A Promise to await on.
 */

  if (tracingCxt.traceId && tracingCxt.spanId) {
    return new TraceId({
      traceId: tracingCxt.traceId,
      spanId: tracingCxt.spanId,
      sampled: new option.Some(tracingCxt.sampled),
      debug: new option.Some(tracingCxt.debug),
      shared: false
    })
  }
}
} else {
    return tracer.createRootId(
        new option.Some(tracingCxt.sampled),
        new option.Some(tracingCxt.debug)
    )
}

/**
 * A ZipkinJS 'TraceId' can be created directly from the function invocation
 * context.
 * This configuration will automatically add the function meta-data as APM
 * dimensions to each trace. Function environment variable and other
 * dimensions could also be added.
 * @param {*} ctx The function invocation context.
 * @returns       A map of key-value pairs, that will be added as APM
 *                dimensions to the traces.
 */
function createOCITags (ctx) {
    return {
        appID: ctx.appID,
        appName: ctx.appName,
        fnID: ctx.fnID,
        fnName: ctx.fnName
    }
}

/**
 * A ZipkinJS 'Sampler' can be created directly from the function invocation
 * context.
 * This configuration will only create a trace if the function is configured
 * for tracing.
 * @param {*} ctx The function invocation context.
 * @returns       A ZipkinJS 'TraceId' created from the invocation context.
 */
function createOCISampler (ctx) {
    return new sampler.Sampler((traceId) => ctx.tracingContext.isEnabled)
}

Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use these API operations to enable and disable tracing for applications and the functions they contain:

- CreateApplication
- UpdateApplication
- CreateFunction
- UpdateFunction

Function Metrics

You can monitor the health, capacity, and performance of functions you've deployed to Oracle Functions by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_faas (the Oracle Functions service).
Resources: functions

**Overview of the Oracle Functions Service Metrics**

Oracle Functions monitors function execution, and collects and reports metrics such as:

- The number of times a function is invoked.
- The length of time a function runs for.
- The number of requests to invoke a function that failed with an error response (including the error code and error message).
- The number of requests to invoke a function that returned a ‘429 Too Many Requests’ error in the response (known as ‘throttled function invocations’).

While frequency varies by metric, default service metrics typically have a frequency of 60 seconds (that is, at least one data point posted per minute).

**Prerequisites**

IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

For more information about the policy statement required to access metrics emitted by Oracle Functions, see Policy Statements to Give Oracle Functions Users Access to Function-Related Resources on page 3083.

**Available Metrics: oci.faas**

The metrics listed in the following tables are automatically available for any functions you create. You do not need to enable monitoring on the resource to get these metrics.

Oracle Functions metrics include the following dimensions:

**APPLICATIONID**

The OCID of the application containing functions.

**RESOURCEID**

The OCID of the function.

**RESPONSETYPE**

The response when a function is invoked (one of Success, Error, or Throttled).

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>FunctionExecutionDuration</td>
<td>FunctionExecution</td>
<td>ms</td>
<td>Total function execution duration. Expressed in milliseconds.</td>
<td>applicationId, resourceId</td>
</tr>
<tr>
<td>FunctionInvocationCount</td>
<td>FunctionInvocations</td>
<td>count</td>
<td>Total number of function invocations.</td>
<td>applicationId, resourceId</td>
</tr>
</tbody>
</table>
### Functions

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>FunctionResponseCount</td>
<td>This metric is used in the following default metric charts: <strong>Errors</strong> (with responseType = &quot;Error&quot;) <strong>Throttles</strong> (with responseType = &quot;Throttled&quot;)</td>
<td>count</td>
<td>Total number of function responses.</td>
<td>applicationId, resourceId, responseType</td>
</tr>
</tbody>
</table>

### Using the Console

**To view default metric charts for a single function**

1. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
2. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
3. Select the compartment containing the application with functions for which you want to view metrics.
   The Applications page shows all the applications in the compartment you selected.
4. Click the name of the application containing the function for which you want to view metrics.
5. Click the name of the function for which you want to view metrics.
   The Metrics page displays a chart for each metric that is emitted by the metric namespace for Oracle Functions. For more information about the emitted metrics, see Available Metrics: oci_faa on page 3064.

For more information about monitoring metrics and using alarms, see Monitoring on page 4078. For information about notifications for alarms, see Notifications on page 4900.

Not seeing the function metrics data you expect?

If you don't see the metrics data for a function that you expect, see the following possible causes and resolutions.

<table>
<thead>
<tr>
<th>Problem</th>
<th>Possible Cause</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Missing functions: A function I invoked is missing from the Invocations chart.</td>
<td>The chart range (time period or x-axis window) does not cover the time of invocation.</td>
<td>Adjust the chart range or time period as necessary.</td>
</tr>
<tr>
<td>Gaps in metrics data: The chart line is discontinuous. I want to see data in the charts as a continuous line over time, but the line has gaps in it.</td>
<td>No metrics data exist in the times indicated by the gaps.</td>
<td>Smooth out the display by increasing the chart interval to see if gaps are removed.</td>
</tr>
<tr>
<td>Problem</td>
<td>Possible Cause</td>
<td>Resolution</td>
</tr>
<tr>
<td>------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Empty charts: The Errors and Throttles charts never show data.</td>
<td>No metrics data exists for these charts in the specified chart range. No errors have occurred, and no requests have been throttled. Empty Errors and Throttles charts are expected.</td>
<td>Not applicable.</td>
</tr>
<tr>
<td>Throttles data: The Throttles chart shows data. What should I do?</td>
<td>Data in the Throttles chart indicates at least one request to invoke a function returned a ‘429 Too Many Requests’ error in the response.</td>
<td>Resubmit the throttled invocation requests. Submit future invocation requests less frequently.</td>
</tr>
</tbody>
</table>

*To view default metric charts for all functions in an application*

1. In the Console, open the navigation menu and click Developer Services. Under Functions, click Applications.
2. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
3. Select the compartment containing the application for which you want to view function metrics.
   - The Applications page shows all the applications in the compartment you selected.
4. Click the name of the application for which you want to view function metrics.
5. Under Resources, click Metrics.
   - The Metrics page displays a chart for each metric that is emitted by the metric namespace for Oracle Functions. For more information about the emitted metrics, see Available Metrics: oci_faas on page 3064.

For more information about monitoring metrics and using alarms, see Monitoring on page 4078. For information about notifications for alarms, see Notifications on page 4900.

*To view default metric charts for all the functions in all the applications in a compartment*

2. Select the region you are using with Oracle Functions. Oracle recommends that you use the same region as the Docker registry that's specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).
3. Select the compartment containing the applications for which you want to view function metrics.
4. For Metric Namespace, select oci_faas.
   - The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace. For more information about the emitted metrics, see Available Metrics: oci_faas on page 3064.

For more information about monitoring metrics and using alarms, see Monitoring on page 4078. For information about notifications for alarms, see Notifications on page 4900.
Using the API

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

Troubleshooting Oracle Functions

This topic covers common issues related to Oracle Functions and how to address them.

Use the following techniques to find out more about an error or issue:

- **Use the Errors chart on the Metrics page in the Console to see error codes and messages for individual functions:** If a function doesn't run or perform as expected when you invoke it, you can use the Errors chart on the Metrics page in the Console to see error codes and error messages for that function. For more information, see Function Metrics on page 3063.

- **Use tracing to observe function execution:** If a function doesn't run or perform as expected when you invoke it, you can use tracing to debug execution and performance issues. To use tracing, you have to enable tracing for the application containing the function, and then enable tracing for one or more functions. You can then view function traces in the APM Trace Explorer. For more information, see Distributed Tracing for Functions on page 3043.

- **Use function logs to review function invocation information:** The Oracle Cloud Infrastructure Logging service is the default and recommended option for accessing, searching, and storing function logs. Note that to store and view logs for a function, the function must include print statements. For more information, see Storing and Viewing Function Logs on page 3039.

- **Use DEBUG=1 to see details about requests and responses sent to and from the Oracle Functions service:** If you encounter an unexpected error when using an Fn Project CLI command, you can see more details about the HTTP requests and responses sent to and from the Oracle Functions service. Start the command with the string DEBUG=1 and run the command again. For example:

  ```
  $ DEBUG=1 fn invoke helloworld-app helloworld-func
  ```

  Note that DEBUG=1 must appear before the command, and that DEBUG must be in upper case.

  If you engage with Oracle Support and raise a support ticket, you can attach the output to the ticket.

  Note also that if you have set up a local machine as your Oracle Functions development environment (specifying --provider oracle in the Fn Project CLI context), you must set the environment variable OCI_GO_SDK_DEBUG=v as well as starting the command with DEBUG=1.

The issues in this topic are organized in the following broad categories:

- Setting up and running Oracle Functions on page 3067
- Creating applications and functions on page 3068
- Deploying applications and functions on page 3068
- Invoking functions on page 3068
- Miscellaneous on page 3070

### Setting up and running Oracle Functions

<table>
<thead>
<tr>
<th>Error number and message (if applicable)</th>
<th>Description and link</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>401:</strong> Not authenticated</td>
<td>Running Fn Project CLI commands returns a 401 error on page 3070</td>
</tr>
<tr>
<td><strong>404:</strong> Resource is not authorized or not found</td>
<td>Running Fn Project CLI commands returns a 404 error on page 3071</td>
</tr>
<tr>
<td>Error number and message (if applicable)</td>
<td>Description and link</td>
</tr>
<tr>
<td>------------------------------------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>x509: decryption password incorrect</td>
<td>Running Fn Project CLI commands returns an X509: decryption password incorrect error on page 3071</td>
</tr>
<tr>
<td>Error response from daemon... unknown: Unauthorized</td>
<td>Performing Docker-related operations with the Fn Project CLI displays an &quot;Error response from daemon... unknown: Unauthorized&quot; message on page 3071</td>
</tr>
<tr>
<td>asn1:structure error: tags don't match</td>
<td>Running an Fn Project CLI command displays an &quot;Fn: asn1:structure error: tags don't match&quot; message on page 3071</td>
</tr>
<tr>
<td>Client version: n.n.nn is not latest: n.n.nn</td>
<td>Running fn version shows that a more recent version of the Fn Project CLI is available on page 3072</td>
</tr>
</tbody>
</table>

Creating applications and functions

<table>
<thead>
<tr>
<th>Error number and message (if applicable)</th>
<th>Description and link</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unable to create your app, please try again.</td>
<td>Creating a new application displays an error message in the New Application dialog on page 3072</td>
</tr>
</tbody>
</table>

Deploying applications and functions

<table>
<thead>
<tr>
<th>Error number and message (if applicable)</th>
<th>Description and link</th>
</tr>
</thead>
<tbody>
<tr>
<td>unauthorized: incorrect username or password</td>
<td>Deploying an application returns an &quot;unauthorized: incorrect username or password&quot; message on page 3072</td>
</tr>
<tr>
<td>denied: requested access to the resource is denied</td>
<td>Deploying a function returns an &quot;error running docker push, are you logged into docker?&quot; message on page 3073</td>
</tr>
<tr>
<td>Fn: error running docker push, are you logged into docker?: exit status 1</td>
<td>Deploying a function returns a ListTriggers message and a 500 error on page 3073</td>
</tr>
<tr>
<td>500: Internal server error</td>
<td>Deploying a function returns a ListTriggers message and a 500 error on page 3073</td>
</tr>
<tr>
<td>Image &lt;image-name&gt; does not exist or you do not have access to use it.</td>
<td>Deploying a function returns an &quot;Image does not exist or you do not have access to use it&quot; message on page 3073</td>
</tr>
<tr>
<td>401: Missing subnets annotation</td>
<td>Deploying a function to Oracle Functions returns &quot;Fn: Missing subnets annotation&quot; message on page 3074</td>
</tr>
</tbody>
</table>

Invoking functions

<table>
<thead>
<tr>
<th>Error number and message (if applicable)</th>
<th>Description and link</th>
</tr>
</thead>
<tbody>
<tr>
<td>413: Request content too large FunctionInvokeRequestContentTooLarge</td>
<td>Invoking a function returns an FunctionInvokeRequestContentTooLarge message and a 413 error on page 3074</td>
</tr>
<tr>
<td>429: User-rate limit exceeded TooManyRequests</td>
<td>Invoking a function returns a TooManyRequests message and a 429 error on page 3074</td>
</tr>
<tr>
<td>Error number and message (if applicable)</td>
<td>Description and link</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>502: Function failed</td>
<td>Invoking a function returns a Function failed message and a 502 error on page 3074</td>
</tr>
<tr>
<td>502: Syslog endpoint unavailable</td>
<td>Invoking a function returns a FunctionInvokeSyslogUnavailable message and a 502 error on page 3074</td>
</tr>
<tr>
<td>502: Failed to pull function image</td>
<td>Invoking a function returns a FunctionInvokeImageNotAvailable message and a 502 error on page 3075</td>
</tr>
<tr>
<td>502: subnet ocid1.subnet.... is out of IPs</td>
<td>Invoking a function returns a FunctionInvokeSubnetOutOfIPs message and a 502 error on page 3076</td>
</tr>
<tr>
<td>502: subnet ocid1.subnet.... does not exist or Oracle Functions is not authorized to use it</td>
<td>Invoking a function returns a FunctionInvokeSubnetNotAvailable message and a 502 error (due to a subnet issue) on page 3076</td>
</tr>
<tr>
<td>502: dhcp options ocid1.dhcpoptions.... does not exist or Oracle Functions is not authorized to use it</td>
<td>Invoking a function returns a FunctionInvokeSubnetNotAvailable message and a 502 error (due to a DHCP Options issue) on page 3076</td>
</tr>
<tr>
<td>502: function response body too large FunctionInvokeResponseBodyTooLarge</td>
<td>Invoking a function returns a FunctionInvokeResponseBodyTooLarge message and a 502 error on page 3076</td>
</tr>
<tr>
<td>502: FunctionInvokeResponseHeaderTooLarge function response header too large</td>
<td>Invoking a function returns a FunctionInvokeResponseHeaderTooLarge message and a 502 error on page 3077</td>
</tr>
<tr>
<td>502: Unable to get resource authorization token due to Function resource matching too many Dynamic Groups. Update your Dynamic Groups' matching rules FunctionInvokeTooManyMatchingDGs</td>
<td>Invoking a function returns a FunctionInvokeTooManyMatchingDGs message and a 502 error on page 3077</td>
</tr>
<tr>
<td>502: error receiving function response FunctionInvokeExecutionError</td>
<td>Invoking a function returns a FunctionInvokeExecutionError message and a 502 error on page 3077</td>
</tr>
<tr>
<td>502: function failed FunctionInvokeExecutionFailed</td>
<td>Invoking a function returns a FunctionInvokeExecutionFailed message and a 502 error on page 3077</td>
</tr>
<tr>
<td>502: invalid function response FunctionInvokeInvalidResponse</td>
<td>Invoking a function returns a FunctionInvokeInvalidResponse message and a 502 error on page 3077</td>
</tr>
<tr>
<td>503: Timed out - server too busy FunctionInvokeServiceUnavailable</td>
<td>Invoking a function returns a FunctionInvokeServiceUnavailable message and a 503 error on page 3078</td>
</tr>
<tr>
<td>Error number and message (if applicable)</td>
<td>Description and link</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>504: Container failed to initialize, please ensure you are using the latest fdk and check the logs 'ModuleNotFoundError: No module named 'contextvars'</td>
<td>Invoking a function returns a FunctionInvokeContainerInitFail error message, a 504 error, and a 'ModuleNotFoundError: No module named 'contextvars'' log message on page 3078</td>
</tr>
<tr>
<td>504: Container failed to initialize, please ensure you are using the latest fdk and check the logs</td>
<td>Invoking a function returns FunctionInvokeContainerInitFail and 'Container initialization timed out' messages, and a 504 error on page 3078</td>
</tr>
<tr>
<td>504: Timed out</td>
<td>Invoking a function returns a FunctionInvokeTimeout message and a 504 error on page 3079</td>
</tr>
<tr>
<td>504: Container initialization timed out, please ensure you are using the latest fdk and check the logs FunctionInvokeContainerInitTimeout</td>
<td>Invoking a function returns a FunctionInvokeContainerInitTimeout message and a 504 error on page 3079</td>
</tr>
<tr>
<td>504: Image pull timed out FunctionInvokeImagePullTimeout</td>
<td>Invoking a function returns a FunctionInvokeImagePullTimeout message and a 504 error on page 3080</td>

**Miscellaneous**

<table>
<thead>
<tr>
<th>Error number and message (if applicable)</th>
<th>Description and link</th>
</tr>
</thead>
<tbody>
<tr>
<td>error getting credentials - err: exit status 1, out: Error spawning command line 'dbus-launch --autolaunch...</td>
<td>When running Oracle Functions on Ubuntu, Docker login returns an &quot;error getting credentials - err: exit status 1...&quot; message on page 3080</td>
</tr>
</tbody>
</table>

**Issues setting up and running Oracle Functions**

You might encounter these issues when setting up and running Oracle Functions.

**Running Fn Project CLI commands returns a 401 error**

If you see a message similar to the following when running an Fn Project CLI command, double-check that the credentials specified for your current profile in the ~/.oci/config file are authenticating you correctly:

```
$ fn list apps
Fn: [GET /apps][401] ListApps default &{Fields: Message:Not authenticated}
```

For example:

- Does user specify the OCID of your Oracle Cloud Infrastructure user account?
- Does fingerprint specify the fingerprint of the public API key value uploaded to the Console?
- Does key_file specify the full path to the private key file?

See [Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File](#) on page 3086. Also see [API Errors](#) on page 6343.
Running Fn Project CLI commands returns a 404 error

If you see a message similar to the following when running an Fn Project CLI command, double-check that you are authorized to access function-related and network resources:

```
$ fn list apps
Fn: [GET /apps][404] ListApps default &{Fields: Message:Resource is not authorized or not found}
```

For example:

- Does oracle.compartment-id in your current context correctly specify the OCID of the compartment that owns deployed functions?
- Have policies been set up correctly to give group access to function-related and network resources?
- If you are using a local machine as your Oracle Functions development environment, has your user account been included correctly in the group to which access to function-related and network resources has been granted?
- If you are using an Oracle Cloud Infrastructure compute instance as your Oracle Functions development environment, has the compute instance's OCID been included correctly in the dynamic group that has been granted access to Oracle Cloud Infrastructure Registry?
- Has a policy been set up to give Oracle Functions access to network resources?

See Different Options for Function Development Environments on page 2962, Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088, and Creating Policies to Control Access to Network and Function-Related Resources on page 3082. Also see API Errors on page 6343.

Running Fn Project CLI commands returns an X509: decryption password incorrect error

If you see a message similar to the following when running an Fn Project CLI command, double-check that the pass_phrase specified for your current profile in the ~/.oci/config file is correct:

```
$ fn list apps
Fn: x509: decryption password incorrect
```

See Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 3086.

Performing Docker-related operations with the Fn Project CLI displays an "Error response from daemon... unknown: Unauthorized" message

To enable the Fn Project CLI to access the Docker registry specified in the Fn Project CLI context, the local Docker client (the Docker daemon on Linux) in your development environment must be logged in to that Docker registry. If the Docker client is not logged in to the Docker registry, you see a message similar to the following:

```
Error response from daemon: Get https://phx.ocir.io/v2/: unknown: Unauthorized
```

Follow the instructions in Logging in to Oracle Cloud Infrastructure Registry on page 3092 to log the Docker client in to the appropriate Oracle Cloud Infrastructure Registry, an Oracle-managed Docker registry available in a number of different regions.

Running an Fn Project CLI command displays an "Fn: asn1:structure error: tags don't match" message

When running an Fn Project CLI command, you might see a message similar to the following:

```
Fn: asn1: structure error: tags don't match (16 vs {class:1 tag:15 length:112 isCompound:true}) (optional:false explicit:false application:false private:false defaultValue:<nil> tag:<nil> stringType:0 timeType:0 set:false omitEmpty:false) pkcs1PrivateKey @2
```
This message indicates a problem with the format of the private key. Double-check the private key is PEM-encoded by opening the private key file in the ~/.oci directory and confirming that the private key starts with BEGIN RSA PRIVATE KEY. For more information about generating keys, see Setting up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions on page 3086.

**Running fn version shows that a more recent version of the Fn Project CLI is available**

If you see a message similar to the following when you enter the `fn version` command, a more recent version of the Fn Project CLI is available:

```
$ fn version
Client version: 0.5.33 is not latest: 0.5.34
Server version: ?
```

To upgrade the Fn Project CLI to the most recent version, reinstall the Fn Project CLI by following the instructions in Installing the Fn Project CLI on page 3087.

**Issues creating applications and functions**

You might encounter these issues when creating applications and functions with Oracle Functions.

**Creating a new application displays an error message in the New Application dialog**

If you've already reached the limit for the number of applications in your tenancy, you might see a message similar to the following in the New Application dialog when trying to create a new application:

```
Unable to create your app, please try again.
```

Double-check how many applications already exist in your tenancy. Compare that with the number of applications you're allowed to create. See Oracle Functions Capabilities and Limits on page 2958.

If you've exceeded the number of applications allowed in your tenancy, consider:

- Deleting unwanted applications (see Deleting Applications and Functions on page 2995).
- Requesting an increase to the application limit (see Service Limits on page 247 for instructions).

**Issues deploying applications and functions**

You might encounter these issues when deploying applications and functions with Oracle Functions.

**Deploying an application returns an "unauthorized: incorrect username or password" message**

When deploying an application, you might see a message similar to the following:

```
$ fn -v deploy --app acme-app
Deploying go-app to app: acme-app
Bumped to version 0.0.2
Building image phx.ocir.io/ansh81vrulzp/acme-repo/go-app:0.0.2
FN_REGISTRY: phx.ocir.io/ansh81vrulzp/acme-repo
Current Context: acme-functions-compartment
Sending build context to Docker daemon 5.12kB
Step 1/10 : FROM fnproject/go:dev as build-stage
Get https://registry-1.docker.io/v2/fnproject/go/manifests/dev: unauthorized: incorrect username or password
```

The message indicates an unnecessary and unsuccessful attempt to log in to Docker Hub. To resolve this situation, log out from Docker using the following command:

```
docker logout
```

Having logged out from Docker, re-run the command to deploy the application.
Deploying a function returns an "error running docker push, are you logged into docker?" message

If you see a message similar to the following when deploying a function, double-check that your development environment doesn't have the FN_REGISTRY environment variable set to your Docker username:

```
The push refers to repository [docker.io. ...  
   .  
   .  
   denied: requested access to the resource is denied  
Fn: error running docker push, are you logged into docker?: exit status 1
See fn <command> --help’ for more information.
```

If you have used the open source Fn Project platform, you might have followed instructions in the Fn Project documentation to set the FN_REGISTRY environment variable to your Docker username to enable interaction with the official Docker registry (docker.io).

The FN_REGISTRY environment variable overrides the value of the registry option in your Fn Project CLI context.

To use the Fn Project CLI with Oracle Functions, do one of the following:

- Unset the FN_REGISTRY environment variable.
- Override the FN_REGISTRY environment variable using the --registry global option whenever you enter an Fn Project CLI command that interacts with Oracle Cloud Infrastructure Registry.

Deploying a function returns a ListTriggers message and a 500 error

When deploying a function that you've previously created using an earlier version of the Fn Project CLI, you might see a message similar to the following:

```
Fn: [GET /triggers][500] ListTriggers default &{Fields: Message:Internal server error}
```

This message indicates that the function's func.yaml file contains one or more HTTP trigger definitions. Oracle Functions does not currently support HTTP triggers. To deploy the function, remove the triggers: section from the func.yaml file.

To avoid creating new func.yaml files containing trigger definitions, follow the instructions in Installing the Fn Project CLI on page 3087 to upgrade the Fn Project CLI to the most recent version.

Deploying a function returns an "Image does not exist or you do not have access to use it" message

When deploying a function using an Oracle Cloud Infrastructure compute instance as your Oracle Functions development environment, you might see a message similar to the following:

```
Fn: Image phx.ocir.io/ansh81vru1zp/acme-repo/helloworld-func:0.0.2 does not exist or you do not have access to use it.
```

This message indicates that the compute instance does not have access to Oracle Cloud Infrastructure Registry.

Double-check that a policy statement (similar to the one below) exists in the tenancy's root compartment to allow a dynamic group that includes the compute instance's OCID to access Oracle Cloud Infrastructure Registry:

```
Allow dynamic-group <dynamic-group-name> to read repos in tenancy
```

For more information about using an Oracle Cloud Infrastructure compute instance as your development environment, see Different Options for Function Development Environments on page 2962.
Functions

Deploying a function to Oracle Functions returns "Fn: Missing subnets annotation" message
When you deploy a function to Oracle Functions, you might see the following message:
$ fn deploy --app joes-helloworld-app
Deploying helloworld-func to app: joes-helloworld-app
.
.
.
Fn: Missing subnets annotation
If you see the Fn: Missing subnets annotation message, confirm that you entered the correct application
name. For example:
•
•

the application might not be in the compartment currently specified by the Fn Project CLI context
the application might have existed previously, but has subsequently been deleted

Issues invoking functions
You might encounter these issues when invoking functions deployed to Oracle Functions.
Invoking a function returns an FunctionInvokeRequestContentTooLarge message and a 413 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeRequestContentTooLarge","message":"Request content
too large"}
Fn: Error invoking function. status: 413 message: Request content too large
The message indicates the content of the request to Oracle Functions exceeds the maximum allowed size of 6 MB.
If you see this error, double-check that the content of the request does not exceed the maximum allowed size.
Invoking a function returns a TooManyRequests message and a 429 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"TooManyRequests","message":"User-rate limit exceeded"}
Fn: Error invoking function. status: 429 message: User-rate limit exceeded
The message indicates that Oracle Functions is already handling the maximum number of requests allowed for your
tenancy, and cannot accept another request.
If you see this error, wait a few minutes before invoking the function again. Alternatively, or if the problem persists,
Contact Us to increase the total memory for concurrent function execution.
Invoking a function returns a Function failed message and a 502 error
If there is a problem with a function's code, you will see the following error when you invoke the function:
Fn: Error invoking function. status: 502 message: Function failed
To investigate the issue with the function's code, check the logs output by the function. The Oracle Cloud
Infrastructure Logging service is the default and recommended option for accessing, searching, and storing function
logs. Note that to store and view logs for a function, the function must include print statements. For more information,
see Storing and Viewing Function Logs on page 3039.
Invoking a function returns a FunctionInvokeSyslogUnavailable message and a 502 error
Oracle Functions enables you to send a function's logs to an external logging destination (like Papertrail) by setting a
syslog URL for the application. See Storing and Viewing Function Logs on page 3039.

Oracle Cloud Infrastructure User Guide

3074


Functions

If the syslog URL is invalid or unreachable, you will see the following error when you invoke the function:
{"code":"FunctionInvokeSyslogUnavailable","message":"Syslog endpoint
unavailable"}
Fn: Error invoking function. status: 502 message: Syslog endpoint
unavailable
To confirm that the external logging destination's URL is the cause of the error:
1. Update the application to unset the syslog URL using the Fn Project CLI. For example, by entering:
fn update app helloworld-app --syslog-url ''
2. Deploy the function you want to run. See Creating and Deploying Functions on page 2985.
3. Invoke the function. See Invoking Functions on page 3005.
If the function runs successfully, the external logging destination's URL is not reachable from the subnet in which the
function is running. Double-check that:
•
•
•

The external logging destination's URL is valid.
The external logging destination's URL is publicly accessible.
The subnet in which the function is running has outbound access to the public internet.

Invoking a function returns a FunctionInvokeImageNotAvailable message and a 502 error
When you invoke a function, Oracle Functions pulls the corresponding image from Oracle Cloud Infrastructure
Registry using the VCN and subnets specified for the application.
If Oracle Functions is unable to pull the image, the following message is returned when you invoke a function:
{"code":"FunctionInvokeImageNotAvailable","message":"Failed to pull function
image"}
Fn: Error invoking function. status: 502 message: Failed to pull function
image

Possible solutions:
•
•
•

Double-check that the image specified for the function still exists in the specified location in Oracle Cloud
Infrastructure Registry.
Double-check that Oracle Cloud Infrastructure is available (this message is returned if Oracle Cloud Infrastructure
is unexpectedly unavailable).
Double-check that the VCN includes an internet gateway or service gateway. For Oracle Functions to be able
to access Oracle Cloud Infrastructure Registry to pull an image, the VCN must include an internet gateway or a
service gateway, as follows:
•

•

If public subnets were specified for the application, the VCN must also include an internet gateway. A route
table must include a route rule that targets the internet gateway, with its Destination CIDR Block property set
to 0.0.0.0/0. A security list must include a stateful egress rule that allows access to Oracle Cloud Infrastructure
Registry (for example, with its Destination Type property set to Service, its Destination Service property
set to All <region> services In Oracle Services Network, and its IP Protocol property set
to All).
If private subnets were specified for the application, the VCN must also include a service gateway. The
service gateway must be set up to allow access to All <region> Services In Oracle Services
Network. A route table must include a route rule that targets the service gateway, with its Destination
Service property set to All <region> Services In Oracle Services Network. A security
list must include a stateful egress rule that allows access to Oracle Cloud Infrastructure Registry (for example,

Oracle Cloud Infrastructure User Guide

invoking a function returns a functioninvokesubnetoutofips message and a 502 error

when you invoke a function that you've deployed to oracle functions, you might see the following error message:

```
{"code":"FunctionInvokeSubnetOutOfIPS","message":"subnet ocid1.subnet.oc1.phx.aaaaaaaac... is out of IPs"}
Fn: Error invoking function. status: 502 message: subnet ocid1.subnet.oc1.phx.aaaaaaaac... is out of IPs
```

if you see this error, double-check that each subnet in the VCN has at least the required minimum number of free IP addresses specified in creating the VCN and subnets to use with Oracle Functions, if they don't exist already on page 3081.

invoking a function returns a functioninvokesubnetnotavailable message and a 502 error (due to a subnet issue)

when you invoke a function that you've deployed to oracle functions, you might see the following error message:

```
{"code":"FunctionInvokeSubnetNotAvailable","message":"subnet ocid1.subnet.oc1.phx.aaaaaaaac... does not exist or Oracle Functions is not authorized to use it"}
Fn: Error invoking function. status: 502 message: subnet ocid1.subnet.oc1.phx.aaaaaaaac... does not exist or Oracle Functions is not authorized to use it
```

if you see this error, double-check that the subnet specified for the application still exists.

invoking a function returns a functioninvokesubnetnotavailable message and a 502 error (due to a dhcp options issue)

when you invoke a function that you've deployed to oracle functions, you might see the following error message:

```
{"code":"FunctionInvokeSubnetNotAvailable","message":"dhcp options ocid1.dhcpoptions.oc1.phx.aaaaaaaac... does not exist or Oracle Functions is not authorized to use it"}
Fn: Error invoking function. status: 502 message: dhcp options ocid1.dhcpoptions.oc1.phx.aaaaaaaac... does not exist or Oracle Functions is not authorized to use it
```

if you see this error, double-check that the set of DHCP Options in the VCN specified for the application still exists.

invoking a function returns a functioninvokeresponsebodytooLarge message and a 502 error

when you invoke a function that you've deployed to oracle functions, you might see the following error message:

```
{"code":"FunctionInvokeResponseBodyTooLarge","message":"function response body too large"}
Fn: Error invoking function. status: 502 message: function response body too large
```

the message indicates that the response returned by executing the function exceeds the maximum size allowed of 6 MB.

if you see this error, review the function code and reduce the size of responses that the function returns.
Functions

Invoking a function returns a FunctionInvokeResponseHeaderTooLarge message and a 502 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeResponseHeaderTooLarge","message":"function response
header too large"}
Fn: Error invoking function. status: 502 message: function response body too
large
The message indicates that the response header returned by executing the function exceeds the maximum size
allowed.
If you see this error, review the function code and reduce the number and/or size of any custom headers that the
function returns.
Invoking a function returns a FunctionInvokeTooManyMatchingDGs message and a 502 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":" FunctionInvokeTooManyMatchingDGs","message":"Unable to get
resource authorization token due to Function resource matching too many
Dynamic Groups. Update your Dynamic Groups' matching rules"}
Fn: Error invoking function. status: 502 message: Unable to get resource
authorization token due to Function resource matching too many Dynamic
Groups. Update your Dynamic Groups' matching rules
The message indicates that the function belongs to more dynamic groups than the supported maximum number.
If you see this error, reduce the number of dynamic groups to which the function belongs by updating dynamic group
matching rules. To find out the maximum number of dynamic groups to which a function can belong, see Limits on
Dynamic Groups (the limit shown for a single compute instance applies to a function as well).
Invoking a function returns a FunctionInvokeExecutionError message and a 502 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeExecutionError","message":"error receiving function
response"}
Fn: Error invoking function. status: 502 message: error receiving function
response
The message indicates that the response from executing the function returns an error.
If you see this error unexpectedly, review the function code to understand the conditions in which the function does
not execute successfully.
Invoking a function returns a FunctionInvokeExecutionFailed message and a 502 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeExecutionFailed","message":"function failed"}
Fn: Error invoking function. status: 502 message: function failed
The message indicates that an error was detected during function execution, which was most likely caused by a bug in
the function code.
If you see this error, review the function code and fix any bugs you find.
Invoking a function returns a FunctionInvokeInvalidResponse message and a 502 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeInvalidResponse","message":"invalid function
response"}

Oracle Cloud Infrastructure User Guide

3077


Functions

Fn: Error invoking function. status: 502 message: invalid function response
The message indicates that invoking the function returns an invalid HTTP response code (neither a function failure
nor a timeout).
If you see this error, review the function code and fix any bugs you find.
Invoking a function returns a FunctionInvokeServiceUnavailable message and a 503 error
When you invoke a function that you've deployed to Oracle Functions, you might see the following error message:
{"code":"FunctionInvokeServiceUnavailable","message":"Timed out - server too
busy"}
Fn: Error invoking function. status: 503 message: Timed out - server too
busy
The message indicates that Oracle Functions is currently unable to handle the request, possibly because of insufficient
capacity.
If you see this error, invoke the function again.
Invoking a function returns a FunctionInvokeContainerInitFail error message, a 504 error, and a
'ModuleNotFoundError: No module named 'contextvars'' log message
When you invoke a Python 3.6 function that you've deployed to Oracle Functions, you might see the following error
message:
{"code":"FunctionInvokeContainerInitFail","message":"Container failed to
initialize, please ensure you are using the latest fdk and check the logs"}
Fn: Error invoking function. status: 504 message: Container failed to
initialize, please ensure you are using the latest fdk and check the logs
If you see this error, check the function's logs. If you see a "ModuleNotFoundError: No module named
'contextvars' message in the function's logs:
1. Add the following line to the function's requirements.txt file:
fdk>=0.1.21
2. Re-deploy the function to Oracle Functions.
3. Invoke the function again.
Invoking a function returns FunctionInvokeContainerInitFail and 'Container initialization timed out'
messages, and a 504 error
When you invoke a function that you've deployed to Oracle Functions, the function execution is subject to a
maximum memory threshold. If this limit is exceeded, function execution stops and the following error message is
returned:
{"code":"FunctionInvokeContainerInitFail","message":"Container failed to
initialize, please ensure you are using the latest fdk and check the logs"}
Fn: Error invoking function. status: 504 message: Container failed to
initialize, please ensure you are using the latest fdk and check the logs
If you see this error, increase the maximum memory threshold when you invoke the function. Valid values for
the maximum memory threshold are 128MB, 256MB, 512MB, and 1024MB (see Changing Default Memory and
Timeout Settings on page 2996).
For example, to set a function's maximum memory threshold to 256MB, do one of the following:
•

Click Edit Function on the Function Details page in the Console, and select 256 from the Memory (in MBs)
drop-down list.

Oracle Cloud Infrastructure User Guide

3078


Functions

•

Add the following line to the function's func.yaml file. This will set the maximum memory threshold to 256MB
whenever the function is invoked:
memory: 256
Note that if you edit the func.yaml file, you must re-deploy the function to Oracle Functions before invoking it
again.

It's a good idea to use the latest version of the Fn Project CLI when creating a helloworld Python function. When you
enter the fn init --runtime python <function-name> command to create the helloworld function, the
line memory: 256 is added to the func.yaml file automatically.
Invoking a function returns a FunctionInvokeTimeout message and a 504 error
When you invoke a function that you've deployed to Oracle Functions, the function is only allowed to run for a
certain amount of time. If this time limit is exceeded, function execution stops and the following error message is
returned:
{"code":"FunctionInvokeTimeout","message":"Timed out"}
Fn: Error invoking function. status: 504 message: Timed out
If you see this error, increase the maximum time a function is allowed to run for. For example, to set the maximum
time to 120 seconds, do one of the following:
•
•

Click Edit Function on the Function Details page in the Console, and enter 120 in the Timeout field.
Add the following line to the function's func.yaml file. This will set the maximum time limit to 120 seconds
whenever the function is invoked:
timeout: 120
Note that if you edit the func.yaml file, you must re-deploy the function to Oracle Functions before invoking it
again.

You might also see this error message when a function running in a public subnet is unable to connect to an Oracle
Autonomous Database instance that has access control lists (ACLs) enabled. If this is the case, see Connecting to
Oracle Autonomous Database Instances from Running Functions on page 3015 for more information about:
•
•

Configuring the subnet to send all outgoing internet traffic to a NAT gateway, and to allow internet traffic.
Adding the NAT gateway's public IP address to the database's access control list.

Invoking a function returns a FunctionInvokeContainerInitTimeout message and a 504 error
When you invoke a function that you've deployed to Oracle Functions, the function's image is pulled from the Docker
registry and run inside a container. Depending on the function's dependencies, the container might take a long time to
start. If the container takes too long to start, you might see the following error message:
{"code":"FunctionInvokeContainerInitTimeout","message":"Container
initialization timed out, please ensure you are using the latest fdk and
check the logs"}
Fn: Error invoking function. status: 504 message: Container initialization
timed out, please ensure you are using the latest fdk and check the logs
If you see this error, increase the maximum memory threshold when you invoke the function. Valid values for
the maximum memory threshold are 128MB, 256MB, 512MB, and 1024MB (see Changing Default Memory and
Timeout Settings on page 2996).
For example, to set a function's maximum memory threshold to 256MB, do one of the following:
•

Click Edit Function on the Function Details page in the Console, and select 256 from the Memory (in MBs)
drop-down list.

Oracle Cloud Infrastructure User Guide

3079


Functions

•

Add the following line to the function's func.yaml file. This will set the maximum memory threshold to 256MB
whenever the function is invoked:
memory: 256
Note that if you edit the func.yaml file, you must re-deploy the function to Oracle Functions before invoking it
again.

It's a good idea to use the latest version of the Fn Project CLI when creating a helloworld Python function. When you
enter the fn init --runtime python <function-name> command to create the helloworld function, the
line memory: 256 is added to the func.yaml file automatically.
Invoking a function returns a FunctionInvokeImagePullTimeout message and a 504 error
When you invoke a function that you've deployed to Oracle Functions, the function's image is pulled from the Docker
registry. Depending on the size of the image, it might take a long time to pull the image. If it takes too long to pull the
image, you might see the following error message:
{"code":"FunctionInvokeImagePullTimeout","message":"Image pull timed out"}
Fn: Error invoking function. status: 504 message: Image pull timed out
If you see this error:
•
•

Use standard techniques to reduce the size of the image.
Double-check that the image specified for the function still exists in the specified location in Oracle Cloud
Infrastructure Registry.

Miscellaneous issues when using Oracle Functions
You might encounter these miscellaneous issues when using Oracle Functions.
When running Oracle Functions on Ubuntu, Docker login returns an "error getting credentials - err:
exit status 1..." message
When you configure your development environment for Oracle Functions, you have to install Docker (see Installing
Docker for Use with Oracle Functions on page 3087). If your development environment is running Ubuntu, when
you follow the subsequent instructions to log in to Oracle Cloud Infrastructure Registry using Docker (see Logging in
to Oracle Cloud Infrastructure Registry on page 3092), you might see a message similar to the following:
error getting credentials - err: exit status 1, out: Error spawning command
line 'dbus-launch --autolaunch=d7159335070ef1c0854c75de55c8f588 --binarysyntax --close-stderr': Child process exited with code 1
For more information about this Docker issue, including likely causes and possible resolutions, see https://
github.com/docker/docker-credential-helpers/issues/60.

Appendix: Configuration Notes for Oracle Functions
To get set up and running quickly with Oracle Functions, use the Functions QuickStart Guides on page 2963.
This section provides more information and notes about the tasks you perform using the Functions QuickStart Guides
on page 2963 to configure your tenancy and development environment for Oracle Functions:
•
•
•

Tenancy Configuration Notes for Oracle Functions on page 3080
Client Environment Configuration Notes for Oracle Functions on page 3086
Verifying Your Configuration for Function Development on page 3093

Tenancy Configuration Notes for Oracle Functions
Before you can start using Oracle Functions to create and deploy functions, you have to set up your tenancy for
function development.

Oracle Cloud Infrastructure User Guide

3080


Use the **Functions QuickStart Guides** on page 2963 to get set up quickly.

When a tenancy is created, an Administrators group is automatically created for the tenancy. Users that are members of the Administrators group can perform any operation on resources in the tenancy. Oracle Functions users are typically not members of the Administrators group, and do not have to be. However, a member of the Administrators group does need to perform a number of administrative tasks to enable users to use Oracle Functions.

This section provides more information and notes about the tasks you perform using the **Functions QuickStart Guides** on page 2963 to configure your tenancy for Oracle Functions.

When you have set up your tenancy for function development, you can go on to use the **Functions QuickStart Guides** on page 2963 to set up your client development environment.

### Creating Groups and Users to use with Oracle Functions, if they don't exist already

Before users can start using Oracle Functions to create and deploy functions, as a tenancy administrator you have to create Oracle Cloud Infrastructure user accounts, along with a group to which the user accounts belong. Later on, you’ll define policies to give the group (and the user accounts that belong to it) access to function-related resources. If a suitable group and user accounts already exist, there’s no need to create new ones.

For more information about creating groups and users, see:

- To create a group
- To create a user
- To add a user to a group

### Creating Compartments to Own Network Resources and Oracle Functions Resources in the Tenancy, if they don't exist already

Before users can start using Oracle Functions to create and deploy functions, as a tenancy administrator you have to create:

- a compartment to own network resources (a VCN, a public or private subnet, and other resources such as an internet gateway or service gateway, a route table, security lists)
- a compartment to own function-related resources (functions, applications)

Note that the same compartment can own both network resources and function-related resources. Alternatively, you can create two separate compartments for network resources and function-related resources.

If suitable compartments already exist, there’s no need to create new ones.

For more information about creating a compartment to own network resources and/or function-related resources in the tenancy, see **To create a compartment**.

### Creating the VCN and Subnets to Use with Oracle Functions, if they don't exist already

Before users can start using Oracle Functions to create and deploy functions, a VCN containing the subnets in which to create functions and applications must already exist. The VCN can be, but need not be, owned by the same compartment to which other function-related resources will belong.

Each subnet in the VCN must have a CIDR block that provides at least a certain minimum number of free IP addresses, as follows:

- AD-specific subnets must have a minimum of 12 free IP addresses
- regional subnets must have a minimum of 32 free IP addresses

Note that Oracle strongly recommends each subnet has a CIDR block that provides more than the minimum number of free IP addresses.

To support the largest possible number of concurrent connections, Oracle also strongly recommends that the security lists used by subnets in the VCN only have stateless rules.

If a suitable VCN already exists, there’s no need to create a new one.

If you do decide to create a new VCN, you have several options, including the following:
Functions

- You can create the new VCN and have related resources created automatically at the same time, using one of the VCN wizards (such as the VCN with Internet Connectivity wizard). As well as creating the VCN, the VCN with Internet Connectivity wizard creates a public regional subnet and a private regional subnet, along with an internet gateway, a NAT gateway, and a service gateway. The VCN with Internet Connectivity wizard also creates route tables and security lists. For more information about the VCN wizards, see Virtual Networking Quickstart on page 4320.

- You can create just the VCN initially, and then create the related resources yourself later (see VCNs and Subnets on page 4321). In this case, you can choose which of the following to create:
  
  - Public subnets and an internet gateway (see Internet Gateway on page 4763). In this case, a route table must include a route rule that targets the internet gateway, with its Destination CIDR Block property set to 0.0.0.0/0. A security list must include a stateful egress rule that allows access to Oracle Cloud Infrastructure Registry (for example, with its Destination Type property set to Service, its Destination Service property set to All <region> services In Oracle Services Network, and its IP Protocol property set to All).
  
  - Private subnets and a service gateway (see Access to Oracle Services: Service Gateway on page 4776). In this case, the service gateway must be set up to allow access to All <region> Services In Oracle Services Network. A route table must include a route rule that targets the service gateway, with its Destination Service property set to All <region> Services In Oracle Services Network. A security list must include a stateful egress rule that allows access to Oracle Cloud Infrastructure Registry (for example, with its Destination Type property set to Service, its Destination Service property set to All <region> services In Oracle Services Network, and its IP Protocol property set to All).

For example, if you don't want to expose traffic over the public internet, create private subnets and a service gateway (see Oracle Functions Support for Private Network Access on page 3022).

Note that to use an external logging destination like Papertrail, you have to create a VCN with public subnets (see Storing and Viewing Function Logs on page 3039).

Creating Policies to Control Access to Network and Function-Related Resources

Before users can start using Oracle Functions to create and deploy functions, as a tenancy administrator you have to create a number of Oracle Cloud Infrastructure policy statements to grant access to function-related and network resources.

Use the Policy Builder to create a suitable policy, by selecting Functions as the Policy Use Case, and then selecting the Let users create, deploy, and manage functions and applications policy template. That policy template contains all the necessary policy statements required to use Oracle Functions. See Writing Policy Statements with the Policy Builder.

Alternatively, you can create one or more policies containing the policy statements (follow the instructions in To create a policy).

Policy statements

Policy Statements to Give Oracle Functions Users Access to Oracle Cloud Infrastructure Registry Repositories

<table>
<thead>
<tr>
<th>Purpose:</th>
<th>Create in:</th>
<th>Statement:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enables users to obtain the Object Storage namespace string of the tenancy</td>
<td>Root compartment</td>
<td>Allow group &lt;group-name&gt; to read objectstorage-namespaces in tenancy</td>
</tr>
<tr>
<td>Gives users access to repositories in Oracle Cloud Infrastructure Registry</td>
<td>Root compartment</td>
<td>Allow group &lt;group-name&gt; to manage repos in tenancy</td>
</tr>
</tbody>
</table>
When Oracle Functions users work with functions, they have to access repositories in Oracle Cloud Infrastructure Registry. Users can only access repositories that the groups to which they belong have been granted access. To enable users to access a repository, policy statements must grant the groups access to that repository.

The policy statement `Allow group <group-name> to read objectstorage-namespaces in tenancy` enables users to obtain the auto-generated Object Storage namespace string of the tenancy, which is required to log in to Oracle Cloud Infrastructure Registry. This policy statement also provides access to function logs stored in a storage bucket in Oracle Cloud Infrastructure Object Storage (see Storing and Viewing Function Logs on page 3039).

The policy statement `Allow group <group-name> to manage repos in tenancy` gives users access to repositories in Oracle Cloud Infrastructure Registry. This policy statement gives the group permission to manage all repositories in the tenancy. If you consider this to be too permissive, then you can restrict the repositories to which the group has access by including a where clause in the `manage repos` statement. Note that if you do include a where clause, you must also include a second statement in the policy to enable the group to inspect all repositories in the tenancy (when using the Console). For example, the following policy statements restrict the group to accessing only repositories with names that start 'acme-web-app', but also enables the group to inspect all repositories in the tenancy:

```
Allow group acme-functions-developers to inspect repos in tenancy
```

```
Allow group acme-functions-developers to manage repos in tenancy where all 
{target.repo.name=/acme-web-app*/ }
```

### Policy Statements to Give Oracle Functions Users Access to Function-Related Resources

<table>
<thead>
<tr>
<th>Purpose:</th>
<th>Create in:</th>
<th>Statement:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gives users access to function-related resources</td>
<td>Compartment that owns function-related resources</td>
<td>Allow group &lt;group-name&gt; to manage functions-family in compartment &lt;compartment-name&gt;</td>
</tr>
<tr>
<td>Gives users access to metrics emitted by Oracle Functions</td>
<td>Compartment that owns function-related resources</td>
<td>Allow group &lt;group-name&gt; to read metrics in compartment &lt;compartment-name&gt;</td>
</tr>
</tbody>
</table>

When Oracle Functions users create functions and applications, they have to specify a compartment for those function-related resources (including for metrics emitted by Oracle Functions). Users can only specify a compartment that the groups to which they belong have been granted access. To enable users to specify a compartment, policy statements must grant the groups access to that compartment.

The policy statement `Allow group <group-name> to manage functions-family in compartment <compartment-name>` gives users access to function-related resources.

The policy statement `Allow group <group-name> to read metrics in compartment <compartment-name>` gives users access to metrics emitted by Oracle Functions.

### Policy Statement to Give Oracle Functions Users Access to Logging Resources

<table>
<thead>
<tr>
<th>Purpose:</th>
<th>Create in:</th>
<th>Statement:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gives users access to logging resources</td>
<td>Root compartment</td>
<td>Allow group &lt;group-name&gt; to manage logging-family in compartment &lt;compartment-name&gt;</td>
</tr>
</tbody>
</table>
When Oracle Functions users define an application, they can enable logging to store and view function logs in the Oracle Cloud Infrastructure Logging service. Users can only view logs that the groups to which they belong have been granted access. To enable users to store and view function logs in the Oracle Cloud Infrastructure Logging service, a policy statement must grant the groups access to logging resources.

The policy statement `Allow group <group-name> to manage logging-family in compartment <compartment-name>` gives users full access to logging resources in the compartment that will own logging resources.

### Policy Statement to Give Oracle Functions Users Access to Network Resources

<table>
<thead>
<tr>
<th>Purpose:</th>
<th>Create in:</th>
<th>Statement:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gives users access to network resources</td>
<td>Compartment that owns network resources</td>
<td>Allow group &lt;group-name&gt; to use virtual-network-family in compartment &lt;compartment-name&gt;</td>
</tr>
</tbody>
</table>

When Oracle Functions users create a function or application, they have to specify a VCN and a subnet in which to create them. Users can only specify VCNs and subnets in compartments that the groups to which they belong have been granted access. To enable users to specify a VCN and subnet, a policy statement must grant the groups access to the compartment.

When Oracle Functions users want to define ingress and egress rules that apply to all the functions in a particular application using an NSG, they can add the application to that NSG. To add an application to an NSG, a similar policy statement must grant the groups to which users belong access to the compartment to which the NSG belongs. Note that the NSG might belong to a different compartment to the function's subnet. For more information, see Adding Applications to Network Security Groups (NSGs) on page 3022.

### Policy Statements to Give the Oracle Functions Service and Oracle Functions Users Access to Tracing Resources

<table>
<thead>
<tr>
<th>Purpose:</th>
<th>Create in:</th>
<th>Statement:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gives the Oracle Functions service access to tracing resources</td>
<td>Compartment that owns tracing resources, or the root compartment</td>
<td>Allow service faas to use apm-domains in tenancy</td>
</tr>
<tr>
<td>Gives users access to tracing resources</td>
<td>Compartment that owns tracing resources, or the root compartment</td>
<td>Allow group &lt;group-name&gt; to use apm-domains in tenancy</td>
</tr>
</tbody>
</table>

When Oracle Functions users want to investigate why a function doesn't run or perform as expected, they can use tracing to debug execution and performance issues. To use tracing, users have to enable tracing for the application containing the function, and then enable tracing for one or more functions. Users can then view function traces in the Application Performance Monitoring (APM) Trace Explorer. For more information, see Distributed Tracing for Functions on page 3043.

Users can only enable tracing if the group to which they belong can access existing APM domains (or create new APM domains), and if Oracle Functions can access APM domains. To enable users to turn on tracing and view traces, policy statements must grant the group and Oracle Functions access to APM domains.

The policy statement `Allow group <group-name> to use apm-domains in tenancy|compartment <compartment-name>` gives users access to tracing resources in the compartment or in the entire tenancy. If you want to enable users to create new APM domains (and delete APM domains), specify `manage apm-domains` instead of `use apm-domains`. 
The policy statement `Allow service faas to use apm-domains in tenancy|compartment <compartment-name>` gives Oracle Functions access to APM domains in the compartment or in the entire tenancy.

Policy Statements to Give the Oracle Functions Service and Oracle Functions Users Access to Oracle Vault Resources

<table>
<thead>
<tr>
<th>Purpose:</th>
<th>Create in:</th>
<th>Statement:</th>
</tr>
</thead>
</table>
| Gives the Oracle Functions service access to verify master encryption keys in Oracle Cloud Infrastructure Vault | Compartment that owns the vault and/or master encryption key, or the root compartment | Allow service faas to (KEY_READ) in tenancy|compartment <compartment-name> where request.operation='GetKeyVersion'  
Allow service faas to (KEY_VERIFY) in tenancy|compartment <compartment-name> where request.operation='Verify'  
(if you require more restrictive policy statements, see below for examples) |
| Gives the Oracle Functions service access to signed images in Oracle Cloud Infrastructure Registry | Root compartment | Allow service faas to read repos in tenancy where request.operation='ListContainerImageSignatures' |
| Gives users access to vaults and master encryption keys in Oracle Cloud Infrastructure Vault | Compartment that owns the vault and/or master encryption key, or the root compartment | Allow group <group-name> to read vaults in tenancy|compartment <compartment-name>  
Allow group <group-name> to use keys in tenancy|compartment <compartment-name>  
(if you require more restrictive policy statements, see below for examples) |
| Gives users access to signed images in Oracle Cloud Infrastructure Registry | Root compartment | Allow group <group-name> to read repos in tenancy |

Users can configure Oracle Functions applications to only allow the creation, updating, deployment, and invocation of functions based on images in Oracle Cloud Infrastructure Registry that have been signed by particular master encryption keys.

To create a signature verification policy, and to create and deploy signed function images, users must have access to master encryption keys in vaults defined in Oracle Cloud Infrastructure Vault. Similarly, to enforce a signature verification policy defined for an application, the Oracle Function service must also have access to master encryption keys defined in Oracle Cloud Infrastructure Vault.
Functions

You can restrict the master encryption keys that can be used for function image signing, and signature verification. For example, by using policies like:

```
Allow service faas to {KEY_READ} in compartment <compartment-name>
where target.key.id = '<ocid-of-key-in-verification-policy>' and
request.operation = 'GetKeyVersion'
```

```
Allow service faas to {KEY_VERIFY} in compartment <compartment-name>
where target.key.id = '<ocid-of-key-in-verification-policy>' and
request.operation = 'Verify'
```

```
Allow group <groupname> to {KEY_READ} in compartment <compartment-name>
where ALL {target.key.id = '<ocid-of-key-in-verification-policy>', ANY
{request.operation = 'GetKey', request.operation = 'GetKeyVersion'}}
```

```
Allow group <groupname> to {KEY_VERIFY} in compartment <compartment-name>
where target.key.id = '<ocid-of-key-in-verification-policy>' and
request.operation = 'Verify'
```

For more information and examples, see Signing Function Images and Enforcing the Use of Signed Images from Registry on page 2998.

**Client Environment Configuration Notes for Oracle Functions**

Before you can start using Oracle Functions to create and deploy functions, you have to set up your client environment for function development.

Use the Functions QuickStart Guides on page 2963 to get set up quickly.

Note that prior to setting up your client environment, you must already have set up your tenancy.

This section provides more information and notes about the tasks you perform using the Functions QuickStart Guides on page 2963 to configure your client development environment for Oracle Functions:

**Setting up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions**

Before using Oracle Functions, you have to set up an Oracle Cloud Infrastructure API signing key.

If you are using Cloud Shell as your development environment, an Oracle Cloud Infrastructure API signing key has already been set up for you.

If you are using a local host as your development environment and your user account doesn't already have an Oracle Cloud Infrastructure API signing key, follow the instructions in Functions QuickStart on Local Host to set up an API signing key. Note that if the ~/.oci directory already exists and already contains a private key file and public key file, there's no need to create new private and public key files. Instead, follow the instructions to upload or paste an API key in To add an API signing key, and obtain a configuration file snippet containing a fingerprint.

If you are using a local host as your development environment and your user account already has an API signing key, go straight to Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 3086.

**Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File**

Before using Oracle Functions, you must have an Oracle Cloud Infrastructure CLI configuration file that contains the credentials of the user account that you will be using to create and deploy functions. These user account credentials are referred to as a 'profile'. By default, the Oracle Cloud Infrastructure CLI configuration file is located at ~/.oci/config.

If you are using Cloud Shell as your development environment, an ~/.oci/config file with a suitable profile has already been created for you.
If you are using a local host as your development environment, follow the instructions in the Functions QuickStart on Local Host to create a profile in the ~/.oci/config file by copying and pasting a configuration file snippet. Note the following:

- You might already have a configuration file as a result of installing the Oracle Cloud Infrastructure CLI. However, you don't need to have installed the Oracle Cloud Infrastructure CLI in order to use Oracle Functions.
- The ~/.oci/config file can contain several profiles. If you already have an ~/.oci/config file containing one or more profiles, you have to add a new profile to the existing file for the Oracle Cloud Infrastructure user who will be using Oracle Functions to create and deploy functions.
- Change the name of the new profile you paste into the ~/.oci/config file in the configuration file snippet, from DEFAULT to a name of your choosing. Note that the ~/.oci/config file cannot contain two profiles with the same name.

This topic assumes you have already obtained an API signing key, as described in Setting up an Oracle Cloud Infrastructure API Signing Key for Use with Oracle Functions on page 3086. When you have created a profile in the ~/.oci/config file, go on to Installing Docker for Use with Oracle Functions on page 3087.

**Installing Docker for Use with Oracle Functions**

Before using Oracle Functions, a version of Docker supported by Fn Project must be installed in your development environment.

If you are using Cloud Shell as your development environment, a suitable version of Docker has already been installed for you.

If Docker is not already installed, or the installed version of Docker is not supported, you'll have to install or upgrade Docker.

The instructions in this topic assume:

- you are not using Cloud Shell as your development environment
- you are using Linux
- you have already completed the steps in Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 3086

To confirm that a supported version of Docker is installed in your development environment:

1. Log in to your development environment as a functions developer.
2. In a terminal window, confirm that Docker is installed by entering:

   ```bash
docker version
   ```

3. Do one of the following, depending on the message you see:

   - If you see an error message indicating that Docker is not installed, you have to install Docker before proceeding to the next step. See the Docker documentation for information about installing Docker on your platform. If your platform is Oracle Linux, see Oracle Container Runtime for Docker User's Guide.
   - If you see a message indicating the version of Docker that's installed, go to the next step.

4. Assuming Docker is installed, go to the Fn Project home page on GitHub to confirm that the installed version of Docker is at least the minimum version specified in the Pre-Requisites section.

   If the installed version of Docker is not supported by Fn Project, you have to upgrade the version of Docker before proceeding. See the Docker documentation for information about upgrading Docker on your platform. If your platform is Oracle Linux, see Oracle Container Runtime for Docker User's Guide.

When you have completed the steps in this topic, go on to Installing the Fn Project CLI on page 3087.

**Installing the Fn Project CLI**

Before using Oracle Functions, the Fn Project CLI must be installed in your development environment.

If you are using Cloud Shell as your development environment, the Fn Project CLI has already been installed for you.
You can install the Fn Project CLI in a number of different ways according to your environment.

The instructions in this topic assume:

- you are not using Cloud Shell as your development environment
- you are using Linux
- you have already completed the steps in Installing Docker for Use with Oracle Functions on page 3087

To install the Fn Project CLI:

1. Log in to your development environment as a functions developer.
2. Open the README.md file in the fnproject/cli repository on GitHub and follow the appropriate instructions for installing the Fn Project CLI in your development environment. As a convenient overview, the instructions are summarized below:

   - In a MacOS environment using Homebrew, install the Fn Project CLI by entering:
     ```bash
     brew update && brew install fn
     ```
   - In a Linux or MacOS environment, install the Fn Project CLI by entering:
     ```bash
     curl -Ls https://raw.githubusercontent.com/fnproject/cli/master/install | sh
     ```
     If prompted for a password, enter the superuser's password.
   - In a Windows environment, install the Fn Project CLI by following the Install Fn Client instructions in the How-to: Run Fn client on Windows and connect to a remote Fn server topic on GitHub.
   - In a Linux, MacOS, or Windows environment, install the Fn Project CLI by downloading the binary from the Releases page and running it.
3. In a terminal window, confirm that the CLI has been installed by entering:

   ```bash
   fn version
   ```

   Assuming the Fn Project CLI has been installed correctly, you'll see a message indicating the version of the CLI that has been installed.

When you have completed the steps in this topic, go on to Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088.

**Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure**

Before using Oracle Functions, you have to configure the Fn Project CLI to connect to your Oracle Cloud Infrastructure tenancy.

When the Fn Project CLI is initially installed, it's configured for a local development 'context'. To configure Fn Project CLI to connect to your Oracle Cloud Infrastructure tenancy instead, you have to create a new context. The context specifies Oracle Functions endpoints, the OCID of the compartment to which deployed functions will belong, and the address of the Docker registry to and from which to push and pull images.

You can define multiple contexts, each stored in a different context file in .yaml format. By default, the individual context files are stored in the `~/.fn/contexts` directory. The `~/.fn/config.yaml` file specifies which context file Fn Project uses.

To create a new context, you can create a new context file manually and edit the `~/.fn/config.yaml` file by hand to point to that file. Alternatively, you can use the Fn Project CLI to interactively create the new context file and instruct the Fn Project CLI to start using that file, as described below.

If you are using Cloud Shell as your development environment, two Fn Project CLI contexts have already been created for you (a default context and a context for the current region). For more information, see Oracle Functions on Cloud Shell QuickStart Guide. You simply have to copy and paste commands from the Getting Started page into the Cloud Shell window:

- to instruct the Fn Project CLI to use the context for the current region
To create a new context file using the Fn Project CLI:

1. Log in to your development environment as a functions developer.

2. In a terminal window, create the new Fn Project CLI context for Oracle Cloud Infrastructure by entering:

   ```
   fn create context <my-context> --provider oracle
   ```

   where `<my-context>` is a name of your choosing. For example:

   ```
   fn create context johns-oci-context --provider oracle
   ```

   Note that you specify `--provider oracle` to enable authentication and authorization using Oracle Cloud Infrastructure request signing, private keys, user groups, and policies that grant permissions to those user groups.

3. Specify that the Fn Project CLI is to use the new context by entering:

   ```
   fn use context <my-context>
   ```

   where `<my-context>` is the name you specified in the previous step. For example:

   ```
   fn use context johns-oci-context
   ```

4. Configure the new context with the OCID of the compartment that you want to own the deployed functions (you might have created a new compartment specifically for this purpose, see Creating Compartments to Own Network Resources and Oracle Functions Resources in the Tenancy, if they don't exist already on page 3081) by entering:

   ```
   fn update context oracle.compartment-id <compartment-ocid>
   ```

   For example:

   ```
   fn update context oracle.compartment-id ocid1.compartment.oc1..aaaaaaaarvd72n...
   ```

5. Configure the new context with the api-url endpoint to use when calling the API by entering:

   ```
   fn update context api-url <api-endpoint>
   ```

   where `<api-endpoint>` is one of the endpoints in the list of Functions endpoints in Functions API, in the format https://functions.<region-identifier>.oci.oraclecloud.com. The `<region-identifier>` in `<api-endpoint>` is the identifier of the Oracle Cloud Infrastructure region in which you'll be creating and deploying functions. For example, us-phoenix-1.

   For example:

   ```
   fn update context api-url https://functions.us-phoenix-1.oci.oraclecloud.com
   ```
6. Configure the new context with the address of the Docker registry that you want to use with Oracle Functions by entering:

```
fn update context registry <region-key>.ocir.io/<tenancy-namespace>/<repo-name-prefix>
```

where:
- `<region-key>` is the key of the Oracle Cloud Infrastructure Registry region. For example, phx for Phoenix. See Availability by Region on page 5086.
- `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy in which to create repositories (as shown on the Tenancy Information page). For example, the namespace of the acme-dev tenancy might be ansh81vru1zp. Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, acme-dev).
- `<repo-name-prefix>` is a repository name prefix to pre-pend to the names of functions that you deploy.

For example:

```
fn update context registry phx.ocir.io/ansh81vru1zp/acme-repo
```

7. (Optional) Verify the Fn Project CLI context you've created by viewing the context file. For example, by entering:

```
more ~/.fn/contexts/johns-oci-context.yaml
```

The context file contains:

```
api-url: https://functions.us-phoenix-1.oci.oraclecloud.com
provider: oracle
registry: phx.ocir.io/ansh81vru1zp/acme-repo
```

When you have completed the steps in this topic, go on to Setting the Context for the Fn Project CLI Using the oracle.profile Parameter on page 3090.

**Setting the Context for the Fn Project CLI Using the oracle.profile Parameter**

Before using Oracle Functions, you have to configure the Fn Project CLI to use the new profile you added to the Oracle Cloud Infrastructure CLI configuration file `~/.oci/config` (see Creating a Profile in the Oracle Cloud Infrastructure CLI Configuration File on page 3086). The profile you added contains the credentials of the user account you'll be using to create and deploy functions.

Note that unless you specify otherwise, the Fn Project CLI will attempt to use a profile in the `~/.oci/config` file named default.

If you are using Cloud Shell as your development environment, the Fn Project CLI has already been configured for you to use the profile in the Oracle Cloud Infrastructure CLI configuration file.

The instructions in this topic assume:
- you are not using Cloud Shell as your development environment
- you are using Linux
- you have already completed the steps in Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088

To configure the Fn Project CLI to use the profile you've created for use with Oracle Functions:

1. Log in to your development environment as a functions developer.
2. In a terminal window, configure the Fn Project CLI context with the name of the profile you've created for use with Oracle Functions by entering:

```
fn update context oracle.profile <profile-name>
```

For example:

```
fn update context oracle.profile john-oci-profile
```

When you have completed the steps in this topic, go on to Generating an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry on page 3091.

**Generating an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry**

Before using Oracle Functions, the user account you'll be using to create and deploy functions must have an Oracle Cloud Infrastructure auth token. You use the auth token as the password when logging Docker in to Oracle Cloud Infrastructure Registry

The instructions in this topic assume you have already completed the steps in Setting the Context for the Fn Project CLI Using the oracle.profile Parameter on page 3090.

If the user account already has an auth token, go straight on to Starting Docker on page 3091. Otherwise, if the user account does not have an auth token, generate an auth token now.

To generate an auth token for the user account you'll be using to create and deploy functions:

1. Sign in to the Console as a functions developer.
2. In the top-right corner of the Console, open the Profile menu ( ) and then click User Settings to view the details.
3. On the Auth Tokens page, click Generate Token.
4. In the Generate Token dialog:
   a. Enter a meaningful description for the auth token. For example, John's auth token for use with Oracle Functions. Avoid entering confidential information.
   b. Click Generate Token. The new auth token is displayed. For example, 6aN____________6MqX.
5. Copy the auth token immediately to a secure location from where you can retrieve it later, because you won't see the auth token again in the Console.
6. Close the Generate Token dialog.

When you have completed the steps in this topic, go on to Starting Docker on page 3091.

**Starting Docker**

Before using Oracle Functions, Docker must be running in your development environment. If it is not running, you must start Docker before proceeding.

If you are using Cloud Shell as your development environment, Docker has already been started for you.

The instructions in this topic assume:

- you are not using Cloud Shell as your development environment
- you are using Linux
- you have already completed the steps in Generating an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry on page 3091

To verify that Docker is running:

1. Log in to your development environment as a functions developer.
2. In a terminal window, launch the standard hello-world Docker image as a container to confirm that Docker is running by entering:

```
docker run hello-world
```
3. Do one of the following, depending on the message you see:

- If you see an error message indicating that Docker is not running, you have to start the Docker daemon before proceeding. See the Docker documentation for information about starting Docker on your platform.
- If you see an error message indicating that the network timed out while trying to connect and advising you to check your internet connection or whether you are behind a proxy, your development environment might be behind a corporate proxy server or firewall. In which case, you will probably need to set the http_proxy, https_proxy, and no_proxy environment variables. Ask your network administrator for advice.
- If you see a message like the one shown below, Docker is already running and you can proceed:

  Hello from Docker.
  This message shows that your installation appears to be working correctly.

When you have completed the steps in this topic, go on to Logging in to Oracle Cloud Infrastructure Registry on page 3092.

**Logging in to Oracle Cloud Infrastructure Registry**

Before using Oracle Functions, you have to log Docker in to the Docker registry in which you are going to store your functions as Docker images. This is the Docker registry specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088).

You can store functions in public and private repositories in Oracle Cloud Infrastructure Registry, an Oracle-managed registry built on top of Oracle Cloud Infrastructure.

When you log Docker into a Docker registry, you have to provide the appropriate authentication details. For example, in the case of Oracle Cloud Infrastructure Registry, you have to provide the tenancy Object Storage namespace, the user name, and the user's auth token.

If you are using Cloud Shell as your development environment, you simply have to copy and paste commands from the Getting Started page into the Cloud Shell window. For more information, see Oracle Functions on Cloud Shell QuickStart Guide.

The instructions in this topic assume:

- you are not using Cloud Shell as your development environment
- you are using Linux
- you have already completed the steps in Starting Docker on page 3091

To log Docker into Oracle Cloud Infrastructure Registry:

1. Log in to your development environment as a functions developer.
2. In a terminal window, log in to Oracle Cloud Infrastructure Registry by entering:

   ```bash
docker login <region-key>.ocir.io
   
   where <region-key> is the key for the Oracle Cloud Infrastructure Registry region specified in the Fn Project CLI context (see Creating an Fn Project CLI Context to Connect to Oracle Cloud Infrastructure on page 3088). For example, phx for Phoenix. See Availability by Region on page 5086.
   
   For example:
   ```

   ```bash
docker login phx.ocir.io
   ```
Functions

3. When prompted for **Username**, enter the name of the user you will be using with Oracle Functions to create and deploy functions, in the format:

   `<tenancy-namespace>/<username>`

   where `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy in which to create repositories (as shown on the **Tenancy Information** page). For example, `anzh1vru1zp/jdoe@acme.com`.

   Note that for some older tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, `acme-dev`).

   If your tenancy is federated with Oracle Identity Cloud Service, use the format `<tenancy-namespace>/oracleidentitycloudservice/<username>`.

   You must have already generated an Oracle Cloud Infrastructure auth token for the user you specify (see Generating an Auth Token to Enable Login to Oracle Cloud Infrastructure Registry on page 3091).

4. When prompted for **Password**, enter the user's Oracle Cloud Infrastructure auth token. Having entered the password, Docker might warn you that the password is stored unencrypted in the Docker configuration file. The warning includes a link to the Docker documentation where you can find out how to configure a credential helper. Oracle recommends you review the information in the Docker documentation and consider using an external credentials store for increased security.

When you have completed the steps in this topic, you have completed the configuration tasks for your client environment. Go on to Verifying Your Configuration for Function Development on page 3093 to confirm that the Fn Project CLI can communicate with the API endpoint.

**Verifying Your Configuration for Function Development**

Before using Oracle Functions, it's a good idea to confirm that you have successfully completed the prerequisite steps for using Oracle Functions as described in Preparing for Functions on page 2981 and the Functions QuickStart Guides on page 2963. Specifically, that you have:

- set up your tenancy (see Tenancy Configuration Notes for Oracle Functions on page 3080)
- set up your development environment (see Client Environment Configuration Notes for Oracle Functions on page 3086)

If you have successfully completed the configuration tasks, the Fn Project CLI will be able to communicate with the API endpoint.

To confirm that the Fn Project CLI can communicate with the API endpoint:

1. Log in to your development environment as a functions developer.
2. In a terminal window, try and view a list of applications that have been defined in Oracle Functions by entering:

   ```
   fn list apps
   ```

3. If you see either of the following, you can proceed to create and deploy functions because your system is configured correctly:

   - A message indicating that no applications have been found, which is expected if this is the first time the tenancy has been configured for Oracle Functions.
   - A list of applications that have already been created, which is expected if other users are already using the tenancy for functions development.

4. If you see an error message, it's likely that the Fn Project CLI cannot communicate with the API endpoint due to some incorrect configuration. Do the following:

   - Review the configuration tasks to confirm you completed them as instructed (see Functions QuickStart Guides on page 2963, Tenancy Configuration Notes for Oracle Functions on page 3080, and Client Environment Configuration Notes for Oracle Functions on page 3086).
   - Review the solutions for common problems (see Troubleshooting Oracle Functions on page 3067).
This chapter explains how to monitor the health of your endpoints.

The Health Checks service provides external monitoring to help you determine the availability and performance of any public-facing service, load balancer, or API endpoint.

Overview of the Health Checks Service

The Oracle Cloud Infrastructure Health Checks service provides users with high frequency external monitoring to determine the availability and performance of any publicly facing service, including hosted websites, API endpoints, or externally facing load balancers. By using Health Checks, users can ensure that they are immediately aware of any availability issue affecting their customers.

Health Checks Service Components

The following list describes the key components used in creating a health check.

MONITORS

Monitors allow you to continuously monitor the health of public-facing endpoints. You can configure monitors to use either HTTP and ping protocols. Monitors are classified as either Basic or Premium, based on the configured test interval. A monitor is considered Premium if the test interval is set to 10 seconds, and considered Basic if the test interval is greater than 10 seconds. Behavioral differences do not exist between a Basic and Premium monitor, other than the frequency that the monitor is run.
ON-DEMAND PROBES

On-demand probes allow you to run a one-time probe to assess the health of a public-facing endpoint. You can configure on-demand probes to use either or both HTTP and ping protocols. This feature is only available through the REST API. A limit exists on how many on-demand probes can be run in a 24-hour period. On-demand credits are consumed as the probes are run, and replenished gradually over time.

VANTAGE POINTS

Vantage points are geographic locations from which monitors and probes can be run to your specified target. Oracle Cloud Infrastructure maintains dozens of vantage points around the world.

PROTOCOLS

The Health Checks service allows you to configure both HTTP and ping type monitors. Each type has respective protocols.

Ways to Access the Health Checks Service

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide.

To access the Console, you must use a supported browser. You can use the Console link at the top of this page to go to the sign-in page. Enter your tenancy, user name, and your password.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies. For specific details about writing policies for each of the different services, see Policy Reference on page 3347.

If you're a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Health Checks Service Capabilities and Limits

The Oracle Cloud Infrastructure Health Checks service is limited to 1000 endpoint tests per account.

See Service Limits on page 247 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies and Common Policies. For more details about policies for Health Checks, see Details for the Health Checks Service.

Policy examples:

- To enable all operations on Health Checks for all users in a tenant:

```
Allow any-user to manage health-check-family in tenancy
```
• To enable all operations on Health Checks for all users in a compartment:

```
Allow any-user to manage health-check-family in compartment <Compartment Name>
```

• To enable all operations on Health Checks for a specific user group:

```
Allow group <Your Group Name> to manage health-check-family in compartment <Compartment Name>
```

**Moving Health Checks to a Different Compartment**

You can move health checks from one compartment to another. When you move a health check to a new compartment, its associated monitor and test results moves with it. After the move, health checks are accessible through the SDK, CLI, and Console. For more information, see [Managing Compartments](#).

**Tagging Resources**

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see [Resource Tags](#) on page 243.

**Getting Started With the Health Checks API**

The Health Checks service allows you to configure and deploy monitors and on-demand probes using the Health Checks API. Use the following guide to learn how to set up monitors and probes then retrieve their results using the REST API.

**Note:**

Monitors, metrics, and probes created with the API, SDK and CLI are associated with the region where they were configured. While using the API, you must perform monitor updates (including compartment changes), metrics retrieval, and probe results retrieval in the region where they were configured. However, you can get a list of currently configured monitors and monitor details in every region, no matter where the monitors were configured.

**Authentication and Authorization**

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see [Getting Started with Policies](#). For specific details about writing policies for each of the different services, see [Policy Reference](#) on page 3347.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

**Endpoints**

The Health Checks API can be accessed via the following endpoints:

- https://healthchecks.ap-chuncheon-1.oraclecloud.com/20180501
- https://healthchecks.ap-hyderabad-1.oraclecloud.com/20180501
- https://healthchecks.ap-melbourne-1.oraclecloud.com/20180501
Available Protocols For Probes and Monitors

You can configure monitors and probes to use HTTP or ping requests. You will need to ensure that the endpoint being monitored is configured to accept the specified protocol.

**HTTP** - Configure a GET or HEAD request using HTTP/1.1 to test the target for availability. The probe results are returned in JSON and include the HTTP Status Code and DNS lookup, connection and response timings.

**HTTPS** - Configure an encrypted HTTPS GET or HEAD request to test the availability of any secure hosted target. Defaults to port 443. The probe results are returned in JSON and include the HTTP Status Code and DNS lookup, connection and response timings.

**ICMP** - Configure an ICMP echo request ping. The results include the round trip time (RTT) latency.

**TCP** - Configure a TCP handshake to the specified end point. You should be sure to own this endpoint as testing this connection can be costly to the recipient. The results include the round trip time (RTT) latency.

Create A Monitor

Monitors allow you to monitor the health of endpoints over time. The following example shows how to create an HTTPS monitor that checks the health of www.example.com at an interval of every 30 seconds using a GET request.

```json
POST /20180501/httpMonitors
{
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "protocol": "HTTPS",
    "port": 443,
    "targets": [
        "www.example.com"
    ],
    "timeoutInSeconds": 30,
```
Targets can be either hostnames or IP addresses and the path field can be used to specify an optional path, such as www.example.com/project/help.htm. Optionally, you can specify which geographic locations you would like the monitor to launch from by using the vantagePointNames field. At least one vantage point must be listed when using this field. For a list of available vantage points, see Vantage Points on page 3100.

A 200 response will be returned with the successful creation of a probe and the results of the probe can be retrieved from the URL in the resultsUrl field of the response.

For more information about creating an HTTP monitor, see CreateHttpMonitor.

**Note:**

You can configure a similar style monitors using TCP or ICMP protocols. For more information, see CreatePingMonitor.

### Create An On-Demand Probe

Probes are one-off health assessments of an endpoint that can be deployed at anytime. The following example shows how to create an on-demand HTTP probe that checks the health of www.example.com with a GET request.

```
POST /20180501/httpProbeResults
```

```
{
  "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
  "protocol": "HTTP",
  "targets": [
    "www.example.com"
  ],
  "timeoutInSeconds": 30,
  "method": "GET"
}
```

Targets can be either hostnames or IP addresses and the path field can be used to specify an optional path, such as www.example.com/project/help.htm. Additionally, you can specify which geographic locations you would like the probe to launch from by using the vantagePointNames field. For a list of available vantage points, see Vantage Points on page 3100.
A 200 response will be returned with the successful creation of a probe and the results of the probe can be retrieved from the URL in the resultsUrl field of the response. It will take a few moments for results to display once the tests have been configured.

```
{
    "id": "ocid1.pingprobe.OC2..<unique_ID>",
    "compartmentId": "ocid1.compartment.oc1..<unique_ID>",
    "resultsUrl": "https://healthchecks.us-ashburn-1.oraclecloud.com/20180501/pingProbeResults/ocid1.pingprobe.OC2..<unique_ID>",
    "targets": [
        "www.example.com"
    ],

    "timeoutInSeconds": 30
}
```

For more information about creating a probe, see CreateOnDemandHttpProbe.

**Note:**

You can configure similar style probes using TCP or ICMP protocols. For more information, see CreateOnDemandPingProbe.

## Retrieving Probe And Monitor Results

Probe and monitor results can be retrieved from URL in the resultsUrl field of a monitor or probe creation response. It will take a few moments for results to display once the tests have been configured. Results can also be retrieved at anytime using the following methods:

- **ListPingProbeResults** - For monitors or on-demand probes using TCP or ICMP protocols.
- **ListHttpProbeResults** - For monitors or on-demand probes using HTTP protocols.

Retrieving results for an on-demand probe or monitor requires the probe or monitor's configuration ID as a parameter. On-demand probe and configuration IDs are assigned upon their creation and are returned in the id field of the POST response. You can also use the ListHttpMonitor method to retrieve a list of currently configured monitors and probes using HTTP protocols. Use the ListPingMonitors method to retrieve a list of currently configured monitors and probes using TCP and ICMP protocols.

The following is an example of results retrieved using GET /httpProbeResults/ {probeConfigurationId}.

```
{
    "key": "651b9f3a46041cace0530204060ae27e",
    "probeConfigurationId": "ocid1.httpmonitor.OC2..<unique_ID>",
    "startTime": 1517323711505,
    "target": "www.example.com",
    "vantagePointName": "dgo-nyc",
    "protocol": "HTTPS",
    "connection": {
        "connectDuration": 114,
        "secureConnectDuration": 99,
        "address": "93.184.216.34",
        "port": 443
    },
    "dns": {
        "domainLookupDuration": 29,
        "addresses": [
```
Vantage Points

Vantage points are geographic locations from which monitors and probes can be launched. Oracle Cloud Infrastructure maintains vantage points on the infrastructure of cloud providers around the world, including AWS, IBM, and Azure. The list below is a sampling of the vantage points available. The list of vantage points is dynamic and changes frequently. Use the ListHealthChecksVantagePoints method to return a list of available vantage points.

<table>

### Managing Health Checks

The Health Checks service allows you to monitor the health of IP addresses and hostnames, as measured from geographic vantage points of your choosing, using HTTP and ping probes. After configuring a health check, you can view the monitor's results. The results include the location from which the host was monitored, the availability of the endpoint, and the date and time the test was performed.

### Using the Console

#### To add a health check

**Important:**

If you have selected the HTTPS protocol for this monitor and have entered an IP address as a Target to be monitored, you must specify a Host header with the domain name associated with the TLS certificate for that target. If you do not add the Host header, the TLS connection phase will not complete successfully and the target endpoint will be declared unavailable. Note that this Host header is only required with IP address targets and HTTPS monitors.

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Health Checks**.
2. Click **Create Health Check**.
3. In the **Create Health Check** dialog box, enter the following:

- **Health Check Name**: The name used for the health check. Avoid entering confidential information.
- **Compartment**: Select the compartment the health check runs in.
- **Target(s)**: The IP address or fully qualified domain name (FQDN) of the host being monitored. Additional targets can be added.
- **Vantage Points**: Select the location from which the health of the target is monitored. No more than ten vantage points can be added.
- **Request Type**: Select the type of request sent to monitor the target.
  - **HTTP** - Enter the following:
    - **Protocol**: The network protocol used to interact with your endpoint, such as HTTP protocol, which initializes an HTTP handshake with your endpoint.
    - **Port**: The port for the monitor to look for a connection. The default is port 80 for HTTP. For HTTPS, use port 443.
    - **Path**: The specific path on the target to be monitored.
    - **Header Name**: (Optional) The name displayed in the request header as part of the health check. Avoid entering confidential information.
    - **Header Value**: (Optional) Specifies the data requested by the header. Click + **Additional Header** to add multiple headers in succession.
    - **Method**: Select the HTTP method used for the health check.
    - **Timeout**: Select the maximum time to wait for a reply before marking the health check as failed.
    - **Interval**: Select the period of time between health checks of the target.
  - **Ping** - Enter the following:
    - **Protocol**: The network protocol used to interact with your endpoint, such as HTTP protocol, which initializes an HTTP handshake with your endpoint.
    - **Port**: If you have selected the TCP protocol, enter the port for the monitor to look for a connection. The default port is 80.
    - **Timeout**: Select the maximum time to wait for a reply before marking the health check as failed.
    - **Interval**: Select the period of time between health checks of the target.
  - **Tags**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

4. Click **Create Health Check**.

The health check is added to the health check list. To view more details, click the health check name. It will take a few moments for results to display once the tests have been configured.

**To edit a health check**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Health Checks**.
2. Select the check box for the health check you want to edit.
3. Select **Edit** from the **Actions** drop-down menu.
4. In the **Edit Health Check** dialog box, make the needed changes, and then click **Save**.

**To disable a health check**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Health Checks**.
2. Select the check box for the health check you want to disable.

   **Tip:**
   
   To help find a health check, you can enter the name of the health check in the Search field.

3. Select **Disable** from the Actions drop-down menu.

4. In the confirmation dialog box, click **Disable**.

   The status of the health check changes to **Disabled** in the health check list.

**To duplicate a health check**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Health Checks**.

2. Select the check box for the health check you want to duplicate.

3. Select **Duplicate** from the Actions drop-down menu.

4. In the Create Health Check dialog box, make any updates to the duplicated health check, and then click **Create Health Check**.

**To delete a health check**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Health Checks**.

2. Select the check box for the health check you want to delete.

   **Tip:**
   
   To help find a health check, you can enter the name of the health check in the Search field.

3. Select **Delete** from the Actions drop-down menu.

4. In the confirmation dialog box, click **Delete**.

**To view the history of a health check**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Health Checks**.

2. Click the name of the health check you want to view.

   The list of results for the past 90 days is displayed under **Health Check History**.

   **Tip:**
   
   To help find a result, go to Filters on the left and use the options **Start Date**, **Start Time**, **End Date**, **End Time**, and **Targets**.

3. Click the drop-down arrow beside the **Timestamp** to view the monitor result details. You can use the API to download the data.

**To manage tags for a health check**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Health Checks**.

2. Click the name of the health check you want to view.

3. Click the **Tags** tab to view or edit the existing tags. Or click **Add Tags** to add new ones.

   For more information, see **Resource Tags** on page 243.

**To move a health check to a different compartment**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Health Checks**.

2. In the **Scope** section, select a compartment.

3. Find the health check in the list, click the Actions icon (three dots), and then click **Move Resource**.

4. Choose the destination compartment from the list.

5. Click **Move Resource**.

   For more information, see **Managing Compartments**.
Health Checks

Tip:

If your health checks are continually failing, please ensure that you have permission to monitor the host and that the ports on the host have been configured to receive traffic from Health Checks.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

• Use the CreateHTTPMonitor operation to create a Health Check monitor that uses the HTTP protocol.
• Use the CreatePingMonitor operation to create a Health Check monitor that uses the ping protocol.
• Use the ListHealthChecksVantagePoints to retrieve a list of available vantage points from which to execute monitors.
• Use the UpdateHttpMonitor operation to update the configuration of an HTTP health check monitor. You can also use this operation to disable an HTTP monitor by setting the isEnabled field to false.
• Use the UpdatePingMonitor operation to update the configuration of ping health check monitor. You can also use this operation to disable a ping monitor by setting the isEnabled field to false.
• Use the DeleteHttpMonitor operation to remove an HTTP health check monitor from your setup.
• Use the DeletePingMonitor operation to remove a ping health check monitor from your setup.
• Use the ListHttpProbeResults operation to retrieve the results of an HTTP health check monitor.
• Use the ListPingProbeResults operation to retrieve results of a ping health check monitor.

Health Checks Metrics

You can monitor the health, capacity, and performance of your health checks by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace oci_healthchecks (the Health Checks service).

Overview of the Health Checks Service Metrics

Oracle Cloud Infrastructure Health Checks provides users with high frequency external monitoring to determine the availability and performance of any publicly facing service, including hosted websites, API endpoints, or externally facing load balancers. The Health Checks service metrics help you monitor the performance of your endpoints over a 24 hour period.

Prerequisites

• IAM policies: To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_healthchecks

The metrics listed in the following table are automatically available for each health check that you create. You do not need to enable monitoring on the health check to get these metrics.

Each metric includes the following dimensions:

RESOURCEID

The OCID of the policy to which the metric applies.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP.StatusCode</td>
<td>HTTP(S) Response Status Code</td>
<td>count</td>
<td>The HTTP response code.</td>
<td>vantagePoint resourceId resourceDisplayName statusCode2xx statusCode3xx statusCode4xx statusCode5xx protocol errorMessage</td>
</tr>
<tr>
<td>PING.isHealthy</td>
<td>Ping Test Success Rate</td>
<td>percent</td>
<td>Displays availability of end point being monitored.</td>
<td>vantagePoint resourceId resourceDisplayName protocol errorMessage</td>
</tr>
<tr>
<td>HTTP.DNSLookupTime</td>
<td>HTTP(S) DNS Lookup Time</td>
<td>ms</td>
<td>The time taken for domain name lookup in milliseconds.</td>
<td>vantagePoint resourceId resourceDisplayName protocol icmpCode</td>
</tr>
<tr>
<td>HTTP.TCPConnectTime</td>
<td>HTTP(S) Connection Duration</td>
<td>ms</td>
<td>The total TCP connection duration for the test which applies to both HTTP and HTTPS protocols.</td>
<td>vantagePoint resourceId resourceDisplayName protocol errorMessage</td>
</tr>
<tr>
<td>HTTP.RequestTime</td>
<td>HTTP(S) Request Duration</td>
<td>ms</td>
<td>The total duration of the request in milliseconds.</td>
<td></td>
</tr>
<tr>
<td>HTTP.ResponseTime</td>
<td>HTTP(S) Response Duration</td>
<td>ms</td>
<td>The total duration of response in milliseconds.</td>
<td></td>
</tr>
<tr>
<td>HTTP&gt;TotalDuration</td>
<td>HTTP(S) Total Duration</td>
<td>ms</td>
<td>The total duration of the test run in milliseconds.</td>
<td></td>
</tr>
<tr>
<td>PING.Latency</td>
<td>Ping Latency Measurement</td>
<td>ms</td>
<td>Latency measurement for ping test in milliseconds.</td>
<td></td>
</tr>
</tbody>
</table>

Using the Console
To view metric charts for resources related to a health check monitor
1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Health Checks**.
2. Click the name of the health check you want to view metrics for.
3. Click Metrics.

**To view health check metric charts using monitoring**

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Metrics Explorer**. For **Metric Namespace**, select **oci_healthchecks**.
2. Select a metric to view from the **Metric Name** field.
3. Select a qualifier specified in the Dimension Name field. For example, the dimension **resourceId** is specified in the metric definition for **BasicCount**.
4. Select the value you want to use for the specified dimension in the **Dimension Value** field. For example, the resource identifier for your instance of interest.
5. Click **Update Chart**.

The chart will be updated with the metrics that have been requested.

For more information about monitoring metrics and using alarms, see **Monitoring** on page 4078. For information about notifications for alarms, see **Notifications** on page 4900.

**Using the API**

Use the following APIs for monitoring:

- **Monitoring API** for metrics and alarms
- **Notifications API** for notifications (used with alarms)
Chapter 28

IAM

This chapter explains how to set up identity and access management features such as authentication, single sign-on (SSO), and identity lifecycle management for applications.

IAM

Oracle Cloud Infrastructure Identity and Access Management (IAM) provides identity and access management features such as authentication, single sign-on (SSO), and identity lifecycle management for Oracle Cloud as well as Oracle and non-Oracle applications, whether SaaS, cloud-hosted, or on-premises.

Overview of IAM
Oracle Cloud Infrastructure Identity and Access Management (IAM) provides identity and access management features such as authentication, single sign-on (SSO), and identity lifecycle management for Oracle Cloud as well as Oracle and non-Oracle applications, whether SaaS, cloud-hosted, or on-premises. Employees, business partners, and customers can access applications at any time, from anywhere, and on any device in a secure manner.

IAM integrates with existing identity stores, external identity providers, and applications across cloud and on-premises to facilitate easy access for end users. It provides the security platform for Oracle Cloud, which allows users to securely and easily access, develop, and deploy business applications such as Oracle Human Capital Management (HCM) and Oracle Sales Cloud, and platform services such as Oracle Java Cloud Service, Oracle Business Intelligence (BI) Cloud Service, and others.

Administrators and users can use IAM to help them effectively and securely create, manage, and use a cloud-based identity management environment without worrying about setting up any infrastructure or platform details.

IAM Technologies
Get introduced to some concepts you'll come across when you work with IAM with identity domains.

Oracle Cloud Services
Learn about Software as a Service (SaaS), Data as a Service (DaaS), Platform as a Service (PaaS), and Infrastructure as a Service (IaaS) services used in Oracle Cloud.

Oracle Cloud offers a host of cloud services.

Application services are classified into two categories:
• Software as a Service (SaaS): Provides a software licensing and delivery model in which software is licensed on a subscription basis and is centrally hosted.
• Data as a Service (DaaS): Provides data on demand to a user regardless of geographic or organizational separation of the provider and consumer.

Platform services are also classified into two categories:
• Platform as a Service (PaaS): Provides a platform allowing customers to develop, run, and manage applications without the complexity of building and maintaining the infrastructure typically associated with developing and deploying an application.
• Infrastructure as a Service (IaaS): Provides access to computing resources (that is, virtualized hardware and computing infrastructure) in Oracle Cloud across a public connection.

For a comprehensive list of the available Oracle Cloud SaaS, DaaS, PaaS, and IaaS services, go to https://www.oracle.com/cloud and from the Oracle Cloud menu, select that category of services that interests you. From the page that opens, you can find links to detailed information about each service.

Oracle Cloud securely integrates its different cloud services, customer applications, and cloud services from other vendors. For example; this integration let’s you,
• Embed Oracle Sales Cloud within your own application running on Oracle Java Cloud Service - SaaS Extension.
• Extend Oracle Fusion Customer Relationship Management Cloud Service with a custom application.
• Tie together an Oracle Cloud service with functionality from other sites, such as Salesforce.
• Use an Oracle Cloud service as the infrastructure for building your own applications.

SAML, OAuth, and OpenID Connect
Learn about the basic concepts behind the SAML, OAuth, and OpenID Connect standards used in IAM.

Security Assertion Markup Language (SAML) supports both authentication and authorization and is an open framework for sharing security information on the internet through XML documents. SAML includes three parts:
• SAML Assertion: How you define authentication and authorization information.
• SAML Protocol: How you ask (SAML Request) and get (SAML Response) the assertions you need.
• SAML Bindings and Profiles: How SAML assertions ride on (Bindings) and in (Profiles) industry-standard transport and messaging frameworks.
The OAuth 2.0 token service provided by the Oracle Cloud identity infrastructure provides secure access to the Representational State Transfer (REST) endpoints of cloud services by other cloud services and user applications. OAuth 2.0 provides the following benefits:

- It increases security by eliminating the use of passwords in service-to-service REST interactions.
- It reduces the lifecycle costs by centralizing trust management between clients and servers. OAuth reduces the number of configuration steps to secure service-to-service communication.

IAM leverages the power of OpenID Connect and OAuth to deliver a highly-scalable, multi-tenant token service for securing programmatic access to custom applications by other custom applications, and for federated SSO and authorization integration with these applications:

- Use OAuth 2.0 to define authorization in IAM for your custom applications. OAuth 2.0 has an authorization framework, commonly used for third-party authorization requests with consent. Custom applications can implement both two-legged and three-legged OAuth flows.
- Use OpenID Connect to externalize authentication to IAM for your custom applications. OpenID Connect has an authentication protocol that provides Federated SSO, leveraging the OAuth 2.0 authorization framework as a way to federate identities in the cloud. Custom applications participate in an OpenID Connect flow.

Using the OAuth 2.0 and OpenID Connect standards provides the following benefits:

- Federated SSO between the custom application and IAM. Resource owners (users accessing the custom application) need a single login to access IAM plus all applications integrated. IAM handles the authentication and credentials itself, insulating custom applications. This capability is provided by OpenID Connect with OAuth 2.0.
- Authorization to perform operations on third-party servers with consent. Resource owners can decide at runtime whether the custom applications should have authorization to access data or perform tasks for them. This capability is provided by OAuth 2.0.

**SCIM**

Learn about the basic concepts behind the SCIM standard used in IAM.

With REST APIs, you can use a System for Cross-Domain Identity Management (SCIM) to securely manage your IAM resources, including identities and configuration data. These APIs provide an alternative to using the web-based user interface when you want to use Identity Domains for your own UI or for clients.

You can manage users, groups, and applications, perform identity functions and administrative tasks, and manage your identity domain settings.

IAM provides SCIM templates to help you integrate your applications for provisioning and synchronization.

**IAM Components**

IAM uses the components described in this section. To better understand how the components fit together, see Example Scenario on page 3299.

**RESOURCE**

The cloud objects that your company's employees create and use when interacting with Oracle Cloud Infrastructure (for example, compute instances, block instances, block storage volumes, virtual cloud networks, subnets, etc.), third-party applications, Software-as-a-Service (SaaS) applications, on-premises software, and retail web applications.

**USER**

An individual employee or system that needs to manage or use your company's Oracle Cloud Infrastructure resources. Users might need to launch instances, manage remote disks, work with your virtual cloud network, etc. End users of your application are not typically IAM users. Users have one or more IAM credentials (see User Credentials on page 3124).

**GROUP**

A collection of users who all need the same type of access to a particular set of resources or compartment.
DYNAMIC GROUP
A special type of group that contains resources (such as compute instances) that match rules that you define (thus the membership can change dynamically as matching resources are created or deleted). These instances act as "principal" actors and can make API calls to services according to policies that you write for the dynamic group.

NETWORK SOURCE
A group of IP addresses that are allowed to access resources in your tenancy. The IP addresses can be public IP addresses or IP addresses from a VCN within your tenancy. After you create the network source, you use policy to restrict access to only requests that originate from the IPs in the network source.

COMPARTMENT
A collection of related resources. Compartments are a fundamental component of Oracle Cloud Infrastructure for organizing and isolating your cloud resources. You use them to clearly separate resources for the purposes of measuring usage and billing, access (through the use of policies), and isolation (separating the resources for one project or business unit from another). A common approach is to create a compartment for each major part of your organization. For more information, see “Setting Up Your Tenancy” in the Oracle Cloud Infrastructure Getting Started Guide.

TENANCY
The root compartment that contains all of your organization's Oracle Cloud Infrastructure resources. Oracle automatically creates your company's tenancy for you. Directly within the tenancy are your IAM entities (users, groups, compartments, and some policies; you can also put policies into compartments inside the tenancy). You place the other types of cloud resources (e.g., instances, virtual networks, block storage volumes, etc.) inside the compartments that you create.

POLICY
A document that specifies who can access which resources, and how. You can write policies to control access to all of the services within Oracle Cloud Infrastructure. Access is granted at the group and compartment level, which means you can write a policy that gives a group a specific type of access within a specific compartment, or to the tenancy itself. If you give a group access to the tenancy, the group automatically gets the same type of access to all the compartments inside the tenancy. For more information, see Example Scenario on page 3299 and How Policies Work on page 3307. The word "policy" is used by people in different ways: to mean an individual statement written in the policy language; to mean a collection of statements in a single, named "policy" document (which has an Oracle Cloud ID (OCID) assigned to it); and to mean the overall body of policies your organization uses to control access to resources.

HOME REGION
The region where your IAM resources reside. All IAM resources are global and available across all regions, but the master set of definitions reside in a single region, the home region. You must make changes to your IAM resources in your home region. The changes will be automatically propagated to all regions. For more information, see Managing Regions on page 3287.

FEDERATION
A relationship that an administrator configures between an identity provider and a service provider. When you federate Oracle Cloud Infrastructure with an identity provider, you manage users and groups in the identity provider. You manage authorization in Oracle Cloud Infrastructure's IAM service.

IDENTITY DOMAIN
An identity domain is a container for managing users and roles, federating and provisioning of users, secure application integration through Oracle Single Sign-On (SSO) configuration, and OAuth administration. It represents a user population in Oracle Cloud Infrastructure and its associated configurations and security settings (such as MFA).
The Administrators Group, Policy, and Administrator Roles

When your company signs up for an Oracle account and identity domain, Oracle sets up a default administrator for the account. This person will be the first IAM user for your company and will be responsible for initially setting up additional administrators. Your tenancy comes with a group called Administrators, and the default administrator automatically belongs in this group. You can't delete this group, and there must always be at least one user in it.

Your tenancy also automatically has a policy that gives the Administrators group access to all of the Oracle Cloud Infrastructure API operations and all of the cloud resources in your tenancy. You can neither change nor delete this policy. Any other users you put into the Administrators group will have full access to all of the services. This means they can create and manage IAM resources such as groups, policies, and compartments. And they can create and manage cloud resources such as virtual cloud networks (VCNs), instances, block storage volumes, and any other new types of Oracle Cloud Infrastructure resources that become available in the future.

Aside from the default administrator and default policy, you can assign user accounts to predefined administrator roles in order to delegate administrative responsibilities. Administrator roles exist within identity domains. You can assign any user account in an identity domain to one or more administrator roles in that identity domain. While policies give access to compartments and the resources in those compartments, if you use administrator roles, you can grant access to resources without learning policy language or writing and maintaining policies.

Granting a user or a group the Identity domain administrator role in the Default domain is equivalent to granting them full administrator permissions for the tenancy. This behavior applies to the Default domain only. Granting users or groups the Identity domain administrator role for domains other than the Default domain, grants them full administrator permissions to only that domain.

IAM evaluates policies and administrator roles together when determining whether a user has access to resources and what that user can do with those resources. If the tenancy already relies on policies, you can continue using them. You can even write policies to grant access to specific identity domains. However, Oracle recommends that you start using administrator roles to grant users access to resources in identity domains moving forward.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 6152.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For the REST API Reference for the IAM API, see Identity and Access Management Service API. For the REST API Reference for the IAM Identity Domains API, see IAM Identity Domains API. For general information about using the API, see REST APIs on page 6339.

Documentation to Use for Cloud Identity

To help you administer identity in Oracle Cloud Infrastructure (OCI), you need the right documentation.

The documentation that you choose depends on the following factors:

- Whether your OCI region has been updated to use Identity and Access Management (IAM) identity domains
- Whether your Oracle Identity Cloud Service (IDCS) stripes have been migrated to IAM identity domains

Read the following sections to find the documentation that’s right for you.

Do You Have Access to Identity Domains?

Sign in to the Oracle Cloud Console. In the navigation menu, click Identity & Security. Under Identity, check for Domains. If you see Domains, your cloud account has been updated.
Region with identity domains

Region without identity domains
If you sign in and see the IDCS Admin Console instead of the Oracle Cloud Console, as shown in the following image, your stripes haven't been migrated into IAM. You don't have access to identity domains.

Identity Cloud Service
Which documentation do you need?

After determining whether your region was updated or whether your IDCS stripes migrated, choose the right documentation for you.

<table>
<thead>
<tr>
<th>Has your region been updated?</th>
<th>Use this documentation.</th>
</tr>
</thead>
</table>
| I see **Domains** in the Console. My region was updated. | When using the Console:  
  • To administer IAM in regions with identity domains, see [*Oracle Cloud Infrastructure Identity and Access Management*](#).  
  • For user self-service instructions, such as setting up MFA, see the [*IAM User Guide*](#).  
  When using the API:  
  • To manage identity domains (for example, creating or deleting a domain), see [*IAM API*](#).  
  • To manage resources (for example, users and groups) within identity domains, see [*IAM Identity Domains API*](#).  
  If your region has been updated recently, for information about what to expect post update, see:  
  • [*OCI IAM Identity Domains: What OCI IAM customers need to know*](#) |
<table>
<thead>
<tr>
<th>Has your region been updated?</th>
<th>Use this documentation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>I don't see <strong>Domains</strong> in the Console. My region wasn't updated.</td>
<td>• <strong>OCI IAM Identity Domains: What Oracle IDCS customers need to know</strong></td>
</tr>
</tbody>
</table>
| I see the IDCS Admin Console. My stripes weren’t migrated to identity domains. | To use the Console to administer IAM in regions without identity domains, see **Oracle Cloud Infrastructure Identity and Access Management**.  
To use the API to administer IAM in regions without identity domains, see **IAM API**.  
For information about what to expect when the update happens, see **OCI IAM Identity Domains: What OCI IAM customers need to know**. |

### IAM Identity Domain Types

#### Learn about identity domain types.

An IAM identity domain is deployed with one of five identity domain types. Each identity domain type is associated with a different set of features and object limits. Use this information to decide which domain type is appropriate for what you want to do.

This section summarizes:

- The different identity domain types
- SKUs associated with each
- Object limits
- Rate limits
- Meters for each identity domain type

### Understand Identity Domain Types

Learn about the features associated with each identity domain type.

IAM has five different domain types to suit different organizational needs. Start here to understand which suits your requirements best, and which type to choose when you create a domain.

Here's a summary of the domain types. Decide which looks closest to what you need and check the features and limits that you get with that domain type to decide which best suits your purposes.

#### Free

When you create an OCI tenancy, you are automatically provisioned with a Free tier identity domain. This domain type allows you to use IAM to manage access to OCI Infrastructure as a Service and PaaS resources. Use this domain type to start to use and understand IAM, and to manage access to OCI Infrastructure as a Service and PaaS resources.
It includes everything you need. But if you find you need extra features or higher limits, you can change to a different identity domain type.

**Use case:** Your organization uses Oracle Cloud and your employees need secure access to subscribed OCI services. Your users might currently be managed in Active Directory or a third-party Identity Provider. As you consider how IAM can help manage access to third-party applications, you can sign up for a 30-day Oracle Cloud promotion and try extra features.

**Oracle Apps**

Many Oracle Applications automatically provision an Oracle Apps identity domain which allows you to use IAM to manage access to the subscribed application. It includes everything you need. But if you find you need extra features or higher limits, you can change to a different identity domain type.

**Use Case:** Your organization has a vested interest in Oracle SaaS, PaaS, or GBU applications, and you would like your users to seamlessly authenticate across all Oracle cloud applications without having to present credentials each time. You want to use modern authentication and authorization features for your users such as passwordless authentication, FIDO2 hardware tokens, and adaptive security. You might also have a one or two non-Oracle applications that you’d like users to seamlessly move across without having to reauthenticate.

**Oracle Apps Premium**

Oracle Apps Premium domains add support for hybrid IAM including the proxies, gateways, and bridges which extend the service to on-prem or OCI-hosted Oracle applications such as Oracle E-Business Suite, PeopleSoft, and Oracle Database. This domain type is limited to use with Oracle applications.

**Use Case:** Your organization is already using Oracle SaaS, PaaS, or GBU applications. You would like your users to seamlessly authenticate to on-premises or cloud-hosted Oracle applications such as E-Business Suite, JD Edwards, PeopleSoft, Oracle Database, and Oracle Linux. You want to use modern authentication and authorization features for your users such as passwordless authentication, FIDO2 hardware tokens, and adaptive security. You might also want bidirectional synchronization with AD or other on-prem systems and you might have several non-Oracle applications that you’d like users to seamlessly move across without having to reauthenticate.

**Premium**

Premium identity domains provide the full IAM feature set for workforce use-cases giving you enterprise-ready access management across hybrid IT environments. It gives you support for all apps and services, and for third-party applications. If you are standardizing on Oracle as your enterprise identity and access manager provider, this is the domain type you want.

**Use Case:** You want a full-featured Identity-as-a-Service (IDaaS) solution that helps you manage workforce authentication and access to all of your Oracle and non-Oracle applications whether they’re SaaS apps, on-premises enterprise apps, or apps that are hosted in the cloud. You want to use modern authentication and authorization features for your users such as passwordless authentication, FIDO2 hardware tokens, and adaptive security. You might also want automated provisioning and deprovisioning of accounts across these systems.

**External User**

External identity domains provide a robust IAM feature set for non-employee use-cases, consumer-facing IAM, and custom app development. The functionality provides relevant features for these scenarios such as user self-service, social login, and consent management.

**Use Case:** You want a full-featured Identity-as-a-Service (IDaaS) solution that helps you manage authentication and access to custom or consumer-facing applications. The solution should support social login, user self-service password and profile management, and terms of use consent. And you might need the solution to scale for millions of users.

**Feature Availability for Identity Domain Types**

This table shows the features available to each domain type.

1. External or third-party apps are defined as either commercial applications offered by a provider other than Oracle or as custom-developed applications (including, for example, applications built on OCI using Visual Builder Cloud Service).

2. SaaS Extensions are custom-developed applications that are only used as extensions to subscribed Oracle SaaS applications such as HCM, ERP, SCM, and so on. The sole purpose of these applications is to augment Oracle SaaS apps.
IAM Object Limits

This table shows the limits of the number of each type of object for each identity domain type.

You can create different domain types subject to the limit allowed by your subscription type. To find out the identity domain limits for each subscription type, see IAM With Identity Domains Limits on page 267.

1 Non-Oracle or third-party apps are defined as either commercial applications offered by a provider other than Oracle or as custom-developed applications (including, for example, applications built on OCI using Visual Builder Cloud Service).

### API Rate Limits

Oracle APIs are subject to rate limiting to protect the API service usage for all of Oracle's customers.

If you reach the API limit for the identity domain type, then IAM returns a 429 error code.

<table>

</tr>
</tbody>
</table>

### Other Restrictions

These restrictions are for Bulk, Import, and Export for all tiers:

- Payload size: 1 MB
- Bulk API: 50 operations limit per call
• Only one of these can be run at a time:
  • Import: For Users, Groups & App Role Memberships
  • Full sync from apps
  • Bulk APIs
  • Export: For Users, Groups & App Role Memberships
• CSV Import: 100 K rows limit per CSV & Max file size: 10 MB
• CSV Export: 100 K rows limit

**Meters for Identity Domain Types**

Free and Oracle Apps identity domain types do not use meters.

Oracle Apps Premium, Premium, and External User identity domain types use these meters:

• **Users per Month**: The number of active and inactive users in the system, reported per hour. These meters are aggregated at the end of the billing cycle.
• **SMS**: The number of SMS messages sent from the system, reported every hour. These meters are aggregated at the end of the billing cycle.
• **Tokens**: The number of tokens issued by the system, reported every hour.
• **Replicated Users per Month**: If you configure replication to more regions, this meter applies to the number of active and inactive users in each replicated region, reported per hour. These meters are aggregated at the end of the billing cycle.

After you have provisioned your service, Oracle Cloud Infrastructure has tools to help you analyze and understand the costs associated with your account. See [Checking Your Expenses and Usage](#) on page 81.

**Changing your Identity Domain Type**

You can change from one identity domain type to another.

When you change the domain type, IAM validates the change you are making.

1. You cannot change the default domain to External User identity domain type.
2. Your subscription type controls the number of identity domains of each type. If the change would exceed the number of identity domains of that type for your subscription type, you cannot change to the new identity domain type. See [*IAM With Identity Domains Limits*](#) on page 267.
3. If the number of objects of any type in your identity domain is higher than is allowed in the target identity domain type, you cannot change to the new identity domain type. See [*IAM Object Limits*](#) on page 3122.
4. The features available in your current identity domain type are checked. See [*Feature Availability for Identity Domain Types*](#) on page 3117. A warning message appears reminding you to exercise caution when changing from one identity domain type to another. You can proceed after the warning message, but some of your existing features might no longer work.
5. You can only change an identity domain to the Oracle Apps identity domain type if you have at least one Oracle App registered in that identity domain.

**User Credentials**

There are several types of credentials that you manage with Oracle Cloud Infrastructure Identity and Access Management (IAM):

• **Console password**: For signing in to the Console, the user interface for interacting with Oracle Cloud Infrastructure. Note that federated users can't have Console passwords because they sign in through their identity provider. See [*Federating with Identity Providers*](#) on page 3602.
• **API signing key (in PEM format)**: For sending API requests, which require authentication.
• **Auth token**: An Oracle-generated token that you can use to authenticate with third-party APIs. For example, use an auth token to authenticate with a Swift client when using Recovery Manager (RMAN) to back up an Oracle Database System (DB System) database to Object Storage.
• **Customer Secret Keys**: For using the Amazon S3 Compatibility API with Object Storage. See [*Amazon S3 Compatibility API*](#) on page 5064.
• **OAuth 2.0 Client Credentials**: For interacting with the APIs of those services that use OAuth 2.0 authorization. See OAuth 2.0 Client Credentials on page 3126.

• **SMTP Credentials**: For using the Email Delivery service.

**Important:**

API signing keys are different from the SSH keys you use to access a compute instance (see Security Credentials on page 209). For more information about API signing keys, see Required Keys and OCIDs on page 6103. For more information about instance SSH keys, see Managing Key Pairs.

**User Password**

When the user signs in to the Console the first time, they’ll be immediately prompted to change the password. If the user waits more than 7 days to initially sign in and change the password, it will expire and an administrator will need to reset the password for the user.

After the user successfully signs in to the Console, they can use Oracle Cloud Infrastructure resources according to permissions they’ve been granted through policies.

**Note:**

A user automatically has the ability to change their password in the Console. An administrator does not need to create a policy to give a user that ability.

**Changing a Password**

If a user wants to change their own password *sometime after* they change their initial one-time password, they can do it in the Console. Remember that a user can automatically change *their own* password; an administrator does not need to create a policy to give the user that ability.

For more information, see To Change your Console Password on page 3583.

**If a User Needs Their Console Password Reset**

If a user forgets their Console password and also has no access to the API, they can use the Console’s **Forgot Password** link to have a reset password link sent to the email address configured for the user account. (All user profiles require an email address.)

Users can also ask an administrator to reset their password for them. All administrators (and anyone else who has permission to the tenancy) can reset Console passwords. The process of resetting the password generates and sends a reset password email. The user will need to change their password before the link expires and before they can sign in to the Console again.

If you’re an administrator who needs to reset a user’s Console password, see To Reset Another User’s Console Password on page 3583.

**If a User Is Blocked from Signing In to the Console**

If a user tries to sign in to the Console and is unsuccessful more times in a row than is allowed by the identity domain’s password policy, they will be automatically blocked from further attempts. If automatic account unlock is not enabled for the identity domain by the password policy, the user must contact an administrator to get unblocked (see To Unblock a User on page 3584).

**API Signing Keys**

A user who needs to make API requests must have an **RSA public key in PEM format (minimum 2048 bits)** added to their IAM user profile and sign the API requests with the corresponding private key (see Required Keys and OCIDs on page 6103).

**Important:**

A user automatically has the ability to generate and manage *their own* API keys in the Console or API. An administrator does not need to write a policy.
IAM

To give the user that ability. Remember that a user can't use the API to change or delete their own credentials until they themselves save a key in the Console, or an administrator adds a key for that user in the Console or the API.

If you have a non-human system that needs to make API requests, an administrator needs to create a user for that system and then add a public key to the IAM service for the system. There's no need to generate a Console password for the user.

For instructions on generating an API key, see To Add an API Signing Key on page 3584.

**OAuth 2.0 Client Credentials**

Note:

OAuth 2.0 Client Credentials are not available in the United Kingdom Government Cloud (OC4).

OAuth 2.0 client credentials are required to interact programmatically with those services that use the OAuth 2.0 authorization protocol. The credentials enable you to obtain a secure token to access those service REST API endpoints. The allowed actions and endpoints granted by the token depend on the scopes (permissions) that you select when you generate the credentials. For more information, see Working With OAuth 2.0 Client Credentials on page 3582.

**Auth Tokens**

Auth tokens are authentication tokens generated by Oracle. You use auth tokens to authenticate with third-party APIs that do not support the Oracle Cloud Infrastructure signature-based authentication, for example, the Swift API. If your service requires an auth token, the service-specific documentation instructs you to generate one and how to use it.

**Working with Identity Domains**

Manage IAM resources.

**Managing Identity Domains**

An identity domain is a container for managing users and roles, federating and provisioning of users, secure application integration through Oracle Single Sign-On (SSO) configuration, and OAuth administration. It represents a user population in Oracle Cloud Infrastructure and its associated configurations and security settings (such as MFA).

**Overview**

Identity domains are like other OCI resources. As an administrator, you can create, move, tag, and delete an identity domain. Oracle Cloud Infrastructure access policies can be written to allow users in a given domain to access resources in other domains. You can also assign user accounts to predefined administrator roles to delegate administrative responsibilities within a domain. For more information about administrator roles and the privileges associated with each role, see Understanding Administrator Roles on page 3295.

You manage identity domains (for example, creating or deleting a domain) using the user interface or the IAM API. You manage resources (for example, users and groups) within an identity domain using the user interface or with the SCIM-based IAM Identity Domains API.

Each tenancy includes a **Default** identity domain created in the root compartment that contains the initial tenant administrator user and group and a default Policy that allows administrators to manage any resource in the tenancy. The **Default** identity domain lives with the lifecycle of the tenancy and can’t be deleted.

You can create additional identity domains. Multiple identity domains are useful when you need separate environments for a single cloud service or application (for example, one environment for development and one for production). For added security, you can configure each identity domain to have its own Password and Sign-On policies. An identity domain can also be configured to enable an identity domain for consumer-facing applications and allow consumer users to perform self-registration and social login.
You can upgrade a domain to a different domain type. Each *identity domain type* is associated with a different set of features and object limits. For information to help you decide which domain type is appropriate for what you want to do, see IAM Identity Domain Types on page 3116.

Users in identity domains can request access to groups and applications. Users can also perform self-service tasks such as updating profile information, changing passwords, and configuring settings for 2-Step Verification.

**Information for Existing IAM and IDCS Administrators**

If you're an existing IAM or IDCS administrator and you don't see identity domains in your regions, read the following information to learn what to expect when the update happens.

- OCI IAM Identity Domains: What OCI IAM customers need to know
- OCI IAM Identity Domains: What Oracle IDCS customers need to know

If you're an existing IAM or IDCS administrator and your region has been updated recently, read the following information to learn about what to expect post update.

- OCI IAM Identity Domains: What OCI IAM customers need to know
- OCI IAM Identity Domains: What Oracle IDCS customers need to know

**Required Policy or Role**

To manage identity domain settings, you must have one of the following access grants:

- Be a member of the Administrators group
- Be granted the Identity Domain Administrator role
- Be a member of a group granted manage domains

To understand more about policies and roles, see The Administrators Group, Policy, and Administrator Roles on page 3112, Understanding Administrator Roles on page 3295, and Understanding Policies on page 3298.

**The Default Identity Domain**

Each tenancy includes a Default identity domain in the root compartment.

A Default identity domain:

- Can’t be deactivated or deleted. (Lives with the lifecycle of the tenancy.)
- Can’t be hidden from the sign-in page.

The Default identity domain contains the initial tenant Administrator user and Administrators group and a default policy that allows administrators to manage any resource in the tenancy. The Administrators policy and the Administrators group may not be deleted and there must be at least one user in the Administrators group. You can also assign user accounts to predefined administrator roles to delegate administrative responsibilities it the Default domain.

Granting a user or a group the Identity domain administrator role in the Default domain is equivalent to granting them full administrator permissions for the tenancy. This behavior applies to the Default domain only. Granting users or groups the Identity domain administrator role for domains other than the Default domain, grants them full administrator permissions to only that domain.

You can upgrade a domain to a different domain type. Each *identity domain type* is associated with a different set of features and object limits. For information to help you decide which domain type is appropriate for what you want to do, see IAM Identity Domain Types on page 3116.

**Creating Identity Domains**

To create an identity domain, administrators only need to know which identity domain type they want to create, in which compartment to create it, and the new identity domain administrator’s sign-in credentials, if needed. The default groups created in a new identity domain are All Tenant Users, and Administrators. During identity domain creation, if you choose to create an administrative user for the identity domain, that administrator is placed in the Administrators group. The Administrators group may not be deleted and there must be at least one user in the group. Unlike the Default identity domain, administrators can hide any identity domain they create from the sign-in page.
You can upgrade a domain to a different domain type. Each identity domain type is associated with a different set of features and object limits. For information to help you decide which domain type is appropriate for what you want to do, see IAM Identity Domain Types on page 3116.

**Note:**

Granting a user or a group the Identity domain administrator role in the Default domain is equivalent to granting them full administrator permissions for the tenancy. This behavior applies to the Default domain only. Granting users or groups the Identity domain administrator role for domains other than the Default domain, grants them full administrator permissions to only that domain.

### Using Multiple Identity Domains

Create and manage multiple identity domains (for example, one domain for development and one for production) each with different identity and security requirements to protect your applications and Oracle Cloud services.

There are several benefits to using multiple identity domains. By having separate identity domains, the users who work in one identity domain don't impact the work of users in another identity domain. Using multiple identity domains can help you maintain the isolation of administrative control over each identity domain. This is necessary if, for example, your security standards prevent development user IDs from existing in the production environment, or require that different administrators have control over different environments.

Each tenancy contains a **Default** identity domain, the identity domain which comes with your tenancy. Administrators can create as many additional identity domains as their license allows. Administrators can:

- Create additional identity domains and be the identity domain administrator for them or assign another user to be the administrator.
- Create additional identity domains and, as part of the identity domain creation process, assign users to be identity domain administrators of the identity domains.
- Delegate the creation of additional identity domains to other administrators.

An identity domain administrator is assigned to an identity domain during the creation of the identity domain. Although the identity domain administrator identity may have the same user name as a user in the Default identity domain, they are different users who might have different privileges in each identity domain, and will have separate passwords.

The identity domain administrator can use the entire feature set of the identity domain. In an identity domain, the identity domain administrator can:

- Manage users, groups, applications, system configuration, and security settings.
- Perform delegated administration by assigning users to different administrative roles.
- Enable and disable Multi-Factor Authentication (MFA), configure MFA settings, and configure authentication factors.
- Create self-registration profiles to manage different sets of users, approval policies, and applications.

### Limits on Identity Domains

Each identity domain type is associated with a different set of features and object limits.

See IAM Identity Domain Types on page 3116 for object limits, rate limits, and meters for each identity domain type.

See Service Limits on page 247 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

### Changing Identity Domain Types

Upgrade your current identity domain type by changing the domain type.

See Understand Identity Domain Types on page 3116 to learn about the different domain types and the features associated with each one.
Identity Domains and Region Expansion
This topic covers information about identity domains and region expansion.

Default Identity Domain
You can’t change to which regions the Default domain replicates. The Default domain always replicates to all regions to which the tenant is subscribed. When an administrator subscribes to another region, then only the Default domain replicates to that region.

The Default domain's home region is the tenancy's home region. This cannot be changed.

Additional Identity Domains
Additional identity domains can have their own home region, but only within the set of regions the tenancy is subscribed to. Additional identity domains can also be replicated to regions within the set of regions the tenancy is subscribed to.

To take advantage of the Disaster Recovery (DR) feature which establishes a DR region outside of the primary region, you might need to update your firewall policies to enable communication with the additional (DR) regions. Refer to OCI documentation for details.

Moving Identity Domains
You can’t move the Default identity domain from the root compartment of the tenancy.

You can move any other identity domain to a different compartment within the same tenancy. When you move a domain all its resources are moved with it. For more information about moving resources, see Moving Resources to a Different Compartment on page 3275

Deactivating Identity Domains
Domains must be deactivated before they are deleted.

The Default identity domain and the identity domain to which you’re signed in can’t be deactivated.

Before deactivating an identity domain, all Cloud, Oracle, Custom, and Enterprise applications must be deactivated. All applications created by App Services in Oracle Cloud Services (like AnalyticsINST-OAC1) must also be deactivated, but “entitlement” apps in Oracle Cloud Services like (ADWC) do not need to be deactivated.

Immediately after the administrator starts deactivating an identity domain, the identity domain moves to a deactivating state and users won't be able to authenticate at this point.

Deleting Identity Domains
After the applications have been deactivated, an administrator can deactivate the identity domain and delete it. Deleting an identity domain invalidates any IAM Policy that references it, and all resources in the identity domain are deleted. Deleted domains don’t display in the identity domain Console.

Recovering Domains
Administrators can’t recover a deleted identity domain. See Getting Help and Contacting Support on page 152 to contact Oracle support to recover a deleted identity domain.

Tagging Resources
You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 243.

Disaster Recovery and Domains
To take advantage of the Disaster Recovery (DR) feature which establishes a DR region outside of the primary region, you might need to update your firewall policies to enable communication with the additional (DR) regions. Refer to OCI documentation for details.
Using the Console
Viewing Identity Domains for a Tenancy
View the identity domains associated with a tenancy.

1. Open the navigation menu and click Identity & Security. Under Identity, click Domains. You will see a table with a list of the identity domains for the tenancy. If you only have one identity domain, it will be the Default identity domain. For more information about the Default domain, see The Default Identity Domain on page 3127.

2. (Optional) Change the Compartment, if necessary.

3. (Optional) In the table, you can:
   - See the details of the identity domain, by clicking the name.
   - Access the Users page of the identity domain, by clicking the Users link.
   - Access the Groups page of the identity domain, by clicking the Groups link.
   - Copy the domain OCID.

Viewing Identity Domain Details
View and copy information from the details tab.

Open the navigation menu and click Identity & Security. Under Identity, click Domains. Select the identity domain you want to work in.

The Domain information tab of the identity domain is displayed. From this tab, you can view or copy:

- OCID.
- Description
- Domain URL

Copying an Identity Domain OCID
OCIDs can be lengthy strings. Copy the OCID so that you can paste it in the search field when searching for resources related to an OCID in a tenancy. Also, OCIDs can be used to specify a group or a compartment in a policy.

2. Click a link for an identity domain.
3. Next to the OCID field, click Copy.

The OCID is copied to the clipboard.

Creating an Identity Domain

2. Click Create domain.
3. On the **Create domain** page, enter the following:

- **Display name**: Give the identity domain a name. Use only letters, numerals, hyphens, periods, or underscores. The name can contain up to 100 characters.

  **Note:**
  
  Choose your Display name carefully. Changing the identity domain Display name has consequences, for example, bookmarked URLs need updated to use the new Display name.

  - **Description**: Enter a description.
  - **Domain type**: Choose from one of the available **Domain types**. For information to help you decide which domain type is appropriate for what you want to do, see IAM Identity Domain Types on page 3116.
  - **Domain administrator**: If you want to use your administrative user account for this identity domain, then uncheck **Create an administrative user for this account**. Otherwise, enter the details of the user you want to administer this identity domain. See <topic title> for a more information about administrator roles.
  - Optionally, choose a different compartment.
  - To add tagging, click **Show Advanced Options** and enter the tagging details.

4. Click **Create Domain**.

   Ensure that the identity domain status is **Creating**.

   **Changing an Identity Domain Type**
   
   You can upgrade your identity domain by changing the domain type.

   You can upgrade a domain to a different domain type. Each **identity domain type** is associated with a different set of features and object limits. For information to help you decide which domain type is appropriate for what you want to do, see IAM Identity Domain Types on page 3116.

   For more information for what validations to expect when changing domain types, see Changing your Identity Domain Type on page 3124.

   1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in.
   2. Under Domain type, click **Change domains type**.
   3. Click the domain type to which you want to upgrade.
   4. Click **Change domain type**.
   5. Click **Save**.

   **Viewing or Editing Tags**
   
   You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 243.

   1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in.
   2. Click the **Tags** tab to see the tags defined for the identity domain.
   3. Click **Add Tags** to add more tags to the identity domain.

   **Editing Identity Domain Details**
   
   You can edit certain details for an identity domain. For example, you can choose whether to show the identity domain on login or upgrade your domain type.

   1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in.
2. Click **Edit domain**. Change any of the following settings:
   - Display name. Use only letters, numerals, hyphens, periods, or underscores. The name can contain up to 100 characters.

   **Note:**
   Choose your Display name carefully. Changing the identity domain Display name has consequences, for example, bookmarked URLs need updated to use the new Display name.

   - Description
   - Compartment
   - Domain type. To upgrade, see IAM Identity Domain Types on page 3116.
   - Show identity domain on login

3. Click **Save**.

*Moving Resources to a Different Compartment*

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in.

2. Click **Move resource**.

3. Choose a new compartment and then click **Move Resource**.

*Resetting All Passwords for a Domain*

Resetting all passwords for an identity domain resets the passwords for all users and administrators in the identity domain, including the identity domain administrators. After the passwords are reset, users and administrators will receive an email notification, requesting them to reset their passwords.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in.

2. Click **Reset all passwords**.

3. Confirm resetting all passwords for the identity domain.

*Managing Regions for Identity Domains*

You can replicate an identity domain to multiple regions if the tenancy is subscribed to multiple regions.

Ensure that the tenancy is subscribed to the regions to which you want to replicate the identity domain. For more information about the home regions and the basics of managing your region subscriptions, see Managing Regions on page 3287. For more information about the replication behavior of the Default domain versus additional domains you create, see Identity Domains and Region Expansion on page 3129.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in.

2. Click **More Actions**, and then **Manage regions**.

   The Manage regions window displays with a list of regions to which your tenancy is subscribed.

3. For the region to which you want to replicate, click **Enable replication**.

4. Confirm the replication.

*Deactivating an Identity Domain*

Identity domains must be first deactivated to delete them.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in.

2. Click **More Actions**, and then **Deactivate**.

3. Confirm the deactivation.

   The identity domain will be in an **Inactive** status.
**Deleting an Identity Domain**

First, deactivate the apps in the identity domain, deactivate the identity domain, and then you can delete it.

Deleting an identity domain invalidates any IAM Policy that references it.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in.
2. Click **Delete**.
3. Confirm the deletion.

**Managing Domain Settings**

Domain settings are applied to this identity domain in the Cloud. You can specify settings such as the time zone, password recovery email, and language.

**Required Policy or Role**

To change domain settings, you must have one of the following access grants:

- Be a member of the Administrators group
- Be granted the Identity Domain Administrator role or the Security Administrator role
- Be a member of a group granted `manage domains`

To understand more about policies and roles, see The Administrators Group, Policy, and Administrator Roles on page 3112, Understanding Administrator Roles on page 3295, and Understanding Policies on page 3298.

**Using the Console**

**Changing Domain settings**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Settings** and then **Domain settings**.
3. Set the locale. Users can override the default time zone and language settings in the **My Profile Details** tab in the **My Profile** console.
   - To specify a default time zone, from the **Timezone Setting** list, select a time zone.
   - To specify a default language, from the **Language Setting** list, select a language.

   **Important:**

   Choose the language of the target audience. Do not choose a country-specific language unless you are targeting a specific country. For example, choose **French** to display the text to all **French** users. Choose **French (Canada)** to display the text to all **Canadian French** users but not other **French** speaking users.

4. Set the **Access Signing Certificate** option.
   - Turn on this option to allow clients to access the tenant signing certificate and the SAML metadata without logging in to the identity domain.
   - Turn off this option to prevent clients from accessing the tenant signing certificate and the SAML metadata until they authenticate by logging in to the identity domain.
5. In the **Email Addresses** field, provide the default contact email addresses.
   These email addresses appear in notifications sent to users. Enter the email addresses that you want users to contact if they need help. To separate multiple email addresses, use a comma.
6. Select **Audit Retention Interval** as either 30, 60 or 90 days. The tenant purges the audit data for all the users, based on the interval set here. As an administrator, when you delete a user, you can manually purge the audit data of that user by entering the GUID. The entire audit data of that user is permanently deleted from the Tenant.
7. Click **Save**.
**Purging Audit Data for a Deleted User**

When you delete a user, the audit data of the user remains in the system. Using Purge option, you can manually and immediately purge the audit data of that deleted user.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Settings** and then **Domain settings**.
3. Under the **Audit** section, in the **Purge audit data for the deleted user** text box, enter the GUID of the deleted user and click **Purge**.

**Obtaining the Root CA Certificate**

When you set up service providers and identity providers for Federated SSO, you need to download the metadata file and the signing and encryption certificates. However, these certificates are not self-signed and are issued by a root certificate. Hence, for a proper setup and function, you need to get the root certificate and install it at the Federation partner. Follow this procedure to obtain the root certificate.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Settings** and then **Domain settings**.
3. Turn on the switch under **Access Signing Certificate** to enable clients to access the tenant signing certificate without logging in to IAM.
4. Click **Save** to save the default settings.
5. Refer to the REST API document for the detailed installation of cURL.
6. Use this URL `https://tenant-base-url/admin/v1/SigningCert/jwk` as the endpoint.
7. Run the following cURL command to save the root certification file:

   ```bash
   curl -k -i -H "Accept: application/scim+json,application/json" --request GET "https://tenant-base-url/admin/v1/SigningCert/jwk"
   ```

   After you run the command, the following code is returned:

   ```json
   "keys": "-----BEGIN CERTIFICATE-----
   [Paste the highlighted key here]
   "-----END CERTIFICATE-----"
   ```

8. Open a Notepad and paste the key in the following manner:

   ```plaintext
   -----BEGIN CERTIFICATE-----
   [Paste the highlighted key here]
   ```
For example, (abbreviated):

"MIIDdDCCAlygAwIBAgIGAVw4Ns68MA0GCS....../VaWgoMQ6J9t9CLarai"

9. Save this file as your root certification file.

Managing Session Settings
Define session expiration, the sign-in, sign-out, and error URLs, and configure Allow Cross-Origin Resource Sharing (CORS) to allow client applications that run on one domain to obtain data from another domain.

Required Policy or Role
To change session settings, you must have one of the following access grants:

- Be a member of the Administrators group
- Be granted the Identity Domain Administrator role or the Security Administrator role
- Be a member of a group granted manage domains

To understand more about policies and roles, see The Administrators Group, Policy, and Administrator Roles on page 3112, Understanding Administrator Roles on page 3295, and Understanding Policies on page 3298.

Using the Console
Changing Session Settings

2. Select the identity domain you want to work in and click Settings and then Session settings.
3. In the Session duration (in minutes) field, enter the duration in minutes for which the user’s session is valid. The user's session times out after the session duration has been reached regardless of actual user activity or inactivity.
4. In the My Apps idle timeout (in minutes) field, enter the duration after which a user is automatically signed out of the My Apps console of this identity domain because of inactivity.
5. In the Login URL field, enter the URL where you want the user redirected to log in.
6. To allow login-customization for the Admin Console, select Enable custom login page for the admin console.
7. To show only the username field on the Sign In page, check Enable username first flow.
8. Enter a Logout URL. For example, to redirect the user to the My profile console, enter /ui/v1/myconsole.
9. In the Error URL field, enter the tenant-specific error page URL to which a user is redirected after an error. This URL is used when the Application-specific Custom Error URL is not specified for an Application.
10. In the Social linking callback URL field, enter the URL to redirect to after linking a user between social providers and IAM is complete. This URL is used when the Application-specific Social linking callback URL is not specified for an Application.
11. (Optional) Turn on Allow cross-origin resource sharing (CORS). CORS allows client applications from one domain to obtain data from another domain. If you turn on this option, you might also want to set the Allowed CORS domain names option.
12. Leave the Show the specific error message for login policy violation option on.
   This option is turned on by default and allows the system to display the specific policy-violation error-message if the login policy is violated. If the option is turned off, the system displays the standard error message.
13. Click Save changes.
Customizing Notifications
Learn how to customize the email notifications sent by an identity domain.

Required Policy or Role
To manage identity domain settings, you must have one of the following access grants:

- Be a member of the Administrators group
- Be granted the Identity Domain Administrator role or the Security Administrator role
- Be a member of a group granted manage domains

To understand more about policies and roles, see The Administrators Group, Policy, and Administrator Roles on page 3112, Understanding Administrator Roles on page 3295, and Understanding Policies on page 3298.

About Email Notifications
An identity domain can automatically send email notifications to users and administrators to alert them to events in their account (for users) or events in the identity domain (administrators). You can choose which notifications to activate for an identity domain. After you choose which notifications to activate, you can customize some features of the email sent for each event type.

The following tables list the types of email notifications that can be automatically sent to users and administrators.

### User Email Notifications

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Welcome</td>
<td>A user is notified that an administrator created an account for the user. The notification contains a link that the user clicks to activate the account.</td>
</tr>
<tr>
<td>Self-registration email verification</td>
<td>After a user creates an account successfully through the self-registration process, this notification is sent to the user to verify the user's email address.</td>
</tr>
<tr>
<td>Federated SSO user welcome</td>
<td>A federated SSO user is notified that an administrator created an account for the user. The notification contains a link that the user clicks to activate the account.</td>
</tr>
<tr>
<td>Delegated authentication user welcome</td>
<td>A user whose authentication is delegated is notified that an administrator created an account for the user. The notification contains a link that the user clicks to activate the account.</td>
</tr>
<tr>
<td>Welcome (resend)</td>
<td>If a user doesn’t activate the account using the link provided in the welcome notification, then the administrator can send this notification. The user is notified again that the administrator created the account for the user. The notification contains a link that the user clicks to activate the account.</td>
</tr>
<tr>
<td>Delegated authentication user welcome (resend)</td>
<td>If a user whose authentication is delegated doesn’t activate the account using the link provided in the delegated authentication user welcome notification, then the administrator can send this notification. The user is notified again that the administrator created the account for the user. The notification contains a link that the user clicks to activate the account.</td>
</tr>
<tr>
<td>Name</td>

<tr>
<td>------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Password recovery</td>
<td>This notification is sent to a user if the user requests a password reset. This notification contains a URL that the user clicks to be redirected to the Password Reset page. The user provides a password as part of the password recovery process. After the recovery process is complete, the user is logged in automatically.</td>
</tr>
<tr>
<td>Recovery email verification</td>
<td>After a user changes their password recovery email address, this notification is sent to the user to verify the address.</td>
</tr>
<tr>
<td>Primary email verification</td>
<td>After a user changes their primary email address, this notification is sent to the user to verify the address.</td>
</tr>
<tr>
<td>Secondary email verification</td>
<td>After a user changes their secondary email address, this notification is sent to the user to verify the address.</td>
</tr>
<tr>
<td>Recovery email update</td>
<td>After a user updates their recovery email address, this notification is sent to the user at their existing recovery email address.</td>
</tr>
<tr>
<td>Primary email update</td>
<td>After a user updates their primary email address, this notification is sent to the user at their existing primary email address.</td>
</tr>
<tr>
<td>Secondary email update</td>
<td>After a user updates their secondary email address, this notification is sent to the user at their existing secondary email address.</td>
</tr>
<tr>
<td>Password change</td>
<td>This notification is sent to the user to inform the user that the password was changed successfully. This event is initiated by the user.</td>
</tr>
<tr>
<td>Password reset</td>
<td>This notification is sent to the user to inform them that the password was reset successfully. This event is initiated by the user.</td>
</tr>
<tr>
<td>Password has been changed by an administrator to a known value</td>
<td>This notification is sent to users when the administrator changes the passwords for users to a known value. This notification is used for testing purposes only. Both the administrator and the users know the common password.</td>
</tr>
<tr>
<td>Admin requesting a password reset on behalf of a user</td>
<td>This notification is sent to a user if the administrator initiates changing the password for the user. The system creates a randomly generated value for the password. If the administrator initiates resetting the password for the user, then a notification is sent to the user along with a URL where the user can reset the password.</td>
</tr>
<tr>
<td>User activation</td>
<td>A user is notified that an administrator activated the their account. The notification contains a link that the user clicks to sign in to the account.</td>
</tr>
<tr>
<td>User deactivation</td>
<td>A user is notified that an administrator deactivated their account.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>User account locked</td>
<td>This notification is sent to a user if the user account is locked because the user was unsuccessful in logging in after a consecutive number of attempts. This notification contains a link that the user can click to unlock the account.</td>
</tr>
<tr>
<td>User exceeded the maximum number of account recovery attempts</td>
<td>After a user exceeds the maximum number of attempts to reset their password to recover their account, this notification is sent to the user’s primary email address.</td>
</tr>
<tr>
<td>User account unlocked</td>
<td>This notification is sent to a user after the user’s account is unlocked. This occurs after the user accesses the link in the User Locked notification to unlock the account.</td>
</tr>
<tr>
<td>User profile updated by administrator</td>
<td>An administrator can update a user's profile by changing attribute values associated with the user's account. A notification is sent to the user. A user can modify their profile and receive the same notification. The user accesses the My Profile page to see the modifications made to the profile. The changes appear in a different foreground or background color.</td>
</tr>
<tr>
<td>User profile replaced by administrator</td>
<td>An administrator can replace attribute values of a user's profile. A notification is sent to the user. A user can replace attribute values of their profile and receive the same notification. The user accesses the My Profile page to see the attribute value replacements made to the profile. The changes appear in a different foreground or background color.</td>

### Administrator Email Notifications

<table>
<thead>
<tr>
<th><strong>Name</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Job started</td>
<td>An administrator is notified that a job for importing or exporting groups, users, or application roles, or for resetting passwords for all identity domain users, has been started.</td>
</tr>
<tr>
<td>Job cancelled</td>
<td>An administrator is notified that a job for importing or exporting groups, users, or application roles, or for resetting passwords for all identity domain users, has been canceled.</td>
</tr>
<tr>
<td>Job completed</td>
<td>An administrator is notified that a job for importing or exporting groups, users, or application roles, or for resetting passwords for all identity domain users, is complete.</td>
</tr>
<tr>
<td>Job failed</td>
<td>An administrator is notified that a job for importing or exporting groups, users, or application roles, or for resetting passwords for all identity domain users, has failed.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Quota limit exceeded</td>
<td>This notification is sent to an administrator when the administrator has exceeded the allowed resource quota for the identity domain. To increase the quota limit, upgrade your subscription.</td>
</tr>
<tr>
<td>From email domain validation initiated</td>
<td>An administrator is notified that validation of the email domain that's entered in the email address in the <strong>Sender's email address</strong> field on the <strong>Notifications</strong> page has been initiated, and a validation email will be sent to the postmaster account of this domain.</td>
</tr>
<tr>
<td>Email address validation initiated for Sender’s email address</td>
<td>An administrator is notified that validation of the email address that's entered in the <strong>Sender's email address</strong> field on the <strong>Notifications</strong> page has been initiated, and a validation email will be sent to this email address.</td>
</tr>
<tr>
<td>Synchronization job summary</td>
<td>After synchronizing users, groups, application accounts, and entitlements from an application into an identity domain, an administrator receives an email notification. The notification contains a summary of the synchronization and a link. Clicking the link takes the administrator to a URL that lets the administrator view the status of the synchronization job.</td>
</tr>
<tr>
<td>Notify an administrator when connectivity between AD, AD Bridge, and OCI IAM is broken</td>
<td>This notification is sent to an administrator when the connectivity between Microsoft Active Directory (AD), the AD Bridge or AD Bridges, and the identity domain is broken.</td>
</tr>
<tr>
<td>Notify an administrator when connectivity between AD, AD Bridge, and OCI IAM is restored</td>
<td>This notification is sent to an administrator when the connectivity between Microsoft Active Directory (AD), the AD Bridge or AD Bridges, and the identity domain is restored.</td>
</tr>
<tr>
<td>Bridge update available</td>
<td>This notification is sent to an administrator when an update to the Microsoft Active Directory (AD) Bridge is available.</td>
</tr>
<tr>
<td>Notify an administrator when sync between AD, AD Bridge, and OCI IAM has succeeded</td>
<td>This notification is sent to an administrator when the sync between Microsoft Active Directory (AD), the AD Bridge or AD Bridges, and the identity domain has succeeded.</td>
</tr>
<tr>
<td>Notify an administrator when sync between AD, AD Bridge, and OCI IAM has failed</td>
<td>This notification is sent to an administrator when the sync between Microsoft Active Directory (AD), the AD Bridge or AD Bridges, and the identity domain has failed.</td>
</tr>
<tr>
<td>Secondary domain creation</td>
<td>This notification is sent to an administrator when a secondary identity domain has been created.</td>
</tr>
</tbody>
</table>

**Note:**

The job started, job cancelled, job completed, and job failed administrator notifications contain a link. Clicking the link for each notification takes the administrator to the **Jobs** page of the identity domain where the administrator can view details about the job.
Workflow for Customizing Notifications

The general workflow you follow to customize notifications is:

1. Activate notifications. By activating notifications, you enable the identity domain to send notifications to users and administrators.
2. Select the specific notifications you want sent by this identity domain.
3. Edit the notification templates to include the elements and text wanted.
4. Verify notifications. You can verify the customizations that you made by sending them to a limited number of recipients.
5. After verification, enable notifications for all users to begin sending your customized notifications.

Using the Console

Activating notifications for the identity domain

2. Select the identity domain you want to work in and click Settings.
3. Click Notifications.
4. To activate notifications, select the Enable notifications for all identity domain users check box.
5. To send a validation email to the postmaster account of the email’s domain, click Verify sender's domain. After the domain is verified, any email address from the domain is valid.

OR

To send a validation email to the email address that you enter in the Sender's email address field, click Verify sender's email address. Unlike the Verify sender's domain option, a validation is initiated for every email address even though they’re from the same domain.
6. In the Sender's email address field, enter the email address that will appear in the From email field for all notifications.
7. Click Save changes.
   If you selected Verify sender's domain in step 5, then an email notification is sent to the postmaster to verify the email address and validate the domain associated with the address. Otherwise, if you selected Verify sender's email address, then a validation email is sent to the email address that you entered in the Sender's email address field.
8. In the confirmation window, click Save changes.
9. If you do not see a Verified status, then click Check Status.
   IAM checks the status of the email verification. If it's verified, then the status changes to Verified.
   If the email address isn't verified, then access the notification that's sent to the email address you provided, click the verification link in the notification, and click Check Status again. The status will change to Verified.

OR

If the domain isn't verified, then contact the postmaster of your company so that the postmaster can verify the domain associated with the email address.

Selecting notifications

Select the notifications you want sent to users and administrators by this identity domain.

2. Select the identity domain you want to work in and click Settings.
3. Click Notifications.
4. Click the Configure tab.
   On this tab, you see a list of user and administrator notifications that you can send.
5. Select the check box for each notification that you want sent by this identity domain.
6. Click Save changes.
Modifying notification templates
After activating and selecting notifications, and specifying their recipients, you can modify the notification templates that you selected. To meet the business and security requirements for your enterprise applications, tailor the content of these notifications.

2. Select the identity domain you want to work in and click Settings.
3. Click Notifications.
4. Click the Email templates tab.

| Tip: |
The notification templates that appear in the Email templates tab reflect the selections you made in the Configure tab. See Selecting notifications on page 3141.

5. Expand a notification template.
6. To modify a notification template, use the following table:

| Important: |
When adding or changing a variable in an email template, ensure that you use the correct syntax. For example, to use the variable user.displayName, the correct syntax is ${user.displayName}.

<table>
<thead>
<tr>
<th>Template Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language</td>
<td>Select the language for the notification. To see a preview of the notification in the language you select, click View and access the Email body text area.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Verify that UTF-8 appears as the character encoding for the notification (for security, encryption, and backward-compatibility purposes). This character encoding can encode all possible characters of the notification, or code points, in Unicode.</td>
</tr>
<tr>
<td>Sender</td>
<td>Verify that the email address for this field matches the email address you entered in the Sender's email address field. This field is the email address that will appear in the From email field for all notifications. If you haven't verified the domain or the email address, then this value will be the previously validated email address or email address from the previously validated domain. As soon as the domain or the email address is validated (the status changes to Verified), then the verified email address will appear in the Sender field for all notifications.</td>
</tr>
<tr>
<td>Subject</td>
<td>Enter or provide variables for content that appears in the Subject field of the email notification.</td>
</tr>
<tr>
<td>Template Field</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Email body</td>
<td>The content of the notification template. In this text area, you can customize the content to meet your needs. In addition to a customization toolbar, you can use the following variables. These variables are replaced with values specific to your business at runtime. They are:</td>
</tr>
<tr>
<td></td>
<td>- ${account.emailID}: The email address of the user's account from which an attempt is made to log in using a device, IP address, or web browser that the identity domain doesn't recognize.</td>
</tr>
<tr>
<td></td>
<td>- ${actorDisplayName}: The identity domain administrator's email address.</td>
</tr>
<tr>
<td></td>
<td>- ${admin.resource.name}: The name of the Kerberos application.</td>
</tr>
<tr>
<td></td>
<td>- ${app.displayName}: The display name of the application that contains the users, groups, application accounts, and entitlements that are synchronized into this identity domain.</td>
</tr>
<tr>
<td></td>
<td>- ${app.id}: The ID of this application.</td>
</tr>
<tr>
<td></td>
<td>- ${authentication.targetApp}: The name of the Microsoft Active Directory domain that contains the account of the user who’s authenticating into this identity domain.</td>
</tr>
<tr>
<td></td>
<td>- ${bypasscode.expiry}: The time (in minutes) before a bypass code expires.</td>
</tr>
<tr>
<td></td>
<td>- ${bypasscode.usage}: How many times a bypass code can be used.</td>
</tr>
<tr>
<td></td>
<td>- ${bypasscode.value}: The bypass code that the user or administrator generates for use as part of the 2-Step Verification process.</td>
</tr>
<tr>
<td></td>
<td>- ${companyName}: The name of the company that will appear in the notification. Note: When you use the ${companyName} variable, be sure to add your company name to the Company name field in the Branding page. If you don't, then your company's details won't appear in email notifications, SMS notifications, or in the Oracle Mobile Authenticator (OMA) app when a user completes MFA enrollment. See To customize the sign-in page on page 3148 for more information about populating the Company name field.</td>
</tr>
<tr>
<td></td>
<td>- ${contactEmails}: The system administrator's email address.</td>
</tr>
<tr>
<td></td>
<td>- ${date}: The date associated with the action of the notification (for example, resetting a password).</td>
</tr>
<tr>
<td></td>
<td>- ${device.ipAddress}: The IP address from which an attempt is made to log in to a user's account, but which the identity domain doesn't recognize.</td>
</tr>
<tr>
<td></td>
<td>- ${homePageRedirectUrl}: The redirect URL for the notification that can be used if the link in the notification doesn't work. This URL redirects users to the details page of the identity domain.</td>
</tr>
<tr>
<td></td>
<td>- ${image}: The image that will appear in the header region of the notification.</td>
</tr>
<tr>
<td></td>
<td>- ${imageUrl}: The configuration URL containing parameters used to configure the Oracle Mobile Authenticator (OMA) app when a user completes MFA enrollment. See To customize the sign-in page on page 3148 for more information about populating the configuration URL field.</td>
</tr>
<tr>
<td></td>
<td>- ${headerImage}: The image that will appear in the header region of the notification.</td>
</tr>
<tr>
<td></td>
<td>- ${job.displayName}: The display name of the job that's started, canceled, completed, or failed.</td>
</tr>
<tr>
<td></td>
<td>- ${masked_UID}: The one-time passcode (OTP) that's used to identify the user.</td>
</tr>
<tr>
<td></td>
<td>- ${mobileAuthAppDisplayName}: The name of the Kerberos application.</td>
</tr>
<tr>
<td></td>
<td>- ${mobileAuthAppId}: The ID number of the job that's started, canceled, completed, or failed.</td>
</tr>
<tr>
<td></td>
<td>- ${monitorTime}: The time associated with the action of the job that's used to synchronize users, groups, application accounts, then 600,000 represents the quota usage. If an administrator created 600,000 accounts, there is a quota limit (for example, users).</td>
</tr>
<tr>
<td></td>
<td>- ${quota.resourceType}: The classification type of the resource type. If an administrator can create users, groups, application accounts, then 600,000 represents the quota usage. If an administrator created 600,000 accounts, there is a quota limit (for example, users).</td>
</tr>
<tr>
<td></td>
<td>- ${quota.limit}: The amount of time (in minutes), after which the link in the notification will be expired.</td>

7. Click **Save template**.
8. Click **Save changes**.

**Testing notifications**
After modifying the email notification templates, you can send the notifications to selected recipients to test and verify your changes.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Settings**.
3. Click **Notifications**.
4. Click the **Recipients** tab.
5. To turn on testing of notifications, select the **Limited recipients list** check box.
6. Click the **Test recipient email addresses** text box, and enter the email addresses to send the test notifications to.
7. Click **Save changes**.
8. To verify notifications, use the following table:

<table>
<thead>
<tr>
<th>Notification</th>
<th>Action (Administrator)</th>
<th>Action (User)</th>

</tbody>
</table>

9. After you are satisfied with the test, clear the Limited recipients list check box to begin sending the customized notifications for all users.

Deactivating notifications
You stop sending notifications to users and administrators by this identity domain, deactivate notifications.

2. Select the identity domain you want to work in and click Settings.
3. Click Notifications.
4. Clear the **Enable notifications for all identity domain users** check box.
5. Click **Save changes**.

**Customizing the Interface**

You can add a logo to the following interfaces to customize them with your company branding:

- Sign-in page
- Console pages, including: My Apps page, Catalog page
- Notification templates

You can also customize the text that users see on the sign-in page and choose the language it is displayed in.

**Required Policy or Role**

To manage identity domain settings, you must have one of the following access grants:

- Be a member of the Administrators group
- Be granted the Identity Domain Administrator role or the Security Administrator role
- Be a member of a group granted manage domains

To understand more about policies and roles, see The Administrators Group, Policy, and Administrator Roles on page 3112, Understanding Administrator Roles on page 3295, and Understanding Policies on page 3298.

To understand more about policies and roles, see The Administrators Group, Policy, and Administrator Roles on page 3112, Understanding Administrator Roles on page 3295, and Understanding Policies on page 3298.

**Image Requirements for Logos and Background Images**

The files that you upload for logos or background images must be in one of these allowed file types: GIF, JPEG, JPG or PNG.

The images must also meet the size requirements shown in the following table. All measurements are in pixels.

<table>
<thead>
<tr>
<th>Image or Icon</th>
<th>Max Width and Height Allowed</th>
<th>Recommended Dimensions Width X Height</th>
<th>Maximum File Size</th>
<th>Ratio</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sign-in page logo</td>
<td>250W X 50H</td>
<td>250W X 50H</td>
<td>300 KB</td>
<td>5:1</td>
<td>If you use larger images, be aware that larger images will be resized to maintain a 5:1 ratio.</td>
</tr>
<tr>
<td>Sign-in page background image</td>
<td>None</td>
<td>None</td>
<td>300 KB</td>
<td>Not applicable</td>
<td>If the image is too small, the image is repeated horizontally and vertically.</td>
</tr>
<tr>
<td>My Apps and Catalog page logos</td>
<td>64H No restriction in width</td>
<td>250W x 50H</td>
<td>300 KB</td>
<td>5:1</td>
<td>If you use an image that is 250 pixels wide or larger, the text on My Console might be displaced.</td>
</tr>
</tbody>
</table>
Using the Console

To customize the sign-in page

You can customize the following features of the sign-in page:

- Change the language of the text in the page.
- Add a company name, logo, and background image.
- Add text to the sign-in page to help a user sign in to the identity domain.

2. Select the identity domain you want to work in and click Settings.
3. Click Branding.
4. To update the language that the sign-in page is displayed in, under Sign in page, click Translation, and then select the language.
5. To update the company name on the sign-in page: Click Company name and enter the name of your organization.
6. To update the text that displays on the sign-in page: In the Login text field, enter and format the text. This text can be a hint to help your uses sign in.
7. To include a logo on the sign-in page: Under Company logos, in the Sign in page region, upload the image file to the Logo slot.
8. To include a background image on the sign-in page: Upload the image file to the Background image slot.
9. Preview your changes: Click Preview Sign In and a new web page opens that displays a preview of the customizations you made to the sign-in page.
10. Reduce the size of the preview web page so that the dimensions of the page resemble the dimensions of a mobile device.
11. Verify that the logo appears properly again.
12. Click Save changes.

To add a logo to the consoles

You can add a logo to display a company logo in the header regions of the Catalog and My Apps pages in the console. You can preview your customizations before saving them. This way, you can ensure that they meet your business requirements.

2. Select the identity domain you want to work in and click Settings.
3. Click Branding.
4. If Oracle branding (default) is selected, then click Custom branding.
5. Under Company logos, upload a Logo or a Background image for either or both the Sign in page and My Apps page.
   Select the company logo that will appear in the header region of the sign-in page and the My Apps and Catalog console pages when the user accesses the console using a web browser.
6. To preview your changes, click Preview Sign In or Preview My Apps.
7. Verify that the logo appears properly.
8. Reduce the size of the preview web page so that the dimensions of the page resemble the dimensions of a mobile device.
9. Verify that the logo appears properly again.
10. When you are finished, click **Save changes**.

**To add a logo to email notification templates**
You can brand notification templates to display a logo in the header and footer regions of the templates.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Settings**.
3. Click **Branding**.
4. If **Oracle branding (default)** is selected, then click **Custom branding**.
5. Under **Email templates**, upload a **Header logo** to display in the header region of all email notifications from this identity domain.
   Select the company logo that will appear in the header region of email notifications sent to users in this identity domain.
6. When you are finished, click **Save changes**.

**Managing Users**
User life cycle is a term to describe the process flow of how a user account is created, managed, and deleted in an identity domain based on certain events or time factors.

A user account goes through various stages in the life cycle. The stages are non-existent, deactivated, activated, and deleted.

You can define business requirements for each transition of the user life cycle. Use the sample scenarios listed in the following table to establish the link between user life-cycle transitions and business objectives.

<table>
<thead>
<tr>
<th>Current State</th>
<th>Operation</th>
<th>Sample Scenario</th>
<th>Process Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-existent</td>
<td>Create</td>
<td>Human resources (HR) enters user profile information for a new hire.</td>
<td>If the new hire's start date isn't a future date, then the user account is introduced with an <strong>Activated</strong> status. If the new hire's start date is a future date, then the user account is created, and is then deactivated.</td>
</tr>
<tr>
<td>Deactivated</td>
<td>Activate</td>
<td>The user's start date is in effect.</td>
<td>The user account is activated, and the user can now log in and use this Oracle Cloud service. The user can access all groups, applications, and administration role privileges assigned to the user account.</td>
</tr>
<tr>
<td>Activated</td>
<td>Modify</td>
<td>The user is promoted to a new position. HR changes the job title of the user.</td>
<td>New groups, applications, and administration roles are assigned to the user account. Old irrelevant groups, applications, and administration roles are removed from the user account.</td>
</tr>
<tr>
<td>Current State</td>
<td>Operation</td>
<td>Sample Scenario</td>
<td>Process Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------</td>
<td>-----------------</td>
<td>---------------------</td>
</tr>
<tr>
<td>Activated</td>
<td>Deactivate</td>
<td>The user takes a one-year sabbatical from the company. HR manually deactivates the user account on the last working day of the user. The user rejoins the company after some period. HR activates the user account.</td>
<td>The user account is deactivated, and the user can no longer login and use this Oracle Cloud service. The user account can be activated again.</td>
</tr>
<tr>
<td>Activated</td>
<td>Delete</td>
<td>The user retires from the company. HR manually deletes the user account on the last working day of the user.</td>
<td>The user account is removed. All groups, applications, and administration role privileges assigned to the user account are revoked as part of the workflow. If you remove (delete) the user, the audit data of the user remains in the system. To manually (and immediately) purge the audit data of the deleted user, see Purging Audit Data for a Deleted User on page 3134.</td>
</tr>
</tbody>
</table>

The following concepts are integral to user lifecycle management:

- **User Account**: A user account represents a user in an identity domain, and enables the user to access the Oracle Cloud service to which they belong. In an identity domain, there is a one-to-one relationship between a user and a user account. By default, all users can use their accounts to perform self-service capabilities. Users can update their profiles, reset their passwords, unlock their accounts, and change their email preferences.

- **Administrator Role**: You might want to provide a user account with administrative capabilities in IAM. To do this, you assign administrator roles to user accounts. See Assigning Users to Roles on page 3153.

- **Group**: Identity domains provide easy and controlled privilege management through groups. Groups are the links between user accounts and applications in the identity domain. Groups are designed to ease the administration of privileges that you grant to user accounts or other groups. See Managing Groups on page 3158.

- **Application**: Oracle applications are a complete and modular set of enterprise applications, engineered from the ground up to be cloud-ready and to coexist seamlessly in mixed environments.

You can use identity domains in IAM to grant access to Oracle applications in two ways:

- **Directly**: Assigning users to the applications
- **Indirectly**: Assigning groups to the applications. Any users who are members of the groups are granted access to the applications.

In addition to granting users and groups access to Oracle applications, you can grant users and groups access to entitlements within applications. For example, you use IAM to grant John Doe and Jane Doe access to Oracle Java...
Cloud Service. You want John Doe to have administrator privileges for Oracle Java Cloud Service, but Jane Doe to have user privileges only.

Each entitlement in an Oracle application is represented by an application role. So by assigning John Doe to the application administrator role of Oracle Java Cloud Service, he can not only access this Oracle Cloud service, but he can also function as an administrator within it.

See Managing Applications on page 3167 for more information about how you can use IAM to grant and revoke access rights for users and groups to applications and application roles.

Using the Console

Creating users

2. Select the identity domain you want to work in and click Users.
3. Click Create user.
4. In the First name and Last name fields of the Create user window, enter the user’s first and last name.
5. To have the user log in with their email address:
   a) Leave the Use the email address as the username check box selected.
   b) In the Username / Email field, enter the email address for the user account.
   OR
6. To have the user log in with their user name:
   a) Clear the Use the email address as the username check box.
   b) In the Username field, enter the user name that the user is to use to log in to the Console.

   **Note:**

   The value that you enter into the Username field can be either a valid email address or a non-email string. If it's a non-email string, then the following characters are allowed:
   - a-z
   - A-Z
   - 0-9
   - Special characters !@#$%^&*()_+=-{}\[\]\\|:\'";'<>?/,.
   - White space
   c) In the Email field, enter the email address for the user account.

   **Note:**

   If the Primary email address required check box is selected on the Domain settings page, then you must provide an email address in the Email field to create the user account.

   If you cleared the Primary email address required check box, then you can create the account without entering an email address in the Email field.

7. To assign the user to a group, select the check box for each group that you want to assign to the user account.
8. Click Create.

Linking a User to a My Oracle Support Account

To file support requests directly from the Console, each user must link their IAM user account with their My Oracle Support (MOS) account. You only need to complete this step once.

2. Select the identity domain you want to work in and click Users.
3. Click the user you want to link to My Oracle Support. The user's details are displayed.
4. Click More Actions.
5. Click Link support account.

**Viewing and Editing User Details**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Users**.
3. Click the user account that you want to modify.
4. Click **Edit user**.
5. Modify an attribute value for the user account by:
   a) Entering a value in the attribute field (for example, the **City** field).
   b) Turning on or off a switch (for example, the **Federated** switch).
   c) Selecting a value from the list (for example, a Microsoft Active Directory (AD) domain from the **Authenticated by** list).

   **Note:**
   You can't edit attribute values for your user account. To do this, access the **My Profile** page of the Console.

6. After editing attribute values for the user account, click **Save changes**.

**Assigning Applications to Users**

After viewing details about a user account, you can modify the account by assigning applications to it.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Users**.
3. Click the user account that you want to modify.
4. Click **Applications**.
5. Click **Assign applications**.
6. In the **Assign applications** window, click the Actions menu and select **Assign** for each application that you want to assign to the user account.
7. If you're assigning a managed application to the user account, then an **Assign Application** window appears, containing a form for the application. To populate this form:
   a) Enter the required values for the form.
   b) If the form contains multi-valued attributes, then an **Add** button appears to the right of each attribute. Click **Add**, and then in the **Allowed Values** window, select the values for the attribute, and click **OK**.

   **Tip:**
   To remove an existing value from the attribute, click the **X** button to the right of the value.
   c) Click **Save**.

**Note:**

The **Active** icon for each application in the **Access** tab represents the active status of the user account and not the application status. The status remains active as long as the user account is active, regardless of whether the application is active or inactive.

8. Click **Finish**.

**Note:**

If you assigned a managed application to the user account, then you can modify the values of the application form. To do this, click the **Action** menu, select **Edit**, change the appropriate values, and then click **Save**.
Also, if you have enabled and configured synchronization for an App Catalog app, and assigned the app to a user account, then you can activate or deactivate the user’s account with the app. To do so:

a. Click the **Action** menu to the right of the App Catalog app that you assigned to the user.
b. Click **Activate** or **Deactivate**.
c. In the **Confirmation** window, click **OK**.

**Removing Applications from Users**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Users**.
3. Click the user that you want to modify.
4. Click **Applications**.
5. Select the check box for each application that you want to remove from the user.
6. Click **Remove application**.
7. Click **Remove application** to confirm.

**To Edit a User’s Capabilities**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Users**.
3. Click a user to see the user details.
4. Click **Edit user capabilities**.
5. Select or clear the check box to add or remove a capability.
6. Click **Save changes**.

**Assigning Users to Roles**

By default, all users can perform self-service capabilities such as updating their profiles, resetting their passwords, and changing their email preferences. You might want to provide a user account with administrative capabilities. For example, you might want a user to manage applications. So, you would assign the user account to the application administrator role.

A user account can be assigned to more than one administrator role. The user account inherits the privileges for each administrator role assigned to the account. If a user account is assigned to both the application administrator role and the user administrator role, then the user can manage applications, users, groups, and group memberships.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Security** and then **Administrators**.
3. Expand the node for the administrator role for which you want to add or remove a user account, and then perform one of the following:

- To add a user account to an administrator role, click Add user, select the check box for each user account that you want to add, and then click Add users.

If you're adding users to the user manager role, then after selecting the check box for each user that you're adding to this role, you must also select one of the following options:

- **Manage all users**: These users can manage all users in the IAM identity domain.
- **Manage selected groups of users**: These users can manage only those users who belong to the groups that you select. After selecting this option, enter or select the groups to be managed by these users.

After making this selection, click Add users. If you want to modify either the users who are assigned to the user manager role or the groups that these users can manage, click the Actions menu, and select Edit from the that appears.

- To remove a user account from an administrator role, select the user account that you want to remove, click Remove, and then in the Confirmation window, click Remove user.

### Adding Users to Groups

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Users**.
3. Select the user that you want to modify.
4. Click **Groups**.
5. Click **Assign user to groups**. To search for groups to assign to the user account, in the search field, enter all or part of the beginning of the group names or descriptions that you want to locate.
6. In the **Assign user to groups** window, select the check box for each group that you want to assign to the user account.
7. Click **Assign user**.

### Removing Users from Groups

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Users**.
3. Click the user account that you want to modify.
4. Click **Groups**.
5. Select the check box for each group that you want to remove from the user account.
6. Click **Remove user from group**.
7. In the **Remove group** window, click **Remove group**.

### Resetting User Passwords

You can reset the password for a user account. When you request a password change, a notification is sent to the user so that the user can provide a new password for the account.

You can reset a password for a single account, for multiple accounts, or for all accounts in the identity domain.

You can't reset the passwords for deactivated user accounts. To activate all deactivated user accounts, search for accounts with a status of Inactive. Then select the Select All check box.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Users**.
3. Select the check box for each user account for which you want to reset the password.

**Tip:**

To reset the passwords for all user accounts, do not select any check boxes, and go to Step 4.
4. Click **More actions**, and then perform one of the following choices.

   • If you selected either a single or multiple user accounts:
      a. Select **Reset password**.
      b. In the **Reset password** window, click **Reset password**.
   • If you didn’t select any user accounts (because you want to reset the passwords for all accounts):
      a. Select **Reset all passwords**.
      b. In the **Reset all passwords** window, click **Reset all passwords**.

**Unlocking Users**

After a consecutive number of unsuccessful login attempts, a user account is locked. The user receives a notification that contains a link that the user can click to reset their password and unlock their account. An administrator can unlock accounts without requiring a password reset.

If a user’s account is locked, and the user or an administrator doesn’t unlock the account, then IAM unlocks it automatically. An administrator can set this time period ranging between 5 minutes and 24 hours.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Users**.
3. Click the user account that you want to unlock.

   **Tip:**
   To display all user accounts that are locked, click the search field and select the **Locked** status.

4. Click the the Actions menu, and select **Unlock User**.
5. In the **Confirmation** window, click **OK**.

**Adding or Removing a User Account from an Administrator Role**

After you create or import user accounts in IAM, you can delegate administrative responsibilities for these accounts.

By default, all users can perform self-service capabilities in IAM, such as updating their profiles, resetting their passwords, and changing their email preferences. You might want to provide a user account with administrative capabilities. For example, you might want a user to manage applications in IAM. So, you would assign the user account to the application administrator role.

A user account can be assigned to more than one administrator role. The user account inherits the privileges for each administrator role assigned to the account. If a user account is assigned to both the application administrator role and the user administrator role, then the user can manage applications, users, groups, and group memberships in IAM.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Security** and then **Administrators**.
3. Expand the node for the administrator role for which you want to add or remove a user account, and then perform one of the following:

   - To add a user account to an administrator role, click **Add user**, select the check box for each user account that you want to add, and then click **Add users**.

     If you're adding users to the user manager role, then after selecting the check box for each user that you're adding to this role, you must also select one of the following options:

     - **Manage all users**: These users can manage all users in the IAM identity domain.
     - **Manage selected groups of users**: These users can manage only those users who belong to the groups that you select. After selecting this option, enter or select the groups to be managed by these users.

     After making this selection, click **Add users**. If you want to modify either the users who are assigned to the user manager role or the groups that these users can manage, then click the Actions menu, and select **Edit** from the menu that appears.

   - To remove a user account from an administrator role, select the user account that you want to remove, click **Remove**, and then in the **Confirmation** window, click **Remove user**.

*Deactivating and Reactivating User Accounts*

Deactivating a user account temporarily disables the access rights that the user account has. Deactivated users are not able to log in until you reactivate the user account. Group memberships and application roles remain intact and are available after the user account is reactivated.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Users**.
3. Select the check box for each activated user account that you want to deactivate.
4. Click **More actions**.
5. Click **Deactivate**.
6. In the **Confirm deactivation** window, click **Deactivate**.
7. To reactivate an account, select the check box for each deactivated user account that you want to activate, then click **More actions** and click **Activate**.

*Linking a User to a My Oracle Support Account*

To file support requests directly from the Console, each user must link their IAM user account with their My Oracle Support (MOS) account. You only need to complete this step once.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Users**.
3. Click the user you want to link to My Oracle Support. The user's details are displayed.
4. Click **More Actions**.
5. Click **Link support account**.

*Resetting Authentication Factors for User Accounts*

Reset all verification factors for users enrolled in Multi-Factor Authentication (MFA) if a user’s device can't be used to provide a second factor for authentication. Resetting all verification factors removes any existing factors in which the user is enrolled.

Resetting all verification factors removes any existing factors in which the user is enrolled. The next time the user logs in, the user is prompted to enroll in 2–Step Verification and account recovery.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Users**.
3. Click the user account for which you want to reset authentication factors.
4. Click **Reset factors**.
5. In the **Reset factors** window, click **Reset factors**.
**Generating Bypass Codes for Users**

You can increase security for user accounts by using Multi-Factor Authentication (MFA) capabilities provided by IAM. MFA adds an extra layer of identity verification to the login process by requiring a user to provide a second verification method, such as a one-time passcode (OTP) for the device associated with the user’s account, notification, short message service (SMS), also known as a text message, or security questions.

The ability to generate a bypass code is available to the user after the user enrolls in 2-Step Verification. The user can generate a bypass code and store it for later use or request that an administrator generate a bypass code for the user. For example, when a user has forgotten their phone, doesn’t have cell service, or can’t access their computer, at the 2-Step Verification page, the user can contact the help desk to have an administrator generate a bypass code.

As a result, the user can use this bypass code as a one-time 2-Step Verification method to log in.

In addition, the administrator can set when the bypass code expires, and how often the bypass code can be used for the user account.

---

**Note:**
The user must already be enrolled in MFA to use a bypass code or request that one is generated for the user.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Users**.
3. Click the user for which you want to generate a bypass code.
4. Click **More Actions** and then select **Generate bypass code**.
5. In the **Bypass Code expires after** region of the **Generate Bypass Code** window, set when the bypass code expires.
   a) Set the time (in days, hours, and minutes) that the bypass code will expire. After this time elapses, the user can't use the bypass code.
   b) If you don't want the bypass code to expire, then click **Never Expires**.
6. In the **Bypass Code can be used** region of the **Generate Bypass Code** window, specify how often the bypass code can be used.
   a) If the bypass code can be used only one time, then click **Once**.
   b) If the bypass code can be used for a finite number of times, then click the button to the left of the text box. Enter a number in the text box that represents how many times the bypass code can be used.
   c) If the bypass code can be used for an unlimited number of times, then click **Unlimited**.
7. Click **OK**.
8. In the **Bypass Code** window, click **Email**. A notification is sent to the user. This notification contains the bypass code that the user uses as a one-time 2-Step Verification method to log in.

---

**Resending Invitations to Users to Activate their Accounts**

After a user account is created, a Welcome invitation is sent to the user, requesting that the user activates the account. The new user account must be activated before it can be used.

If the user account isn't activated after a designated amount of time, then the identity domain administrator can send another invitation to the user to activate the account.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Users**.
3. Select the check box for each user account to which you want to send an invitation.
   **Tip:**
   To send invitations to all user accounts, select the **Select All** check box.
4. Click **More actions**, and then select **Resend invitation**.
5. In the **Confirmation** window, click **Send invitation**.
Removing User Accounts
You can remove user accounts who no longer need access to the service. You can remove either a single user account or multiple accounts.

2. Select the identity domain you want to work in and click Users.
3. Select the check box for each user account that you want to remove.
4. Click More actions, and then click Delete.
5. In the Delete user window, click Delete user.

Note:
If you remove (delete) a user, the audit data of the user remains in the system.

Managing Groups
This topic describes the basics of working with groups.

Required Policy or Role
To manage groups, you must have one of the following access grants:

- Be a member of the Administrators group
- Be granted the Identity Domain Administrator role or the Security Administrator role
- Be a member of a group granted manage identity-domains or manage groups

To understand more about policies and roles, see The Administrators Group, Policy, and Administrator Roles on page 3112, Understanding Administrator Roles on page 3295, and Understanding Policies on page 3298.

About Groups
Create groups to manage user access to applications and resources.

A group has no permissions until you do one of the following:

- Write at least one policy that gives that group permission to either the tenancy or a compartment. When writing the policy, you can specify the group by using either the unique name or the group's OCID. For information about writing policies, see Managing Policies.
- Assign the group to an application.
- Assign the group to a role.

Note:
The All Tenant Users group is a group that's created by IAM. All identity domain users are assigned to this group by default. If you assign this group to any of your applications, then all users are assigned to these applications indirectly.

For a user, the All Tenant Users group doesn't appear in the Groups tab because this group is assigned automatically when a new user is created. Also, because this group is created by IAM, and not by an administrator, you can't delete this group.

For information about the number of groups you can have, see IAM Object Limits.

Using the Console
Creating a Group

2. Select the identity domain you want to work in and click Groups.
3. Click Create group.
4. In the **Name** and **Description** fields of the **Create group** window, enter the name of and descriptive information about the group.

5. To allow users to request access to this group, select **User can request access**.

6. To add users to the group, select the check box for each user that you want to add to the group.

   **Tip:**

   To search for a user, click the text box, enter all or part of the beginning of the user name, first name, or last name of the user, and then press **Enter**.

7. Click **Create**.

---

**Adding Users to a Group**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.

2. Select the identity domain you want to work in and click **Groups**.

3. Click the group you want to add users to.

4. Click **Assign user to groups**.

5. To add users to the group, select the check box for each user that you want to add to the group.

   **Tip:**

   To search for a user, click the text box, enter all or part of the beginning of the user name, first name, or last name of the user, and then press **Enter**.

6. Click **Add**.

---

**Removing Users from a Group**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.

2. Select the identity domain you want to work in and click **Groups**.

3. Click the group you want to remove users from.

4. Select the check box for each user that you want to remove from the group.

   **Tip:**

   To search for a user, enter all or part of the beginning of the user name, first name, or last name of the user and then press **Enter**.

5. Click **Remove user from group**. Confirm when prompted.

---

**Assigning Applications to a Group**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.

2. Select the identity domain you want to work in and click **Groups**.

3. Do one of the following:

   - To assign an application to all users, search for and click the **All Tenant Users** group.
   - To assign an application a group that contains a subset of users, click the name of the group, and then click **Applications**.

4. Click **Assign applications**.

5. In the **Assign applications** window, select each application that you want to assign to the group by clicking the Actions menu (three dots) for the application, and then click **Assign**.

6. When you are done assigning applications, click **Finish**.

---

**Removing Applications from a Group**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.

2. Select the identity domain you want to work in and click **Groups**.

3. Click the group that you want to modify.
4. Click **Applications**.
5. Select the check box next to the applications that you want to remove.
6. Click **Revoke access**. Confirm when prompted.

**Deleting Groups**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Groups**.
3. Select the check box for each group that you want to delete.
4. From the **More actions** menu, select **Delete**.
5. Confirm when prompted.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 6339 and Security Credentials on page 209. For information about SDKs, see Software Development Kits and Command Line Interface on page 6152.

Use these API operations to manage groups:

- **CreateGroup**
- **ListGroups**
- **GetGroup**
- **UpdateGroup**: You can update only the group's description.
- **DeleteGroup**
- **ListUserGroupMemberships**: Use to get a list of which users are in a group, or which groups a user is in.
- **AddUserToGroup**: This operation results in a UserGroupMembership object with its own OCID.
- **GetUserGroupMembership**
- **RemoveUserFromGroup**: This operation deletes a UserGroupMembership object.

For API operations related to group mappings for identity providers, see Federating with Identity Providers on page 3602.

**Managing Dynamic Groups**

This topic describes how to manage dynamic groups and define the rules to determine a dynamic group's members.

**About Dynamic Groups**

Dynamic groups allow you to group compute instances and other resources as "principal" actors (similar to user groups). You can then create policies to permit the resources to **make API calls against services**. When you create a dynamic group, rather than adding members explicitly to the group, you instead define a set of **matching rules** to define the group members. Resources that match the rules are members of the group. For example, a rule could specify that all instances in a particular compartment are members of the dynamic group. The members can change dynamically as instances are launched and terminated in that compartment.

**Required Policy or Role**

To manage dynamic groups, you must have one of the following access grants:

- Be a member of the Administrators group
- Be granted the Identity Domain Administrator role or the Security Administrator role
- Be a member of a group granted **manage identity-domains** or **manage dynamic-groups**

To understand more about policies and roles, see The Administrators Group, Policy, and Administrator Roles on page 3112, Understanding Administrator Roles on page 3295, and Understanding Policies on page 3298.

**Working with Dynamic Groups**

When you create a dynamic group, you must provide a unique, unchangeable name for the dynamic group. The name must be unique across all groups within your tenancy. You must also provide the dynamic group with a description (although it can be an empty string), which is a non-unique, changeable description for the group. Oracle will also
assign the dynamic group a unique ID called an Oracle Cloud ID (OCID). For more information, see Resource Identifiers.

**Note:**

If you delete a dynamic group and then create a new dynamic group with the same name, they'll be considered different groups because they'll have different OCIDs.

A dynamic group has no permissions until you write at least one policy that gives that dynamic group permission to access resources in either the tenancy or a compartment. In the policy, you can specify the dynamic group by using either the unique name or the dynamic group's OCID. Per the preceding note, even if you specify the dynamic group name in the policy, IAM internally uses the OCID to determine the dynamic group. For information about writing policies, see Managing Policies on page 3575.

You can delete a dynamic group, but only if the group is empty.

### Updating Dynamic Groups

You can update the matching rules that define the members of a dynamic group. For example, you might change a matching rule that includes all instances in a compartment to exclude a particular instance. Or, you might update a rule to include a new tag value.

**Important:**

When you make a change to a matching rule you must allow about one hour for the updated policy to take effect. For example, if you update a rule to include instances with a specific tag in the dynamic group, you must wait about one hour before instances with that tag have the access granted in the policy.

Any policy that references a renamed dynamic group will continue to work. However, Oracle strongly recommends that you update policy statements to stay current with intended dynamic group names or to reference dynamic group OCIDs instead. Also delete any policies with outdated references you no longer need.

### Limits on Dynamic Groups

A single compute instance can belong to a maximum of 5 dynamic groups.

You can have a maximum of 50 dynamic groups in your tenancy.

### Using the Console

**Creating a dynamic group**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Dynamic groups**.
3. Click **Create dynamic group**.
4. Enter the following:
   - **Name**: A unique name for the group. The name must be unique across all groups in your tenancy (dynamic groups and user groups). You can't change this later. Avoid entering confidential information.
   - **Description**: A friendly description.
5. Enter the **Matching rules**. Resources that meet the rule criteria are members of the group.
   - **Rule 1**: Enter a rule following the guidelines in Writing Matching Rules to Define Dynamic Groups on page 3162. You can manually enter the rule in the text box or launch the rule builder.
   - Enter additional rules as needed. To add a rule, click **Additional rule**.
6. If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 243. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
7. Click **Create**.

   The matching rule syntax is verified, but the OCIDs are not. Be sure that the OCIDs you enter are correct.

Next, to give the dynamic group permissions, you need to write a policy. See Writing Policies for Dynamic Groups on page 3293.

**Updating a dynamic group's matching rules**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Dynamic groups**.
3. Click the dynamic group you want to update.
4. Click **Edit all matching rules**.
5. Edit the matching rule in the text box; or, you can use the rule builder if the change is supported by the rule builder.
6. Enter additional rules as needed. To add a rule, click **+Additional rule**.
7. When you are finished, click **Save**.

**Updating a dynamic group's description**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Dynamic groups**.
3. Click the dynamic group you want to update.
4. Click **Edit dynamic group**.
5. Click **Description**, and edit the description.
6. When you are ready, click **Save**.

**Deleting a dynamic group**

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Dynamic groups**.
3. Select the check box next to the name of the dynamic group that you want to delete, and then click **Delete**.
4. Confirm when prompted.

**Assigning a domain role**

By default, every dynamic group is associated with the IDCS application. You can assign a domain role to that application to allow members of the dynamic group to perform certain actions with IDCS in the identity domain.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Select the identity domain you want to work in and click **Dynamic groups**.
3. Select the check box next to the name of the dynamic group that you want to delete, and then click **Delete**.
4. Confirm when prompted.

**Writing Matching Rules to Define Dynamic Groups**

Matching rules define the resources that belong to the dynamic group. In the Console, you can either enter the rule manually in the provided text box, or you can use the **rule builder**. The rule builder lets you make selections and entries in a dialog, then writes the rule for you, based on your entries. The rule builder supports the instance and compartment variables. To write a rule based on other variables, enter it manually.

You can define the members of the dynamic group based on the following:

- compartment OCID
- instance OCID (for instances) or resource OCID (for other resources)
- resource type
• tag namespace and tag key - include (or exclude) instances tagged with a specific tag namespace and tag key. All tag values are included. For example, include all instances tagged the with tag namespace department and the tag key operations.
• tag namespace, tag key, and tag value - include (or exclude) instances tagged with a specific value for the tag namespace and tag key. For example include all instances tagged with the tag namespace department and the tag key operations and with the value '45'.

A matching rule has the following syntax:

For a single condition:

```
variable =|!= 'value'
```

For multiple conditions:

```
any|all {<condition>,<condition>,...}
```

Supported variables are:

For instances, you can use:

• `instance.compartment.id` - the OCID of the compartment where the instance resides
• `instance.id` - the OCID of the instance

For all supported resource types, you can use:

• `resource.id` - the OCID of the resource
• `resource.compartment.id` - the OCID of the compartment where the resource resides
• `resource.type` - the type of resource. Valid resource type values can be found in the policy reference page for the service. For example, the valid resource type for a function is fn-function, the valid resource type for an api gateway is api-gateways. The policy reference pages for most services are listed here: Policy Reference on page 3347.
• `tag.<tagnamespace>.<tagkey>.value` - the tag namespace and tag key. For example, `tag.department.operations.value`.
• `tag.<tagnamespace>.<tagkey>.value='<tagvalue>'` - the tag namespace, tag key, and tag value. For example, `tag.department.operations.value='45'`

Here are some examples:

**Include all instances in a compartment**

To include all instances that are in a specific compartment, add a rule with the following syntax:

```
instance.compartment.id = '<compartment_ocid>'
```

You can type the rule directly in the text box, or you can use the rule builder.

Example entry in text box:

```
instance.compartment.id = 'ocid1:compartment:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv'
```

To add the same rule using the Console rule builder:

• For **Include Instances That Match**: Select **All of the following**.
• For **Match Instances with**: Select **Compartment OCID**.
• For **Value**: Enter the compartment OCID. For this example, you would enter
  `ocid1:compartment:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv`

All instances that currently exist or get created in the compartment (identified by the OCID) are members of this group.
Include all instances in any of two or more compartments

To include all instances that reside in any of two (or more) compartments, add a rule with the following syntax:

```
Any {instance.compartment.id = '<compartment_ocid>', instance.compartment.id = '<compartment_ocid>'}
```

separating each compartment entry with a comma.

You can type the rule directly in the text box, or you can use the rule builder.

Example entry in the text box:

```
```

To add the same rule using the Console rule builder:

1. For **Include Instances That Match**: Select *Any of the following*.
2. For **Match Instances With**: Select Compartment OCID.
3. For **Value**: Enter the compartment OCID. For this example, you would enter `ocid1:compartment:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv`
4. Click **+Additional Line**. Enter the following on the second line:
   - For **Match Instances With**: Select Compartment OCID.
   - For **Value**: Enter the additional compartment OCID. For this example, you would enter `ocid1:compartment:oc1:phx:samplecompartmentocidythksk89ekslsoelu2`

Instances that currently exist or are later created in either of the specified compartments are members of this group.

Include a specific resource in a specific compartment

To include a specific resource that's in a specific compartment, add a rule with the following syntax:

```
All {resource.id = '<resource_ocid>', resource.compartment.id=<compartment_ocid>}
```

Type the rule directly in the text box.

For example, to include a specific API gateway in a specific compartment, enter a statement like the following:

```
All {resource.id = 'ocid1.apigateway.oc1.phx.amaaaaaexampleuniqueid', resource.compartment.id='ocid1:compartment:oc1:phx:samplecompartmentocid'}
```

The API gateway with the specified OCID in the specified compartment belongs to this dynamic group.

Include all occurrences of a resource type in a specific compartment

To include all occurrences of a specific resource type in a specific compartment, add a rule with the following syntax:

```
All {resource.type = '<resource_type', resource.compartment.id=<compartment_ocid>}
```

Type the rule directly in the text box.

For example, to include all vaults in a specific compartment, enter a statement like the following:

```
All {resource.type = 'vaults', resource.compartment.id='ocid1:compartment:oc1:phx:samplecompartmentocid'}
```

All vaults in the specified compartment will be members of this dynamic group.
**Include all instances tagged with a specific namespace and tag key**

To include all instances that are tagged with a specific tag namespace and tag key, add a rule with the following syntax:

```
tag.<tagnamespace>.<tagkey>.value
```

All instances assigned the tagnamespace.tagkey combination are included. Note that the tag value is not evaluated, so all values are included.

**Example:** Assume you have a tag namespace called `department` and a tag key called `operations`. You want to include all instances that are tagged with the namespace and tag key.

Enter the following rule in the text box:

```
tag.department.operations.value
```

All instances that currently exist or get created with the tag namespace and tag key `department.operations` are members of this group.

**Include all instances in a specific compartment with a specific tag namespace, tag key, and tag value**

To include all instances in a specific compartment that are tagged with a specific tag namespace, key, and value, add a rule with the following syntax:

```
All {instance.compartment.id='<compartment_ocid>', tag.<tagnamespace>.<tagkey>.value='<tagvalue>'}
```

All instances that are in the identified compartment and that are assigned the tagnamespace.tagkey with the specified tag value are included.

**Example:** Assume you have a tag namespace called `department` and a tag key called `operations`. You want to include all instances that are tagged with the value 45, that are in a particular compartment.

Enter the following statement in the text box:

```
All {instance.compartment.id='ocid1:compartment:oc1:phx:oc1:phx:samplecompartmentocid6q6igvfauxmima74jv, tag.department.operations.value='45'}
```

**Using the Rule Builder**

The rule builder is a tool available from the Console to help you write matching rules. The rule builder provides menus and text boxes for you to make entries and then writes the rule for you. The rule builder does have some limitations, so you can't use it for all cases.

**Limitations of the Rule Builder**

The rule builder does not support the following:

- Exclusion rules - the rule builder lets you select compartment IDs and instance IDs to include only.
- Rules based on tags - the rule builder does not allow you to select tags to include in your rule. To add a rule based on tag values, you need to enter the rule in the Rule text box using the syntax above.
- Rules using the `resource.type`, `resource.id`, or `resource.compartment.id` variables.

**Launching the Rule Builder**

When you click Create Dynamic Group, the Rule Builder is displayed in the Create Dynamic Group dialog.

To create a matching rule using the rule builder

1. Under the Matching Rules section, click Rule Builder.
2. From the **Include Instances That Match** menu, select **All of the following** or **Any of the following**.

   **All of the following** includes only instances that match all of the statements in the rule.

   **Any of the following** includes instances that match any of the statements in the rule.

3. Select a resource type from the **Match Instances With** menu, and then enter the OCID for the resource in the **Value** field:

   **Compartment OCID** includes instances in the compartment you specify.

   **Instance OCID** includes the instances with the OCIDs you specify.

4. Click **+Additional line** to add more statements to this rule.

   When you add multiple statements to a rule, remember that **Any of the following** includes instances that match any of the statements. If you choose **All of the following**, instances must match all of the specifications in the statements to be included in the group.

**Examples Using the Rule Builder**

### Include all instances in a specific compartment in the dynamic group

To include all instances that are in a specific compartment, using the rule builder:

- Select **All of the following**.
- For **Match Instances With**: Select **Compartment OCID**.
- For **Value**: Enter the compartment OCID, for example, `ocid1:compartment:oc1:phx:samplecompartment:ocid:thksk89ekslsoelu2`

All instances that currently exist or are later created in the compartment (identified by the OCID) are members of this group.

### Include all instances in any of two or more compartments

To include all instances that reside in any of two (or more) compartments using the rule builder:

1. From the **Include Instances That Match** menu, select **Any of the following**.

2. In the first line, enter:

   - For **Match Instances With**, select **Compartment OCID**.
   - For **Value**, enter the compartment OCID, for example: `ocid1:compartment:oc1:phx:samplecompartment:ocid:thksk89ekslsoelu2`

3. Click **+Additional Line**. Enter the following on the second line:

   - For **Match Instances With**, select **Compartment OCID**
   - For **Value**, enter the compartment OCID, for example: `ocid1:compartment:oc1:phx:samplecompartment:ocid:thksk89ekslsoelu2`

4. Continue adding additional lines as needed for each compartment you want to include.

   Instances that currently exist or get created in any of the specified compartments are members of this group.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 6339 and **Security Credentials** on page 209. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 6152.

Use these API operations to manage dynamic groups:

- CreateDynamicGroup
- ListDynamicGroups
- GetDynamicGroup
- UpdateDynamicGroup
- DeleteDynamicGroup
Managing Applications
Identity domains provide a secure and centralized cloud service to manage your cloud, Oracle, custom, and enterprise applications.

Required Policy or Role
To manage applications, you must have one of the following access grants:

- Be a member of the Administrators group
- Be granted the Identity Domain Administrator role or the Application Administrator role
- Be a member of a group granted manage domains

To understand more about policies and roles, see The Administrators Group, Policy, and Administrator Roles on page 3112, Understanding Administrator Roles on page 3295, and Understanding Policies on page 3298.

Cloud Applications
Cloud applications are web-based applications that function in the cloud. These applications can be accessed from anywhere, and at any time, over the web. Examples of cloud applications are Google, Salesforce, and Dropbox.

Oracle and Custom Applications
Oracle applications are a complete and modular set of enterprise applications, engineered to be cloud-ready. In Oracle Cloud, you'll find a broad range of software as a service (SaaS), platform as a service (PaaS), and infrastructure as a service (IaaS) applications. You can use these applications as part of a subscription-based service; there's no software license or hardware to buy and manage. Oracle handles all the supporting underlying technologies.

You can extend Oracle applications or even build your own custom cloud applications in Oracle Cloud. Custom applications are applications (such as a mobile application, a web page, a client application, or a server application) that you can integrate with IAM. By default, for security purposes, custom applications are trusted or confidential.

IAM leverages the power of OpenID Connect and OAuth to deliver a highly-scalable, multi-tenant token service for securing programmatic access to custom applications by other custom applications, and for federated SSO and authorization integration with these applications:

- Use OAuth 2.0 to define authorization in IAM for your custom applications. OAuth 2.0 has an authorization framework, commonly used for third-party authorization requests with consent. Custom applications can implement both two-legged and three-legged OAuth flows.
- Use OpenID Connect to externalize authentication to IAM for your custom applications. OpenID Connect has an authentication protocol that provides Federated SSO, leveraging the OAuth 2.0 authorization framework as a way to federate identities in the cloud. Custom applications participate in an Open ID Connect flow.

Using the OAuth 2.0 and OpenID Connect standards provides the following benefits:

- Federated SSO between the custom application and IAM. Resource owners (users accessing the custom application) need a single login to access IAM plus all applications integrated. IAM handles the authentication and credentials itself, insulating custom applications. This capability is provided by OpenID Connect with OAuth 2.0.
- Authorization to perform operations on third-party servers with consent. Resource owners can decide at runtime whether the custom applications should have authorization to access data or perform tasks for them. This capability is provided by OAuth 2.0.

Enterprise Applications
Enterprise applications are web applications that require App Gateway to integrate with IAM for authentication and authorization purposes.

Enterprise applications work similarly to confidential applications if you configure the Client configuration and Resource server configurations section under OAuth configuration tab.

To configure an enterprise application to work with App Gateway for authentication and authorization purposes, you need to know the following information about your web application:

- The web application's base URL. For example, if a known URL of your application is http://myapp.internal.example.com:3266/myapp/private/home, then the base URL is http://myapp.internal.example.com:3266.
IAM

- The list of resources of your web application. For example, if your web application exposes the following URLs: functionalities A to Z in the following format /myapp/private/funcA to /myapp/private/funcZ, a home page /myapp/private/home, a logout URL /myapp/logout, an about page myapp/public/about, and an index page /myapp/index, then the list of all resources of your web application is:
  - URLs from /myapp/private/funcA to /myapp/private/funcZ
  - /myapp/private/home
  - /myapp/logout
  - /myapp/public/about
  - /myapp/index

- For each resource, define which resources require the user to be authenticated, which don't require user authentication, and which resource represents the log out action. Below are examples of authenticated and non-authenticated resources:
  - Resources from /myapp/private/funcA to /myapp/private/funcZ, and /myapp/private/home require the user to be authenticated.
  - /myapp/logout logs out the user.
  - Both myapp/public/about and /myapp/index are public resources and don't require the user to be authenticated.

- For each resource, define who can access which resource and which HTTP Method will be allowed or denied access. For example, you can define that all members of group Employees are allowed access to make GET and POST HTTP requests to resource /myapp/private/home, only members of group MyGroupA can access /myapp/private/funcA, and only users accessing from within network perimeter IntranetIPs can access resources from /myapp/private/funcB to /myapp/private/funcZ.

- Identify URL patterns that apply to your list of resources. In the previous example, the URL pattern /myapp/private/.* matches all the application's functionality URLs and the home page URL. All these URLs may require the same kind of authentication and authorization.

Use Case: Adding Applications
To understand how to add custom applications in an identity domain, read this use case.

For this use case, a user accesses the Customer Quotes trusted application. This trusted application is a client application that makes REST API calls to the abccorp.com resource server application. A resource server application is a third-party application that provides services that a trusted application can consume on behalf of the user.

For this example, the abccorp.com resource server application is a financial application that contains REST APIs that can be used to make a quote (/quote), request for a quote (/rfq), or get information about the user (/user).

When the user accesses the Customer Quotes trusted application, the application makes REST API calls to the abccorp.com resource server application on behalf of the user. In this example, the user doesn't communicate directly with the abccorp.com application.
Because the Customer Quotes application performs actions on behalf of the user, the application needs access to the /quote, /rfq, and /user REST APIs available with the abccorp.com application. To make these REST API calls, the Customer Quotes application might ask for the user's consent. This consent can come at any time that the Customer Quotes application calls for these REST APIs in the abccorp.com application.

The user logs in to IAM and accesses the Custom Quotes application, through single sign-on, by using OAuth 2.0 and Open ID connect, as this is a way of federating identities in the cloud. Because the Customer Quotes application is authorized on behalf of the user to make the /quote, /rfq, and /user REST API calls to the abccorp.com application, the user can use the Customer Quotes application to make a quote, request for a quote, and get information about the user. Any additional actions that the user wants to perform through the Customer Quotes application isn't allowed.

To build this workflow, you create and activate two custom applications in IAM:

- The abccorp.com resource server application. This application has REST APIs (resources) that other applications, such as the Customer Quotes application, can access. In this example, the user doesn't access the resource server application directly, but indirectly through the Customer Quotes application. You register resources of the abccorp.com resource server application. Application resources are API calls that are authorized by IAM. For this example, the application resources are the /quote, /rfq, and /user REST APIs. For security and auditing purposes, you can specify whether the user must give consent to access these resources.

- The Customer Quotes trusted application. The user uses this application to access the REST APIs of the abccorp.com application.

When you create this custom application, you want to generate an authorization code for the user when the user logs in to IAM. The authorization code is then sent to the Customer Quotes application to retrieve an access token. The access token contains all the rights that the user has to access the resource server application. For this example, these rights include making a quote, requesting a quote, and retrieving information about the user. Because the access token's lifetime is short, you might want to generate a refresh token. A refresh token is a secure mechanism to obtain a new access token when the current access token expires. This way, the Customer Quotes application can access the APIs of the abccorp.com application without asking for user consent again.

See Add Applications, Activate Applications, and Deactivate Applications for more information about creating and activating custom applications in IAM.

Using the Console
Adding Applications

You can add Custom Applications, if you are assigned to either the identity domain administrator role or the application administrator role.

See Add or Remove a User Account from an Administrator Role for information about assigning users to administrator roles.

You can add the following types of custom applications in IAM:

- App Catalog application: Add an application from the Application Catalog, which contains pre-configured application templates.
- SAML application: Accessed by multiple users and hosted in a secure and protected place (server). Create a Security Assertion Markup Language (SAML) application that supports SAML for single sign-on. This allows users to single sign-on (SSO) into your software as a service (SaaS) applications that support SAML for SSO.
- Mobile application: Hosted directly on the resource owner's browser, machine, or mobile device. An example of this type of application is an Android or iPhone application. A mobile application can run in multiple environments outside of your control. Since these environments are not trusted, this type of application has reduced integration options.
- Confidential application: Accessed by multiple users and hosted in a secure and protected place (server). The application uses OAuth 2.0. Applications that can protect their OAuth client id and client secret are called confidential applications.
- Enterprise application: Web applications that require App Gateway to integrate with IAM for authentication purposes. App Gateway passes HTTP headers to the application after authenticating and authorizing user's access.
Tip:

- You can access the Onboarding Applications infographic to see how to add custom applications in IAM.
- You can access the Integrating a Custom Client Application tutorial to see how to integrate a custom client application with IAM.
- You can access the Integrating a Custom Resource Server Application tutorial to see how to integrate a custom resource server application with IAM.
- See Manage IAM App Gateways for information on integrating an enterprise application with IAM.

Adding an App Catalog Application

Oracle creates and maintains the Application Catalog, which is a collection of application templates, for you and provides step-by-step instructions on how to configure most of the popular Software as a Service (SaaS) applications, such as Amazon Web Services and Google Suite.

The configuration options for each Application Catalog application can differ slightly. The steps below are for a basic configuration.

1. Open the navigation menu and click Identity & Security. Under Identity, click Domains. Select the identity domain you want to work in and click Applications.
2. Click Add application.
3. In the Add application window, click Application Catalog, and then Launch app catalog.
4. Locate and select an application by choosing a Category (predefined by Oracle), searching for the application by entering a string that begins with the application name, or to see all applications, click All.
5. Click the application.
6. Complete the application details by entering a Name, Description, and Application URL.

Note:

For applications with lengthy names, the application name appears truncated in the My Apps page. Consider keeping your application names as short as possible.

7. In the Custom error URL field, enter the error page URL to which a user has to be redirected, after a failure. This field is optional. However, if not specified, the tenant-specific Error page URL is used. If both the error URLs are not configured, then the error is redirected to the IAM Error Page (/ui/v1/error).

When a user tries to use social authentication (ex: Google, Facebook, and so on) for logging into IAM, the Custom social linking callback URL must be configured in the Custom error URL field. Social providers need this callback URL to call IAM and send the response back after social authentication. The provided callback URL is used to verify whether the user exists or not (after first-time social login), and displays an error if the social authentication has failed.

8. In the Custom social linking callback URL field, enter the URL that IAM can redirect to after linking of a user between social providers and IAM is complete.

When you create a custom app using the IAM custom SDK and integrate with IAM Social Login, the custom app needs to have the Custom social linking callback URL which can be redirected after linking of the user between social provider and IAM is complete.
9. In the **Display settings** section, select **Display in My Apps**.

    **Important:**
    If you do not select **Display in My Apps**, the application does not display in the **My Apps** page.

When you select the **Display in My Apps** check box in applications, the app is then visible in the **My Apps** page, but selecting this check box doesn’t enable or disable SSO to the app.

The flag to enable or disable SSO comes from the app template.

10. Select the **User can request access** check box, if you want the app to be listed in the **Catalog**. This option allows end users to request access to applications from their **My Apps** page by clicking **Add** and then selecting the app from the **Catalog**.

    Don’t forget to activate the application so that users can request access.

11. Click **Next** and configure SSO.

    - Click **Download signing certificate** to import the IAM signing certificate into your application. This certificate is used by the SAML application to verify that the SAML assertion is valid.
    - Click **Download identity provider metadata** to import the IAM Identity Provider metadata into your application. The SAML application needs this information so that it can trust and process the SAML assertion that is generated by IAM as part of the federation process. This information includes, for example, profile and binding support, connection endpoints, and certificate information.

    To get the issuing IAM root certificate, see **Obtaining the Root CA Certificate** on page 3134.

12. Click **Finish**. The application has been added in deactivate state. To activate your application see **Activating Applications**.

13. Click **Activate**.

14. Select the application.

15. To assign users to the application, click **Users**.

16. To assign groups to the application, click **Groups**.

The applications you assign to the user display on the **My Apps** page. Newly assigned applications and applications that a user has not yet accessed appear first in the application list and have an asterisk icon in the application tile. The icon appears on the tile until the user accesses the application.

**Enabling Provisioning for an App Catalog Application**

User provisioning and synchronization are an important aspect of application management. Provisioning allows you to manage the lifecycle of accounts in applications like creating and deleting accounts using IAM. For example, when you grant the user access to an application such as Google Suite, then this user account is automatically created in Google Suite. This allows you to quickly add new users to multiple applications and de-provision users from those applications instantly when they change roles or leave your organization.

You can enable and configure provisioning for App Catalog applications either when adding the app or later when modifying it. When you enable provisioning by selecting the option, the following steps appear:

1. Configure the app connectivity.

    Configure your app connectivity by providing values for the respective fields and by testing connectivity.

2. Configure the attribute mapping.

    Using **Attribute mapping** you can map IAM attributes to the attributes in your application account. You can verify the existing default mapping and, if necessary, change mappings by selecting appropriate values from the list for the required user attribute. You can add rows to map missed attributes and delete rows to exclude duplicate attribute mapping. To add a new attribute for provisioning, click **Add row**, specify the attributes in the **User** and your application account columns, and then click **Save changes**. For example, if you want to add the **External ID** field, enter $(user.externalId) in the **User** column, and then select the corresponding field from the list in the applications account column.
3. Select the provisioning operations.

Any app that supports provisioning and synchronization can be an authoritative app. If **Authoritative Sync** is configured, using IAM, you can automatically create, modify, delete, and activate or disable users based only on the corresponding data from the authoritative application. However, the regular provisioning operations are not allowed while authorization sync is enabled.

When authoritative sync is enabled, the following actions happen automatically:

- If a user is not present in IAM, then the user is automatically created.
- If an authoritative synced user is deleted from the application, then the user is also deleted from IAM.
- If attributes of an authoritative synced user are modified, then the attributes for the user are also modified in IAM.

When **Authoritative Sync** is enabled, then the provisioning operations aren’t permitted from IAM to the target application. To manage users in the application using provisioning, clear the **Authoritative Sync** check box. The following provisioning operations appear:

- **Create Account**: Select to create an account when the app is granted to the user.
- **De-activate Account**: Select to disable this account. To activate the account, clear the check box.
- **Delete Account**: Select to delete the account in the app when the IAM user is deleted.

**Important:**

When you configure the connection between your app and IAM, check and verify any pre-filled username and password field entries as these might not be the credentials to access your application.

To configure provisioning and synchronization for your application, follow the specific application catalog instructions for the application.

After you have enabled Provisioning, you can perform the following actions:

- Assign users or groups to your App Catalog application to start the user provisioning process for your application. See **Assigning Users to Custom Applications** and **Assigning Groups to Custom Applications**.
- Enable and configure synchronization. To enable and configure synchronization, see **Enable Synchronization for an App Catalog Application**.

Enabling Synchronization for an App Catalog Application

User provisioning and synchronization is an important aspect of application management. After enabling provisioning, synchronization allows you to control how operations like creating and deleting accounts in Software as a Service (SaaS) applications are reflected in IAM.

You can enable and configure synchronization for App Catalog applications either when adding the app or later when modifying it. You can only enable synchronization after enabling provisioning. To enable provisioning, see **Enabling Provisioning for an App Catalog Application**. Follow the application catalog instructions for your specific SaaS app to enable and configure synchronization.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click the name of the SaaS app that you want to configure.
3. Click **Configure provisioning**.
4. Click the **Enable synchronization** switch.
5. In the **Configure synchronization** section, modify the attributes following the application catalog instructions for your specific SaaS application.

Enable synchronization to import users from your SaaS app.

**Note:**

If the number of created objects (users) and deleted recorded objects (synced users) exceeds the maximum number allowed, the sync job quits.
maximum number of objects created or recorded objects deleted is an approximate maximum limit, not a precise limit because of the parallel processing of synced objects.

See Importing User Accounts from a Software as a Service Application.

Importing Users from a SaaS Application

After enabling provisioning and synchronization for your App Catalog app, you might want to import the existing users from your Software as a Service (SaaS) applications and link them to IAM users.

Before you import your SaaS users, verify that:

• The app is activated. To activate your app, see Activating Applications.
• Provisioning is enabled. See Enabling Provisioning for an App Catalog Application.
• Synchronization is enabled. See Enabling Synchronization for an App Catalog Application.

1. If not already there, click Applications and then the name of the app that you want to configure.
2. Verify that the app is activated.
3. Click Import.
   The page lists the result of the last import if any and the actions you need to perform. See Synchronizing User Accounts.
4. If you want to invoke an on-demand synchronization, click the Import icon. If the icon is unavailable, click the Provisioning tab and verify that Provisioning and Synchronization are enabled, and the app is activated.
5. A message confirms that the job for importing users is running successfully.

After the import finishes, the page lists the imported users.

Synchronizing Users

After synchronizing your SaaS app with an identity domain, you will see the result of the import including the number of users created, deleted, and updated. You can do a general search based on account name, user e-mail, or username. You can also filter and search the results based on Situation and Synchronization Status. Select values from the respective lists to view users matching the search criteria. These are helpful when you have to find a set of users based on their situation or status from a huge number of results.

The Import page provides you with the overall status information, whether the Last import succeeded, failed, or is still running. If the import succeeded, then the result is listed as follows:

• Start date is the date and time you started the import job.
• End date determines date and time the import job finished.
• Accounts created shows the number of identity domain accounts that got created during the import based on your synchronization settings.
• Accounts deleted lists the number of identity domain accounts that got deleted during the import based on your synchronization settings.
• Accounts updated notes the number of identity domain accounts that got changed during the import.

1. This table summarizes the result of successfully running an import. For each SaaS app account, it shows whether there exists a matching identity domain user and the action that you need to perform to link the SaaS user account to an identity domain user.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account</td>
<td>Shows the name of the SaaS app user account.</td>
</tr>
</tbody>
</table>
### Column Description

<table>
<thead>
<tr>
<th>Situation</th>
<th>Lists whether a matching identity domain user exists or does not exist based on your synchronization configuration:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>No match is found</strong></td>
<td>Indicates that you need to manually select which action to take.</td>
</tr>
<tr>
<td><strong>Exact match is found</strong></td>
<td>Indicates that an identity domain user exists that matches the synchronization criteria that you configured.</td>
</tr>
<tr>
<td><strong>Multiple matches are found</strong></td>
<td>Indicates that there are multiple matches found for a user. You need to manually select one of the available actions.</td>
</tr>
<tr>
<td><strong>Manually linked</strong></td>
<td>Is the result of any action that you performed to link this SaaS app account to an identity domain user.</td>
</tr>
</tbody>
</table>

| User | Shows the email address and user name of the identity domain user. |

<table>
<thead>
<tr>
<th>Action</th>
<th>If there is no matching identity domain user, you need to select the appropriate action from the list:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Assign existing user</strong></td>
<td>The Assign user page lists all existing identity domain users and allows you to select the one that you want to link with this SaaS app account.</td>
</tr>
<tr>
<td><strong>Create new user and link</strong></td>
<td>The Add user page allows you to create a new identity domain user.</td>
</tr>
</tbody>
</table>

| Status | Lists the status or whether you need to confirm linking the SaaS app account to the identity domain user. |

### Accessing the Synchronization Failure Report

You can view the synchronization failure report of a provisioning application from the Import tab. The report contains the sync failures for the selected application. This report is useful in finding out the reason behind sync failures that occurred during account and object sync of an application.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click the application that you want to modify.
3. Select **Import** and click **Synchronization failure**.
4. In the **Synchronization failure report** page, you can use the filters to narrow down the result based on the following criteria:
   a) **Dates range**
      
      Choose the number of days for which you need the failure report. The possible values are: **30 Days**, **60 Days**, **90 Days**, and **Custom dates**. Select **Custom dates** to run the filter for a customized date range. Enter the **Start date** and the **End date** in the text box or select them from the calendar.
   b) **Application**
      
      The Application filter is case-sensitive.
   c) **Object type**
      
      To narrow down the result based on **Application** or **Object type**, choose a value from the menu and enter a corresponding value in the text box. The available values are: **Equals**, **Contains**, **Begins with** and **Ends with**.

### Tip:

If you select **Equals** and enter Google App in the text box, the filter displays entries only for Google App. If you select **Begins with** and enter...
In the text box, the filter displays entries for applications starting with the letter G.

5. After you have set the filter, click **Run** to display the search result.

The following table describes the various columns in the search filter:

<table>
<thead>
<tr>
<th>Filter Columns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application</td>
<td>Displays the name of the Application.</td>
</tr>
<tr>
<td>Object type</td>
<td>Displays the type of the Object, for example, Account, Group, Organization,</td>
</tr>
<tr>
<td></td>
<td>Printer, and so on.</td>
</tr>
<tr>
<td>Object identifier</td>
<td>Displays the unique ID of the object from which sync is performed.</td>
</tr>
<tr>
<td>Name</td>
<td>Displays the name of the object on which sync is performed.</td>
</tr>
<tr>
<td>Date</td>
<td>Displays the time when the sync was performed on the object.</td>
</tr>
<tr>
<td>ECID</td>
<td>Displays the value of the Event Correlation Identifier (ECID).</td>
</tr>
<tr>
<td>Failure reason</td>
<td>Displays the reason behind the synchronization failure.</td>
</tr>
</tbody>
</table>

6. Click **Download** to export the search result in the tabular column to a CSV file.

Adding a SAML Application

Create a Security Assertion Markup Language (SAML) application and grant it to users so that your users can single sign-on (SSO) into your SaaS applications that support SAML for SSO.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.

2. Click **Add application**.

3. In the Add application window, click **SAML Application**, and then **Launch workflow**.
4. In the Add SAML Application page, provide values for the following fields:

- In the Name field, enter a name for the application.
  
  For applications with lengthy names, the application name appears truncated in the My Apps page. Consider keeping your application names as short as possible.
- In the Description field, enter 250 or fewer characters to provide a description of the application.
- Click Application icon to add an icon for your application.
- Select Add app links to add links that are associated with the application.
- Select Add app links to add links that are associated with the application. Click Add and the Add app link window appears. App links are services such as Mail or Calendar that are offered by applications such as Google or Office 365.

In the Add app link window:

a. In the Name field, enter the App link name.

b. In the Relay state field, enter the URL used to access the application.

c. Drag and drop and image file to upload an Application icon.

d. Select Visible if you want your application to appear automatically on each user’s My Apps page.

Note:

Selecting this check box does not enable or disable SSO into the application.

e. Click Add.

The App link information appears in the table in the App links section.

To remove an App link, select the row, and then click Remove.

Note:

There is a delay (a few seconds) between clicking Remove and the App no longer appearing on the My Apps page. App link deletion (and grants related to those App links) is asynchronous. Wait a few seconds for the asynchronous task to remove the App and its grants before trying My Apps again.

- In the Relay state field, enter a value which is sent to the SAML SP as the SAML RelayState parameter.
- In the Custom sign-in URL field, specify a custom sign-in URL. However, if you are using a default login page provided by IAM, then leave this field blank.
- In the Custom error URL field, enter the error page URL to which a user has to be redirected, if there is a failure. This is an optional field. However, if not specified, the tenant-specific Error page URL is used. If both the error URLs are not configured, then the error is redirected to the IAM Error Page (/ui/v1/error).

When a user tries to use social authentication (ex: Google, Facebook, and so on) for logging into IAM, the callback URL must be configured in the Custom Error URL field. Social providers need this callback URL to call IAM> and send the response back after social authentication. The provided callback URL is used to verify whether the user exists or not (in the case of first-time social login), and display an error if the social authentication has failed.

- In the Custom social linking callback URL field, enter the URL that IAM> can redirect to after linking of a user between social providers and IAM> is complete. This is an optional field.

When you create a custom app using IAM> custom SDK and integrate with IAM> Social Login, the custom app needs to have the Linking callback URL which can be redirected after linking of the user between social provider and IAM is complete.
5. In the **Display settings** sections of the Add SAML Application page, make the following selections:

   - Select **Display in My Apps** check box to specify whether you want the SAML App to be listed on the My Apps page.

      When you select the **Display in My Apps** check box in applications, the app is then visible in the My Apps page, but selecting this check box doesn’t enable or disable SSO to the app.

      The flag to enable or disable SSO comes from the app template.

   - Select the **User can request access** check box if you want the app to be listed in the Catalog. This option allows end users to request access to the app from their My Apps page by clicking **Add** and then selecting the app from the Catalog.

     **Note:**
     Don’t forget to activate the application so that users can request access.

6. When you are creating SAML app from scratch rather than creating a preconfigured SAML app created from the App Catalog, the **Authentication and authorization** section appears. The **Enforce grants as authorization** check box is selected by default. This check box enables users to access only the application that you assigned or granted access to. If the check box is selected, IAM can control access to the SAML application based on grants to users and groups. If the check box is not selected, any authenticated user has access to the application regardless of the assignment status.

7. Click **Next** to configure SSO details for the SAML application.

8. In the **General** section of the Configure single sign-on page, define the following:

   - **Entity ID**: Enter a globally unique name for a SAML entity. It usually takes a URL of an identity provider or a service provider as a value.

   - **Assertion consumer URL**: Enter the URL to which the SAML identity provider sends the SAML assertion. This URL must begin with either the HTTP or HTTPS protocol.

   - **Name ID format**: Select the type of format to use for the NameID. The service provider and the identity provider use this format to easily identify a subject during their communication.

      **Note:**
      When you integrate IAM with MS SharePoint app based on WS Fed 1.1 protocol, the following options are not available in the NameID format: **Persistent**, **Kerberos**, and **Transient**.

   - **Name ID value**: Select the NameID Value to identify the user that is logged in. The available options are **Username**, the user’s **Primary email** address and **Expression**. When you select the **Expression** option, enter a regular expression as a value in the text box. There is no character limit for the value, however, there are validation rules that are performed on the value for any invalid characters that cannot be mapped.

   - **Signing certificate**: Upload the signing certificate that is used to encrypt the SAML assertion.

      **Note:**
      Some browsers show file paths prepended with `c:\fakepath\`. This behavior is a security feature of the browser and does not disrupt the upload process.

9. Use the following table to define a more fine-grained SAML configuration in the **Additional configurations** section.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Signed SSO</td>
<td>Select <strong>Assertion</strong> to indicate that you want the SAML assertion signed.</td>
</tr>
<tr>
<td></td>
<td>Select <strong>Response</strong> when you want the SAML authentication response signed.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Include signing certificate in signature</td>
<td>Select the check box to include the signing certificate in the signature, for example, when the application requires that the signing certificate is sent along with the assertion.</td>
</tr>
<tr>
<td>Signature hashing algorithm</td>
<td>Select the type of signing algorithm that you want to use to sign the assertion or the response, either SHA-256 or SHA-1. SHA-256 generates a fixed 256-bit hash. SHA-1 generates a 160-bit hash value known as a message digest.</td>
</tr>
<tr>
<td>Note:</td>
<td>In a FIPS enabled environment, set the <strong>Signature hashing algorithm</strong> to SHA-256, the only supported hashing algorithm, to avoid errors during SSO.</td>
</tr>
<tr>
<td>Enable single logout</td>
<td>Select to configure SAML single logout. Single logout enables a user to log out of all participating sites in a federated session almost simultaneously. This check box is selected by default. Clear it if you do not want to enable single logout.</td>
</tr>
<tr>
<td>Logout binding</td>
<td>Select whether the log out request is sent as a REDIRECT (transported using HTTP 302 status-code response messages) or a POST (transported in HTML form-control content, which uses a base-64 format). This list box appears only if you select the <strong>Enable single logout</strong> check box.</td>
</tr>
<tr>
<td>Single logout URL</td>
<td>Enter the location (HTTP or HTTPS) where the log out request is sent. This field appears only if you select the <strong>Enable single logout</strong> check box.</td>
</tr>
<tr>
<td>Logout response URL</td>
<td>Enter the location (HTTP or HTTPS) where the log out response is sent. This field appears only if you select the <strong>Enable single logout</strong> check box.</td>
</tr>
<tr>
<td>Encrypt assertion</td>
<td>Select if you want to encrypt the assertion, and then define the encryption algorithm that you want to use and upload the encryption certificate.</td>
</tr>
<tr>
<td>Encryption certificate</td>
<td>Click <strong>Upload</strong> to upload the encryption certificate that's used to encrypt the SAML assertion. This button appears only if you select the <strong>Encrypt assertion</strong> check box.</td>
</tr>
<tr>
<td>Encryption algorithm</td>
<td>Select which encryption algorithm you want to use to encrypt the SAML assertion. This list box appears only if you select the <strong>Encrypt assertion</strong> check box.</td>
</tr>
<tr>
<td>Key Encryption algorithm</td>
<td>Select which key encryption algorithm you want to use to encrypt the SAML assertion. This list box appears only if you select the <strong>Encrypt assertion</strong> check box.</td>
</tr>
</tbody>
</table>

10. In the **Attribute configuration** section, add user-specific and group-specific attributes to the SAML assertion. This is useful if your application uses user-specific or group-specific attributes, and you want to send that information as part of the SAML assertion.
11. Click **Additional attributes**, and then use the following table to specify the user attribute that you want to include. User information in the attribute statement contains a list of attributes. Each attribute includes a name and a list of values (if there are multiple attribute values). Each value includes a value and the format of the value.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter the name of the SAML assertion attribute.</td>
</tr>
<tr>
<td>Format</td>
<td>Select the format of this SAML assertion attribute: <strong>Basic</strong>, <strong>URI Reference</strong>, or <strong>Unspecified</strong>.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>When you integrate IAM with MS SharePoint app based on WS Fed 1.1 protocol, <strong>Format</strong> menu is replaced with <strong>Namespace</strong>.</td>
</tr>
<tr>
<td>Type</td>
<td>Select one of the following options to specify the value of the assertion attribute.:</td>
</tr>
<tr>
<td><strong>User attribute</strong></td>
<td>Select this option to choose one of the predefined list of user attributes or group attributes in the <strong>Value</strong> menu as the value of the assertion attribute. To specify group attributes, select <strong>User attribute</strong> and in the <strong>Value</strong> field, select <strong>Group membership</strong>.</td>
</tr>
<tr>
<td><strong>Expression/literal</strong></td>
<td>Select this option when you cannot use any of the predefined values in the <strong>Value</strong> menu. You can provide an expression in the <strong>Value</strong> text box to specify the value of the SAML assertion attribute. To specify group attributes, select <strong>Expression/literal</strong> and specify an expression to fetch the groups. Example: The following expression specifies that the value of the SAML attribute should be the names of all the groups to which the user belongs: $(user.groups[*].display)</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Type value       | Select or enter the value to send as part of the assertion based on the Type that you have selected. When the type is User attribute, you can select one of the predefined list of user attributes as the value of the assertion attribute. Select the Group membership option in the menu if you want to send the users group membership as the value of the assertion attribute. The Condition and Value columns appear when you choose Group membership. When the type is Expression/literal, the value field is a text box and you can enter any path expression to specify what should be the value of the assertion attribute. The following are some examples of path expressions:  
  • To send a list of literal values as the value of the assertion attribute, use `"["value1", "value2", "value3"]`.  
  • To send “home email” as the value of the assertion attribute, use `$(user.emails[type eq "home"].value)`.  
  • To send users first name concatenated with last name as the assertion attribute, use `#concat($(user.name.givenName), $(user.name.familyName))`.  
  • To send an account attribute called SALARY as the value of the assertion attribute, use `$(account.SALARY)`.  
  • To include an attribute department from custom schema extension, use `$(user.urn:ietf:params:scim:schemas:idcs:extension:custom:User:department)`.  
  • To send a literal value as the value of assertion, use aLiteralValue. |
| Condition        | Select a condition from the menu to filter the group memberships. This field is enabled only when you select User attribute as Type and Group membership as Type value. The available values are: Equals, Starts with, and All groups. |
| Condition value  | Enter the filter value to use when filtering the group memberships.                                                                                                                                          |

12. Click Finish. The application is added in a deactivated state. To activate your application, see Activating Applications.

13. To import the IAM signing certificate into your application, click Download signing certificate to first download the certificate file in PEM format. This certificate is used by the SAML application to verify that the SAML assertion is valid.

14. To import the IAM Identity Provider metadata into your application, click Download identity provider metadata to first download the metadata file in XML format. The SAML application needs this information so that it can trust and process the SAML assertion that is generated by IAM as part of the federation process. This
information includes, for example, profile and binding support, connection endpoints, and certificate information.
To get the issuing IAM root certificate, see Obtain the Root CA Certificate on page 3134.

Editing SSO Configuration Information for SAML Applications
You can edit SSO configuration information for SAML applications.

See Add a SAML Application for more information about the SSO configuration settings for SAML applications.

1. Open the navigation menu and click Identity & Security. Under Identity, click Domains. Select the identity domain you want to work in and click Applications.
2. Select the SAML application from the list of applications listed.
3. Click Edit SSO configuration.
4. In the General section, modify required SAML assertion attributes for the SAML application.
5. In the Additional configurations section, modify optional advanced SAML assertion settings for the SAML application (for example, selecting Assertion from the Signed SSO list to indicate that you want the SAML assertion signed).
6. In the Attribute configuration section, modify user-specific and group-specific attributes for the SAML application (for example, selecting the type of user attribute from the User attribute list or selecting the condition by which you want to filter the group memberships from the Condition list).
7. Click Save changes.

Adding a Mobile Application
Add mobile applications that use OAuth 2.0 and they cannot maintain the confidentiality of their client secrets.

1. Open the navigation menu and click Identity & Security. Under Identity, click Domains. Select the identity domain you want to work in and click Applications.
2. Click Add application.
3. In the Add application window, click Mobile Application.
4. Click Launch workflow.
5. In the Add applications details page, use the following table to configure the application details.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name for the mobile application. You can enter up to 125 characters. For applications with lengthy names, the application name appears truncated in the My Apps page. Consider keeping your application names as short as possible.</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a description of the mobile application. You can enter up to 250 characters.</td>
</tr>
<tr>
<td>Application icon</td>
<td>Click Upload to add an icon that represents the application. This icon appears next to the name of the application on the My Apps page and the Applications page.</td>
</tr>
<tr>
<td>Custom sign-in URL</td>
<td>In the Custom sign-in URL field, specify a custom sign-in URL. However, if you are using a default login page provided by IAM, then leave this field blank.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Custom sign-out URL</td>
<td>In the <strong>Custom sign-out URL</strong> field, specify a custom sign-out URL. However, if you are using a default login page provided by IAM, then leave this field blank.</td>
</tr>
<tr>
<td>Custom error URL</td>
<td>This is an optional field. Enter the error page URL to which a user has to be redirected, if there is a failure. If not specified, the tenant-specific Error page URL is used. If both the error URLs are not configured, then the error is redirected to the IAM Error Page (/ui/v1/error).</td>
</tr>
<tr>
<td></td>
<td>When a user tries to use social authentication (ex: Google, Facebook, and so on) for logging into IAM, the callback URL must be configured in the <strong>Custom error URL</strong> field. Social providers need this callback URL to call IAM and send the response back after social authentication. The provided callback URL is used to verify whether the user exists or not (if this a first-time social login), and display an error if the social authentication has failed.</td>
</tr>
<tr>
<td>Custom social linking callback URL</td>
<td>This is an optional field. Enter the URL that IAM can redirect to after linking of a user between social providers and IAM is complete.</td>
</tr>
<tr>
<td></td>
<td>When you create a custom app using IAM custom SDK and integrate with IAM Social Login, the custom app needs to have the Custom social linking callback URL which can be redirected after linking of the user between social provider and IAM is complete.</td>
</tr>
<tr>
<td>Display in My Apps</td>
<td>Select the check box if you want the mobile application to be listed for users on their My Apps pages. In this case, you need to configure the application as a resource server.</td>
</tr>
<tr>
<td></td>
<td>When you select the <strong>Display in My Apps</strong> check box in applications, the app is then visible in the My Apps page, but selecting this check box doesn’t enable or disable SSO to the app.</td>
</tr>
<tr>
<td></td>
<td>The flag to enable or disable SSO comes from the app template. Use the IAM REST APIs to update this flag. You cannot set the SSO flag from the UI.</td>
</tr>
<tr>
<td>Enforce grants as authorization</td>
<td>Select the check box if you want end users to be able to request access to the app from their My Apps page by clicking <strong>Add access</strong>. If self-service is not enabled, users won’t see the <strong>Add access</strong> button.</td>
</tr>
</tbody>
</table>

6. Click Next.
7. In the **Authorization** and **Accessing APIs from other application** sections of the Add Mobile Application page, use the following table to configure application details.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Allowed grant types</strong></td>
<td>Select the check box for the grant types that this application is allowed to use when requesting validation.</td>
</tr>
<tr>
<td></td>
<td>• Select the <strong>Refresh token</strong> grant type when you want a refresh token supplied by the authorization server, and then use it to obtain a new access token. Refresh tokens are used when the current access token becomes invalid or expires and don’t require the resource owner to reauthenticate.</td>
</tr>
<tr>
<td></td>
<td>• Select the <strong>Authorization code</strong> check box when you want to obtain an authorization code by using an authorization server as an intermediary between the client application and resource owner. An <strong>authorization code</strong> is returned to the client through a browser redirect after the resource owner gives consent to the authorization server. The client then exchanges the authorization code for an access (and often a refresh) token. Resource owner credentials are never exposed to the client.</td>
</tr>
<tr>
<td></td>
<td>• Select the <strong>Implicit</strong> check box if the application can't keep client credentials confidential for use in authenticating with the authorization server. An access token is returned to the client through a browser redirect in response to the resource owner authorization request (rather than an intermediate authorization code).</td>
</tr>
<tr>
<td></td>
<td>• Select the <strong>Device code</strong> grant type if the client doesn't can't receive requests from the OAuth Authorization Server, for example, it cannot act as an HTTP server such as game consoles, streaming media players, digital picture frames, and others. In this flow, the client obtains the user code, device code, and verification url. The user then accesses the verification url in a separate browser to approve the access request. Only then can the client obtain the access token using the device code.</td>
</tr>
<tr>
<td><strong>Allow non-HTTPS URLs</strong></td>
<td>Select this check box if you want to use HTTP URLs for the <strong>Redirect URL</strong>, <strong>Logout URL</strong>, or <strong>Post logout redirect URL</strong> fields. For example, if you are sending requests internally, want a non-encrypted communication, or want to be backward-compatible with OAuth 1.0, then you can use an HTTP URL. Also, select this check box when you are developing or testing your application and you might not have configured SSL. This option is provided as a convenience and is not recommended for production deployments.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Redirect URL</td>
<td>Enter the application URL where the user is redirected after authentication.</td>
</tr>
<tr>
<td>Post logout redirect URL</td>
<td>Enter the URL where you want to redirect the user after logging out of the application.</td>
</tr>
<tr>
<td>Logout URL</td>
<td>Enter the URL where the user is redirected after logging out of the application.</td>
</tr>
</tbody>
</table>
| Allowed operations            | • Select the **Introspect** check box, if you want to allow access to a token introspection end point for your application.  
• Select the **On behalf of** check box, if you want to ensure that access privileges can be generated from the user’s privileges alone, so that a client application can access endpoints to which the user has access, even if the client application by itself would not normally have access. |
| Bypass consent                | If enabled, this attribute overwrites the **Require consent** attribute for all the scopes configured for the application, and then no scope will require consent. |
| Client IP address             | • Anywhere  
• Restrict by network perimeter |
| Add resources                 | If you want your application to access APIs from other applications, then click **Add scope** in the **Token issuance policy** section. Then, in the **Add scope** window, select the applications that your application will reference. |
| Add app roles                 | Click **Add** to enable your mobile application to access IAM APIs.  
In the **Add app roles** window, select the application roles that you want to assign to this application. This enables your application to access the REST APIs that each of the assigned application roles can access.  
For example, select **Identity Domain Administrator** from the list. All REST API tasks available to the identity domain administrator will be accessible to your application.  
You can delete the application roles by clicking the x icon for the row of the required application role.  
**Note:** You can’t delete protected application roles.  
See **Apps/App Roles endpoint** for a complete list of which endpoints each application role can access. |

8. Click **Next**.
9. Click **Finish**. A message confirms that the application has been added in deactivated state. To activate your application see [Activating Applications](#).

10. Note that the Client ID appears General information section for the application. To integrate with your application, use this ID as part of your connection settings. Because a mobile application runs on a mobile device, a Client Secret is not generated for this type of application.

11. Click **Close**.

Adding a Confidential Application

Confidential applications run on a protected server.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.

2. Click **Add application**.

3. In the **Add application** window, click **Confidential Application**, and then click **Launch workflow**.

4. In the Add application details page, use the following table to configure application details and the display settings.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name for the confidential application. You can enter up to 125 characters. For applications with lengthy names, the application name appears truncated in the My Apps page. Consider keeping your application names as short as possible.</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a description for the confidential application. You can enter up to 250 characters.</td>
</tr>
<tr>
<td>Application icon</td>
<td>Click <strong>Upload</strong> to add an icon that represents the application. This icon appears next to the name of the application on the My Apps page and the Applications page.</td>
</tr>
<tr>
<td>Application URL</td>
<td>Enter the URL (HTTP or HTTPS) where the user is redirected after a successful login. This value is also known as the SAML RelayState parameter. HTTPS format is suggested. Only use HTTP for testing purposes. For Enterprise applications, the application URL is the URL that you want users to use to access your enterprise application. Use the host name and port number of the App Gateway. If you have multiple instances of App Gateway, then use the host name and port number of the load balancer.</td>
</tr>
<tr>
<td>Custom sign-in URL</td>
<td>In the <strong>Custom sign-in URL</strong> field, specify a custom sign-in URL. However, if you are using a default login page provided by IAM, then leave this field blank.</td>
</tr>
<tr>
<td>Custom sign-out URL</td>
<td>In the <strong>Custom sign-out URL</strong> field, specify a custom sign-out URL. However, if you are using a default login page provided by IAM, then leave this field blank.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Custom error URL</td>
<td>This is an optional field. Enter the error page URL to which a user has to be redirected, if there is a failure. If not specified, the tenant-specific Error page URL is used. If both the error URLs are not configured, then the error is redirected to the IAM Error Page (/ui/v1/error). When a user tries to use social authentication (ex: Google, Facebook, and so on) for logging into IAM, the callback URL must be configured in the Custom Error URL field. Social providers need this callback URL to call IAM and send the response back after social authentication. The provided callback URL is used to verify whether the user exists or not (if this is a first-time social login), and display an error if the social authentication has failed. This is the URL where the callback is sent with social registration user details, if a successful logged-in social user account does not exist in IAM.</td>
</tr>
<tr>
<td>Custom social linking callback URL</td>
<td>This is an optional field. Enter the URL that IAM can redirect to after linking of a user between social providers and IAM is complete. When you create a custom app using IAM custom SDK and integrate with IAM Social Login, the custom app needs to have the Linking callback URL which can be redirected after linking of the user between social provider and IAM is complete.</td>
</tr>
<tr>
<td>Display in My Apps</td>
<td>Select the check box if you want the confidential application to be listed for users on their My Apps pages. In this case, you need to configure the application as a resource server. When you select the Display in My Apps check box in applications, the app is then visible in the My Apps page, but selecting this check box doesn’t enable or disable SSO to the app. The flag to enable or disable SSO comes from the app template. Use the IAM REST APIs to update this flag. You cannot set the SSO flag from the UI. See REST API for IAM.</td>
</tr>
<tr>
<td>User can request access</td>
<td>Select the check box if you want end users to be able to request access to the app from their My Apps page by clicking Add Access. If self-service is not enabled, users won’t see the Add Access button.</td>
</tr>
<tr>
<td>Enforce grants as authorization</td>
<td>If you want IAM to control access to the application based on grants to users and groups, select this option. If you clear this option, any authenticated user has access to the application.</td>
</tr>
</tbody>
</table>

5. Click Next.
6. On the **Configure OAuth** pane, to protect resources for your application now, and to make the application visible on the **My Apps** page, click **Configure this application as a resource server now**.

Use the following table to provide the information needed to configure this application as a resource server.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access token expiration (seconds)</td>
<td>Define how long (in seconds) the access token associated with your confidential application remains valid.</td>
</tr>
<tr>
<td>Allow token refresh</td>
<td>Select this check box if you want to use the refresh token that you obtain when using the Resource Owner, Authorization Code, or Assertion grant types.</td>
</tr>
<tr>
<td>Refresh token expiration (seconds)</td>
<td>Define how long (in seconds) the refresh token, which is returned with your access token and is associated with your confidential application, remains valid.</td>
</tr>
<tr>
<td>Primary audience</td>
<td>Enter the primary recipient where the access token of your confidential application is processed.</td>
</tr>
<tr>
<td>Add secondary audience</td>
<td>Enter the secondary recipients where the access token of your confidential application is processed, and click Add. The secondary recipient appears in <strong>Secondary audience</strong> column, and the <strong>Protected</strong> column allows you to know whether the secondary audience is protected or not.</td>
</tr>
<tr>
<td>Add scopes</td>
<td>To specify which parts of other applications that you want your application to access, add those scopes to your confidential application. Applications must interact securely with external partner or confidential applications. Also, applications from one Oracle Cloud service must interact securely with applications in another Oracle Cloud service. Each application has application scopes that determine which of its resources are available to other applications.</td>
</tr>
</tbody>
</table>

7. On the **Configure OAuth** pane, click **Configure this application as a client now**.

Use the following table to provide the information needed to configure this application as a client.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource owner</td>
<td>Use when the resource owner has a trust relationship with the confidential application, such as a computer operating system or a highly privileged application, because the confidential application must discard the password after using it to obtain the access token.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Client credentials</td>
<td>Use when the authorization scope is limited to the protected resources under the control of the client or to the protected resources registered with the authorization server. The client presents its own credentials to obtain an access token. This access token is either associated with the client’s own resources, and not a particular resource owner, or is associated with a resource owner for whom the client is otherwise authorized to act.</td>
</tr>
<tr>
<td>JWT assertion</td>
<td>Use when you want to use an existing trust relationship expressed as an assertion and without a direct user approval step at the authorization server. The client requests an access token by providing a user JSON web token (JWT) assertion or a third-party user JWT assertion and client credentials. A JWT assertion is a package of information that facilitates the sharing of identity and security information across security domains.</td>
</tr>
<tr>
<td>SAML2 assertion</td>
<td>Use when you want to use an existing trust relationship expressed as a SAML2 assertion and without a direct user approval step at the authorization server. The client requests an access token by providing a user SAML2 assertion or a third-party user SAML2 assertion and client credentials. A SAML2 assertion is a package of information that facilitates the sharing of identity and security information across security domains.</td>
</tr>
<tr>
<td>Refresh token</td>
<td>Select this grant type when you want a refresh token supplied by the authorization server, and then use it to obtain a new access token. Refresh tokens are used when the current access token becomes invalid or expires and don’t require the resource owner to reauthenticate.</td>
</tr>
<tr>
<td>Authorization code</td>
<td>Select this grant type when you want to obtain an authorization code by using an authorization server as an intermediary between the client application and resource owner. An authorization code is returned to the client through a browser redirect after the resource owner gives consent to the authorization server. The client then exchanges the authorization code for an access (and often a refresh) token. Resource owner credentials are never exposed to the client.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Implicit</td>
<td>If the application can't keep client credentials confidential for use in authenticating with the authorization server, then select this check box. For example, your application is implemented in a web browser using a scripting language such as JavaScript. An access token is returned to the client through a browser redirect in response to the resource owner authorization request (rather than an intermediate authorization).</td>
</tr>
<tr>
<td>Device code</td>
<td>Select the Device Code grant type if the client doesn't have the capability to receive requests from the OAuth Authorization Server, for example, it cannot act as an HTTP server such as game consoles, streaming media players, digital picture frames, and others. In this flow, the client obtains the user code, device code, and verification URL. The user then accesses the verification URL in a separate browser to approve the access request. Only then can the client obtain the access token using the device code.</td>
</tr>
<tr>
<td>TLS client authentication</td>
<td>Select the TLS Client Authentication grant type to use the client certificate to authenticate with the client. If a token request comes with an X.509 client certificate and the requested client is configured with the TLS Client Authentication grant type, the OAuth service uses the Client_ID in the request to identify the client and validate the client certificate with the certificate in the client configuration. The client is successfully authenticated only if the two values match. For added security, before enabling the TLS Client Authentication grant type, enable and configure OCSP validation and import a trusted partner certificate.</td>
</tr>
<tr>
<td>Allow non-HTTPS URLs</td>
<td>Select this check box if you want to use HTTP URLs for the Redirect URL, Logout URL, or Post logout redirect URL fields. For example, if you are sending requests internally, want a non-encrypted communication, or want to be backward-compatible with OAuth 1.0, then you can use an HTTP URL. Also, select this check box when you are developing or testing your application and you might not have configured SSL. This option is provided as a convenience and is not recommended for production deployments.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Redirect URL</strong></td>
<td>Enter the application URL where the user is redirected after authentication.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>Provide an absolute URL. Relative URLs are not supported.</td>
</tr>
<tr>
<td><strong>Logout URL</strong></td>
<td>Enter the URL where the user is redirected after logging out of the confidential application.</td>
</tr>
<tr>
<td><strong>Post logout redirect URL</strong></td>
<td>Enter the URL where you want to redirect the user after logging out of the application.</td>
</tr>
<tr>
<td><strong>Client type</strong></td>
<td>Select the client type. The available client types are <strong>Trusted</strong> and <strong>Confidential</strong>. Choose <strong>Trusted</strong> if the client can generate self-signed user assertions. Then, to import your signing certificate that the client uses to sign its self-signed assertion, click <strong>Import certificate</strong>.</td>
</tr>
<tr>
<td><strong>Allowed operations</strong></td>
<td>• Select the <strong>Introspect</strong> check box if you want to allow access to a token introspection end point for your application. If the confidential application can't keep client credentials confidential for use in authenticating with the authorization server, then select this check box. For example, your confidential application is implemented in a web browser using a scripting language such as JavaScript. An access token is returned to the client through a browser redirect in response to the resource owner authorization request (rather than an intermediate authorization code). • Select the <strong>On behalf of</strong> check box if you want to ensure that access privileges can be generated from the user's privileges alone. This allows the client application to access endpoints to which the user has access, even if the client application by itself would not normally have access.</td>
</tr>
<tr>
<td><strong>ID token encryption algorithm</strong></td>
<td>Select one of the content encryption algorithms.</td>
</tr>
<tr>
<td><strong>Bypass consent</strong></td>
<td>If enabled, this attribute overwrites the <strong>Require consent</strong> attribute for all the scopes configured for the application, and then no scope will require consent.</td>
</tr>
<tr>
<td><strong>Client IP address</strong></td>
<td>• Anywhere • Restrict by network perimeter</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Authorized resources</td>
<td>Select one of the following options to allow a client application to access authorized resources:</td>
</tr>
<tr>
<td></td>
<td>• <strong>All</strong> – Access any resource within a domain (All). See <a href="#">Accessing All Resources</a>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Tagged</strong> – Access any resource with matching tags (Tagged). See <a href="#">Accessing Resources With Matching Tags</a>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Specific</strong> – Access only those resources where an explicit association between the client and the resource (Specific) exists. See <a href="#">Accessing Resources With Specific Scopes</a>.</td>
</tr>
<tr>
<td>Note:</td>
<td>The option to define an authorized resource is available to only Confidential applications. Trust scope cannot be defined for Mobile applications.</td>
</tr>
<tr>
<td></td>
<td>See <a href="#">Account Trust Scope</a> for additional scope information as well as request and response examples for use with the IAM REST APIs.</td>
</tr>
<tr>
<td>Add resources</td>
<td>If you want your application to access APIs from other applications, then click <strong>Add</strong> in the <strong>Token issuance policy</strong> section. Then, in the <strong>Add scope</strong> window, select the applications that your application references.</td>
</tr>
<tr>
<td>Note:</td>
<td>You can delete scopes by clicking the <strong>x</strong> icon next to the scope. However, you can’t delete scopes that are protected.</td>
</tr>
<tr>
<td>Add app roles</td>
<td>In the <strong>Add app roles</strong> window, select the application roles that you want to assign to this application. This enables your application to access the REST APIs that each of the assigned application roles can access. For example, select <strong>Identity Domain Administrator</strong> from the list. All REST API tasks available to the identity domain administrator will be accessible to your application. You can delete the application roles by selecting the application role and then clicking <strong>Remove</strong>.</td>
</tr>
<tr>
<td>Note:</td>
<td>You can’t delete protected application roles.</td>
</tr>
<tr>
<td></td>
<td>See <a href="#">Apps/App Roles endpoint</a> for a complete list of which endpoints each application role can access.</td>
</tr>
</tbody>
</table>
8. Click Next.
9. Configure the web tier policy in **Simple mode** by completing the fields or in **Advanced mode** by editing a JSON file.

10. Click Finish.
   The application has been added in a deactivated state.

11. Record the **Client ID** and **Client secret** that appear in the **Application added** dialog box.
   To integrate with your confidential application, use this ID and secret as part of your connection settings. The **Client ID** and **Client secret** are equivalent to a credential (for example, an ID and password) that your application uses to communicate with IAM.

12. Click Close.
   The new application’s details page is displayed.

13. At the top of the page, to the right of the application name, click **Activate**.
14. In the **Activate application?** dialog box, click **Activate application**.

**Configuring Authorized Resources**

Authorized resources define the way a client can access the resources in a Confidential application.

**Accessing All Resources**

The **All** authorized resource option enables the client to access any resource within a domain.

Select **All** to allow your application to request an access token for trusted or confidential client using the scope `urn:opc:resource:consumer::all`. This option provides a wide scope. The access token in the response contains the audience `urn:opc:resource:scope:account` and the scope `urn:opc:resource:consumer::all`, which gives access to any of the services that are in the same domain without requiring explicit association with target services.

Use only the `urn:opc:resource:consumer::all` scope in the request. An invalid scope error is returned if you attempt to include both the `urn:opc:resource:consumer::all` scope and another scope in the same request, such as `urn:opc:idm:__myscopes__`.

In the account mode, clients can get token for any specific resource provided either `urn:opc:resource:consumer::all` or the specific resource is added in the allowed scopes.

Apart from the scope defined above, you can also specify fine-grained scope as follows:

- `urn:opc:resource:consumer:paas::read`
- `urn:opc:resource:consumer:paas:stack::all`
- `urn:opc:resource:consumer:paas:analytics::read`

**Note:**
The requested scope should always exist and match, either directly or hierarchically, the client's defined allowed scopes to allow the client access to the resource.

For example, a client uses the `urn:opc:resource:consumer:paas:analytics::read` scope in its request for access to a resource. If the scope directly matches an allowed scope defined, then in the returned access token the audience is `urn:opc:resource:scope:account` and the scope is `urn:opc:resource:consumer:paas:analytics::read`.

If the allowed scope defined by the client is `urn:opc:resource:consumer:paas::read`, then the client is allowed to access the resource hierarchically if the client requests one of the following scopes:

- `urn:opc:resource:consumer:paas::read`
- `urn:opc:resource:consumer:paas:analytics::read`

However, if the requested scope is `urn:opc:resource:consumer:paas:analytics::write` with a different qualifier, then the client isn’t allowed access to the resource.
The All option doesn't provide access to the IAM admin APIs. You must continue to use the scope urn:opc:idm:__myscopes__ to access the admin APIs.

To generate a refresh token in addition to the access token, use the scope urn:opc:resource:consumer::all offline_access in the request.

Accessing Resources with Matching Tags
The Tagged authorized resource option enables the client to access any resource with matching tags.

Request an access token using the trusted or confidential client and request the scope urn:opc:resource:consumer::all. The access token in the response contains the audience urn:opc:resource:scope:tag=<base64 encoded JSON> and the scope urn:opc:resource:consumer::all, which gives access to Resource Apps that have tags that match the allowed tags specified in the Client App.

In the tags mode, clients can get token for any specific resource provided either the client has matching tags with the resource and urn:opc:resource:consumer::all or the specific resource is added in the allowed scopes.

Select Tagged to enable your confidential application to access tags from other applications.

When you select Tagged, you can choose scopes from an OPC application that aren't specific, such as urn:opc:resource:consumer.

1. Select Tagged.
2. Select Add Scope under Resources.
4. Select the OPC scopes that you want to add and provide a named qualifier, such as read and write to each of the scopes. You can edit these qualifiers dynamically.
5. Click Add.
   The scopes appear under Resources.

In addition to using the urn:opc:resource:consumer::all scope, you can also specify the following fine-grained scopes:

- urn:opc:resource:consumer:paas::read
- urn:opc:resource:consumer:paas:stack::all
- urn:opc:resource:consumer:paas:analytics::read

The requested scope must always exist and match, either directly or hierarchically, the client's defined allowed scopes to allow the client access to the resource.

For example, a client uses the urn:opc:resource:consumer:paas:analytics::read scope in its request for access to a resource. If the scope directly matches an allowed scope defined, then in the returned access token the audience is urn:opc:resource:scope:tag=<base64 encoded JSON> and the scope is urn:opc:resource:consumer:paas:analytics::read.

For client allowed tags color:green and color:blue, the sample JSON is as follows:

{"tags": [{ "key": "color", "value": "green" }, { "key": "color", "value": "blue" } ]}

If the allowed scope defined by the client is urn:opc:resource:consumer:paas::read, then the client is allowed to access the resource hierarchically if the client requests one of the following scopes:

- urn:opc:resource:consumer:paas::read
- urn:opc:resource:consumer:paas:analytics::read
However, if the requested scope is `urn:opc:resource:consumer:paas:analytics::write`, then the client isn't allowed access to the resource, since that isn't one of the allowed scopes defined by the client.

Accessing Resources with Specific Scopes

The **Specific** authorized resource option enables the client to access only those resources where an explicit association between the client and the resource exists.

Leave **Specific** selected (the default) to allow your application to acquire an access token with permissions based on an explicit association between the client and target services. Then, use the **Add** button to select the applications that your application references.

Regenerating a Client Secret for Confidential Applications

When you create a confidential application, you use a Client ID and a Client Secret as part of your connection settings. You can regenerate your Client Secret at any time for a confidential application using the identity domains console.

An active confidential application.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click the confidential application for which you want to regenerate a Client Secret.
3. In the **General information** section, click **Regenerate**. The new Client Secret appears in the **New client secret** dialog box.
4. Click **Close**.

Generating Tokens for Confidential Applications

When you create a confidential application and you configure the client to use the **JWT Assertion** grant type, you can generate access tokens at any time using the identity domain console.

An active trusted application with the client configured to use the **JWT Assertion** grant type.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click the confidential application for which you want to generate an access token.
3. Click **Access token**.
4. In the **Access token** section, use the following table to configure which scopes are included in the access token:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Available scopes</strong></td>
<td>Click <strong>Available scopes</strong> to get the access token to access any resources configured for the application. If the scopes are defined from multiples resource servers, the token cannot be generated. Use the <strong>Customized scopes</strong> option and ensure that the selected scopes are from the same resource server.</td>
</tr>
<tr>
<td><strong>Customized scopes using Invokes identity domain APIs</strong></td>
<td>a. Click <strong>Customized scopes</strong> and <strong>Invokes identity domain APIs</strong>. b. From the list of roles that are assigned to the client application, select those roles that you want to include or remove to limit the scopes to be populated in the resulting token.</td>
</tr>
<tr>
<td><strong>Customized scopes using Invokes other APIs</strong></td>
<td>a. Click <strong>Customized scopes</strong> and <strong>Invokes other APIs</strong>. b. The UI displays a list of all the scopes assigned to the application. You can select any scopes as long as those scopes are from the same resource server.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Include refresh token</td>
<td>The <strong>Include refresh token</strong> check box is enabled if the <strong>Refresh token</strong> grant type is configured for your client application and the resource server to which the scopes belong to allows refresh token generation. The refresh token is used to obtain a new access token without requiring the user to reauthenticate.</td>
</tr>
</tbody>
</table>

5. Click **Download token**.

**Note:**
The downloaded token gets saved as a `tokens<n>.tok` file in the download folder of your browser.

Adding an Enterprise Application
An enterprise application enables you to secure web applications that are protected by the App Gateway.

To add an enterprise application in an identity domain, you need to configure the list of application resources (web application's URLs or URL patterns), create an authentication policy for each resource, and create an authorization policy for each resource. For each authentication policy, you define an authentication method, and header variables for App Gateway to include in the request before forwarding the request to the application.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click **Add application**.
3. In the **Add application** window, click **Enterprise Application**.
4. In the Add application details page, use the following table to configure application details and the display settings.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name for the confidential application. You can enter up to 125 characters. For applications with lengthy names, the application name appears truncated in the <strong>My Apps</strong> page. Consider keeping your application names as short as possible.</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a description for the confidential application. You can enter up to 250 characters.</td>
</tr>
<tr>
<td>Application icon</td>
<td>Click <strong>Upload</strong> to add an icon that represents the application. This icon appears next to the name of the application on the <strong>My Apps</strong> page and the Applications page.</td>
</tr>
<tr>
<td><strong>Option</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>------------</td>
<td>----------------</td>
</tr>
<tr>
<td><strong>Application URL</strong></td>
<td>Enter the URL (HTTP or HTTPS) where the user is redirected after a successful login. This value is also known as the SAML RelayState parameter. HTTPS format is suggested. Only use HTTP for testing purposes. For Enterprise applications, the application URL is the URL that you want users to use to access your enterprise application. Use the host name and port number of the App Gateway. If you have multiple instances of App Gateway, then use the host name and port number of the load balancer.</td>
</tr>
<tr>
<td><strong>Custom sign-in URL</strong></td>
<td>In the Custom sign-in URL field, specify a custom sign-in URL. However, if you are using a default login page provided by IAM, then leave this field blank.</td>
</tr>
<tr>
<td><strong>Custom sign-out URL</strong></td>
<td>In the Custom sign-out URL field, specify a custom sign-out URL. However, if you are using a default login page provided by IAM, then leave this field blank.</td>
</tr>
<tr>
<td><strong>Custom error URL</strong></td>
<td>This is an optional field. Enter the error page URL to which a user has to be redirected, if there is a failure. If not specified, the tenant-specific Error page URL is used. If both the error URLs are not configured, then the error is redirected to the IAM Error Page (/ui/v1/error). When a user tries to use social authentication (ex: Google, Facebook, and so on) for logging into IAM, the callback URL must be configured in the Custom Error URL field. Social providers need this callback URL to call IAM and send the response back after social authentication. The provided callback URL is used to verify whether the user exists or not (if this is a first-time social login), and display an error if the social authentication has failed. This is the URL where the callback is sent with social registration user details, if a successful logged-in social user account does not exist in IAM.</td>
</tr>
<tr>
<td><strong>Custom social linking callback URL</strong></td>
<td>This is an optional field. Enter the URL that IAM can redirect to after linking of a user between social providers and IAM is complete. When you create a custom app using IAM custom SDK and integrate with IAM Social Login, the custom app needs to have the Linking callback URL which can be redirected after linking of the user between social provider and IAM is complete.</td>
</tr>
</tbody>
</table>
Option | Description
---|---
**Display in My Apps** | Select the check box if you want the confidential application to be listed for users on their My Apps pages. In this case, you need to configure the application as a resource server.
When you select the **Display in My Apps** check box in applications, the app is then visible in the My Apps page, but selecting this check box doesn’t enable or disable SSO to the app.
The flag to enable or disable SSO comes from the app template. Use the IAM REST APIs to update this flag. You cannot set the SSO flag from the UI. See REST API for IAM.
**User can request access** | Select the check box if you want end users to be able to request access to the app from their My Apps page by clicking Add Access. If self-service is not enabled, users won’t see the Add Access button.
**Enforce grants as authorization** | If you want IAM to control access to the application based on grants to users and groups, select this option.
If you clear this option, any authenticated user has access to the application.

5. Click Next.
6. On the **Configure OAuth** pane, to protect resources for your application now, and to make the application visible on the My Apps page, click **Configure this application as a resource server now**

Use the following table to provide the information needed to configure this application as a resource server.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Access token expiration (seconds)</strong></td>
<td>Define how long (in seconds) the access token associated with your confidential application remains valid.</td>
</tr>
<tr>
<td><strong>Allow token refresh</strong></td>
<td>Select this check box if you want to use the refresh token that you obtain when using the Resource Owner, Authorization Code, or Assertion grant types.</td>
</tr>
<tr>
<td><strong>Refresh token expiration (seconds)</strong></td>
<td>Define how long (in seconds) the refresh token, which is returned with your access token and is associated with your confidential application, remains valid.</td>
</tr>
<tr>
<td><strong>Primary audience</strong></td>
<td>Enter the primary recipient where the access token of your confidential application is processed.</td>
</tr>
<tr>
<td><strong>Add secondary audience</strong></td>
<td>Enter the secondary recipients where the access token of your confidential application is processed, and click Add. The secondary recipient appears in Secondary audience column, and the Protected column allows you to know whether the secondary audience is protected or not.</td>
</tr>
</tbody>
</table>
Add scopes

To specify which parts of other applications that you want your application to access, add those scopes to your confidential application.

Applications must interact securely with external partner or confidential applications. Also, applications from one Oracle Cloud service must interact securely with applications in another Oracle Cloud service. Each application has application scopes that determine which of its resources are available to other applications.

7. On the Configure OAuth pane, click Configure this application as a client now.

Use the following table to provide the information needed to configure this application as a client.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource owner</td>
<td>Use when the resource owner has a trust relationship with the confidential application, such as a computer operating system or a highly privileged application, because the confidential application must discard the password after using it to obtain the access token.</td>
</tr>
<tr>
<td>Client credentials</td>
<td>Use when the authorization scope is limited to the protected resources under the control of the client or to the protected resources registered with the authorization server. The client presents its own credentials to obtain an access token. This access token is either associated with the client’s own resources, and not a particular resource owner, or is associated with a resource owner for whom the client is otherwise authorized to act.</td>
</tr>
<tr>
<td>JWT assertion</td>
<td>Use when you want to use an existing trust relationship expressed as an assertion and without a direct user approval step at the authorization server. The client requests an access token by providing a user JSON web token (JWT) assertion or a third-party user JWT assertion and client credentials. A <strong>JWT assertion</strong> is a package of information that facilitates the sharing of identity and security information across security domains.</td>
</tr>
<tr>
<td>SAML2 assertion</td>
<td>Use when you want to use an existing trust relationship expressed as a SAML2 assertion and without a direct user approval step at the authorization server. The client requests an access token by providing a user SAML2 assertion or a third-party user SAML2 assertion and client credentials. A <strong>SAML2 assertion</strong> is a package of information that facilitates the sharing of identity and security information across security domains.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Refresh token</td>
<td>Select this grant type when you want a refresh token supplied by the authorization server, and then use it to obtain a new access token. Refresh tokens are used when the current access token becomes invalid or expires and don’t require the resource owner to reauthenticate.</td>
</tr>
</tbody>
</table>
| Authorization code     | Select this grant type when you want to obtain an authorization code by using an authorization server as an intermediary between the client application and resource owner.  
An authorization code is returned to the client through a browser redirect after the resource owner gives consent to the authorization server. The client then exchanges the authorization code for an access (and often a refresh) token. Resource owner credentials are never exposed to the client. |
| Implicit               | If the application can't keep client credentials confidential for use in authenticating with the authorization server, then select this check box. For example, your application is implemented in a web browser using a scripting language such as JavaScript. An access token is returned to the client through a browser redirect in response to the resource owner authorization request (rather than an intermediate authorization). |
| Device code            | Select the Device Code grant type if the client doesn't have the capability to receive requests from the OAuth Authorization Server, for example, it cannot act as an HTTP server such as game consoles, streaming media players, digital picture frames, and others.  
In this flow, the client obtains the user code, device code, and verification URL. The user then accesses the verification URL in a separate browser to approve the access request. Only then can the client obtain the access token using the device code. |
| TLS client authentication | Select the TLS Client Authentication grant type to use the client certificate to authenticate with the client. If a token request comes with an X.509 client certificate and the requested client is configured with the TLS Client Authentication grant type, the OAuth service uses the Client_ID in the request to identify the client and validate the client certificate with the certificate in the client configuration. The client is successfully authenticated only if the two values match.  
For added security, before enabling the TLS Client Authentication grant type, enable and configure OCSP validation and import a trusted partner certificate. |
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Allow non-HTTPS URLs</strong></td>
<td>Select this check box if you want to use HTTP URLs for the <strong>Redirect URL</strong>, <strong>Logout URL</strong>, or <strong>Post logout redirect URL</strong> fields. For example, if you are sending requests internally, want a non-encrypted communication, or want to be backward-compatible with OAuth 1.0, then you can use an HTTP URL. Also, select this check box when you are developing or testing your application and you might not have configured SSL. This option is provided as a convenience and is not recommended for production deployments.</td>
</tr>
<tr>
<td><strong>Redirect URL</strong></td>
<td>Enter the application URL where the user is redirected after authentication.</td>
</tr>
<tr>
<td><strong>Logout URL</strong></td>
<td>Enter the URL where the user is redirected after logging out of the confidential application.</td>
</tr>
<tr>
<td><strong>Post logout redirect URL</strong></td>
<td>Enter the URL where you want to redirect the user after logging out of the application.</td>
</tr>
<tr>
<td><strong>Client type</strong></td>
<td>Select the client type. The available client types are <strong>Trusted</strong> and <strong>Confidential</strong>. Choose <strong>Trusted</strong> if the client can generate self-signed user assertions. Then, to import your signing certificate that the client uses to sign its self-signed assertion, click <strong>Import certificate</strong>.</td>
</tr>
<tr>
<td><strong>Allowed operations</strong></td>
<td>• Select the <strong>Introspect</strong> check box if you want to allow access to a token introspection end point for your application. If the confidential application can't keep client credentials confidential for use in authenticating with the authorization server, then select this check box. For example, your confidential application is implemented in a web browser using a scripting language such as JavaScript. An access token is returned to the client through a browser redirect in response to the resource owner authorization request (rather than an intermediate authorization code). • Select the <strong>On behalf of</strong> check box if you want to ensure that access privileges can be generated from the user's privileges alone. This allows the client application to access endpoints to which the user has access, even if the client application by itself would not normally have access.</td>
</tr>
<tr>
<td><strong>ID token encryption algorithm</strong></td>
<td>Select one of the content encryption algorithms.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Bypass consent</strong></td>
<td>If enabled, this attribute overwrites the <strong>Require consent</strong> attribute for all the scopes configured for the application, and then no scope will require consent.</td>
</tr>
<tr>
<td><strong>Client IP address</strong></td>
<td>• Anywhere</td>
</tr>
<tr>
<td></td>
<td>• Restrict by network perimeter</td>
</tr>
<tr>
<td><strong>Authorized resources</strong></td>
<td>Select one of the following options to allow a client application to access authorized resources:</td>
</tr>
<tr>
<td></td>
<td>• <strong>All</strong> – Access any resource within a domain (All). See <a href="#">Accessing All Resources</a>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Tagged</strong> – Access any resource with matching tags (Tagged). See <a href="#">Accessing Resources With Matching Tags</a>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Specific</strong> – Access only those resources where an explicit association between the client and the resource (Specific) exists. See <a href="#">Accessing Resources With Specific Scopes</a>.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>The option to define an authorized resource is available to only Confidential applications. Trust scope cannot be defined for Mobile applications.</td>
</tr>
<tr>
<td></td>
<td>See <a href="#">Account Trust Scope</a> for additional scope information as well as request and response examples for use with the IAM REST APIs.</td>
</tr>
</tbody>
</table>

**Add resources**

If you want your application to access APIs from other applications, then click **Add** in the **Token issuance policy** section. Then, in the **Add scope** window, select the applications that your application references.

**Note:**

You can delete scopes by clicking the **x** icon next to the scope. However, you can’t delete scopes that are protected.
### Option Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add app roles</td>
<td>In the Add app roles window, select the application roles that you want to assign to this application. This enables your application to access the REST APIs that each of the assigned application roles can access. For example, select <strong>Identity Domain Administrator</strong> from the list. All REST API tasks available to the identity domain administrator will be accessible to your application. You can delete the application roles by selecting the application role and then clicking <strong>Remove</strong>.</td>
</tr>
</tbody>
</table>

**Note:**
You can’t delete protected application roles.

See Apps/App Roles endpoint for a complete list of which endpoints each application role can access.

8. Click **Next**.
9. Configure single sign-on.
   - To configure single sign-on now, see:
     - Configuring SSO Resources on page 3202
     - Configuring an SSO Authentication Policy on page 3203
     - Configuring an SSO Authorization Policy on page 3206
   - To configure single sign on later, click **Finish**.
10. Click **Activate**, and then click **Activate application**.

#### Configuring SSO Resources
Create resources individually by adding one resource for each of your application's URLs, or use regular expression to create a resource which represents a collection of URLs for your application.

A resource represents a URL or URL Pattern for which you want to restrict access or intend to give anyone to access. You need the list of resources of your application. See Enterprise Applications on page 3167.

Policy mapping is hierarchical in App Gateway. So, order of the resources defined is important. See the following example:

If the user is accessing a resource `/myapp/logout.html`, and we have authentication policy in below order:

1. `.*` (public)
2. `.*logout.html` (Form+logout)

Then policy match stops at step #1 (`.*`) and the same policy is applied which is "public" in this case.

Similarly, if user is accessing a resource `/myapp/logout.html` and we have authentication policy in below order.

1. `.*logout.html` (Form+logout)
2. `.*` (public)

In this case, policy match stops at point 1 (`.*logout.html`) and same policy is applied which is "Form +logout".

Something else to be aware of is that applications which do their own login integrations can run into problems when their integrations accessed static resources during login, but the resources were not made public. This causes the login
process to fail. To avoid this happening, you should use the public authentication method for your public static resources such as CSS, JavaScript, image files as follows:

- Group all public static resources together, for example under /myapp/public/resources.
- State that these directories should use the public authentication method using a regex such as /myapp/public/.*.

To configure resources:

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click the enterprise application that you want to modify.
3. In the **Application details** page, click **SSO configuration**, and then click **Edit SSO configuration**. In the **Resources** section, click **Add resource** to add a resource.
4. In **Add resource**, provide a name for the resource and the resource URL. If you want to use a regular expression, then select **Regex**, so that App Gateway evaluates the **Resource URL** value as a pattern.

For example, if you want to protect the application endpoint http://myapp.internal.example.com:3266/private/home, you can enter /private/home as the value for **Resource URL**. If you want to protect any page under the /private context, then enter /private/.* as value for **Resource URL**, and select **Regex**.

See **Using Regular Expressions** on page 3208.

### Configuring an SSO Authentication Policy

Create an authentication policy for each resource you created for your enterprise application.

An authentication policy defines which authentication method to use to protect your enterprise application's resources, and whether App Gateway adds header variables to the request it forwards to the application.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click the enterprise application that you want to modify.
3. In the **Application details** page, click **SSO configuration**, and then click **Edit SSO configuration**. In the **Authentication policy** section, Check **Audience validation**, **Allow CORS**, or **Require secure cookies**, if needed.

   - **Require secure cookies**: If App Gateway is configured in SSL mode (HTTPs), then confirm that **Require secure cookies** is selected. This flag sets the secure header to avoid cookies being used in non-secure HTTP communication. If App Gateway is configured in non-SSL mode (HTTP), then deselect **Require secure cookies**.

   - **Audience validation**: For security reasons, ensure the **Audience validation** check box is selected. The audience validation check box is used to ensure that the token has been issued by App Gateway's known issuer, in this case IAM. If you clear audience validation, App Gateway won't validate the audience of the token, which makes the application vulnerable to attacks.

4. Check **Add managed resources**.
5. In the **Add managed resource** window, select the resource for which you want to configure an authentication policy from the list of resources that you created in the **Resources** section.
6. Use the following table to define the **Authentication method** for the resource you have selected:

<table>
<thead>
<tr>
<th>Authentication Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basic Auth</td>
<td>The <strong>Basic Auth</strong> method performs HTTP Basic authentication. If the request doesn't contain an <strong>Authentication Basic</strong> header, then user's browser will prompt for credentials. The credentials sent in the header are in the <strong>AuthenticationBasic</strong> validated in IAM.</td>
</tr>
<tr>
<td>Authentication Method</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Basic Auth+Logout        | This method is used to protect the application's resource (URL) that represents the application's logout process.  
When App Gateway intercepts a request to this resource, the HTTP logout process is initiated. This process deletes any HTTP session cookie created by the **Basic Auth+Session** authentication method.  
After the logout process finishes, App Gateway forwards the user browser to the requested application's resource.  
The HTTP logout process doesn't clear any credentials cached by the browser in the current browser session and then the user may not be prompted again for later requests. |
| Basic Auth+Session       | Works the same as **Basic Auth**. After the credential is validated, it creates an HTTP session cookie (ORA_OCIS.CG.BA_SESSION).                                                                                                                                                                                                          |
| Form or Access Token     | In this authentication method, App Gateway delegates credentials collection and validation to IAM.  
If an Authorization Bearer header is present in the request, then the authentication is similar to a resource server flow. If a user-agent header is present, then a user browser flow takes place.  
The user browser flow redirects the user browser to IAM for credentials collection and validation, and then creates an OAuth session cookie (ORA_OCIS.CG_SESSION_*).  
If an Authorization session header is present in the request and the OAuth session cookie is missing or invalid, then the usual OAuth login flow is suppressed and a 401 HTTP error code will be returned along with a WWW-Authenticate: Bearer error="invalid_session" header. This is used by applications that may trigger an unwanted login when their requests contain a user-agent header, but not an Authorization Bearer header, allowing them to handle reauthentication themselves. |
<table>
<thead>
<tr>
<th>Authentication Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Form+Logout</strong></td>
<td>This method is used to protect the application's resource (URL) that represents the application's logout process. This resource's URL doesn't need to be exposed by the application, as App Gateway redirects the user browser to IAM's OAuth logout endpoint (/oauth2/v1/userlogout), instead of forwarding the request to the application URL. In the Add Resource window, the <strong>Post-Logout URL</strong> is the URL which App Gateway redirects the user browser after signing out the user. You can also provide a <strong>Post-Logout State</strong> parameter value to be used by the post-logout URL page of the application.</td>
</tr>
<tr>
<td><strong>Multitoken</strong></td>
<td>Performs authentication based on the contents of the Authorization header of the request: • If the request contains an Authorization Basic header, then App Gateway handles this authentication as <strong>Basic Auth</strong>. • If the request contains an Authorization Bearer or Authorization Session header, App Gateway handles this authentication as <strong>Form or Access Token</strong>. • If the Authorization header is missing or has any other value, then a 401 Unauthorized HTTP error is returned.</td>
</tr>
<tr>
<td><strong>Multitoken+Fallthrough</strong></td>
<td>Same as Multitoken, but if the Authorization header is not Basic, Bearer, or session, then instead of presenting the 401 Unauthorized HTTP error, request App Gateway acts as authentication method was <strong>Basic Auth</strong>.</td>
</tr>
<tr>
<td><strong>Anonymous</strong></td>
<td>• If a valid OAuth session cookie is present, then the headers configured in the authentication policy are added to the request and the request is forwarded to the application. • If the OAuth session cookie is missing or expired, works the same as the <strong>Public</strong> authentication method. In this case, a REMOTE_USER header with value anonymous is added to the request. For both options, the headers configured in the authentication policy are added to the request, but authentication is not performed.</td>
</tr>
<tr>
<td><strong>Public</strong></td>
<td>No authentication is performed. The request is forwarded to the application as is.</td>
</tr>
</tbody>
</table>
### IAM

<table>
<thead>
<tr>
<th>Authentication Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unsupported</td>
<td>This method always returns 500 Not Supported HTTP error code. For example, you can use this method to disable access to a protected URL that is available in the application but you don’t want users to access it.</td>
</tr>
</tbody>
</table>

#### 7. The authentication method you selected in the previous step is valid for all HTTP Methods (GET, HEAD, DELETE, PUT, OPTIONS, CONNECT, POST, or PATCH). If you want to specify different authentication methods for HTTP methods (for example, the Form + Access Token authentication method for the GET HTTP method and the Multitoken authentication method for the POST HTTP method), then you can do so by using the Authentication method overrides menu. Select the HTTP method, and then the Authentication method you want. If you need to override more than one HTTP method, then repeat this step multiple times.

#### 8. If you want to add a header variable to the request so that App Gateway forwards it to the application, click the plus + icon for Headers, provide the name, and then either select the value for the header variable from the list of user attributes, enter a fixed value, or provide an expression. To add more than one header variable, click the + icon for Headers multiple times.

For example, let’s suppose the application requires a header variable named USERLOGGEDIN to be present in every request so that the application knows the ID of user signed in to IAM. You must add one header variable, enter USERLOGGEDIN for the Name field, and then either select User name from the list or enter $subject.user.userName for Value.

#### 9. Click Add managed resource.

#### 10. Click Save changes.

**Configuring an SSO Authorization Policy**

Create an authorization policy for each resource in your enterprise application and define the conditions in which users are allowed or denied access to the resource.

#### Note:

Authorization policies only work for resources that you protect with Form or Access Token authentication method in an authentication policy. If your resource is protected with any other authentication method, App Gateway doesn’t perform authorization check when users try to access the resource using a web browser.

Authorization policies define under what conditions users are allowed or denied access to application resources. When App Gateway intercepts an HTTP request to a resource endpoint, App Gateway verifies whether the enterprise application in IAM contains authorization policies for the resource. If so, then App Gateway verifies whether the HTTP request matches one of the rules configured to allow or deny access.

For example, you can configure an allow rule to allow all members of the Employees group to access the /myapp/private/home resource, and configure a deny rule to deny access to this resource for users authenticated by the My External SAML IDP identity provider.

1. Open the navigation menu and click Identity & Security. Under Identity, click Domains. Select the identity domain you want to work in and click Applications.
2. Click the enterprise application that you want to modify.
3. In the Application details page, click SSO configuration, and then click Edit SSO configuration.
4. In the Authorization policy section, select Time to live (minutes) to define for how long App Gateway caches any authorization policy evaluation that has been performed.

By caching these policy evaluations, App Gateway doesn't need to communicate with IAM in subsequent HTTP request made by the user for the same resource.

5. In the Allow rules section, click Add allow rule, specify a Rule name, and then complete the following fields.

### Add Allow Rule Options

<table>
<thead>
<tr>
<th>Conditions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource to include</td>
<td>Select one of the resources configured in the enterprise application.</td>
</tr>
<tr>
<td>HTTP Method</td>
<td>Select the HTTP Methods associated with this rule. The rule is valid only for the selected HTTP Methods.</td>
</tr>
<tr>
<td>Authenticating identity provider</td>
<td>Select the identity providers that are active in IAM. If the user is signed in using one of these identity providers, then App Gateway allows access to the resource. Local IDP refers to users authenticated by IAM.</td>
</tr>
<tr>
<td>Group membership</td>
<td>Select IAM's groups. If the signed in user is a member of one of the selected groups, then App Gateway allows access to the resource.</td>
</tr>
<tr>
<td>Exclude users</td>
<td>Select IAM users. If the signed in user is not one of the selected users, then App Gateway allows access to the resource.</td>
</tr>
<tr>
<td>Filter by client IP address</td>
<td>Select the IP address range the HTTP request are made from.</td>
</tr>
<tr>
<td></td>
<td>• Anywhere: App Gateway doesn't validate the IP address from where the HTTP request was made.</td>
</tr>
<tr>
<td></td>
<td>• Restrict to the following network perimeters: Select this option, and then select the network perimeters associated with this rule. If the IP address from where the HTTP request was made is specified in one of the network perimeters, then Access Gateway allows access to the resource.</td>
</tr>
<tr>
<td>Restrict access time period</td>
<td>Select a time of the day (From and To), select which days of the week, and then the time zone in which the rule is valid. App Gateway allows access to the resource only if the HTTP Request is made within the period configured.</td>
</tr>
</tbody>
</table>

All the conditions configured for an allow rule must be met so that App Gateway can perform the action configured for the rule.

6. In the Actions section of the Add allow rule window, click Add for Headers, enter name for the HTTP header and then select a user attribute as value. Repeat this step for all headers you want to configure for this rule.

If the user is allowed access to the resource, App Gateway adds these header variables with the corresponding values to the HTTP request before forwarding the request to the application.
7. Click Add allow rule to add the allow rule.

8. In the Deny rules section, click Add deny rule, specify a Rule name, and then complete the following fields.

### Add Deny Rule Options

<table>
<thead>
<tr>
<th>Conditions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource to include</td>
<td>Select one of the resources configured for the enterprise application.</td>
</tr>
<tr>
<td>HTTP Method</td>
<td>Select the HTTP Methods to associate with this rule.</td>
</tr>
<tr>
<td>Authenticating identity provider</td>
<td>Select identity providers that are active in IAM. If the user is signed in using one of these identity providers, then App Gateway denies access to the resource. <strong>Local IDP</strong> refers to users authenticated by IAM.</td>
</tr>
<tr>
<td>Group membership</td>
<td>Select IAM groups. If the signed in user is member of one of the selected groups, then App Gateway denies access to the resource.</td>
</tr>
<tr>
<td>Exclude users</td>
<td>Select the IAM users. If the signed in user is not one of the selected users, then App Gateway denies access to the resource.</td>
</tr>
<tr>
<td>Filter by client IP address</td>
<td>Select the IP address range the HTTP request are made from.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Anywhere</strong>: App Gateway doesn't validate the IP address from where the HTTP request was made.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Restrict to the following network perimeters</strong>: Select this option, and then select the network perimeters to associate with this rule. If the IP address from where the HTTP request was made is specified as one of the network perimeters, then Access Gateway denies access to the resource.</td>
</tr>
<tr>
<td>Restrict access time period</td>
<td>Select a time of the day (<strong>From</strong> and <strong>To</strong>), select which days of the week, and then the time zone in which the rule is valid.</td>
</tr>
<tr>
<td></td>
<td>App Gateway denies access to the resource if the HTTP Request is made within the period configured.</td>
</tr>
</tbody>
</table>

All the conditions configured for a deny rule must be met so that App Gateway can perform the action configured for the rule.

9. In the Actions section of the Add deny rule window, select the action App Gateway must perform when a deny rule condition matches the resource's HTTP request.

- **Sign out the user**: Logs the user out from IAM.

10. Click Add deny rule to add the deny rule.

11. Click Save changes.

Using Regular Expressions
Use regular expressions (regex) to define a URL pattern which represents more than one URL of your enterprise application and for which you can apply the same authentication policy and the same authorization policy.

Create a list of all URLs for your application, and then to define URL patterns that map similar URLs, in which you want to define common authentication and authorization policies.

The authorization engine of App Gateway supports all tokens available to create regular expressions, such as Character Classes, Anchors, Escaped Characters, Group & References, Lookaround, Quantifiers & Alternation, and Substitution.

The following is a list of common operators supported by App Gateway’s authorization engine:

### Common Regex Operators Supported by App Gateway Authorization Engine

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Match-any-character Operator (. )</td>
<td>The period character represents this operator.</td>
<td>a.b matches any three-character string beginning with a and ending with b</td>
</tr>
<tr>
<td>Match-zero-or-more Operator (*)</td>
<td>This operator repeats the smallest possible preceding regular expression as many times as necessary (including zero) to match the pattern</td>
<td>a* matches any string made up of zero or more a’s. In another example, fo* has a repeating o, not a repeating fo. Hence, fo* matches f, fo, foo, and so on.</td>
</tr>
<tr>
<td>Match-one-or-more Operator (+)</td>
<td>This operator is similar to the match-zero-or-more operator except that it repeats the preceding regular expression at least once.</td>
<td>ca+r matches car and caaaar, but not cr</td>
</tr>
<tr>
<td>Match-zero-or-one Operator (?)</td>
<td>This operator is similar to the match-zero-or-more operator except that it repeats the preceding regular expression once or not at all.</td>
<td>ca?r matches both car and cr, but nothing else.</td>
</tr>
<tr>
<td>Negate (^)</td>
<td>Negate an expression.</td>
<td>^a matches any character except a</td>
</tr>
<tr>
<td>Grouping Operators ( ( . . ) )</td>
<td>Regex treats expressions inside the parenthesis just as mathematics and programming languages treat a parenthesized expression as a unit. The expressions are processed before the expression outside the parenthesis.</td>
<td>f (a</td>
</tr>
<tr>
<td>Alternation Operator ([ ])</td>
<td>Alternatives match one of a choice of regular expressions: if you put one or more characters representing the alternation operator between any two regular expressions a and b, the result matches the union of the strings that a and b match.</td>
<td>foo</td>
</tr>
</tbody>
</table>
List Operators ([ . . . ] and [^ . . . ])

A matching list matches a single character represented by one of the list items. An item is a character, a character class expression, or a range expression.

Non matching lists are similar to matching lists except that they match a single character not represented by one of the list items.

Example:

- [ab] matches either a or b.
- [ad]* matches the empty string and any string composed of just a’s and d’s in any order.
- As a non matching example, [^ab] matches any character except a or b.

Range Operator (−)

Represents those characters that fall between two elements in the current collating sequence.

Example:

- [a–f] represents all the characters from a through f inclusively.

Digit (\d)

Matches any digit character (0-9).

Example:

- Same as [0–9]

Not Digit (\D)

Matches any character that is not a digit character (0-9).

Example:

- Same as [^0–9]

Escape (\)

Makes the next character in the expression means the character itself but not an operator.

Example:

- \. means period, not the Match-any-character operator.

Use of Regular Expression

For example, if you want to allow only authenticated users access for any page of the application that starts with my and are under the path /mybank, then you can use the regular expression /mybank/my.*

The dot (.) and the star (*) together represents any sequence of zero or more consecutive characters after the prefix my.

In this example, the URLs /mybank/myCredits and /mybank/myDebits match the /mybank/my.* pattern, but /mybank/about doesn't.

Supported Header Value Expressions for Authentication Policies

When you configure enterprise application's authentication policies, you can add header variables to requests forwarded to the application, by selecting a user attribute from a list of predefined user attributes, or by entering an expression.

In the header Value field for Authentication Policies, you can provide a simple literal string or an attribute identifier instead of selecting the user attribute from the list. If you use an attribute identifier, App Gateway attempts to replace the attribute identifier by the value of the attribute after authentication happens.

The following types of attribute identifiers are supported by authentication policies:

- **Application**: This attribute identifier accesses the information of the enterprise application registered in IAM.
  
  Format: $subject.client.<attr>

- **User**: This attribute identifier accesses information of the user signed in to IAM.

  Format: $subject.user.<attr>

- **Request**: This attribute identifier accesses request information.

  Format: $request.<attr>

For user attribute scope, App Gateway supports any simple top-level attribute in the JSON Response from /admin/v1/Users such as string, boolean, or int values.

App Gateway also supports user extension attributes as header value expressions for authentication policies, using the following format
$subject.user.urn:ietf:params:scim:schemas:extension:enterprise:2.0:User:<attributeName>., and custom attributes using the following format

### Example of User Attribute Scope Names and Return Values

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Header Value Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full Name</td>
<td>$subject.user.name</td>
<td>The user's full name.</td>
</tr>
<tr>
<td>User Name</td>
<td>$subject.user.userName</td>
<td>The user's login username.</td>
</tr>
<tr>
<td>Emails</td>
<td>$subject.user.emails</td>
<td>The user's primary email address.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Other types of emails also supported:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$subject.user.emails.recovery,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$subject.user.emails.other,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$subject.user.emails.home,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>and</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$subject.user.emails.work.</td>
</tr>
<tr>
<td>Phone Numbers</td>
<td>$subject.user.phoneNumbers</td>
<td>The user's phone number.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Other types of phone numbers supported:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$subject.user.phoneNumbers.mobile,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$subject.user.phoneNumbers.home,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>and</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$subject.user.phoneNumbers.work.</td>
</tr>
<tr>
<td>Addresses</td>
<td>$subject.user.addresses</td>
<td>The user's mailing address.</td>
</tr>
<tr>
<td>Groups</td>
<td>$subject.user.groups</td>
<td>A list of comma-separated group names to which the user is assigned to through direct or indirect membership.</td>
</tr>
<tr>
<td>idcsCreatedBy</td>
<td>$subject.user.idcsCreatedBy</td>
<td>The display name of the user or application who created this resource.</td>
</tr>
<tr>
<td>idcsLastModifiedBy</td>
<td>$subject.user.idcsLastModified</td>
<td>The display name of the user or application who modified this resource.</td>
</tr>
</tbody>
</table>

Example of supported values for request attribute scope:
### Example of Request Attribute scope names and supported values

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Header Value Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policy_appname</td>
<td>$request.policy_appname</td>
<td>Returns the name of the enterprise application registered in IAM.</td>
</tr>
<tr>
<td>policy_name</td>
<td>$request.policy_name</td>
<td>Returns the policy name of the specific policy matched for the request.</td>
</tr>
<tr>
<td>policy_res</td>
<td>$request.policy_res</td>
<td>Returns the resource URL pattern matched for the request. The format is: &quot;&lt;type&gt;:&lt;pattern&gt;&quot;. Example: text:/my/resource or regex:/my/resource/.*</td>
</tr>
<tr>
<td>policy_action</td>
<td>$request.policy_action</td>
<td>Returns the HTTP Method (GET, POST, and so on) used to access the requested resource.</td>
</tr>
<tr>
<td>res_host</td>
<td>$request.res_host</td>
<td>Returns the host name from the original Request.</td>
</tr>
<tr>
<td>res_port</td>
<td>$request.res_port</td>
<td>Returns the port number from the original Request.</td>
</tr>
<tr>
<td>res_type</td>
<td>$request.res_type</td>
<td>Returns the protocol (HTTP or HTTPS) of the original Request.</td>
</tr>
<tr>
<td>res_url</td>
<td>$request.res_url</td>
<td>Returns the full requested URL.</td>
</tr>
</tbody>
</table>

### Default Headers and Cookies App Gateway Adds to the Request

By Default App Gateway adds header variables and cookies to any request forwarded to a protected enterprise application. The following is a list of these headers and cookies and their respective values.

#### Headers

<table>
<thead>
<tr>
<th>Header Name</th>
<th>Description</th>
<th>Authentication Method Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>idcs_service_url</td>
<td>The value of this header is your IAM's base URL. For example, <a href="https://idcs-tenant.identity.oraclecloud.com">https://idcs-tenant.identity.oraclecloud.com</a></td>
<td>Used by all authentication method.</td>
</tr>
<tr>
<td>idcs_cloudgate_id</td>
<td>The Client ID value for the App Gateway registered in IAM.</td>
<td>Used by all authentication method.</td>
</tr>
<tr>
<td>idcs_client_id</td>
<td>The Client ID value for the App Gateway registered in IAM.</td>
<td>App Gateway adds this header to the request forwarded to the enterprise application if the resource is protected by Anonymous or Public authentication methods.</td>
</tr>
<tr>
<td>Header Name</td>
<td>Description</td>
<td>Authentication Method Usage</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>idcs_authn_method</td>
<td>The authentication method configured in the enterprise application's authentication policy. Value depending on the authentication method used:</td>
<td>App Gateway adds this header to the request forwarded to the enterprise application if the resource is protected by any authentication method except <strong>Public</strong>.</td>
</tr>
<tr>
<td></td>
<td>• If resource is protected by <strong>Anonymous</strong> authentication method, then value is anonymous.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If resource is protected by <strong>Form or Access Token</strong> authentication method, then value is oauth.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If resource is protected by <strong>Basic Auth or Basic Auth+ Session</strong> authentication methods, then value is http.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If resource is protected by <strong>Multitoken</strong> authentication method, then value is multitoken.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If resource is protected by <strong>Multitoken+Fallthrough</strong> authentication method, then value is multitoken or fallthrough depending if the authorization header is a known value or not.</td>
<td></td>
</tr>
<tr>
<td>idcs_authn_strength</td>
<td>Identifies if the user authentication has happened in one or two steps. If the user has signed in with IAM using their credentials only, then the authentication strength is 1. If the user has signed in using multi-factor authentication, then authentication level is 2.</td>
<td>App Gateway adds this header to the request forwarded to the enterprise application if the resource is protected by any authentication method except <strong>Public</strong> and <strong>Anonymous</strong>.</td>
</tr>
<tr>
<td>remote_user</td>
<td>Username of the user signed in to IAM.</td>
<td>App Gateway adds this header to the request forwarded to the enterprise application if the resource is protected by any authentication method except <strong>Public</strong>.</td>
</tr>
<tr>
<td></td>
<td>If the resource is protected by <strong>Anonymous</strong> authentication method, then the value of this header is anonymous.</td>
<td></td>
</tr>
<tr>
<td>idcs_remote_user</td>
<td>Username of the user signed in to IAM.</td>
<td>App Gateway adds this header to the request forwarded to the enterprise application if the resource is protected by any authentication method except <strong>Public</strong>.</td>
</tr>
<tr>
<td></td>
<td>If the resource is protected by <strong>Anonymous</strong> authentication method, then the value of this header is anonymous.</td>
<td></td>
</tr>
<tr>
<td>Header Name</td>
<td>Description</td>
<td>Authentication Method Usage</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>idcs_remote_user_mappingattr</td>
<td>The IAM user schema attribute used to identify the signed in user.</td>
<td>App Gateway adds this header to the request forwarded to the enterprise application if the resource is protected by any authentication method except <strong>Public</strong> and <strong>Anonymous</strong>.</td>
</tr>
<tr>
<td></td>
<td>For example, <code>userName</code>.</td>
<td></td>
</tr>
<tr>
<td>idcs_session_id</td>
<td>The session ID value IAM creates after user signs in.</td>
<td>App Gateway adds this header to the request forwarded to the enterprise application if the resource is protected by <strong>Form or Access Token</strong> or <strong>Basic Auth+ Session</strong> authentication method.</td>
</tr>
<tr>
<td>idcs_user_assertion</td>
<td>Value of the identity token issued by IAM.</td>
<td>App Gateway adds this header to the request forwarded to the enterprise application if the resource is protected by <strong>Form or Access Token</strong> authentication method.</td>
</tr>
<tr>
<td>idcs_user_display_name</td>
<td>Value of the <code>displayname</code> attribute of the user signed in with IAM.</td>
<td>App Gateway adds this header to the request forwarded to the enterprise application if the resource is protected by any authentication method except <strong>Public</strong> and <strong>Anonymous</strong>.</td>
</tr>
<tr>
<td>idcs_user_id</td>
<td>Value of the unique identifier attribute of the user signed in with IAM.</td>
<td>App Gateway adds this header to the request forwarded to the enterprise application if the resource is protected by any authentication method except <strong>Public</strong> and <strong>Anonymous</strong>.</td>
</tr>
<tr>
<td>idcs_user_tenant_name</td>
<td>IAM tenant name.</td>
<td>App Gateway adds this header to the request forwarded to the enterprise application if the resource is protected by any authentication method except <strong>Public</strong> and <strong>Anonymous</strong>.</td>
</tr>
</tbody>
</table>
## Cookies

<table>
<thead>
<tr>
<th>Cookie Name</th>
<th>Description</th>
<th>Authentication Method Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA_OCIS.CG_SESSION_&lt;idcs-tenant&gt;_&lt;aapgateway_host&gt;</td>
<td>After the user authenticates with IAM, App Gateway sets this cookie to the request forwarded to the application. The cookie name is composed by ORA_OCIS.CG_SESSION prefix, concatenated with IAM’s tenant name, and suffixed with the App Gateway’s Host value.</td>
<td>App Gateway adds this header to the request forwarded to the enterprise application if the resource is protected by <strong>Form or Access Token</strong> authentication method.</td>
</tr>
</tbody>
</table>

Adding Tags to an Application

You're an identity domain administrator or application administrator who wants to create custom attributes for your applications that can be used to search for the applications more effectively. To do this, you add tags to your applications. Tags are key-value pairs that are used to organize and identify applications.

For example, suppose you're creating three versions of an application: one for development purposes, one for testing purposes, and one that will be used in production. You can create the following tags for these versions: **Version:** "Development," **Version:** "Testing," and **Version:** "Production."

You can create new tags for your confidential, mobile, SAML, enterprise, and app catalog applications using the Tags tab in the Details pane. You can use these tags to identify and organize your applications.

- **Tags**

To add new tags to your application:

1. In the Tags area of the Details pane, click Add Tag.
2. Choose a Tag Namespace or leave the namespace as None to add a free-form tag.
3. In the Tag Key and Tag Value fields of the Add Tags window, enter or select the key-value pair for the tag you're creating.
4. (Optional) To create more tags, click Add Tag, and repeat the process.
5. Click Add Tags.

Assigning Applications to a User Using Account Form

Account Form will be visible in the user interface with account attributes for a provisioning application if the underlying App Template supports it. With Account Form, when you grant a provisioning application to a user, you can provide account values and when you edit a provisioned account, you can update existing account values.

To provide specific values using account form:

1. Open the navigation menu and click **Identity & Security.** Under **Identity,** click **Domains.** Select the identity domain you want to work in and click **Applications.**
2. Click the application that you want to modify.
3. Select the User tab and click **Assign users.**
4. In the Assign users window, select a user who needs access to the application.
5. Click **Assign** for each user you want to assign to the application.
6. In the Assign application window, the attribute values are populated based on the mappings already provided in the Attribute mapping section in the Provisioning configuration tab. You can choose to keep the populated values or update any attribute value.

7. Click **Save** to create the account for the user chosen in step 3.

8. Select the next user you want to provide access to this application. Repeat steps 3 through 5 for the next user.

9. Click **OK** after you have assigned the application to the users. The user account is assigned.

Creating a Custom Secure Form Fill App

Custom secure form fill apps give you the flexibility to define tenant-level form fill apps that are not in the global Oracle App Catalog.

Secure Form Fill is the IAM alternative for single sign-on into apps that require auto-form fill but don't support OAuth, SAML, or federated sign-on methods.

Users enter their application credentials for form-fill-enabled apps in IAM once. IAM stores and encrypts the information, and automatically fills in the login form so that users can sign in without having to reenter the information each time.

IAM stores the user's credentials in an encrypted format using strong encryption combined with a customer-specific private key. When a user opens the secure form fill application, which in turn prompts the login page, IAM detects and securely fills the user's credentials, submits the credentials to the app login page, and then the user is automatically signed in.

Prerequisites for Creating a Custom Secure Form Fill App

Learn the prerequisites for creating a custom secure form fill app.

Ensure that you have the following prerequisites in place before creating and testing a secure form fill app.

- A Windows operating system version 7, 8 or 10 with:
  - Local admin rights enabled
  - 32-bit Java Runtime Environment (JRE) to access local help content for the Secure Form Fill Admin Client.
- At least one of the following supported desktop browsers:
  - Mozilla Firefox
  - Google Chrome

  **Note:**
  The mobile browsers are not certified. To view the list of certified browsers, see [Supported Web Browsers](#).

- Secure Form Fill Admin Client. See [Install the Secure Form Fill Admin Client](#).

  **Note:**
  The ESSO Administrative Console is part of the Secure Form Fill Admin Client.

- Administrator privileges for an identity domain. See [Understanding Administrator Roles](#) on page 3295.

Installing the Secure Form Fill Admin Client

You use the Secure Form Fill Admin Client (Oracle Enterprise Single Sign-On (ESSO) Administrative Console) to create and update secure form fill configuration files for your custom secure form fill apps in IAM. Use these instructions to install the Secure Form Fill Admin Client.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Settings** and then **Downloads**.
2. On the Download page, locate the Secure Form Fill Admin Client and download it. See Downloading SDKs and Applications on page 3264.

   |Note:|
   |The ESSO Administrative Console is part of the Secure Form Fill Admin Client.

3. In the download location, unzip the file.

4. Double-click the installer to launch the install wizard, and then click Next.

5. Choose the Complete installation option, click Next, and then click Install.

6. When the installation completes, click Finish.

   |Note:|
   |This documentation explains, at a high level, how to use the ESSO Administrative Console only as it pertains to custom secure form fill apps and IAM. For additional instructions, see the help in the ESSO Administrative Console.

Creating a Secure Form Fill Configuration File

You use the Secure Form Fill Admin Client (Oracle Enterprise Single Sign-On (ESSO) Administrative Console) to create secure form fill configuration files for your custom secure form fill apps in IAM. Use these instructions to create secure form fill configuration files and then import those files into IAM.

Install the Secure Form Fill Admin Client. See Install the Secure Form Fill Admin Client.

1. Launch the Secure Form Fill Admin Client.

2. Right-click Applications, and then choose New Web App. Alternatively, use any of the following options:
   
   • Click Applications, Add, and then choose Application Type: Web in the first pane of the wizard.
   
   • Choose Insert, Application, and then choose Application Type: Web in the first pane of the wizard.

3. On the Add Application dialog, enter the name of the application.

   |Important:|
   |The application name must be the same name that you use when you create the secure form fill application in IAM.

4. Leave all other default options selected, and then click Finish.

5. Choose the Logon form type. This form is used to set up your Web app template.

   |Note:|
   |No other form type is supported.

6. In the Address field, enter the URL for the Web app, click Go, and then navigate to the login page. A list of all fields on the login page appear on the bottom of the screen. Select any field in the list on the bottom of the screen to highlight the field on the page.

7. Using the fields on the bottom of the screen, complete the following steps:

   |Note:|
   |Do no use the Third Field or Fourth Field options.
   
   Do not use the Allow multiple field designation option.
Only use ordinals if field names or attribute level matching is not possible. Using ordinals is less amenable to page changes or differences across browsers, and are not recommended in most scenarios.

a) Select the user name field, right-click, and then choose **Username/ID**.
b) Select the password field, right-click, and then choose **Password**.
c) Select the submit button, right-click, and then choose **Submit**.

8. Click **OK**.
9. On the Web dialog, make any of the following changes as necessary.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Identification Tab</strong></td>
<td>Click <strong>Edit</strong> to make changes. This is the URL or the URLs of the form to configure. For applications that have varying text in their URLs, you can use substrings or regular expressions to specify how to match the variable text. Your Match Type change options are:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Exact Match.</strong> Exact match matches a URL exactly as specified. This is generally an edge case and rarely used.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Wildcards.</strong></td>
</tr>
<tr>
<td></td>
<td>• ? matches any single character.</td>
</tr>
<tr>
<td></td>
<td>• * matches zero or more occurrences of any character. If wild cards are used, to avoid a potential security issue, do not perform mid-string wildcard matches. Always exact match the start of the URL, for example, <a href="https://server?.somesite.com/">https://server?.somesite.com/</a>*.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Regular Expressions.</strong> This is the recommended option. Use the set of regular expressions to specify a string pattern that the form-fill agent should recognize as a match, for example, URL1=.<em>? <a href="https://www%5C.expedia%5C.co%5C,.jp/user/login">https://www\.expedia\.co\,.jp/user/login</a>.</em></td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Fields Tab</td>
<td>Click a field, and then using the Edit button, adjust the primary form fields used for detection and injection of the user name and password fields as well as the submit button.</td>
</tr>
</tbody>
</table>

**Note:**  
Do not use the SendKeys or the SendKeys using journal hook options.  
Check each field type to ensure that it is the appropriate type (such as Password for password input fields, and so on).

Your Field options are:

- **Field Identification.** Allows you to fine-tune how the input fields for the form are located. Field identification can be adjusted for any form field. Click the ellipsis to display the Field identification options. Identify fields by:
  - **Name.** The default and recommended option. Beware that not every input field has a name or sometimes the name is not consistent every time the page is loaded. If so, then it's recommended to use the Matching option.
  - **Ordinal.** This option identifies fields based on sequence. This option is not the recommended alternative since it is easily impacted by minor changes to the page. Also, the fields and the field ordinals can be inconsistent across browsers.
  - **Matching.** Identifies fields based on tag types, attribute values, HTML, and so on. This option is the recommended option if Name is not possible. Often, matching is used to match the “id” attribute of the input field or a regex on the name attribute. Matching can be a regex, substring match, or whole string match.
  - **Events.** Pre Inject and Post Inject events allow secure form fill to trigger a specific event on the field before and after injecting the credentials into that field. This is useful as some fields will not recognize that injection has occurred unless a specific event is triggered in that field. Event values are: blur, change, click, focus, focusin, focusout, input, keydown, keypress, keyup, and mouseover.
10. Click OK.

11. Use the following tabs to make any necessary changes:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Matching Tab</strong></td>
<td>Create or modify granular page matching criteria for the selected web form. Secure Form Fill in IAM uses the matching criteria you supply here to distinguish among similar forms. Matching can also be used to refine the detection match criteria, that is, the set of HTML tags and values you use to identify a specific field to perform more specific matching beyond just the form fields themselves.</td>
</tr>
<tr>
<td><strong>Proxy Tab</strong></td>
<td>Do not change these settings.</td>
</tr>
</tbody>
</table>

**Note:**
Do not change any other options on any other sub tabs other than those listed in the table below.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>General Tab</strong></td>
<td>Enter a description for the Web app. Add, edit, or delete forms. This option allows you to set all the forms relevant for this Web app. Use this option if you have multiple login forms for your Web app. All other settings are not required for secure form fill and should not be changed.</td>
</tr>
<tr>
<td><strong>Error Loop Tab</strong></td>
<td>Secure form fill supports the detection of an error loop condition. Error loop conditions generally occur if secure form fill has the wrong credentials for the Web app and attempts to submit these credentials repeatedly to the Web app.</td>
</tr>
<tr>
<td><strong>Logon timeout (sec.)</strong></td>
<td>The maximum time in seconds between successive logon attempts before a logon error is triggered.</td>
</tr>
<tr>
<td><strong>Max. retries</strong></td>
<td>The maximum number of retries (after first try) allowed before a logon error is triggered.</td>
</tr>
<tr>
<td><strong>Miscellaneous Tab</strong></td>
<td>• <strong>Logon Loop Grace Period.</strong> Allows control over the response during login grace period (for example, controls reinjection). • <strong>Auto-submit.</strong> Use this option to turn auto-submit on or off for all forms used by the app.</td>
</tr>
</tbody>
</table>

12. Click **File**, and then **Save**.

**Tip:**
Name the Web app file, the *.ini file, and the name of the IAM app with the same name.

13. To export the file, click **File**, **Export**, select the application to export, and then click **OK**.
14. Name the file.

**Important:**
The *.ini file name must match the name of the application created in IAM.

**Post requisite:** Create an IAM secure form fill app.

Creating a Secure Form Fill App

After you create a configuration file in the Oracle Enterprise Single Sign-On (ESSO) Administrative Console, the next step is to create a secure form fill app.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click **Add application**, and then click **Application Catalog**.
3. In the Type of integration section, click **Secure form fill**, locate **Generic Secure FormFill App Template**, and then select it.
4. Complete the application details by entering a **Name**, **Description**, and **Application URL**.

**Important:**
The application name must match the file name of the .ini file created in the ESSO Administrative Console.

5. In the **Display settings** section, select **Display in My Apps**.

**Important:**
If you do not select **Display in My Apps**, the application does not display in the **My Apps** page for users.

When you select the **Display in My Apps** check box in applications, the app is then visible in the **My Apps** page, but selecting this check box doesn’t enable or disable SSO to the app.

6. Select the **User can request access** check box, if you want the app to be listed in the **Catalog**. This option allows end users to request access to applications from their **My Apps** page by clicking **Add** and then selecting the app from the **Catalog**.

7. Select **User can view their credentials** if you want users to view their credentials in **My Profile**.

8. Click **Finish**.

9. Click **Import** to import the secure form fill configuration file that you created in the ESSO Administrative Console.

   The application has been added in deactivate state. To activate your application, click **Activate** next to the app name.

10. To assign users to the application, click **Users**.

    **Tip:**
    Assign the application to yourself or a test user. This saves you time when testing the secure form fill app.

11. To assign groups to the application, click **Groups**.

    The applications you assign to the user or group displays on the **My Apps** page. Newly assigned applications and applications that a user has not yet accessed appear first in the application list and have an asterisk icon in the application tile. The icon appears on the tile until the user accesses the application.

Installing and Using the Secure Form Fill Plugin

Install the Oracle Secure Form Fill Plugin so that you can launch secure form fill apps. Once installed, you are able to access **My Apps** from your browser toolbar.

Installing the Google Chrome Plugin
If you are using Google Chrome and you need to install the plugin, you are prompted to go to the Extensions on Google Chrome and install the Oracle Secure Form Fill Plugin from the IAM user interface. You will be prompted to download the plug-in from the My Apps page the first time that you access to a secure form fill app.

Installing the Mozilla Firefox Plugin

If you are using Mozilla Firefox and you need to install the plugin, instead of downloading the Secure Form Fill Mozilla Firefox plug-in from the Mozilla Store, install the Secure Form Fill Mozilla Firefox plug-in from the My Apps page. You will be prompted to download the plug-in from the My Apps page the first time that you access to a secure form fill app.

Accessing My Apps from the browser using the plugin

After you install the Oracle Secure Form Fill Plugin, when you are logged in to IAM you can access My Apps from your browser toolbar.

Testing a Custom Secure Form Fill App

After you create a custom secure form fill app in an identity domain, test the app before deploying it to your organization.

1. Log in to the identity domain console to access the My Apps page.
2. Install the secure form fill plug in, if you have not already installed it, and then refresh your browser.
3. Open the app, enter the credentials for the application, and then click **Login**.

A successful result is IAM injecting the user name and password, and then clicking the submit button.

If you are having issues, check the settings for your Web app in the Oracle Enterprise Single Sign-On (ESSO) Administrative Console, export the *.ini file if necessary, check the settings for your app in the identity domain, and try again.

Updating a Custom Secure Form Fill App

To update a custom secure form fill app, you first update the Web app using the Secure Form Fill App, export the configuration file in (*.ini), and then update the custom secure form fill app in the identity domain.

1. Create a Web app in the Secure Form Fill Admin Client. See **Installing the Secure Form Fill Admin Client**.
2. Create a custom secure form fill app created in the identity domain.

1. If you need to update the Web app and configuration file created in Secure Form Fill Admin Client, update the Web app first, and then save and export the file. See **Create a Secure Form Fill Configuration File**.
2. To change the custom secure form fill app, access the application as an Identity domain administrator, make any necessary changes, import the new configuration file (if necessary), and then save the app. See **Create a Secure Form Fill App in IAM**.

Test your new configuration. See **Test a Custom Secure Form Fill App**.

Importing and Synchronizing Users in Applications

You can import and synchronize users of third-party cloud applications using a flat file and manage them in an identity domain.

Importing Users into Applications

You can perform a full sync import of the users of third-party Cloud applications using a flat file. In a full sync import, the imported user in the CSV file replaces any existing user who is already assigned to the application.

1. Create a CSV file for import in the following format or download the CSV file along with user data from the target system apps:

   ID, NAME, ACTIVE
This table provides a description of the attributes in the CSV format file:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description</th>
<th>Sample Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The unique identifier of the account in the target.</td>
<td><a href="mailto:hercule.poirot@sampleapp.com">hercule.poirot@sampleapp.com</a>,<a href="mailto:hercule.poirot@sampleapp.com">hercule.poirot@sampleapp.com</a>,true</td>
</tr>
<tr>
<td>NAME</td>
<td>The name of the account. NAME is the primary input that is matched with the username of a particular user in IAM.</td>
<td><a href="mailto:hercule.poirot@sampleapp.com">hercule.poirot@sampleapp.com</a></td>
</tr>
<tr>
<td>ACTIVE</td>
<td>The status of the account on the target. The possible values are true and false. If the value is true, the user account is imported and activated. If the value is false, the user is imported in a deactivated state.</td>
<td>true</td>
</tr>
</tbody>
</table>

2. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
3. Click the application that in which you want to import users.
4. Click **Import**.
5. Browse for the CSV file, and import it.

    **Note:**
    Import from CSV file is enabled for applications that support flat file synchronization.

6. Refresh the page to view the import result. If the import succeeds, then the users present in the CSV file displays.
7. Select **Users** to view the imported users.

    **Note:**
    Refresh the **Users** tab to view the imported users.

8. Observe that the users with a true value for **ACTIVE** attribute are activated. However, if a user account has false value for **ACTIVE** attribute, the user account is imported in a deactivated state.

    **Note:**
    The **Users** tab displays only the matched and confirmed users.

9. Synchronize the imported users. See **Synchronizing Imported User Accounts** to synchronize the imported user accounts with the users in an identity domain.

    **Synchronizing Imported User Accounts**
    After you import the users, if a matching user account doesn't exist in the identity domain, you can either assign the user account to an existing user or create a new user for the user account.
    If the imported user account exists, an exact match is found and no further action is required. The synchronization status of the user account is set as confirmed.

    **Assigning an Existing User**
You can assign an existing user to the imported user account in the **Import** tab if the user is present in IAM and the import failed to match the user.

1. On the row of the imported user, select **Assign existing user** from the **Actions** menu.
2. In the **Assign user** window, search for an existing user, select the required user and click **Assign**.

The user account is manually linked to the existing user and the synchronization status is confirmed.

### Creating and Linking a New User with the User Account

You can create a new user and link the user with the imported user account if there are no existing users to assign.

1. On the row of the imported user, select **Create new user and link** from the **Actions** menu.
2. In the **Assign user** window, enter the following user details: **First name**, **Last name**, and **Username / Email**.
3. Select **Use the email address as the user name** option if you want to use the email address as your user name and click **Assign**.

The user account is manually linked to the new user and the synchronization status is confirmed.

### Managing synchronized users

You can activate, deactivate, assign, and revoke imported users from the **Users** tab.

You can perform the following actions on the synchronized users:

- To activate an imported user account, select the **Actions** menu, and click **Activate**.
- To deactivate an imported user account, select the **Actions** menu, and click **Deactivate**.
- To remove any imported user account, select the user, and click **Revoke**.
- To assign any other user to the application apart from the synchronized users from the flat file, click **Assign**.

Choose a user from the list of existing users and click **OK**. The assigned user account is displayed and is in an activated state.

### Configuring OAuth

Configure the your Enterprise or Confidential application to act as a confidential application by providing client and resource server configurations.

1. On the **Configure OAuth** pane, to protect resources for your application now, and to make the application visible on the **My Apps** page, click **Configure this application as a resource server now**

Use the following table to provide the information needed to configure this application as a resource server.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Access token expiration (seconds)</strong></td>
<td>Define how long (in seconds) the access token associated with your confidential application remains valid.</td>
</tr>
<tr>
<td><strong>Allow token refresh</strong></td>
<td>Select this check box if you want to use the refresh token that you obtain when using the Resource Owner, Authorization Code, or Assertion grant types.</td>
</tr>
<tr>
<td><strong>Refresh token expiration (seconds)</strong></td>
<td>Define how long (in seconds) the refresh token, which is returned with your access token and is associated with your confidential application, remains valid.</td>
</tr>
<tr>
<td><strong>Primary audience</strong></td>
<td>Enter the primary recipient where the access token of your confidential application is processed.</td>
</tr>
</tbody>
</table>
2. On the **Configure OAuth** pane, click **Configure this application as a client now**.

Use the following table to provide the information needed to configure this application as a client.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Resource owner</strong></td>
<td>Use when the resource owner has a trust relationship with the confidential application, such as a computer operating system or a highly privileged application, because the confidential application must discard the password after using it to obtain the access token.</td>
</tr>
</tbody>
</table>
| **Client credentials** | Use when the authorization scope is limited to the protected resources under the control of the client or to the protected resources registered with the authorization server.  
The client presents its own credentials to obtain an access token. This access token is either associated with the client's own resources, and not a particular resource owner, or is associated with a resource owner for whom the client is otherwise authorized to act. |
| **JWT assertion**  | Use when you want to use an existing trust relationship expressed as an assertion and without a direct user approval step at the authorization server.  
The client requests an access token by providing a user JSON web token (JWT) assertion or a third-party user JWT assertion and client credentials.  
**A JWT assertion** is a package of information that facilitates the sharing of identity and security information across security domains.                                      |
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAML2 assertion</td>
<td>Use when you want to use an existing trust relationship expressed as a SAML2 assertion and without a direct user approval step at the authorization server. SAML2 assertion is a package of information that facilitates the sharing of identity and security information across security domains.</td>
</tr>
<tr>
<td>Refresh token</td>
<td>Select this grant type when you want a refresh token supplied by the authorization server, and then use it to obtain a new access token. Refresh tokens are used when the current access token becomes invalid or expires and don’t require the resource owner to reauthenticate.</td>
</tr>
<tr>
<td>Authorization code</td>
<td>Select this grant type when you want to obtain an authorization code by using an authorization server as an intermediary between the client application and resource owner. An authorization code is returned to the client through a browser redirect after the resource owner gives consent to the authorization server. The client then exchanges the authorization code for an access (and often a refresh) token. Resource owner credentials are never exposed to the client.</td>
</tr>
<tr>
<td>Implicit</td>
<td>If the application can't keep client credentials confidential for use in authenticating with the authorization server, then select this check box. For example, your application is implemented in a web browser using a scripting language such as JavaScript. An access token is returned to the client through a browser redirect in response to the resource owner authorization request (rather than an intermediate authorization).</td>
</tr>
<tr>
<td>Device code</td>
<td>Select the Device Code grant type if the client doesn’t have the capability to receive requests from the OAuth Authorization Server, for example, it cannot act as an HTTP server such as game consoles, streaming media players, digital picture frames, and others. In this flow, the client obtains the user code, device code, and verification URL. The user then accesses the verification URL in a separate browser to approve the access request. Only then can the client obtain the access token using the device code.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>TLS client authentication</strong></td>
<td>Select the <strong>TLS Client Authentication</strong> grant type to use the client certificate to authenticate with the client. If a token request comes with an X.509 client certificate and the requested client is configured with the <strong>TLS Client Authentication</strong> grant type, the OAuth service uses the Client ID in the request to identify the client and validate the client certificate with the certificate in the client configuration. The client is successfully authenticated only if the two values match. For added security, before enabling the <strong>TLS Client Authentication</strong> grant type, enable and configure OCSP validation and import a trusted partner certificate. ⚠️ This option is not recommended for production deployments.</td>
</tr>
<tr>
<td><strong>Allow non-HTTPS URLs</strong></td>
<td>Select this check box if you want to use HTTP URLs for the <strong>Redirect URL</strong>, <strong>Logout URL</strong>, or <strong>Post logout redirect URL</strong> fields. For example, if you are sending requests internally, want a non-encrypted communication, or want to be backward-compatible with OAuth 1.0, then you can use an HTTP URL. Also, select this check box when you are developing or testing your application and you might not have configured SSL. This option is provided as a convenience and is not recommended for production deployments.</td>
</tr>
<tr>
<td><strong>Redirect URL</strong></td>
<td>Enter the application URL where the user is redirected after authentication. ☑️ <strong>Note:</strong> Provide an absolute URL. Relative URLs are not supported.</td>
</tr>
<tr>
<td><strong>Logout URL</strong></td>
<td>Enter the URL where the user is redirected after logging out of the confidential application.</td>
</tr>
<tr>
<td><strong>Post logout redirect URL</strong></td>
<td>Enter the URL where you want to redirect the user after logging out of the application.</td>
</tr>
<tr>
<td><strong>Client type</strong></td>
<td>Select the client type. The available client types are <strong>Trusted</strong> and <strong>Confidential</strong>. Choose <strong>Trusted</strong> if the client can generate self-signed user assertions. Then, to import your signing certificate that the client uses to sign its self-signed assertion, click <strong>Import certificate</strong>.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **Allowed operations**         | • Select the **Introspect** check box if you want to allow access to a token introspection end point for your application.  
If the confidential application can't keep client credentials confidential for use in authenticating with the authorization server, then select this check box. For example, your confidential application is implemented in a web browser using a scripting language such as JavaScript.  
An access token is returned to the client through a browser redirect in response to the resource owner authorization request (rather than an intermediate authorization code).  
• Select the **On behalf of** check box if you want to ensure that access privileges can be generated from the user's privileges alone. This allows the client application to access endpoints to which the user has access, even if the client application by itself would not normally have access. |
| **ID token encryption algorithm** | Select one of the content encryption algorithms.                                                                                                                                                                                                                                                                                           |
| **Bypass consent**             | If enabled, this attribute overwrites the **Require consent** attribute for all the scopes configured for the application, and then no scope will require consent.                                                                                                           |
| **Client IP address**          | • Anywhere  
• Restrict by network perimeter                                                                                                                                                                                                                                                                                                   |
| **Authorized resources**       | Select one of the following options to allow a client application to access authorized resources:  
• **All** – Access any resource within a domain (All). See [Accessing All Resources](#).  
• **Tagged** – Access any resource with matching tags (Tagged). See [Accessing Resources With Matching Tags](#).  
• **Specific** – Access only those resources where an explicit association between the client and the resource (Specific) exists. See [Accessing Resources With Specific Scopes](#).                                                                 |

**Note:**  
The option to define an authorized resource is available to only Confidential applications. Trust scope cannot be defined for Mobile applications.

See [Account Trust Scope](#) for additional scope information as well as request and response examples for use with the IAM REST APIs.
### Add resources

If you want your application to access APIs from other applications, then click **Add** in the **Token issuance policy** section. Then, in the **Add scope** window, select the applications that your application references.

**Note:**

You can delete scopes by clicking the x icon next to the scope. However, you can’t delete scopes that are protected.

### Add app roles

In the **Add app roles** window, select the application roles that you want to assign to this application. This enables your application to access the REST APIs that each of the assigned application roles can access.

For example, select **Identity Domain Administrator** from the list. All REST API tasks available to the identity domain administrator will be accessible to your application.

You can delete the application roles by selecting the application role and then clicking **Remove**.

**Note:**

You can’t delete protected application roles.

See [Apps/App Roles endpoint](#) for a complete list of which endpoints each application role can access.

---

3. Click **Save changes**.

---

### Deleting Applications

You can use IAM to delete multiple applications simultaneously.

Deactivate all applications that you want to delete.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.

2. Select the check box for each application that you want to delete, or to delete all applications, select the **select all** check box in the heading row of the table.

3. Select **Actions**, **Delete**, then **Delete application**.

**Note:**

You cannot delete an Oracle Public Cloud application from the UI. You will encounter an error if you try removing any Oracle Public Cloud application.

---

### Activating Applications

Activating applications reinstates the access rights to applications for users and groups.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.

2. Select the check box for each deactivated application that you want to activate.

3. Select **Actions**, **Activate**, and then **Activate application**.
Deactivating Applications
Deactivating an application temporarily disables the access rights to applications that users or groups have.

1. Open the navigation menu and click Identity & Security. Under Identity, click Domains. Select the identity domain you want to work in and click Applications.
2. Select the check box for each activated application that you want to deactivate.
3. Select Actions, Deactivate, and then Deactivate application.

Viewing Details About Applications
By default, you can see the name and description for each application in IAM.

By clicking an application name, you can view high-level and configuration information about the application. For Oracle applications, you can also see the roles associated with the application, and the IAM groups and users assigned to the application.

1. Open the navigation menu and click Identity & Security. Under Identity, click Domains. Select the identity domain you want to work in and click Applications.
2. Click the application name for which you want additional information.

   Tip:
   To search for applications, enter all or part of the beginning of the application name that you want to locate in the search field, and then press Enter. To fine-tune your search, click the search field again, and then select a status.

3. To view high-level information about the application, such as the application type, name, description, icon, URL, links, and whether the application will appear on the My Apps page, click Details.
4. To view configuration information about the application, click Configuration. For custom SAML applications, this tab is labeled SSO configuration because, by granting SAML applications to users, they can single sign-on (SSO) into SaaS applications that support SAML for SSO. See Add a Confidential Application, Add a Mobile Application, and Add a SAML Application.
5. For Oracle applications, to view roles associated with the application, click Application roles. You can assign users and groups to an application role or remove users and groups from the application role. See Modifying Oracle and Custom Applications on page 3230.
6. For Oracle applications, to view the names and descriptions of any groups assigned to the application, click Groups.
7. For Oracle applications, to view the names, email addresses, and phone numbers of any users assigned to the application, click Users. You can filter and sort this list of users.
   • To display only those users who are assigned to a particular application role, click Show, and then select the application role.
   • To display users who are assigned to any application role, click Show, and then select All role members.
   • To sort the users in ascending order by their names or email addresses, click Sort By, and then select Name or Email.

Modifying Oracle and Custom Applications
After configuring, you can modify Oracle and custom applications to assign users and groups, edit high-level information, import users and groups into the applications, export users and groups from applications, and perform specific configuration tasks for custom applications.

To modify applications:
1. Open the navigation menu and click Identity & Security. Under Identity, click Domains. Select the identity domain you want to work in and click Applications.
2. Click the application you want to modify. The Applications page expands to open a sub page that displays high-level information about the application.

You can perform the following tasks in Oracle and custom applications:

- **Oracle applications**:
  - Assign users and groups.
  - Remove users and groups.

  The Groups and Users tabs are used to display groups and users assigned to application roles of an Oracle application. Although you can filter and sort this list of users and groups, you can't modify the list. You can't edit values that appear in these tabs.

  - Import Users and Groups for Oracle Application Roles.
  - Export Users and Groups for Oracle Application Roles.

  **Note:**
  If you assign users to Oracle application roles and then deactivate the accounts, IAM prevents the users from accessing the roles. To enable the users to access the Oracle application roles to which they are assigned, activate the users.

  - View High-Level Information

  See Modify Oracle Applications.

- **Custom applications**:
  - Assign users and groups.
  - Remove users and groups.
  - Edit high-level information and configuration information.
  - Edit Web Tier Policies for Trusted Applications.
  - Regenerating a Client Secret and generating tokens for Trusted Applications
  - Edit single sign-on (SSO) configuration for SAML Applications.

  See Modify Custom Applications.

Modifying Oracle Applications

You can assign and remove users and groups to Oracle Applications, and import and export users and groups for Oracle Application Roles. You can view the high-level information but can't edit any of the values in Oracle Applications.

Assigning Users to Oracle Applications

You can assign users to Oracle applications only after you activate the applications.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click the application that you want to modify.
3. Click Application roles.
4. Select the check box for the application role of the Oracle application to which you want to assign users.
5. Click More, and then select Assign users.
6. In the Assign users window, select the check box for each user that you want to assign to the application role.
7. Click Assign.
   The application role displays a user icon and a Users assigned link. The link displays the number of users that you assigned to the application role.
8. Click Users assigned.
9. In the Users assignments window, verify that you see the users that you assigned to the application role.
10. Click Close.
Removing Users from Oracle Applications

To remove users from Oracle applications, use the **Application Roles** tab. You can remove users from Oracle applications only after you activate the applications.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click the application that you want to modify.
3. Click **Application roles**.
4. Select the check box for the application role of the Oracle application from which you want to remove users.

   **Tip:**

   You can see which application roles have users assigned to them by the user icon and the **Users Assigned** link that appears in the application role.

5. Click **More**, and then select **Revoke users**.
6. In the **Revoke users** window, select the check box for each user that you want to remove from the application role.
7. Click **Revoke**.

Assigning Groups to Oracle Applications

After you activate the applications, you can assign groups to Oracle applications by using the **Application roles** tab.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click the application that you want to modify.
3. Click **Application roles**.
4. Select the check box for the application role of the Oracle application to which you want to assign groups.
5. Click **More**, and then select **Assign Groups**.
6. In the **Assign groups** window, select the check box for each group that you want to assign to the application role.
7. Click **Assign**.

   **Note:**

   The All tenant users group is a default group that's created by IAM. All IAM users are assigned to this group, by default. If you assign this group to any of your applications, then all users are assigned to these applications indirectly.

   The application role displays a group icon and a **Groups assigned** link. The link displays the number of groups that you assigned to the application role.

8. Click **Groups assigned**.
9. In the **Groups assignments** window, verify that you see the groups that you assigned to the application role.
10. Click **Close**.

Removing Groups from Oracle Applications

You can remove groups from Oracle applications from the **Application Roles** tab. You can remove groups from Oracle applications only after you activate the applications.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click the application that you want to modify.
3. Click **Application roles**.
4. Select the check box for the application role of the Oracle application from which you want to remove groups.

   **Tip:**
   You can see which application roles have groups assigned to them by the group icon and the **Groups assigned** link that appears in the application role.

5. Click **More**, and then select **Revoke groups**.

6. In the **Revoke groups** window, select the check box for each group that you want to remove from the application role.

   **Note:**
   The **All tenant users** group is a default group that's created by IAM. All IAM users are assigned to this group, by default. If you remove the **All tenant users** group from your applications, then access rights to these applications are revoked for every IAM user.

7. Click **Revoke**.

**Editing High-Level Information for Oracle Applications**

When you create an instance of an Oracle application in your identity domain, the application instance appears in the **Applications** page. As a Service Administrator, you can edit some of the high-level information for Oracle Applications. However, you can’t edit attributes that are protected. Even in an editable attribute, you can’t update certain values that were seeded by the system.

To view and edit high-level information about Oracle application, such as the application type, name, description, icon, URL, links, and whether the application appears on the **My Apps** page, click **Details**.

Not all attributes correspond to UI fields:

- `grantedAppRoles` attribute records each App Role defined by another application that has been granted to the client.
- `signonPolicy` editable attribute indicates that you can assign Oracle Applications to Sign-On Policy.

**Note:**
You cannot change any of the fields other than the ones listed above for Oracle Public Cloud applications. You will encounter an error if you click Save after you try editing any of these values.

Apart from editing certain attributes, you can perform the following with Oracle Public Cloud Applications:

- Edit only single scope. Bulk removal of scopes is not supported.
- Grant client access to the IAM APIs
  
  To enable your application to access IAM APIs, click Add.
  
  In the Add App Role window, select the application roles that you want to assign to this application. This enables your application to access the REST APIs that each of the assigned application roles can access.
  
  For example, select Identity Domain Administrator from the list. All REST API tasks available to the identity domain administrator will be accessible to your application.
  
  You can’t remove the following:
  
  - The assigned application roles from the application by clicking the x icon for the row of the required application role
  - The App Roles that were granted when an Oracle Public Cloud application was created because those seeded values are protected
  
  See Apps/App Roles endpoint for a complete list of which endpoints each application role can access.

Modifying Custom Applications

You can assign and remove users and edit high-level information in custom applications.

Assigning Users to Custom Applications

Custom applications are non Oracle Public Cloud (OPC) services. You can modify custom applications by assigning users to them. Users can access the My Apps page to view these applications.

- The application must be activated.
- The application must be assigned to the current user who is accessing the My Apps page
- The Display in My Apps check box must be selected in the Details tab in the applications.

1. Open the navigation menu and click Identity & Security. Under Identity, click Domains. Select the identity domain you want to work in and click Applications.
2. Click the application that you want to modify.
3. Click Users.
4. Click Assign users.
5. In the **Assign users** window, do one of the following:
   a) Select the check box for each user that you want to assign to the application.
   b) For a provisioned application, select **Assign** next to the user that you want to assign to the application. Enter the required values for the form, and then click **Save**.

   ![Note:](image)
   If the form contains multi-valued attributes, then an **Add** button appears to the right of each attribute. Click **Add**, and then in the **Allowed values** window, select the values for the attribute, and click **OK**.

6. Click **Assign**.

   ![Note:](image)
   If you assigned a provisioned application to the user, then you can modify the values of the application form. To do this, click the **Actions** menu, select **Edit**, change the appropriate values, and then click **Save**.

   You can activate or deactivate a user's account assigned to a synchronized app that's created from the App Catalog. To do so:

   1. Click the **Actions** menu to the right of the user account that you assigned to the application.
   2. Click **Activate** or **Deactivate**
   3. In the **Activate account?** or **Deactivate account?** window, click **OK**.

   See [Enabling Provisioning for an App Catalog Application](#) for more information about configuring provisioning for an application to manage the lifecycle of users in the application.

---

Removing Users from Custom Applications

You can modify custom applications by removing users from them. Users can no longer view these applications through the **My Apps** page.

The application must be activated.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click the application that you want to modify.
3. Click **Users**.
4. Select the check box for each user that you want to remove from the application.
5. Click **Revoke**.
6. Complete one of the following choices:
   - To remove one user from the custom application, in the **Revoke user?** dialog box, click **Revoke user**.
   - To remove multiple users from the custom application, in the **Revoke users?** dialog box, click **Revoke users**.

Assigning Groups to Custom Applications

You can modify custom applications by assigning groups to them. Users who are members of these groups can access the **My Apps** page to view these applications.

**Prerequisite:** The application must be activated.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click the application that you want to modify.
3. Click **Groups**.
4. Click **Assign**.
5. In the **Assign groups** window, do one of the following.
   a) Select the check box for each group that you want to assign to the application.
   b) For a provisioned application, select **Assign** next to the group that you want to assign to the application. Enter the required values for the form, and then click **Save**.

   **Note:**
   If the form contains multi-valued attributes, then an **Add** button appears to the right of each attribute. Click **Add**, and then in the **Allowed values** window, select the values for the attribute, and click **OK**.

   The **All tenant users** group is a default group that's created by IAM. All IAM users are assigned to this group, by default. If you assign this group to any of your applications, then all users are assigned to these applications indirectly.

6. Click **OK**.

   **Note:**
   If you assigned a provisioned application to the group, then you can modify the values of the application form. To do this, click the **Actions** menu, select **Edit**, change the appropriate values, and then click **Save**.

Removing Groups from Custom Applications
You can modify custom applications by removing groups from them. Users who are members of these groups can no longer view these applications through the **My Apps** page.

Activate the application.
1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**. Select the identity domain you want to work in and click **Applications**.
2. Click the application that you want to modify.
3. Click **Groups**.
4. Select the check box for each group that you want to remove from the application.

   The **All tenant users** group is a default group that's created by IAM. All IAM users are assigned to this group, by default. If you remove the **All tenant users** group from your applications, then access rights to these applications are revoked for every IAM user.

5. Click **Revoke**.

Editing High-Level Information for Custom Applications
You can edit high-level information for custom applications.
1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Click the application that you want to modify.
3. Click **Details**.
4. To modify an attribute value, enter the modification in the attribute field (for example, modify the application name in the **Name** field).

5. Click **Save**.

Editing Configuration Information for Custom Applications
You can edit configuration information for custom applications.
1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Domains**.
2. Click the application that you want to modify.
3. Click **Configuration**.
4. Expand the **Client configuration** node.
Modify a configuration value for the custom application by:

- Entering the value in the attribute field (for example, in the Redirect URL field, entering the application URL where the user is redirected after authentication)
- Clicking a button (for example, adding a resource to the custom application by clicking Add or removing a scope for a trusted application by clicking Remove)
- Selecting or clearing the check box (for example, allowing the resource owner to be a grant type for the custom application by selecting Resource owner)
- Selecting the value from the menu (for example, selecting User administrator from the Grant the client access to Oracle Identity Cloud Service admin APIs list to enable the custom application to access user administrator-related APIs)

If your custom application is a confidential or a mobile application, then you can switch Bypass consent on or off.

If your custom application is a confidential application, then expand the Resources node. If your custom application is a mobile application, then the Resources node doesn’t appear in the Configuration tab. This is because confidential applications run on a protected server, and mobile applications run on an unauthenticated web browser or a mobile device.

Modify a configuration value for the protected resources of your confidential application. See step 3 for more information about how to edit configuration values.

Click Save.

See Add a Confidential Application, Add a Mobile Application, and Add a SAML Application for more information about the configuration settings for client applications.

Edit Consent Information for Custom Applications

Application administrators can customize the information that appears in the OAuth consent page for applications. If your application's resources is configured to require consent, then IAM provides a consent page in which users must allow to access the application's resources. By default, this consent page is branded with IAM information, but you can customize the information that appears in the page.

1. Open the navigation menu and click Identity & Security. Under Identity, click Domains. Select the identity domain you want to work in and click Applications.
2. Click the application that you want to modify, and then click the Configuration tab.
3. Expand the Consent information node.
4. Provide values for the fields that you want to customize, and then click Save.

Integrating Custom Applications with IAM

Learn how to use the SCIM interface to integrate custom applications with an identity domain.

Integrating with Custom Applications

Let's say that you want to integrate your applications with an identity domain. Your applications are homegrown or aren’t listed in the App Catalog, and an AD Bridge or Provisioning Bridge can’t be used as a link between your applications and an identity domain.

A custom application is an application where the App Catalog or a bridge can’t be used to integrate it with an identity domain. By integrating your custom applications with an identity domain, from one centralized cloud service, you can provide SSO capabilities for your applications, and provision and synchronize your users between the applications and IAM.
