• **Access:** You must access the detector and responder rules from the **Targets** page to change these settings.

The table below summarizes which detector and responder rule settings you can change at the recipe level and at the target level, for Oracle-managed and user-managed recipes.

<table>

Using Conditional Groups with Recipe Rules

Conditional groups let you quickly set the scope for which a detector or responder rule should be activated.
Conditional Groups for Detectors

A conditional group sets parameters that you specify, to limit the scope of situations for which the violation of a detector rule actually triggers a problem:

- **For configuration detectors**, conditional groups allow for inclusion or exclusion of specific resources from monitoring.
- **For activity detectors**, conditional groups allow for limiting activity detectors to certain IP spaces, regions, users, groups, or resources.
- To implement conditional groups, when you are modifying a detector recipe rule:
  1. Select the Parameter, Operator, and Custom List or a Managed List.
  2. Input one or more entries for the Value to be matched.

  • To set a condition on a parameter other than tags:
    1. In the Parameter list, select a parameter other than Tags.
    2. Select an Operator.
    3. Select a Value.
    4. To add another condition, click Add Condition and repeat the last three steps.

    **Note:**
    Specifying multiple conditions acts as an AND operator. The rule is enforced only if all the conditions are met.

  5. To delete a condition, click the “X” at the right end of the row for the condition.

  - To set a condition on tags:
    1. In the Parameter list, select Tags.
    2. A Value box appears below the Parameter box.
    3. Select an Operator (In or Not In).
    4. Click Select Tags, to right of Value box.
    5. In the Select Tags dialog box:
      - To set a condition for defined tags:
        a. Select a Tag Namespace other than None (add a free-form tag).
        b. Select a Tag Key.
        c. Select or enter the Value.
      - To set a condition for free-form tags:
        a. For Tag Namespace, select None (add a free-form tag).
        b. Enter a Tag Key.
        c. (Optional) Enter a Value.
      - To add another tag:
        a. Click Additional Tag.
        b. Repeat the steps above for either defined or free-form tags.

    **Note:**
    When you specify multiple tags, the rule is enforced only if all the conditions are met.

  - To delete a tag, click the “X” at the right end of the row for the tag.
  - To save your tag selections, click Select at the bottom of the Select Tags dialog box.
  - You can add a condition for a single resource and input at a time using a custom list, or add multiple resources and inputs at once using managed lists.
Example: You have 10 Compute Instances. Two instances (Instance1 and Instance2) should be public, so you don't want the "Instance is publicly accessible" rule to trigger problems on these instances. You can use conditional groups to exclude these two instances, using either custom lists or managed lists.

Valid Values for Conditional Group Parameters

With both detector and responder recipes, some rules have Parameter options that require you to type one or more valid Value entries. The following list provides links to sources that the valid values for each parameter type. Where links are not available, a brief explanation of how to find valid values is provided.

- **IPV4**: Parts of the IPv4 Address
- **IPV6**: Parts of the IPv6 address
- **City**: There is no international standard for city names or codes. Cloud Guard uses the actual city names, and a complete list of supported city names is not available.
- **State or Province**: ISO 3166-2 State or Province Codes
- **Country**: ISO 3166-1 alpha-2 codes, as shown in List of ISO 3166 country codes
- **User name**: User name as displayed in the Oracle Cloud Infrastructure console
- **Resource OCID**: resource ID as displayed in the Oracle Cloud Infrastructure console screen for the resource
- **Region**: One of the supported Oracle Cloud Infrastructure regions listed in About Regions and Availability Domains

Exclusion of Resources Using Custom Lists

Use custom lists when the number of items to be matched is small, and you don't expect to need to reuse the same list multiple times.

1. Open the details page for the detector recipe where the "Instance is publicly accessible" rule is enabled.
   
   See Modifying a Detector Recipe on page 828.
2. On the detector recipe's detail page, under Detector Rules, locate the row for the "Instance is publicly accessible" rule.
3. At the right end of that row, open the Actions menu, and select Edit.
4. In the Edit Detector Rule dialog box, Conditional Group section:
   a. Set Parameter to Instance OCID.
   b. Set Operator to Not in.
   c. Set List to Custom List.
   d. For Value, enter the OCID for Instance1.
5. Click Add Condition.
6. In the new condition row:
   a. Set Parameter to Instance OCID.
   b. Set Operator to Not in.
   c. Set List to Custom List.
   d. For Value, enter the OCID for Instance2.
7. Click Save.

The "Instance is publicly accessible" rule now monitors all instances for public configuration, except Instance1 and Instance2.

Exclusion of Resources Using Managed Lists

Use managed lists when the number of items to be matched is large, or you expect to need to reuse the same list multiple times.
1. First, create a managed list of instance OCIDs that contains the OCIDs for Instance1 and Instance2.
   See Creating a Managed List on page 875.
   Let's assume you name that list "Public Compute Instance OCIDs."
2. Open the details page for the detector recipe where the "Instance is publicly accessible" rule is enabled.
   See Modifying a Detector Recipe on page 828.
3. On the detector recipe's detail page, under Detector Rules, locate the row for the "Instance is publicly accessible" rule.
4. At the right end of that row, open the Actions menu, and select Edit.
5. In the Edit Detector Rule dialog box, Conditional Group section:
   a. Set Parameter to Instance OCID.
   b. Set Operator to Not in.
   c. Set List to Managed List.
   d. For Value, select the name of the managed list you created ("Public Compute Instance OCIDs" in the example in step 1).
6. Click Save.
   The "Instance is publicly accessible" rule now monitors all instances for public configuration, except Instance1 and Instance2.

   **Note:**
   Any Compute Instance OCIDs you add to your managed list in the future is also excluded from monitoring.

**Using Managed and Custom Lists with Recipe Rules**

Managed lists let you quickly set the scope for which a recipe rule should be applied, by including or excluding a predefined list of parameters. Custom lists let you enter a short list of parameters for the same purpose.

**Applying a Managed List to a Configuration Detector**

**Example:** If a compute instance has a public IP address, you would like to trigger a problem. But you have some instances that should have public IP addresses and you don't want those instances to trigger problems.

1. Create a managed list containing all the resource OCIDs of the compute instances that should have public IP addresses.
   See Creating a Managed List on page 875.
2. Assign this managed list as a Conditional Group entry for the “Instance has a public IP” configuration detector rule.
   See Modifying a Detector Recipe on page 828.

**Applying a Managed List to an Activity Detector**

**Example:** If activity that's initiated from specific suspicious IP addresses creates a bucket or instance, you would like to trigger a problem.

1. Create a managed list containing the known suspicious IP addresses.
   See Creating a Managed List on page 875.
2. Assign this managed list as a Conditional Group entry for the "Suspicious IP activity" detector rule.
   See Modifying a Detector Recipe on page 828.

Alternatively, if you knew that buckets or instances should be created only from certain, trusted IP addresses, you could:

- Create a managed list containing trusted IP addresses.
- Then use the "Not In" operator in the Conditional Group entry for the "Suspicious IP activity" detector rule.
Managing Targets

You can add targets to expand or change the scope of resources that Cloud Guard monitors.

A target defines the scope of what Cloud Guard checks. A target can consist of your entire OCI tenancy, or any combination of compartments below the top level. Specify at least one target when you enable Cloud Guard. You can define more targets later.

Viewing Details for a Target

View the details for a target to see exactly what scope of resources it specifies for Cloud Guard to monitor.

1. From the Cloud Guard options panel on the left, select Targets.

   The Targets page lists all targets currently defined.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initially, the list shows only what was specified in the Compartments to Monitor option. If None was selected, this list is initially empty.</td>
</tr>
</tbody>
</table>

2. To filter the list of targets, start typing in the Filter by target name box.

3. To view details for a specific target, click the link in the Target Name column.

   You can also open the Actions menu ⚙️, and select View Details.

4. To view the OCID for the target, click the Cloud Guard Target Information tab near the top.

5. To view tags assigned to the target, click the Tags tab.

6. To add tags to the target, click Add Tags, below the target name, then in the Add One Or More Tags To This Resource dialog box:
   a) Select a Tag Namespace from the list.
      Selecting None... makes it a free-form tag.
   b) Enter a Tag Key.
   c) Enter a Value.
   d) To add another tag, click + Additional Tag, and repeat preceding steps a-c.
   e) To remove a tag you have added, click the X at the right end of the row for that tag.
      If you've only added one tag, click the Close link at the top right.
   f) When you are done, click Add Tags.

7. To view compartments assigned to the target:
   a) In the Resources panel on the left, click Compartment Assignment.
      A list of compartments assigned to the target is displayed in the Compartment Assignment section.
   b) To view inheritance information for a compartment, expand the compartment row using the Expand icon at the right end.

8. To view detector recipes enabled for the target:
   a) In the Resources panel on the left, click Detector Recipes.
      A list of detector recipes enabled for the target is displayed in the Detector Recipes section. A check mark in the (Oracle Managed) column indicates that the recipe is Oracle managed.
   b) To view the rules in a detector recipe, click the link in the Recipe Name column.
      You can also open the Actions menu ⚙️, and select View Details.
      The rules for the detector recipe are listed in the Detector Rules section of the page that opens.
   c) To edit a detector rule (that's not Oracle managed) from this page, open the Actions menu ⚙️, and select Edit.
      See Modifying a Detector Recipe on page 828.
9. To view responder recipes enabled for the target:
   a) In Resources panel on the left, click Responder Recipes.
      A list of responder recipes enabled for the target is displayed in the Responder Recipes section. A check mark
      in the (Oracle Managed) column indicates that the recipe is Oracle managed.
   b) To view the rules in a responder recipe, click the link in the Recipe Name column.
      You can also open the Actions menu  and select View Details.
      The rules for the detector recipe are listed in the Detector Rules section of the page that opens.
   c) To see the Description and Conditional Group information for a responder recipe rule, open the Actions
      menu  and select Edit.
   d) To edit a responder rule (that's not Oracle managed) from this page, open the Actions menu  and select Edit.
      See Modifying a Responder Recipe on page 871.

What's Next
   • To create a new target, see Creating a Target on page 820.
   • To make changes in an existing target, see Modifying Recipes Added to a Target on page 821.
   • To delete a target, see Deleting a Target on page 825.

Creating a Target
Create a target to define an extra scope of resources for Cloud Guard to monitor.

1. From the Cloud Guard options panel on the left, select Targets.
2. On the Targets page, click Create New Target.
3. In the Create New Target dialog box, enter a Name for the new target.
4. (Optional) Enter a Description.
5. Select a Compartment Assignment.
      Select a compartment from the list. The list is an expandable, collapsible hierarchy of all the compartments
      available.
      
      | Note: |
      |------|
      | You can select only a single compartment. Any child compartments under the selected compartment inherit the detector and responder recipe settings for the target. |
      | To exclude a child compartment from the monitoring that applies to the rest of the target, create a separate target and specify that compartment in the Compartment Assignment. |

6. Select an OCI Configuration Detector Recipe.
7. Select an OCI Activity Detector Recipe.
8. (Optional) Select a Responder Recipe.
      If no responder recipes are available, responders are not enabled. See Managing Responder Recipes on page 869.
      
      | Note: |
      |------|
      | If responders are enabled, and you do not add a responder to the target, full functionality for responders is not available within the target. |
9. (Optional) To add tags to the target, click Show Advanced Options, then:
   a) Select a Tag Namespace from the list.
      Selecting None... makes it a free-form tag.
   b) Select a Tag Key.
   c) Enter a Value.
   d) To add another tag, click + Additional Tag, and repeat preceding steps a-c.
   e) To remove a tag you have added, click the X at the right end of the row for that tag.
      If you've only added one tag, you can't remove it. If removing the tag is important, click Cancel at the bottom of the dialog box, then click Create New Target to start over.

10. Click Create.

    The detail page for the new target displays.

What's Next

- To modify a target, see Modifying Recipes Added to a Target on page 821.
- To modify settings for detector and responder recipes added to a target, first see Modifying Recipes at Recipe and Target Levels on page 812. Determine where to start to access the particular settings you want to change, then see the appropriate topic:
  - Modifying Recipes Added to a Target on page 821
  - Modifying a Detector Recipe on page 828
  - Modifying a Responder Recipe on page 871
- To disable or delete a target, see Deleting a Target on page 825.

Modifying Recipes Added to a Target

You can change the detector and responder recipes added to a target.

1. From the Cloud Guard options panel on the left, select Targets.
2. On the Targets page, locate the target you want to modify and click its link in the Target Name column.
3. The detail page for the target displays, with the Compartment Assignment selected.
4. To view tags currently defined for the target, click the Tags tab.
   To modify or remove a tag, click the pencil icon to the left of the tag entry.
5. To add tags to the target, click Add Tags near the top, then:
   a) Select a Tag Namespace from the list.
      Selecting None... makes it a free-form tag.
   b) Enter a Tag Key.
   c) Enter a Value.
   d) To add another tag, click + Additional Tag, and repeat preceding steps a-c.
   e) To remove a tag you have added, click the X at the right end of the row for that tag.
      If you've only added one tag, click the Close link at the top right.
   f) When you are done, click Add Tags.
5. To change an associated detector recipe, in the options panel on the left click Detector Recipes, then follow these steps:
   a) To add a recipe, click Add Recipe.

   **Note:**
   If the Add Recipe button is not available, the target already has both a configuration detector recipe and an activity detector recipe that have been added. First remove the type of detector recipe that you want to add.
   b) To remove a recipe, open the Actions menu /dat: and select Remove.
Modifying Rule Settings in a Target's Recipes

After a detector or responder recipe has been added to a target, you can change the settings for individual rules in the recipe.

1. From the Cloud Guard options panel on the left, select Targets.
2. On the Targets page, locate the target for which you want to modify recipe rules and click its link in the Target Name column.

   The detail page for the target displays. With the Compartment Assignment selected.

What's Next

To change settings for individual rules in detector or responder recipes, see:

- To modify detector recipe rules, see Modifying Detector Rule Settings in a Target's Recipes on page 822.
- To modify responder recipe rules, see Modifying Responder Rule Settings in a Target's Recipes on page 823.

Modifying Detector Rule Settings in a Target's Recipes

Make tactical changes in detector rules from the Targets page.

Prerequisite: Complete steps in Modifying Rule Settings in a Target's Recipes on page 822 to open the details page for the target for which you want to modify detector rule settings.

Note:

Enabling or disabling rules for user-managed (cloned) detector recipes must be done from the recipe level, See Modifying a Detector Recipe on page 828.

For complete information on what you can modify in Oracle-managed and user-managed (cloned) detector recipes, see Modifying Recipes at Recipe and Target Levels on page 812.

1. On the details page for the target, under Resources on the left, click Detector Recipes.
2. In the row for a detector rule for which you want to change settings, open the Actions menu, and select Edit.
3. In the **Conditional Groups** section at the bottom:
   
   - If you want the rule to be applied to a compartment below the top-level compartment that's defined for the target:
     
     a. Open the **Apply to Compartment** list.
     
     b. Select a compartment to which the rule should be applied.
   
   - To set a condition on a parameter other than tags:
     
     a. In the **Parameter** list, select a parameter other than **Tags**.
     
     b. Select an **Operator**.
     
     c. Select a **Value**.
     
     d. To add another condition, click **Add Condition** and repeat the last three steps.

```
<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifying multiple conditions acts as an AND operator. The rule is enforced only if all the conditions are met.</td>
</tr>
</tbody>
</table>
```

   e. To delete a condition, click the "X" at the right end of the row for the condition.

   - To set a condition on tags:
     
     a. In the **Parameter** list, select **Tags**.

     A **Value** box appears below the **Parameter** box.

     b. Select an **Operator** (**In** or **Not In**).

     c. Click **Select Tags**, to right of **Value** box.

     d. In the **Select Tags** dialog box:

     - To set a condition for defined tags:
       
       1. Select a **Tag Namespace** other than **None (add a free-form tag)**.
       
       2. Select a **Tag Key**.
       
       3. Select or enter the **Value**.

     - To set a condition for free-form tags:

       1. For **Tag Namespace**, select **None (add a free-form tag)**.
       
       2. Enter a **Tag Key**.
       
       3. (Optional) Enter a **Value**.

     - To add another tag:

       1. Click **Additional Tag**.
       
       2. Repeat the steps above for either defined or free-form tags.

```
<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you specify multiple tags, the rule is enforced only if all the conditions are met.</td>
</tr>
</tbody>
</table>
```

   - To delete a tag, click the "X" at the right end of the row for the tag.

   - To save your tag selections, click **Select** at the bottom of the **Select Tags** dialog box.

For more information on **Conditional Groups**, see **Using Conditional Groups with Recipe Rules** on page 815.

4. To change settings for another detector rule, repeat the preceding steps, beginning with step 3.

5. Click **Save**.

**Modifying Responder Rule Settings in a Target's Recipes**

Make tactical changes in detector rules from the Targets page.

**Prerequisite:** Complete steps in **Modifying Rule Settings in a Target's Recipes** on page 822 to open the details page for the target for which you want to modify responder rule settings.
Cloud Guard

**Note:**

Enabling or disabling rules for user-managed (cloned) responder recipes must be done from the recipe level, See Modifying a Responder Recipe on page 871.

For complete information on what you can modify in Oracle-managed and user-managed (cloned) detector recipes, see Modifying Recipes at Recipe and Target Levels on page 812.

1. On the details page for the target, under **Resources** on the left, click **Responder Recipes**.

2. In the row for a responder rule for which you want to change settings, open the **Actions** menu ı, and select **Edit**.

3. If the **Required Policy Statements** section, **Policy Statements** list, has any statements with "Not Added" showing on the right, click **Add Statements**.

**Note:**

These policy statements must be added to allow the responder rule to operate. For detailed information on specific Cloud Guard policies listed, see Cloud Guard Policies on page 906.

4. If you want the responder rule to execute automatically:
   a) In the **Setting** section, for **Rule Trigger**, select **Execute Automatically**.
   b) Read the informational text describing the consequences of this selection.
   c) To confirm that you want to select automatic execution, select the **CONFIRM EXECUTE AUTOMATICALLY** check box.

**Note:**

Now specify at least one condition in the **Conditional Group** section at the bottom. Automatic execution mode is not allowed when no conditions are defined.

If you don't want to limit the scope of resources to which the rule is applied, specify a condition that is always true. For example:

- **Parameter** = **Region**
- **Operator** = **In**
- **Value** = **abc** (assuming there's no region named "abc")

5. In the **Conditional Group** section at the bottom, you can:
   a) Select a **Parameter**.
   b) Select an **Operator**.
   c) Select a **Value**.
   d) To add another condition, click **Add Condition** and repeat the last three steps.

**Note:**

When you specify multiple conditions, the conditions are ANDed. The rule is enforced only if all conditions are met. If you need to OR multiple conditions, clone a separate recipe for each condition and specify only one condition for the rule in each recipe.

6. To control post-remediation notifications, in the **Input Settings** section, select or deselect **POST REMEDIATION NOTIFICATION**.

   When this option is selected, a Cloud Event is triggered after the rule successfully remediates a problem.

7. Click **Save**.

8. To change settings for another responder rule, repeat the preceding steps, beginning with step 2.
Deleting a Target
If a target is no longer needed, you can delete it.

Caution:
When you delete a target, information for all problems associated with that target disappears from the Cloud Guard console and can no longer be accessed through the API. The information remains in the Cloud Guard database until it’s purged at 180 days.

1. From the Cloud Guard options panel on the left, select Targets.
2. On the Targets page, select the check box for each target you want to delete.
3. Click Delete to confirm the deletion.

Managing Detector Recipes
View, clone, and modify detector recipes to fit the specific security needs of your environment.

A detector is a Cloud Guard component that identifies potential security problems, based on resource configuration or activity. Each detector uses a detector recipe that defines what the detector should identify as a problem.

Each detector recipe consists of a set of detector rules, that provide a specific definition of a class of resources, with specific actions or configurations, that cause a detector to report a problem. A detector recipe consists of multiple detector rules. If any one rule is triggered, it causes the detector to report a problem.

About Detector Recipes
Cloud Guard detectors follow rules, combined into recipes, to identify problems.

Each detector recipe uses multiple detector rules, each of which a specific definition of a class of resources, with specific actions or configurations, that cause a detector to report a problem. If any one rule is triggered, it causes the detector to report a problem.

Cloud Guard provides two types of detector recipes:

- **Oracle-Managed** recipes are provided by Oracle and you can't modify them.
- **User-Managed** recipes have to be created, by cloning an Oracle-managed recipe. You can modify user-managed recipes as needed.

Compartment Inheritance
You apply detector recipes to compartments.

If a compartment has other compartments below it, the detector recipe's rules automatically apply to all lower level compartments in the hierarchy.

When a compartment hierarchy has detector recipes applied to compartments at different levels, whenever the rules conflict, the rules from the detector recipe applied at a lower level override the rules from any detector recipe that is applied at a higher level. This applies to the compartment on which a detector recipe is applied and all compartments below it.

Inheritance Details for Detector Rule Fields
There are four levels at which the fields within a detector recipe and its detector rules can be modified. Each has its own set of restrictions.

Note:
The precedence for detector recipe rules applied at these different levels is similar to the precedence for a compartment hierarchy: whenever the rules conflict, the rules at a more specific level (higher number in list below) override rules at a broader level (lower number in list below).

1. **Oracle**: When Cloud Guard needs to update or create new Oracle managed recipes, they are available to all tenants.
2. **Tenant:** These are changes applicable only to a particular tenant.
   - These fields can be modified at the tenant level for an Oracle managed recipe:
     - **Labels** (can only be added)
     - **Configurations** (also called **Settings**)
     - **Conditions**
   - These fields can’t be modified at the tenant level for an Oracle managed recipe:
     - **Status** (enabled/disabled)
     - **Risk Level**
   - These fields can be modified at the tenant level for a non-Oracle managed recipe:
     - **Status** (enabled/disabled)
     - **Risk Level**
     - **Labels**
     - **Configurations** (also called **Settings**)
     - **Conditions**

3. **Target:** These are changes applicable only to a particular target.
   - These fields can be modified at the target level for both Oracle managed and non-Oracle managed recipes:
     - **Conditions**
   - These fields can be modified at the target level for a non-Oracle managed recipe:
     - **Status** (enabled/disabled)
     - **Risk Level**
     - **Labels**
     - **Configurations** (also called **Settings**)

4. **Subcompartments of a target:** These are changes applicable only to a compartment selected from the descendant tree of a target.
   - These fields can be modified at the target level for both Oracle managed and non-Oracle managed recipes:
     - **Conditions**
   - These fields can be modified at the target level for a non-Oracle managed recipe:
     - **Status** (enabled/disabled)
     - **Risk Level**
     - **Labels**
     - **Configurations** (also called **Settings**)

**Viewing Details for a Detector Recipe**
Open the Detector Recipes page, sort and filter the list, and view details for a specific detector recipe.

1. From the Cloud Guard options panel on the left, select **Detector Recipes**.
   - The column headers provide summary information for the detector recipes:
     - **Recipe Name** - the name of the detector recipe.
     - **Oracle Managed** - shows a check mark if the detector recipe is Oracle-managed.
     - **Type** - indicates that the detector recipe is an **Activity** or **Configuration** recipe.
2. To filter the list of detector recipes, you can:
   • Start typing in the **Filter by name** box at the top right.
   • Under **Scope** at lower left, select a different **Compartment**.
   • To right of **Tag Filters** at lower left:
     a. Click the **add** link.
     b. In the **Apply a Tag Filter** dialog box, select a **Tag Namespace**.
     Select **None (free-form tag)** if you want to manually enter the **Tag Key**.
     c. Select a **Tag Key**.
     Manually enter the **Tag Key** if you selected **None (free-form tag)** for the **Tag Namespace**.
     d. For **Value**:
        • Select **Match any value** if you want any tag value to count as a match.
        • Select **Match any of the following** and manually enter values, separated by commas, if you want only the values you enter to count as a match.
        • To add more values for this tag, click the plus sign (+) at the lower right.
     e. Click **Apply Filter**.

3. To view the details for a particular detector recipe, click its link in the **Recipe Name** column.

4. In the **Details** tab, **OCID** row:
   • Click the **Show** link to show the full OCID.
   • Click the **Copy** link to copy the full OCID to the clipboard.
   You can use OCIDs in lists, or directly in some detector configurations to include or exclude resources from the detector.

5. If the detector recipe you're viewing is user-managed, you can view tags that have been assigned:
   Tagging isn't supported in Oracle-managed detector recipes.
   a) Click the **Tags** tab.
   b) View the tags that have been assigned.
   If no tags have been assigned, you see "There are no Tags associated with this resource."

6. In the **Detector Rules** section, use the column headers to identify the information shown:
   • **Detector Rules** - the name of each detector rule in the recipe.
   • **Risk Level** - the severity of the risk posed if the rule is triggered.
   • **Status** - each rule can be **Enabled** or **Disabled** independently.
   • **Settings Configured** - are settings configured? **Yes** or **No**.
   • **Conditional Group** - are conditions configured for the rule? **Yes** or **No**.

7. In the **Detector Rules** section,
   • To show summary information for a detector rule, click the **Expand** icon at the right end of its row.
   • To show configuration information for a detector rule, open the **Actions** menu and select **Edit**.
   For information on rule parameters, and best practice recommendations for changes from default settings, see the reference for the detector recipe type:
   • **OCI Configuration Detector Rules** on page 831
   • **OCI Activity Detector Rules** on page 851

**What's Next**
• To make a copy in which you can modify the rules, see **Cloning a Detector Recipe** on page 828.
• To modify a detector recipe, see **Modifying a Detector Recipe** on page 828.
• To delete a user-managed (cloned) detector recipe, see **Deleting a User-Managed (Cloned) Detector Recipe** on page 830.
**Cloning a Detector Recipe**

Clone detector recipes to fine-tune the set of detector recipes available to use in your environment.

You can use Oracle-managed detector recipes as is, but you can't change many of their settings. Also, you might want to create another detector recipe that's similar to a user-managed detector recipe that you cloned previously.

Whenever you want to create a detector recipe, you can clone the existing (Oracle-managed or user-managed) recipe with the settings that are most similar to what you want in the new recipe.

1. From the Cloud Guard options panel on the left, select *Detector Recipes*.
2. (Optional) In the *Scope* section at lower left, set parameters to filter what appears in the list:
   - Set *Compartment* to display only detector recipes attached to a specific compartment.
   - If you also want detector recipes attached to compartments below the selected compartment to appear in the list, select *Include Child Compartments*.
3. Click *Clone*, then in the *Clone Detector Recipe* dialog box:
   a) From the *Cloning* list, select the detector recipe you want to clone.
   b) Enter a *Name* for the new detector recipe.
   c) (Optional) Enter a *Description* for the new detector recipe.
   d) Specify a *Compartment Assignment* by selecting from the list.
   e) Click *Clone*.

The new detector recipe appears in the *Detector Recipes* list.

**What's Next**

- To change the cloned detector recipe's rules, see *Modifying Rule Settings in a Detector Recipe* on page 829.
- Ensure that your cloned detector recipe is added to targets where you want it to be used. See *Modifying Recipes Added to a Target* on page 821.

**Modifying a Detector Recipe**

You can modify a few recipe settings in an Oracle-managed detector recipe, and more settings in a user-managed (cloned) detector recipe.

When you modify detector recipes, you change settings for detector rules:

- **Oracle-managed** detector recipes only allow you to change the scope of resources to which a rule is applied, by specifying *Conditional Group* statements.
- **User-managed** (cloned) detector recipes add the capability to set *Status* (enabled or disabled) and *Risk Level*, and add *Labels*.

For complete information on what you can modify in Oracle-managed and user-managed (cloned) detector recipes, see *Modifying Recipes at Recipe and Target Levels* on page 812.

1. From the Cloud Guard options panel on the left, select *Detector Recipes*.
2. Locate the detector recipe you want to modify.
   - Oracle-managed detector recipes have "Yes" in the *Oracle-Managed* column.
3. Click the recipe's link in the *Recipe Name* column.
   - The details page for the detector recipe opens. Here you can modify settings for the detector recipe's individual rules.
4. If the detector recipe is user-managed (cloned):
   
   • To change the detector recipe's name or description:
     a. Click **Edit** below the detector recipe's name on the details page.
     b. In the **Edit Detector Recipe** dialog box, edit the **Name** or **Description** entries, then click **Save**
   
   • To attach the detector recipe to a different compartment:
     a. Click **Move Resource** below the detector recipe's name on the details page.
     b. In the **Move Resource to a Different Compartment** dialog box, select the new compartment from the **Choose New Compartment** list, then click **Move Resource**.
   
   • To see tags that have been added to the detector recipe, click the **Tags** tab below the detector recipe's name on the details page.
   
   • To enable or disable groups of rules:
     a. Select check boxes to the left of the rule names (current **Status** for all must be the same).
     b. Click **Enable** or **Disable** at the top of the list.
   
   • To delete the detector recipe:
     a. Click **Delete** below the detector recipe's name on the details page.
     b. In the **Delete Detector Recipe** dialog box, click **Yes**.

**Next Steps**

Ensure that you:

• Make any changes needed in detector rule settings at the recipe level, before adding the recipe to targets. See **Modifying Rule Settings in a Detector Recipe** on page 829.

• Add your detector recipe to all targets where you want it to be used. See **Modifying Recipes Added to a Target** on page 821.

• Make any changes needed to customize detector rule settings for the target to which your detector recipe is added. See **Modifying Rule Settings in a Target's Recipes** on page 822.

**Modifying Rule Settings in a Detector Recipe**

You can modify a few rule settings in an Oracle-managed detector recipe, and more settings in a user-managed (cloned) detector recipe.

1. Navigate to the detail page for the detector recipe in which you want to modify rule settings.
   See **Modifying a Detector Recipe** on page 828.

2. Locate a detector rule that you want to modify, open the **Actions** menu ; and select **Edit**.
   For information on rule parameters, and best practice recommendations for changes from default settings, see the reference for the detector recipe type:
   • **OCI Configuration Detector Rules** on page 831
   • **OCI Activity Detector Rules** on page 851

3. If the detector recipe is user-managed (cloned), in the top part of the **Edit Detector Rule** dialog box, you can:
   • Change the rule's **Status** (**Enabled** vs. **Disabled**).
     
     **Note:**
     
     When you disable a detector recipe rule, any problems that the rule has already triggered remain active on the **Problems** page. If you are certain that these problems pose no security risk, you can clear them all in one action. See **Processing and Resolving Problems on the Problems Page** on page 887.

     • Set a different **Risk Level**.
     • Edit the **Labels** entry.
       
       Separate multiple labels with a semicolon (",").
4. In the **Conditional Groups** section at the bottom:

- To set a condition on a parameter other than tags:
  a. In the **Parameter** list, select a parameter other than **Tags**.
  b. Select an **Operator**.
  c. Select a **Value**.
  d. To add another condition, click **Add Condition** and repeat the last three steps.

  Note:
  
  Specifying multiple conditions acts as an AND operator. The rule is enforced only if all the conditions are met.

  e. To delete a condition, click the “X” at the right end of the row for the condition.

- To set a condition on tags:
  a. In the **Parameter** list, select **Tags**.
     - A **Value** box appears below the **Parameter** box.
  b. Select an **Operator** (**In** or **Not In**).
  c. Click **Select Tags**, to right of **Value** box.
  d. In the **Select Tags** dialog box:
     - To set a condition for defined tags:
       1. Select a **Tag Namespace** other than **None (add a free-form tag)**.
       2. Select a **Tag Key**.
       3. Select or enter the **Value**.
     - To set a condition for free-form tags:
       1. For **Tag Namespace**, select **None (add a free-form tag)**.
       2. Enter a **Tag Key**.
       3. (Optional) Enter a **Value**.
  e. To add another tag:
    1. Click **Additional Tag**.
    2. Repeat the steps above for either defined or free-form tags.

   Note:
   
   When you specify multiple tags, the rule is enforced only if all the conditions are met.
  
  f. To delete a tag, click the “X” at the right end of the row for the tag.
  
  g. To save your tag selections, click **Select** at the bottom of the **Select Tags** dialog box.

For more information on **Conditional Groups**, see **Using Conditional Groups with Recipe Rules** on page 815.

5. When you are finished modifying the detector rule, click **Save**.

6. To change settings for another detector rule, repeat the previous steps, beginning with step 2.

**Next Steps**

Ensure that you:

- Add your detector recipe to all targets where you want it to be used. See **Modifying Recipes Added to a Target** on page 821.
- Make more changes needed to customize detector rule settings for the target to which your detector recipe is added. See **Modifying Rule Settings in a Target's Recipes** on page 822.

**Deleting a User-Managed (Cloned) Detector Recipe**

You can delete any cloned copy of an Oracle-managed detector.

1. From the Cloud Guard options panel on the left, select **Detector Recipes**.
2. Locate the cloned detector recipe you want to delete.  
   Cloned detector recipes have "No" in the **Oracle Managed** column.

3. Open the **Actions** menu and select **Delete**.

4. Click **Yes** to confirm the deletion.

**Detector Recipe Reference**

Review summary information for detectors in the Oracle-managed detector recipes.

**Note:**

The following tables include best practice recommendations for modifying detector recipe rules. Oracle-managed recipes allow different types of rule changes, compared with user-managed (cloned) recipes. Accessing a detector recipe from the **Detector Recipes** page allows different types of rule changes, compared with accessing from the **Targets** page. See Modifying Recipes at Recipe and Target Levels on page 812.

**OCI Configuration Detector Rules**

Reference material for the Oracle-managed configuration detector recipes that Cloud Guard provides is grouped below by resource type. Expand a Rule Display Name to view the details.

**Compute Resources**

**Instance has a public IP address**

**Description:** Alert when a Compute instance has a public IP address.

**Recommendation:** Carefully consider allowing internet access to any instances. For example, you do not want to accidentally allow internet access to sensitive database instances.

**Background:** For an instance to be publicly addressable, it must:

- Have a public IP address
- Exist in a public virtual computer network (VCN) subnet
- Be on a VCN that has an internet gateway enabled that is configured for outbound traffic
- Be on a subnet where the security list is configured for all IP addresses and all ports (0.0.0.0/0)

**Rule Parameters:**

- **Service Type:** Compute
- **Resource Type:** Instance
- **Risk Level:** HIGH
- **Labels:** CIS_OCI_V1.0_NETWORK, CIS_OCI_V1.1_NETWORK, Compute

**Compliance Control Mapping:**

- **PCI-DSS 3.2.1:** 1.3 - Prohibit direct public access between the Internet and any system component in the cardholder data environment.
- **CIS 1.1:**
  
  2.1 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 22.
  
  2.2 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 3389.
  
  2.3 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 22.
  
  2.4 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 3389.
Cloud Guard

• **CIS 1.0:**
  2.1 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 22.
  2.2 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 3389.
  2.3 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 22.
  2.4 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 3389.

**Best Practice for Rule Modifications:**

• **Conditional Groups:** Filter out OCIDs for any instance that should have a public IP address.

  Filter on CIDR blocks if specific OCIDs are not known. For example, an automated process might be spinning up new instances within a CIDR range.

**Instance is publicly accessible**

**Description:** Alert when an instance is publicly accessible.

**Recommendation:** Carefully consider allowing internet access to any instances.

**Background:** For an instance to be publicly addressable, it must:

- Have a public IP address
- Exist in a public VCN subnet
- Be on a VCN that has an internet gateway enabled that is configured for outbound traffic
- Be on a subnet where the security list is configured for all IP addresses and all ports (0.0.0.0/0)

**Rule Parameters:**

- **Service Type:** Compute
- **Resource Type:** Instance
- **Risk Level:** CRITICAL
- **Labels:** Compute

**Compliance Control Mapping:**

• **PCI-DSS 3.2.1:** 1.3 Prohibit direct public access between the Internet and any system component in the cardholder data environment.

• **CIS 1.1:**
  2.1 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 22.
  2.2 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 3389.
  2.3 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 22.
  2.4 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 3389.

• **CIS 1.0:**
  2.1 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 22.
  2.2 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 3389.
  2.3 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 22.
  2.4 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 3389.

**Best Practice for Rule Modifications:**

• **Conditional Groups:** Filter out instance OCIDs for any that should have a public IP address.

**Instance is running an Oracle public image**

**Description:** Alert when a Compute instance that's running is built from an Oracle public image.
Recommendation: Ensure that your instances are all running sanctioned images from trusted sources.

Rule Parameters:
- **Service Type:** Compute
- **Resource Type:** Instance
- **Risk Level:** LOW
- **Labels:** Compute

Compliance Control Mapping:
- **PCI-DSS 3.2.1:** Not applicable.

Best Practice for Rule Modifications:
- Leave default settings.

**Instance is running without required Tags**

Description: Alert when a Compute instance is running without required configured tags.

Recommendation: Ensure that the instances are using required tags.

Background: Tags are important for auditing and tracking purposes.

Rule Parameters:
- **Service Type:** Compute
- **Resource Type:** Instance
- **Risk Level:** MEDIUM
- **Labels:** CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, TAGS

Compliance Control Mapping:
- **PCI-DSS 3.2.1:** Not applicable.

Best Practice for Rule Modifications:
- **Configuration:** Add required tags in the rule's **Input Setting** section.
  These formats are allowed in the **Input Setting** box. Separate multiple entries with commas.
  - `<namespace>.<definedkey>=<definedValue>
  - `<namespace>.<definedKey>
  - `<freeformkey>=<freeformValue>
  - `<freeformkey`

Examples:
- `<namespace>.<definedkey>=<definedValue>
  - Operations.Environment=Production - Rule doesn't trigger a problem if resource has a tag set to Operations namespace, defined key of Environment, and defined value of Production.
  - Operations.*=* - Rule doesn't trigger a problem if resource has a tag set Operations namespace, with any defined key and any defined value.

- `<namespace>.<definedkey>
  - Operations.Environment - Rule doesn't trigger a problem if resource has a tag set to Operations namespace, with a defined key of Environment, and any defined value.

- `<freeformKey`
- `<freeformKey>=<freeformValue`
  - Project=APPROVED - Rule doesn't trigger a problem if resource has a tag set to freeform key Project with a value of APPROVED.
Database Resources

Database is not backed up automatically
Description: Alert when automatic backup isn't enabled for a database.
Recommendation: Ensure that automatic backup is enabled.
Background: Enabling automatic backup ensures that if a catastrophic hardware failure occurs, you are able to restore the database with minimal data loss.
Rule Parameters:
• Service Type: Database
• Resource Type: DB System
• Risk Level: HIGH
• Labels: Database

Compliance Control Mapping:
• PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:
• Conditional Groups: Filter out database OCIDs for any that do not need to be backed up automatically, for example, OCIDs in developer test environments.

Database patch is not applied
Description: Alert when an available database patch has not been applied within your specified number of days.
Recommendation: Apply released patches to the database when they are available.
Background: Database patches address functionality, security, and performance issues. Most security breaches can be prevented by applying available patches.
Rule Parameters:
• Service Type: Database
• Resource Type: DB System
• Risk Level: MEDIUM
• Labels: Database

Compliance Control Mapping:
• PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:
• Configuration: Set Number of days to apply patch in the rule's Input Setting section.
• Conditional Groups: Filter out database OCIDs for any that do not need to have latest patch applied, for example, OCIDs in developer test environments.

Database System has public IP address
Description: Alert when a database system has a public IP address assigned.
Recommendation: Ensure that the database system does not have a public IP address.
Background: Use of a public IP address to access a database increases your exposure to potential security and business continuity risks.
Rule Parameters:
• Service Type: Database
• Resource Type: DB System
• **Risk Level**: HIGH
• **Labels**: Database

**Compliance Control Mapping:**
• **PCI-DSS 3.2.1**: Not applicable.

**Best Practice for Rule Modifications:**
• **Conditional Groups**: Filter out database OCIDs for any that are supposed to be public.

**Database system patch is not applied**
**Description**: Alert when an available database system patch has not been applied.
**Recommendation**: Apply released patches to the database system when they are available.
**Background**: Database system patches often include updates that eliminate known security vulnerabilities.

**Rule Parameters:**
• **Service Type**: Database
• **Resource Type**: DB System
• **Risk Level**: MEDIUM
• **Labels**: Database

**Compliance Control Mapping:**
• **PCI-DSS 3.2.1**: Not applicable.

**Best Practice for Rule Modifications:**
• **Configuration**: Set Number of days to apply patch in the rule's Input Setting section.
• **Conditional Groups**: Filter out database system OCIDs for any that do not need to have latest patch applied, for example, OCIDs in developer test environments.

**Database System version is not sanctioned**
**Description**: Alert when a database system is running with a version that's not sanctioned.
**Recommendation**: Ensure that the deployed database system version is approved and tested.

**Background**: Running unsanctioned versions of database systems might increase your chances of a security breach, putting your data confidentiality, integrity, and availability at risk.

**Rule Parameters:**
• **Service Type**: Database
• **Resource Type**: DB System
• **Risk Level**: CRITICAL
• **Labels**: Database

**Compliance Control Mapping:**
• **PCI-DSS 3.2.1**: Not applicable.

**Best Practice for Rule Modifications:**
• **Conditional Groups**: Filter out database system OCIDs for any that do not need to have a sanctioned version, for example, OCIDs in developer test environments.

**Database version is not sanctioned**
**Description**: Alert when a database is running with a version that's not sanctioned.
**Recommendation**: Ensure that the deployed database version is approved and tested.
Background: The sanctioned version of a database has the most recent security features and vulnerability patches. Running unsanctioned versions of a database might increase your chances of a security breach, putting your data confidentiality, integrity, and availability at risk.

Rule Parameters:

- **Service Type:** Database
- **Resource Type:** DB System
- **Risk Level:** CRITICAL
- **Labels:** Database

Compliance Control Mapping:

- **PCI-DSS 3.2.1:** Not applicable.

Best Practice for Rule Modifications:

- **Conditional Groups:** Filter out database OCIDs for any that do not need to have a sanctioned version, for example, OCIDs in developer test environments.

IAM Resources

API key is too old

Description: Alert when an IAM private/public key pair assigned to a user is too old.

Recommendation: Rotate API keys regularly, at least every 90 days.

Background: Changing IAM API keys at least every 90 days is a security best practice. The longer that IAM credentials remain unchanged, the greater the risk that they can become compromised.

Rule Parameters:

- **Service Type:** IAM
- **Resource Type:** IAMKey
- **Risk Level:** MEDIUM
- **Labels:** CIS_OCI_V1.0_IAM, CIS_OCI_V1.1_IAM, IAM

Compliance Control Mapping:

- **PCI-DSS 3.2.1:** 8.2.4 - Credentials must be rotated at least every 90 days.
- **CIS 1.1:** 1.8 - Ensure that user API keys rotate within 90 days or less.
- **CIS 1.0:** Doesn't cover.

Best Practice for Rule Modifications:

- **Configuration:** (Optional) You can change the default value of 90 days in the rule's **Input Setting** section.

IAM Auth Token is too old

Description: Alert when IAM Auth Tokens are older than your specified maximum number of days.

Recommendation: Rotate IAM Auth Tokens regularly, at least every 90 days.

Background: Changing IAM Auth Tokens at least every 90 days is a security best practice. The longer that IAM Auth Tokens remain unchanged, the greater the risk that they can become compromised.

Rule Parameters:

- **Service Type:** IAM
- **Resource Type:** User
- **Risk Level:** MEDIUM
- **Labels:** CIS_OCI_V1.1_IAM, IAM
Cloud Guard

Compliance Control Mapping:

• **PCI-DSS 3.2.1**: 8.2.4 - Credentials must be rotated at least every 90 days.
• **CIS 1.1**: 1.9 Ensure user Auth tokens rotate within 90 days or less.
• **CIS 1.0**: None

Best Practice for Rule Modifications:

• **Configuration**: Set the maximum number of days for IAM Auth Tokens (default is 90) in the rule's **Input Setting** section.

IAM Customer Secret Key is too old

**Description**: Alert when IAM Customer Secret Keys are older than your specified maximum number of days.

**Recommendation**: Rotate IAM Customer Secret Keys regularly, at least every 90 days.

**Background**: Changing IAM Customer Secret Keys at least every 90 days is a security best practice. The longer that IAM Customer Secret Keys remain unchanged, the greater the risk that they can become compromised.

**Rule Parameters**:

• **Service Type**: IAM
• **Resource Type**: User
• **Risk Level**: MEDIUM
• **Labels**: CIS_OCI_V1.1_IAM, IAM

Compliance Control Mapping:

• **PCI-DSS 3.2.1**: 8.2.4 - Credentials must be rotated at least every 90 days.
• **CIS 1.1**: 1.9 Ensure user customer secret keys rotate within 90 days or less.
• **CIS 1.0**: None

Best Practice for Rule Modifications:

• **Configuration**: Set the maximum number of days for IAM Customer Secret Keys (default is 90) in the rule's **Input Setting** section.

IAM group has too few members

**Description**: Alert when an IAM group has fewer than your specified minimum number of members.

**Recommendation**: Increase the number of group members to be fewer than your specified minimum number of members.

**Background**: IAM group membership frequently grants access to resources and features. Group memberships that have too few members might represent excess privileges being "orphaned" (no longer available to any users).

**Rule Parameters**:

• **Service Type**: IAM
• **Resource Type**: Group
• **Risk Level**: LOW
• **Labels**: IAM

Compliance Control Mapping:

• **PCI-DSS 3.2.1**: Not applicable.

Best Practice for Rule Modifications:

• Leave default settings.
IAM group has too many members

**Description:** Alert when an IAM group has more than your specified maximum number of members.

**Recommendation:** Reduce number of group members to be less than your specified maximum number of members.

**Background:** IAM group membership frequently grants access to resources and features. Group memberships that have too many members might represent overly permissive privileges being given to too many users.

**Rule Parameters:**
- **Service Type:** IAM
- **Resource Type:** Group
- **Risk Level:** MEDIUM
- **Labels:** IAM

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
- Leave default settings.

Password is too old

**Description:** Alert when an IAM password is older than your specified maximum number of days.

**Recommendation:** Rotate IAM passwords regularly, at least every 90 days.

**Background:** Changing IAM passwords at least every 90 days is a security best practice. The longer that IAM credentials remain unchanged, the greater the risk that they can become compromised.

**Rule Parameters:**
- **Service Type:** IAM
- **Resource Type:** User
- **Risk Level:** MEDIUM
- **Labels:** CIS_OCI_V1.0_IAM, CIS_OCI_V1.1_IAM, IAM

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** 8.2.4 - Credentials must be rotated at least every 90 days.
- **CIS 1.1:** 1.5 - Ensure that IAM password policy expires passwords within 365 days.
- **CIS 1.0:** 1.9 Ensure that IAM password policy expires passwords within 365 days.

**Best Practice for Rule Modifications:**
- **Configuration:** Set the maximum number of days for passwords (default is 90) in the rule's **Input Setting** section.

Password policy does not meet complexity requirements

**Description:** Password policy does not meet complexity requirements.

**Recommendation:** Oracle recommends that a strong password policy include at least one lower case letter.

**Background:** Complex passwords are harder to guess and can decrease the chances of unauthorized access or compromised data.

**Rule Parameters:**
- **Service Type:** IAM
- **Resource Type:** Policy
- **Risk Level:** LOW
- **Labels:** CIS_OCI_V1.1_IAM, CIS_OCI_V1.0_IAM, IAM
Compliance Control Mapping:

- **PCI-DSS 3.2.1**: 8.2.3 - Passwords/passphrases must meet the following:
  - Require a minimum length of at least seven characters.
  - Contain both numeric and alphabetic characters.
  Alternatively, the passwords or passphrases must have complexity and strength at least equivalent to the parameters specified above.
- **CIS 1.1**: 1.4 - Ensure that IAM password policy requires minimum length of 14 or greater.
- **CIS 1.0**:
  1.4 - Ensure that IAM password policy requires minimum length of 14 or greater.
  1.5 - Ensure that IAM password policy requires at least one uppercase letter.
  1.6 - Ensure that IAM password policy requires at least one lowercase letter.
  1.7 - Ensure that IAM password policy requires at least one symbol.
  1.8 - Ensure that IAM password policy requires at least one number.

**Best Practice for Rule Modifications:**
- Leave default settings.

**Policy gives too many privileges**

**Description:** Alert when an IAM policy grants any administrator role access to a user who is not member of the Administrators group.

**Recommendation:** Ensure that the policy is restricted to allow only specific users to access the resources required to accomplish their job functions.

**Background:** A policy is a document that specifies who can access which OCI resources that your company has, and how. A policy simply allows a group to work in certain ways with specific types of resources in a particular compartment.

**Rule Parameters:**
- **Service Type:** IAM
- **Resource Type:** Policy
- **Risk Level:** MEDIUM
- **Labels:** CIS_OCI_V1.1_IAM, CIS_OCI_V1.0_IAM, IAM

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1**: 7.1.2 - Restrict access to privileged user IDs to least privileges necessary to perform job responsibilities.
- **CIS 1.1**: 1.2 Ensure that permissions on all resources are given only to the tenancy administrator group.
- **CIS 1.0**: 1.2 Ensure that permissions on all resources are given only to the tenancy administrator group.

**Best Practice for Rule Modifications:**
- **Configuration:** Add OCIDs for any groups that should be allowed these privileges in the rule's **Input Setting** section.

**Tenancy admin privilege granted to group**

**Description:** Alert when the tenancy administrator privilege is granted to an extra IAM group.

**Recommendation:** Verify with the OCI administrator that this entitlement grant was sanctioned, and that the membership of the group remains valid after the grant of the administrator privilege.
Cloud Guard

**Background:** Default tenancy administrator group members can perform any action on all resources in that tenancy. This high-privilege entitlement must be controlled and restricted to only those users who need it to perform their job functions.

**Rule Parameters:**
- **Service Type:** IAM
- **Resource Type:** Policy
- **Risk Level:** LOW
- **Labels:** CIS_OCI_V1.1_IAM, CIS_OCI_V1.0_IAM, IAM

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** 7.1.2 - Restrict access to privileged user IDs to least privileges necessary to perform job responsibilities.
- **CIS 1.1:** 1.3 Ensure that IAM administrators cannot update tenancy Administrators group.
- **CIS 1.0:** 1.3 - Ensure that IAM administrators cannot update tenancy Administrators group.

**Best Practice for Rule Modifications:**
- **Configuration:** Add OCIDs of groups that should have admin privilege in the rule's **Input Setting** section.

**User does not have MFA enabled**

**Description:** Alert when a user doesn't have multifactor authentication (MFA) enabled.

**Recommendation:** Enable MFA for all users, using the Oracle Mobile Authenticator (OMA) application on each user's mobile device and the one-time passcode (OTP) sent to the user's registered email address.

**Background:** MFA provides an extra layer of security, on top of user name and password. A second verification factor is required each time a user logs in. During the authentication process, users can enable a single device as a trusted device for a maximum period of one day. The email passcode must not be valid for more than 10 minutes. These features combine to provide a degree of protection from password spraying, credential stuffing, and account takeover attacks.

**Note:**

Only applicable to local users. Not applicable to IDCS users, unless they are mapped to local users.

**Rule Parameters:**
- **Service Type:** IAM
- **Resource Type:** User
- **Risk Level:** MEDIUM
- **Labels:** CIS_OCI_V1.0_IAM, CIS_OCI_V1.1_IAM, IAM

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** 8.3 - Secure all individual non-console administrative access and all remote access to the CDE using multi-factor authentication.
- **CIS 1.1:** 1.7 - Ensure that MFA is enabled for all users with a console password.
- **CIS 1.0:** 1.11 - Ensure that MFA is enabled for all users with a console password.

**Best Practice for Rule Modifications:**
- Leave default settings.

**User has API keys**

**Description:** Alert when a user has API keys enabled.
**Recommendation:** Ensure that OCI access by administrators through API keys is performed as an exception. Do not hard-code IAM credentials directly in software or documents to a wide audience.

**Background:** IAM API keys are credentials used to grant programmatic access to resources. Actual human users should not use API keys.

**Rule Parameters:**
- **Service Type:** IAM
- **Resource Type:** User
- **Risk Level:** LOW
- **Labels:** CIS_OCI_V1.0_IAM, CIS_OCI_V1.1_IAM, IAM

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** 8.6 - Where other authentication mechanisms are used, such as physical or logical security tokens, smart cards, or certificates, use of these mechanisms must be assigned as follows:
  - Authentication mechanisms must be assigned to an individual account and not shared among multiple accounts.
  - Physical or logical controls, or both, must be in place to ensure that only the intended account can use that mechanism to gain access.
- **CIS 1.1:** 1.11 - Ensure that API keys are not created for tenancy administrator users.
- **CIS 1.0:** 1.13 - Ensure that API keys are not created for tenancy administrator users.

**Best Practice for Rule Modifications:**
- Leave default settings.

---

**KMS Resources**

**Key has not been rotated**

**Description:** Alert when a KMS key has not been rotated within your specified time period.

**Recommendation:** Ensure that you rotate the KMS keys regularly.

**Background:** For information security, you should periodically change or rotate, passwords, keys, and cryptographic materials. Rotating your keys in KMS reduces the impact and probability of key compromise. Set the minimum. You can change the default time for rotating keys from 180 days in the rule's Input Setting section.

**Rule Parameters:**
- **Service Type:** KMS
- **Resource Type:** KMS Key
- **Risk Level:** CRITICAL
- **Labels:** CIS_OCI_V1.1_MONITORING, KMS

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** 8.2.4 - Credentials must be rotated at least every 90 days.
- **CIS 1.1:** 3.16 - Ensure that customer created Customer Managed Key (CMK) is rotated at least annually.
- **CIS 1.0:** Not Covered by CIS 1.0

**Best Practice for Rule Modifications:**
- **Configuration:** Set the default time for rotating keys in the rule's Input Setting section.

---

**Multiple Resources**

**Resource is not tagged appropriately**

**Description:** Alert when a resource is not tagged in compliance with the tagging requirements you’ve specified.
**Recommendation:** Verify that the configured tags are in use for compute images, compute instances, database systems, VCNs, object storage, and storage block volumes.

**Background:** Verify that the configured tags are in use for compute images, compute instances, database systems, VCNs, object storage, and storage block volumes.

**Rule Parameters:**
- **Service Type:** Multiple
- **Resource Type:** Multiple
- **Risk Level:** LOW
- **Labels:** CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, TAGS

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** 2.4 - Maintain an inventory of system components that are in scope for PCI DSS.
- **CIS 1.1:** 3.2 - Ensure that default tags are used on resources.
- **CIS 1.0:** 4.2 - Ensure that default tags are used on resources.

**Best Practice for Rule Modifications:**
- **Configuration:** Add appropriate tags in the rule's **Input Setting** section.

---

**Networking Resources**

**Load balancer allows weak cipher suites**

**Description:** Alert when a load balancer has a cipher suite configured that is `oci-wider-compatible-ssl-cipher-suite-v1`. This cipher suite includes algorithms like DES and RC4 that are considered weak and prone to attacks. Only applicable for predefined cipher suites and not the custom cipher suite values.

**Recommendation:** Use default, modern cipher suites that support stronger encryption.

**Background:** Certain versions of cipher suites with algorithms like DES are not recommended.

**Rule Parameters:**
- **Service Type:** Networking
- **Resource Type:** Load Balancer
- **Risk Level:** MEDIUM
- **Labels:** Network

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
- Leave default settings.

---

**Load balancer allows weak SSL communication**

**Description:** Alert when a load balancer has a protocol configured as part its SSL policy that includes any version less than TLS 1.2.

**Recommendation:** Ensure that the SSL policy version configured is at least TLS1.2.

**Background:** Older versions of Transport Layer Security (TLS) are risky and vulnerable to many types of attacks. Several standards, such as PCI-DSS and NIST, strongly encourage the use of TLS 1.2.

**Rule Parameters:**
- **Service Type:** Networking
- **Resource Type:** Load Balancer
- **Risk Level:** HIGH
• **Labels:** Network

**Compliance Control Mapping:**
• **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
• Leave default settings.

**Load balancer has no backend set**

**Description:** Alert when a load balancer has no associated backend sets.

**Recommendation:** Ensure that you configure load balancers with backend sets to control the health and access to a load balancer by defined instances.

**Background:** A backend set is a logical entity defined by a load balancing policy, a health check policy, and a list of backend servers.

**Rule Parameters:**
• **Service Type:** Networking
• **Resource Type:** Load Balancer
• **Risk Level:** CRITICAL
• **Labels:** Network

**Compliance Control Mapping:**
• **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
• Leave default settings.

**Load balancer has no inbound rules or listeners**

**Description:** Alert when a security list of a load balancer has ingress rules that accept traffic from an open source (0.0.0.0/0).

**Recommendation:** Ensure that your OCI load balancers use inbound rules or listeners to only allow access from known resources.

**Background:** OCI load balancers enable end-to-end TLS connections between a client's applications and your VCN. A listener is a logical entity that checks for incoming traffic on the load balancer's IP address. To handle TCP, HTTP, and HTTPS traffic, you must configure at least one listener per traffic type.

**Rule Parameters:**
• **Service Type:** Networking
• **Resource Type:** Load Balancer
• **Risk Level:** MINOR
• **Labels:** Network

**Compliance Control Mapping:**
• **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
• Leave default settings.

**Load balancer SSL certificate expiring soon**

**Description:** Alert when the SSL certificate in a load balancer is set to expire within your specified time period.

**Recommendation:** Ensure that certificates are rotated on a timely basis.
Cloud Guard

Background: To ensure continuous security and usability, SSL certificates must be rotated in OCI.

Rule Parameters:
- Service Type: Networking
- Resource Type: Load Balancer
- Risk Level: CRITICAL
- Labels: Network

Compliance Control Mapping:
- PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:
- Configuration: Set Days before expiring (default is 48) in the rule's Input Setting section.

NSG egress rule contains disallowed IP/port

Description: Alert when the egress rule for a network security group (NSG) contains a disallowed destination IP address and port number.

Recommendation: Ensure that the egress rules for communication with the IP/port are permitted for this NSG.

Background: NSGs act as a virtual firewall for compute instances and other kinds of resources. NSG's outbound (egress) security rules apply to a set of virtual NICs in a VCN to allow access to specific ports and IP addresses.

Rule Parameters:
- Service Type: Networking
- Resource Type: Network Security Group
- Risk Level: MEDIUM
- Labels: CIS_OCI_V1.0_NETWORK, CIS_OCI_V1.1_NETWORK, Network

Compliance Control Mapping:
- PCI-DSS 3.2.1: 1.3.4 - Do not allow unauthorized outbound traffic from the cardholder data environment to the Internet.
- CIS 1.1:
  - 2.3 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 22.
  - 2.4 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 3389.
- CIS 1.0:
  - 2.3 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 22.
  - 2.4 - Ensure that no network security groups allow that ingress from 0.0.0.0/0 to port 3389.

Best Practice for Rule Modifications:
- Configuration: Add disallowed ports in the rule's Input Setting section.

NSG ingress rule contains disallowed IP/port

Description: Alert when the ingress rule for a network security group contains a disallowed destination IP address and port number.

Recommendation: Ensure that the ingress rules for communication with the IP/port are permitted for this NSG.

Background: NSGs act as a virtual firewall for compute instances and other kinds of resources. NSGs inbound (ingress) security rules apply to a set of virtual NICs in a VCN to allow access to specific ports and IP addresses.

Rule Parameters:
- Service Type: Networking
Cloud Guard

- **Resource Type:** Network Security Group
- **Risk Level:** HIGH
- **Labels:** CIS_OCI_V1.0_NETWORK, CIS_OCI_V1.1_NETWORK, Network

**Compliance Control Mapping:**

- **PCI-DSS 3.2.1:** 1.2.1 - Restrict inbound and outbound traffic to what's necessary for the cardholder data environment, and specifically deny all other traffic.
- **CIS 1.1:**
  2.3 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 22.
  2.4 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 3389.
- **CIS 1.0:**
  2.3 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 22.
  2.4 - Ensure that no network security groups allow ingress from 0.0.0.0/0 to port 3389.

**Best Practice for Rule Modifications:**

- **Configuration:** Add disallowed ports in the rule's **Input Setting** section.

---

VCN has Internet Gateway attached

**Description:** Alert when a VCN is attached to an internet gateway.

**Recommendation:** Ensure that internet gateways are authorized to be attached to a VCN, and that this attachment doesn’t expose resources to the internet. Ensure that security lists with ingress / inbound rules and those security lists are not configured to allow access from all IP addresses 0.0.0.0/0.

**Background:** Gateways provide external connectivity to hosts in a VCN. They include internet gateway (IGW) for internet connectivity.

**Rule Parameters:**

- **Service Type:** Networking
- **Resource Type:** VCN
- **Risk Level:** LOW
- **Labels:** CIS_OCI_V1.0_NETWORK, CIS_OCI_V1.1_NETWORK, CIS_OCI_V1.1_MONITORING, Network

**Compliance Control Mapping:**

- **PCI-DSS 3.2.1:** 1.3.4 - Do not allow unauthorized outbound traffic from the cardholder data environment to the Internet.
- **CIS 1.1:**
  2.1 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 22
  2.2 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 3389
  2.5 - Ensure that the default security list of every VCN restricts all traffic except ICMP
  3.13 - Ensure that a notification is configured for changes to network gateways
- **CIS 1.0:**
  2.1 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 22
  2.2 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 3389
  2.7 - Ensure that the default security list of every VCN restricts all traffic except ICMP

**Best Practice for Rule Modifications:**

- Leave default settings.
**VCN has Local Peering Gateway attached**

**Description:** Alert when a VCN is attached to a local peering gateway.

**Recommendation:** Ensure that local peering gateways are authorized to be attached to a VCN, and that this attachment doesn’t expose resources to the internet.

**Background:** Gateways provide external connectivity to hosts in a VCN. They include local peering gateway (LPG) for connectivity to peered VCN.

**Rule Parameters:**
- **Service Type:** Networking
- **Resource Type:** VCN
- **Risk Level:** LOW
- **Labels:** CIS_OCI_V1.0_NETWORK, CIS_OCI_V1.1_NETWORK, CIS_OCI_V1.1_MONITORING, Network

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** 1.2 Build firewall and router configurations that restrict connections between untrusted networks and any system components in the cardholder data environment.
- **CIS 1.1:**
  2.1 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 22.
  2.2 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 3389.
  2.5 - Ensure that the default security list of every VCN restricts all traffic except ICMP.
  3.13 - Ensure that a notification is configured for changes to network gateways.
- **CIS 1.0:**
  2.1 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 22.
  2.2 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 3389.
  2.5 - Ensure that the default security list of every VCN restricts all traffic except ICMP.

**Best Practice for Rule Modifications:**
- Leave default settings.

**VCN has no inbound Security List**

**Description:** Alert when a VCN has no inbound security list.

**Recommendation:** Ensure that your OCI VCN’s use security lists with ingress or inbound rules to only allow access from known resources.

**Background:** Security lists provide stateful and stateless firewall capability to control network access to your instances. A security list is configured at the subnet level and enforced at the instance level. You can apply multiple security lists to a subnet where a network packet is allowed, if it matches any rule in the security lists.

**Rule Parameters:**
- **Service Type:** Networking
- **Resource Type:** VCN
- **Risk Level:** MEDIUM
- **Labels:** Network

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
- Leave default settings.
VCN Security list allows traffic to non-public port from all sources (0.0.0.0/0)

**Description:** Alert when a VCN security list allows unrestricted traffic to a non-public port from an open source (0.0.0.0/0).

**Recommendation:** Use VCN security lists to restrict network access to instances in a subnet. To prevent unauthorized access or attacks on compute instances, Oracle recommends that you:

- Use a VCN security list to allow SSH or RDP access only from authorized CIDR blocks
- Do not leave compute instances open to the internet (0.0.0.0/0)

**Background:** A VCN has a collection of features for enforcing network access control and securing VCN traffic. Security lists provide stateful and stateless firewall capability to control network access to your instances. A security list is configured at the subnet level and enforced at the instance level. You can apply multiple security lists to a subnet where a network packet is allowed, if it matches any rule in the security lists.

**Rule Parameters:**

- **Service Type:** Networking
- **Resource Type:** VCN
- **Risk Level:** CRITICAL
- **Labels:** CIS_OCI_V1.0_NETWORK, CIS_OCI_V1.1_NETWORK, Network

**Compliance Control Mapping:**

- **PCI-DSS 3.2.1:** 1.3 - Prohibit direct public access between the Internet and any system component in the cardholder data environment.
- **CIS 1.1:**
  2.1 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 22.
  2.2 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 3389.
- **CIS 1.0:**
  2.1 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 22.
  2.2 - Ensure that no security lists allow ingress from 0.0.0.0/0 to port 3389.

**Best Practice for Rule Modifications:**

- Leave default settings.

VCN Security list allows traffic to restricted port

**Description:** Alert when a VCN security list allows certain restricted ports (see Input Settings, Restricted Protocol:Ports List) as part of the Security list ingress rule.

**Recommendation:** If "Restricted Protocol:Ports List" includes port values that are identified or allowed for your workloads, then modify the list of ports in Input Settings accordingly. Additional details section of the problem provides a list of open Restricted ports that triggered this problem. Ensure that your OCI VCNs use security lists with ingress or inbound rules to only allow traffic access to identified ports. Review if detected ports should be open on this security list Ingress rule and close them if they are not required to be open. Oracle also recommends checking the "Restricted Protocol:Ports List" in the Input setting of this detector rule and modify it to allow certain required ports and thus notifying Cloud Guard to not detect a problem for those ports.

**Background:** Security lists provide stateful and stateless firewall capability to control network access to your instances. A security list is configured at the subnet level and enforced at the instance level. You can apply multiple security lists to a subnet where a network packet is allowed, if it matches any rule in the security lists.

**Rule Parameters:**

- **Service Type:** Networking
- **Resource Type:** VCN
- **Risk Level:** MINOR
Cloud Guard

- **Labels:** CIS_OCI_V1.0_NETWORK, CIS_OCI_V1.1_NETWORK, Network

**Compliance Control Mapping:**

- **PCI-DSS 3.2.1:** 1.2 - Build firewall and router configurations that restrict connections between untrusted networks and any system components in the cardholder data environment.
- **CIS 1.1:** 2.5 - Ensure that the default security list of every VCN restricts all traffic except ICMP.
- **CIS 1.0:** 2.7 - Ensure that the default security list of every VCN restricts all traffic except ICMP.

**Best Practice for Rule Modifications:**

- **Configuration:**
  - Add **Allowed Protocol:Ports List**, in the rule's **Input Setting** section.
  - Modify **Restricted Protocol:Ports List** as needed, in the rule's **Input Setting** section.

You can enter ports lists manually, or you can enter names of one or more security lists that you've defined. See **Security Lists**.

**Note:**

Choosing between use of **Allowed... List** and **Restricted... List**:

- If you leave both lists empty, accesses to all ports generate problems. You must specify one or both lists to avoid this.
- If you specify allowed ports, accesses to all other ports generate problems.
- If you specify only restricted ports, accesses to only those ports generate problems.
- If you specify the same port number in both lists, you are not allowed to save your changes.

**VNIC without associated network security group**

**Description:** Alert when a virtual network interface card (VNIC) has no associated (NSG).

**Recommendation:** Ensure that all VNICs have an associated NSG.

**Background:** A VNIC is a networking component that enables a resource such as a compute instance to connect to a VCN. The VNIC determines how the instance connects with endpoints inside and outside the VCN. Each VNIC resides in a subnet in a VCN. A VNIC without an NSG might trigger a connectivity issue.

**Rule Parameters:**

- **Service Type:** Networking
- **Resource Type:** VCN
- **Risk Level:** MINOR
- **Labels:** Network

**Compliance Control Mapping:**

- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**

- **Configuration:** Modify Restricted Protocol:Ports List as needed, in the rule's **Input Setting** section.

**Scanning Resources**
Scanned host has open ports

**Description:** Alert when Oracle Vulnerability Scanning Service (VSS) scans Compute instances (hosts) and identifies open ports. To use this rule, you must create a Host Scan Recipe and a Host Scan Target in the Scanning service. See [Getting Started](#) in the Scanning documentation.

**Recommendation:** Review the identified ports and close them if you determine that they should not be open on this host.

**Background:** Certain ports are required for operation and delivery of services, but any open ports beyond the intended list can potentially be used to exploit the services.

**Rule Parameters:**
- **Service Type:** Scanning, Compute
- **Resource Type:** Compute
- **Risk Level:** CRITICAL
- **Labels:** VSS

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
- **Configuration:** Add any Allowed Ports that should be ignored in the rule's Input Setting section.

Scanned host has vulnerabilities

**Description:** Alert when Oracle Vulnerability Scanning Service (VSS) scans Compute instances (hosts) and identifies known cybersecurity vulnerabilities. To use this rule, you must create a Host Scan Recipe and a Host Scan Target in the Scanning service. See [Getting Started](#) in the Scanning documentation.

**Recommendation:** Perform the recommended actions that are documented for each vulnerability, such as applying an OS patch.

**Background:** The Scanning service identifies vulnerabilities for applications, libraries, operating systems, and services. Each vulnerability in the database has a distinct identifier or CVE.

**Rule Parameters:**
- **Service Type:** Scanning, Compute
- **Resource Type:** Compute
- **Risk Level:** CRITICAL
- **Labels:** VSS

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
- **Configuration:** Leave the default settings (all CVEs are detected)

Storage Resources

**Block Volume is encrypted with Oracle-managed key**

**Description:** Alert when a block volume is encrypted with Oracle-managed keys.

**Recommendation:** Assign a KMS key to this volume.

**Background:** Encryption of volumes provides an extra level of security on your data. Management of encryption keys is critical to protecting and accessing protected data. Some customers want to identify block volumes encrypted with Oracle-managed keys vs the user-managed keys.
Cloud Guard

Rule Parameters:
• Service Type: Storage
• Resource Type: Block Volume
• Risk Level: MINOR
• Labels: KMS

Compliance Control Mapping:
• PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:
• Oracle-Managed Keys: Recommended to secure block volumes.
• User-Managed Keys:
  • Use KMS wherever possible.
  • Implement Oracle Security Zones on compartments to ensure that practice is followed.
• Conditional Groups: Avoid using, because of the large number of volumes.

Block Volume is not attached
Description: Alert when a block volume is not attached to its associated instance.
Recommendation: Ensure that the volume is attached.
Background: Detaching a block volume decouples the volume from its associated instance and could affect data availability, from business-critical data to point-in-time copies of volumes as backups.

Rule Parameters:
• Service Type: Storage
• Resource Type: Block Volume
• Risk Level: MEDIUM
• Labels: Storage

Compliance Control Mapping:
• PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:
• Conditional Groups: Avoid using, because of large number of volumes.

Bucket is public
Description: Alert when a bucket is public.
Recommendation: Ensure that the bucket is sanctioned for public access, and if not, direct the OCI administrator to restrict the bucket policy to allow only specific users access to the resources required to accomplish their job functions.
Background: Object Storage supports anonymous, unauthenticated access to a bucket. A public bucket that has read access enabled for anonymous users allows anyone to obtain object metadata, download bucket objects, and optionally list bucket contents.

Rule Parameters:
• Service Type: Storage
• Resource Type: Bucket
• Risk Level: CRITICAL
• Labels: CIS_OCI_V1.1_ObjectStorage, ObjectStorage

Compliance Control Mapping:
• **PCI-DSS 3.2.1**: 1.2.1 - Restrict inbound and outbound traffic to what's necessary for the cardholder data environment, and specifically deny all other traffic.

• **CIS 1.1**: 4.1 - Ensure that no Object Storage buckets are publicly visible.

• **CIS 1.0**: Not Covered by CIS 1.0.

**Best Practice for Rule Modifications:**

• **Conditional Groups**: Filter out bucket names (<namespace>/<name>) for any that are supposed to be public.

### Object Storage bucket is encrypted with Oracle-managed key

**Description**: Alert when an Object Storage bucket is encrypted with an Oracle-managed key.

**Recommendation**: Assign a KMS key to this bucket.

**Background**: Encryption of storage buckets provides an extra level of security on your data. Management of encryption keys is critical to protecting and accessing protected data. Some customers want to identify storage buckets encrypted with Oracle-managed keys.

**Rule Parameters**:

• **Service Type**: Storage

• **Resource Type**: Bucket

• **Risk Level**: MINOR

• **Labels**: CIS_OCI_V1.1_ObjectStorage, ObjectStorage, KMS

**Compliance Control Mapping**:

• **PCI-DSS 3.2.1**: Not an issue for PCI.

• **CIS 1.1**: 4.2 - Ensure Object Storage Buckets are encrypted with a Customer Managed Key (CMK).

• **CIS 1.0**: Not Covered by CIS 1.0.

**Best Practice for Rule Modifications**:

• **Configuration**: If you require strict key control using user-managed keys through KMS, create an Oracle Security Zone compartment and create resources in that compartment.

### OCI Activity Detector Rules

Reference material for the Oracle-managed activity detector recipe that Cloud Guard provides is grouped below by resource type. Expand a Rule Display Name to view the details.

#### Bastion Resources

**Bastion created**

**Description**: Alert when a new Bastion instance is created.

**Recommendation**: Ensure that only authorized users create Bastion instances.

**Background**: Bastions provide users with secure and seamless SSH access to target hosts in private subnets, while still restricting direct public access.

**Rule Parameters**:

• **Service Type**: Bastion

• **Resource Type**: Instance

• **Risk Level**: LOW

• **Labels**: Bastion

**Compliance Control Mapping**:

• **PCI-DSS 3.2.1**: Not applicable.

**Best Practice for Rule Modifications**:
Bastion session created

**Description:** Alert when a new Bastion session is created.

**Recommendation:** Ensure that only authorized users create Bastion sessions.

**Background:** A Bastion Session provides time-bound, secure, and seamless SSH access to a target host in private subnets, while still restricting direct public access.

**Rule Parameters:**
- **Service Type:** Bastion
- **Resource Type:** Instance
- **Risk Level:** LOW
- **Labels:** Bastion

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
- Leave default settings.

Compute Resources

Export Image

**Description:** Alert when a Compute image is exported.

**Recommendation:** Images that contain anything proprietary should be tagged accordingly with export privileges allowed only to suitable OCI administrators.

**Background:** Compute images might be equivalent to "data drives" and contain sensitive information. Images that might contain anything proprietary should be identified accordingly with export privileges permitted only to suitable OCI administrators.

**Rule Parameters:**
- **Service Type:** Compute
- **Resource Type:** Instance
- **Risk Level:** MINOR
- **Labels:** Compute

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
- Leave default settings.

Import Image

**Description:** Alert when a Compute image is exported.

**Recommendation:** Ensure that a person expected to bring new images into your environment imports the compute image from trusted sources, such as Oracle or a trusted Compute administrator.

**Background:** Compute images are the foundations for compute instances. A new image impacts every future compute instance launched from that image and imported images should come from known and trusted sources.

**Rule Parameters:**
Cloud Guard

- **Service Type**: Compute
- **Resource Type**: Instance
- **Risk Level**: MINOR
- **Labels**: Compute

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1**: Not applicable.

**Best Practice for Rule Modifications:**
- Leave default settings.

**Instance terminated**

**Description**: Alert when a Compute instance is terminated.

**Recommendation**: Use IAM policies to restrict instance termination operations.

**Background**: Compute instances might deliver critical functions.

**Rule Parameters:**
- **Service Type**: Compute
- **Resource Type**: Instance
- **Risk Level**: HIGH
- **Labels**: Compute

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1**: Not applicable.

**Best Practice for Rule Modifications:**
- Leave default settings.

**Update Image**

**Description**: Alert when a Compute image is updated.

**Recommendation:**

Ensure that:

- A person expected to bring new images into your environment imports the image.
- The image is imported from trusted sources, such as Oracle or a trusted Compute administrator.

**Background**: Compute images are the foundations for compute instances. A modification to images impacts every future compute instance launched from that image. Images and any changes related to them should come from known and trusted sources.

**Rule Parameters:**
- **Service Type**: Compute
- **Resource Type**: Instance
- **Risk Level**: LOW
- **Labels**: Compute

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1**: Not applicable.

**Best Practice for Rule Modifications:**
- Leave default settings.
**Database Resources**

**Database System terminated**

**Description:** Alert when a database system is terminated.

**Recommendation:** Ensure that a permitted administrator sanctions and performs the termination of the database system and related databases.

**Background:** Database systems might hold sensitive data and provide critical functionality. Termination of a database system permanently deletes the system, any databases running on it, and any storage volumes attached to it.

**Rule Parameters:**
- **Service Type:** DB System
- **Resource Type:** System
- **Risk Level:** HIGH
- **Labels:** Database

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
- Leave default settings.

**IAM Resources**

**IAM API keys Created**

**Description:** Alert when IAM API keys are created for a user.

**Recommendation:** Ensure that API keys are created only by users who are authorized to create API keys, for themselves or for other users.

**Background:** API keys are needed to use one of Oracle SDKs or other developer tools. Use of these developer tools by persons whose job function doesn't require it is a security vulnerability.

**Rule Parameters:**
- **(Status: Disabled)**
- **Service Type:** IAM
- **Resource Type:** User
- **Risk Level:** LOW
- **Labels:** IAM

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
- **Enable** rule if you want to see which users are doing group-related operations.
- **Conditional Groups:** Trigger a problem only if user is not in an admin group with permission to create API keys for users.

**IAM API keys Deleted**

**Description:** Alert when a user's IAM API key is deleted.

**Recommendation:** Ensure that API keys are deleted only by users who are authorized to create and delete API keys.

**Background:** API keys are needed to use one of Oracle SDKs or other developer tools. Deletion of API keys for a user who is working with Oracle developer tools can seriously impact productivity.
**Rule Parameters:**
- **Status:** Disabled
- **Service Type:** IAM
- **Resource Type:** User
- **Risk Level:** LOW
- **Labels:** IAM

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
- Enable rule if you want to see which users are doing group-related operations.
- **Conditional Groups:** Trigger a problem only if user is not in an admin group with permission to delete users' API keys.

**IAM Auth Token Created**

**Description:** Alert when an IAM Auth Token is created for a user.

**Recommendation:** Ensure that IAM Auth Tokens are created by and for authorized users.

**Background:** Auth Tokens can be used to authenticate with third-party APIs. Availability of Auth Tokens to people whose job function doesn't require them creates a security vulnerability. See User Credentials.

**Rule Parameters:**
- **Status:** Disabled
- **Service Type:** IAM
- **Resource Type:** User
- **Risk Level:** LOW
- **Labels:** IAM

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
- Enable rule if you want to see which users are doing group-related operations.
- **Conditional Groups:** Trigger a problem only if user is not in an admin group with permission to create IAM Auth Tokens.

**IAM Auth Token Deleted**

**Description:** Alert when an IAM Auth Token is deleted for a user.

**Recommendation:** Ensure that IAM Auth Tokens are deleted by authorized users.

**Background:** Auth Tokens can be used to authenticate with third-party APIs. Availability of Auth Tokens to people whose job function doesn't require them creates a security vulnerability. See User Credentials.

**Rule Parameters:**
- **Status:** Disabled
- **Service Type:** IAM
- **Resource Type:** User
- **Risk Level:** LOW
- **Labels:** IAM

**Compliance Control Mapping:**
• PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:
• Enable rule if you want to see which users are doing group-related operations.
• Conditional Groups: Trigger a problem only if user is not in an admin group with permission to delete IAM Auth Tokens.

IAM Customer Keys created
Description: Alert when IAM customer keys are created.
Recommendation: Ensure that these keys are created only for authorized users.
Background: Customer secret keys are created for Amazon S3 Compatibility API use with Object Storage.
Rule Parameters:
• (Status: Disabled)
• Service Type: IAM
• Resource Type: User
• Risk Level: LOW
• Labels: IAM

Compliance Control Mapping:
• PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:
• Enable rule if you want to see which users are doing group-related operations.
• Conditional Groups: Trigger a problem only if user is not in an admin group with permission to create IAM customer keys.

IAM Customer Keys Deleted
Description: Alert when IAM customer keys are deleted.
Recommendation: Ensure that deletion of these keys is expected.
Background: Customer secret keys are created for Amazon S3 Compatibility API use with Object Storage.
Rule Parameters:
• (Status: Disabled)
• Service Type: IAM
• Resource Type: User
• Risk Level: LOW
• Labels: IAM

Compliance Control Mapping:
• PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:
• Enable rule if you want to see which users are doing group-related operations.
• Conditional Groups: Trigger a problem only if user is not in an admin group with permission to delete IAM customer keys.

IAM Group created
Description: Alert when an IAM group is created.
Recommendation: Ensure that only authorized users create IAM groups.
Background: Groups control access to resources and privileges.

Rule Parameters:
- Service Type: IAM
- Resource Type: Group
- Risk Level: MINOR
- Labels: IAM

Compliance Control Mapping:
- PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:
- Leave default settings.

IAM Group deleted

Description: Alert when an IAM group is deleted.

Recommendation: Ensure that only authorized users perform IAM group deletions.

Background: Groups control access to resources and privileges.

Rule Parameters:
- Service Type: IAM
- Resource Type: GROUP
- Risk Level: MINOR
- Labels: IAM

Compliance Control Mapping:
- PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:
- Leave default settings.

IAM OAuth 2.0 credentials created

Description: Alert when IAM OAuth 2.0 credentials are created.

Recommendation: Ensure that these credentials are created only for authorized users.

Background: IAM OAuth 2.0 credentials are for interacting with the APIs of those services that use OAuth 2.0 authorization. See User Credentials.

Rule Parameters:
- (Status: Disabled)
- Service Type: IAM
- Resource Type: User
- Risk Level: LOW
- Labels: IAM

Compliance Control Mapping:
- PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:
- Enable rule if you want to see which users are doing group-related operations.
- Conditional Groups: Trigger a problem only if user is not in an admin group with permission to create IAM OAuth 2.0 credentials.
IAM OAuth 2.0 credentials Deleted

**Description:** Alert when IAM OAuth 2.0 credentials are deleted.

**Recommendation:** Ensure that deletion of these credentials is expected.

**Background:** IAM OAuth 2.0 credentials are for interacting with the APIs of those services that use OAuth 2.0 authorization. See User Credentials.

**Rule Parameters:**
- Status: Disabled
- Service Type: IAM
- Resource Type: User
- Risk Level: LOW
- Labels: IAM

**Compliance Control Mapping:**
- PCI-DSS 3.2.1: Not applicable.

**Best Practice for Rule Modifications:**
- Enable rule if you want to see which users are doing group-related operations.
- Conditional Groups: Trigger a problem only if user is not in an admin group with permission to delete IAM OAuth 2.0 credentials.

IAM User capabilities modified

**Description:** Alert when an IAM user's capabilities are edited.

**Recommendation:** Ensure that only authorized users change an IAM user's capabilities.

**Background:** To access Oracle Cloud Infrastructure, a user must have the required credentials like API keys, auth tokens, and, other credentials.

**Rule Parameters:**
- Status: Disabled
- Service Type: IAM
- Resource Type: User
- Risk Level: LOW
- Labels: IAM

**Compliance Control Mapping:**
- PCI-DSS 3.2.1: Not applicable.

**Best Practice for Rule Modifications:**
- Enable rule if you want to see which users are doing group-related operations.
- Leave default settings.

IAM User created

**Description:** Alert when a local or federated user is created in OCI IAM.

**Recommendation:** Ensure that only authorized users create IAM users.

**Background:** An IAM user can be an individual employee or system that needs to manage or use your company's Oracle Cloud Infrastructure resources.

**Rule Parameters:**
- Service Type: IAM
- Resource Type: User
• **Risk Level:** MINOR
• **Labels:** IAM

**Compliance Control Mapping:**
• **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
• Leave default settings.

**IAM User UI password created or reset**

**Description:** Alert when a user's Console password is create or reset.

**Recommendation:** Ensure that a user's password is reset by the user, or by an admin user who is authorized to reset passwords.

**Background:** Resetting a user's password multiple times, or resetting by a user who is not authorized to reset user passwords, might indicate a security risk.

**Rule Parameters:**
• *(Status: Disabled)*
• **Service Type:** IAM
• **Resource Type:** User
• **Risk Level:** LOW
• **Labels:** IAM

**Compliance Control Mapping:**
• **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
• **Enable** rule if you want to see which users are doing group-related operations.
• **Conditional Groups:** Trigger a problem only if user is not in an admin group with permission to reset user passwords.

**Security policy modified**

**Description:** Alert when a security policy is modified.

**Recommendation:**

Ensure that:
• The policy is restricted to allow only specific users to access the resources required to accomplish their job functions
• The modification is sanctioned

**Background:** Changing policies impact the all users in the group and might give privileges to users who do not need them.

**Rule Parameters:**
• **Service Type:** IAM
• **Resource Type:** Policy
• **Risk Level:** LOW
• **Labels:** CIS_OCI_V1.1_MONITORING, IAM

**Compliance Control Mapping:**
• **PCI-DSS 3.2.1:** Not applicable.
• **CIS 1.1:** 3.7 - Ensure that a notification is configured for IAM policy changes.
Best Practice for Rule Modifications:

- Leave default settings.

User added to group

Description: Alert when a user is added to a group.

Recommendation: Ensure that the user is entitled to be a member of the group.

Background: Groups control access to resources and privileges. Sensitive groups should be closely monitored for membership changes.

Rule Parameters:

- Service Type: IAM
- Resource Type: Group
- Risk Level: MINOR
- Labels: CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, IAM

Compliance Control Mapping:

- PCI-DSS 3.2.1: Not applicable.
- CIS 1.1: 3.6 - Ensure that a notification is that configured for IAM group changes.
- CIS 1.0: 4.6 Ensure that a notification is configured for IAM group changes.

Best Practice for Rule Modifications:

- Leave default settings.

User removed from group

Description: Alert when a user is removed from a group.

Recommendation: Ensure that the user is entitled to be a member of the group.

Background: Groups control access to resources and privileges. Sensitive groups should be closely monitored for membership changes.

Rule Parameters:

- Service Type: IAM
- Resource Type: User
- Risk Level: MINOR
- Labels: IAM

Compliance Control Mapping:

- PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:

- Conditional Groups: Trigger a problem only if user is not in an admin group with permission to remove users from this group.

Networking Resources

DRG attached to a VCN

Description: Alert when a dynamic routing gateway (DRG) is attached to a VCN.

Recommendation: Ensure that the attaching of this DRG to the VCN is permitted and expected in this compartment by the resource (user).
Background: DRGs are used to connect existing on-premises networks to a virtual cloud network (VCN) with IPSec VPN or FastConnect.

Rule Parameters:

• (Status: Disabled)
• Service Type: Networking
• Resource Type: DRG
• Risk Level: MINOR
• Labels: Network

Compliance Control Mapping:

• PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:

• Enable rule if you want to see which users are doing group-related operations.
• Conditional Groups: Trigger a problem only if user is not in an admin group with permission to attach DRGs to VCNs.

DRG created

Description: Alert when a dynamic routing gateway (DRG) is created.

Recommendation: Ensure that the creation of this DRG is permitted and expected in this compartment by the resource (user).

Background: DRGs are used to connect existing on-premises networks to a virtual cloud network (VCN) with IPSec VPN or FastConnect.

Rule Parameters:

• (Status: Disabled)
• Service Type: Networking
• Resource Type: DRG
• Risk Level: MINOR
• Labels: Network

Compliance Control Mapping:

• PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:

• Enable rule if you want to see which users are doing group-related operations.
• Conditional Groups: Trigger a problem only if user is not in an admin group with permission to create DRGs.

DRG deleted

Description: Alert when a dynamic routing gateway (DRG) is deleted.

Recommendation: Ensure that deletion of this DRG is permitted and expected by the resource (user).

Background: DRGs are used to connect existing on-premises networks to a virtual cloud network (VCN) with IPSec VPN or FastConnect.

Rule Parameters:

• (Status: Disabled)
• Service Type: Networking
• Resource Type: DRG
• Risk Level: MINOR
• Labels: Network
Compliance Control Mapping:
- PCI-DSS 3.2.1: Not applicable.

Best Practice for Rule Modifications:
- **Enable** rule if you want to see which users are doing group-related operations.
- **Conditional Groups**: Trigger a problem only if user is not in an admin group with permission to delete DRGs.

**DRG detached from a VCN**

**Description:** Alert when a dynamic routing gateway (DRG) is detached from a VCN.

**Recommendation:** Ensure that the detaching of this DRG from the VCN is permitted and expected in this compartment by the resource (user).

**Background:** DRGs are used to connect existing on-premises networks to a virtual cloud network (VCN) with IPSec VPN or FastConnect.

**Rule Parameters:**
- **(Status: Disabled)**
- **Service Type:** Networking
- **Resource Type:** DRG
- **Risk Level:** MINOR
- **Labels:** Network

Compliance Control Mapping:
- **PCI-DSS 3.2.1:** Not applicable.

Best Practice for Rule Modifications:
- **Enable** rule if you want to see which users are doing group-related operations.
- **Conditional Groups:** Trigger a problem only if user is not in an admin group with permission to delete DRGs from VCNs.

**Subnet Changed**

**Description:** Alert when a subnet is changed.

**Recommendation:** Ensure that the change to the VCN is permitted and expected in this compartment.

**Background:** Subnets are subdivisions of a VCN. Compute instances that are connected in the same subnet use the same route table, security lists, and DHCP options.

**Rule Parameters:**
- **Service Type:** Networking
- **Resource Type:** Subnet
- **Risk Level:** LOW
- **Labels:** Network

Compliance Control Mapping:
- **PCI-DSS 3.2.1:** Not applicable.

Best Practice for Rule Modifications:
- Leave default settings.

**Subnet deleted**

**Description:** Alert when a subnet is deleted.
**Recommendation:** Enable multi-factor authentication (MFA) to ensure that the user is a genuinely logged in user and the credentials are not compromised.

**Background:** Subnets are subdivisions of a VCN. Compute instances that are connected in the same subnet use the same route table, security lists, and DHCP options.

**Rule Parameters:**
- **Service Type:** Networking
- **Resource Type:** Subnet
- **Risk Level:** LOW
- **Labels:** Network

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
- Leave default settings.

**VCN created**

**Description:** Alert when a VCN is created.

**Recommendation:** Ensure that the creation of a new VCN is permitted and expected in this compartment.

**Background:** A VCN is a virtual, private network that you set up in Oracle data centers. Like a traditional network, it might contain firewall rules and specific types of communication gateways.

**Rule Parameters:**
- **Service Type:** Networking
- **Resource Type:** VCN
- **Risk Level:** LOW
- **Labels:** CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.
- **CIS 1.1:** 3.9 - Ensure that a notification is configured for VCN changes.
- **CIS 1.0:** 4.6 Ensure that a notification is configured for IAM group changes.

**Best Practice for Rule Modifications:**
- Leave default settings.

**VCN deleted**

**Description:** Alert when a VCN is created.

**Recommendation:** Ensure that the deletion of a VCN is permitted and expected in this compartment.

**Background:** A VCN is a virtual, private network that you set up in Oracle data centers. Like a traditional network, it might contain firewall rules and specific types of communication gateways. VCN deletion can change routing, FQDN resolution, and other networking operations.

**Rule Parameters:**
- **Service Type:** Networking
- **Resource Type:** VCN
- **Risk Level:** MEDIUM
- **Labels:** CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1**: Not applicable.
- **CIS 1.1**: 3.9 - Ensure that a notification is configured for VCN changes.
- **CIS 1.0**: 4.6 Ensure that a notification is configured for IAM group changes.

**Best Practice for Rule Modifications:**
- Leave default settings.

### VCN DHCP Option changed

**Description**: Alert when a VCN DHCP option is changed.

**Recommendation**: Ensure that the change to DHCP and DNS information is permitted for this VCN and related resources.

**Background**: DHCP options control certain types of configuration on the instances in a VCN, including specification of search domains and DNS resolvers that can direct communications within VCNs across to Internet resources. VCN changes can change routing, FQDN resolution, and other networking operations.

**Rule Parameters**:
- **Service Type**: Networking
- **Resource Type**: DHCP
- **Risk Level**: MEDIUM
- **Labels**: CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

**Compliance Control Mapping**:
- **PCI-DSS 3.2.1**: Not applicable.
- **CIS 1.1**: 3.9 - Ensure that a notification is configured for VCN changes.
- **CIS 1.0**: 4.6 Ensure that a notification is configured for IAM group changes.

**Best Practice for Rule Modifications**:
- Leave default settings.

### VCN Internet Gateway created

**Description**: Alert when a VCN internet gateway is created.

**Recommendation**: Ensure that the creation of an internet gateway is permitted for this VCN and its related resources.

**Background**: Internet gateways are virtual routers you can add to your VCN to enable direct connectivity (inbound from or outbound) to the internet. VCN changes can change routing, FQDN resolution, and other networking operations.

**Rule Parameters**:
- **Service Type**: Networking
- **Resource Type**: Internet Gateway
- **Risk Level**: MEDIUM
- **Labels**: CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

**Compliance Control Mapping**:
- **PCI-DSS 3.2.1**: Not applicable.
- **CIS 1.1**: 3.13 - Ensure that a notification is configured for changes to network gateways.
- **CIS 1.0**: 4.6 Ensure that a notification is configured for IAM group changes.

**Best Practice for Rule Modifications**:
- Leave default settings.
VCN Internet Gateway terminated

**Description:** Alert when a VCN internet gateway is terminated.

**Recommendation:** Ensure that the deletion of an internet gateway is permitted for this VCN and its related resources.

**Background:** Internet gateways are virtual routers you can add to your VCN to enable direct connectivity (inbound from or outbound) to the internet. VCN changes can change routing, FQDN resolution, and other networking operations.

**Rule Parameters:**
- **Service Type:** Networking
- **Resource Type:** Internet Gateway
- **Risk Level:** LOW
- **Labels:** CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.
- **CIS 1.1:** 3.13 - Ensure that a notification is configured for changes to network gateways.
- **CIS 1.0:** 4.6 Ensure that a notification is configured for IAM group changes.

**Best Practice for Rule Modifications:**
- Leave default settings.

VCN Local Peering Gateway changed

**Description:** Alert when a VCN local peering gateway is changed.

**Recommendation:** Ensure that the changes to the LPG are permitted for this VCN and its related resources.

**Background:** VCN local peering gateways (LPG) connect two VCNs in the same region without routing traffic over the internet. LPG resources in the VCNs to communicate directly with private IP addresses. Changes to LPGs can impact resource access and cross-VCN communications. VCN changes can change routing, FQDN resolution, and other networking operations.

**Rule Parameters:**
- **Service Type:** Networking
- **Resource Type:** Local Peering Gateway
- **Risk Level:** MEDIUM
- **Labels:** CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.
- **CIS 1.1:** 3.13 - Ensure that a notification is configured for changes to network gateways.
- **CIS 1.0:** 4.6 Ensure that a notification is configured for IAM group changes.

**Best Practice for Rule Modifications:**
- Leave default settings.

VCN Network Security Group Deleted

**Description:** Alert when a VCN's NSG is deleted.

**Recommendation:** Ensure that the removal of the NSG is permitted for this VCN and its related resources.

**Background:** Network security groups (NSGs) act as a virtual firewall for compute instances and other kinds of resources. NSGs have a set of inbound (ingress) and outbound (egress) security rules applied to a set of virtual NICs in a VCN. Deleting NSGs can remove protections between resources in the VCN, and cause denial of access to resources or data loss.
Rule Parameters:

- **Service Type:** Networking
- **Resource Type:** Network Security Group
- **Risk Level:** HIGH
- **Labels:** CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

Compliance Control Mapping:

- **PCI-DSS 3.2.1:** Not applicable.
- **CIS 1.1:** 3.12 - Ensure that a notification is configured for network security group changes.
- **CIS 1.0:** 4.6 Ensure that a notification is configured for IAM group changes.

Best Practice for Rule Modifications:

- Leave default settings.

VCN Network Security Group egress rule changed

**Description:** Alert when a VCN's NSG egress rule is changed.

**Recommendation:** Ensure that the new egress rules are permitted for this NSG and its related resources.

**Background:** Network security groups (NSGs) act as a virtual firewall for compute instances and other kinds of resources. NSGs have a set of inbound (ingress) and outbound (egress) security rules applied to a set of virtual NICs in a VCN. Egress rule changes can cause denial of access to resources.

Rule Parameters:

- **Service Type:** Networking
- **Resource Type:** Network Security Group
- **Risk Level:** MEDIUM
- **Labels:** CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

Compliance Control Mapping:

- **PCI-DSS 3.2.1:** Not applicable.
- **CIS 1.1:** 3.12 - Ensure that a notification is configured for network security group changes.
- **CIS 1.0:** 4.6 Ensure that a notification is configured for IAM group changes.

Best Practice for Rule Modifications:

- Leave default settings.

VCN Network Security Group ingress rule changed

**Description:** Alert when a VCN's NSG ingress rule is changed.

**Recommendation:** Ensure that the new ingress rules are permitted for this NSG and its related resources.

**Background:** Network security groups (NSGs) act as a virtual firewall for compute instances and other kinds of resources. NSGs have a set of inbound (ingress) and outbound (egress) security rules applied to a set of virtual NICs in a VCN. Changes to NSGs ingress rules might allow connections and traffic to new resources and VNICs in the VCN.

Rule Parameters:

- **Service Type:** Networking
- **Resource Type:** Network Security Group
- **Risk Level:** MEDIUM
- **Labels:** CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

Compliance Control Mapping:
• PCI-DSS 3.2.1: Not applicable.
• CIS 1.1: 3.12 - Ensure that a notification is configured for network security group changes.
• CIS 1.0: 4.6 Ensure that a notification is configured for IAM group changes.

Best Practice for Rule Modifications:
• Leave default settings.

VCN Route Table changed

Description: Alert when a VCN's route table is changed.

Recommendation: Ensure that the change to the route table is permitted and expected in this compartment.

Background: Virtual route tables have rules that look and act like traditional network route rules. Misconfigured route tables might send network traffic to be dropped (blackholed) or sent to an unintended target. VCN changes can change routing, FQDN resolution, and other networking operations.

Rule Parameters:
• Service Type: Networking
• Resource Type: Route Table
• Risk Level: MEDIUM
• Labels: CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

Compliance Control Mapping:
• PCI-DSS 3.2.1: Not applicable.
• CIS 1.1: 3.10 - Ensure that a notification is configured for changes to route tables.
• CIS 1.0: 4.6 Ensure that a notification is configured for IAM group changes.

Best Practice for Rule Modifications:
• Leave default settings.

VCN Security List created

Description: Alert when security list is created for a VCN.

Recommendation: Ensure that the creation of this security list is permitted for this VCN and its related resources.

Background: Security lists act as virtual firewalls for compute instances and other resources and consists of sets of ingress and egress rules that apply to all the VNICs in any subnet associated with that security list. Multiple security lists might apply to resources and give access to ports and IP addresses for those resources. VCN changes can change routing, FQDN resolution, and other networking operations.

Rule Parameters:
• Service Type: Networking
• Resource Type: Security List
• Risk Level: LOW
• Labels: CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

Compliance Control Mapping:
• PCI-DSS 3.2.1: Not applicable.
• CIS 1.1: 3.11 - Ensure that a notification is configured for security list changes.
• CIS 1.0: 4.6 Ensure that a notification is configured for IAM group changes.

Best Practice for Rule Modifications:
• Leave default settings.
VCN Security List deleted

Description: Alert when security list for a VCN is deleted.

Recommendation: Ensure that the removal of this security list is permitted for this VCN and its related resources.

Background: Security lists act as virtual firewalls for compute instances and other resources and consists of sets of ingress and egress rules that apply to all the VNICS in any subnet associated with that security list. Multiple security lists might apply to resources and give access to ports and IP addresses for those resources. VCN changes can change routing, FQDN resolution, and other networking operations.

Rule Parameters:
- Service Type: Networking
- Resource Type: Security List
- Risk Level: MEDIUM
- Labels: CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

Compliance Control Mapping:
- PCI-DSS 3.2.1: Not applicable.
- CIS 1.1: 3.11 - Ensure that a notification is configured for security list changes.
- CIS 1.0: 4.6 Ensure that a notification is configured for IAM group changes.

Best Practice for Rule Modifications:
- Leave default settings.

VCN Security List egress rules changed

Description: Alert when a VCN's security list egress rules are changed.

Recommendation: Ensure that the changes to the egress rules are permitted for this security list and its related resources.

Background: Security lists act as virtual firewalls for compute instances and other resources and consists of sets of ingress and egress rules that apply to all the VNICS in any subnet associated with that security list. Multiple security lists might apply to resources and give access to ports and IP addresses for those resources. VCN changes can change routing, FQDN resolution, and other networking operations.

Rule Parameters:
- Service Type: Networking
- Resource Type: Security List
- Risk Level: MEDIUM
- Labels: CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

Compliance Control Mapping:
- PCI-DSS 3.2.1: Not applicable.
- CIS 1.1: 3.11 - Ensure that a notification is configured for security list changes.
- CIS 1.0: 4.6 Ensure that a notification is configured for IAM group changes.

Best Practice for Rule Modifications:
- Leave default settings.

VCN Security List ingress rules changed

Description: Alert when a VCN's security list ingress rules are changed.

Recommendation: Ensure that the changes to the ingress rules are permitted for this security list and its related resources.
**Background:** Security lists act as virtual firewalls for compute instances and other resources and consists of sets of ingress and egress rules that apply to all the VNICs in any subnet associated with that security list. Multiple security lists might apply to resources and give access to ports and IP addresses for those resources. VCN changes can change routing, FQDN resolution, and other networking operations.

**Rule Parameters:**
- **Service Type:** Networking
- **Resource Type:** Security List
- **Risk Level:** MEDIUM
- **Labels:** CIS_OCI_V1.0_MONITORING, CIS_OCI_V1.1_MONITORING, Network

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.
- **CIS 1.1:** 3.11 - Ensure that a notification is configured for security list changes.
- **CIS 1.0:** 4.6 Ensure that a notification is configured for IAM group changes.

**Best Practice for Rule Modifications:**
- Leave default settings.

**Suspicious Ip Activity**

**Description:** Alert when a user logs in from a suspicious IP address.

**Recommendation:** Enable multi-factor authentication (MFA) to ensure that the user is a genuinely logged in user and the credentials are not compromised.

**Background:** A user logging in from a suspicious IP address is a potential threat.

**Rule Parameters:**
- **Service Type:** Cloud Guard
- **Resource Type:** Security
- **Risk Level:** CRITICAL
- **Labels:** Network

**Compliance Control Mapping:**
- **PCI-DSS 3.2.1:** Not applicable.

**Best Practice for Rule Modifications:**
- **Configuration:** Blocklist or allowlist CIDR blocks or specific IP addresses in the rule’s **Input Setting** section.

**Managing Responder Recipes**

View, clone, and modify responder recipes to fit the specific security needs of your environment.

A responder is action that Cloud Guard can take when a detector has identified a problem. The available actions are resource-specific. Each responder uses a responder recipe that defines the action or set of actions to take in response to a problem that a detector has identified.

Each responder recipe uses multiple responder rules, each of which defines the specific actions to take.

Cloud Guard provides a set of responders with default rules. You can:
- Use these responders as is.
- Clone any of the default responders and modify the rules to meet specific needs.
- Enable and disable responder rules individually.
- Limit the scope for applying individual rules by specifying conditions that must be met.

**Policy Statements for Responders**
Add policy statements that may be required for particular responders.
Cloud Guard

Caution:

Enabling responders gives Cloud Guard permissions to modify security settings in your environment to remediate, on your behalf, problems that the responders detect. Ensure that granting these permissions does not violate your organizations security policies.

The following policy statements may be required for particular responders. Based on the responder type, one of these policies is needed during manual or automatic remediation.

```plaintext
allow service cloudguard to manage instance-family in compartment <compartment_name>
allow service cloudguard to manage object-family in compartment <compartment_name>
allow service cloudguard to manage buckets in compartment <compartment_name>
allow service cloudguard to manage users in compartment <compartment_name>
allow service cloudguard to manage policies in compartment <compartment_name>
allow service cloudguard to manage keys in compartment <compartment_name>
```

Viewing Details for a Responder Recipe

Open the Responder Recipes page, sort and filter the list, and view details for a specific detector recipe.

1. From the Cloud Guard options panel on the left, select Responder Recipes.

   The column headers provide summary information for the detector recipes:
   - **Recipe Name** - the name of the responder recipe.
   - **Oracle Managed** - shows a check mark if the responder recipe is Oracle-managed.
   - **Created** - the date the responder recipe was created.

   **Note:**

   If you have not yet cloned the **OCI Responder Recipe (Oracle Managed)**, that is the only recipe that appears in the list.

2. To filter the list of responder recipes, you can:
   - Start typing in the **Filter by name** box at the top right.
   - Under **Scope** at lower left, select a different **Compartment**.
   - To right of **Tag Filters** at lower left:
     a. Click the **add** link.
     b. In the **Apply a Tag Filter** dialog box, select a **Tag Namespace**.
        Select **None (free-form tag)** if you want to manually enter the **Tag Key**.
     c. Select a **Tag Key**.
        Manually enter the **Tag Key** if you selected **None (free-form tag)** for the **Tag Namespace**.
     d. For **Value**:
        - Select **Match any value** if you want any tag value to count as a match.
        - Select **Match any of the following** and manually enter values, separated by commas, if you want only the values you enter to count as a match.
        - To add more values for this tag, click the plus sign (+) at the lower right.
     e. Click **Apply Filter**.

3. To view details for a particular responder recipe, click its link in the **Responder Name** column.

4. In the **Details** tab, **OCID** row:
   - Click the **Show** link to show the full OCID.
   - Click the **Copy** link to copy the full OCID to the clipboard.
Cloud Guard

5. If the responder recipe you're viewing is user-managed, you can view tags that have been assigned:
   a) Click the Tags tab.
   b) View the tags that have been assigned.
      If no tags have been assigned, you see "There are no Tags associated with this resource."

6. In the Responder Rules section, use the column headers to identify the information shown:
   a) Responder Rules - the name of each responder rule in the recipe.
   b) Type - the rule type.
      - NOTIFICATION rules only send a notification when the violation occurs.
      - REMEDIATION rules actually remediate the violation.
   c) Status - each rule can be Enabled or Disabled independently.
   d) Conditional Group - are conditions configured for the rule? Yes or No.

7. In the Responder Rules section,
   a) To show summary information for a responder rule, click the Expand icon at the right end of its row.
   b) To show configuration information for a responder rule, open the Actions menu, and select Edit.

What's Next
   a) See Cloning a Responder Recipe on page 871 to make a copy in which you can modify the rules.

Cloning a Responder Recipe
Clone responder recipes to fine-tune the set of responder recipes available to use in your environment.

You can use Oracle-managed responder recipes as is, but you can't change many of their settings. Also, you might want to create another responder recipe that's similar to a user-managed responder recipe that you cloned previously.

Whenever you want to create a responder recipe, you can clone the existing (Oracle-managed or user-managed) recipe with the settings that are most similar to what you want in the new recipe.

1. From the Cloud Guard options panel on the left, select Responder Recipes.
2. (Optional) In the Scope section at lower left, set parameters to filter what appears in the list:
   a) Set Compartment to display only responder recipes attached to a specific compartment.
   b) If you also want responder recipes attached to compartments below the selected compartment to appear in the list, select Include Child Compartments.
3. Click Clone, then in the Clone Responder Recipe dialog box:
   a) From the Cloning list, select the responder recipe you want to clone.
   b) Enter a Name for the new responder recipe.
   c) (Optional) Enter a Description for the new responder recipe.
   d) Specify a Compartment Assignment by selecting from the list.
   e) Click Clone.

The new responder recipe appears in the Responder Rules list.

What’s Next
   a) To change the cloned responder recipe’s rules, see Modifying Rule Settings in a Responder Recipe on page 873.
   b) Ensure that your cloned responder recipe is added to targets where you want it to be used. See Modifying Recipes Added to a Target on page 821.

Modifying a Responder Recipe
You can modify a few recipe settings in an Oracle-managed responder recipe, and more settings in a user-managed (cloned) responder recipe.

1. From the Cloud Guard options panel on the left, select Responder Recipes.
2. Locate the responder recipe you want to modify.
   Oracle-managed responder recipes have a check mark in the **Oracle Managed** column.

3. Click the recipe's link in the **Recipe Name** column.
   The details page for the responder recipe opens. Here you can modify the responder recipe's individual rules.

4. If the responder recipe is user-managed (cloned):
   - To change the responder recipe's name or description:
     a. Click **Edit** below the responder recipe's name on the details page.
     b. In the **Edit Responder Recipe** dialog box, edit the **Name** or **Description** entries, then click **Save**
   - To attach the responder recipe to a different compartment:
     a. Click **Move Resource** below the responder recipe's name on the details page.
     b. In the **Move Resource to a Different Compartment** dialog box, select the new compartment from the **Choose New Compartment** list, then click **Move Resource**.
   - To see tags that have been added to the responder recipe, click the **Tags** tab below the responder recipe's name on the details page.

**Note:**
Tagging isn't supported in Oracle-managed responder recipes.

- To add tags to the responder recipe:
  a. Click **Add Tags** below the responder recipe's name on the details page.
  b. In the **Add One Or More Tags To This Resource** dialog box, select a **Tag Namespace**, then enter a **Tag Key** and a **Value**.
  c. To add another tag, click **Additional Tag**, then repeat the previous step.
  d. When you finish adding tags, click **Add Tags**.

- To enable or disable groups of rules:
  a. Select check boxes to the left of the rule names (current **Status** for all must be the same).
  b. Click **Enable** or **Disable** at the top of the list.
- To see tags that have been added to the responder recipe, click the **Tags** tab below the responder recipe's name on the details page.
- To add tags to the responder recipe:
  a. Click **Add Tags** below the responder recipe's name on the details page.
  b. In the **Add One Or More Tags To This Resource** dialog box, select a **Tag Namespace**, then enter a **Tag Key** and a **Value**.
  c. To add another tag, click **Additional Tag**, then repeat the previous step.
  d. When you finish adding tags, click **Add Tags**.
- To delete the responder recipe:
  a. Click **Delete** below the responder recipe's name on the details page.
  b. In the **Delete Responder Recipe** dialog box, click **Yes**.

**Next Steps**

Ensure that you:
- Make any changes needed in responder rule settings at the recipe level, before adding the recipe to targets. See **Modifying Rule Settings in a Responder Recipe** on page 873.
- Add your responder recipe to all targets where you want it to be used. See **Modifying Recipes Added to a Target** on page 821.
Cloud Guard

• Make any changes needed to customize responder rule settings for the target to which your responder recipe is added. See Modifying Rule Settings in a Target's Recipes on page 822.

Modifying Rule Settings in a Responder Recipe

You can modify a few rule settings in an Oracle-managed responder recipe, and more settings in a user-managed (cloned) responder recipe.

You can make some changes in responder rules at either the recipe level or the target level. But you have to make certain changes must at the target level:

• Oracle-managed responder recipes do not allow you to Enable and Disable rules.
• User-managed (cloned) responder recipes do allow you to Enable and Disable rules.
• If you need to change any of these settings:
  • Required Policy Statements enabling
  • Rule Trigger (how the rule executes) between manual ("Ask me before executing...") and automatic ("Execute automatically")
  • Post Remediation Notification enabling or disabling

Modify the responder recipe from the Targets page. See Modifying Recipes Added to a Target on page 821.

For complete information on what you can modify in Oracle-managed and user-managed (cloned) responder recipes, see Modifying Recipes at Recipe and Target Levels on page 812.

1. Navigate to the detail page for the responder recipe in which you want to modify rule settings.

   See Modifying a Responder Recipe on page 871.

2. Locate an individual responder rule that you want to modify, open the Actions menu, and select Edit.

3. If the responder recipe is user-managed (cloned), in the top part of the Edit Responder Rule dialog box, you can Change the rule's Status (Enabled vs. Disabled).

4. If the Required Policy Statements section, Policy Statements list, has any statements with "Not Added" showing on the right, click Add Statements.

   Note:
   These policy statements must be added to allow the detector rule to operate.

5. To change settings for another responder rule, repeat the preceding steps, beginning with step 2.

6. Click Save.

Next Steps

Ensure that you:

• Add your responder recipe to all targets where you want it to be used. See Modifying Recipes Added to a Target on page 821.

• Make more changes needed to customize responder rule settings for the target to which your detector recipe is added. See Modifying Rule Settings in a Target's Recipes on page 822.

Deleting a User-Managed (Cloned) Responder Recipe

You can delete responder rules for any cloned copy of an Oracle-managed responder.

1. From the Cloud Guard options panel on the left, select Responder Recipes.

2. Locate the cloned responder recipe you want to delete.

   Cloned responder recipes have "No" in the Oracle Managed column.

3. Open the Actions menu and select Delete.

4. Click Yes to confirm the deletion.

Using Managed Lists

You can create, modify, and delete your own managed lists as needed to meet your specific security needs.
About Managed Lists
A managed list is a reusable list of parameters that makes it easier to set the scope for detector and responder rules. A managed list is a tool that can be used to apply certain configurations to detectors.
A predefined "Trusted Oracle IP address space" list contains all the Oracle IP addresses that you want to regard as trusted when you define rules for detectors and responders.
Cloud Guard also lets you define your own managed lists as needed. For example, you can define lists of states or provinces, zip or postal codes, OCIDs, or whatever else you may need.
Examples of specific use cases for custom managed lists:

<table>
<thead>
<tr>
<th>Manage List Content</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trusted IP addresses</td>
<td>Exempt listed IP addresses from triggering alerts that should be triggered from IP addresses that are not trusted.</td>
</tr>
<tr>
<td>Resources that should be public</td>
<td>Exempt listed resources from all detectors related to identifying public configurations.</td>
</tr>
<tr>
<td>Groups of users with specific authorizations</td>
<td>Exempt listed groups or users from triggering alerts on activities users are authorized to perform.</td>
</tr>
</tbody>
</table>

Viewing Details for a Managed List
You can view the details for a managed list anytime you need to check the list of items that's included.

1. From the Cloud Guard options panel on the left, select Managed Lists.

The Managed Lists page lists all managed lists that are currently defined.

Note:
Initially, the list shows only the Oracle Cloud Guard CIDR Managed List.

The column headers provide summary information for the managed lists:

- **List Name** - the name of the managed list.
- **Type** - the type of item in the list (for example, CIDR Block, Country, Users).
- **Total Entries** - the total number of entries currently in the list.
- **Feed Provider** - the original source of list items, Oracle or Customer.
- **Created** - when the list was first created.
To filter the list:
• Start typing in the Filter by name box at the top right.
• Under Scope at lower left, select a different Compartment.
• To right of Tag Filters at lower left:
  a. Click the add link.
  b. In the Apply a Tag Filter dialog box, select a Tag Namespace.

Select None (free-form tag) if you want to manually enter the Tag Key.
  c. Select a Tag Key.

Manually enter the Tag Key if you selected None (free-form tag) for the Tag Namespace.
  d. For Value:

Select Match any value if you want any tag value to count as a match.
Select Match any of the following and manually enter values, separated by commas, if you want only the values you enter to count as a match.
• To add more values for this tag, click the plus sign (+) at the lower right.
  e. Click Apply Filter.

To view details for a particular managed list, click the name in the List Name column.

In the Template Details tab, OCID row:
• Click the Show link to show the full OCID.
• Click the Copy link to copy the full OCID to the clipboard.

To view tags that have been assigned to this managed list:
  a) Click the Tags tab.
  b) View the tags that have been assigned.

If no tags have been assigned, you see "There are no Tags associated with this resource."

In the Entries section, view the individual items in the list.
To filter the list, start typing in the Filter by name box.

Creating a Managed List
Create your own managed lists, anytime you see the need to reuse the same list of items to define a detector or responder rule.

1. From the Cloud Guard options panel on the left, select, select Managed Lists.
2. On the Managed Lists page, click Create New Managed List above the column headers.
3. On the first, Basic Information page of the Create New Managed List dialog box, enter a Name.
4. (Optional) Enter a Description.
5. Select a List Type.
6. Click Next.

A box appears on the second, List Entries page of the dialog box where you can enter the value for the first item in the list.
7. Enter the text for an item in the box.
8. To enter text for another item, click Additional List Item.
9. Repeat the previous two steps until you have finished entering items,

If you want to remove an item from the list, click the "X" to the right of the item.
10. Click Submit.

Your list now appears in the list on the Managed Lists page.

Cloning a Managed List
Clone managed lists as needed to fine-tune the selection of managed lists available to use in your environment.
When you want to create a managed list that is similar to one that exists, you can save time by cloning the existing list. You can clone any managed list that appears on the Managed Lists page.

1. From the Cloud Guard options panel on the left, select Managed Lists.

2. (Optional) In the Scope section at lower left, set parameters to filter what appears in the list:
   - Set Compartment to display only managed lists attached to a specific compartment.
   - If you also want managed lists attached to compartments below the selected compartment to appear in the list, select Include Child Compartments.

3. Click Clone at the top of the list.

4. In the Clone Managed List panel, select the managed list to clone from the Cloning list.
   A default List Name and Description appear.

5. (Optional) Edit the default List Name and Description entries.

6. (Optional) Select a different Compartment Assignment.
   The default is the tenancy root.

7. Click Next.

8. (Optional) On the Clone Managed List panel's List Entries page, modify list entries:
   - To change the value for an existing entry, edit the entry directly in its text box
   - To delete an unwanted entry, click the “X” on the right end of the entry.

   **Note:**
   To add new entries, or to delete or edit more existing entries, complete the next step to finish cloning the managed list, then see Modifying a Managed List on page 876.

9. Click Submit.
   The cloned managed list appears in the list on the Managed Lists page.

**Modifying a Managed List**

You can modify a managed list anytime you need to add or delete items to the list.

When you modify managed lists, the entry in the Feed Provider column for the managed list on the Managed Lists page determines what you can change:

- When Oracle provides the feed for the managed list, Oracle controls the list content and you can only add tags.
- When Customer provides the feed for the managed list, you are in complete control of the list content and you can change whatever you want to.

1. From the Cloud Guard options panel on the left, select Managed Lists.

2. Locate the managed list you want to modify and click the name in the List Name column.

3. To see tags that have been added to the managed list, click the Tags tab below the detector recipe's name on the details page.

4. To add tags to the managed list:
   a. Click Add Tags below the managed list's name on the details page.
   b. In the Add One Or More Tags To This Resource dialog box, select a Tag Namespace, then enter a Tag Key and a Value.
   c. To add another tag, click Additional Tag, then repeat the previous step.
   d. When you finish adding tags, click Add Tags.
5. If the Feed Provider for the managed list is Customer:
   • To attach the managed list to a different compartment:
     a. Click Move Resource below the managed list name at the top.
     b. In the Move Resource to a Different Compartment dialog box, select the new compartment from the Choose New Compartment list, then click Move Resource.
   • To add one or more entries to the list:
     a. In the Entries section, click Add Entry.
     b. In the Add Entry dialog box, enter the text for the first entry you want to add.
     c. To add another entry, click Additional List Item and enter the text.
     d. Repeat the previous two steps until you are done adding entries, then click Save.
   • To modify an entry in the list:
     a. Locate the entry that you want to modify, open the Actions menu, and select Edit.
     b. In the Update Entry panel, edit the entry and click Save.
   • To edit the entire list:
     a. Click Edit below the managed list name at the top.
     b. In the Update Entry dialog box, edit the text for any of the items listed, then click Save.
     c. To add a new entry to the list, click Additional List Item at the bottom.
   • To delete entries from the list:
     a. Select the check box for each entry you want to delete.
     b. Click Delete at the top of the list.
     c. In the Delete List dialog box, click Yes.
   • To delete the entire list:
     a. Click Delete below the list name on the list details page.
     b. In the Delete List dialog box, click Yes.

Deleting a User-Managed List
You can delete a user-managed list that you no longer need.
1. From the Cloud Guard options panel on the left, select Managed Lists.
2. Locate the managed list you want to delete, open the Actions menu, and select Delete.
3. Click Yes to confirm the deletion.

Managing Data Masking
Data Masking lets you restrict viewing of different categories of sensitive problem information to authorized users.

About Data Masking
Data Masking lets you define rules that hide or redact categories of sensitive information from users who don't have a specific need to view it.

Cloud Guard applies the masking rules to sensitive information that would otherwise be displayed on the Problems page, in the problem details and history.

Overview

Note:
Different countries have different requirements as to how tightly access to sensitive information must be restricted. You are legally required to comply with the national requirements on data privacy for the country where Cloud Guard's reporting region is hosted. To look up the reporting region, see Viewing the Reporting Region or Restarting the Guided Tour on page 881.
Data masking allows you to selectively redact sensitive problem information for unauthorized users. The objective is to restrict different categories of information to viewing only by users whose job function requires them to view that type of information. Each data masking rule specifies categories of sensitive problem information that are to be redacted for:

- A particular IAM user group,
- in a specified combination of Cloud Guard targets.

And you can apply data masking rules at three levels:

- **Global** - rules apply globally to your entire OCI tenancy.
- **Target** - rules apply only to specified Cloud Guard targets.

**Tip:**

Best practice is to define masking rules at different levels like this:

- **Target** - rules that have the highest precedence. Set up the IAM groups of admin users that you want to allow to view different categories of sensitive information at this level, and redact only those categories that users' job functions in different groups don't require them to view.
- **Global** - rules that have the lowest precedence. Consider redacting all sensitive problem information at this level.

How you apply data masking rules at the different levels is detailed in [Creating Data Masking Rules](#) on page 879.

### How Conflicting Masking Rules at Same Level Are Resolved

You can be certain that a particular user belongs to multiple groups. And you can expect that two or more of those groups might have masking rules with conflicting settings for what's redacted for those groups.

**Same Level Conflict**: A conflict between rules at the same level (global, target) arises when the same user belongs to two groups, and masking rules defined at the same level for those groups redact categories differently: one group's rule redacts a category of sensitive information, and other group's rule doesn't. Whenever this type of conflict occurs, the more restrictive rule takes precedence and the category for that user is redacted.

### How Conflicting Masking Rules at Different Levels Are Resolved

The intent of the data masking design is to allow you to create data masking rules at a lower level that override the rules at a higher level. So, at the global level, you might specify in rules that *all* sensitive information id to be redacted for *all* users; then, at lower levels, specify that selected categories *not* be redacted for selected users.

**Different Level Conflict**: A conflict between rules at different levels (global, service type, target) arises when the same user belongs to two groups, and masking rules defined at different levels for those groups redact categories differently – one group redacts a category of sensitive information, and other doesn't. Whenever this type of conflict occurs, the rule assigned to the group at the lower level takes precedence – whether the category is redacted depends on the rule for the group at the lower level.

**Note:**

Data masking rule conflicts at the same-level are resolved before conflicts at different levels.

### Viewing Data Masking Rules

View the list of existing data masking rules, and access details for individual rules.

**Note:**

The Data Masking page contains no rules until you create them. See [Creating Data Masking Rules](#) on page 879.
1. From the Cloud Guard options panel on the left, select **Data Masking**.

   The column headers provide summary information for the data masking rules:
   
   • **Masking Rule** - the name of the masking rule.
   • **Group Membership** - the name of the group to which the rule applies.
   • **Redacted Categories** - the categories that are redacted for the specified group.
   • **Target** - the target to which the rule applies.
   • **Status** - the rule's current status, **Enabled** or **Disabled**.
   • **Created** - when the rule was created.

2. To filter the list of data masking rules, start typing in the **Filter by masking rule** box.

3. To view the details for a particular data masking rule, open the **Actions** menu, and select **Edit**.

**Creating Data Masking Rules**

From the **Data Masking** page, you can create more data masking rules as needed.

**Prerequisite:** Have IAM groups in place that clearly group users in a way that maps to the categories of sensitive information which they are authorized to view. See About Data Masking on page 877.

1. From the Cloud Guard options panel on the left, select **Data Masking**.

2. Click **Create Masking Rule** above the list.
3. In the **Create Masking Rule** dialog box:
   a) In the **Masking Rule** box, enter a name for this masking rule.
   b) From the **Compartment Assignment** list, select the root compartment.
   c) From the **Group Membership** list, select the group to which you want this rule to apply.
   d) For **Targets**:
      - Select **All** to have the rule apply to all targets defined in Cloud Guard.
        Configuring the rule to apply all target instances makes it a global level rule.
      - Select **Instance** to have the rule apply only to a specific instance, then select the instance from the **Target Instance(s)** list.
        Configuring the rule to apply only to specific target instances makes it a target level rule.
   e) Under Activity Detector Recipe, select the categories of sensitive information to be redacted for the group you specified in **Group Membership**:
      - **Actor** - name or ID of an individual.
      - **Personal Identifying Information (PII)** - any information that could identify an individual, such as social security number or national health ID, email address,
      - **Protected Health Information (PHI)** - any information on an individual's health.
      - **Financial** - all information involving monetary values, such as salary or tax figures.
      - **Location** - geographic information, such as city or country, including IP addresses.
      - **Custom** - another type of sensitive information that you define.

      | Note: |
      | Some of the categories might not be available. |

      • Set **Status** as **Enabled** (default) or **Disabled**.
      • To specify tags for the rule:
        1. Click **Show Advanced Options**.
        2. Select a **Tag Namespace**.
        3. Enter a **Tag Key** and then select or enter a **Value** as they appear in the **Tag Namespace** you selected.

      | Note: |
      | If you set **Tag Namespace** to **None** (add a free-form tag), you manually enter both **Tag Key** and |

        4. To add another tag, click **Additional Tag**, then repeat the three previous substeps.

4. Click **Create**.

**Modifying Data Masking Rules**
From the **Data Masking** page, you can modify any of the masking rules that are listed.
You can change the **Status** of a masking rule (between **Disabled** and **Enabled**) directly from the **Data Masking** page. All other changes must be made by editing the details for the rule.

1. From the Cloud Guard options panel on the left, select **Data Masking**.
2. Locate a data masking rule that you want to modify, open the **Actions** menu  
3. Make any needed changes in the rule settings and click **Save**.

**Deleting Data Masking Rules**
From the **Data Masking** page, you can delete a selection of masking rules in one step, or you can delete masking rules individually, using the **Action** menu for the rule.

1. From the Cloud Guard options panel on the left, select **Data Masking**.
2. To delete a group of data masking rules in one step:
   a) Select the rules you want to delete.
   b) Click Delete, above the list.
3. To delete a single data masking rule:
   a) Locate a data masking rule that you want to modify, open the Actions menu ⚙, and select Delete.
   b) When prompted, confirm the deletion.

Managing Cloud Guard Settings
Access global settings for Cloud Guard on the Settings page.

From the Settings page, you can find the name of the reporting region that Cloud Guard is monitoring, restart an overview guided tour that you've stopped, and disable Cloud Guard.

Viewing the Reporting Region or Restarting the Guided Tour
Open the Settings page to view the name of the reporting region that Cloud Guard is monitoring.

1. From the Cloud Guard options panel on the left, select Settings.
2. On the Settings section, you can view the information for the Reporting Region in the table.
3. In the Guided Tour section, you can view the status of the guided tour of the Cloud Guard Overview page.
   The overview guide is a series of pop-ups that guide you through the features on the Overview page.
   If the Status of the guided tour is Skipped, it means that the guided tour is skipped when you navigate to the Overview page. You can restart it by clicking the Actions menu ⚙ and selecting Start Guide. The guided tour then starts on the Overview page.
   • The guided tour is enabled by default when you first log in to Oracle Cloud Guard.
   • You disable the guided tour by clicking the Stop Tour link on any of the pop-ups.
   • You restart the guided tour by navigating to the Settings page, Overview Guide section, and selecting Start Guide from the Actions menu ⚙.

Disabling Cloud Guard
You can disable Cloud Guard from the Settings page.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disabling Cloud Guard deletes all the existing targets, user-managed (cloned) detector and responder recipes, and other customizations. If you later decide to re-enable Cloud Guard, you have to manually re-create this infrastructure.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Guard can only be disabled from the reporting region. If the Disable Cloud Guard button is not available, you must switch to the reporting region to make it available.</td>
</tr>
</tbody>
</table>

The region in which you are currently working is displayed to the right near the top of your browser window. If the region name displayed is not the reporting region, drop down that list and select the reporting region.

1. From the Cloud Guard options panel on the left, select Settings.
2. On the Settings page, click Disable Cloud Guard at the top.
3. Click Yes to confirm.

What’s Next
If you decide to re-enable Cloud Guard, see Re-Enabling Cloud Guard on page 881.

Re-Enabling Cloud Guard
You can re-enable Cloud Guard after disabling.
Cloud Guard

**Prerequisite:** Disable Cloud Guard. See Disabling Cloud Guard on page 881.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you re-enable Cloud Guard, none of the targets, user-managed (cloned) detector and responder recipes, and other customizations that Cloud Guard had before it was disabled are restored, you have to manually re-create this infrastructure after re-enabling Cloud Guard.</td>
</tr>
</tbody>
</table>

1. Verify that the prerequisites are still in place.
   See Prerequisites on page 797.

2. Perform the same used to enable Cloud Guard for the first time.
   See Enabling Cloud Guard on page 808.

   If you want to get Cloud Guard up and running as quickly as possible, before you restore previous customizations, follow the "fast track" option.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you re-enable Cloud Guard in a different reporting region, it takes up to an extra 15 minutes for the enablement process to complete.</td>
</tr>
</tbody>
</table>

3. After the re-enablement process completes, restore the customizations that Cloud Guard had before it was disabled.
   See Customizing Cloud Guard Configuration on page 812.

**Processing Reported Problems**

Learn about the different tools that Cloud Guard provides to process the potential problems that it reports.

Processing problems, which is at the core of the functionality that Cloud Guard provides, involves:

- Prioritizing problems to focus on highest risks.
- Examining problem details to determine what's happening.
- Resolving each problem to ensure that risks are countered and "false alarms" do not continue in the future.

The four key pages linked below work together to help you process the problems that Cloud Guard detects.

**Overview**

- Is the first page you see when you start a Cloud Guard session.
- Shows you summary information on different types of problems that have been detected, so that you can quickly focus on resolving the most serious problems first.
- Lets you click through from the summary information to see the list of individual problems behind the summary.

To understand what you can do on the **Overview** page, see Getting Summary Information on the Overview Page on page 883.

**Problems**

- Is where a list of individual problems is displayed.
- Lets you sort and filter the problems list to focus on any subset that you want to inspect or resolve.
- When you click through from the summary information on the **Overview** page, automatically filters the list to show the individual problems behind the summary information.

To understand what you can do on the **Problems** page, see Processing and Resolving Problems on the Problems Page on page 887.

**Responder Activity Page**

- Shows the status of recent responders that have been triggered.
- When you click through from the **Responder Status** tile on the **Overview** page, automatically filters the list to show the individual responders behind the summary information.
• Lets you specify further actions to take on responders that have not completed processing.

To understand what you can do on the Responder Activity page, see Using the Responder Activity Page on page 892.

**About Cloud Guard Data Retention**
Understand how long Cloud Guard retains problem data, how to access data that’s retained, and how to preserve data for longer term availability.

Cloud Guard maintains problem data for 180 days. The console displays problem data for only the past 90 days. Cloud Guard APIs can access the data that’s from 91 to 180 days old. Other OCI services can export data outside of Cloud Guard longer term access.

- The Cloud Guard database maintains problem data, from both activity and configuration detectors, for 180 days.
- After 180 days, Cloud Guard permanently deletes problem data in the next purge.
- Purges occur on the last Saturday of each month, so some problem data actually remains in the database for a little longer than 180 days.
- The age of problem data is calculated from the date the problem was last updated.
- Cloud Guard automatically displays problem data from the past 90 days in the console.
- To access data from the past 91–180 days, use the Cloud Guard APIs to extract the data from the Cloud Guard database. See Cloud Guard APIs.
- To retain problem data beyond 180 days, use OCI Events, Notifications, and Functions services to send the data to external tools, or to an object storage within OCI. See Configuring Notifications on page 895 in the main Cloud Guard documentation, or Integrate Oracle Cloud Guard with External Systems Using OCI Events and Functions in the Oracle A-Team Chronicles.

**Getting Summary Information on the Overview Page**
Use the Overview page to quickly get a sense of the overall state of security in your environment, and quickly focus on the highest risk problems Cloud Guard has detected.

**Guided Tour**
When you first navigate to the Cloud Guard Overview page, it automatically provides a guided tour of its features. You can stop that tour at any point, and you can restart it later.

- The guided tour is enabled by default when you first log in to Oracle Cloud Guard.
- You disable the guide tour by clicking the Stop Tour link on any of the pop-ups.
- You restart the guided tour by navigating to the Settings page, Overview Guide section, and selecting Start Guide from the Actions menu.

See Viewing the Reporting Region or Restarting the Guided Tour on page 881.

**Overall Security State Statistics**
These tiles on the Overview page provide summary information on the overall state of security in your environment:

- **Security Score** - a rough estimate of how secure your system is. See Understanding the Security Score on page 884.

- **Risk Score** - a rough estimate of the risk level to your environment that's being posed by the problems that are being detected. See Understanding the Risk Score on page 884.

- **Trendline Charts** - the change over time in the Security Score number, the Problems Snapshot total number, and total number reflected in Security Recommendations. See Interpreting the Trendline Charts on page 885.

**Problem Subset Summary Statistics**
These tiles on the Overview page provide summary information on specific subsets of problems detected in your environment, and let you drill down to see the list of individual problems reflected in the summary:
Cloud Guard

- **Security Recommendations** - accesses the current list of Cloud Guard recommendations for resolving detected problems.

  See Processing Security Recommendations on page 885.

- **Problems Snapshot** - breaks down problems by severity level, and lets you drill down to see the list of problems from each severity level on the Problems page.

  See Processing Problems from the Problems Snapshot on page 886.

- **Problems by Compartment, Region, or Resource Type** - shows information on problems, broken out by compartment, region, or resource type, then lets you drill down to see the problems behind the summary, listed on the Problems page.

  See Processing Problems by Region, Compartment, or Resource Type on page 886.

- **User Activity Problems** - displays a map showing geographic origins of user activity, based on the source IP address, and lets you drill down to see details for specific problems on the Problems page.

  See Processing User Activity Problems on page 886.

- **Responder Status** - shows recent remediations that have been performed through Cloud Guard responders., and lets you drill down to see the details for each.

  See Processing Responder Status Problems on page 887.

### Understanding the Security Score

The Security Score on the Overview page provides a rough estimate of how secure your system is.

1. From the Cloud Guard options panel on the left, select **Overview**.
2. View the **Security Score** tile in the top-left corner.

   - The numeric security score indicates the percentage of resources that Cloud Guard has examined which it did not flag as potential problems.

   - A higher security score is better. A security score of 100 would mean that no problems were detected for any resources.

   **Note:**

   The security score reflects monitoring for the past 30 days. Cloud Guard updates the security score calculation continuously.

### Understanding the Risk Score

The Risk Score on the Overview page provides a rough estimate of the risk level to your environment that's posed by the problems that Cloud Guard detects.

The risk score is related to the number and severity of problems. In general, organizations with many more resources are likely to have more problems, and thus a higher risk scores. The risk score is closely related to the "potential surface area" of risk. If you have many OCI resources, you might have an excellent security score (overall assessment) and still have a higher risk score.

### How the Risk Score is Calculated

1. From the Cloud Guard options panel on the left, select **Overview**.
2. View the **Risk Score** tile in the top center:
   - The numeric risk score is updated every 15 minutes, and reflects the total number of problems that Cloud Guard has detected, the risk level of each problem, and the types of resources involved.
   
   Different categories of resources are more sensitive to security threats and that sensitivity weights the scoring. For example, users (IAM) and buckets are considered more sensitive, based on factors such as how easy they are to access and how they can be used as a target of attack.
   
   - The raw risk score that’s calculated is normalized to fall within the range of 0-9,999. A risk score of zero would mean that no problems were detected for any resources.
   
   A high risk score generally means there are a larger number of problems that have higher risk levels (HIGH or CRITICAL). If the problems and the resources involved are less sensitive, a large number of problems doesn’t produce a high risk score.
   
   - Best practice for security is to give priority to addressing the problems with the highest risk levels, that Cloud Guard detects on the most sensitive resources. Following this best practice also produces the greatest reduction in the risk score.

   **Note:**
   The risk score reflects monitoring for the past 30 days. Cloud Guard updates the risk score calculation continuously.

### Interpreting the Trendline Charts

The trendline charts show the change over time in the Security Score number, the Problems Snapshot total number, and total number reflected in Security Recommendations.

1. From the Cloud Guard options panel on the left, select **Overview**.
2. On the **Overview** page, scroll to the bottom to view the trendline charts.

   Each trendline chart tracks a number displayed in one of the tiles at the top of the **Overview** over time:

   - **Security Score Trendline** - tracks the **Security Score** number.
   - **Problems Trendline** - tracks the **Total** number in the **Problems Snapshot** tile.
   - **Remediation Trendline** - tracks the total number of open recommendations you would see if you click **View All Recommendations** on the **Security Recommendations** tile.

3. Click the **Start Date** and **End Date** controls to change the time period that's covered.
   
   The default is the last 30 days.

4. To see a breakdown of the information going into a data point, move your mouse pointer over that data point in any chart.

5. In the **New Problems Trendline** chart, click a data point to view all the new problems for that data point on the **Problems** page.

### What's Next

**Processing Security Recommendations**

Follow links from the Security Recommendations tile to implement Cloud Guard recommendations for resolving the highest priority problems that have been detected.

1. From the Cloud Guard options panel on the left, select **Overview**.
2. View the **Security Recommendations** tile in the top-right corner.

   The **Security Recommendations** tile provides links to suggestions to improve your security and risk scores. Only the top two are listed in the tile.

3. Click **View Recommendations** to see the full list.

   The full list of recommendations is displayed on the **Recommendations** page.

### What's Next
Continue with Processing Recommendations on page 892.

**Processing Problems from the Problems Snapshot**
View a breakdown of problems by severity level and drill down to see the list of problems from each severity level on the Problems page.

1. From the Cloud Guard options panel on the left, select **Overview**.
2. View the **Problems Snapshot** tile, just below the **Security Score** tile in the top-left corner.

   The **Problems Snapshot** tile shows the breakdown of detected problems by severity level in a pie chart, with the total number of problems displayed in the center. This chart is updated continuously.

Cloud Guard categorizes problems by these severity levels;

- **Critical** - the most serious problems detected, which should be your highest priority to resolve.
- **High** - the next most serious problems.
- **Medium** - problems that are a bit less serious.
- **Low** - problems that are still less serious.
- **Minor** - the least serious problems detected; they still need be resolved eventually, but can be your lowest priority.

3. To see the number of problems in that severity level, move your mouse pointer over one of the color sections.
4. Click a color section in the pie chart to open the **Problems** page, filtered to display the list of problems in that severity level.

**What's Next**
See Processing and Resolving Problems on the Problems Page on page 887.

**Processing Problems by Region, Compartment, or Resource Type**
View summary information on problems, broken out by compartment, region, or resource type, then drill down to see the problems behind the summary, listed on the Problems page.

1. From the Cloud Guard options panel on the left, select **Overview**.
2. In the **Problem by...** tile, use the **Group by** list to select the way you want problems to be summarized: **...by Region**, **...by Compartment**, or **...by Resource Type**.

   The **Problems by...** tile shows a bar chart for each region, compartment, or resource type covered. The length of the bar is proportional to the number of problems.

3. To see the number of problems in a bar, move your mouse pointer over the bar.
4. To see the actual list of problems represented in a bar, click the part of the bar representing problems of that severity level.

   The **Problems** page opens, filtered to display the list of problems represented in the part of the bar that you clicked.

**What's Next**
Continue with Processing and Resolving Problems on the Problems Page on page 887.

**Processing User Activity Problems**
View the map showing geographic origins of user activity, based on the source IP address.

1. From the Cloud Guard options panel on the left, select **Overview**.
2. Interpret the symbols in the **User Activity Problems** tile map:

   - 🌍 A cluster of problems.
   - 📍 A single problem, or multiple instances of the same problem.
3. Click links in the **User Activity Problems** map to get more information:
   - Click a large circle symbol to zoom in until you can see symbols representing individual problems.
   - To see summary information about the problem, click the symbol for an individual problem.
     A pop-up opens, showing the number of instances of the problem, the geographic origin, and a link to view all instances of the problem on the **Problems** page.
   - To see more details on the problem, click the **View** link in the pop-up.

**What's Next**

Continue with **Processing and Resolving Problems on the Problems Page** on page 887.

**Processing Responder Status Problems**

Review recent remediations that have been performed through Cloud Guard responders.

1. From the Cloud Guard options panel on the left, select **Overview**.
2. In the **Responder Status** tile, view:
   - **Total Pending** - the total number of responder actions that are on hold, pending administrative approval.
   - **Recently Performed Remediations** - summary information about remediations that have been performed through Cloud Guard responders in the past 30 days.
3. To process responder actions on the **Responder Activity** page, when the **Total Pending** number is greater than zero, click the **Total Pending** link.

   The **Responder Activity** page opens, showing the list of pending recommendations.

**What's Next**

Continue with **Using the Responder Activity Page** on page 892.

**Processing and Resolving Problems on the Problems Page**

View, sort, and filter the list of problems detected. View details for individual problems, and take actions on problems individually or in groups.

**Overview of Problems**

- A problem is action or setting on a resource that could potentially cause a security problem.
- Problems are triggered through detectors.
- The **Problems** page displays information about each problem, including:
  - Problem Name
  - Risk Level
  - Detector Type
  - Resource affected
  - Target
  - Region
  - Labels
  - Date Last Detected
- Within the **Problems** page you can filter problems by Compartment, Status, Date, Risk Level, Resource Type, Detector Type, and Region.
- You can click an individual problem to:
  - Learn more about that problem
  - View problem history
  - Take action to resolve or dismiss the problem

**Problem Lifecycle**

Here is how Cloud Guard manages problems as they occur, are processed, and reoccur.
• Problems can be:
  • Remediated – Fix using Cloud Guard responder
  • Resolved – Fixed by other process
  • Dismissed – Ignore and close
• If Cloud Guard detects an issue again for:
  • An Open (unresolved) problem, it updates the problem history, but doesn't create a new problem.
  • A previously solved problem, it reopens the issue and updates the history.
  • A previously dismissed problem, it updates the history.

**Taking Actions on Problems**
You can take the following actions on problems:

• **Remediate**: When you remediate a problem, you're telling Cloud Guard to do one of two things:
  • Either execute a responder to fix something in your environment so that the problem doesn't happen again.
  • Or automatically resolve future instances that do occur, by executing the same responder.
• **Mark as Resolved**: When you mark a problem as resolved, you're telling Cloud Guard that it was in fact a problem, but you've taken an action that handled it. If another instance of this same problem occurs, it's detected again.
• **Dismiss**: When you dismiss a problem, you're telling Cloud Guard to ignore this instance of the problem for that resource, and simply ignore it if it happens in the future. Only the problem history of the dismissed problem is updated.

The following table summarizes the differences between the three problem actions.

<table>
<thead>
<tr>
<th>Number of problems resolved at one time</th>
<th>Remediate</th>
<th>Mark as Resolved</th>
<th>Dismiss</th>
</tr>
</thead>
<tbody>
<tr>
<td>Current problem only</td>
<td>Current problem only</td>
<td>Current problem or all selected problems</td>
<td>Current problem or all selected problems</td>
</tr>
<tr>
<td>Same problem occurring later</td>
<td>Can be automatically resolved in same way; future instances appear in Responder Status tile in Overview page, but still appear in Problems page list. Automatically resolved problems can also be viewed from the Problems page by choosing the Resolved filter.</td>
<td>Will be detected and reported again; future instances appear in Problems page list.</td>
<td>Will not be detected as a new problem. Problem history's last detected time will be updated.</td>
</tr>
</tbody>
</table>

**Viewing the Problems List**
View, sort, and filter the list of problems detected.

The way that you access the Problems page determines what problems are listed there:

• **Directly** - by clicking Problems in the Cloud Guard options panel on the left. All problems are listed.
• **Indirectly** - by clicking an option on the Overview page or elsewhere, that automatically filters the problems list to display a subset of problems. Only that subset of problems is displayed.

Once you are on the Problems page, all the same options are available.

The Problems page displays this information for each problem listed:

• **Problem Name** - text identifying the problem.
Cloud Guard

- **Risk Level** - the severity of the risk associated with the problem (Critical, High, Medium, Low, Minor).
  
  For definitions of these severity levels, see Processing Problems from the Problems Snapshot on page 886.
- **Detector Type** - Activity or Configuration.
- **Resource** - an identifier for the resource affected by the problem.
- **Target** - the target in which the problem was detected.
- **Region** - the region in which the problem was detected.
- **Labels** - any labels associated with the problem.
- **Last Detected** - the date and time at which the problem was last detected.

1. From the Cloud Guard options panel on the left, select **Problems**.

   You also go to the Problems page automatically, when you click through from summary information displayed on the Overview page. In this case, the Problems page is automatically filtered to show the subset of problems that was summarized on the Overview page.

   **Note:**
   
   The retention period for problems is 90 days after which problems are deleted.

2. To change the scope for which problems are included, in the **Scope** section, below the Cloud Guard options panel on the left select a different:

   - **Compartment**.
     
     The compartment you select, and all compartments below it, are included in the scope.
   - **Status**.
     
     By default, only Open problems are listed. You can also choose to list only Resolved or Dismissed problems.
   - **Resource Type**.

3. To filter the list within the selected scope, make selections from the lists at the top of the page.

   To use the **Filters** box:

   a. Click in the Filters box.
   b. Select a parameter from the list.
   c. Click the equal sign that appears below the parameter.
   d. Select a value from the list.

   The list is immediately filtered to display only items that match your filter.

   e. To specify more filters, repeat the last four steps as needed.

   Multiple filters are ANDed.

   **Note:**
   
   When the parameter you select is Labels:
   - Type values to be matched.
   - Separate multiple values with commas.
   - Multiple values are ORed.

4. To switch the sort order for the problems, click the **Last Detected** column header.

   The default order is descending (most recently detected at top).

5. To control which columns are displayed, click **Manage Columns**, then:

   - Deselect columns you want to hide.
   - Select columns you want to display.
   - Click **Save**.
To view details for a specific problem, click the link in the Problem Name column or open the Actions menu and select View Details.

On the Details tab, select from the Resources panel on the left:

- Problem History to see a list of events and findings related to the problem.
- Responder Activity to see a list of any responders that have been triggered for the problem.

Resolving Problems
After you determine how you want to handle a particular problem, you can implement the resolution from the problem details page or the Problems page.

1. From the Cloud Guard options panel on the left, select Problems.

You can also reach the Problems page by clicking through from summary information on the Overview page. See Getting Summary Information on the Overview Page on page 883.

If you click through from summary information on the Overview page, the problems list is automatically filtered to show only the problems represented in the summary information.

2. First view the details for a particular problem to determine how you want to resolve it.

Click the link in the Problem Name column, or open the Actions menu and select View Details.

3. To remediate a problem from the Problems page:

   Note:
   Not all problem types support remediation.

   a) Open the Actions menu and select Remediate to open the Remediate dialog box.
   b) If you see policies listed in a Policy Required to Execute section, click the Enable link for each policy listed.
   c) Click Save, at the bottom of the Remediate dialog box.
   d) Confirm that you want to execute the responder to remediate the problem.

4. To mark one or more problems as resolved from the Problems page:

   a) Select the check box for each problem to be resolved.

   Note:
   You can only select a maximum of 20 problems to process at one time through the UI. If you do the processing through the Cloud Guard APIs, you can process up to 50 problems at one time.

   b) Click Mark as Resolved near the top of the page.
   c) In the Mark as Resolved confirmation, optionally add a Comment, then click Mark as Resolved.

5. To mark a single problem as resolved from the Problems page, you can also:

   a) Open the Actions menu and select Mark as Resolved.
   b) In the Mark as Resolved dialog box, enter Comments indicating how the problem was resolved.

   Note:
   While this comment is not required, it’s a best practice to make a note here as an audit trail for future reference.
   c) Click Mark as Resolved.
6. To mark a single problem as resolved from the problem's detail page:
   a) From the Problems page, click the link in the Problem Name column or open the Actions menu; and select View Details.
   b) On the problem's detail page, click Mark as Resolved near the top.
   c) In the Mark as Resolved dialog box, enter Comments indicating how the problem was resolved.
   
       Note:
       While this comment is not required, it's a best practice to make a note here as an audit trail for future reference.
   
   d) Click Mark as Resolved.

7. To dismiss one or more problems from the Problems page:
   a) Select the check box for each problem to be dismissed.
   
       Note:
       You can only select a maximum of 20 problems to process at one time through the UI. No such limits apply when the processing is done through the Cloud Guard APIs.
   
   b) Click Dismiss near the top of the page.
   c) (Optional) In the Dismiss confirmation, enter a Comment indicating how the problems were resolved.
   
       Note:
       While this comment is not required, it's a best practice to make a note here as an audit trail for future reference.
   
   d) In the Dismiss confirmation, click Dismiss.

8. To dismiss a single problem from the Problems page, you can also:
   a) Open the Actions menu and select Dismiss.
   b) In the Dismiss dialog box, enter Comments indicating how the problem was resolved.
   
       Note:
       While this comment is not required, it's a best practice to make a note here as an audit trail for future reference.
   
   c) Click Dismiss.

9. To dismiss a single problem from the problem's detail page:
   a) From the Problems page, click the link in the Problem Name column or open the Actions menu; and select View Details.
   b) On the problem's detail page, click Dismiss near the top.
   c) In the Dismiss dialog box, enter Comments indicating how the problem was resolved.
   
       Note:
       While this comment is not required, it's a best practice to make a note here as an audit trail for future reference.
   
   d) Click Dismiss, at the bottom of the Dismiss dialog box.

10. To reopen a dismissed problem:
    a) From the Problems page, click the link in the Problem Name column or open the Actions menu; and select View Details.
    b) On the problem's detail page, click Reopen near the top.
    c) Click Reopen, at the bottom of the Reopen dialog box.
**Processing Recommendations**

Use the **Recommendations** page to quickly locate and resolve the highest priority problems that Cloud Guard has detected.

The way that you access the **Recommendations** page determines what recommendations are listed there:

- **Directly** - by clicking **Recommendations** in the Cloud Guard options panel on the left. All recommendations are listed.
- **Indirectly** - by clicking an option on the **Overview** page or elsewhere, that automatically filters the recommendations list to display a subset of recommendations. Only that subset of recommendations is displayed.

Once you are on the **Recommendations** page, all the same options are available.

The **Recommendations** page displays this information for each recommendation listed:

- **Recommendations** - text identifying the recommendation.
- **Total** - the total number of instances of the problem to which the recommendation applies.

1. From the Cloud Guard options panel on the left, select **Recommendations**, or from the **Overview** page's **Security Recommendations** tile, click the **View Recommendations** link.

2. To change the scope of compartments for which recommendations are listed:
   a) From the **Scope** section below the Cloud Guard options panel on the left, drop down the **Compartment** list and select a different compartment.
   b) Deselect the check box for **Include all child compartments** to narrow the scope to only the compartment selected, excluding any compartments below it in the compartment hierarchy.

3. To view the description for a recommendation, expand the recommendation row using the **Expand** icon at the right end.

4. To process the recommendation for the instances of a problem:
   a) Open the **Actions** menu and select **View Problem**.
      The **Problems** page opens, filtered to list only problem instances for this recommendation.
   b) Follow instructions in **Resolving Problems** on page 890 to complete your processing of the recommendation.

   **Tip:**
   When multiple problems are listed, you can probably select all and process them the same way in one step, because they are all instances of the same problem.
   c) To return to the **Recommendations** page, click your browser's **Back** button.

**Using the Responder Activity Page**

View the status of recent responders that have been triggered, and specify further actions to be taken on responders that have not completed processing.

**Navigating to the Responder Activity Page**

Understand the two ways you can reach the **Responder Activity** page, and the content that each way displays.

The way that you access the **Responder Activity** page determines what responders are listed there:

- **Directly** - by clicking **Responder Activity** in the Cloud Guard options panel on the left. All responders are listed.
- **Indirectly** - by clicking in the **Responder Status** tile on the **Overview** page, that automatically filters the responders list to display a subset of responders. Only that subset of responders is displayed.

After you are on the **Responder Activity** page, all the same options are available.

**Understanding the Responder Activity Page**

Understand what information is displayed in the different columns on the **Responder Activity** page.

The column headers identify the information displayed:
• **Responder Name** - the name of the responder that was triggered. The name also describes the action to be taken.

• **Responder Activity OCID** - the Oracle Cloud Infrastructure ID (OCID) of the responder that was triggered.

• **Resource** - the name of the resource related to the problem that the response would modify.

• **Region** - the Oracle region in which the responder that was triggered. For IAM resources, or other global resources, the home region of the tenant.

• **Execution Status** - The current status of a response activity:
  - **Awaiting confirmation** - The response is pending and requires user approval before the action is taken.
  - **Failed** - The attempted response action failed.
  - **Skipped** - While awaiting confirmation, the response action a Cloud Guard operator skipped the response.

### Note:

When multiple response options are available, a Cloud Guard administrator might choose to skip one response action in preference for another.

• **Started** - The response has been initiated, but has not yet logged as completed with a resolution status.

• **Succeeded** - The response action completed successfully.

• **Execution Type** - The responder execution can be either **Manual** or **Automated**.

• **Problem Name** - The name of the problem that the responder identified.

• **Time Created** - The date and time that a response activity record was created for the related problem.

• **Time Completed** - The date and time the response activity was completed.

### Responder Execution Types and Execution Status

View the rules for how Cloud Guard resolves manual and automated execution types, and the different status values that each execution type can have.

Responders are executed either manually or automatically. Each responder **Execution Type** (Manual or Automated) can be in a different **Execution Status**:

<table>
<thead>
<tr>
<th>Execution Type</th>
<th>How Problems Are Resolved</th>
<th>Possible Execution Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manual</td>
<td>Problems are resolved manually (from the Problems page, Mark as Resolved or Dismissed).</td>
<td>• Succeeded</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Failed</td>
</tr>
<tr>
<td>Automatic</td>
<td>Problems are resolved by first getting user confirmation or input. Then problems are remediated, either by Cloud Guard or directly by the user.</td>
<td>• Awaiting confirmation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Awaiting input</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Skipped</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Succeeded</td>
</tr>
<tr>
<td></td>
<td>Problems are resolved immediately by Cloud Guard, with no user intervention.</td>
<td>• Failed</td>
</tr>
</tbody>
</table>

### Working with the Responder Activity Page

Use the Responder Activity page to monitor responder activity and take actions as needed.

1. Navigate to the **Responder Activity** page.

   From the Cloud Guard options panel on the left, select **Responder Activity**.

   You can also navigate to the **Responder Activity** page by clicking in the **Responder Status** tile on the **Overview** page. That automatically filters the responders list to display only a subset of responders.
2. To control which columns are displayed:
   a) Click **Manage Columns** at the top of the list.
   b) Select columns you want displayed.
   c) Deselect columns you want to hide.
   d) Click **Save**.

3. To change the scope of compartments for which recommendations are listed:
   a) From the **Scope** section below the Cloud Guard options panel on the left, drop down the **Compartment** list and select a different compartment.
   b) Deselect the check box for **Include all child compartments** to narrow the scope to only the compartment selected, excluding any compartments below it in the compartment hierarchy.

4. To filter the list within the set scope, make selections from the lists at the top of the page.
   To use the **Filters** box:
   a. Click in the **Filters** box.
   b. Select a parameter from the list.
   c. Click the equal sign that appears below the parameter.
   d. Select a value from the list.

   The list is immediately filtered to display only items that match your filter.
   e. To specify more filters, repeat the last four steps as needed.

   Multiple filters are ANDed.

5. To view details for a responder's problem, click the **Problem Name** link, or open the **Actions** menu and select **View Details**.
   Use the browser’s **Back** button to return to the **Responder Activity** page.

6. From the **Responder Activity** page, to specify a further action for a responder, open the **Actions** menu and select from available actions.
   The available actions depend on the responder's **Execution Status**:

<table>
<thead>
<tr>
<th>Execution Status Description</th>
<th>Possible Actions</th>
<th>Action Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Started</td>
<td>None</td>
<td>No actions are available for this execution state.</td>
</tr>
<tr>
<td>Awaiting Confirmation</td>
<td>Execute</td>
<td>Responder will take the action indicated in the <strong>Responder Name</strong>. For example, if the Responder Name is &quot;Make Bucket Private,&quot; selecting <strong>Execute</strong> makes the public bucket private.</td>
</tr>
<tr>
<td>Awaiting Input</td>
<td>View Problem Details</td>
<td>Opens the details page for the problem. From that page, you can execute the responder, or skip execution.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Execution Status Description</th>
<th>Possible Actions</th>
<th>Action Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Awaiting Confirmation</td>
<td>Skip Execution</td>
<td>Responder will <em>not</em> take the action indicated in the <strong>Responder Name</strong>. For example, if the Responder Name is &quot;Make Bucket Private,&quot; selecting <strong>Skip Execution</strong> leaves the bucket public.</td>
</tr>
<tr>
<td>Awaiting Input</td>
<td>Execute</td>
<td>Responder will take the action indicated in the <strong>Responder Name</strong>. For example, if the Responder Name is &quot;Make Bucket Private,&quot; selecting <strong>Execute</strong> makes the public bucket private.</td>
</tr>
<tr>
<td>Execution Status</td>
<td>Execution Status Description</td>
<td>Possible Actions</td>
</tr>
<tr>
<td>------------------</td>
<td>------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>Skip Execution</td>
<td>Responder will not take the action indicated in the Responder Name. For example, if the Responder Name is &quot;Make Bucket Private,&quot; selecting Skip Execution leaves the bucket public.</td>
<td></td>
</tr>
<tr>
<td>Failed</td>
<td>Cloud Guard tried to execute a manual remediation to the problem, but that failed.</td>
<td>View Problem Details</td>
</tr>
<tr>
<td>Skipped</td>
<td>Cloud Guard skipped the action on this problem</td>
<td>View Problem Details</td>
</tr>
<tr>
<td>Succeeded</td>
<td>Cloud Guard has successfully resolved the problem.</td>
<td>View Problem Details</td>
</tr>
</tbody>
</table>

### Configuring Notifications

Use the Events and Notifications services to send notifications, whenever Cloud Guard detects a problem for which you want to be notified.

**Prerequisite:** If you want to configure notifications to be sent through Slack, create a Webhook for the Slack channel to receive the notifications before proceeding with the steps in the "Configure Notifications..." that follows. See Slack documentation.

**Note:**

If you are processing problems entirely within Cloud Guard, you do not need to configure notifications.

Cloud Guard provides a notification responder, Cloud Event, that can emit problem details to the Events service. The Cloud Event responder rule is part of the Responder recipe, which needs to be attached to a corresponding target or...
targets. The Cloud Event rule is enabled by default. The Cloud Event responder does not require other IAM policies and is configured to execute automatically.

Emitting from Cloud Event to the Events service allows for integration with the Notifications service, which can push notifications to:

- Email
- Slack
- Oracle Cloud Infrastructure Functions

Notifications can be sent for any of these event types in Cloud Guard:

- **Problem detected** – when Cloud Guard detects a potential security issue that appears on the Problems page. These are the details for the different actions that can occur under this event type:

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Action Leading to Event</th>
<th>Status Field in Event Details</th>
<th>Reason Field in Event Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Detected-Problem</td>
<td>New Problem Created</td>
<td>OPEN</td>
<td>New Problem detected by CloudGuard</td>
</tr>
<tr>
<td>Detected-Problem</td>
<td>Problem Updated</td>
<td>OPEN</td>
<td>Existing Problem updated by CloudGuard</td>
</tr>
<tr>
<td>Detected-Problem</td>
<td>Problem Reopened by Cloud Guard</td>
<td>OPEN</td>
<td>Existing Problem re-opened by CloudGuard</td>
</tr>
<tr>
<td>Detected-Problem</td>
<td>Problem Reopened By User</td>
<td>OPEN</td>
<td>Existing Problem re-opened by User</td>
</tr>
</tbody>
</table>

- **Problem remediated** - when a responder that is configured to automatically remEDIATE a detected problem performs the remediation. These are the details for the different actions that can occur under this event type:

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Action Leading to Event</th>
<th>Status Field in Event Details</th>
<th>Reason Field in Event Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remediated-Problem</td>
<td>User Marked the problem as Resolved</td>
<td>RESOLVED</td>
<td>Problem marked as RESOLVED by &lt;User OCID&gt;</td>
</tr>
<tr>
<td>Remediated-Problem</td>
<td>Problem Dismissed</td>
<td>RESOLVED</td>
<td>Problem marked as DISMISSED by &lt;User&gt;</td>
</tr>
<tr>
<td>Remediated-Problem</td>
<td>Problem Auto Resolved</td>
<td>RESOLVED</td>
<td>Problem is auto resolved by CloudGuard</td>
</tr>
<tr>
<td>Remediated-Problem</td>
<td>User does manual problem remediation / Responder Rules configured for Automatic Remediation</td>
<td>RESOLVED</td>
<td>Problem remediated by CloudGuard</td>
</tr>
</tbody>
</table>

- **Problem threshold reached** - when Cloud Guard discovers that certain threshold limits are reached, because of excessive audit signals from services such as VCN or Identity.

**Note:**

You must set up Events and Notifications from your Cloud Guard Reporting Region, which aggregates problems from the monitored regions and send out the Cloud Event from the Reporting Region.

To receive notifications when a responder recipe is triggered, you must:

1. For OCI Functions, create the function code to call and place the function application in the compartment from which it’s to be called.
2. In Cloud Guard, ensure that the Cloud Event rule is enabled for the responder recipe.
3. For email or Slack notifications, in the Notification service, create a Topic and a Subscription to that topic.
4. In the Events service, configure a rule that specifies the Action to take.

What’s Next
To set up notifications through email or Slack, continue with Notifying through Email or Slack on page 897.
To use OCI Functions to relay notification information to another service, see Notifying through OCI Functions on page 899.

Notifying through Email or Slack
Use the Events and Notifications services to send notifications through email or Slack, whenever Cloud Guard detects a problem for which you want to be notified.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To add notifications for more than one event type, perform all the following steps for the first notification, then repeat steps 3 and 4 for each additional notification.</td>
</tr>
</tbody>
</table>

1. In Cloud Guard, ensure that the Cloud Event rule is enabled for the responder recipe for which you want to receive notifications.
   a) From the Cloud Guard options panel on the left, select Responder Recipes.
   b) Click the name of the recipe for which you want to configure notifications.
   c) On the detail page for the responder recipe, in the Responder Rules section, locate the row for the Cloud Events rule.
   d) If the entry in the Status column for the Cloud Events rule is Disabled:
      1. Open the Actions menu and select Edit.
      2. In the Edit Responder Rule dialog box, drop down the Status list and select Enabled.
      3. Click Save.
2. In Cloud Guard, ensure that the target for which you want to receive notifications has the responder recipe that you just checked added, with automatic execution enabled.
   a) From the Cloud Guard options panel on the left, select Targets.
   b) On the Targets page, in the Target Name column, click the name of the target about which you want to receive notifications.
   c) On the details page for that target, under Resources on the left, click Detector Recipes.
      • If the name of the responder recipe appears under Recipe Name, it is already added.
      • If there is nothing listed under Recipe Name, click Add Recipe and select the responder recipe to add.
      • If a different responder recipe appears under Recipe Name:
         1. Open the Actions menu and select Remove, then confirm the removal.
         2. Click Add Recipe and select the responder recipe to add.
   d) Ensure that the Cloud Event responder rule is set to execute automatically:
      1. Under Recipe Name, click the link for the responder recipe.
      2. On the details page for the responder recipe, in the Responder Rules section, locate the row for Cloud Event responder rule.
      3. In that row, open the Actions menu and select Edit.
      4. In the Configure Responder Rule dialog box, Setting section, check the Rule Trigger setting.
      5. If Rule Trigger is set to Ask me before executing rule:
         a. Select Execute Automatically.
         b. Select the CONFIRM EXECUTE AUTOMATICALLY check box.
         c. Click Save.
3. In the Notifications service, create a topic.
   a) From the Oracle Cloud menu, select Developer Services, then click Application Integration, then click Notifications.
   b) On the Topics page, click Create Topic.
   c) In the Create Topic dialog box:
      1. Enter a Name for the topic.
      2. (Optional) Enter a Description for the topic.
      3. (Optional) Specify tagging information.
      4. Click Create.

     The topic you created appears in the list on the Topics page.

4. Create a subscription to the topic.
   a) On the Topics page, in the Name column, click the name of the topic you created.
   b) On the details page for the topic, under Resources, click Create Subscription.
   c) In the Create Subscription dialog box:
      1. Set Protocol for email or Slack notification:
         - Email:
            a. Set Protocol to Email.
            b. Enter the email address that should receive the notifications.
         - Slack:
            a. Set Protocol to Slack.
            b. For URL, enter the URL for your Slack Webhook.
      2. Specify tag information for one or more tag namespaces.
         Click Additional Tag to specify tag information for another tag namespace.
      3. Click Create.

     The details page for the subscription you just created appears:
     - The large "T" icon is orange, with "Pending" under it.
     - The Subscription Information tab displays "Pending confirmation" just below the tab title.

4. When you receive the subscription confirmation email, click the Confirm Subscription link in the body of the message.

     An Oracle Cloud Infrastructure page appears in your browser, indicating that your subscription is confirmed.

     On the details page for the subscription you created:
     - The large "T" icon is green, with "Active" under it.
     - The Subscription Information tab no longer displays "Pending confirmation" at the top.
5. In the Events service, configure a rule to specify conditions under which a notification is sent.
   a) Ensure that you are in the reporting region of the tenancy where the responder recipe is active.
      To see the reporting region, from the Cloud Guard options panel on the left select **Settings**.
      To see the region that you are in, drop down the regions list at the top of the page.
   b) From the Oracle Cloud menu, select **Observability & Management**, then click **Events Service**.
   c) Under **List Scope**, ensure that the **Compartment** selected is either the compartment where the resource exists, or a parent of that compartment.
   d) Click **Create Rule**.
   e) On the **Create Rule** page, enter a **Display Name** for the rule.
   f) (Optional) Enter a **Description** for the rule.
   g) In the **Rule Conditions** section:
      - Set **Condition** to **Event Type**.
      - Set **Service Name** to **Cloud Guard**.
      - Set **Event Type** to the type of event for which you want to be notified:
        - **Detected - Problem**
        - **Remediated - Problem**
        - **Target - Information**
   h) To add another rule condition, in the **Rule Conditions** section, click **Another Condition**.
      
      **Note:**
      Multiple rules are ANDed to limit the scope for which a notification is sent. To trigger a notification, all conditions must be true.

1. Set first item, for example, to **Attribute**.
2. Set second item to the parameter on which you want to filter.
   For example, if first item is **Attribute**, you might set **Attribute Name** to **riskLevel**.
3. Set third item to the value for the parameter on which you want to filter.
   For example, if you set first item to **Attribute**, and then set **Attribute Name** to **riskLevel**, you might set third item to **Critical**.
4. (Optional) To add another rule condition to further limit the scope for which a notification is sent, click **Another Condition**, then repeat the preceding substeps.
   i) In the **Actions** section:
      1. Set **Action Type** to **Notifications**.
      2. Select the **Notifications Compartment**.
      3. For **Topic**, select the name of the Notifications topic you created.
   j) Click **Create Rule** at the bottom of the page.
      The details page for the rule you created appears.

6. Watch for activity for the Cloud Event responder rule with status **Succeeded**, on either the **Problems** or **Responder Activity** page.
   This activity confirms that the Cloud Event responder rule is being triggered and it is creating events for that problem in the Events service.

**Notifying through OCI Functions**
Use the Events and Notifications services to send notifications through Oracle Cloud Infrastructure Functions, whenever Cloud Guard detects a problem for which you want to be notified.
1. Familiarize yourself with Oracle Functions.
   If you are working with Oracle Functions for the first time:
   
   • Review the Overview of Functions documentation.
   • Ensure that your environment is set up correctly, as described in Preparing for Oracle Functions.
   • In particular, review the tasks involved in Creating Applications and Creating and Deploying Functions.
   • Check out the available Oracle Functions Quick Start Guides.

2. Examine the data contained in the event envelope for a Cloud Guard problem.
   The following sample shows key pieces of information in bold:

   ```json
   {
     "eventType": "com.oraclecloud.cloudguard.problemdetected",
     "cloudEventsVersion": "0.1",
     "eventTypeVersion": "2.0",
     "source": "CloudGuardResponderEngine",
     "eventTime": "2020-09-21T18:21:49Z",
     "contentType": "application/json",
     "data": {
       "compartmentId": "<compartment_OCID>",
       "compartmentName": "<compartment_name>",
       "resourceName": "Object Storage bucket is encrypted with Oracle-managed key",
       "resourceId": "ocid1.cloudguardproblem.oc1.iad.<unique_resource_id>"
     },
     "additionalDetails": {
       "tenantId": "<oci_tenant_id>",
       "problemDescription": "Encryption of storage buckets provides an additional level of security on your data. Management of encryption keys is critical to protecting and accessing protected data. Some customers want to identify storage buckets encrypted Oracle-managed keys in order to apply their own key lifecycle management to the bucket."
     },
     "riskLevel": "MINOR",
     "problemRecommendation": "Assign a vault key to this bucket",
     "status": "OPEN",
     "problemType": "CONFIG_CHANGE",
     "resourceName": "<oci_resource_name>",
     "resourceId": "<resource_ocid>",
     "resourceType": "Bucket",
     "targetId": "ocid1.cloudguardtarget.oc1.iad.<unique_target_id>"
   }
   ```
3. Create the function application code.

You can use Python, Java, and several other languages to develop your function. This example uses Python.

a) The Event service invokes this function. You can obtain event data by using a code fragment like this:

```python
def handler(ctx, data: io.BytesIO = None):
    funDataStr = data.read().decode('utf-8')
    funData = json.loads(funDataStr)
```

The `ctx` parameter passes the function configuration, and the `data` parameter passes the data.

b) Obtain the function configuration from the `ctx` parameter of the `handler` function:

```python
config = ctx.Config()
```

c) To invoke OCI APIs from inside the function, use a resource principal:

```python
ociResPrncplSigner = oci.auth.signers.get_resource_principals_signer()
ociObjStoreSvc = oci.object_storage.ObjectStorageClient(config={},
    signer=ociResPrncplSigner)
```

d) Use standard JSON techniques to extract the values of various fields from within the `data` element.

e) Then use other standard manipulation techniques to perform transformations and analyses to support whatever logic you require to complete the function.

f) (Optional) Invoke APIs for external services from inside the function to integrate with external systems, for example:

- If the `riskLevel` is `CRITICAL`, call the public APIs for a service management system to open a ticket, with relevant details populated from other fields in the event envelope for the problem.
- To send the entire data across for further analysis, call an external SIEM system's APIs.
- Use OCI APIs to enrich the data before sending to an external SIEM.

If you are using JSON, the resulting function code might look something like this:

```python
import io
import sys
import oci
import json

from fdk import response

# This Python function creates an object in a Object Store Bucket when
# triggered by OCI Events Service with a Cloud Problem as input. The JSON
# format data for 'additionalDetails' is simply written out as content of
# the
# created object. This function takes two parameters:
#
# OCI_CMPT_ID - Compartment OCID of the OCI Bucket
# OCI_OBJ_BUCKET_NAME - Name of the OCI Bucket where the object will be
# created
#
# Object names comprise of two parts - resource Id and event Id
#
def handler(ctx, data: io.BytesIO = None):
    try:
        respData = {}

        # Get Config
        ctxConfig = ctx.Config()

        # Get Data
        funDataStr = data.read().decode('utf-8')

        # Load JSON from String
        funData = json.loads(funDataStr)

        respData['RECVD_DATA'] = funDataStr
```
# Read the configuration parameters
ociCmptID = ctxConfig['OCI_CMPT_ID']
ociBucketName = ctxConfig['OCI_OBJ_BUCKET_NAME']

# Create Object name string
ociObjName = funData['data']['resourceId'] + '-' +
funData['eventID']

# Create signer and Object Store API client
ociResPrncplSigner =
oci.auth.signers.get_resource_principals_signer()
ociObjStoreSvc = oci.object_storage.ObjectStorageClient(config={},
signer=ociResPrncplSigner)

# Get 'additionalDetails' field from data
cgProblem = funData['data']['additionalDetails']

# Call function to create the object
objStoreRespStatus = storeToOCIObjStore(ociObjStoreSvc, ociCmptID,
ociBucketName, ociObjName, json.dumps(cgProblem))

respData['OBJ_STORE_RESP_STATUS'] = objStoreRespStatus
except Exception as e:
    respData['EXCEPTION_MESSAGE'] = str(e)
    respData['EXCEPTION_MESSAGE_CLASS'] = str(e.__class__)
    sys.stderr.write(json.dumps(respData))

def storeToOCIObjStore(ociObjStoreSvc, cmptID, bucketName, objName,
    dataStr):
    objStoreNS = ociObjStoreSvc.get_namespace(compartment_id=cmptID).data
    objBody = io.BytesIO(dataStr.encode('utf-8'))
    objStoreResp = ociObjStoreSvc.put_object(objStoreNS, bucketName,
        objName, objBody)
    return objStoreResp.status

4. Create an application for your function and locate it in the compartment from which you plan to call the function.
   See Creating Applications.

5. In Cloud Guard, ensure that the Cloud Event rule is enabled for the responder recipe for which you want to
   receive notifications.
   a) From the Cloud Guard options panel on the left, select Responder Recipes.
   b) Click the name of the recipe for which you want to configure notifications.
   c) On the detail page for the responder recipe, in the Responder Rules section, locate the row for the Cloud
      Events rule.
   d) If the entry in the Status column for the Cloud Events rule is Disabled:
      1. Open the Actions menu ; and select Edit.
      2. In the Edit Responder Rule dialog box, drop down the Status list and select Enabled.
      3. Click Save.
6. In Cloud Guard, ensure that the target for which you want to receive notifications has the responder recipe that you just checked added, with automatic execution enabled.
   a) From the Cloud Guard options panel on the left, select Targets.
   b) On the Targets page, in the Target Name column, click the name of the target about which you want to receive notifications.
   c) On the details page for that target, under Resources on the left, click Responder Recipes.
      • If the name of the responder recipe appears under Recipe Name, it is already added.
      • If nothing is listed under Recipe Name, click Add Recipe and select the responder recipe to add.
      • If a different responder recipe appears under Recipe Name:
        1. Open the Actions menu and select Remove, then confirm the removal.
        2. Click Add Recipe and select the responder recipe to add.
   d) Ensure that the Cloud Event responder rule is set to execute automatically:
      1. Under Recipe Name, click the link for the responder recipe.
      2. On the details page for the responder recipe, in the Responder Rules section, locate the row for Cloud Event responder rule.
      3. In that row, open the Actions menu and select Edit.
      4. In the Configure Responder Rule dialog box, Setting section, check the Rule Trigger setting.
      5. If Rule Trigger is set to Ask me before executing rule:
         a. Select Execute Automatically.
         b. Select the CONFIRM EXECUTE AUTOMATICALLY check box.
         c. Click Save.
7. In the Events service, configure a rule to specify conditions under which a notification is sent.
   a) Ensure that you are in the reporting region of the tenancy where the responder recipe is active.
      To see the reporting region, from the Cloud Guard options panel on the left, select Settings.
      To see the region that you are in, drop down the regions list at the top of the page.
   b) From the Oracle Cloud menu, select Observability & Management, then click Events Service.
   c) Under List Scope, ensure that the Compartment selected is either the compartment where the resource exists, or a parent of that compartment.
   d) Click Create Rule.
   e) On the Create Rule page, enter a Display Name for the rule.
   f) (Optional) Enter a Description for the rule.
   g) In the Rule Conditions section:
      • Set Condition to Event Type.
      • Set Service Name to Cloud Guard.
      • Set Event Type to the type of event for which you want to be notified:
        • Detected - Problem
        • Remediated - Problem
        • Target - Information
   h) To add another rule condition, in the Rule Conditions section, click Another Condition.

   [Note:]
   Multiple rules are ANDed to limit the scope for which a notification is sent. To trigger a notification, all conditions must be true.

   1. Set first item, for example, to Attribute.
   2. Set second item to the parameter on which you want to filter.
      For example, if first item is Attribute, you might set Attribute Name to riskLevel.
   3. Set third item to the value for the parameter on which you want to filter.
      For example, if you set first item to Attribute, and then set Attribute Name to riskLevel, you might set third item to Critical.
   4. (Optional) To add another rule condition to further limit the scope for which a notification is sent, click Another Condition, then repeat the preceding substeps.
   i) In the Actions section:
      1. Set Action Type to Functions.
      2. Select the Functions Compartment that contains the function application.
      3. Select the Function Application that contains the function that you want to run.
         If you see "None available in selected compartment," the function application you created is not found in the Functions Compartment that you selected.
      4. Select the Function to run.
   j) Click Create Rule at the bottom of the page.
      The details page for the rule you created appears.

8. Watch for activity for the Cloud Event responder rule with status Succeeded, on either the Problems or Responder Activity page.
   This activity confirms that the Cloud Event responder rule is being triggered and is creating events for that problem in the Events service.

Troubleshooting Cloud Guard

Identify the causes and fixes for common problems with the Oracle Cloud Guard service.
No Problems Detected
Fix enablement problems that prevent Cloud Guard from detecting problems.

You have completed the steps in Enabling Cloud Guard on page 808, and no problems start to appear on the Problems page after about 30-60 minutes.

Ensure that a Detector Recipe Is Added to the Target
Steps in Enabling Cloud Guard on page 808 force you to define a target, by specifying Compartments To Monitor in the OCI tenancy. If you didn't also select either an OCI Configuration Detector Recipe or an OCI Activity Detector Recipe, then no detectors were added to the target. Without adding at least one detector to the target, no problems can be reported.

See Modifying Recipes Added to a Target on page 821.

Some Categories of Problems Not Detected
Fix enablement problems that prevent Cloud Guard from detecting all categories of problems.

You have completed the steps in Enabling Cloud Guard on page 808, and problems are appearing on the Problems page, but an entire category of problems still is not appearing.

Ensure that a Detector Recipe Is Added to the Target for Each Category
If you skipped select a detector recipe for particular problem category in Enabling Cloud Guard on page 808, then a detector recipe for that problem category is not added to the target. If a detector for a particular problem category is not added to the target, Cloud Guard doesn't detect problems for that category.

See Modifying Recipes Added to a Target on page 821.

No Events Generated
Fix enablement problems that prevent Cloud Guard from generating events.

You have completed the steps in Enabling Cloud Guard on page 808, and problems are appearing on the Problems page, but no events are being generated for the Notifications service to pick up (see Configuring Notifications on page 895).

Ensure that the OCI Responder Recipe Is Added to the Target
Steps in Enabling Cloud Guard on page 808 force you to define a target, by specifying Compartments To Monitor in the OCI tenancy. If you didn't also select the OCI Responder Recipe, then the Cloud Event responder rule in the OCI Responder Recipe is unable to send events to the Notifications service.

See Modifying Recipes Added to a Target on page 821.

Can't Process PSM Problems
You can't dismiss or resolve problems related to the PaaS Service Manager (PSM) compartment (named ManagedCompartmentForPaaS).

You have completed the steps in Enabling Cloud Guard on page 808 and all categories of problems are appearing on the Problems page. You are able to dismiss or resolve all problems, except problems related to the PSM compartment.

For more information on the ManagedCompartmentForPaaS compartment, see Resources Created in Your Tenancy by Oracle.

Create a Support Ticket to Provide Special Privileges
The PSM service controls access to the PSM compartment in your OCI tenancy, so the policies required by Cloud Guard do not affect your access through Cloud Guard to resources in the PSM compartment. To obtain the privileges necessary to dismiss or resolve problems related to the PSM compartment:
1. Create an Oracle support ticket.
2. Provide the following details on how these privileges necessary for Cloud Guard:
   - OCI tenancy ID
   - OCIDs of the Cloud Guard problems that you are trying to dismiss
3. The PSM and the OCI Identity team then add the following policy:
   
   ```plaintext
   allow group administrators to use cloud-guard-problems in compartment managedcompartmentforpaas
   ```
   
   **Note:**
   This is a special compartment, for which the ability to resolve Cloud Guard problems can only be granted to an administrative group.

4. After the support team informs you that they’ve added the policy, you can dismiss and resolve problems with the PSM compartment.

### Cloud Guard Policies

To control who has access to Oracle Cloud Guard, and the type of access for each group of users, you must create policies.

By default only the users in the **Administrators** group have access to all Cloud Guard resources. For everyone else who’s involved with Cloud Guard, you must create new policies that assign them proper rights to Cloud Guard resources.

For a complete list of Oracle Cloud Infrastructure policies, see [policy reference](#).

### Resource Types

Data Catalog offers both aggregate and individual resource types for writing policies.

You can use aggregate resource types to write fewer policies. For example, instead of allowing a group to manage `data-catalogs` and `data-catalog-data-assets`, you can have a policy that allows the group to manage the aggregate resource type, `data-catalog-family`. 

Cloud Guard

<table>
<thead>
<tr>
<th>Aggregate Resource Type</th>
<th>Individual Resource Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>cloud-guard-family</td>

<td>cloud-guard-targets</td>
</tr>
<tr>
<td></td>
<td>cloud-guard-user-preferences</td>
</tr>
</tbody>
</table>

The APIs covered for the aggregate `cloud-guard-family` resource type cover every API listed under "Individual Resource Types" in the preceding table.

For example,

```plaintext
allow group cloudguard-admins to manage cloud-guard-family in compartment <x>
```

...is the same as writing 20 policies with this format:

```plaintext
allow group cloudguard-admins to manage <resource_type> in compartment <x>
```

**Details for Verbs + Resource-Type Combinations**

Tables of permissions and API operations covered by each verb for Cloud Guard.

The level of access is cumulative as you go from inspect > read > use > manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access. For more information on permissions in Oracle Cloud Infrastructure, see Permissions.

**cloud-guard-condition-metadata-types**

The APIs covered for the `cloud-guard-condition-metadata-types` resource-type are listed here. The APIs are displayed alphabetically for each permission.

### Creating a Policy

Steps to create a policy to support Cloud Guard REST API calls.

Here's how you create a policy:

1. Open the Console navigation menu and select **Identity & Security**, then click **Identity**, then click **Policies**.
2. Click **Create Policy**.
3. Enter a name and description for the policy.
4. In the **Statement** field, enter a policy rule in the following format:
   
   ```allow service cloudguard to <verb> <resource_type> in <compartment or tenancy details>```

5. Click **Create**.

For more information on creating policies, see **how policies work** and **policy reference**.
Chapter 14

Compliance Documents

This chapter explains how to view and download compliance documents.

Overview of Compliance Documents

The Oracle Cloud Infrastructure Compliance Documents service lets you view and download compliance documents that you could previously access only by submitting a request to the Elevated Support Portal.

Note:
Compliance Documents is not available in Oracle Cloud Infrastructure Government Cloud realms.

Types of Compliance Documents

When viewing compliance documents, you can filter on the following types:

- **Audit.** A general audit report.
- **Bridge Letter (BridgeLetter).** A bridge letter. Bridge letters provide compliance information for the period of time between the end date of an SOC report and the date of the release of a new SOC report.
- **Certificate.** A document indicating certification by a particular authority, with regard to certification requirements and examination results conforming to said requirements.
- **SOC3.** A Service Organization Controls 3 audit report that provides information relating to a service organization's internal controls for security, availability, confidentiality, and privacy.
- **Other.** A compliance document that doesn't fit into any of the preceding, more specific categories.

If you need to further narrow down what documents are displayed, you can combine the type filter with the environment filter.

Types of Environments

The environments, or business pillars or platforms, to which the documents belong include:

- **OCI.** Oracle Cloud Infrastructure is a set of complementary cloud infrastructure services that let you build and run applications and services in a highly available hosted environment.
- **PAAS.** Oracle Platform as a Service (PaaS) provides various platforms to build and deploy applications within the public, private, or hybrid cloud.

Regions and Availability Domains

You can use the Compliance Documents service in all regions. For a list of supported regions, see Regions and Availability Domains on page 208.
Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. However, you cannot specifically access Compliance Documents by using the API or Command Line Interface (CLI). Compliance Documents does not have public API, SDK, or CLI support at this time.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

Viewing and Downloading Compliance Documents

This section describes how to view compliance documents. The Console displays documents available to your tenancy for the currently selected region.

To view a list of all compliance documents

1. Open the navigation menu, click Identity & Security, and then click Compliance.
2. The Compliance Documents page displays all documents you have permission to view. From this page, you can do the following:
   - Filter. You can filter documents by environment or by type.
   - Sort. You can sort documents by name, type, or creation date.
   - Download. You can download documents to your local computer.

To download a compliance document

1. Open the navigation menu, click Identity & Security, and then click Compliance.
2. The Compliance Documents page displays all documents you have permission to view.
3. Next to the name of the document, click Download.
4. Review the terms of use.
5. When you're ready, select the I have reviewed and accept these terms and conditions check box, and then click Download File.

To sort a list of compliance documents

1. Open the navigation menu, click Identity & Security, and then click Compliance.
2. By default, the list displays documents according to the document name, in alphabetical order. To sort the list another way, do one of the following:
   - Click Name. The list sorts alphabetically, according to the summary of the announcement. If you begin by viewing the default sort order, the sort order will change to show documents in reverse alphabetical order by name.
   - Click Type. The list sorts according to the type of the document, in alphabetical order by type.
   - Click Created. The list sorts according to the date and time the document was created.
3. To sort the list again, repeat the previous step.
Chapter 15

Compute

This chapter explains how to launch, access, manage, and terminate compute instances.

## Compute

Use the Compute service to create bare metal compute or virtual machine (VM) instances to deploy and run your applications.

### Get Started
- Tutorial: Create your first Linux instance
- Tutorial: Create your first Windows instance
- Compute shapes

### Images and OSs
- Create a custom image
- Export and import images across tenancies or regions
- Use a platform image

### Connect to Instances
- Connect to an instance
- Manage SSH key pairs

### Manage Capacity
- Reserve capacity
- Use preemptible capacity
- Scale the cores and memory for an instance
- Create instances with burstable performance

### Manage Groups of Instances
- Automatically scale groups of instances (autoscaling)
- Create templates for instances (instance configurations)
- Manage instances in a group (instance pools)

### Support
- Get help and contact Support
- Create a service request

### Developer Tools
- SDKs, CLI, and API for Compute
- Overview of SDKs and the CLI
- Cloud Shell

### Troubleshooting
- Troubleshoot using a serial or VNC console connection
- Troubleshoot Oracle Cloud Agent plugins
- Display the serial console history
- Send a diagnostic interrupt

### Community
- Oracle Cloud Infrastructure blog
- Cloud infrastructure community forum
Overview of the Compute Service

Oracle Cloud Infrastructure Compute lets you provision and manage compute hosts, known as *instances*. You can create instances as needed to meet your compute and application requirements. After you create an instance, you can access it securely from your computer, restart it, attach and detach volumes, and terminate it when you're done with it. Any changes made to the instance's local drives are lost when you terminate it. Any saved changes to volumes attached to the instance are retained.

Oracle Cloud Infrastructure offers both bare metal and virtual machine instances:

- **Bare Metal**: A bare metal compute instance gives you dedicated physical server access for highest performance and strong isolation.
- **Virtual Machine**: A virtual machine (VM) is an independent computing environment that runs on top of physical bare metal hardware. The virtualization makes it possible to run multiple VMs that are isolated from each other. VMs are ideal for running applications that do not require the performance and resources (CPU, memory, network bandwidth, storage) of an entire physical machine.

An Oracle Cloud Infrastructure VM compute instance runs on the same hardware as a bare metal instance, leveraging the same cloud-optimized hardware, firmware, software stack, and networking infrastructure.

Be sure to review *Best Practices for Your Compute Instance* on page 931 for important information about working with your Oracle Cloud Infrastructure Compute instance.

Oracle Cloud Infrastructure uses *Oracle Ksplice* to apply important security and other critical kernel updates to the hypervisor hosts without a reboot. Oracle Cloud Infrastructure can apply these patches transparently without the need to pause any VMs, and all hypervisor hosts support this capability. For more information, see *Installing and Running Oracle Ksplice* on page 987.

Compute is Always Free eligible. For more information about Always Free resources, including capabilities and limitations, see *Oracle Cloud Infrastructure Free Tier* on page 166.

Instance Types

When you create a Compute instance, you can select the most appropriate type of instance for your applications based on characteristics such as the number of CPUs, amount of memory, and network resources.

Shape Types

Oracle Cloud Infrastructure offers a variety of *shapes* that are designed to meet a range of compute and application requirements:

- **Standard shapes**: Designed for general purpose workloads and suitable for a wide range of applications and use cases. Standard shapes provide a balance of cores, memory, and network resources. Standard shapes are available with Intel, AMD, and Arm-based processors.
- **DenseIO shapes**: Designed for large databases, big data workloads, and applications that require high-performance local storage. DenseIO shapes include locally-attached NVMe-based SSDs.
- **GPU shapes**: Designed for hardware-accelerated workloads. GPU shapes include Intel or AMD CPUs and NVIDIA graphics processors.
- **High performance computing (HPC) shapes**: Designed for high-performance computing workloads that require high frequency processor cores and cluster networking for massively parallel HPC workloads.
- **Optimized shapes**: Designed for computing workloads that require high frequency processor cores. Optimized shapes are also suitable for HPC workloads that require high-performance coupled with low latency. Optimized shapes support cluster networking.

For more information about the available bare metal and VM shapes, see *Compute Shapes* on page 973, *Bare Metal Instances, Virtual Machines, and Virtual Machines and Bare Metal (GPU)*.

Flexible Shapes

Flexible shapes let you customize the number of OCPUs and the amount of memory allocated to an instance. When you create a VM instance using a flexible shape, you select the number of OCPUs and the amount of memory...
that you need for the workloads that run on the instance. The network bandwidth and number of VNICs scale proportionately with the number of OCPUs. This flexibility lets you build VMs that match your workload, enabling you to optimize performance and minimize cost.

**Capacity Types**

You can choose the type of host capacity to use when launching compute instances. On-demand capacity is the default, but you can use preemptible capacity, capacity reservations, or dedicated capacity instead.

- **On-demand capacity**: Pay for only the compute capacity that you use. With on-demand capacity, you pay for compute capacity by the second, and you pay only for the seconds that your instances are running. Capacity availability is not guaranteed when launching large workloads.

- **Preemptible capacity**: Preemptible capacity allows you to save money by using preemptible instances to run workloads that only need to run for brief periods or that can be interrupted when the capacity is reclaimed. Preemptible instances behave the same as regular compute instances, but the capacity is reclaimed when it's needed elsewhere, and the instances are terminated. For more information, see Preemptible Instances on page 1043.

- **Reserved capacity**: Reserve capacity for future usage, and ensure that capacity is available to create compute instances whenever you need them. The reserved capacity is used when you launch instances against the reservation. When these instances are terminated, the capacity is returned to the reservation, and the unused capacity in the reservation increases. Unused reserved capacity is metered differently than used reserved capacity. For more information, see Capacity Reservations.

- **Dedicated capacity**: Run VM instances on dedicated servers that are a single tenant and not shared with other customers. This feature lets you meet compliance and regulatory requirements for isolation that prevent you from using shared infrastructure. You can also use this feature to meet node-based or host-based licensing requirements that require you to license an entire server. For more information, see Dedicated Virtual Machine Hosts on page 1051.

Service limits and compartment quotas apply to all types of host capacity. For reserved capacity, if your request for reserved capacity exceeds your service limits, request a service limit increase before you reserve the capacity. For more information, see Service Limits.

**Components for Launching Instances**

The components required to launch an instance are:

- **availability domain**: The Oracle Cloud Infrastructure data center within your geographical region that hosts cloud resources, including your instances. You can place instances in the same or different availability domains, depending on your performance and redundancy requirements. For more information, see Regions and Availability Domains on page 208.

- **virtual cloud network**: A virtual version of a traditional network—including subnets, route tables, and gateways—on which your instance runs. At least one cloud network has to be set up before you launch instances. For information about setting up cloud networks, see Networking Overview on page 3604.

- **key pair (for Linux instances)**: A security mechanism required for Secure Shell (SSH) access to an instance. Before you launch an instance, you’ll need at least one key pair. For more information, see Managing Key Pairs on Linux Instances on page 1021.

- **tags**: You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.
**Password (for Windows instances)**

A security mechanism required to access an instance that uses a Windows platform image. The first time you launch an instance using a Windows image, Oracle Cloud Infrastructure will generate an initial, one-time password that you can retrieve using the console or API. This password must be changed after you initially log on.

**Image**

A template of a virtual hard drive that determines the operating system and other software for an instance. For details about Oracle Cloud Infrastructure platform images, see Platform Images on page 943. You can also launch instances from these sources:

- Trusted third-party images published by Oracle partners from the Partner Image catalog. For more information about partner images, see Overview of Marketplace on page 3440 and Working with Listings on page 3441.
- Pre-built Oracle enterprise images and solutions enabled for Oracle Cloud Infrastructure.
- Custom images, including bring your own image scenarios.
- Boot Volumes on page 689.

**Shape**

A template that determines the number of CPUs, amount of memory, and other resources allocated to a newly created instance. You choose the most appropriate shape when you launch an instance. See Compute Shapes on page 973 for a list of available bare metal and VM shapes.

You can optionally attach volumes to an instance. For more information, see Overview of Block Volume on page 640.

**Creating Automation with Events**

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2382.

The following Compute resources emit events:

- Autoscaling configurations and autoscaling policies
- Cluster networks
- Console histories
- Images
- Instances and instance attachments
- Instance configurations
- Instance console connections
- Instance pools

**Resource Identifiers**

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 225.

**Work Requests**

Compute is one of the Oracle Cloud Infrastructure services that is integrated with the Work Requests API. For general information on using work requests in Oracle Cloud Infrastructure, see Work Requests in the user guide, and the Work Requests API.
Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the API, see REST APIs on page 5528.

Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Storage for Compute Instances

You can expand the storage that’s available for your Compute instances with the following services:

- **Block Volume**: Lets you dynamically provision and manage block volumes that you can attach to one or more Compute instances. See Overview of Block Volume on page 640 for more information. For steps to attach block volumes to Compute instances, see Attaching a Volume on page 657 and Attaching a Volume to Multiple Instances on page 660.
- **File Storage**: A durable, scalable, secure, enterprise-grade network file system that you can connect to from any Compute instance in your virtual cloud network (VCN). See Overview of File Storage on page 2529 for more information.
- **Object Storage**: An internet-scale, high-performance storage platform that lets you store an unlimited amount of unstructured data of any content type. This storage is regional and not tied to any specific Compute instance. See Overview of Object Storage on page 4290 for more information.
- **Archive Storage**: A storage platform that lets you store an unlimited amount of unstructured data of any content type that doesn't require instantaneous data retrieval. This storage is regional and not tied to any specific Compute instance. See Overview of Archive Storage on page 566 for more information.

Limits on Compute Resources

See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

Additional limits include:

- To attach a volume to an instance, both the instance and volume must be within the same availability domain.
- Many Compute operations are subject to throttling.

A service limit is different from host capacity. A service limit is the quota or allowance set on a resource. Host capacity is the physical infrastructure that resources such as Compute instances run on.
**Metadata Key Limits**

Custom metadata keys (any key you define that is not `sshAuthorizedKeys` or `user_data`) have the following limits:

- Max number of metadata keys: 128
- Max size of key name: 255 characters
- Max size of key value: 255 characters

`sshAuthorizedKeys` is a special key that does not have these limits, but its value is validated to conform to a public key in the OpenSSH format.

`user_data` has a maximum size of 16KB. For Linux instances with cloud-init configured, you can populate the `user_data` field with a Base64-encoded string of cloud-init user data. For more information on formats that cloud-init accepts, see cloud-init formats.

**Best Practices for Your Compute Instance**

Oracle Cloud Infrastructure Compute provides bare metal and virtual machine (VM) compute capacity that delivers performance, flexibility, and control without compromise. It's powered by Oracle's next generation, internet-scale infrastructure, designed to help you develop and run your most demanding applications and workloads in the cloud.

You can provision compute capacity through an easy-to-use web console or the API, SDKs, or CLI. The compute instance, once provisioned, provides you with access to the host. This gives you complete control of your instance.

Though you have full management authority for your instance, we recommend a variety of best practices to ensure system availability and top performance.

**IP Addresses Reserved for Use by Oracle**

Certain IP addresses are reserved for Oracle Cloud Infrastructure use and may not be used in your address numbering scheme.

**169.254.0.0/16**

These addresses are used for iSCSI connections to the boot and block volumes, instance metadata, and other services.

**Class D and Class E**

All addresses from 224.0.0.0 to 239.255.255.255 (Class D) are prohibited for use in a VCN, they are reserved for multicast address assignments in the IP standards. See RFC 3171 for details.

All addresses from 240.0.0.0 to 255.255.255.255 (Class E) are prohibited for use in a VCN, they are reserved for future use in the IP standards. See RFC 1112, Section 4 for details.

**Three IP Addresses in Each Subnet**

These addresses consist of:

- The first IP address in the CIDR (the network address)
- The last IP address in the CIDR (the broadcast address)
- The first host address in the CIDR (the subnet default gateway address)

For example, in a subnet with CIDR 192.168.0.0/24, these addresses are reserved:

- 192.168.0.0 (the network address)
- 192.168.0.255 (the broadcast address)
- 192.168.0.1 (the subnet default gateway address)

The remaining addresses in the CIDR (192.168.0.2 to 192.168.0.254) are available for use.
**Essential Firewall Rules**

All platform images include rules that allow only "root" on Linux instances or "Administrators" on Windows Server instances to make outgoing connections to the iSCSI network endpoints (169.254.0.2:3260, 169.254.2.0/24:3260) that serve the instance's boot and block volumes.

- We recommend that you do not reconfigure the firewall on your instance to remove these rules. Removing these rules allows non-root users or non-administrators to access the instance’s boot disk volume.
- We recommend that you do not create custom images without these rules unless you understand the security risks.
- Running Uncomplicated Firewall (UFW) on Ubuntu images might cause issues with these rules. Because of this, we recommend that you do not enable UFW on your instances. See [Ubuntu instance fails to reboot after enabling Uncomplicated Firewall (UFW)](#) for more information.

**System Resilience**

Follow industry-wide hardware failure best practices to ensure the resilience of your solution in the event of a hardware failure. Some best practices include:

- Design your system with redundant compute nodes in different availability domains to support failover capability.
- Create a custom image of your system drive each time you change the image.
- Back up your data drives, or sync to spare drives, regularly.

If you experience a hardware failure and have followed these practices, you can terminate the failed instance, launch your custom image to create a new instance, and then apply the backup data.

**Uninterrupted Access to the Instance**

Make sure to keep the DHCP client running so you can always access the instance. If you stop the DHCP client manually or disable NetworkManager (which stops the DHCP client on Linux instances), the instance can't renew its DHCP lease and will become inaccessible when the lease expires (typically within 24 hours). Do not disable NetworkManager unless you use another method to ensure renewal of the lease.

Stopping the DHCP client might remove the host route table when the lease expires. Also, loss of network connectivity to your iSCSI connections might result in loss of the boot drive.

**User Access**

If you created your instance using a Linux platform image, you can use SSH to access your instance from a remote host as the opc user. After logging in, you can add users on your instance.

If you do not want to share SSH keys, you can create additional SSH-enabled users.

If you created your instance using a Windows platform image, you can access your instance using a Remote Desktop client as the opc user. After logging in, you can add users on your instance.

For more information about user access, see [Adding Users on an Instance](#) on page 1088. For steps to log in to an instance, see [Connecting to an Instance](#) on page 1083.

**NTP Service**

Oracle Cloud Infrastructure offers a fully managed, secure, and highly available NTP service that you can use to set the date and time of your Compute and Database instances from within your virtual cloud network (VCN). The NTP service is enabled by default on all of the platform images that are available in Oracle Cloud Infrastructure. For information about this service, see [Configuring the Oracle Cloud Infrastructure NTP Service for an Instance](#) on page 1011.

**Fault Domains**

A fault domain is a grouping of hardware and infrastructure that is distinct from other fault domains in the same availability domain. Each availability domain has three fault domains. By properly leveraging fault domains, you can
increase the availability of applications running on Oracle Cloud Infrastructure. See Fault Domains on page 210 for more information.

Your application's architecture determines whether you should separate or group instances using fault domains.

**Scenario 1: Highly Available Application Architecture**

In this scenario, you have a highly available application, for example you have two web servers and a clustered database. In this scenario, you should group one web server and one database node in one fault domain and the other half of each pair in another fault domain. This placement ensures that a failure of any one fault domain does not result in an outage for your application.

**Scenario 2: Single Web Server and Database Instance Architecture**

In this scenario, your application architecture is not highly available, for example you have one web server and one database instance. In this scenario, both the web server and the database instance should be placed in the same fault domain to minimize customer outages. This placement ensures that your application is only impacted by the failure of that single fault domain, providing greater application availability overall.

**Customer-Managed Virtual Machine (VM) Maintenance**

When an underlying infrastructure component needs to undergo maintenance, by default, Oracle Cloud Infrastructure sends a notification about the upcoming maintenance event. After 14 to 16 days, the VM instances are live migrated from the physical VM host that needs maintenance to a healthy VM host without disrupting running instances. Alternately, you can choose to have your instances automatically live migrated without a notification. If a VM cannot be live migrated, a short downtime occurs while the instance is reboot migrated.

You can control how and when your applications experience maintenance downtime by proactively rebooting (or stopping and starting) the instances at any time before the scheduled maintenance event. A maintenance reboot is different from a normal reboot. When you reboot an instance for maintenance, the instance is stopped on the physical VM host that needs maintenance, and then restarted on a healthy VM host.

If you choose not to reboot before the scheduled time, then Oracle Cloud Infrastructure migrates the instances before proceeding with the planned infrastructure maintenance. Optionally, you can configure the instances to remain stopped after they are reboot migrated. For more information, see Recovering a Virtual Machine (VM) During Planned Maintenance on page 1149.

**Protecting Data on NVMe Devices**

Some instance shapes in Oracle Cloud Infrastructure include locally attached NVMe devices. These devices provide extremely low latency, high performance block storage that is ideal for big data, OLTP, and any other workload that can benefit from high-performance block storage.

Note that these devices are not protected in any way; they are individual devices locally installed on your instance. Oracle Cloud Infrastructure does not take images, back up, or use RAID or any other methods to protect the data on NVMe devices. It is your responsibility to protect and manage the durability the data on these devices.

Oracle Cloud Infrastructure offers high-performance remote block (iSCSI) LUNs that are redundant and can be backed up using an API call. See Overview of Block Volume on page 640 for more information.

See Compute Shapes on page 973 for information about which shapes support local NVMe storage.

**Finding the NVMe devices on your instance**

You can identify the NVMe devices by using the `lsblk` command. The response returns a list. NVMe devices begin with "nvme", as shown in the following example for a BM.DenseIO1.36 instance:

```
[opc@somehost ~]$ lsblk
NAME  MAJ:MIN  RM  SIZE  RO  TYPE  MOUNTPOINT
sda   8:0      0  46.6G  0  disk
##sda1  8:1      0  512M  0  part  /boot/efi
```
## Compute

### Failure Modes and How to Protect Against Them

There are three primary failure modes you should plan for:

- Protecting Against the Failure of an NVMe Device on page 934
- Protecting Against the Loss of the Instance or Availability Domain on page 942
- Protecting Against Data Corruption or Loss from Application or User Error on page 942

### Protecting Against the Failure of an NVMe Device

A protected RAID array is the most recommended way to protect against an NVMe device failure. There are three RAID levels that can be used for the majority of workloads:
• RAID 1: An exact copy (or mirror) of a set of data on two or more disks; a classic RAID 1 mirrored pair contains two disks, as shown:
- RAID 10: Stripes data across multiple mirrored pairs. As long as one disk in each mirrored pair is functional, data can be retrieved, as shown:

Blocks mirrored and striped
- RAID 6: Block-level striping with two parity blocks distributed across all member disks, as shown.

**RAID 6**

Blocks striped with dual parity across drives

For more information about RAID and RAID levels, see [RAID](#).

Because the appropriate RAID level is a function of the number of available drives, the number of individual LUNs needed, the amount of space needed, and the performance requirements, there isn't one correct choice. You must understand your workload and design accordingly.

**Important:**

If you're partitioning or formatting your disk as part of this process and the drive is larger than 2 TB, you should create a GUID Partition Table (GPT). If you want to create a GPT, use `parted` instead of the `fdisk` command. For more information, see [About Disk Partitions](#) in the Oracle Linux Administrator's Guide.

**Options for Using a BM.DenseIO1.36 Shape**

There are several options for BM.DenseIO1.36 instances with nine NVMe devices.

For all options below, you can optionally increase the default RAID resync speed limit value. Increasing this value to more closely match the fast storage speed on the bare metal instances can decrease the amount of time required to set up RAID.

Use the following command to increase the speed limit value:

```
$ sysctl -w dev.raid.speed_limit_max=10000000
```

**Option 1: Create a single RAID 6 device across all nine devices**

This array is redundant, performs well, will survive the failure of any two devices, and will be exposed as a single LUN with about 23.8TB of usable space.
Use the following commands to create a single RAID 6 device across all nine devices:

```bash
$ sudo yum install mdadm -y

$ sudo mdadm --create /dev/md0 --raid-devices=9 --level=6 /dev/nvme0n1 /dev/nvme1n1 /dev/nvme2n1 /dev/nvme3n1 /dev/nvme4n1 /dev/nvme5n1 /dev/nvme6n1 /dev/nvme7n1 /dev/nvme8n1

$ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf >> /dev/null
```

**Option 2: Create a four device RAID 10 and a five device RAID 6 array**

These arrays would be exposed as two different LUNs to your applications. This is a recommended choice when you need to isolate one type of I/O from another, such as log and data files. In this example, your RAID 10 array would have about 6.4TB of usable space and the RAID 6 array would have about 9.6TB of usable space.

Use the following commands to create a four-device RAID 10 and a five-device RAID 6 array:

```bash
$ sudo yum install mdadm -y

$ sudo mdadm --create /dev/md0 --raid-devices=4 --level=10 /dev/nvme5n1 /dev/nvme6n1 /dev/nvme7n1 /dev/nvme8n1

$ sudo mdadm --create /dev/md1 --raid-devices=5 --level=6 /dev/nvme0n1 /dev/nvme1n1 /dev/nvme2n1 /dev/nvme3n1 /dev/nvme4n1

$ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf >> /dev/null
```

**Option 3: Create an eight-device RAID 10 array**

If you need the best possible performance and can sacrifice some of your available space, then an eight-device RAID 10 array is an option. Because RAID 10 requires an even number of devices, the ninth device is left out of the array and serves as a hot spare in case another device fails. This creates a single LUN with about 12.8 TB of usable space.

Use the following commands to create an eight-device RAID 10 array:

```bash
$ sudo yum install mdadm -y

$ sudo mdadm --create /dev/md0 --raid-devices=8 --level=10 /dev/nvme0n1 /dev/nvme1n1 /dev/nvme2n1 /dev/nvme3n1 /dev/nvme4n1 /dev/nvme5n1 /dev/nvme6n1 /dev/nvme7n1

The following command adds /dev/nvme8n as a hot spare for the /dev/md0 array:

```bash
$ sudo mdadm /dev/md0 --add /dev/nvme8n1
```

```bash
$ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf >> /dev/null
```

**Option 4: Create two four-device RAID 10 arrays**

For the best possible performance and I/O isolation across LUNs, create two four-device RAID 10 arrays. Because RAID 10 requires an even number of devices, the ninth device is left out of the arrays and serves as a global hot spare in case another device in either array fails. This creates two LUNS, each with about 6.4 TB of usable space.
Use the following commands to create two four-device RAID 10 arrays with a global hot spare:

```
$ sudo yum install mdadm -y
$ sudo mdadm --create /dev/md0 --raid-devices=4 --level=10 /dev/nvme4n1 /dev/nvme5n1 /dev/nvme6n1 /dev/nvme7n1
$ sudo mdadm --create /dev/md1 --raid-devices=4 --level=10 /dev/nvme0n1 /dev/nvme1n1 /dev/nvme2n1 /dev/nvme3n1
```

Creating a global hot spare requires the following two steps:

1. Add the spare to either array (it does not matter which one) by running these commands:

```
$ sudo mdadm /dev/md0 --add /dev/nvme8n1
$ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf >> /dev/null
```

2. Edit `/etc/mdadm` to put both arrays in the same spare-group. Add `spare-group=global` to the end of the line that starts with `ARRAY`, as follows:

```
$ sudo vi /etc/mdadm.conf
```

```
ARRAY /dev/md0 metadata=1.2 spares=1 name=mdadm.localdomain:0 UUID=43f93ce6:4a19d07b:51762f1b:250e2327 spare-group=global

ARRAY /dev/md1 metadata=1.2 name=mdadm.localdomain:1 UUID=7521e51a:83999f00:99459a19:0c836693 spare-group=global
```

### Monitoring Your Array

It's important for you to be notified if a device in one of your arrays fails. Mdadm has built-in tools that can be utilized for monitoring, and there are two options you can use:

- Set the `MAILADDR` option in `/etc/mdadm.conf` and then run the `mdadm` monitor as a daemon
- Run an external script when `mdadm` detects a failure

**Set the MAILADDR option in `/etc/mdadm.conf` and run the mdadm monitor as a daemon**

The simplest method is to set the `MAILADDR` option in `/etc/mdadm.conf`, and then run the `mdadm` monitor as a daemon, as follows:

1. The `DEVICE partitions` line is required for `MAILADDR` to work; if it is missing, you must add it, as follows:

```
$ sudo vi /etc/mdadm.conf
```

```
DEVICE partitions

ARRAY /dev/md0 level=raid1 UUID=1b70e34a:2930b5a6:016we78d:eese14532
MAILADDR <my.name@example.com>
```

2. Run the monitor using the following command:

```
$ sudo nohup mdadm --monitor --scan --daemonize &
```
Compute

3. To verify that the monitor runs at startup, run the following commands:

```
$ sudo chmod +x /etc/rc.d/rc.local

$ sudo vi /etc/rc.local
```

Add the following line to the end of /etc/rc.local:

```
nohup mdadm --monitor --scan --daemonize &
```

4. To verify that the email and monitor are both working run the following command:

```
$ sudo mdadm --monitor --scan --test -1
```

Note that these emails will likely be marked as spam. The PROGRAM option, described later in this topic, allows for more sophisticated alerting and messaging.

**Run an external script when a failure is detected**

A more advanced option is to create an external script that would run if the `mdadm` monitor detects a failure. You would integrate this type of script with your existing monitoring solution. The following is an example of this type of script:

```
#!/bin/bash

event=$1
device=$2

if [ "$event" == "Fail" ]; then
  "do something"
else
  if [ "$event" == "FailSpare" ]; then
    "do something else"
  else
    if [ "$event" == "DegradedArray" ]; then
      "do something else other"
    else
      if [ "$event" == "TestMessage" ]; then
        "do something else else other"
      fi
    fi
  fi
fi

$ sudo chmod +x /etc/mdadm.events
```

Next, add the PROGRAM option to /etc/mdadm.conf, as shown in the following example:
1. The `DEVICE partitions` line is required for `MAILADDR` to work; if it is missing, you must add it, as follows:

   ```
   $ sudo vi /etc/mdadm.conf
   DEVICE partitions
   ARRAY /dev/md0 level=raid1 UUID=1b70e34a:2930b5a6:016we78d:eesel4532
   MAILADDR <my.name@example.com>
   PROGRAM /etc/mdadm.events
   ```

2. Run the monitor using the following command:

   ```
   $ sudo nohup mdadm --monitor --scan --daemonize &
   ```

3. To verify that the monitor runs at startup, run the following commands:

   ```
   $ sudo chmod +x /etc/rc.d/rc.local
   $ sudo vi /etc/rc.local
   ```

   Add the following line to the end of `/etc/rc.local`:

   ```
   nohup mdadm --monitor --scan --daemonize &
   ```

4. To verify that the email and monitor are both working run the following command:

   ```
   $ sudo mdadm --monitor --scan --test -1
   ```

   Note that these emails will likely be marked as spam. The `PROGRAM` option, described later in this topic, allows for more sophisticated alerting and messaging.

**Simulate the failure of a device**

You can use `mdadm` to manually cause a failure of a device to see whether your RAID array can survive the failure, as well as test the alerts you have set up.

1. Mark a device in the array as failed by running the following command:

   ```
   $ sudo mdadm /dev/md0 --fail /dev/nvme0n1
   ```

2. Recover the device or your array might not be protected. Use the following command:

   ```
   $ sudo mdadm /dev/md0 --add /dev/nvme0n1
   ```

   Your array will automatically rebuild in order to use the "new" device. Performance will be decreased during this process.

3. You can monitor the rebuild status by running the following command:

   ```
   $ sudo mdadm --detail /dev/md0
   ```

**What To Do When an NVMe Device Fails**

Compute resources in the cloud are designed to be temporary and fungible. If an NVMe device fails while the instance is in service, you should start another instance with the same amount of storage or more, and then copy the data onto the new instance, replacing the old instance. There are multiple toolsets for copying large amounts of data, with `rsync` being the most popular. Since the connectivity between instances is a full 10 Gb/sec, copying data should
be quick. Remember that with a failed device, your array may no longer be protected, so you should copy the data off of the impacted instance as quickly as possible.

**Using the Linux Logical Volume Manager**

The Linux Logical Volume Manager (LVM) provides a rich set of features for managing volumes. If you need these features, we strongly recommend that you use `mdadm` as described in preceding sections of this topic to create the RAID arrays, and then use LVM's `pvcreate`, `vgcreate`, and `lvcreate` commands to create volumes on the `mdadm` LUNs. You should not use LVM directly against your NVMe devices.

**Protecting Against the Loss of the Instance or Availability Domain**

Once your data is protected against the loss of a NVMe device, you need to protect it against the loss of an instance or the loss of the availability domain. This type of protection is typically done by replicating your data to another availability domain or backing up your data to another location. The method you choose depends on your objectives. For details, see the disaster recovery concepts of Recovery Time Objective (RTO) and Recovery Point Objective (RPO).

**Replication**

Replicating your data from one instance in one availability domain to another has the lowest RTO and RPO at a significantly higher cost than backups; for every instance in one availability domain, you must have another instance in a different availability domain.

For Oracle database workloads, you should use the built-in Oracle Data Guard functionality to replicate your databases. Oracle Cloud Infrastructure availability domains are each close enough to each other to support high performance, synchronous replication. Asynchronous replication is also an option.

For general-purpose block replication, `DRBD` is the recommended option. You can configure DRBD to replicate, synchronously or asynchronously, every write in one availability domain to another availability domain.

**Backups**

Traditional backups are another way to protect data. All commercial backup products are fully supported on Oracle Cloud Infrastructure. If you use backups, the RTO and RPO are significantly higher than using replication because you must recreate the compute resources that failed and then restore the most recent backup. Costs are significantly lower because you don't need to maintain a second instance. Do not store your backups in the same availability domain as their original instance.

**Protecting Against Data Corruption or Loss from Application or User Error**

The two recommended ways of protecting against data corruption or loss from application or user error are regularly taking snapshots or creating backups.

**Snapshots**

The two easiest ways to maintain snapshots are to either use a file system that supports snapshots, such as ZFS, or use LVM to create and manage the snapshots. Because of the way LVM has implemented copy-on-write (COW), performance may significantly decrease when a snapshot is taken using LVM.

**Backups**

All commercial backup products are fully supported on Oracle Cloud Infrastructure. Make sure that your backups are stored in a different availability domain from the original instance.
## Platform Images

An image is a template of a virtual hard drive. The image determines the operating system and other software for an instance. The following table lists the platform images that are available in Oracle Cloud Infrastructure. For specific image and kernel version details, along with changes between versions, see the [Image Release Notes](#).

<table>
<thead>
<tr>
<th>Image</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Autonomous Linux 7 Unbreakable Kernel Release 6</td>
<td>Autonomous-Oracle-Linux-7.x-&lt;date&gt;-&lt;number&gt;</td>
<td>Oracle Autonomous Linux provides autonomous capabilities such as automated patching with zero downtime, and known exploit detection, to help keep the operating system highly secure and reliable. Oracle Autonomous Linux is based on Oracle Linux. x86 shapes and GPU shapes are supported with this image.</td>
</tr>
<tr>
<td>Oracle Linux 8 Unbreakable Enterprise Kernel Release 6</td>
<td>Oracle-Linux-8.x-&lt;date&gt;-&lt;number&gt;</td>
<td>The Unbreakable Enterprise Kernel (UEK) is Oracle's optimized operating system kernel for demanding Oracle workloads. x86 shapes, Arm-based shapes, and GPU shapes are supported with this image.</td>
</tr>
<tr>
<td>Oracle Linux 7 Unbreakable Enterprise Kernel Release 6</td>
<td>Oracle-Linux-7.x-&lt;date&gt;-&lt;number&gt;</td>
<td>The Unbreakable Enterprise Kernel (UEK) is Oracle's optimized operating system kernel for demanding Oracle workloads. x86 shapes, Arm-based shapes, and GPU shapes are supported with this image.</td>
</tr>
<tr>
<td>Oracle Linux 6 Unbreakable Enterprise Kernel Release 4</td>
<td>Oracle-Linux-6.x-&lt;date&gt;-&lt;number&gt;</td>
<td>The Unbreakable Enterprise Kernel (UEK) is Oracle's optimized operating system kernel for demanding Oracle workloads. x86 shapes are supported with this image.</td>
</tr>
<tr>
<td>Oracle Linux Cloud Developer 8 Unbreakable Enterprise Kernel Release 6</td>
<td>Oracle-Linux-Cloud-Developer-8.x-&lt;date&gt;-&lt;number&gt;</td>
<td>Oracle Linux Cloud Developer provides the latest development tools, languages and Oracle Cloud Infrastructure software development kits (SDKs) to rapidly launch a comprehensive development environment. x86 shapes and Arm-based shapes are supported with this image.</td>
</tr>
<tr>
<td>Image</td>
<td>Name(^1)</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CentOS 8</td>
<td>CentOS-8-&lt;date&gt;-&lt;number&gt;</td>
<td>CentOS is a free, open-source Linux distribution that is suitable for use in enterprise cloud environments. x86 shapes and GPU shapes are supported with this image. <strong>Tip:</strong> Looking for an alternative to CentOS 8? Oracle Linux is a great option. For details and a script to switch from CentOS to Oracle Linux, read our blog post.</td>
</tr>
<tr>
<td>CentOS 7</td>
<td>CentOS-7-&lt;date&gt;-&lt;number&gt;</td>
<td>CentOS is a free, open-source Linux distribution that is suitable for use in enterprise cloud environments. x86 shapes are supported with this image.</td>
</tr>
<tr>
<td>Ubuntu 20.04 LTS</td>
<td>Canonical-Ubuntu-20.04-&lt;date&gt;-&lt;number&gt;</td>
<td>Ubuntu is a free, open-source Linux distribution that is suitable for use in the cloud. <strong>Minimal Ubuntu</strong> is designed for automated use at scale. It uses a smaller boot volume, boots faster, and has a smaller surface for security patches than standard Ubuntu images. x86 shapes and Arm-based shapes are supported with this image. For Arm-based shapes, use the Ubuntu image, not Minimal Ubuntu.</td>
</tr>
<tr>
<td>Ubuntu 18.04 LTS</td>
<td>Canonical-Ubuntu-18.04-&lt;date&gt;-&lt;number&gt;</td>
<td>Ubuntu is a free, open-source Linux distribution that is suitable for use in the cloud. <strong>Minimal Ubuntu</strong> is designed for automated use at scale. It uses a smaller boot volume, boots faster, and has a smaller surface for security patches than standard Ubuntu images. x86 shapes, Arm-based shapes, and GPU shapes are supported with this image. You must install the appropriate GPU drivers from NVIDIA. For Arm-based shapes, use the Ubuntu image, not Minimal Ubuntu.</td>
</tr>
</tbody>

<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows-Server-2019-&lt;edition&gt;-&lt;gen&gt;-&lt;date&gt;-&lt;number&gt;</td>
<td>Windows Server 2019 supports running production Windows workloads on Oracle Cloud Infrastructure. <strong>Server Core</strong> is a minimal installation option that has a smaller disk footprint and therefore a smaller attack surface. x86 shapes and GPU shapes are supported with this image. You must install the appropriate GPU drivers from NVIDIA.</td>
</tr>
</tbody>
</table>

### Windows Server 2016

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows-Server-2016-&lt;edition&gt;-&lt;gen&gt;-&lt;date&gt;-&lt;number&gt;</td>
<td>Windows Server 2016 supports running production Windows workloads on Oracle Cloud Infrastructure. <strong>Server Core</strong> is a minimal installation option that has a smaller disk footprint and therefore a smaller attack surface. x86 shapes and GPU shapes are supported with this image. You must install the appropriate GPU drivers from NVIDIA.</td>
</tr>
</tbody>
</table>

### Windows Server 2012 R2

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows-Server-2012-R2-&lt;edition&gt;-&lt;gen&gt;-&lt;date&gt;-&lt;number&gt;</td>
<td>Windows Server 2012 R2 supports running production Windows workloads on Oracle Cloud Infrastructure. x86 shapes and GPU shapes are supported with this image. You must install the GPU drivers from NVIDIA.</td>
</tr>
</tbody>
</table>

1: Image names can include additional information about the processor architecture, operating system, or supported shapes. For example:

- **Images with "aarch64" in the name**, such as Oracle-Linux-8.x-aarch64-<edition>, are for shapes that use Arm-based processors. **Images without "aarch64" in the name** are for shapes that use x86 processors.
- **Images with "GPU" in the name**, such as Oracle-Linux-8.x-Gen2-GPU-<edition>, are for GPU shapes. Some images, such as Windows Server, have a single image build that supports both GPU shapes and non-GPU shapes.

---

You also can create custom images of your boot disk OS and software configuration for launching new instances.

### Essential Firewall Rules

All platform images include rules that allow only "root" on Linux instances or "Administrators" on Windows Server instances to make outgoing connections to the iSCSI network endpoints (169.254.0.2:3260, 169.254.2.0/24:3260) that serve the instance's boot and block volumes.
• We recommend that you do not reconfigure the firewall on your instance to remove these rules. Removing these rules allows non-root users or non-administrators to access the instance’s boot disk volume.
• We recommend that you do not create custom images without these rules unless you understand the security risks.
• Running Uncomplicated Firewall (UFW) on Ubuntu images might cause issues with these rules. Because of this, we recommend that you do not enable UFW on your instances. See Ubuntu instance fails to reboot after enabling Uncomplicated Firewall (UFW) for more information.

User Data
Platform images give you the ability to run custom scripts or supply custom metadata when the instance launches. To do this, you specify a custom user data script in the Initialization Script field when you create the instance. For more information about startup scripts, see cloud-init for Linux-based images and cloudbase-init for Windows-based images.

OS Updates for Linux Images
Oracle Linux and CentOS images are preconfigured to let you install and update packages from the repositories on the Oracle public yum server. The repository configuration file is in the /etc/yum.repos.d directory on your instance. You can install, update, and remove packages by using the yum utility.

On Oracle Autonomous Linux images, Oracle Ksplice is installed and configured by default to run automatic updates.

Note:
OS Security Updates for Oracle Linux and CentOS images
After you launch an instance using an Oracle Linux image, Oracle Linux Cloud Developer image, or CentOS image, you are responsible for applying the required OS security updates published through the Oracle public yum server. For more information, see Installing and Using the Yum Security Plugin.

The Ubuntu image is preconfigured with suitable repositories to allow you to install, update, and remove packages.

Note:
OS Security Updates for the Ubuntu image
After you launch an instance using the Ubuntu image, you are responsible for applying the required OS security updates using the sudo apt-get upgrade command.

Linux Kernel Updates
Oracle Linux images on Oracle Cloud Infrastructure include Oracle Linux Premier Support at no extra cost. This gives you all the services included with Premier Support, including Oracle Ksplice. Ksplice enables you to apply important security and other critical kernel updates without a reboot. For more information, see About Oracle Ksplice and Ksplice Overview.

Ksplice is available for Linux instances launched on or after February 15, 2017. For instances launched before August 25, 2017, you must install Ksplice before running it. See Installing and Running Oracle Ksplice on page 987 for more information.

Note:
Ksplice Support
Oracle Ksplice is not supported for CentOS and Ubuntu images, or on Linux images launched before February 15, 2017.
**Configuring Automatic Package Updating on Instance Launch**

You can configure your instance to automatically update to the latest package versions when the instance first launches using a cloud-init startup script. To do this, add the following code to the startup script:

```bash
package_upgrade: true
```

The upgrade process starts when the instance launches and runs in the background until it completes. To verify that it completed successfully, check the cloud-init logs in `/var/log`.

See [User Data](#) on page 946 and [Cloud config examples - Run apt or yum upgrade](#) for more information.

**Linux Image Details**

See [Lifetime Support Policy: Coverage for Oracle Linux and Oracle VM](#) for details about the Oracle Linux support policy.

**Users**

For instances created using Oracle Linux and CentOS images, the username `opc` is created automatically. The `opc` user has `sudo` privileges and is configured for remote access over the SSH v2 protocol using RSA keys. The SSH public keys that you specify while creating instances are added to the `/home/opc/.ssh/authorized_keys` file.

For instances created using the Ubuntu image, the username `ubuntu` is created automatically. The `ubuntu` user has `sudo` privileges and is configured for remote access over the SSH v2 protocol using RSA keys. The SSH public keys that you specify while creating instances are added to the `/home/ubuntu/.ssh/authorized_keys` file.

Note that `root` login is disabled.

**Remote Access**

Access to the instance is permitted only over the SSH v2 protocol. All other remote access services are disabled.

**Firewall Rules**

Instances created using platform images have a default set of firewall rules that allow only SSH access. Instance owners can modify those rules as needed, but must not restrict link local traffic to address 169.254.0.2 in accordance with the warning in [Essential Firewall Rules](#) on page 945.

Be aware that the Networking service uses network security groups and security lists to control packet-level traffic in and out of the instance. When troubleshooting access to an instance, make sure all of the following items are set correctly: the network security groups that the instance is in, the security lists associated with the instance's subnet, and the instance's firewall rules.

**Disk Partitions**

Starting with Oracle Linux 8.x, the main disk partition is managed using Logical Volume Management (LVM). This gives you increased flexibility to create and resize partitions to suit your workloads. In addition, there is no dedicated swap partition. Swap is now handled by a file on the file system, giving you more detailed control over swap.

**Cloud-init Compatibility**

Instances created using platform images are compatible with cloud-init. When launching an instance with the Core Services API, you can pass cloud-init directives with the metadata parameter. For more information, see [LaunchInstance](#).
Oracle Autonomous Linux

**Important:**

Beginning with the December 2020 Oracle Autonomous Linux platform image, the image is based on Unbreakable Enterprise Kernel (UEK) 6 and is configured to use the standard Oracle Linux yum repositories. The Autonomous Linux repository (al7) is deprecated and all customers with existing Oracle Autonomous Linux instances are migrated to the new repositories automatically.

The following repositories are enabled by default beginning with the December 2020 Oracle Autonomous Linux platform image:

- `ol7_UEKR6`
- `ol7_addons`
- `ol7_ksplice`
- `ol7_latest`
- `ol7_oci_included`
- `ol7_optional_latest`
- `ol7_software_collections`
- `ol7_x86_64_userspace_ksplice`

The image includes the release packages for the `ol7_developer` and `ol7_developer_EPEL` repositories, but these repositories are disabled by default.

For existing Oracle Autonomous Linux instances, after yum migration, the `ol7_developer` and `ol7_developer_EPEL` repositories are not available. If you need packages from these repositories, you can install the appropriate release package to obtain the correct repository configuration before enabling the repository by using the following commands:

```bash
sudo yum install oraclelinux-developer-release-el7
sudo yum install oracle-epel-release-el7
```

**Note:**

Packages found in either the `ol7_developer` and `ol7_developer_EPEL` repositories are considered unsupported and are only entitled to basic installation support. Content from these repositories is not recommended for production environments and is intended for developer purposes only.

To verify that your Oracle Autonomous Linux instance has been migrated to the new repositories, use the following command:

```bash
yum repolist
```

For example:

```bash
# yum repolist
Loaded plugins: langpacks, ulninfo
repo id                                          repo name                      status
ol7_UEKR6/x86_64                                Latest Unbreakable Enterprise Kernel Release 6 for Oracle Linux 7Server (x86_64) 197
ol7_addons/x86_64                               Oracle Linux 7Server Addons (x86_64) 473
```

**Note:**

For existing Oracle Autonomous Linux instances, after yum migration, the UEK6 repository is enabled and the next daily update installs the latest UEK6. After reboot, the instance boots into UEK6.

For more information about installing and configuring Oracle Autonomous Linux, see [Getting Started: Deploying and Configuring Oracle Autonomous Linux on Oracle Cloud Infrastructure](#) and [Oracle Autonomous Linux for Oracle Cloud Infrastructure](#).

Oracle Instant Client 18.3 basic package cannot be updated to Version 19.5 because of changes in packaging. To update Oracle Instant Client on Oracle Autonomous Linux images that were launched before March 18, 2020, you must first manually remove the Oracle Instant Client 18.3, and then install 19.5. Use the following commands:

```
sudo yum remove oracle-instantclient18.3-basic
sudo yum install oracle-instantclient19.5-basic
```

On Oracle Autonomous Linux images that were launched after March 18, 2020, Oracle Instant Client is not installed by default. To install Oracle Instant Client 19.5, you must manually install the package. Use the following command:

```
sudo yum install oracle-instantclient19.5-basic
```

On Oracle Autonomous Linux images that were launched after December 9, 2020, the Oracle Instant Client repository (ol7_oracleinstant_client) is not available by default. To add the repository, you must first install the `oracle-release-el7` release package and then enable the `ol7_oracle_instantclient` repository. You can then install the appropriate Oracle Instant Client version package. Use the following commands:

```
sudo yum install oracle-release-el7
sudo yum-config-manager --enable ol7_oracle_instantclient
```

Oracle Autonomous Linux instances cannot be managed by the OS Management service.

For more information about using Oracle Autonomous Linux, see [Known Issues](#).

**Oracle Linux Cloud Developer**

Oracle Linux Cloud Developer provides the latest development tools, languages and Oracle Cloud Infrastructure software development kits (SDKs) to rapidly launch a comprehensive development environment.

For a comprehensive list of preinstalled components in the Oracle Linux Cloud Developer image, and yum repositories that are enabled by default, see [Oracle Linux Cloud Developer](#).
Note:

Packages found in the `ol8_codeready_builder`, `ol7_developer` and `ol7_developer_EPEL` repositories are considered unsupported and are only entitled to basic installation support. Content from these repositories is not recommended for production environments and is intended for developer purposes only.

The Oracle Linux Cloud Developer image requires at least 8 GB of memory.

**OCI Utilities**

Instances created using Oracle Linux include a preinstalled set of utilities that are designed to make it easier to work with Oracle Linux images. These utilities consist of a service component and related command line tools.

For more information, see the [OCI Utilities](#) on page 955 reference.

**Windows OS Updates for Windows Images**

Windows images include the Windows Update utility, which you can run to get the latest Windows updates from Microsoft. You have to configure the instance's network security group or the security list used by the instance's subnet to allow instances to access Windows update servers.

**Windows Image Details**

**Windows Editions**

Depending on whether you create a bare metal instance or a virtual machine (VM) instance, different editions of Windows Server are available as platform images. Windows Server Standard edition is available only for VMs. Windows Server Datacenter edition is available only for bare metal instances.

**Users**

For instances created using Windows platform images, the username `opc` is created automatically. When you launch an instance using the Windows image, Oracle Cloud Infrastructure will generate an initial, one-time password that you can retrieve using the console or API. This password must be changed after you initially log on.

**Remote Access**

Access to the instance is permitted only through a Remote Desktop connection.

**Firewall Rules**

Instances created using the Windows image have a default set of firewall rules that allow Remote Desktop protocol or RDP access on port 3389. Instance owners can modify these rules as needed, but must not restrict link local traffic to 169.254.169.253 for the instance to activate with Microsoft Key Management Service (KMS). This is how the instance stays active and licensed.

Be aware that the Networking service uses network security groups and security lists to control packet-level traffic in and out of the instance. When troubleshooting access to an instance, make sure all of the following items are set correctly: the network security groups that the instance is in, the security lists associated with the instance's subnet, and the instance's firewall rules.

**User Data on Windows Images**

On Windows images custom user data scripts are executed using `cloudbase-init`, which is the equivalent of `cloud-init` on Linux-based images. All Windows platform images on Oracle Cloud Infrastructure include cloudbase-init installed by default. When an instance launches, cloudbase-init runs PowerShell, batch scripts, or additional user data content. See [cloudbase-init Userdata](#) for information about supported content types.
You can use user data scripts to perform various tasks, such as:

- Enable GPU support using a custom script to install the applicable GPU driver.
- Add or update local user accounts.
- Join the instance to a domain controller.
- Install certificates into the certificate store.
- Copy any required application workload files from the Object Storage service directly to the instance.

**Caution:**

Do not include anything in the script that could trigger a reboot, because this could impact the instance launch, causing it to fail. Any actions requiring a reboot should only be performed after the instance state is **RUNNING**.

### Windows Remote Management

Windows Remote Management (WinRM) is enabled by default on Windows platform images. WinRM provides you with the capability to remotely manage the operating system.

To use WinRM you need to add a stateful ingress **security rule** for TCP traffic on destination port 5986. You can implement this security rule in either a **network security group** that the instance belongs to, or a **security list** that is used by the instance's subnet.

**Caution:**

The following procedure allows WinRM connections from 0.0.0.0/0, which means any IP address, including public IP addresses. To allow access only from instances within the VCN, change the source CIDR value to the VCN's CIDR block. For more information, see **Security Recommendations** on page 4693.

**To enable WinRM access**

1. Open the navigation menu, click **Networking**, and then click **Virtual Cloud Networks**.
2. Click the VCN that you're interested in.
3. To add the rule to a network security group that the instance belongs to:
   a. Under **Resources**, click **Network Security Groups**. Then click the network security group that you're interested in.
   b. Click **Add Rules**.
   c. Enter the following values for the rule:
      - **Stateless**: Leave the check box cleared.
      - **Source Type**: CIDR
      - **Source CIDR**: 0.0.0.0/0
      - **IP Protocol**: TCP
      - **Source Port Range**: All
      - **Destination Port Range**: 5986
      - **Description**: An optional description of the rule.
   d. When done, click **Add**.
4. Or, to add the rule to a security list that is used by the instance's subnet:
   a. Under Resources, click Security Lists. Then click the security list you're interested in.
   b. Click Add Ingress Rules.
   c. Enter the following values for the rule:
      • Stateless: Leave the check box cleared.
      • Source Type: CIDR
      • Source CIDR: 0.0.0.0/0
      • IP Protocol: TCP
      • Source Port Range: All
      • Destination Port Range: 5986
      • Description: An optional description of the rule.
   d. When done, click Add Ingress Rules.

To use WinRM on an instance

1. Get the instance's public IP address.
2. Open Windows PowerShell on the Windows client that you're using to connect to the instance.
3. Run the following command:

   ```powershell
   # Get the public IP from your OCI running windows instance
   $ComputerName = Public IP Address

   # Store your username and password credentials (default username is opc)
   $c = Get-Credential

   # Options
   $opt = New-PSSessionOption -SkipCACheck -SkipCNCheck -SkipRevocationCheck

   # Create new PSSession (Pre-requisite: ensure network security group or security list has Ingress Rule for port 5986)
   $PSSession = New-PSSession -ComputerName $ComputerName -UseSSL -SessionOption $opt -Authentication Basic -Credential $c

   # Connect to Instance PSSession
   Enter-PSSession $PSSession

   # To close connection use: Exit-PSSession
   ```

You can now remotely manage the Windows instance from your local PowerShell client.

**Operating System Lifecycle and Support Policy**

When an operating system reaches the end of its support lifecycle, the OS vendor (such as Microsoft) no longer provides security updates for the OS. You should upgrade to the latest version to remain secure.

Here's what you should expect when an OS version reaches the end of its support lifecycle:

- Oracle Cloud Infrastructure no longer provides new images for the OS version. Images that were previously published are deprecated, and are no longer updated.
- Although you can continue to run instances that use deprecated images, Oracle Cloud Infrastructure does not provide any support for operating systems that have reached the end of the support lifecycle.
- If you have an instance that runs an OS version that will be deprecated, and you want to launch new instances with this OS version after the end of support, you can create a custom image of the instance and then use the custom image to launch new instances in the future. For custom Linux images, you must purchase extended support from the OS vendor. For custom Windows images, see Can I purchase Microsoft Extended Security Updates for end-of-support Windows OSs? on page 1176. Oracle Cloud Infrastructure does not provide any support for custom images that use end-of-support operating systems.
Be aware of these end-of-support dates:

- **CentOS 6**: Support ended on November 30, 2020.
- **Ubuntu 14.04**: Support ended on April 19, 2019.
- **Ubuntu 16.04**: Support ended in April 2021.

### Using NVIDIA GPU Cloud with Oracle Cloud Infrastructure

NVIDIA GPU Cloud (NGC) is a GPU-accelerated cloud platform optimized for deep learning and scientific computing. This topic provides an overview of how to use NGC with Oracle Cloud Infrastructure.

NVIDIA makes available on Oracle Cloud Infrastructure a customized Compute image that is optimized for the NVIDIA Tesla Volta and Pascal GPUs. Running NGC containers on this instance provides optimum performance for deep learning jobs.

### Prerequisites

- An Oracle Cloud Infrastructure tenancy with a GPU quota. For more information about quotas, see Compute Quotas on page 283.
- A cloud network to launch the instance in. For information about setting up cloud networks, see Using the Console on page 3696 in VCNs and Subnets on page 3693.
- A key pair, to use for connecting to the instance via SSH. For information about generating a key pair, see Managing Key Pairs on Linux Instances on page 1021.
- Security group and policy configured for the File Storage service. For more information, see Managing Groups on page 3115, Getting Started with Policies on page 2799, and Details for the File Storage Service on page 2963.
- An NGC API key for authenticating with the NGC service.

**To generate your NGC API key**

1. Sign in to the NGC website.
2. On the NGC Registry page, click Get API Key.
3. Click Generate API Key and then click Confirm to generate the key. If you have an existing API key it will become invalid once you generate a new key.

### Launching an Instance Based on the NGC Image

### Using the Console

1. Open the Console. For steps, see Signing In to the Console on page 63.
2. Open the navigation menu and click Compute. Under Compute, click Instances.
3. Select a Compartment that you have permission to work in.
4. Click Create Instance.
5. Enter a name for the instance. Avoid entering confidential information.
6. In the Placement section, select the Availability Domain that you want to create the instance in.
7. In the Image and Shape section:
   a. On the Shape card, click Change Shape. Then, do the following:
      1. For Instance type, select Virtual Machine or Bare Metal Machine.
      2. Select a GPU shape for the instance. For more information about GPU shapes, see virtual machine GPU shapes and bare metal GPU shapes.

   **Important:**

   In order to access the GPU shapes, your tenancy must have a GPU quota. If your tenancy does not have a GPU quota, the GPU shapes...
3. Click Select Shape.
   b. To select the NGC image, on the Image card, click Change Image. Then do the following.

   **Important:**
   In order to access the NVIDIA GPU Cloud images, your tenancy must have a GPU quota and you must select a GPU shape.

1. In the Image source list, select Oracle Images.
2. Select the check box next to NVIDIA GPU Cloud Machine Image.
3. Review and accept the terms of use, and then click Select Image.

8. In the Networking section, leave Select existing virtual cloud network selected, and then select the virtual cloud network (VCN) compartment, VCN, subnet compartment, and subnet.

9. In the Add SSH keys section, upload the public key portion of the key pair that you want to use for SSH access to the instance. Browse to the key file that you want to upload, or drag and drop the file into the box.

10. Click Create.

You should now see the NGC instance with the state of Provisioning. After the state changes to Running, you can connect to the instance. For general information about launching Compute instances, see Creating an Instance on page 1023.

See the following topics for steps to access and work with the instance:

- Connecting to an Instance on page 1083
- Stopping and Starting an Instance on page 1145
- Terminating an Instance on page 1147

When you connect to the instance using SSH, you are prompted for the NGC API key. If you supply the API key at the prompt, the instance automatically logs you in to the NGC container registry so that you can run containers from the registry. You can choose not to supply the API key at the prompt and still log in to the instance. You can then log in later to the NGC container registry. See Logging in to the NGC Container Registry for more information.

**Using the CLI**

Oracle Cloud Infrastructure provides a Command Line Interface (CLI) on page 5316 you can use to complete tasks. For more information, see Quickstart on page 5320 and Configuring the CLI on page 5327.

Use the launch command to create an instance, specifying image for sourceType and the image OCID ocid1.image.oc1..aaaaaaaaknl6phck7e3uiui4r4axpwhenw5qtnnsk3tqppajdjb5nhoma3q in InstanceSourceDetails for LaunchInstanceDetails.

**Using the File Storage Service for Persistent Data Storage**

You can use the File Storage service for data storage when working with NGC. For more information, see Overview of File Storage on page 2529. See the following tasks for creating and working with the File Storage service:

- Creating File Systems on page 2557
- Using the Console on page 2566
- Using the API on page 2589
- Managing File Systems on page 2579
- Using the Command Line Interface (CLI) on page 2586

**Using the Block Volume Service for Persistent Data Storage**

You can use the Block Volume service for data storage when working with NGC. For more information, see Overview of Block Volume on page 640. See the following tasks for creating and working with the Block Volume service:

- Creating a Volume on page 655
Examples of Running Containers

You first need to log into the NGC container registry. You can skip this section if you provided your API key when logging into the instance via SSH. If you did not provide your API key when connecting to your instance, then you must perform this step.

To log into the NGC container registry

1. Run the following Docker command:

   `docker login nvcr.io`

2. When prompted for a username, enter `$oauthtoken`.

3. When prompted for a password enter your NGC API key.

At this point you can run Docker commands and access the NGC container registry from the instance.

Example: MNIST Training Run Using PyTorch Container

This sample demonstrates running the MNIST example under PyTorch. This example downloads the MNIST dataset from the web.

1. Pull and run the PyTorch container with the following Docker commands:

   `docker pull nvcr.io/nvidia/pytorch:17.10`
   `docker run --gpus all --rm -it nvcr.io/nvidia/pytorch:17.10`

2. Run the MNIST example with the following commands:

   `cd /opt/pytorch/examples/mnist`
   `python main.py`

Example: MNIST Training Run Using TensorFlow Container

This sample demonstrates running the MNIST example under TensorFlow. This example downloads the MNIST dataset from the web.

1. Pull and run the TensorFlow container with the following Docker commands:

   `docker pull nvcr.io/nvidia/tensorflow:17.10`
   `docker run --gpus all --rm -it nvcr.io/nvidia/tensorflow:17.10`

2. Run the MNIST_with_summaries example with the following commands:

   `cd /opt/tensorflow/tensorflow/examples/tutorials/mnist`
   `python mnist_with_summaries.py`

OCI Utilities

Instances created using platform images based on Oracle Linux include a pre-installed set of utilities that are designed to make it easier to work with Oracle Linux images. These utilities consist of a service component and related command line tools that can help with managing block volumes (attach, remove, and automatic discovery), secondary VNIC configuration, discovering the public IP address of an instance, and retrieving instance metadata.

The following table summarizes the components that are included in the OCI utilities.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ocid</td>
<td>The service component of <code>oci-utils</code>, which runs as a daemon started by <code>systemd</code>. This service scans for changes in the iSCSI and VNIC device configurations and caches the OCI metadata and public IP address of the instance.</td>
</tr>
<tr>
<td>oci-growfs</td>
<td>Expands the root filesystem of the instance to its configured size.</td>
</tr>
<tr>
<td>oci-iscsi-config</td>
<td>Lists or configures iSCSI devices attached to a compute instance. If no command line options are specified, lists devices that need attention.</td>
</tr>
<tr>
<td>oci-metadata</td>
<td>Displays metadata for the compute instance. If no command line options are specified, lists all available metadata. Metadata includes the instance OCID, display name, compartment, shape, region, availability domain, creation date, state, image, and any custom metadata that you provide, such as an SSH public key.</td>
</tr>
<tr>
<td>oci-network-config</td>
<td>Lists or configures virtual network interface cards (VNICs) attached to the compute instance. When a secondary VNIC is provisioned in the cloud, it must be explicitly configured on the instance using this script or similar commands.</td>
</tr>
<tr>
<td>oci-network-inspector</td>
<td>Displays a detailed report for a given compartment or network.</td>
</tr>
<tr>
<td>oci-notify</td>
<td>Sends a message to a Notifications service topic.</td>
</tr>
<tr>
<td>oci-public-ip</td>
<td>Displays the public IP address of the current system in either human-readable or JSON format.</td>
</tr>
</tbody>
</table>

### Installing the OCI Utilities

The OCI utilities (`oci-utils`) are automatically included with instances launched with Oracle Linux 7 and later images. They are not currently available on other distributions.

Much of the OCI utilities functionality requires that you have the Oracle Cloud Infrastructure SDK for Python and the Oracle Cloud Infrastructure CLI installed and configured.

**Note:**

Beginning with 0.11 release, `oci-utils` can no longer be used with Python 2 in favor of Python 3.

To install the Oracle Cloud Infrastructure SDK and CLI using `yum`, install the required packages corresponding to the image used by the instance.

**Oracle Linux 7**

```
sudo yum install -y python36-oci-sdk python36-oci-cli
```

**Oracle Linux 8**

```
sudo dnf config-manager --enable ol8_oci_included
sudo dnf config-manager --enable ol8_developer
sudo dnf install -y python36-oci-sdk python36-oci-cli
```
For configuration information, see the Oracle Cloud Infrastructure SDK for Python documentation and the documentation for configuring the Oracle Cloud Infrastructure CLI.

For a training video that demonstrates how to install and set up the OCI utilities, see Enabling OCI Utilities in Oracle Linux on Oracle Cloud Infrastructure Instances in the Oracle Learning Library.

### Updating the OCI Utilities

To update to the latest version of `oci-utils`:

```
sudo yum update oci-utils
```

### Using the OCI Utilities

To use the OCI utilities, you first need to start the `ocid` service. This example starts the `ocid` daemon using `systemd` and sets the `ocid` service to start automatically during system boot.

```
sudo systemctl enable --now ocid.service
```

#### The `ocid` Daemon

**Description**

The `ocid` daemon is the service component of the `oci-utils`. It monitors for changes in the VNIC and iSCSI configuration of the instance and attempts to automatically attach or detach devices as they appear or disappear - for example, when they are created or deleted using the Oracle Cloud Infrastructure Console, CLI, or the API.

**Configuration**

The `ocid` daemon requires root privileges. You can configure root privileges for `ocid` using one of the following methods:

- Run the `oci setup config` configuration command as root to create SDK configuration files for the host. For more information, see SDK and CLI Configuration File on page 5308.
- Use instance principals by adding the instance to a dynamic group that was granted access to Oracle Cloud Infrastructure services. For more information, see Managing Dynamic Groups on page 3118.
- Configure `oci-utils` to allow root to use a non-privileged user's Oracle Cloud Infrastructure configuration files. For more information, see the configuration file located in the `/etc/oci-utils.conf.d` directory of the instance.

**Usage**

To start the `ocid` daemon using `systemd` and set the `ocid` service to start automatically during system boot:

```
sudo systemctl enable --now ocid.service
```

To confirm that the service is active (running):

```
sudo service ocid status
```

For example:

```
$ sudo service ocid status
Redirecting to /bin/systemctl status ocid.service
oci.service - Oracle Cloud Infrastructure utilities daemon
   Loaded: loaded (/etc/systemd/system/oci.service; enabled; vendor preset: enabled)
   Active: active (running) since Thu 2021-02-04 18:01:25 GMT; 1min 42s ago
 Main PID: 16630 (python3)
   CGroup: /system.slice/oci.service
     ##16630 /usr/bin/python3 /usr/lib/python3.6/site-packages/oci_util...
```
oci-growfs

Description
Expands the root filesystem of the instance to its configured size. This command must be run as root.

Usage
oci-growfs [-y] [-n] [-h | --help]

Options

-y
Answer "yes" to all prompts.

-n
Answer "no" to all prompts.

-h | --help
Display a summary of the command line options.

Example

$ sudo /usr/libexec/oci-growfs
CHANGE: disk=/dev/sda partition=3: start=17188864 old:
   size=80486399, end=97675263 new: size=192526302, end=209715166
Confirm? [y/n]: y
CHANGED: disk=/dev/sda partition=3: start=17188864 old:
   size=80486399, end=97675263 new: size=192526302, end=209715166

oci-iscsi-config

Description
Lists and configures iSCSI devices attached to a compute instance. When run without any command line options, 
oci-iscsi-config lists devices that need attention.

For a training video that demonstrates how to use the oci-iscsi-config utility, see Using OCI Utilities for 
Managing iSCSI Storage for Oracle Cloud Infrastructure Instances in the Oracle Learning Library.
Caution:
Avoid entering confidential information when assigning descriptions, tags, or friendly names to your cloud resources through the Oracle Cloud Infrastructure Console, API, or CLI.

Usage
oci-iscsi-config

oci-iscsi-config [-h | --help]

oci-iscsi-config sync

oci-iscsi-config sync [-a | --apply] [-y | --yes] [-h | --help]

oci-iscsi-config show

oci-iscsi-config create

oci-iscsi-config create [-S | --size size] [-v | --volume-name volume_name] [-a | --attach-volume] [-h | --help]

oci-iscsi-config attach

oci-iscsi-config detach

oci-iscsi-config detach [-I | --iqns IQNS] [-f | --force] [-h | --help]

oci-iscsi-config destroy

oci-iscsi-config destroy [-O | --ocids OCIDS] [-y | --yes] [-h | --help]

Options
oci-iscsi-config sync

sync
Attempt to attach available block devices. This option requires root privileges.
-a | --apply
Perform sync operations.
-y | --yes
Answer "yes" to all prompts.
-h | --help
Display a summary of the command line options.

oci-iscsi-config show

show
List block volumes and iSCSI information. If ocid is not running, then this option requires root privileges.
-C | --compartments compartment_name
Display iSCSI devices in the given compartment or all compartments (if all is specified for compartment_name).
-A | --all
Display all iSCSI devices. By default only devices that are not attached to an instance are listed.
--output-mode mode
Set output mode. For mode, specify a valid output mode, either parsable, table, json, or text.

--details
Display detailed information.

--no-truncate
Do not truncate values in output.

-h | --help
Display a summary of the command line options.

oci-iscsi-config create

create
Create a block volume. This option requires the Oracle Cloud Infrastructure SDK for Python to be installed and configured. This option also requires root privileges.

-S | --size size
Set the size of the block volume in gigabytes (GB). The minimum size is 50 GB.

-v | --volume-name volume_name
Set the display name for the volume. Avoid entering confidential information for the display name.

--attach-volume
Attach the volume after its creation.

-h | --help
Display a summary of the command line options.

oci-iscsi-config attach

attach
Attach a block volume to this instance and make it available to the system. The Oracle Cloud Infrastructure SDK for Python is required for selecting volumes using their Oracle Cloud Identifier (OCID). This option requires root privileges.

-I | --iqns IQNS
Attempt to attach the device with the given IQN (a unique ID assigned to a device) or OCID. When using an IQN, the volume must already be attached (assigned) to the instance in the Console. This option can be used to attach multiple devices at the same time by providing a comma-separated list of IQNs.

-u | --username username
Use the specified username as the CHAP username when authentication is needed for attaching a device. This option is not needed when the Oracle Cloud Infrastructure SDK for Python is available.

-p | --password password
Use the supplied password as the CHAP password when authentication is needed for attaching a device. This option is not needed when the Oracle Cloud Infrastructure SDK for Python is available.

-h | --help
Display a summary of the command line options.

oci-iscsi-config detach

detach
Detach a block volume. This option requires root privileges.

-I | --iqns IQNS
Detach the device with the given IQN (a unique ID assigned to a device) or OCID. If the volume (or any partition of the volume) is mounted, this option attempts to unmount it first. This option can be used to detach multiple devices at the same time by providing a comma-separated list of IQNs.

-f | --force
Compute

Continue detaching even if device cannot be unmounted.
-h | --help
Display a summary of the command line options.

oci-iscsi-config destroy

destroy

Destroy block storage volumes. Be sure that the volume is not attached to any instances before performing this operation. This option requires root privileges. Avoid entering confidential information.

-O | --ocids OCIDS
Destroy the block storage volume with the given OCID. This option can be used to destroy multiple volumes at the same time by specifying a comma-separated list of OCIDs.

-y | --yes
Answer "yes" to prompts.
-h | --help
Display a summary of the command line options.

Examples

Displaying iSCSI Configuration

The oci-iscsi-config utility works with the ocid daemon to monitor device creation and deletion through the Oracle Cloud Infrastructure Console, CLI, or the API and automatically discover those changes. You can use the oci-iscsi-config show option to display a list of all devices attached to an instance.

The following example shows the output of the oci-iscsi-config show option after adding a 50-GB block volume using the Console:

```
$ oci-iscsi-config show
Currently attached iSCSI devices:
 Volume name | Attached device | Size |
-----------------------------
 mor-demo-bv20          |      sdb      | 50G  |

Block volumes information:
 Name | Size | Attached to |
 OCID |      |
-----------------------------
 mor-demo-bv30          |  50GB |               -                |
 ocid1.volume.oc1.exampleuniqueID
```

The following example shows the output of oci-iscsi-config show with the --details and --no-truncate options:

```
$ oci-iscsi-config show --details --no-truncate
Currently attached iSCSI devices:
 Target | Volume name | Volume OCID | Persistent portal | Current portal | Session State | Attached device | Size |
-----------------------------
 iqn.2015-12.com.oracleiaas:exampleuniqueID| mor-demo-bv20 | ocid1.volume.oc1.id.exampleuniqueID | 172.16.10.4:3260 | 172.16.10.4:3260 | LOGGED_IN | sdb | 50G |

Block volumes information:
 Name | Size | Attached to |
 OCID | IQN | Compartment | Availability |
-----------------------------
```
By default, the `oci-iscsi-config show` option lists the output in a tabular presentation. You can change the output presentation by using the `--output-mode` mode option. For example, the following example shows the output of `oci-iscsi-config show` using `--output-mode text` option to display the output in a textual presentation.

```
$ oci-iscsi-config show --output-mode text
Currently attached iSCSI devices
Volume name: mor-demo-bv20
Attached device: sdb
Size: 50G

Block volumes information
Name: mor-demo-bv30
Size: 50GB
Attached to: -
OCID: ocid1.volume.oc1.iad..exampleuniqueID
```

**Creating and Attaching a Volume**

The following example shows how to create and attach a volume:

```
$ sudo oci-iscsi-config create -S 70 --volume-name=mor-demo-by70 --attach-volume
Creating a new 70 GB volume
Volume name=mor-demo-by70 created
Attaching the volume to this instance
Attaching iSCSI device
iscsiadm attach Result: command executed successfully
```

**Detaching a Volume**

The following example shows how to detach a volume:

```
$ sudo oci-iscsi-config detach -I
iqn.2015-12.com.oracleiaas:exampleuniqueID
Detaching volume mor-demo-bv70 (iqn.2015-12.com.oracleiaas:exampleuniqueID)
Updating detached volume cache file:
['iqn.2015-12.com.oracleiaas:oracleiaas:exampleuniqueID']
```

**Deleting a Volume**

The following example shows how to destroy a volume:

```
$ sudo oci-iscsi-config destroy -O ocid1.volume.oc1.exampleuniqueID
WARNING: the volume(s) will be destroyed. This is irreversible. Continue?
y
Volume [ocid1.volume.oc1.iad.exampleuniqueID] is destroyed
```

**oci-metadata**

**Description**

Displays or sets metadata for a compute instance. When run without any command line options, `oci-metadata` lists all available metadata.
For more information about instance metadata, see Getting Instance Metadata on page 1117.

Usage

Options

-h | --human-readable
Display human readable output (default).

-j | --json
Display output in JSON.

-g key | --get key
Retrieve data only for the specified key.

--export
Used with the -g or --get option, display a shell command to export the key as an environment variable.

--trim
Used with the -g or --get option, trim the key path to the last component to make the output more concise; for example, instance/metadata/ssh_authorized_keys to ssh_authorized_keys. If the key matches multiple keys, only the first matching key is displayed.

--value-only
Used with the -g or --get option, display only the values matching the get key.

-u key_value
Update the value for the given key (or keys). For key_value, specify a string, a JSON value, or a pointer to a file with JSON content in the following format: key=file:/path/to/file

-i | --instance-id OCID
Get or update the metadata of the instance with the given OCID. By default, oci-metadata works with the metadata from the instance that you logged in to.

--help
Display a summary of the command line options.

Examples

Getting all metadata for the instance

Running oci-metadata with no options returns all metadata for the instance:

```
$ oci-metadata
Instance details:
  Display Name: my-example-instance
  Region: phx - us-phoenix-1 (Phoenix, AZ, USA)
  Canonical Region Name: us-phoenix-1
  Availability Domain: cumS:PHX-AD-1
```
Fault domain: FAULT-DOMAIN-3
OCID: ocid1.instance.oc1.phx.exampleuniqueID
Compartment OCID: ocid.compartment.oc1..exampleuniqueID
Instance shape: VM.Standard2.1
Image ID: ocid1.image.oc1.phx.exampleuniqueID
Created at: 1569529065596
state: Running
agentConfig:
  managementDisabled: False
  monitoringDisabled: False
Instance Metadata:
  sshAuthorizedKeys: example-key
Networking details:
  VNIC OCID: ocid1.vnic.oc1.phx.exampleuniqueID
  VLAN Tag: 2392
  Private IP address: 10.0.0.16
  MAC address: 02:00:17:03:D8:FE
  Subnet CIDR block: 10.0.0.0/24
  Virtual router IP address: 10.0.0.1

Getting only specific metadata
The following example shows how to retrieve metadata for a specified key by using the --get parameter:

# oci-metadata --get state
Instance details:
Instance state: Running

oci-network-config

Description
Configures network interfaces for a compute instance.

For a training video that demonstrates how to use the oci-network-config utility, see Network Interface Management Using OCI Utilities on Oracle Linux Instances in the Oracle Learning Library.

Usage
oci-network-config

oci-network-config [-q | --quiet] [-h | --help]

oci-network-config show

oci-network-config show [-I | --include item] [-X | --exclude item] [--output-mode mode] [--details] [-h | --help]

oci-network-config show-vnics

oci-network-config configure

oci-network-config configure [-n | --namespace format] [-r | --start-sshd] [-I | --include item] [-X | --exclude item] [-h | --help]

oci-network-config unconfigure

oci-network-config unconfigure [-I | --include item] [-X | --exclude item] [-h | --help]
oci-network-config attach-vnic

oci-network-config detach-vnic

    oci-network-config detach-vnic [-I | --ip-address ip_address] [--ocid OCID] [-h | --help]

oci-network-config add-secondary-addr

    oci-network-config add-secondary-addr [-I | --ip-address ip_address] [--ocid OCID] [-h | --help]

oci-network-config remove-secondary-addr

    oci-network-config remove-secondary-addr [-I | --ip-address ip_address] [-h | --help]

Options

oci-network-config

Display information about VNICS configured on the Oracle Cloud Infrastructure instance.

By default this command displays the currently provisioned VNICS and the current IP configuration for this instance. VNICS that are not yet configured are flagged as ADD and IP configurations that no longer have an associated VNIC are marked with DELETE.

-q | --quiet
Do not display information messages.

-h | --help
Display a summary of the command line options.

oci-network-config show

    show

Display the current VNICS provisioned and configured on the Oracle Cloud Infrastructure instance.

-1 | --include item
Include an item (IP address or VLAN interface) that was previously excluded using the --exclude option in automatic configuration/deconfiguration.

-X | --exclude item
Persistently exclude an item (IP address or VLAN interface) from automatic configuration/deconfiguration.

Use the --include option to include the item again.

--output-mode mode
Set output mode. For mode, specify a valid output mode, either parsable, table, json, or text.

--details
Display detailed information.

-h | --help
Display a summary of the command line options.

oci-network-config show-vnics

    show-vnics

Display information about VNICS configured on the instance.

--output-mode mode
Set output mode. For mode, specify a valid output mode, either parsable, table, json, or text.
--details
Display detailed information.
--ocid VNIC_OCID
Show information about the VNIC that matches the given Oracle Cloud Identifier (OCID).
--name VNIC_name
Show information about the VNIC associated with the given name.
--ip-address primary_IP
Show information about the VNIC associated with the given primary IP address.
-h | --help
Display a summary of the command line options.

oci-network-config configure

configure
Configure VNICs that do not have an IP configuration and delete the IP configurations of VNICs that are not currently provisioned. Using this option synchronizes the IP configuration with Oracle Cloud Infrastructure provisioning. This option requires root privileges.
-n | --namespace format
When configuring, place interfaces in namespace identified by the given format. Format can include $nic
and $vltag variables.
The configured interfaces can optionally be placed inside separate network namespaces. Network namespaces are necessary when VNICs are in different VCNs with overlapping address blocks and the network applications are not bound directly to interfaces. Network namespaces require applications to be launched in them explicitly (using the ip netns exec command) to establish the association with the interface. When namespaces are not used, policy-based routing is configured to provide a default route to the default gateway of the secondary VNIC when the address of the VNIC is the source address.
-r | --start-sshd
Start sshd in namespace (if -n is present).
-I | --include item
Include an item (IP address or VLAN interface) that was previously excluded using the --exclude option in automatic configuration/deconfiguration.
-X | --exclude item
Persistently exclude an item (IP address or VLAN interface) from automatic configuration/deconfiguration.
Use the --include option to include the item again.
-h | --help
Display a summary of the command line options.

oci-network-config unconfigure

unconfigure
Delete all IP configuration for provisioned secondary VNICs. The primary VNIC cannot be deleted. This option requires root privileges.
-I | --include item
Include an item (IP address or VLAN interface) that was previously excluded using the --exclude option in automatic configuration/deconfiguration.
-X | --exclude item
Persistently exclude an item (IP address or VLAN interface) from automatic configuration/deconfiguration.
Use the --include option to include the item again.
-h | --help
Display a summary of the command line options.
oci-network-config attach-vnic

attach-vnic
Create a VNIC and attach it to this instance. This option requires root privileges.

-I | --ip-address ip_address
Assign the given private IP address to the VNIC. If this option is not used, an unused IP address from the subnet is assigned automatically to the VNIC.

-i | --nic-index index
Assign the VNIC to the specified physical NIC card. For index, specify the index number assigned to the physical NIC card. The default value is 0. This option is used only for bare metal instances.

--subnet subnet
Connect the VNIC to the given subnet. For subnet, specify an OCID or a regular expression that is matched against the display name of all available subnets. When --ip-address is used, the subnet is inferred from the IP address, or defaults to the subnet of the primary VNIC.

-n | --name name
Set the display name for the VNIC. Avoid entering confidential information.

--assign-public-ip
Assign a public IP address to the VNIC. By default, only a private IP address is assigned.

--configure
Configure the network interface on the system after the VNIC is created and attached, c

-h | --help
Display a summary of the command line options.

oci-network-config detach-vnic

detach-vnic
Detach and delete the VNIC with the given OCID or IP address. The primary VNIC cannot be detached. Any secondary private IP addresses associated with the VNIC are also deleted. This option requires root privileges.

-I | --ip-address ip_address
Detach the VNIC with the given IP address.

--ocid OCID
Detach the VNIC with the given OCID.

-h | --help
Display a summary of the command line options.

oci-network-config add-secondary-addr

add-secondary-addr
Add secondary private IP address to an existing VNIC. This option requires root privileges.

-I | --ip-address ip_address
Specify secondary private IP address to add to the VNIC.

-ocid OCID
Assign the secondary address to the VNIC associated with the given OCID.

-h | --help
Display a summary of the command line options.

oci-network-config remove-secondary-addr

remove-secondary-addr
Remove secondary private IP address from an existing VNIC. This option requires root privileges.

-I | --ip-address ip_address
Specify the secondary private IP address to remove from the VNIC.

-h | --help

Display a summary of the command line options.

Examples

Displaying current network configuration

Running `oci-network-config` with no options returns the network configuration of the current instance:

```bash
$ sudo oci-network-config show --details
Network configuration:
State | Link | Status | Ip address | Hostname | Subnet
| MAC | Router IP | Namespace | Index | VLAN tag | VLAN | Subnet
- | - | - | - | - | - | -
| ens3 | 02:00:17:02:C6:B2 | mor-demo-inst-10 | 10.102.118.251 | - | - | -
| 10.102.112.1 | - | common.sub | 2 | - | - | -
```

Creating a VNIC

This example shows how to create a VNIC named `ex-demo-inst-10` and attaches it to the instance:

```bash
$ sudo oci-network-config attach-vnic -n ex-demo-inst-10
creating VNIC: 10.102.119.140
```

Running `oci-network-config show` with the `--details` option shows information for the new VNIC:

```bash
$ sudo oci-network-config show --details
Network configuration:
State | Link | Status | Ip address | Hostname | Subnet
| MAC | Router IP | Namespace | Index | VLAN tag | VLAN | Subnet
- | - | - | - | - | - | -
| ens3 | 02:00:17:02:C6:B2 | mor-demo-inst-10 | 10.102.118.251 | - | - | -
| 10.102.112.1 | - | common.sub | 2 | 3814 | - | -
ADD | ens5 | DOWN | 10.102.119.140 | mor-demo-inst-10-ex-dem... | 10.102.112.0/20 (common.sub) | 7 | 3387 | - | -
```

Running `oci-network-config show-vnics` shows information about VNICs configured on the instance:

```bash
$ sudo oci-network-config show-vnics
VNI Information:
Name | OCID | Private IP | MAC
ex-demo-inst-10 | ocid1.vnic.oc1.idc.exampleuniqueID | 10.102.119.140 | 00:00:17:02:CC:CB
mor-demo-inst-10 | ocid1.vnic.oc1.idc.exampleuniqueID | 10.102.118.251 | 00:00:17:02:CC:CB
```

Oracle Cloud Infrastructure User Guide 968
Detaching a VNIC

The following example shows how to detach the given VNIC:

```
$ sudo oci-network-config detach-vnic -I 10.102.119.136
```

oci-network-inspector

Description

Displays a detailed network report for a given compartment or network.

Usage

```
oci-network-inspector [-C | --compartment OCID] [-N | --vcn OCID] [-h | --help]
```

Options

- `-C | --compartment OCID`

Show report for the specified compartment.

- `-N | --vcn OCID`

Show report for the specified virtual cloud network.

- `-h | --help`

Display a summary of the command line options.

Examples

Displaying a detailed report for a specified compartment

Running the `oci-network-inspector` command and specifying an OCID with the `-C` parameter returns a detailed network report for that compartment:

```
$ oci-network-inspector -C ocid1.compartment.oc1..example_OCID
```

Compartment: scottb_sandbox (ocid1.compartment.oc1..example_OCID)

```
vcn: scottb_vcn
  Security List: Default Security List for scottb_vcn
    Ingress: tcp 0.0.0.0/0:- ---:22

    Ingress: tcp 0.0.0.0/0:43 ---:43
```

oci-notify

Description

Sends a message to a Notifications service topic. This command must be run as root.

A message is composed of a message header (subject) and file. The Notifications service configuration for the topic determines where and how the messages are delivered. Topics are configured using the Oracle Cloud Infrastructure Console, API, or CLI.

For more information about the Notifications service, including how to create topics, see Notifications Overview.

Usage

oci-notify [-c topic_OCID] [-t subject -f file] [-h | --help]
Options

-c topic_OCID
Write the topic to the /etc/oci-utils/oci.conf file. The path to the configuration file can be overridden by using OCI_CONFIG_DIR environment variable.

For topic_OCID, specify the Oracle Cloud Identifier (OCID) associated with the Notifications service topic.

-t subject -f file
Publish the contents of specified file with the specified subject to the topic, which is sent to each subscription for the topic.

For subject, enter an appropriate subject to be used as the message header (for example, 'log messages' if you are sending log files). The subject must be enclosed in either single or double quotation marks. Message headers are truncated to 128 characters.

Note:
When the message is published, the oci-notify utility prepends the instance name to the subject of the message, for example, instance name:log messages.

For file, enter the full or relative directory path, HTTP, or FTP URL of the message file to be sent. Large files are split into 64-KB chunks.

Note:
The oci-notify utility writes log and error messages to the /var/log/oci-notify.log file.

-h | help
Display a summary of the command line options.

Examples

Configuring a Topic on an Instance
The following example shows how to write the OCID of a configured Notifications service topic to the oci.conf file. After configured, you can publish messages to the configured topic.

$ sudo oci-notify -c ocid1.onstopic.oc1..example_OCID

Publishing a Message to a Topic
The following example shows how to send the contents of the /var/log/messages file with the subject 'logging messages' to the configured topic:

$ sudo oci-notify -t 'logging messages' -f /var/log/messages

The following example shows how to send the contents of the /proc/meminfo file with the subject 'memory information' to the configured topic:

$ sudo oci-notify -t 'memory information' -f /proc/meminfo
The following example shows how to send the contents of the /tmp/uptrack-show file with the subject 'installed Ksplice updates' to the configured topic:

```
$ sudo oci-notify -t 'installed Ksplice updates' -f /tmp/uptrack-show
```

**oci-public-ip**

**Description**

Displays the public IP address of the current system in either human-readable or JSON format.

The `oci-public-ip` utility uses the Oracle Cloud Infrastructure SDK to discover the IP address. If the IP address cannot be obtained through this method, the `oci-public-ip` utility then tries the Session Traversal Utilities for NAT (STUN) protocol as a last resort to discover the IP address. For more information on STUN, see the STUN Wikipedia article.

**Usage**

```
```

**Options**

- **-h | --human-readable**
  Display human readable output (default).

- **-j | --json**
  Display output in JSON.

- **-g | get**
  Print the IP address only.

- **-a | all**
  Display all public IP addresses.

- **-s | --sourceip source_IP**
  Specify the source IP address to use.

- **-S | --stun-server STUN_server**
  Specify the STUN server to use.

- **-L | --list-servers**
  Print a list of known STUN servers and exit.

- **--instance-id OCID**
  Display the public IP address of the given instance instead of the current one. Requires the Oracle Cloud Infrastructure SDK for Python to be installed and configured.

- **--help**
  Display a summary of the command line options.
Examples

Displaying current IP address
Running the `oci-public-ip` command with no options returns the IP address of the current instance:

```
$ oci-public-ip
Public IP address: 203.0.113.2
```

Displaying the IP address of another instance
You can pass in the OCID of a running instance with the `--instance-id` option to return the IP address for that instance:

```
$ oci-public-ip --instance-id ocid1.instance.oc1.phx.example_OCID
Public IP address: 203.0.113.2
```

Listing STUN servers
Use the `--list-servers` option to return a list of STUN servers:

```
$ oci-public-ip --list-servers
stun.stunprotocol.org
stun.counterpath.net
stun.voxgratia.org
stun.callwithus.com
stun.ekiga.net
stun.ideasip.com
stun.voipbuster.com
stun.voiparound.com
stun.voipstunt.com
```

Compute Shapes
A shape is a template that determines the number of OCPUs, amount of memory, and other resources that are allocated to an instance. Compute shapes are available with AMD processors, Intel processors, and Arm-based processors.

This topic provides basic information about the shapes that are available for bare metal instances, virtual machines (VMs), and dedicated virtual machine hosts.

Flexible Shapes
A flexible shape is a shape that lets you customize the number of OCPUs and the amount of memory when launching or resizing your VM. When you create a VM instance using a flexible shape, you select the number of OCPUs and the amount of memory that you need for the workloads that run on the instance. The network bandwidth and number of VNICs scale proportionately with the number of OCPUs. This flexibility lets you build VMs that match your workload, enabling you to optimize performance and minimize cost.

These are the flexible shapes:

- VM.Standard.E3.Flex (AMD)
- VM.Standard.E4.Flex (AMD)
- VM.Optimized3.Flex (Intel)
- VM.Standard.A1.Flex (Arm processor from Ampere)

Flexible memory is also available on flexible shapes. The amount of memory allowed is based on the number of OCPUs selected. The ratio of memory to OCPUs depends on the shape.
Compute

<table>
<thead>
<tr>
<th>Shape</th>
<th>Memory per OCPU</th>
<th>Minimum Memory</th>
<th>Maximum Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM.Standard.E3.Flex</td>
<td>64 GB per OCPU</td>
<td>1 GB or a value matching the number of OCPUs, whichever is greater</td>
<td>1024 GB</td>
</tr>
<tr>
<td>VM.Standard.E4.Flex</td>
<td>64 GB per OCPU</td>
<td>1 GB or a value matching the number of OCPUs, whichever is greater</td>
<td>1024 GB</td>
</tr>
<tr>
<td>VM.Optimized3.Flex</td>
<td>64 GB per OCPU</td>
<td>1 GB or a value matching the number of OCPUs, whichever is greater</td>
<td>256 GB</td>
</tr>
<tr>
<td>VM.Standard.A1.Flex</td>
<td>64 GB per OCPU</td>
<td>1 GB or a value matching the number of OCPUs, whichever is greater</td>
<td>512 GB</td>
</tr>
</tbody>
</table>

These resources are billed at a per-second granularity with a one-minute minimum. Optimize your costs by choosing the shape that matches your workload and by changing the shape when your workload changes. For example, you can configure the VM to maximize compute processing power by choosing a low core-to-memory ratio. Or, for applications like in-memory databases or big data processing engines, configure an instance with a high core-to-memory ratio. Modify the OCPUs and memory as your workload changes, scaling up to increase performance or scaling down to reduce costs.

**Supported Images**

Most platform images are compatible with flexible shapes. Refer to the following lists.

**Supported Platform Images for E3 Shapes**

Use an image that was published in March 2020 (for Linux images) or April 2020 (for Windows images) or later.

- Oracle Linux Cloud Developer 8
  
  Oracle Linux Cloud Developer provides the latest development tools, languages and Oracle Cloud Infrastructure software development kits (SDKs) to rapidly launch a comprehensive development environment. The Oracle Linux Cloud Developer image requires at least 8 GB of memory.

- Oracle Autonomous Linux 7.x
- Oracle Linux 8.x
- Oracle Linux 7.x
- Oracle Linux 6.x (VMs only)
- CentOS 8.x
- CentOS 7.x
- Ubuntu 20.04
- Ubuntu 18.04
- Windows Server 2019 (VMs only)
- Windows Server 2016 (VMs only)
- Windows Server 2012 R2 (VMs only)

**Supported Platform Images for E4 Shapes**

Use an image that was published in February 2021 (for Linux images and Windows Server 2012 R2 images) or March 2021 (for Windows Server 2016 and Windows Server 2019 images), or later.

- Oracle Linux Cloud Developer 8
  
  Oracle Linux Cloud Developer provides the latest development tools, languages and Oracle Cloud Infrastructure software development kits (SDKs) to rapidly launch a comprehensive development environment. The Oracle Linux Cloud Developer image requires at least 8 GB of memory.

- Oracle Autonomous Linux 7.x
- Oracle Linux 8.x
- Oracle Linux 7.x
- CentOS 8.x
- CentOS 7.x
- Ubuntu 20.04
- Ubuntu 18.04
- Windows Server 2019 (VMs only)
- Windows Server 2016 (VMs only)
- Windows Server 2012 R2 (VMs only)

**Supported Platform Images for Optimized3 Shapes**

Use an image that was published in February 2021 (for Linux images and Windows Server 2012 R2 images), March 2021 (for VMs running Windows Server 2016 or Windows Server 2019 images), May 2021 (for bare metal instances running Windows Server 2016 or Windows Server 2019 images), or later.

- Oracle Linux Cloud Developer 8

  *Oracle Linux Cloud Developer* provides the latest development tools, languages and Oracle Cloud Infrastructure software development kits (SDKs) to rapidly launch a comprehensive development environment. The Oracle Linux Cloud Developer image requires at least 8 GB of memory.

- Oracle Linux 8.x
- Oracle Linux 7.x
- CentOS 8.x
- CentOS 7.x
- Ubuntu 20.04
- Ubuntu 18.04
- Windows Server 2019
- Windows Server 2016
- Windows Server 2012 R2 (VMs only)

**Supported Platform Images for A1 Shapes**

Use an image that was published in April 2021 (for Oracle Linux and Ubuntu images), May 2021 (for Oracle Linux Cloud Developer images), or later.

- Oracle Linux Cloud Developer 8

  *Oracle Linux Cloud Developer* provides the latest development tools, languages and Oracle Cloud Infrastructure software development kits (SDKs) to rapidly launch a comprehensive development environment. The Oracle Linux Cloud Developer image requires at least 8 GB of memory.

- Oracle Linux 8.x
- Oracle Linux 7.x
- Ubuntu 20.04 (use the Ubuntu image, not Minimal Ubuntu)
- Ubuntu 18.04 (use the Ubuntu image, not Minimal Ubuntu)

Custom images are also supported, depending on the image. You must add flexible shape compatibility to the custom image, and then test the image on the flexible shape to ensure that it actually works on the shape.

**Supported Regions**

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>When a new region becomes available, it might take a few weeks before host capacity also becomes available.</td>
</tr>
<tr>
<td>Capacity might be limited for A1 shapes.</td>
</tr>
</tbody>
</table>

**E3 shapes:** Supported in all regions.

**A1 shapes:** Supported in all commercial regions.
E4 shapes and Optimized3 shapes: Supported in some regions. For a list, see the compute instance service limits for the following shape series:

- BM.Standard.E4 and VM.Standard.E4 cores
- BM.Optimized3 and VM.Optimized3 cores

As host capacity becomes available in additional regions, the list will be updated.

Bare Metal Shapes

The following shapes are available for bare metal instances:

- Standard Shapes on page 976
- Dense I/O Shapes on page 977
- GPU Shapes on page 977
- HPC Shapes on page 978
- Optimized Shapes on page 978

Network bandwidth is based on expected bandwidth for traffic within a VCN. To determine which physical NICs are active for a shape, refer to the network bandwidth specifications in the following tables. If the network bandwidth is listed as "2 x <bandwidth> Gbps," it means that both NIC 0 and NIC 1 are active.

Standard Shapes

Designed for general purpose workloads and suitable for a wide range of applications and use cases. Standard shapes provide a balance of cores, memory, and network resources. Standard shapes are available with Intel, AMD, and Arm-based processors.

These are the bare metal standard series:

- **BM.Standard2**: X7-based standard compute. Processor: Intel Xeon Platinum 8167M. Base frequency 2.0 GHz, max turbo frequency 2.4 GHz.

<table>
<thead>
<tr>
<th>Shape</th>
<th>OCPU</th>
<th>Memory (GB)</th>
<th>Local Disk</th>
<th>Max Network Bandwidth</th>
<th>Max VNICS Total: Linux</th>
<th>Max VNICS Total: Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td>BM.Standard2.52</td>
<td>52</td>
<td>768</td>
<td>Block storage only</td>
<td>2 x 25 Gbps</td>

<td>101 total (1 on the first physical NIC, 100 on the second)</td>
</tr>
<tr>
<td>BM.Standard.E3.28</td>
<td>28</td>
<td>2048</td>
<td>Block storage only</td>
<td>2 x 50 Gbps</td>
<td>256</td>
<td>129 (1 on the first physical NIC, 128 on the second)</td>
</tr>
<tr>
<td>BM.Standard.E4.28</td>
<td>28</td>
<td>2048</td>
<td>Block storage only</td>
<td>2 x 50 Gbps</td>
<td>256</td>
<td>129 (1 on the first physical NIC, 128 on the second)</td>
</tr>
</tbody>
</table>
Dense I/O Shapes

Designed for large databases, big data workloads, and applications that require high-performance local storage. Dense I/O shapes include locally-attached NVMe-based SSDs.

This is the bare metal dense I/O series:

- **BM.DenseIO2**: X7-based dense I/O compute. Processor: Intel Xeon Platinum 8167M. Base frequency 2.0 GHz, max turbo frequency 2.4 GHz.

<table>
<thead>
<tr>
<th>Shape</th>
<th>OCPU</th>
<th>Memory (GB)</th>
<th>Local Disk</th>
<th>Max Network Bandwidth</th>
<th>Max VNICs Total: Linux</th>
<th>Max VNICs Total: Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td>BM.DenseIO2</td>
<td>52</td>
<td>768</td>
<td>51.2 TB NVMe SSD (8 drives)</td>
<td>2 x 25 Gbps</td>
<td>52 total (26 per physical NIC)</td>
<td>27 total (1 on the first physical NIC, 26 on the second)</td>
</tr>
</tbody>
</table>

GPU Shapes

Designed for hardware-accelerated workloads. GPU shapes include Intel or AMD CPUs and NVIDIA graphics processors.

These are the bare metal GPU series:

- **BM.GPU3**: X7-based GPU compute.
  - GPU: NVIDIA Tesla V100 16 GB
  - CPU: Intel Xeon Platinum 8167M. Base frequency 2.0 GHz, max turbo frequency 2.4 GHz.

- **BM.GPU4**: E2-based GPU compute.
  - GPU: NVIDIA A100 40 GB
  - CPU: AMD EPYC 7542. Base frequency 2.9 GHz, max boost frequency 3.4 GHz.

<table>
<thead>
<tr>
<th>Shape</th>

<td>1 x 50 Gbps 8 x 200 Gbps RDMA</td>
<td>64</td>
<td>Windows platform images do not support this shape.</td>
</tr>
</tbody>
</table>

**HPC Shapes**

Designed for high-performance computing workloads that require high frequency processor cores and cluster networking for massively parallel HPC workloads.

This is the bare metal HPC series:
- **BM.HPC2**: X7-based high frequency compute. Processor: Intel Xeon Gold 6154. Base frequency 3.0 GHz, max turbo frequency 3.7 GHz.

<table>
<thead>
<tr>
<th>Shape</th>
<th>OCPU</th>
<th>Memory (GB)</th>
<th>Local Disk</th>
<th>Max Network Bandwidth</th>
<th>Max VNICs Total: Linux</th>
<th>Max VNICs Total: Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td>BM.HPC2.36</td>
<td>36</td>
<td>384</td>
<td>6.4 TB NVMe SSD (1 drive)</td>
<td>1 x 25 Gbps 1 x 100 Gbps RDMA</td>
<td>50</td>
<td>1</td>
</tr>
</tbody>
</table>

**Optimized Shapes**

Designed for computing workloads that require high frequency processor cores. Optimized shapes are also suitable for HPC workloads that require high-performance coupled with low latency. Optimized shapes support cluster networking.

This is the bare metal Optimized series:
- **BM.Optimized3**: Processor: Intel. Base frequency 3.0 GHz, max turbo frequency 3.6 GHz.

<table>
<thead>
<tr>
<th>Shape</th>
<th>OCPU</th>
<th>Memory (GB)</th>
<th>Local Disk</th>

<td>3.84 TB NVMe SSD (1 drive)</td>
<td>2 X 50 Gbps 1 X 100 Gbps RDMA</td>
<td>256</td>
<td>129</td>
</tr>
</tbody>
</table>

**VM Shapes**

The following shapes are available for VMs:
- **Standard Shapes** on page 979
- **Dense I/O Shapes** on page 980
- **GPU Shapes** on page 981
- **Optimized Shapes** on page 981

Network bandwidth is based on expected bandwidth for traffic within a VCN.
**Standard Shapes**

Designed for general purpose workloads and suitable for a wide range of applications and use cases. Standard shapes provide a balance of cores, memory, and network resources. Standard shapes are available with Intel, AMD, and Arm-based processors.

These are the VM standard series:

- **VM.Standard2**: X7-based standard compute. Processor: Intel Xeon Platinum 8167M. Base frequency 2.0 GHz, max turbo frequency 2.4 GHz.
- **VM.Standard.E3**: E3-based standard compute, with a flexible number of OCPUs. Processor: AMD EPYC 7742. Base frequency 2.25 GHz, max boost frequency 3.4 GHz.

<table>
<thead>
<tr>

<td>Windows images are not supported on this shape.</td>
</tr>
</tbody>
</table>

1: Instances are billed for the full amount of memory that you provision. Usable memory is reduced by up to 256 MB per instance. This difference is due to memory reserved to support the VM on the hypervisor.

Dense I/O Shapes

Designed for large databases, big data workloads, and applications that require high-performance local storage. DenseI/O shapes include locally-attached NVMe-based SSDs.

This is the VM dense I/O series:

- **VM.DenseIO2:** X7-based dense I/O compute. Processor: Intel Xeon Platinum 8167M. Base frequency 2.0 GHz, max turbo frequency 2.4 GHz.
**GPU Shapes**

Designed for hardware-accelerated workloads. GPU shapes include Intel or AMD CPUs and NVIDIA graphics processors.

This is the VM GPU series:

- **VM.GPU3**: X7-based GPU compute.
  - GPU: NVIDIA Tesla V100 16 GB
  - CPU: Intel Xeon Platinum 8167M. Base frequency 2.0 GHz, max turbo frequency 2.4 GHz.

<table>
<thead>

<td>48</td>
<td>768</td>
<td>736</td>
<td>VM.DenseIO2 series</td>
</tr>
</tbody>
</table>

1: The difference between total and usable OCPUs and memory is caused by the need to reserve OCPUs and memory for hypervisor use.

2: Because the DVH.Standard.E2.64 shape supports hosted VMs that use a previous generation shape series, it is available by request only.

3: For Standard2, Standard.E2, and DenseIO2 shapes, billing is based on OCPUs, not memory. For Standard.E3 shapes, billing is based on OCPUs and memory, which are billed independently.

Previous Generation Shapes

Oracle Cloud Infrastructure periodically releases new generations of Compute shapes. The latest shapes let you take advantage of newer hardware and a better price-performance ratio. When a shape is several years old, and newer generation shapes that are suited for the same purposes are available, the old shape transitions to become a previous generation shape.

Previous generation shapes are still fully supported. However, because the underlying hardware has reached the sustaining phase of its lifecycle, capacity in certain high-demand regions might be limited.

If you're using a previous generation shape, we encourage you to upgrade to a current generation shape.

Upgrading from a Previous Generation Shape

To upgrade from a previous generation shape to a current generation shape, you can do the following things:

- For supported VM instances, change the shape of the instance.
- For bare metal instances and VM instances that don't support changing the shape, terminate the instance but DO NOT delete the boot volume. Then, use the boot volume to create a new instance.

Previous Generation Bare Metal Shapes

These are the previous generation bare metal shape series.

BM.Standard1

Newer shape recommendation: BM.Standard2 or BM.Standard.E3 series

End of orderability date: December 31, 2020

X5-based standard compute. Processor: Intel Xeon E5-2699 v3. Base frequency 2.3 GHz, max turbo frequency 3.6 GHz.

Arm-Based Compute

Ampere A1 Compute is a general-purpose, Arm-based compute platform based on the Ampere Altra processor. Ampere A1 Compute instances provide superior price-performance, near linear scaling, built-in security due to the single-threaded core architecture, and a broad developer ecosystem.

Arm processors, ubiquitous in mobile computing, are increasingly used in PCs, laptops, and servers. Arm processors use a reduced instruction set computing (RISC) architecture, which requires less power and less silicon for each core than x86 processors. Arm puts more cores in a CPU socket and provides more dedicated resources for each core. As a result, Arm processors provide predictable performance, provide the highest density of cores, and consume overall less power. Ampere A1 Compute eases server-side development on Arm by providing the performance, features, and scalability required for cloud-to-edge infrastructure on Arm.

Ampere A1 Compute instances are suitable for a wide range of applications and use cases. For example:

- Containerized workloads
- Databases and in-memory databases, including MySQL
- Web applications
- Media encoding
- AI and machine learning (ML) inferencing
- Mobile apps and game development
- High performance computing (HPC)

Oracle’s development stack is available on Ampere A1 Compute, including Oracle Linux, Java, MySQL, GraalVM, and Oracle Cloud Infrastructure Container Engine for Kubernetes. To make it easier to start developing on Ampere A1 Compute, you can use the pre-built Oracle Linux Cloud Developer platform image. For a full list of open-source organizations and partners that have developed solutions for Ampere A1 Compute, see the Ampere A1 Compute product page.

Creating Arm-Based Compute Instances

You can create Arm-based virtual machine (VM) and bare metal compute instances using Ampere A1 Compute.

If this is your first time creating an instance, consider following the Getting Started tutorial for a guided workflow through the steps required to create an instance.

If you're already familiar with Oracle Cloud Infrastructure and want to explore the full set of configuration options that are available when you create an instance, follow the detailed steps to create an instance.

Flexible hardware specifications: The Ampere A1 Compute shapes include the BM.Standard.A1.160 shape for bare metal instances and the VM.Standard.A1.Flex shape for VMs. For information about the OCPU count, memory, storage, and networking details of these shapes, see Compute Shapes on page 973.

Because the Ampere A1 Compute shape for VMs is a flexible shape, you can customize the number of OCPUs and amount of memory that are allocated to each instance. This flexibility lets you build VMs that match your workload, enabling you to optimize performance and minimize cost.

Images: We recommend the Oracle Linux Cloud Developer image, available as a platform image. Oracle Linux Cloud Developer provides the latest development tools, languages and Oracle Cloud Infrastructure software development kits (SDKs) to rapidly launch a comprehensive development environment. The Oracle Linux and Ubuntu platform images are also supported.

Managing instances: After you create an Ampere A1 Compute instance, you can use many of the features that are available for compute instances. For example:

- Monitor the health, capacity, and performance of your instances by using metrics, alarms, and notifications.
- Adjust the number of OCPUs, memory, and other resources that are allocated to the instance. This lets you scale up your compute resources for increased performance, or scale down to reduce cost, without having to rebuild your instances or redeploy your applications.
Getting Started with Ampere A1 Compute for Free

All tenancies, including paid, trial, and Always Free accounts, get the first 3,000 OCPU hours and 18,000 GB hours per month for free for Ampere A1 Compute instances. For Always Free tenancies, this is equivalent to 4 OCPUs and 24 GB of memory.

If your project requires more resources, apply to participate in the Arm Accelerator program.

Developing on Arm-based Compute

The Arm developer page is where you can find comprehensive information about Ampere A1 Compute, including use cases, tutorials, blog posts, and more.

Oracle's developer stack for Arm includes the following resources:

- Oracle Java SE Embedded and JDK for ARM documentation
- Get Started with GraalVM for Linux AArch64
- Oracle Linux 7 and Oracle Linux 8 documentation and release notes for Arm (aarch64)

Tutorials and Reference Architectures

To get started with Ampere A1 Compute, follow the step-by-step instructions in these tutorials:

- Deploy Java applications on Oracle Cloud Infrastructure Ampere A1
- Get started with GraalVM on Oracle Cloud Infrastructure Ampere A1
- Deploy Nextcloud on Oracle Cloud Infrastructure Ampere A1
- Get Started with Arm-Based Kubernetes Clusters in Oracle Cloud Infrastructure
- Set up WordPress with MySQL Database and Matomo Analytics using Arm-based Ampere A1 Compute resources
- Deploy Apache Tomcat on Arm-based Ampere A1 compute connected to an Autonomous Database

For more resources, see the Arm developer page.

Deploying Containerized Applications on Ampere A1 Compute

Ampere A1 Compute is a native cloud platform designed for running containers to build native cloud workloads. Use Container Engine for Kubernetes (OKE) to define and create Kubernetes clusters to enable the deployment, scaling, and management of containerized applications. For more information, see Running Applications on Arm-based Nodes on page 1356.

Use Oracle Cloud Infrastructure Registry to store, share, and manage development artifacts like Docker images in an Oracle-managed registry.

Community and Other Resources

To connect with other Arm developers, join the community:

- Stack Overflow
- Arm Compute Forum on Cloud Customer Connect
- Apps for Arm on Marketplace

Installing and Running Oracle Ksplice

Oracle Ksplice lets you apply important security updates and other critical kernel updates without a reboot. For more information, see About Oracle Ksplice and Ksplice Overview.

This topic describes how to install and configure Ksplice. Ksplice is available for Oracle Linux instances that were launched on or after February 15, 2017. Ksplice is installed on instances that were launched on or after August 25, 2017, so you just need to run it on these instances to install the available Ksplice patches. For instances that were launched before August 25, 2017, you must install Ksplice before running it.
On Oracle Autonomous Linux images, Ksplice is installed and configured by default to run automatic updates.

**Installing Ksplice on instances launched before August 25, 2017**

To install Ksplice, you must connect to your Linux instance by using a Secure Shell (SSH). See Connecting to an Instance on page 1083 for more information.

1. Use the following SSH command to access the instance.

   ```bash
   ssh -l opc@<public-ip-address>
   ```

   `<public-ip-address>` is your instance IP address that you retrieved from the Console, see Getting the Instance Public IP Address on page 91.

2. Run the following SSH commands to sudo to the root:

   ```bash
   sudo bash
   ```

3. Download the Ksplice installation script with the following SSH command:

   ```bash
   ```

4. Once the script is downloaded, use the following SSH command to install Ksplice:

   ```bash
   sh install-uptrack-oc
   ```

**Running Ksplice**

To run Ksplice, you must connect to your Linux instance using a Secure Shell (SSH) connection. See Connecting to an Instance on page 1083 for more information.

1. Use the following SSH command to access the instance.

   ```bash
   ssh -l opc <public-ip-address>
   ```

   `<public-ip-address>` is the instance IP address that you retrieved from the Console, see Getting the Instance Public IP Address on page 91.

2. Run the following SSH commands to sudo to the root:

   ```bash
   sudo bash cd
   ```

3. To install available Ksplice patches, run the following SSH command:

   ```bash
   uptrack-upgrade
   ```

**Automatic Updates**

To configure automatic updates, set the value of `autoinstall` to `yes` in `/etc/uptrack/uptrack.conf`.

**Note:**

OS Security Updates for Oracle Linux images

Oracle Linux images are updated regularly with the necessary patches, but after you launch an instance using these images, you are responsible for applying the required OS security updates published through the Oracle public Yum server. For more information, see Installing and Using the Yum Security Plugin.
Managing Custom Images

Oracle Cloud Infrastructure uses images to launch instances. You specify an image to use when you launch an instance.

You can create a custom image of a bare metal instance's boot disk and use it to launch other instances. Instances you launch from your image include the customizations, configuration, and software installed when you created the image.

For details on Windows images, see Creating Windows Custom Images on page 992.

Custom images do not include the data from any attached block volumes. For information about backing up volumes, see Backing Up a Volume on page 716.

Tip:

Follow industry-wide hardware failure best practices to ensure the resilience of your solution in the event of a hardware failure. Some best practices include:

• Design your system with redundant compute nodes in different availability domains to support failover capability.
• Create a custom image of your system drive each time you change the image.
• Back up your data drives, or sync to spare drives, regularly.

If you experience a hardware failure and have followed these practices, you can terminate the failed instance, launch your custom image to create a new instance, and then apply the backup data.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let image admins manage custom images on page 2808 includes the ability to create, delete, and manage custom images.

The policy in Let users launch compute instances on page 2807 includes the ability to create an instance using any custom image. The policy in Let users launch compute instances from a specific custom image on page 2808 restricts the ability to create an instance from a custom image on an image-by-image basis.

Tip:

When users create a custom image from an instance or launch an instance from a custom image, the instance and image don't have to be in the same compartment. However, users must have access to both compartments.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

Limitations and Considerations

• Certain IP addresses are reserved for Oracle Cloud Infrastructure use and may not be used in your address numbering scheme. See IP Addresses Reserved for Use by Oracle on page 3611 for more information.
• Before you create a custom image of an instance, you must disconnect all iSCSI attachments and remove all iscsid node configurations from the instance. For steps, see Disconnecting From a Volume on page 740.
• When you create an image of a running instance, the instance shuts down and remains unavailable for several minutes. The instance restarts when the process completes.
• You cannot create additional custom images of an instance while the instance is engaged in the image creation process. When you start to create a custom image, the system implements a 20-minute timeout, during which you cannot create another image of the same instance. You can, however, create images of different instances at the same time.

• Custom images are available to all users authorized for the compartment in which the image was created.

• Custom images inherit the compatible shapes that are set by default from the base image.

• The maximum size for importing a custom image is 400 GB.

• The maximum size for custom exported images is 400 GB.

• You cannot create an image of an Oracle Database instance.

• If you use a custom image and update the OS kernel on your instance, you must also upload the update to the network drive. See OS Kernel Updates on page 1019 for more information.

• You are charged for stored images, as shown in the Cloud Price List.

For information about how to deploy any version of any operating system that is supported by the Oracle Cloud Infrastructure hardware, see Bring Your Own Image (BYOI) on page 999.

X5 and X7 Compatibility for Custom Images

Oracle X5, X6, and X7 servers have different host hardware. As a result, using an X5 or X6 image on an X7 bare metal or virtual machine (VM) instance may not work without additional modifications. We recommend for X7 hosts that you use the platform images for X7. See Image Release Notes for more information about which images support X7. These images have been explicitly created and tested with X7 hardware.

If you attempt to use an existing X5 image on X7 hardware, note the following:

• No Windows versions are cross-compatible.

• Oracle Autonomous Linux 7 and Oracle Linux 8 are cross-compatible.

• Oracle Linux 6, Oracle Linux 7, Ubuntu 18.04, Ubuntu 20.04, CentOS 7, and CentOS 8 are cross-compatible. However, you must update the kernel to the most recent version to install the latest device drivers. To do this, run the following commands from a terminal session:

  • **Oracle Linux**

    yum update

  • **CentOS 7, CentOS 8**

    yum update

  • **Ubuntu 18.04, Ubuntu 20.04**

    apt-get update
    apt-get dist-upgrade

If you attempt to use an X6 image on non-X6 hardware, note the following:

• Oracle Linux 6, all CentOS versions, and all Windows versions are not cross-compatible.

• Oracle Autonomous Linux 7 and Oracle Linux 8 are cross-compatible.

• Oracle Linux 7, Ubuntu 20.04, and Ubuntu 18.04 are cross-compatible. Use the platform images for X6.

The primary device drivers that are different between X5, X6, and X7 hosts are:

• Network device drivers

• NVMe drive device drivers

• GPU device drivers

Additional updates might be required depending on how you have customized the image.
Using the Console

To create a custom image

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you want to use as the basis for the custom image.
3. Click More Actions, and then click Create Custom Image.
4. In the Create in Compartment list, select the compartment to create the custom image in.
5. Enter a Name for the image. You can change the name later, if needed. You cannot use the name of a platform image for a custom image. Avoid entering confidential information.
6. Show Tagging Options: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
7. Click Create Custom Image.

To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated work request.

Note:
If you see a message indicating that you are at the limit for custom images, you must delete at least one image before you can create another. Or, you can request a service limit increase.

To launch an instance from a custom image

1. Open the navigation menu and click Compute. Under Compute, click Custom Images.
2. Click the custom image that you're interested in.
3. Click Create Instance.
4. Provide additional launch options as described in Creating an Instance on page 1023.

To edit the name or compatible shapes for a custom image

1. Open the navigation menu and click Compute. Under Compute, click Custom Images.
2. Click the custom image that you're interested in.
3. Click Edit Details.
4. Edit the name, or add and remove compatible shapes for the custom image. Avoid entering confidential information.
5. To configure the number of OCPUs and amount of memory that users can select when they use this image on a flexible shape, click the down arrow in the row for the shape. Next, enter values in the fields for minimum and maximum OCPU count and memory.
6. Click Save Changes.

Note:
After you add shape compatibility to an image, test the image on the shape to ensure that the image actually works on the shape. Some images (especially Windows) might never be cross-compatible with other shapes because of driver or hardware differences.

To manage tags for a custom image

1. Open the navigation menu and click Compute. Under Compute, click Custom Images.
2. Click the custom image that you're interested in.
3. Click the Tags tab to view or edit the existing tags. Or click More Actions, and then click Add tags to add new ones.

For more information, see Resource Tags on page 239.
To delete a custom image

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Custom Images**.
2. Click the custom image that you're interested in.
3. Click **More Actions**, and then click **Delete**. Confirm when prompted.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operations to manage custom images:

- CreateImage
- GetImage
- ListImages
- UpdateImage
- DeleteImage
- AddImageShapeCompatibilityEntry
- ListImageShapeCompatibilityEntries
- GetImageShapeCompatibilityEntry
- RemoveImageShapeCompatibilityEntry

Creating Windows Custom Images

You can create a Windows custom image of a bare metal or virtual machine (VM) instance's boot disk and use it to launch other instances. Instances you launch from your image include the customizations, configuration, and software installed when you created the image. For information about custom images, see Managing Custom Images on page 989. For information about the licensing requirements for Windows images, see Microsoft Licensing on Oracle Cloud Infrastructure on page 1170.

Windows supports two kinds of images: generalized and specialized. Generalized images are images that have been cleaned of instance-specific information. Specialized images are point-in-time snapshots of the boot disk of a running instance, and are useful for creating backups of an instance. Oracle Cloud Infrastructure supports bare metal and VM instances launched from both generalized and specialized custom Windows images.

**Generalized images**

A generalized image has a generalized OS disk, cleaned of computer-specific information. The images are generalized using Sysprep. Generalized images can be useful in scenarios such as quickly scaling an environment. Generalized images can be configured to preserve the existing opc user's account, including the password, at the time the image is created, or configured to recreate the opc user account, including generating a new, random password that you retrieve using the API. For background information, see Sysprep (Generalize) a Windows installation.

**Specialized images**

A specialized image has an OS disk that is already fully installed, and is essentially a copy of the original bare metal or VM instance. Specialized images are intended to be used for backups so that you can recover from a failure. Specialized images are useful when you are testing a task and may need to roll back to known good configuration. Specialized images are not recommended for cloning multiple identical bare metal instances or VMs in the same network because of issues with multiple computers having the same computer name and ID. When creating a specialized image, you must remember the opc user's password; a new password is not generated when the instance launches, and it cannot be retrieved from the console or API.

Creating a Generalized Image

**Caution:**

- Creating a generalized image from an instance will render the instance non-functional, so you should first create a custom image from the instance, and then launch a new instance from the custom image. Steps
1. Create the new image using To create a custom image.
2. Launch an instance from the new image using To launch an instance from a custom image.
3. Connect to the instance using a Remote Desktop client.
4. Go to Windows Generalized Image Support Files on page 1202 and download to the instance the file matching the instance shape.
5. Right-click the file, and then click Run as administrator.
6. Extract the files to C:\Windows\Panther. The following files are extracted into the Panther folder for all Windows Server versions:
   - Generalize.cmd
   - Specialize.cmd
   - unattend.xml
   - Post-Generalize.ps1
7. Optional: If you want to preserve the opc user account, edit C:\Program Files\bmcs\imageType.json and change the imageType setting to custom. A new password is not created and the password is not retrievable from the console or API.
   If you want to configure the generalized image to recreate the opc user account when a new instance is launched from the image, leave the imageType setting defaulted to general. The new account's password can be retrieved through the API using GetInstanceDefaultCredentials.
8. Right-click Generalize.cmd, and then click Run as administrator. Keep in mind the following outcomes of running this command:
   - Your connection to the Remote Desktop client might immediately be turned off and you will be logged out of the instance. If this does not occur, you should log out of the instance yourself.
   - Because sysprep generalize turns off Remote Desktop, you won't be able to log in to the instance again.
   - Creating a generalized image essentially destroys the instance's functionality.
   You should wait for a few minutes before proceeding to the following step to ensure the generalization process has completed.
9. Create the new image using To create a custom image.
10. After you create an image from an instance that has been generalized, we recommend that you terminate the instance. Although it may appear to be running, it won't be fully operable.

Creating a Specialized Image

Important:

When creating a specialized image, you must remember the opc user's password. It cannot be retrieved from the Console or API.

You create a specialized image the same way you create other custom images. For steps, see Managing Custom Images on page 989.

Image Import/Export

Oracle Cloud Infrastructure Compute lets you share custom images across tenancies and regions using image import/export.
Important:

To import or export custom images from Object Storage buckets, federated users and users authenticating with instance principals tied to a dynamic group need to create a pre-authenticated request. See this known issue for more information.

Linux-Based Operating Systems

The following operating systems support image import/export:

- Oracle Linux 6.x
- Oracle Linux 7.x
- Oracle Linux 8.x
- Oracle Linux Cloud Developer 8.x
- CentOS 7
- CentOS 8
- Ubuntu 20.04 and later
- Ubuntu 18.04 and later

For more information about platform images, see Platform Images on page 943.

Windows-Based Operating Systems

The following Windows versions support image import/export:

- Windows Server 2012 Standard, Datacenter
- Windows Server 2012 R2 Standard, Datacenter
- Windows Server 2016 Standard, Datacenter
- Windows Server 2019 Standard, Datacenter

Note:

When exporting Windows-based images, you are responsible for complying with the Microsoft Product Terms and all product use conditions, as well as verifying your compliance with Microsoft.

For information about the licensing requirements for Windows images, see Microsoft Licensing on Oracle Cloud Infrastructure on page 1170.

Verify Your Windows Operating System

When importing custom Windows images, ensure that the version you select matches the Windows image that you imported. Failure to provide the correct version and SKU information could be a violation of your Microsoft Licensing Agreement.

Windows System Time Issue on Custom Windows Instances

If you change the time zone from the default setting on Windows VM instances, when the instance reboots or syncs with the hardware clock, the system time will revert back to the time for the default time zone. However, the time zone setting will stay set to the new time zone, so the system clock will be incorrect. You can fix this by setting the HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\TimeZoneInformation registry key to 1.

Windows platform images already have the RealTimeIsUniversal registry key set by default, but you must set this for any custom Windows images that you import.
To fix this issue for custom Windows images:

1. Open the Windows Registry Editor and navigate to the `HKEY_LOCAL_MACHINE\SYSTEM \CurrentControlSet\Control\TimeZoneInformation` registry key.
2. Create a new DWORD key named `RealTimeIsUniversal` and set the value to 1.
3. Reboot the instance.
4. Reset the time and time zone manually.

**Bring Your Own Image Scenarios**

You can also use image import/export to share custom images from Bring Your Own Image (BYOI) on page 999 scenarios across tenancies and regions, so you don't need to recreate the image manually in each region. You must go through the steps required to manually create the image in one of the regions, but after this is done, you can export the image, making it available for import in additional tenancies and regions. Export the image in the `.oci` format, which is a file format that contains a QCOW2 image file and Oracle Cloud Infrastructure-specific metadata.

**Best practices for replicating an image across regions**

You can replicate an image from one region to another region using the Console or API. At a high level:

1. Export the image to an Object Storage bucket in the same region as the image. For steps, see Exporting an Image on page 996.
2. Copy the image to an Object Storage bucket in the destination region. For steps, see Copying Objects on page 4401.
3. Obtain the URL path to the image object. For steps, see To view object details on page 4327.
4. In the destination region, import the image. Use the URL path as the Object Storage URL. For steps, see Importing an Image on page 996.

**Best practices for sharing an image across tenancies**

You can replicate an image from one tenancy to another tenancy using the Console or API. At a high level:

1. Export the image to an Object Storage bucket in the same region as the image. For steps, see Exporting an Image on page 996.
2. Create a pre-authenticated request with read-only access for the image in the destination region. For steps, see Working with Pre-Authenticated Requests on page 4388.
3. In the destination tenancy, import the image. Use the pre-authenticated request URL as the Object Storage URL. For steps, see Importing an Image on page 996.

**Object Storage Service URLs**

When you import or export custom images using the Console, you might need to specify the Object Storage URL pointing to the location that you want to import the image from or export the image to. Object Storage URLs are structured as follows:

```
https://<host_name>/n/<namespace_name>/b/<bucket_name>/o/<object_name>
```

For example:

```
https://objectstorage.us-phoenix-1.oraclecloud.com/n/MyNamespace/b/MyBucket/o/MyCustomImage.qcow2
```

**Pre-Authenticated Requests**

When using import/export across tenancies, you need to use an Object Storage pre-authenticated request. See Working with Pre-Authenticated Requests on page 4388 for steps to create a pre-authenticated request. When you go through these steps, after you click Create Pre-Authenticated Request, the Pre-Authenticated Request Details
dialog box opens. You must make a copy of the pre-authenticated request URL displayed here, because this is the only time this URL is displayed. This is the Object Storage URL that you specify for import/export.

**Note:**

Pre-authenticated requests for a bucket
With image export, if you create the pre-authenticated request for a bucket, you need to append the object name to the generated URL. For example:

/o/MyCustomImage.qcow2

### Exporting an Image

You can use the Console or API to export images, and the exported images are stored in the Oracle Cloud Infrastructure Object Storage service. To perform an image export, you need write access to the Object Storage bucket for the image. For more information, see Overview of Object Storage on page 4290 and Let users write objects to Object Storage buckets on page 2813.

**To export an image using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Custom Images**.
2. Click the custom image that you're interested in.
3. Click **Export**.
4. Specify the Object Storage location to export the image to:
   - **Export to an Object Storage bucket**: Select a bucket. Then, enter a name for the exported image. Avoid entering confidential information.
   - **Export to an Object Storage URL**: Enter the Object Storage URL.
5. In the **Image format** list, select the format that you want to export the image to. The following formats are available:
   - Oracle Cloud Infrastructure file with a QCOW2 image and OCI metadata (.oci). Use this format to export a custom image that you want to import into other tenancies or regions.
   - QEMU Copy On Write (.qcow2)
   - Virtual Disk Image (.vdi) for Oracle VM VirtualBox
   - Virtual Hard Disk (.vhd) for Hyper-V
   - Virtual Machine Disk (.vmdk)
6. Click **Export Image**.

After you click **Export Image**, the image state changes to **Exporting**. Images are a copy of the VM or BM instance boot volume and metadata when the image is created, capturing the current state of the instance. Exporting a custom image copies the data to the Object Storage location that you specified. You can still launch instances while the image is exporting, but you can't delete the image until the export has finished. To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated work request.

When the export is complete, the image state changes to **Available**. If the image state changes to **Available**, but you don't see the exported image in the Object Storage location you specified, the export failed, and you need to go through the steps again to export the image.

### Importing an Image

You can use the Console or API to import exported images from Object Storage. To import an image, you need read access to the Object Storage object containing the image. For more information, see Let users download objects from Object Storage buckets on page 2814.

**To import an image using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Custom Images**.
2. Click **Import Image**.
3. In the **Create in compartment** list, select the compartment that you want to import the image to.
4. Enter a **Name** for the image. Avoid entering confidential information.
5. Select the **Operating system**:
   - For Linux images, select **Linux**.
   - For Windows images, select **Windows**. Select the **Operating system version**, and then certify that the selected operating system complies with Microsoft licensing agreements.
6. Specify the **Object Storage location** to import the image from:
   - **Import from an Object Storage bucket**: Select the **Bucket** that contains the image. In the **Object name** list, select the image file.
   - **Import from an Object Storage URL**: Enter the **Object Storage URL** of the image. When importing across tenancies, you must specify a pre-authenticated request URL.
7. In the **Image type** section, select the format of the image. The following formats are available:
   - **VMDK**: Virtual Machine Disk (.vmdk)
   - **QCOW2**: QEMU Copy On Write (.qcow2)
   - **OCI**: Oracle Cloud Infrastructure file with a QCOW2 image and OCI metadata (.oci). Use this format when importing a custom image that was exported from another tenancy or region.
8. Select the **Launch mode**:
   - For custom images where the image type is .oci, the launch mode is disabled. Oracle Cloud Infrastructure selects the appropriate launch mode based on the launch mode for the source image.
   - For custom images exported from Oracle Cloud Infrastructure where the image type is QCOW2, select **Native Mode**.
   - To import other custom images, select **Paravirtualized Mode** or **Emulated Mode**. For more information, see **Bring Your Own Image**.
9. **Show tagging options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
10. Click **Import Image**.
    
    After you click **Import Image**, you'll see the imported image in the **Custom Images** list for the compartment, with a state of **Importing**. To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated **work request**.

    When the import completes successfully, the state changes to **Available**. If the state does not change, or no entry appears in the **Custom Images** list, the import failed. If the import failed, ensure you have read access to the Object Storage object, and that the object contains a supported image.

### Editing Image Details

You can edit the details of custom images, such as the image name and compatible shapes for the image. For more information, see **To edit the name or compatible shapes for a custom image** on page 991 in **Managing Custom Images** on page 989.

### Managing Tags for an Image

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see **Resource Tags** on page 239.

**To manage tags for an image**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Custom Images**.
2. Click the image that you're interested in.
3. Click the Tags tab to view or edit the existing tags. Or click More Actions, and then click Add tags to add new ones.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following API operations for custom image import/export:

- ExportImage: Exports a custom image to Object Storage.
- CreateImage: To import an exported image, specify ImageSourceDetails in the request body.
- AddImageShapeCompatibilityEntry: Adds a shape to the compatible shapes list for the image.
- ListImageShapeCompatibilityEntries
- GetImageShapeCompatibilityEntry
- RemoveImageShapeCompatibilityEntry: Removes a shape from the compatible shapes list for the image.

X5 and X7 Compatibility for Image Import/Export

Oracle X5, X6, and X7 servers have different host hardware. As a result, using an X5 or X6 image on an X7 bare metal or virtual machine (VM) instance may not work without additional modifications. We recommend for X7 hosts that you use the platform images for X7. See Image Release Notes for more information about which images support X7. These images have been explicitly created and tested with X7 hardware.

If you attempt to use an existing X5 image on X7 hardware, note the following:

- No Windows versions are cross-compatible.
- Oracle Autonomous Linux 7 and Oracle Linux 8 are cross-compatible.
- Oracle Linux 6, Oracle Linux 7, Ubuntu 18.04, Ubuntu 20.04, CentOS 7, and CentOS 8 are cross-compatible. However, you must update the kernel to the most recent version to install the latest device drivers. To do this, run the following commands from a terminal session:
  
  - **Oracle Linux**
    
    ```
    yum update
    ```
  
  - **CentOS 7, CentOS 8**
    
    ```
    yum update
    ```
  
  - **Ubuntu 18.04, Ubuntu 20.04**
    
    ```
    apt-get update
    apt-get dist-upgrade
    ```

If you attempt to use an X6 image on non-X6 hardware, note the following:

- Oracle Linux 6, all CentOS versions, and all Windows versions are not cross-compatible.
- Oracle Autonomous Linux 7 and Oracle Linux 8 are cross-compatible.
- Oracle Linux 7, Ubuntu 20.04, and Ubuntu 18.04 are cross-compatible. Use the platform images for X6.

The primary device drivers that are different between X5, X6, and X7 hosts are:

- Network device drivers
- NVMe drive device drivers
- GPU device drivers

Additional updates might be required depending on how you have customized the image.
Bring Your Own Image (BYOI)

The Bring Your Own Image (BYOI) feature enables you to bring your own versions of operating systems to the cloud as long as the underlying hardware supports it. The services do not depend on the OS you run.

The BYOI feature does the following things:

• Enables virtual machine cloud migration projects.
• Supports both old and new operating systems.
• Encourages experimentation.
• Increases infrastructure flexibility.

Note:

Licensing Requirements
You must comply with all licensing requirements when you upload and start instances based on OS images that you supply.

Bringing Your Own Image

A critical part of any lift-and-shift cloud migration project is the migration of on-premises virtual machines (VMs) to the cloud. You can import your on-premises virtualized root volumes to Oracle Cloud Infrastructure using the custom image import feature, and then launch Compute instances using those images.

You can import Windows and Linux-based custom images and use them to launch VMs on Oracle Cloud Infrastructure. Bringing your own image to a bare metal instance is not supported.

Limitations and Considerations

Be aware of the following information:

• **Licensing requirements:** You must comply with all licensing requirements when you upload and start instances based on OS images that you supply.
• The maximum image size is 400 GB.
• Service limits and compartment quotas apply to custom images. For more information, see Service Limits. You can request a service limit increase.

Launch Modes

You can launch imported Linux VMs in either paravirtualized mode or emulated mode. On AMD and Arm-based shapes, Oracle Linux Cloud Developer images, and Windows images, imported images are supported in paravirtualized mode only.

Paravirtualized mode offers better performance than emulated mode. We recommend that you use paravirtualized mode if your OS supports it. Linux-based operating systems running the kernel version 3.4 or later support paravirtualized drivers. You can verify your system's kernel version using the `uname` command.

**To verify the kernel version using the `uname` command**

Run the following command:

```
uname -a
```

The output should look similar to this sample:

```
Linux ip_bash 4.14.35-1818.2.1.el7uek.x86_64 #2 SMP Mon Aug 27 21:16:31 PDT 2018 x86_64 x86_64 x86_64 GNU/Linux
```

The kernel version is the number at the first part of output string. In the sample output shown previously, the version is 4.14.35.
If your image supports paravirtualized drivers, you can convert your existing emulated mode instances into paravirtualized instances. After you complete the conversion, instances created from the image are launched in paravirtualized mode.

**To convert emulated mode instances into paravirtualized instances**

1. Create a custom image of your instance, navigate to the Custom Image Details page, and then click Edit Image Capabilities.
2. For Firmware and Preferred firmware, select BIOS.
3. For the following fields, select Paravirtualized.
   - Launch mode
   - Preferred launch mode
   - NIC attachment type
   - Preferred network attachment type
   - Boot volume type
   - Preferred boot volume type
   - Local data volume
   - Preferred local data volume type
   - Remote data volume
   - Preferred remote data volume type
4. Click Save Changes.

**Windows images**

These Windows versions support custom image import:

- Windows Server 2012 Standard, Datacenter
- Windows Server 2012 R2 Standard, Datacenter
- Windows Server 2016 Standard, Datacenter
- Windows Server 2019 Standard, Datacenter

For steps to import a Windows image, see Importing Custom Windows Images on page 1002.

Bring your own license (BYOL) for Windows Server is not permitted when launching a VM instance on a shared host. For more information about BYOL and the licensing requirements for Windows images, see Licensing Options for Microsoft Windows on page 1177 and Microsoft Licensing on Oracle Cloud Infrastructure on page 1170.

**Linux images**

The Linux and UNIX-like operating systems in the following table support custom image import.

**Support Details**

- Oracle Cloud Infrastructure has tested the operating systems listed in the following table and supports customers in ensuring that instances launched from these images and built according to the guidelines in this topic are accessible using SSH.
- For any OS version other than those covered by an official support service from Oracle (for example, Oracle Linux with Premier Support), Oracle Cloud Infrastructure provides commercially reasonable support limited to getting an instance launched and accessible through SSH.
- Support from Oracle Cloud Infrastructure in launching an instance from a custom OS does not ensure that the operating system vendor also supports the instance. Customers running Oracle Linux on Oracle Cloud Infrastructure automatically have access to Oracle Linux Premier Support.

<table>
<thead>
<tr>
<th>Linux and UNIX-like Operating Systems</th>
<th>Supported Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>CentOS</td>
<td>4.0, 4.8, 5.11, 6.9, 7 or later</td>
</tr>
<tr>
<td>Debian</td>
<td>5.0.10, 6.0, 7, 8 or later</td>
</tr>
</tbody>
</table>
### Linux and UNIX-like Operating Systems

<table>
<thead>
<tr>
<th>Operating System</th>

</tr>
<tr>
<td>Ubuntu</td>
<td>12.04, 13.04 or later</td>
</tr>
</tbody>
</table>

You might also have success importing other distributions of Linux.

For steps to import a Linux-based image, see Importing Custom Linux Images on page 1006.

### Bringing Your Own Hypervisor Guest OS

You can bring your own hypervisor guest OS using Kernel-based Virtual Machine (KVM) or Hyper-V.

**Note:**

Bring your own hypervisor deployment of ESXi on bare metal Compute instances is not supported. ESXi is supported only by provisioning an Oracle Cloud VMware Solution software-defined data center (SDDC). See Oracle Cloud VMware Solution on page 5086 for more information.

### Bringing Your Own KVM

You can bring your own operating system images or older operating systems, such as Ubuntu 6.x, RHEL 3.x, and CentOS 5.4, using KVM on bare metal instances.

To bring your own KVM, first create a bare metal instance using the KVM image from Marketplace. Then, copy your on-premises guest OS to KVM on the bare metal instance.

For more information, see the following resources:

- Getting Started: Oracle Linux KVM Image for Oracle Cloud Infrastructure
- Installing and Configuring KVM on Bare Metal Instances with Multi-VNIC

### Bringing Your Own Hyper-V

You can bring your own operating system images or older operating systems, such as Windows Server 2003 and Windows Server 2008, using Hyper-V on bare metal instances.

To bring your own Hyper-V, first create a bare metal instance using the Windows Server Datacenter platform image. Oracle Cloud Infrastructure will issue a license for Windows Server when the instance is launched. Then, copy your on-premises guest OS to Hyper-V on the bare metal instance. No additional license is required because Windows Server Datacenter includes unlimited virtual machines.

Be aware of the following considerations:

- Oracle Cloud Infrastructure will issue a license when you launch an instance using a custom image. If you want to bring your own license (BYOL) for Windows Server, you must activate Windows Server with your own license. For steps, see Activating Licenses on a Dedicated Host on page 1178.
- Importing your own ISO image is not supported.

For a list of supported Hyper-V guests, see the following resources:

- Supported Windows guest operating systems for Hyper-V on Windows Server
• Supported Linux and FreeBSD virtual machines for Hyper-V on Windows

For more information about deploying Hyper-V, see Deploying Hyper-V on Oracle Cloud Infrastructure.

**NTP Service**

Oracle Cloud Infrastructure offers a fully managed, secure, and highly available NTP service that you can use to set the date and time of your Compute and Database instances from within your virtual cloud network (VCN). We recommend that you configure your instances to use the Oracle Cloud Infrastructure NTP service. For information about how to configure instances to use this service, see Configuring the Oracle Cloud Infrastructure NTP Service for an Instance on page 1011.

**Importing Custom Windows Images**

The Compute service enables you to import Windows images that were created outside of Oracle Cloud Infrastructure. For example, you can import images running on your on-premises physical or virtual machines (VMs), or VMs running in Oracle Cloud Infrastructure Classic. You can then launch your imported images on Compute virtual machines.

For information about the licensing requirements for Windows images, see Microsoft Licensing on Oracle Cloud Infrastructure on page 1170.

**Supported Operating Systems**

These Windows versions support custom image import:

- Windows Server 2012 Standard, Datacenter
- Windows Server 2012 R2 Standard, Datacenter
- Windows Server 2016 Standard, Datacenter
- Windows Server 2019 Standard, Datacenter

**Note:**

- Oracle Cloud Infrastructure has tested the operating systems listed previously and will support customers in ensuring that instances launched from these images and built according to the guidelines in this topic are accessible using RDP.
- For OS editions not listed previously, Oracle Cloud Infrastructure will provide commercially reasonable support to customers in an effort to get instances that are launched from these images accessible via RDP.
- Support from Oracle Cloud Infrastructure in launching an instance from a custom OS does not ensure that the operating system vendor also supports the instance.
- Oracle Cloud Infrastructure licenses and charges the Windows licensing fee for all instances launched using an imported Windows OS image. This applies whether or not those instances are registered with Oracle Cloud Infrastructure's Microsoft Key Management service.

**Windows Source Image Requirements**

Custom images must meet the following requirements:

- The maximum image size is 400 GB.
- The image must be set up for BIOS boot.
- Only one disk is supported, and it must be the boot drive with a valid master boot record (MBR) and boot loader. You can migrate additional data volumes after you import the image's boot volume.
- The minimum boot volume size is 256 GB. For more information, see Custom Boot Volume Sizes on page 690.
- The boot process must not require additional data volumes to be present for a successful boot.
- The disk image cannot be encrypted.
• The disk image must be a VMDK or QCOW2 file.
  • Create the image file by cloning the source volume, not by creating a snapshot.
  • VMDK files must be either the "single growable" (monolithicSparse) type or the "stream optimized" (streamOptimized) type, both of which consist of a single VMDK file. All other VMDK formats, such as those that use multiple files, split volumes, or contain snapshots, are not supported.
• The network interface must use DHCP to discover the network settings. When you import a custom image, existing network interfaces are not recreated. Any existing network interfaces are replaced with a single NIC after the import process is complete. You can attach additional VNICs after you launch the imported instance.
• The network configuration must not hardcode the MAC address for the network interface.

Preparing Windows VMs for Import

Before you can import a custom Windows image, you must prepare the image to ensure that instances launched from the image can boot correctly and that network connections will work.

You can perform the tasks described in this section on the running source system. If you have concerns about modifying the live source system, you can export the image as-is, import it into Oracle Cloud Infrastructure, and then launch an instance based on the custom image. You can then connect to the instance using the VNC console and perform the preparation steps.

Important:
The system drive where Windows is installed will be imported to Oracle Cloud Infrastructure. All partitions on the drive will follow through the imported image. Any other drives will not be imported and you must re-create them on the instance after import. You will then need to manually move the data on the non-system drives.

To prepare a Windows VM for import:

1. Follow your organization's security guidelines to ensure that the Windows system is secured. This can include, but is not limited to the following tasks:
  • Install the latest security updates for the operating system and installed applications.
  • Enable the firewall, and configure it so that you only enable the rules which are needed.
  • Disable unnecessary privileged accounts.
  • Use strong passwords for all accounts.
2. Configure Remote Desktop Protocol (RDP) access to the image:
  a. Enable Remote Desktop connections to the image.
  b. Modify the Windows Firewall inbound port rule to allow RDP access for both Private and Public network location types. When you import the image, the Windows Network Location Awareness service will identify the network connection as a Public network type.
3. Determine whether the current Windows license type is a volume license by running the following command in PowerShell:

```powershell
Get-CimInstance -ClassName SoftwareLicensingProduct | where {$_._PartialProductKey} | select ProductKeyChannel
```

If the license is not a volume license, after you import the image, you will update the license type.

4. If you plan to launch the imported image on more than one VM instance, create a generalized image of the boot disk. A generalized image is cleaned of computer-specific information, such as unique identifiers. When you create instances from a generalized image, the unique identifiers are regenerated. This prevents two instances that are created from the same image from colliding on the same identifiers.
5. Create a backup of the root volume.
6. If the VM has remotely attached storage, such as NFS or block volumes, configure any services that rely on this storage to start manually. Remotely attached storage is not available the first time that an imported instance boots on Oracle Cloud Infrastructure.
7. Ensure that all network interfaces use DHCP, and that the MAC address and IP addresses are not hardcoded. See your system documentation for steps to perform network configuration for your system.

8. Download the Oracle Windows VirtIO drivers:
   a. Sign in to the Oracle Software Delivery Cloud site.
   b. In the All Categories list, select Release.
   c. Type Oracle Linux 7.7 in the search box and click Search.
   d. Add REL: Oracle Linux 7.7.x to your cart, and then click Continue.
   e. In the Platforms/Languages list, select x86 64 bit. Click Continue.
   f. Accept the license agreement and then click Continue.
   g. Select the check box next to Oracle VirtIO Drivers Version for Microsoft Windows 1.1.5. Clear the other check boxes.
   h. Click Download and then follow the prompts.

9. Install the Oracle VirtIO drivers for Windows:
   a. Follow the prompts in the installation wizard. On the Installation Type page, select Custom, as shown in the following screenshot.

![Drivers Installer](image)

   b. Reboot the VM.

10. Stop the VM.

11. Clone the stopped VM as a VMDK or QCOW2 file, and then export the image from your virtualization environment. See the tools documentation for your virtualization environment for steps.

**Importing a Windows-Based VM**

After you prepare a Windows image for import, follow these steps to import the image:
1. **Upload the image file to an Object Storage bucket.** You can upload the file using the Console or using the command line interface (CLI). If you use the CLI, use the following command:

   ```bash
   oci os object put -bn <destination_bucket_name> --file <path_to_the_VMDK_or_QCOW2_file>
   ```

2. Open the navigation menu and click **Compute.** Under **Compute**, click **Custom Images.**
3. Click **Import Image.**
4. In the **Create in Compartment** list, select the compartment that you want to import the image to.
5. Enter a **Name** for the image. Avoid entering confidential information.
6. For the **Operating System**, select **Windows.**
7. In the **Operating System Version** list, select the version of Windows.
8. Confirm that you chose the operating system version that complies with your Microsoft licensing agreement, and then select the compliance check box.

   **Important:**

   Failure to provide the correct version and SKU information could be a violation of your Microsoft Licensing Agreement.

9. Select the **Import from an Object Storage bucket** option.
10. Select the **Bucket** that you uploaded the image to.
11. In the **Object Name** list, select the image file that you uploaded.
12. For the **Image Type**, select the file type of the image, either **VMDK** or **QCOW2.**
13. In the **Launch Mode** area, select **Paravirtualized Mode.**
14. **Show Tagging Options:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
15. Click **Import Image.**
   
   The imported image appears in the **Custom Images** list for the compartment, with a state of **Importing.** When the import completes successfully, the state changes to **Available.**

   If the state doesn't change, or no entry appears in the **Custom Images** list, the import failed. Ensure that you have read access to the Object Storage object, and that the object contains a supported image.

**Post-Import Tasks for Windows Images**

After you import a custom Windows-based image, do the following:

1. If you want to use the image on AMD or X6-based shapes, add the shapes to the image's list of compatible shapes.
2. **Create an instance based on the custom image.** For the image source, select **Custom Images,** and then select the image that you imported.
3. **Enable Remote Desktop Protocol (RDP) access** to the Compute instance.
4. **Connect to the instance using RDP.**
5. If the instance requires any remotely attached storage, such as **block volumes** or **file storage,** create and attach it.
6. **Create and attach any required secondary VNICS.**
7. Test that all applications are working as expected.
8. Reset any services that were set to start manually.
9. **Configure your instance to use the Network Time Protocol (NTP).** You can use the **Oracle Cloud Infrastructure NTP service,** or you can use the Windows Time service (W32Time).

   **Tip:**

   If you encounter a *no time data was available* error message when setting up NTP on Windows Server, review the information in the **Microsoft known issue** article.
10. Register the instance with the Oracle-provided Key Management Service (KMS) server:

   **Important:**

   To register the instance with the KMS server, the time on your instance must match your time zone.

   a. On the instance, open PowerShell as Administrator.
   b. To set the KMS endpoint, run the following command:

   ```slmgr /skms 169.254.169.253:1688```

   c. If the Windows license type that you noted while preparing the image isn’t a volume license, you must update the license type. Run the following command:

   ```slmgr /ipk <setup key>```

   <setup key> is the KMS client setup key that corresponds to the version of Windows that you imported:

<table>
<thead>
<tr>
<th>Windows Version</th>
<th>KMS Client Setup Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows Server 2012 Standard</td>
<td>XC9B7-NBPP2-83J2H-RHMBY-92BT4</td>
</tr>
<tr>
<td>Windows Server 2012 Datacenter</td>
<td>48HP8-DN98B-MYWDG-T2DCC-8W83P</td>
</tr>
<tr>
<td>Windows Server 2012 R2 Standard</td>
<td>D2N9P-3P6X9-2R39C-7RTCD-MDVJX</td>
</tr>
<tr>
<td>Windows Server 2012 R2 Datacenter</td>
<td>W3GGN-FT8W3-Y4M27-J84CP-Q3VJ9</td>
</tr>
<tr>
<td>Windows Server 2016 Standard</td>
<td>WC2BQ-8NRM3-FDDYY-2BFGV-KHKQY</td>
</tr>
<tr>
<td>Windows Server 2016 Datacenter</td>
<td>CB7KF-BWN84-R7R2Y-793K2-8XDDG</td>
</tr>
<tr>
<td>Windows Server 2019 Standard</td>
<td>N69G4-B89J2-4G8F4-WWYCC-J464C</td>
</tr>
<tr>
<td>Windows Server 2019 Datacenter</td>
<td>WMDGN-G9PQG-XVVXX-R3X43-63DFG</td>
</tr>
</tbody>
</table>

d. To activate Windows, run the following command:

   ```slmgr /ato```

e. To verify the license status, run the following command:

   ```Get-CimInstance -ClassName SoftwareLicensingProduct | where {$_.PartialProductKey} | select Description, LicenseStatus```

   If the LicenseStatus is 1, the instance is properly licensed. It might take up to 48 hours for the license status to update.

**Importing Custom Linux Images**

The Compute service lets you import Linux-based images that were created outside of Oracle Cloud Infrastructure. For example, you can import images running on your on-premises physical or virtual machines (VMs), or VMs running in Oracle Cloud Infrastructure Classic. You can then launch your imported images on Compute virtual machines.

**Launch Modes**

As part of the import process, a launch mode is applied to the image. An image's launch mode is a pre-defined set of launch options. You can launch imported Linux VMs in either paravirtualized mode or emulated mode. On AMD and Arm-based shapes as well as Oracle Linux Cloud Developer images, imported images are supported in paravirtualized mode only.
Paravirtualized mode offers better performance than emulated mode. We recommend that you use paravirtualized mode if your OS supports it. Linux-based operating systems running the kernel version 3.4 or later support paravirtualized drivers. You can verify your system's kernel version using the `uname` command.

**To verify the kernel version using the `uname` command**

Run the following command:

```
uname -a
```

The output should look similar to this sample:

```
Linux ip_bash 4.14.35-1818.2.1.el7uek.x86_64 #2 SMP Mon Aug 27 21:16:31 PDT 2018 x86_64 x86_64 x86_64 GNU/Linux
```

The kernel version is the number at the first part of output string. In the sample output shown previously, the version is 4.14.35.

If your image supports paravirtualized drivers, you can convert your existing emulated mode instances into paravirtualized instances. After you complete the conversion, instances created from the image are launched in paravirtualized mode.

**To convert emulated mode instances into paravirtualized instances**

1. Create a custom image of your instance, navigate to the Custom Image Details page, and then click Edit Image Capabilities.
2. For Firmware and Preferred firmware, select BIOS.
3. For the following fields, select Paravirtualized.
   - Launch mode
   - Preferred launch mode
   - NIC attachment type
   - Preferred network attachment type
   - Boot volume type
   - Preferred boot volume type
   - Local data volume
   - Preferred local data volume type
   - Remote data volume
   - Preferred remote data volume type
4. Click Save Changes.

**Supported Operating Systems**

The Linux and UNIX-like operating systems in the following table support custom image import.

**Support Details**

- Oracle Cloud Infrastructure has tested the operating systems listed in the following table and supports customers in ensuring that instances launched from these images and built according to the guidelines in this topic are accessible using SSH.
- For any OS version other than those covered by an official support service from Oracle (for example, Oracle Linux with Premier Support), Oracle Cloud Infrastructure provides commercially reasonable support limited to getting an instance launched and accessible through SSH.
- Support from Oracle Cloud Infrastructure in launching an instance from a custom OS does not ensure that the operating system vendor also supports the instance. Customers running Oracle Linux on Oracle Cloud Infrastructure automatically have access to Oracle Linux Premier Support.

**Linux Source Image Requirements**

Custom images must meet the following requirements:

- The maximum image size is 400 GB.
- The image must be set up for BIOS boot.
- Only one disk is supported, and it must be the boot drive with a valid master boot record (MBR) and boot loader. You can migrate additional data volumes after you import the image's boot volume.
- The boot process must not require additional data volumes to be present for a successful boot.
- The boot loader should use LVM or a UUID to locate the boot volume.
- The disk image cannot be encrypted.
- The disk image must be a VMDK or QCOW2 file.
  - Create the image file by cloning the source volume, not by creating a snapshot.
  - VMDK files must be either the "single growable" (monolithicSparse) type or the "stream optimized" (streamOptimized) type, both of which consist of a single VMDK file. All other VMDK formats, such as those that use multiple files, split volumes, or contain snapshots, are not supported.
- The network interface must use DHCP to discover the network settings. When you import a custom image, existing network interfaces are not recreated. Any existing network interfaces are replaced with a single NIC after the import process is complete. You can attach additional VNICs after you launch the imported instance.
- The network configuration must not hardcode the MAC address for the network interface.

We recommend that you enable certificate-based SSH, however this is optional. If you want your image to automatically use SSH keys supplied from the User Data field when you launch an instance, you can install cloud-init when preparing the image. See Creating an Instance on page 1023 for more information about providing user data.

**Preparing Linux VMs for Import**

Before you import a custom Linux image, you must prepare the image to ensure that instances launched from the image can boot correctly and that network connections will work. Do the following:

1. Optionally, configure your Linux image to support serial console connections. A console connection can help you remotely troubleshoot malfunctioning instances, such as an imported image that does not complete a successful boot.
2. Create a backup of the root volume.
3. If the VM has remotely attached storage, such as NFS or block volumes, configure any services that rely on this storage to start manually. Remotely attached storage is not available the first time that an imported instance boots on Oracle Cloud Infrastructure.
4. Ensure that all network interfaces use DHCP, and that the MAC address and IP addresses are not hardcoded. See your system documentation for steps to perform network configuration for your system.
5. Stop the VM.
6. Clone the stopped VM as a VMDK or QCOW2 file, and then export the image from your virtualization environment. See the tools documentation for your virtualization environment for steps.

**Importing a Linux-Based VM**

After you prepare a Linux image for import, follow these steps to import the image:

1. **Upload the image file to an Object Storage bucket.** You can upload the file using the Console or using the command line interface (CLI). If you use the CLI, use the following command:

   ```
   oci os object put -bn <destination_bucket_name> --file <path_to_the_VMDK_or_QCOW2_file>
   ```

2. Open the navigation menu and click **Compute**. Under **Compute**, click **Custom Images**.
3. Click **Import Image**.
4. In the **Create in Compartment** list, select the compartment that you want to import the image to.
5. Enter a **Name** for the image. Avoid entering confidential information.
6. For the **Operating System**, select **Linux**.
7. Select the **Import from an Object Storage bucket** option.
8. Select the **Bucket** that you uploaded the image to.
9. In the **Object Name** list, select the image file that you uploaded.
10. For the **Image Type**, select the file type of the image, either **VMDK** or **QCOW2**.
11. Depending on your image's version of Linux, in the **Launch Mode** area, select **Paravirtualized Mode** or **Emulated Mode**. If your image supports paravirtualized drivers, we recommend that you select paravirtualized mode.
12. **Show Tagging Options:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
13. Click **Import Image**.

   The imported image appears in the **Custom Images** list for the compartment, with a state of **Importing**. When the import completes successfully, the state changes to **Available**.

   If the state doesn't change, or no entry appears in the **Custom Images** list, the import failed. Ensure that you have read access to the Object Storage object, and that the object contains a supported image.

**Post-Import Tasks for Linux Images**

After you import a custom Linux-based image, do the following:

1. If you want to use the image on AMD or X6-based shapes, add the shapes to the image's list of compatible shapes.
2. **Create an instance based on the custom image.** For the image source, select **Custom Images**, and then select the image that you imported.
3. **Connect to the instance using SSH.**
4. If the instance requires any remotely attached storage, such as block volumes or file storage, create and attach it.
   - If you are using iSCSI on page 641 attachments, see **Recommended iSCSI Initiator Parameters for Linux-based Images** on page 660.
5. **Create and attach any required secondary VNICS.**
6. Test that all applications are working as expected.
7. Reset any services that were set to start manually.
8. If you enabled serial console access to the image, test it by creating a serial console connection to the instance.

See the **current issues and workarounds** for known issues with imported custom images.

**Enabling Serial Console Access for Imported Linux Images**

You can configure your custom Linux image to support connections using the serial console feature in the Compute service.
For more information about serial console connections, and steps to troubleshoot if your image has network connectivity issues after it is launched, see Troubleshooting Instances Using Instance Console Connections on page 1180.

The serial console connection in Oracle Cloud Infrastructure uses the first serial port, ttyS0, on the VM. The boot loader and the operating system should be configured to use ttyS0 as a console terminal for both input and output.

**Configuring the Boot Loader**

The steps to configure the boot loader to use ttyS0 as a console terminal for both input and output depend on the GRUB version. Run the following command on the operating system to determine the GRUB version:

```
grub install --version
```

If the version number returned is 2.x, use the steps for GRUB 2. For earlier versions, use the steps for GRUB.

**To configure GRUB2**

1. Run the following command to modify the GRUB configuration file:

   ```
sudo vi /etc/default/grub
   ```

2. Confirm that the configuration file contains the following:

   ```
GRUB_SERIAL_COMMAND="serial --unit=0 --speed=115200"
GRUB_TERMINAL="serial console"
```

3. Append the following to the end of the `GRUB_CMDLINE_LINUX` line:

   ```
   console=tty1 console=ttyS0,115200
   ```

   If `GRUB_CMDLINE_LINUX` does not exist, create this line, using `GRUB_CMDLINE_OUTPUT` as a template.

4. Regenerate the GRUB2 configuration using the following command:

   ```
sudo grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

   If you have a beta version of GRUB 2, use this command instead:

   ```
sudo grub-mkconfig -o /boot/grub/grub.cfg
   ```

**To configure GRUB**

1. Run the following command to modify the GRUB configuration file:

   ```
sudo vi /boot/grub/grub.conf
   ```

2. Add following after the line containing `timeout`:

   ```
   serial --unit=0 --speed=115200
terminal --timeout=5 serial console
   ```

3. Append the following to each `kernel` line:

   ```
   console=tty1 console=ttyS0,115200
   ```

**Configuring the Operating System**

The operating system may already be configured to use ttyS0 as a console terminal for both input and output. To verify, run the following command:

```
sudo vi /etc/securetty
```
Check the file for `ttyS0`. If you don't see it, append `ttyS0` to the end of the file.

**Validating Serial Console Access**

After completing the steps to enable serial console access to the image, you should validate that serial console access is working by testing the image with serial console in your virtualization environment. Consult the documentation for your virtualization environment for steps to do this. Verify that the boot output displays in the serial console output and that there is interactive input after the image has booted.

**Troubleshooting the Serial Console**

If no output is displayed on the serial console, verify in the configuration for your virtualization environment that the serial console device is attached to the first serial port.

If the serial console displays output, but there is no interactive input available, check that there is a terminal process listening on the `ttyS0` port. To do this, run the following command:

```
ps aux | grep ttyS0
```

This command should output a terminal process that is listening on the `ttyS0` port. For example, if your system is using `getty`, you will see the following output:

```
/sbin/getty ttyS0
```

If you don't see this output, it is likely that a login process is not configured for the serial console connection. To resolve this, enable the init settings, so that a terminal process is listening on the `ttyS0` at startup.

For example, if your system is using `getty`, add the following command to the init settings to run on system startup:

```
getty -L 9600 ttyS0 vt102
```

The steps to do this will vary depending on the operating system, so consult the documentation for the image's operating system.

**Configuring the Oracle Cloud Infrastructure NTP Service for an Instance**

Oracle Cloud Infrastructure offers a fully managed, secure, and highly available NTP service that you can use to set the date and time of your compute and database instances from within your virtual cloud network (VCN). The Oracle Cloud Infrastructure NTP service uses redundant Stratum 1 devices in every availability domain. The Stratum 1 devices are synchronized to dedicated Stratum 2 devices that every host synchronizes against. The service is available in every region.

This topic describes how to configure your compute instances to use this NTP service.

You can also choose to configure your instances to use a public NTP service or use FastConnect to leverage an on-premises NTP service.

**Note:**

Platform images for Oracle Autonomous Linux 7.x, Oracle Linux 8.x, Oracle Linux 7.x, Oracle Linux Cloud Developer 8.x, CentOS 7.x, and CentOS 8.x released after February 2018 include the Chrony service by default. You do not need to configure the Oracle Cloud Infrastructure NTP service for these instances.

**Oracle Linux 6.x**

Use the following steps to configure your Oracle Linux 6.x instances to use the Oracle Cloud Infrastructure NTP service.
1. Configure IPtables to allow connections to the Oracle Cloud Infrastructure NTP service, using the following commands:

```
sudo iptables -I BareMetalInstanceServices 8 -d 169.254.169.254/32 -p udp -m udp --dport 123 -m comment --comment "Allow access to OCI local NTP service" -j ACCEPT
```

```
sudo service iptables save
```

2. Install the NTP service with the following command:

```
sudo yum install ntp
```

3. Set the date of your instance with the following command:

```
sudo ntpdate 169.254.169.254
```

4. Configure the instance to use the Oracle Cloud Infrastructure NTP service for iburst. To configure, modify the `/etc/ntp.conf` file as follows:

   a. In the `server` section, comment out the lines specifying the RHEL servers:

```
#server 0.rhel.pool.ntp.org iburst
#server 1.rhel.pool.ntp.org iburst
#server 2.rhel.pool.ntp.org iburst
#server 3.rhel.pool.ntp.org iburst
```

   b. Add an entry for the Oracle Cloud Infrastructure NTP server:

```
server 169.254.169.254 iburst
```

The modified `server` section now contains the following:

```
# Please consider joining the pool (http://www.pool.ntp.org/join.html).
#server 0.rhel.pool.ntp.org iburst
#server 1.rhel.pool.ntp.org iburst
#server 2.rhel.pool.ntp.org iburst
#server 3.rhel.pool.ntp.org iburst
server 169.254.169.254 iburst
```

5. Set the NTP service to launch automatically when the instance boots with the following command:

```
sudo chkconfig ntpd on
```

6. Start the NTP service with the following command:

```
sudo /etc/init.d/ntpd start
```

7. Confirm that the NTP service is configured correctly with the following command:

```
ntpq -p
```

The output will be similar to the following:

```
remote refid st t when poll reach delay offset jitter
169.254.169.254 192.168.32.3 2 u 2 64 1 0.338 0.278
0.187
```

Oracle Linux 7.x released in February 2018 or earlier
Use the following steps to configure your Oracle Linux 7.x instances to use the Oracle Cloud Infrastructure NTP service.

1. Run commands in this section as root with the following command:

```bash
sudo su -
```

2. Install the NTP service with the following command:

```bash
yum -y install ntp
```

3. Change the firewall rules to allow inbound and outbound traffic with the Oracle Cloud Infrastructure NTP server, at 169.254.169.254, on UDP port 123 with the following command:

```bash
awk -v n=13 -v s=' <passthrough ipv="ipv4">-A OUTPUT -d 169.254.169.254/32 -p udp -m udp --dport 123 -m comment --comment "Allow access to OCI local NTP service" -j ACCEPT </passthrough>' 'NR == n {print s} {print}' /etc/firewalld/direct.xml > tmp && mv tmp /etc/firewalld/direct.xml
```

At the prompt `mv: overwrite '/etc/firewalld/direct.xml'?`, enter `y`.

4. Restart the firewall with the following command:

```bash
service firewalld restart
```

5. Set the date of your instance with the following command:

```bash
ntpd 169.254.169.254
```

6. Configure the instance to use the Oracle Cloud Infrastructure NTP service for iburst. To configure, modify the `/etc/ntp.conf` file as follows:

   a. In the `server` section comment out the lines specifying the RHEL servers:

   ```
   #server 0.rhel.pool.ntp.org iburst
   #server 1.rhel.pool.ntp.org iburst
   #server 2.rhel.pool.ntp.org iburst
   #server 3.rhel.pool.ntp.org iburst
   server 169.254.169.254 iburst
   ```

   b. Add an entry for the Oracle Cloud Infrastructure NTP service:

   ```
   server 169.254.169.254 iburst
   ```

   The modified `server` section should now contain the following:

   ```
   # Please consider joining the pool (http://www.pool.ntp.org/join.html).
   #server 0.rhel.pool.ntp.org iburst
   #server 1.rhel.pool.ntp.org iburst
   #server 2.rhel.pool.ntp.org iburst
   #server 3.rhel.pool.ntp.org iburst
   server 169.254.169.254 iburst
   ```

7. Start and enable the NTP service with the following commands:

```bash
systemctl start ntpd
systemctl enable ntpd
```

You also need disable the chrony NTP client to ensure that the NTP service starts automatically after a reboot, using the following commands:

```bash
systemctl stop chronyd
systemctl disable chronyd
```
8. Confirm that the NTP service is configured correctly with the following command:

```
ntpq -p
```

The output will be similar to the following:

<table>
<thead>
<tr>
<th>remote</th>
<th>refid</th>
<th>st</th>
<th>when</th>
<th>poll</th>
<th>reach</th>
<th>delay</th>
<th>offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>169.254.169.254</td>
<td>192.168.32.3</td>
<td>2</td>
<td>2</td>
<td>64</td>
<td>1</td>
<td>0.338</td>
<td>0.278</td>
</tr>
</tbody>
</table>

**Windows Server**

**Tip:**

If you encounter a *no time data was available* error message when setting up the NTP service on Windows Server, review the information in the Microsoft known issue article.

You can configure your Windows Server instances to use the Oracle Cloud Infrastructure NTP service by running the following commands in Windows Powershell as Administrator.

```
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Parameters' -Name 'Type' -Value NTP -Type String
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Config' -Name 'AnnounceFlags' -Value 5 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\TimeProviders\NtpServer' -Name 'Enabled' -Value 1 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Parameters' -Name 'NtpServer' -Value '169.254.169.254,0x9' -Type String
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient' -Name 'SpecialPollInterval' -Value 900 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Config' -Name 'MaxPosPhaseCorrection' -Value 1800 -Type DWord
Set-ItemProperty -Path 'HKLM:\System\CurrentControlSet\Services\W32Time\Config' -Name 'MaxNegPhaseCorrection' -Value 1800 -Type DWord
```

Steps 1 - 7 below walk you though these registry changes, you can use these steps to manually edit the registry instead of using PowerShell. If you use the PowerShell commands, you can skip steps 1 - 7, and proceed with steps 8 and 9 to complete the process of configuring your Windows instance to use the Oracle Cloud Infrastructure NTP service.

1. Change the server type to NTP:
   a. From Registry Editor, navigate to:
      ```
      HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\Parameters\Types
      ```
   b. Click *Type*.
   c. Change the value to NTP and click *OK*. 

2. Configure the Windows Time service to enable the Timeserv_Announce_Yes and Reliable_Timeserv_Announce_Auto flags.

To configure, set the AnnounceFlags parameter to 5:

   a. From Registry Editor, navigate to:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\Config\n```

   b. Click AnnounceFlags.

c. Change the value to 5 and click OK.

3. Enable the NTP server:

   a. From Registry Editor, navigate to:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpServer\n```

   b. Click Enabled.

c. Change the value to 1 and click OK.

4. Set the time sources:

   a. From Registry Editor, navigate to:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\Parameters\n```

   b. Click NtpServer.

c. Change the value to 169.254.169.254,0x9 and click OK.

5. Set the poll interval:

   a. From Registry Editor, navigate to:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\TimeProviders\NtpClient\n```

   b. Click SpecialPollInterval.

c. Set the value to the interval that you want the time service to synchronize on. The value is in seconds. To set it for 15 minutes, set the value to 900, and click OK.

6. Set the phase correction limit settings to restrict the time sample boundaries:

   a. From Registry Editor, navigate to:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W32Time\Config\n```

   b. Click MaxPosPhaseCorrection.

c. Set the value to the maximum time offset in the future for time samples. The value is in seconds. To set it for 30 minutes, set the value to 1800 and click OK.

   d. Click MaxNegPhaseCorrection.

c. Set the value to the maximum time offset in the past for time samples. The value is in seconds. To set it for 30 minutes, set the value to 1800 and click OK.

7. Restart the time service by running the following command from a command prompt:

```
net stop w32time && net start w32time
```

8. Test the connection to the NTP service by running the following command from a command prompt:

```
w32tm /query /peers
```

The output will be similar to the following:

```
#Peer: 1
```
Peer: 169.254.169.254,0x9
State: Active
Time Remaining: 22.1901786s
Mode: 3 (Client)
Stratum: 0 (unspecified)
PeerPoll Interval: 10 (1024s)
HostPoll Interval: 10 (1024s)

After the time specified in the poll interval has elapsed, State will change from Pending to Active.

Configuring Image Capabilities for Custom Images

Image capabilities are the configuration options available when launching an instance from an image. Some image capability examples are the firmware used to boot the instance, the volume attachment types supported, and so on. The full set of image capabilities provided by Oracle Cloud Infrastructure Compute are defined in the global image capability schema. You can also create your own custom image capability schemas based on the global image capability schema to specify and configure image capabilities for your custom images. Using these schemas, you can customize the image configuration and options available when users launch instances from your custom images.

You can configure image capability schemas using the REST APIs, SDKs, or the CLI.

Caution:
Using this feature allows you to customize image capabilities from the default capabilities that Oracle recommends and should be used for advanced custom image scenarios only. Ensure that you understand the optimal configuration options for your custom image.

Global Image Capability Schema

The following JSON is what’s returned when you use the GetComputeGlobalImageCapabilitySchemaVersion API operation or the global-image-capability-schema-version CLI command. It represents the full set of image capabilities available for images. The default values specified for each element are the recommended values for each option. You can create a schema to customize these options, however they must be a subset, you cannot specify values that are not included in the global capabilities schema.

```json
{
    "Compute.Firmware": {
        "descriptorType": "enumstring",
        "values": [
            "BIOS",
            "UEFI_64"
        ],
        "defaultValue": "UEFI_64"
    },
    "Compute.LaunchMode": {
        "descriptorType": "enumstring",
        "values": [
            "NATIVE",
            "EMULATED",
            "PARAVIRTUALIZED",
            "CUSTOM"
        ],
        "defaultValue": "PARAVIRTUALIZED"
    },
    "Network.AttachmentType": {
        "descriptorType": "enumstring",
        "values": [
            "E1000",
            "VFIO"
        ]
    }
}
```
Compute

```
"PARAVIRTUALIZED",
"defaultValue": "PARAVIRTUALIZED"
},
"Storage.BootVolumeType": {
  "descriptorType": "enumstring",
  "values": [
    "ISCSI",
    "SCSI",
    "IDE",
    "PARAVIRTUALIZED"
  ],
  "defaultValue": "PARAVIRTUALIZED"
},
"Storage.LocalDataVolumeType": {
  "descriptorType": "enumstring",
  "values": [
    "ISCSI",
    "SCSI",
    "IDE",
    "PARAVIRTUALIZED"
  ],
  "defaultValue": "PARAVIRTUALIZED"
},
"Storage.RemoteDataVolumeType": {
  "descriptorType": "enumstring",
  "values": [
    "ISCSI",
    "SCSI",
    "IDE",
    "PARAVIRTUALIZED"
  ],
  "defaultValue": "PARAVIRTUALIZED"
},
"Storage.ConsistentVolumeNaming": {
  "descriptorType": "boolean",
  "defaultValue": "true"
},
"Storage.ParaVirtualization.EncryptionInTransit": {
  "descriptorType": "boolean",
  "defaultValue": "true"
},
"Storage.ParaVirtualization.AttachmentVersion": {
  "descriptorType": "enuminteger",
  "values": [
    1,
    2
  ],
  "defaultValue": 2
},
"Storage.Iscsi.MultipathDeviceSupported": {
  "descriptorType": "boolean",
  "defaultValue": false
}
```

**Schema Elements**

The following list describes all the available elements in the global image capabilities schema.

- **Compute.Firmware**: The firmware used to boot the virtual machine instance. The default value is UEFI_64.
- **Compute.LaunchMode**: The configuration mode for launching instances. The default value is PARAVIRTUALIZED.
• **Network.AttachmentType**: The emulation type for the primary VNIC, which is automatically created and attached when the instance is launched. The default value is PARAVIRTUALIZED.

• **Storage.BootVolumeType**: Specifies the driver options for the image’s boot volume. The default value is PARAVIRTUALIZED.

• **Storage.LocalDataVolumeType**: Specifies the driver options for the image to access local storage volumes. The default value is PARAVIRTUALIZED.

• **Storage.RemoteDataVolumeType**: Specifies the driver options for the image to access remote storage volumes. The default value is PARAVIRTUALIZED.

• **Storage.ConsistentVolumeNaming**: Specifies whether consistent device paths for iSCSI and paravirtualized attached block volumes are enabled for the image. If enabled, the image must support consistent device names. The default value is true.

• **Storage.ParaVirtualization.EncryptionInTransit**: Specifies whether in-transit encryption is enabled for the image’s boot volume attachment. Applies only to paravirtualized boot volume attachments. The default value is true.

• **Storage.ParaVirtualization.AttachmentVersion**: Specifies the paravirtualization version for boot volume and block volume attachments. Applies only to paravirtualized volume attachments. The default value is 2.

• **Storage.Iscsi.MultipathDeviceSupported**: Specifies whether multipath-enabled attachments are supported for the image. Applies only to iSCSI volume attachments. The default value is false.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

For administrators, the following policy provides full access to the image capability schema framework:

```
Allow group IAM_group_name to manage compute-image-capability-schema in tenancy
```

### Using the Console

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Custom Images**.
2. Click the custom image that you're interested in.
3. Click **Edit Image Capabilities**.
4. Edit the image capabilities you want to configure. See Schema Elements on page 1017 for details about the image capabilities you can configure.
5. Click **Save Changes**.

### Using the CLI

For information about using the CLI, see Command Line Interface (CLI) on page 5316. To work with image capability schemas using the CLI, open a command prompt and run any of the following commands.

To list out the global image capability schema:

```
oci compute global-image-capability-schema list
```

To list out the global image capability schema versions:

```
oci compute global-image-capability-schema-version list --global-image-capability-schema-id <GLOBAL_IMAGE_CAPABILITY_SCHEMA_ID>
```
To retrieve the global image capability schema version:

```
oci compute global-image-capability-schema-version get --global-image-capability-schema-id <GLOBAL_IMAGE_CAPABILITY_SCHEMA_ID> --global-image-capability-schema-version-name <VERSION_NAME>
```

To list the image capability schemas in the specified compartment:

```
oci compute image-capability-schema list --compartment-id <COMPARTMENT_ID>
```

To retrieve the image capability schema for the specified ID:

```
oci compute image-capability-schema get --image-capability-schema-id <IMAGE_CAPABILITY_SCHEMA_ID>
```

To update the specified image capability schema:

```
oci -d compute image-capability-schema update --image-capability-schema-id <IMAGE_CAPABILITY_SCHEMA_ID> --schema-data file://<SCHEMA_DATA_FILE>.json
```

To create an image capability schema:

```
```

When you create the schema, you specify the image OCID for the custom image you want to apply the image capability schema to.

To delete the specified image capability schema:

```
oci -d compute image-capability-schema delete --image-capability-schema-id <IMAGE_CAPABILITY_SCHEMA_ID>
```

### Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following API operations for working with image capability schemas:

- ListComputeGlobalImageCapabilitySchemas
- ListComputeGlobalImageCapabilitySchemaVersions
- GetComputeGlobalImageCapabilitySchema
- GetComputeGlobalImageCapabilitySchemaVersion
- ListComputeImageCapabilitySchemas
- CreateComputeImageCapabilitySchema
- UpdateComputeImageCapabilitySchema
- DeleteComputeImageCapabilitySchema
- ChangeComputeImageCapabilitySchemaCompartment

### OS Kernel Updates

**Note:**

This topic applies only to Linux instances that were launched before February 15, 2017. Linux instances launched on or after February 15, 2017 boot directly from the image and do not require further action for kernel updates.
Oracle Cloud Infrastructure boots each instance from a network drive. This configuration requires additional actions when you update the OS kernel.

Oracle Cloud Infrastructure uses Unified Extensible Firmware Interface (UEFI) firmware and a Preboot eXecution Environment (PXE) interface on the host server to load iPXE from a Trivial File Transfer Protocol (TFTP) server. The iPXE implementation runs a script to boot Oracle Linux. During the boot process, the system downloads the kernel, the initrd file, and the kernel boot parameters from the network. The instance does not use the host's GRUB boot loader.

Normally, the `yum update kernel-uek` command edits the GRUB configuration file, either `grub.cfg` or `grub.conf`, to configure the next boot. Since bare metal instances do not use the GRUB boot loader, changes to the GRUB configuration file are not implemented. When you update the kernel on your instance, you also must upload the update to the network to ensure a successful boot process. The following approaches address this need:

- Instances launched from platform images include an Oracle yum plug-in that seamlessly handles the upload when you run the `yum update kernel-uek` command.
- If you use a custom image based on a platform image, the included yum plug-in will continue to work, barring extraordinary changes.
- If you install your own package manager, you must either write your own plug-in or upload the kernel, initrd, and kernel boot parameters manually.

**Oracle Yum Plug-in**

On instances launched with a platform image, you can find the Oracle yum plug-in at:

```
/usr/share/yum-plugins/kernel-update-handler.py
```

The plug-in configuration is at:

```
/etc/yum/pluginconf.d
```

The plug-in looks for two variables in the `/etc/sysconfig/kernel` file, `UPDATEDEFAULT` and `DEFAULTKERNEL`. It picks up the updates only when the first variable is set to "yes" and the `DEFAULTKERNEL` value matches the kernel being updated. For example:

```
# UPDATEDEFAULT specifies if new-kernel-pkg should make
# new kernels the default
UPDATEDEFAULT=yes

# DEFAULTKERNEL specifies the default kernel package type
DEFAULTKERNEL=kernel-uek
```

Platform images incorporate the Unbreakable Enterprise Kernel (UEK). If you want to switch to a non-UEK kernel, you must update the `DEFAULTKERNEL` value to "kernel" before you run `yum update kernel`.

**Manual Updates**

**Tip:**

Oracle recommends using the Oracle yum plug-in to update the kernel.

If you manually upload the updates, there are four relevant URLs:

```
http://169.254.0.3/kernel
http://169.254.0.3/initrd
http://169.254.0.3/cmdline
http://169.254.0.3/activate
```

The first three URLs are for uploading files (HTTP request type PUT). The fourth URL is for activating the uploaded files (HTTP request type POST). The system discards the uploaded files if they are not activated before the host restarts.
The kernel and initrd are simple file uploads. The cmdline upload must contain the kernel boot parameters found in the `grub.cfg` or `grub.conf` file, depending on the Linux version. The following example is an entry from the `/boot/efi/EFI/redhat/grub.cfg` file in Red Hat Linux 7. The highlighted text represents the parameters to upload.

```
kernel /boot/vmlinuz-4.1.12-37.5.1.el6uek.x86_64
ro root=UUID=8079e287-53d7-4b3d-b708-c519cf6829c8 rd_NO_LUKS
KEYBOARDTYPE=pc KEYTABLE=us
netroot=iscsi:169.254.0.2::3260:iface1:eth0::ign.2015-02.oracle.boot:uefi
rd_NO_MD SYSFONT=latarcyrheb-sun16 ifname=eth0:90:e2:ba:a2:e3:80
crashkernel=auto iscsi_initiator=ign.2015-02. rd_NO_LVM ip=eth0:dhcp
rd_NO_DM LANG=en_US.UTF-8 console=tty0 console=ttyS0,9600 iommu=on
```

The following command returns what is being uploaded to the cmdline file.

```
cat /tmp/cmdline
```

A typical response resembles the following.

```
ro root=UUID=8079e287-53d7-4b3d-b708-c519cf6829c8 rd_NO_LUKS
KEYBOARDTYPE=pc KEYTABLE=us
netroot=iscsi:169.254.0.2::3260:iface1:eth0::ign.2015-02.oracle.boot:uefi
rd_NO_MD SYSFONT=latarcyrheb-sun16 ifname=eth0:90:e2:ba:a2:e3:80
crashkernel=auto iscsi_initiator=ign.2015-02. rd_NO_LVM ip=eth0:dhcp
rd_NO_DM LANG=en_US.UTF-8 console=tty0 console=ttyS0,9600 iommu=on
```

The following commands update the `cmdline` and `initrd` files, and then activate the changes.

```
CKSUM=`md5sum /tmp/cmdline | cut -d ' ' -f 1`

CKSUM=`md5sum /boot/initramfs-3.8.13-118.8.1.el7uek.x86_64.img | cut -d ' ' -f 1`

sudo curl -X POST http://169.254.0.3/activate
```

**Managing Key Pairs on Linux Instances**

Instances launched using Oracle Linux, CentOS, or Ubuntu images use an SSH key pair instead of a password to authenticate a remote user (see Security Credentials on page 207). A key pair consists of a private key and public key. You keep the private key on your computer and provide the public key when you create an instance. When you connect to the instance using SSH, you provide the path to the private key in the SSH command.

You can have as many key pairs as you want, or you can keep it simple and use one key pair for all or several of your instances.

If you're using OpenSSH to connect to an instance, you can use a key pair that is generated by Oracle Cloud Infrastructure at the time that you create the instance. Oracle does not store a copy of the private key generated by the Console. OpenSSH should be installed on UNIX-based systems (including Linux and OS X), Windows 10, and Windows Server 2019.
To create your own key pairs, you can use a third-party tool such as OpenSSH on UNIX-style systems (including Linux, Solaris, BSD, and OS X) or PuTTY Key Generator on Windows.

**Caution:**
Anyone who has access to the private key can connect to the instance. Store the private key in a secure location.

**Required SSH Public Key Format**

If you provide your own key pair, it must use the OpenSSH format.

A public key has the following format:

```
<key_type> <public_key> <optional_comment>
```

For example, an RSA public key looks like this:

```
ssh-rsa AAAAB3BzaC1yc2EAAAADAQABAAABAQD9BRwrU1LDki6P0+j2hwsjS2muM...
...yXDus/5DQ== rsa-key-20201202
```

For platform images, these SSH key types are supported: RSA, DSA, DSS, ECDSA, and Ed25519. If you bring your own image, you're responsible for managing the SSH key types that are supported.

For RSA, DSS, and DSA keys, a minimum of 2048 bits is recommended. For ECDSA keys, a minimum of 256 bits is recommended.

**Prerequisites**

- If you're using a UNIX-style system, you probably already have the `ssh-keygen` utility installed. To determine whether it's installed, type `ssh-keygen` on the command line. If it's not installed, you can download OpenSSH for UNIX from [http://www.openssh.com/portable.html](http://www.openssh.com/portable.html) and install it.
- If you're using a Windows operating system, you will need PuTTY and the PuTTY Key Generator. Download PuTTY and PuTTYgen from [http://www.putty.org](http://www.putty.org) and install them.

**Creating an SSH Key Pair on the Command Line**

1. Open a shell or terminal for entering the commands.
2. At the prompt, enter `ssh-keygen` and provide a name for the key when prompted. Optionally, include a passphrase.

   The keys will be created with the default values: RSA keys of 2048 bits.

Alternatively, you can type a complete `ssh-keygen` command, for example:

```
ssh-keygen -t rsa -N "" -b 2048 -C "<key_name>" -f <path/root_name>
```

The command arguments are shown in the following table:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-t rsa</code></td>
<td>Use the RSA algorithm.</td>
</tr>
</tbody>
</table>
### Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-N &quot;&lt;passphrase&gt;&quot;</td>
<td>A passphrase to protect the use of the key (like a password). If you don't want to set a passphrase, don't enter anything between the quotes. A passphrase is not required. You can specify one as a security measure to protect the private key from unauthorized use. If you specify a passphrase, when you connect to the instance you must provide the passphrase, which typically makes it harder to automate connecting to an instance.</td>
</tr>
<tr>
<td>-b 2048</td>
<td>Generate a 2048-bit key. You don't have to set this if 2048 is acceptable, as 2048 is the default. A minimum of 2048 bits is recommended for SSH-2 RSA.</td>
</tr>
<tr>
<td>-C &quot;&lt;key_name&gt;&quot;</td>
<td>A name to identify the key.</td>
</tr>
<tr>
<td>-f &lt;path/root_name&gt;</td>
<td>The location where the key pair will be saved and the root name for the files.</td>
</tr>
</tbody>
</table>

### Creating an SSH Key Pair Using PuTTY Key Generator

1. Find `puttygen.exe` in the PuTTY folder on your computer, for example, C:\Program Files (x86)\PuTTY. Double-click `puttygen.exe` to open it.
2. Specify a key type of SSH-2 RSA and a key size of 2048 bits:
   - In the **Key** menu, confirm that the default value of **SSH-2 RSA key** is selected.
   - For the **Type of key to generate**, accept the default key type of **RSA**.
   - Set the **Number of bits in a generated key** to 2048 if it is not already set.
3. Click **Generate**.
4. Move your mouse around the blank area in the PuTTY window to generate random data in the key.
5. When the key is generated, it appears under **Public key for pasting into OpenSSH authorized_keys file**.
6. A **Key comment** is generated for you, including the date and time stamp. You can keep the default comment or replace it with your own more descriptive comment.
7. Leave the **Key passphrase** field blank.
8. Click **Save private key**, and then click **Yes** in the prompt about saving the key without a passphrase.
   The key pair is saved in the PuTTY Private Key (PPK) format, which is a proprietary format that works only with the PuTTY tool set.
   You can name the key anything you want, but use the `.ppk` file extension. For example, `mykey.ppk`.
9. Select all of the generated key that appears under **Public key for pasting into OpenSSH authorized_keys file**, copy it using **Ctrl + C**, paste it into a text file, and then save the file in the same location as the private key.
   (Do not use **Save public key** because it does not save the key in the OpenSSH format.)
   You can name the key anything you want, but for consistency, use the same name as the private key and a file extension of `.pub`. For example, `mykey.pub`.
10. Write down the names and location of your public and private key files. You will need the public key when launching an instance. You will need the private key to access the instance via SSH.
   Now that you have a key pair, you're ready to launch instances as described in [Creating an Instance](#) on page 1023.

### Creating an Instance

Use the steps in this topic to create a bare metal or virtual machine (VM) Compute instance.
Compute

Tip:
If this is your first time creating an instance, consider following the Getting Started tutorial for a guided workflow through the steps required to create an instance.

When you create an instance, the instance is automatically attached to a virtual network interface card (VNIC) in the cloud network's subnet and given a private IP address from the subnet's CIDR. You can let the IP address be automatically assigned, or you can specify a particular address of your choice. The private IP address lets instances within the cloud network communicate with each other. If you've set up the cloud network for DNS, instances can instead use fully qualified domain names (FQDNs).

If the subnet is public, you can optionally assign the instance a public IP address. A public IP address is required to communicate with the instance over the internet, and to establish a Secure Shell (SSH) or Remote Desktop Protocol (RDP) connection to the instance from outside the cloud network. You can also create SSH or RDP connections to instances without public IP addresses using a bastion.

Note:
Partner images and pre-built Oracle enterprise images are not available in Government Cloud realms.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

Tip:
When you create an instance, several other resources are involved, such as an image, a cloud network, and a subnet. Those other resources can be in the same compartment with the instance or in other compartments. You must have the required level of access to each of the compartments involved in order to launch the instance. This is also true when you attach a volume to an instance; they don't have to be in the same compartment, but if they’re not, you need the required level of access to each of the compartments.

For administrators: The simplest policy to enable users to create instances is listed in Let users launch compute instances on page 2807. It gives the specified group general access to manage instances and images, along with the required level of access to attach existing block volumes to the instances. If the group needs to create block volumes, they'll need the ability to manage block volumes (see Let volume admins manage block volumes, backups, and volume groups on page 2810). If the group needs access to community images specifically, they'll need the ability to read community images (see Publishing Community Applications on page 3447).

To require that legacy instance metadata service endpoints are disabled on any new instances that are created, use the following policy:

Allow group InstanceLaunchers to manage instances in compartment ABC where request.instanceOptions.areLegacyEndpointsDisabled= 'true'

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.
Partner Image Catalog

If the group needs to create instances based on partner images, they'll need the manage permission for app-catalog-listing to create subscriptions to images from the Partner Image catalog. See Let users list and subscribe to images from the Partner Image catalog on page 2809.

Security Zones

Security Zones ensure that your cloud resources comply with Oracle security principles. If any operation on a resource in a security zone compartment violates a policy for that security zone, then the operation is denied.

The following security zone policies affect your ability to create instances:

- The boot volume for a compute instance in a security zone must also be in a security zone.
- A compute instance that isn't in a security zone can't use a boot volume that is in a security zone.
- A compute instance in a security zone must use subnets that are also in a security zone.
- All compute instances in a security zone must be created using platform images. You can't create a compute instance from a custom image in a security zone.

Recommended Networking Launch Types

When you launch a VM instance, by default, Oracle Cloud Infrastructure chooses a recommended networking type for the VNIC based on the instance shape and OS image. The networking interface handles functions such as disk input/output and network communication. The following options are available:

- **Paravirtualized networking:** For general purpose workloads such as enterprise applications, microservices, and small databases. Paravirtualized networking also provides increased flexibility to use the same image across different hardware platforms. Linux images with paravirtualized networking support live migration during infrastructure maintenance.
- **Hardware-assisted (SR-IOV) networking:** Single root input/output virtualization. For low-latency workloads such as video streaming, real-time applications, and large or clustered databases. Hardware-assisted (SR-IOV) networking uses the VFIO driver framework.

**Important:**
To use a particular networking type, both the shape and the image must support that networking type.

Shapes: The following table lists the default and supported networking types for VM shapes.

<table>
<thead>
<tr>
<th>Shape series</th>
<th>Default Networking Type</th>
<th>Supported Networking Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM.Standard1</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.Standard2</td>
<td>Paravirtualized</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.Standard.E2</td>
<td>Paravirtualized</td>
<td>Paravirtualized only</td>
</tr>
<tr>
<td>VM.Standard.E3</td>
<td>SR-IOV for regular instances</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td></td>
<td>Paravirtualized for burstable instances</td>
<td></td>
</tr>
<tr>
<td>VM.Standard.A1.Flex</td>
<td>Paravirtualized</td>
<td>Paravirtualized only</td>
</tr>
<tr>
<td>VM.Standard.E4</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.DenseIO1</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.DenseIO2</td>
<td>Paravirtualized</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.GPU2</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>Shape series</td>
<td>Default Networking Type</td>
<td>Supported Networking Types</td>
</tr>
<tr>
<td>-------------------</td>
<td>--------------------------</td>
<td>----------------------------------</td>
</tr>
<tr>
<td>VM.GPU3</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.Optimized3</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
</tbody>
</table>

**Images:** Paravirtualized networking is supported on these platform images:

- **Oracle Linux 8, Oracle Linux Cloud Developer 8:** All images.
- **Oracle Linux 7, Oracle Linux 6:** Images published in March 2019 or later.
- **CentOS 8:** All images.
- **CentOS 7:** Images published in July 2019 or later.
- **Ubuntu 20.04:** All images.
- **Ubuntu 18.04:** Images published in March 2019 or later.
- **Windows Server 2019:** All images.
- **Windows Server 2016:** Images published in August 2019 or later.

SR-IOV networking is supported on all platform images, with the following exceptions:

- Images for Arm-based shapes do not support SR-IOV networking.
- On Windows Server 2019, when launched using a VM.Standard2 shape, SR-IOV networking is not supported.
- On Windows Server 2012 R2, SR-IOV networking is supported on platform images released in April 2021 or later.
- The Server Core installation option for Windows Server does not support SR-IOV networking.

You can create an instance that uses a specific networking type instead of the default. However, depending on compatibility between the shape and image that you choose, the instance might not launch properly. You can test whether it succeeded by connecting to the instance. If the connection fails, the networking type is not supported. Relaunch the instance using a supported networking type.

**Creating a Linux Instance**

Use the following steps to create a Linux instance.

**Prerequisites**

Before you start, you need these things:

- (Optional) An existing virtual cloud network (VCN) to launch the instance in. Alternatively, you can create a new VCN while you create the instance. For information about setting up cloud networks, see Networking on page 3604.
- If you want to use your own Secure Shell (SSH) key to connect to the instance using SSH, you need the public key from the SSH key pair that you plan to use. The key must be in OpenSSH format. For more information, see Managing Key Pairs on Linux Instances on page 1021.
- (Optional) If you want to launch the instance using a host capacity type other than on-demand capacity, prepare the capacity:
  - To launch an instance and have it count against a capacity reservation, you must have a capacity reservation in the same availability domain as the instance.
  - To place an instance on a dedicated virtual machine host, you must have a dedicated virtual machine host in the same availability domain and fault domain as the instance.

The capacity types are mutually exclusive.

**To create a Linux instance**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click **Create Instance**.
Compute

3. Enter a name for the instance. You can add or change the name later. The name doesn't need to be unique, because an Oracle Cloud Identifier (OCID) uniquely identifies the instance. Avoid entering confidential information.

4. Select the compartment to create the instance in.

The other resources that you choose can come from different compartments.

5. In the Placement section, make the following selections:

   a. Select the Availability domain that you want to create the instance in.

   b. (Optional) If you want to choose a capacity type or specify a fault domain, click Show advanced options. The following options are available:

      - **Capacity type**: Select one of the following.
        - **On-demand capacity**: The instance is launched on a shared host using on-demand capacity. This is the default.
        - **Preemptible capacity**: This option lets you run the instance on a shared host using preemptible capacity. The capacity is reclaimed when it's needed elsewhere, and the instances are terminated. Choose whether to permanently delete the attached boot volume when the capacity is reclaimed and the instance is terminated.
        - **Capacity reservation**: This option lets you count the instance against a capacity reservation. Select a capacity reservation from the list.
        - **Dedicated host**: This option lets you run the instance in isolation, so that it is not running on shared infrastructure. Select a dedicated virtual machine host from the list. You can only place an instance on a dedicated virtual machine host at the time you create the instance.
        - **Fault domain**: The fault domain to use for the instance. If you do not specify the fault domain, the system selects one for you. You can edit the fault domain after you create the instance. For more information, see Fault Domains on page 210 and Best Practices for Your Compute Instance on page 931.

6. In the Image and shape section, choose the image and shape for the instance:

   a. By default, an Oracle Linux 7.x image is used to boot the instance. To select a different image or a boot volume, in the Image section, click Change Image. Then, select an Image source from the list. The following options are available:

      - **Platform images**: Pre-built images for Oracle Cloud Infrastructure. To select a different OS version or image build, select the check box next to an image, and then select a value from the lists in the row for the image. To see which shapes are compatible with an OS version and image build, click Advanced Options. For more information about platform images, see Platform Images on page 943.
      - **Oracle images**: Pre-built Oracle enterprise images and solutions enabled for Oracle Cloud Infrastructure.
      - **Partner images**: Trusted third-party images published by Oracle partners. To view more details about an image or to change the image build, click the image's down arrow. For more information, see Overview of Marketplace on page 3440 and Working with Listings on page 3441.
      - **Custom images**: Custom images created or imported into your Oracle Cloud Infrastructure environment. For more information, see Managing Custom Images on page 989.
      - **Community images**: Custom images created and published by community members for use by other community members. To filter by operating system, click OS, and then choose from listed operating systems. To find a community image by name, click Search, and then type a full or partial application
Compute

name. To view more details about an image, click the image's down arrow. For more information, see Publishing Community Applications on page 3447.

- **Boot volumes**: Boot volumes that are available for creating a new instance in your Oracle Cloud Infrastructure environment. For more information, see Boot Volumes on page 689.

- **Image OCID**: Create an instance using a specific version of an image by providing the image OCID. To determine the image OCID for Oracle-provided images, see Image Release Notes.

Choose an image or boot volume, and then click **Select Image**.

b. To select a different shape, in the Shape section, click **Change Shape**. Then, do the following:

1. In the **Instance type** section, select Virtual Machine or Bare Metal Machine.

2. If you're creating a virtual machine, in the **Shape series** section, select a processor group, and then choose a shape. The following options are available:

   - **AMD**: The flexible shapes that use current generation AMD processors and have a customizable number of OCPUs and amount of memory.
     - For **Number of OCPUs**, choose the number of OCPUs that you want to allocate to this instance by dragging the slider. You can select from 1 to 64 OCPUs.
     - If you want this to be a *burstable instance*, select the **Burstable** check box. Then, in the **Burstable baseline per OCPU** list, select the baseline OCPU utilization for the instance. This value is the percentage of OCPUs that you want to use most of the time.
     - For **Amount of memory (GB)**, choose the amount of memory that you want to allocate to this instance by dragging the slider. The amount of memory allowed is based on the number of OCPUs selected. For more information about the minimum memory, maximum memory, and ratio of memory to OCPUs for this shape, see Flexible Shapes on page 973.

   The other resources scale proportionately.

   - **Intel**: Standard and optimized shapes that use the current generation Intel processor. Optimized flexible shapes have a customizable number of OCPUs and amount of memory.
     - For **Number of OCPUs**, choose the number of OCPUs that you want to allocate to this instance by dragging the slider. You can select from 1 to 18 OCPUs.
     - For **Amount of memory (GB)**, choose the amount of memory that you want to allocate to this instance by dragging the slider. The amount of memory allowed is based on the number of OCPUs selected. For more information about the minimum memory, maximum memory, and ratio of memory to OCPUs for this shape, see Flexible Shapes on page 973.

   The other resources scale proportionately.

   - **Ampere**: The Ampere A1 Compute flexible shape, which uses current generation Arm-based processors and has a customizable number of OCPUs and amount of memory.
     - For **Number of OCPUs**, choose the number of OCPUs that you want to allocate to this instance by dragging the slider. You can select from 1 to 80 OCPUs.
     - For **Amount of memory (GB)**, choose the amount of memory that you want to allocate to this instance by dragging the slider. The amount of memory allowed is based on the number of OCPUs selected. For more information about the minimum memory, maximum memory, and ratio of memory to OCPUs for this shape, see Flexible Shapes on page 973.

   The other resources scale proportionately.

   - **Specialty and Previous Generation**: Standard shapes with previous generation Intel and AMD processors, the Always Free VM.Standard.E2.1.Micro shape, Dense I/O shapes, GPU shapes, and HPC shapes.

     If a shape is disabled, it means that the shape is either incompatible with the image that you selected previously, or not available in the current availability domain. If you don't see a shape, it means that you don't have service limits for the shape. You can request a service limit increase.

     For more information about shapes, see Compute Shapes on page 973.

3. Click **Select Shape**.
7. In the **Networking** section, configure the network details for the instance:

   a. For **Network** and **Subnet**, specify the virtual cloud network (VCN) and subnet to create the instance in. Decide whether you want to use an existing VCN and subnet, create a new VCN or subnet, or enter an existing subnet's OCID:

   **Select existing virtual cloud network**

   Make the following selections:

   - **Virtual cloud network in `<compartment_name>`**: The cloud network to create the instance in.
   - **Subnet**: A subnet within the cloud network that the instance is attached to. The subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For more information, see *Access to the Internet* on page 3609. Subnets can also be either AD-specific or regional (regional ones have "regional" after the name). We recommend using regional subnets. For more information, see *About Regional Subnets* on page 3694.

   If choosing **Select existing subnet**, for **Subnet in `<compartment_name>`**, select the subnet.

   If choosing **Create new public subnet**, enter the following information:

   - **New subnet name**: A friendly name for the subnet. It doesn't have to be unique, and it cannot be changed later in the Console. You can change it with the API. Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to put the subnet.
   - **CIDR block**: A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). Make sure it's within the cloud network's CIDR block and doesn't overlap with any other subnets. You *cannot* change this value later. See *Allowed VCN Size and Address Ranges* on page 3606. For reference, here's a [CIDR calculator](#).

   **Create new virtual cloud network**

   Make the following selections:

   - **New virtual cloud network name**: A friendly name for the network. Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to put the new network.
   - **Subnet**: A subnet within the cloud network to attach the instance to. The subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For more information, see *Access to the Internet* on page 3609. Subnets can also be either AD-specific or regional (regional ones have "regional" after the name). We recommend using regional subnets. For more information, see *About Regional Subnets* on page 3694.

   Enter the following information:

   - **New subnet name**: A friendly name for the subnet. It doesn't have to be unique, and it cannot be changed later in the Console. You can change it with the API. Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to put the subnet.
   - **CIDR block**: A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). Make sure it's within the cloud network's CIDR block and doesn't overlap with any other subnets. You *cannot*
change this value later. See Allowed VCN Size and Address Ranges on page 3606. For reference, here's a CIDR calculator.

Enter subnet OCID

For Subnet OCID, enter the subnet OCID.

b. If the subnet is public, you can optionally assign the instance a public IP address. A public IP address makes the instance accessible from the internet. Select the Assign a public IPv4 address option. For more information, see Access to the Internet on page 3609.

c. (Optional) If you want to configure advanced networking settings, click Show advanced options. The following options are available:

- **Use network security groups to control traffic**: Select this option if you want to add the instance's primary VNIC to one or more network security groups (NSGs). Then, specify the NSGs. Available only when you use an existing VCN. For more information, see Network Security Groups on page 3718.

- **Private IP address**: An available private IP address of your choice from the subnet's CIDR. If you don't specify a value, the private IP address is automatically assigned.

- **DNS record**: Whether to assign the VNIC a private DNS record. For more information, see DNS in Your Virtual Cloud Network on page 3781.

- **Hostname**: A hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels, and the option to assign a private DNS record is selected.

- **Launch Options**: The networking launch type. Available only for VMs. For more information, see Recommended Networking Launch Types on page 1025.

8. In the Add SSH keys section, generate an SSH key pair or upload your own public key. Select one of the following options:

- **Generate a key pair for me**: Oracle Cloud Infrastructure generates an RSA key pair for the instance. Click Save Private Key, and then save the private key on your computer. Optionally, click Save Public Key and then save the public key.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anyone who has access to the private key can connect to the instance. Store the private key in a secure location.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>To use a key pair that is generated by Oracle Cloud Infrastructure, you must access the instance from a system that has OpenSSH installed. UNIX-based systems (including Linux and OS X), Windows 10, and Windows Server 2019 should have OpenSSH. For more information, see Managing Key Pairs on Linux Instances on page 1021.</td>
</tr>
</tbody>
</table>

- **Upload public key files (.pub)**: Upload the public key portion of your key pair. Either browse to the key file that you want to upload, or drag and drop the file into the box. To provide multiple keys, press and hold down the Command key (on Mac) or the CTRL key (on Windows) while selecting files.

- **Paste public keys**: Paste the public key portion of your key pair in the box.

- **No SSH keys**: Select this option only if you do not want to connect to the instance using SSH. You cannot provide a public key or save the key pair that is generated by Oracle Cloud Infrastructure after the instance is created.

9. In the **Boot volume** section, configure the size and encryption options for the instance's boot volume:

- To specify a custom size for the boot volume, select the Specify a custom boot volume size check box. Then, enter a custom size from 50 GB to 32 TB. The specified size must be larger than the default boot volume size for the selected image. See Custom Boot Volume Sizes on page 690 for more information.

- For VM instances, you can optionally select the Use in-transit encryption check box. For bare metal instances that support in-transit encryption, it is enabled by default and is not configurable. See Block Volume Encryption on page 644 for more information about in-transit encryption. If you are using your own Vault
service encryption key for the boot volume, then this key is also used for in-transit encryption. Otherwise, the Oracle-provided encryption key is used.

- Boot volumes are encrypted by default, but you can optionally use your own Vault service encryption key to encrypt the data in this volume. To use the Vault service for your encryption needs, select the **Encrypt this volume with a key that you manage** check box. Then, select the **Vault compartment** and **Vault** that contain the master encryption key you want to use. Also select the **Master encryption key compartment** and **Master encryption key**. For more information about encryption, see **Overview of Vault** on page 5006. If you enable this option, this key is used for both data at rest encryption and in-transit encryption.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Block Volume service does not support encrypting volumes with keys encrypted using the Rivest-Shamir-Adleman (RSA) algorithm. When using your own keys, you must use keys encrypted using the Advanced Encryption Standard (AES) algorithm. This applies to block volumes and boot volumes.</td>
</tr>
</tbody>
</table>

- Block Volume performance capabilities lets you change the volume performance for boot volumes. When you create an instance, its boot volume is configured with the default volume performance set to **Balanced**. After you launch the instance, you can modify the performance setting. For steps to modify the performance setting, see **Changing the Performance of a Volume** on page 755. For more information, see **Block Volume Performance** on page 744.

10. (Optional) To configure advanced settings, click **Show Advanced Options**. The following options are available:

- On the **Management** tab, you can configure the following:
  - **Require an authorization header**: Select this check box to require that all requests to the instance metadata service (IMDS) use the version 2 endpoint and include an authorization header. Requests to IMDSv1 are denied. The image must support IMDSv2. For more information, see **Getting Instance Metadata** on page 1117.
  - **Initialization Script**: User data to be used by cloud-init to run custom scripts or provide custom cloud-init configuration. Browse to the file that you want to upload, or drag and drop the file into the box. The file or script does not need to be base64-encoded, because the Console performs this encoding when the information is submitted. For information about how to take advantage of user data, see the [cloud-init documentation](#). The total maximum size for user data and other metadata that you provide is 32,000 bytes.
  - **Tagging**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For
more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

- **On the Availability Configuration tab**, you can configure the following:
  
  - In the **Live migration** section, select an option:
    
    - **Let Oracle Cloud Infrastructure choose the best migration option**: Select this option to let Oracle Cloud Infrastructure choose the best option to migrate the instance to a healthy physical VM host if an underlying infrastructure component needs to undergo maintenance.
    
    - **Opt-in**: Select this option to have the instance live migrated to a healthy physical VM host without any notification or disruption. If live migration isn’t successful, reboot migration is used. Some shapes do not support live migration.
    
    - **Opt-out**: Select this option to have a notification sent for the maintenance event. The instance is live migrated if you do not proactively reboot the instance before the due date.
    
    - **Restore instance lifecycle state after infrastructure maintenance**: By default, if a VM instance is running when a maintenance event affects the underlying infrastructure, the instance is rebooted after it is recovered. Clear this check box if you want the instance to be recovered in the stopped state.

- **On the Oracle Cloud Agent tab**, choose which plugins you want to enable when the instance is launched. Plugins collect performance metrics, install OS updates, and perform other instance management tasks. For more information, see Managing Plugins with Oracle Cloud Agent on page 1089.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>After you create the instance, you might need to perform additional configuration tasks before you can use each plugin.</td>
</tr>
<tr>
<td>Oracle Autonomous Linux instances cannot be managed by the OS Management service. See this known issue for more information.</td>
</tr>
</tbody>
</table>

11. **Click Create.**

To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated work request.

After the instance is provisioned, details about it appear in the instance list. To view more details, including IP addresses, click the instance name.

When the instance is fully provisioned and running, you can connect to it using SSH as described in Connecting to an Instance on page 1083.

You also can attach a volume to the instance, provided the volume is in the same availability domain. For background information about volumes, see Overview of Block Volume on page 640.

For steps to let additional users connect to the instance, see Adding Users on an Instance on page 1088.

**Creating a Windows Instance**

Use the following steps to create a Windows instance.

**Prerequisites**

Before you start, you need these things:

- (Optional) An existing virtual cloud network (VCN) to launch the instance in. Alternatively, you can create a new VCN while you create the instance. For information about setting up VCNs, see Networking on page 3604.

- A VCN security rule that enables Remote Desktop Protocol (RDP) access so that you can connect to your instance. Specifically, you need a stateful ingress rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 and any source port. For more information, see Security Rules on page 3710. You can implement
To enable RDP access

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the cloud network that you're interested in.
4. To add the rule to a network security group that the instance belongs to:
   a. Under Resources, click Network Security Groups. Then click the network security group that you're interested in.
   b. Click Add Rules.
   c. Enter the following values for the rule:
      • Stateless: Leave the check box cleared.
      • Source Type: CIDR
      • Source CIDR: 0.0.0.0/0
      • IP Protocol: RDP (TCP/3389)
      • Source Port Range: All
      • Destination Port Range: 3389
      • Description: An optional description of the rule.
   d. When done, click Add.
5. Or, to add the rule to a security list that is used by the instance's subnet:
   a. Under Resources, click Security Lists. Then click the security list you're interested in.
   b. Click Add Ingress Rules.
   c. Enter the following values for the rule:
      • Stateless: Leave the check box cleared.
      • Source Type: CIDR
      • Source CIDR: 0.0.0.0/0
      • IP Protocol: RDP (TCP/3389)
      • Source Port Range: All
      • Destination Port Range: 3389
      • Description: An optional description of the rule.
   d. When done, click Add Ingress Rules.

• (Optional) If you want to launch the instance using a host capacity type other than on-demand capacity, prepare the capacity:
  • To launch an instance and have it count against a capacity reservation, you must have a capacity reservation in the same availability domain as the instance.
  • To place an instance on a dedicated virtual machine host, you must have a dedicated virtual machine host in the same availability domain and fault domain as the instance.

The capacity types are mutually exclusive.

To create a Windows instance

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click Create Instance.
3. Enter a name for the instance. You can add or change the name later. The name doesn't need to be unique, because an Oracle Cloud Identifier (OCID) uniquely identifies the instance. Avoid entering confidential information.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use only these ASCII characters in the instance name: uppercase letters (A-Z), lowercase letters (a-z), numbers (0-9), and hyphens (-). See this <a href="#">known issue</a> for more information.</td>
</tr>
</tbody>
</table>

4. Select the compartment to create the instance in.

The other resources that you choose can come from different compartments.

5. In the **Placement** section, make the following selections:

a. Select the **Availability domain** that you want to create the instance in.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you're creating an instance from a boot volume, you must create the instance in the same availability domain as the boot volume.</td>
</tr>
</tbody>
</table>

b. (Optional) If you want to choose a **capacity type** or specify a **fault domain**, click **Show advanced options**. The following options are available:

- **Capacity type**: Select one of the following.
  - **On-demand capacity**: The instance is launched on a shared host using on-demand capacity. This is the default.
  - **Preemptible capacity**: This option lets you run the instance on a shared host using preemptible capacity. The capacity is reclaimed when it's needed elsewhere, and the instances are terminated. Choose whether to permanently delete the attached boot volume when the capacity is reclaimed and the instance is terminated.
  - **Capacity reservation**: This option lets you count the instance against a capacity reservation. Select a capacity reservation from the list.
  - **Dedicated host**: This option lets you run the instance in isolation, so that it is not running on shared infrastructure. Select a dedicated virtual machine host from the list. You can only place an instance on a dedicated virtual machine host at the time you create the instance.
  - **Fault domain**: The fault domain to use for the instance. If you do not specify the fault domain, the system selects one for you. You can edit the fault domain after you create the instance. For more information, see [Fault Domains](#) on page 210 and [Best Practices for Your Compute Instance](#) on page 931.

6. In the **Image and shape** section, choose the **image** and **shape** for the instance:

a. Choose the image that's used to boot the instance. Click **Change Image**. Then, select an **Image source** from the list. The following options are available:

- **Platform images**: Pre-built images for Oracle Cloud Infrastructure. To select a different OS version or image build, select the check box next to an image, and then select a value from the lists in the row for the
image. To see which shapes are compatible with an OS version and image build, click **Advanced Options**. For more information, see Platform Images on page 943.

- **Oracle images**: Pre-built Oracle enterprise images and solutions enabled for Oracle Cloud Infrastructure.
- **Partner images**: Trusted third-party images published by Oracle partners. To view more details about the image, or to change the image build, click the image's down arrow. For more information, see Overview of Marketplace on page 3440 and Working with Listings on page 3441.
- **Custom images**: Custom images created or imported into your Oracle Cloud Infrastructure environment. For more information, see Managing Custom Images on page 989.
- **Community images**: Custom images created and published by community members for use by other community members. (Community images do not include any Windows custom images.) For more information, see Publishing Community Applications on page 3447.
- **Boot volumes**: Boot volumes that are available for creating a new instance in your Oracle Cloud Infrastructure environment. For more information, see Boot Volumes on page 689.
- **Image OCID**: Create an instance using a specific version of an image by providing the image **OCID**. To determine the image OCID for a platform image, see Image Release Notes.

Choose an image or boot volume, and then click **Select Image**.

b. To select a different shape, in the **Shape** section, click **Change Shape**. Then, do the following:

1. In the **Instance type** section, select **Virtual Machine** or **Bare Metal Machine**.
2. If you're creating a virtual machine, in the **Shape series** section, select a processor group, and then choose a shape. The following options are available:
   - **AMD**: The **flexible shapes** that use current generation AMD processors and have a customizable number of OCPUs and amount of memory.
     - For **Number of OCPUs**, choose the number of OCPUs that you want to allocate to this instance by dragging the slider. You can select from 1 to 64 OCPUs.
     - If you want this to be a **burstable instance**, select the **Burstable** check box. Then, in the **Burstable baseline per OCPU** list, select the baseline OCPU utilization for the instance. This value is the percentage of OCPUs that you want to use most of the time.
     - For **Amount of memory (GB)**, choose the amount of memory that you want to allocate to this instance by dragging the slider. The amount of memory allowed is based on the number of OCPUs selected. For more information about the minimum memory, maximum memory, and ratio of memory to OCPUs for this shape, see Flexible Shapes on page 973.

   The other resources scale proportionately.

   **Important:**
   For Windows Server instances using the VM.Standard.E3.Flex shape, allocate a maximum of 32 OCPUs to the instance. See this known issue for more information.

   - **Intel**: Standard and optimized shapes that use the current generation Intel processor. Optimized **flexible shapes** have a customizable number of OCPUs and amount of memory.
     - For **Number of OCPUs**, choose the number of OCPUs that you want to allocate to this instance by dragging the slider. You can select from 1 to 18 OCPUs.
     - For **Amount of memory (GB)**, choose the amount of memory that you want to allocate to this instance by dragging the slider. The amount of memory allowed is based on the number of OCPUs
selected. For more information about the minimum memory, maximum memory, and ratio of memory to OCPUs for this shape, see Flexible Shapes on page 973.

The other resources scale proportionately.

- **Ampere**: The Arm-based Ampere A1 Compute shape is not supported for Windows images.
- **Specialty and Previous Generation**: Standard shapes with previous generation Intel and AMD processors, the Always Free VM.Standard.E2.1.Micro shape, Dense I/O shapes, GPU shapes, and HPC shapes.

If a shape is disabled, it means that the shape is either incompatible with the image that you selected previously, or not available in the current availability domain. If you don't see a shape, it means that you don't have service limits for the shape. You can request a service limit increase.

For more information about shapes, see Compute Shapes on page 973.

3. Click Select Shape.

7. In the Networking section, configure the network details for the instance:

   a. For Network and Subnet, specify the virtual cloud network (VCN) and subnet to create the instance in. Decide whether you want to use an existing VCN and subnet, create a new VCN or subnet, or enter an existing subnet's OCID:

   **Select existing virtual cloud network**

   Make the following selections:

   - **Virtual cloud network in <compartment_name>**: The cloud network to create the instance in.
   - **Subnet**: A subnet within the cloud network that the instance is attached to. The subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For more information, see Access to the Internet on page 3609. Subnets can also be either AD-specific or regional (regional ones have “regional” after the name). We recommend using regional subnets. For more information, see About Regional Subnets on page 3694.

   If choosing Select existing subnet, for Subnet in <compartment_name>, select the subnet.

   If choosing Create new public subnet, enter the following information:

   - **New subnet name**: A friendly name for the subnet. It doesn't have to be unique, and it cannot be changed later in the Console. You can change it with the API. Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to put the subnet.
   - **CIDR block**: A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). Make sure it's within the cloud network's CIDR block and doesn't overlap with any other subnets. You cannot change this value later. See Allowed VCN Size and Address Ranges on page 3606. For reference, here's a CIDR calculator.

   **Create new virtual cloud network**

   Make the following selections:

   - **New virtual cloud network name**: A friendly name for the network. Avoid entering confidential information.
   - **Create in compartment**: The compartment where you want to put the new network.
   - **Subnet**: A subnet within the cloud network to attach the instance to. The subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For more information, see Access to the Internet on page 3609. Subnets can also be either AD-specific or regional (regional ones...
have "regional" after the name). We recommend using regional subnets. For more information, see About Regional Subnets on page 3694.

Enter the following information:

- **New subnet name**: A friendly name for the subnet. It doesn't have to be unique, and it cannot be changed later in the Console. You can change it with the API. Avoid entering confidential information.
- **Create in compartment**: The compartment where you want to put the subnet.
- **CIDR block**: A single, contiguous CIDR block for the subnet (for example, 172.16.0.0/24). Make sure it's within the cloud network's CIDR block and doesn't overlap with any other subnets. You cannot change this value later. See Allowed VCN Size and Address Ranges on page 3606. For reference, here's a CIDR calculator.

**Enter subnet OCID**

For **Subnet OCID**, enter the subnet OCID.

b. If the subnet is public, you can optionally assign the instance a public IP address. A public IP address makes the instance accessible from the internet. Select the **Assign a public IPv4 address** option. For more information, see Access to the Internet on page 3609.

c. (Optional) If you want to configure advanced networking settings, click **Show advanced options**. The following options are available:

- **Use network security groups to control traffic**: Select this option if you want to add the instance's primary VNIC to one or more network security groups (NSGs). Then, specify the NSGs. Available only when you use an existing VCN. For more information, see Network Security Groups on page 3718.
- **Private IP address**: An available private IP address of your choice from the subnet’s CIDR. If you don't specify a value, the private IP address is automatically assigned.
- **DNS record**: Whether to assign the VNIC a private DNS record. For more information, see DNS in Your Virtual Cloud Network on page 3781.
- **Hostname**: A hostname to be used for DNS within the cloud network. Available only if the VCN and subnet both have DNS labels, and the option to assign a private DNS record is selected.
- **Launch Options**: The networking launch type. Available only for VMs. For more information, see Recommended Networking Launch Types on page 1025.

8. In the **Boot volume** section, configure the size and encryption options for the instance's boot volume:

- To specify a custom size for the boot volume, select the **Specify a custom boot volume size** check box. Then, enter a custom size from 50 GB (256 GB for Windows platform images) to 32 TB. The specified size must be larger than the selected image's default boot volume size. See Custom Boot VolumeSizes on page 690 for more information.
- For VM instances, you can optionally select the **Use in-transit encryption** check box. For **bare metal instances** that support in-transit encryption, it is enabled by default and is not configurable. See Block Volume Encryption on page 644 for more information about in-transit encryption. If you are using your own Vault service encryption key for the boot volume, then this key is also used for in-transit encryption. Otherwise, the Oracle-provided encryption key is used.
- Boot volumes are encrypted by default, but you can optionally use your own Vault service encryption key to encrypt the data in this volume. To use the Vault service for your encryption needs, select the **Encrypt this volume with a key that you manage** check box. Then, select the **Vault compartment** and **Vault** that contain the master encryption key you want to use. Also select the **Master encryption key compartment** and **Master encryption key**. For more information about encryption, see Overview of Vault on page 5006.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Block Volume service does not support encrypting volumes with keys encrypted using the Rivest-Shamir-Adleman (RSA) algorithm. When using your own keys, you must use keys encrypted using the</td>

</table>
Compute

Advanced Encryption Standard (AES) algorithm. This applies to block volumes and boot volumes.

- Block Volume performance capabilities lets you change the volume performance for boot volumes. When you create an instance, its boot volume is configured with the default volume performance set to Balanced. After you launch the instance, you can modify the performance setting. For steps to modify the performance setting, see Changing the Performance of a Volume on page 755. For more information, see Block Volume Performance on page 744.

9. (Optional) To configure advanced settings, click Show Advanced Options. The following options are available:

- On the Management tab, you can configure the following:
  - **Require an authorization header**: Select this check box to require that all requests to the instance metadata service (IMDS) use the version 2 endpoint and include an authorization header. Requests to IMDSv1 are denied. The image must support IMDSv2. For more information, see Getting Instance Metadata on page 1117.
  - **Initialization Script**: User data to be used by cloudbase-init to run custom scripts or provide custom cloudbase-init configuration. Browse to the file that you want to upload, or drag and drop the file into the box. The file or script does not need to be base64-encoded, because the Console performs this encoding when the information is submitted. For information about how to take advantage of user data, see the cloudbase-init documentation. The total maximum size for user data and other metadata that you provide is 32,000 bytes.

    **Caution:**
    
    Do not include anything in the script that could trigger a reboot, because this could impact the instance launch and cause it to fail. Any actions requiring a reboot should only be performed once the instance state is Running.

  - **Tagging**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

- On the Availability Configuration tab, you can configure the following:
  - In the Live migration section, select an option:
    - **Let Oracle Cloud Infrastructure choose the best migration option**: Select this option to let Oracle Cloud Infrastructure choose the best option to migrate the instance to a healthy physical VM host if an underlying infrastructure component needs to undergo maintenance.
    - **Opt-in**: Select this option to have the instance live migrated to a healthy physical VM host without any notification or disruption. If live migration isn't successful, reboot migration is used. Some shapes do not support live migration.
    - **Opt-out**: Select this option to have a notification sent for the maintenance event. The instance is live migrated if you do not proactively reboot the instance before the due date.

  - **Restore instance lifecycle state after infrastructure maintenance**: By default, if a VM instance is running when a maintenance event affects the underlying infrastructure, the instance is rebooted after it is recovered. Clear this check box if you want the instance to be recovered in the stopped state.

- On the Oracle Cloud Agent tab, choose which plugins you want to enable when the instance is launched. Plugins collect performance metrics, install OS updates, and perform other instance management tasks. For more information, see Managing Plugins with Oracle Cloud Agent on page 1089.

    **Important:**
    
    After you create the instance, you might need to perform additional configuration tasks before you can use each plugin.

10. Click Create.

To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated work request.
After the instance is provisioned, details about it appear in the instance list. To view more details, including IP addresses and the initial Windows password, click the instance name.

When the instance is fully provisioned and running, you can connect to it using Remote Desktop as described in Connecting to an Instance on page 1083.

You also can attach a volume to the instance, provided the volume is in the same availability domain. For background information about volumes, see Overview of Block Volume on page 640.

For steps to let additional users connect to the instance, see Adding Users on an Instance on page 1088.

**Monitoring Work Requests**

If the create instance operation fails, or if the instance state moves directly from provisioning to terminating, use work requests to determine where in the workflow the error occurred. Errors can occur because of problems with the configuration or problems with the user data. Synchronous errors occur during the initial call to the Compute API to create the instance. Work requests capture asynchronous validation failures. Asynchronous errors occur during the create instance workflow that occurs after the initial API call. A successful create instance API call that returns an HTTP 200 response might be followed by an asynchronous error during the subsequent create instance workflow.

The response to the REST API call contains the OCID of the work request in the opc-work-request-id header. You can monitor the status of the work request at any time by calling GetWorkRequest in the Work Requests API and passing in the work request ID found in the opc-work-request-id header. If an error occurs during the workflow, you can call ListWorkRequestErrors in the Work Requests API and pass in the work request ID to retrieve a list of errors.

For information about using work requests to troubleshoot errors, see Getting Started with Work Requests on page 300. For detailed information about asynchronous work requests, including how to filter the request response and a sample request and response, see Asynchronous Work Requests on page 5534.

**Managing Tags for an Instance**

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 239.

To manage tags for an instance

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click the Tags tab to view or edit the existing tags. Or click More Actions, and then click Add tags to add new ones.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to create instances:

- LaunchInstance
- GetInstanceDefaultCredentials

You can also launch instances from images that are published by Oracle partners in the Partner Image catalog. Use these APIs to work with the Partner Image catalog listings:

- AppCatalogListing
- AppCatalogListingResourceVersion
- AppCatalogListingResourceVersionAgreements
- AppCatalogListingResourceVersionSummary
- AppCatalogListingSummary
Burstable Instances

A burstable instance is a virtual machine (VM) instance that provides a baseline level of CPU performance with the ability to burst to a higher level to support occasional spikes in usage.

Burstable instances are designed for scenarios where an instance is typically idle, or has low CPU utilization with occasional spikes in usage. They're also ideal for scaled-down workloads that don't require a full core. For example:

- Microservices
- Development and test environments
- Continuous integration and continuous delivery (CI/CD) tools
- Monitoring systems
- Static websites

How Burstable Instances Work

Burstable instances are able to sustain workloads running at a fraction of CPUs most of the time, and can burst up to the full CPUs for a limited amount of time.

When you create a burstable instance, you specify the total OCPU count (or CPU cores) and the baseline CPU utilization. The baseline utilization is a fraction of each CPU core, either 12.5% or 50%. The baseline provides the minimum CPUs that can be used constantly.

When needed, the instance can use more than the baseline CPU, all the way up the total OCPUs that you provision. This usage above the baseline is called bursting, because it happens automatically and for short periods of time.

For an instance with 1 OCPU, a baseline of 12.5% means that 12.5% of the CPU core is available for baseline usage, with a maximum burst of 100% of 1 CPU core. For an instance with 64 OCPUs, the same 12.5% baseline means that 12.5% of 64 CPU cores are available for baseline usage, with a maximum burst of 100% of all 64 CPU cores.

The ability to burst depends on the instance's CPU usage pattern and the underlying server resource usage. If the instance's average CPU utilization over the past 24 hours is below the baseline, the system will allow it to burst above the baseline. The burst is limited to a short period of time to ensure that resources are managed fairly. Because burstable instances are oversubscribed compute resources, there is no guarantee that an instance will be able to burst exactly when needed.

After the burst is finished by the system, the instance is limited to the baseline CPU.

You can monitor CPU utilization using the CpuUtilization metric.

Supported Shapes

You can use the following shape to create burstable instances:

- VM.Standard.E3.Flex

OCPUs, Memory, and Network Bandwidth

Because burstable instances use flexible shapes, you can customize the number of OCPUs and the amount of memory that are allocated to a burstable instance.

- **OCPUs:** You can select from 1 to 64 OCPUs as the total OCPU count, the same range that the VM.Standard.E3.Flex flexible shape supports.

- **Memory:** The amount of memory is based on the total number of OCPUs. For each OCPU, you can select up to 64 GB of memory, the same ratio that the VM.Standard.E3.Flex shape supports. For example, if you create a 1-OCPU instance, you can allocate up to 64 GB of memory, regardless of which baseline OCPU you configure. The minimum amount of memory allowed is either 1 GB or a value matching the total OCPU count, whichever is greater. The maximum amount of memory allowed is 768 GB (note that this value is smaller than for regular instances). Memory does not burst.

- **Network bandwidth:** The maximum network bandwidth is defined in relation to the baseline OCPU. The maximum network bandwidth is 0.5 Gbps for each 12.5% baseline OCPU, with an overall maximum of 40 Gbps. For example, a 2-OCPU instance with a 12.5% baseline is allocated 1 Gbps. Network bandwidth does burst.
The flexibility of burstable instances means that you can create instances that are optimized for small or low-utilization applications. With the VM.Standard.E3.Flex shape, you can create a subcore or burstable instance as small as 12.5% or 50% of an OCPU (1 OCPU is equivalent to 2 hardware execution threads or vCPUs), with a minimum of 1 GB of memory, and have the ability to burst up to 1 OCPU for a limited amount of time. For larger workloads, you can create a burstable instance as large as 64 OCPUs with 12.5% baseline, with a maximum memory of 768 GB, and have the ability to burst up to 64 OCPUs for a limited amount of time.

**Burstable Instances Versus Regular Instances**

With both burstable instances and regular flexible instances, you can optimize the instance for your workload. However, burstable instances and regular instances have several differences.

<table>
<thead>
<tr>
<th>Burstable Instances</th>
<th>Regular Flexible Instances</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>What they're for</strong></td>
<td>Let you optimize your costs for workloads that require minimal resource utilization most of the time. The physical VM host is oversubscribed, so there is no guarantee that an instance will be able to burst.</td>
</tr>
<tr>
<td><strong>How they scale</strong></td>
<td>The instance dynamically scales the available OCPUs between a baseline and a maximum that you define.</td>
</tr>
<tr>
<td><strong>How fast they scale</strong></td>
<td>Rapidly scale up and scale down to handle temporary spikes in workload.</td>
</tr>
</tbody>
</table>

Compare burstable instances with regular instances: If you create a regular instance with 1 OCPU using the VM.Standard.E3.Flex shape, you are required to provision an entire core. If you create an instance using the Always Free VM.Standard.E2.1.Micro shape, the instance would be allocated less than a full OCPU, but it would not have a flexible amount of memory and would not be able to burst.

**Limitations and Considerations**

Be aware of the following information:

- Because the physical VM host is oversubscribed, there is no guarantee that an instance will be able to burst. For critical or production workloads that require full OCPU utilization, you should use a regular instance instead.
- Network bandwidth is oversubscribed, so there is no guarantee that the instance can use the maximum bandwidth.
- Memory does not burst.
- Custom images are supported if the baseline OCPU meets the minimum requirements for the image.
- Each burstable instance can have one ephemeral public IP address. If you need additional public IPs, assign reserved public IPs to the instance.
- You can attach four block volumes for each 12.5% baseline OCPU, up to the maximum limit.
- Burstable instances must use paravirtualized networking. If you create a regular instance using SR-IOV networking (the default for regular VM.Standard.E3.Flex instances), and want to change the instance to a burstable instance, you must also change the networking type to paravirtualized.
- Burstable instances are not supported on dedicated virtual machine hosts, capacity reservations, or preemptible capacity.
- Service limits and compartment quotas for a burstable instance count the baseline OCPUs that are configured for the instance, regardless of actual usage. Burstable instances and regular instances share the same service limits and compartment quotas based on the instance's shape.
Billing

Burstable instances cost less than regular instances with the same total OCPU count. Burstable instances are charged according to the baseline OCPU. The charge for a burstable instance is the same regardless of whether the actual CPU utilization is at the baseline, below the baseline, or bursts above the baseline. Contrast this with regular instances, which are charged for the total OCPU count, even if your usage is lower.

For example, if you create a VM.Standard.E3.Flex instance with 1 OCPU and a 12.5% baseline, you are charged for 12.5% of a Standard E3 OCPU each hour, regardless of whether your actual CPU utilization is below 12.5% of 1 OCPU or bursts to the full 1 OCPU.

Windows Server license costs are also charged according to the baseline OCPU.

Memory is charged based on the amount of memory configured for the instance, the same as regular instances.

For more information about billing, see the Oracle Compute Cloud Services section of Oracle PaaS and IaaS Universal Credits Service Descriptions.

Creating a Burstable Instance

When you create an instance, you specify whether the instance is a burstable instance. You can also edit an existing, regular instance to make it a burstable instance.

Using the Console:

1. Follow the steps to create an instance, until the Shape section.
2. Click Change Shape.
3. In the Shape series section, select AMD.
5. For Number of OCPUs, choose the maximum number of OCPUs for the instance to burst to.
6. Select the Burstable check box.
7. In the Burstable baseline per OCPU list, select the baseline CPU utilization for the instance. This value is the percentage of OCPUs that you want to use most of the time.

   For example, a 12.5% baseline means that the instance has up to 12.5% of the total OCPU count available for baseline usage (that is, normal usage when the instance isn't bursting). For an instance with 1 OCPU, a 12.5% baseline means that up to 1/8 of an OCPU is available for baseline usage.

8. For Amount of memory, choose the amount of memory that you want to allocate to this instance by dragging the slider. The maximum memory you can choose depends on the number of OCPUs and the baseline that you select. Memory does NOT burst.
9. Click Select Shape.
10. Finish creating your instance, and then click Create.

Using the API: Use the LaunchInstance operation, specifying the baseline OCPU in the baselineOcpuUtilization attribute.

Capacity Types

You can choose the type of host capacity to use when launching compute instances. On-demand capacity is the default, but you can use preemptible capacity, capacity reservations, or dedicated capacity instead.

- **On-demand capacity**: Pay for only the compute capacity that you use. With on-demand capacity, you pay for compute capacity by the second, and you pay only for the seconds that your instances are running. Capacity availability is not guaranteed when launching large workloads.

- **Preemptible capacity**: Preemptible capacity allows you to save money by using preemptible instances to run workloads that only need to run for brief periods or that can be interrupted when the capacity is reclaimed. Preemptible instances behave the same as regular compute instances, but the capacity is reclaimed when it's needed elsewhere, and the instances are terminated. For more information, see Preemptible Instances on page 1043.

- **Reserved capacity**: Reserve capacity for future usage, and ensure that capacity is available to create compute instances whenever you need them. The reserved capacity is used when you launch instances against the
reservation. When these instances are terminated, the capacity is returned to the reservation, and the unused capacity in the reservation increases. Unused reserved capacity is metered differently than used reserved capacity. For more information, see Capacity Reservations.

- **Dedicated capacity:** Run VM instances on dedicated servers that are a single tenant and not shared with other customers. This feature lets you meet compliance and regulatory requirements for isolation that prevent you from using shared infrastructure. You can also use this feature to meet node-based or host-based licensing requirements that require you to license an entire server. For more information, see Dedicated Virtual Machine Hosts on page 1051.

Service limits and compartment quotas apply to all types of host capacity. For reserved capacity, if your request for reserved capacity exceeds your service limits, request a service limit increase before you reserve the capacity. For more information, see Service Limits.

### Preemptible Instances

Preemptible instances behave the same as regular compute instances, but the capacity is reclaimed when it's needed elsewhere, and the instances are terminated. If your workloads are fault-tolerant and can withstand interruptions, then preemptible instances can reduce your costs. For example, you can use preemptible instances to optimize costs for workloads that can tolerate interruptions, such as tests that can be stopped and resumed later.

#### How Preemptible Instances Work

Preemptible instances are designed for short-term usage. The capacity is reclaimed when it's needed elsewhere. The capacity is not guaranteed for a minimum amount of time, so instances can be reclaimed at any time. The benefit is that preemptible capacity costs less than on-demand capacity. Therefore, for workloads that can be interrupted, preemptible capacity can lower your costs.

#### Using Preemptible Capacity

To use preemptible capacity, follow the standard process for creating an instance, and for Capacity type, select Preemptible capacity.

When preemptible capacity is reclaimed, the instance is terminated. Use the Events service to receive notifications when this event occurs.

#### Support and Limitations

Preemptible instances have the following limitations and restrictions:

- Preemptible instances can be terminated at any time. As a result, they are not suitable for long-running workloads.
- Preemptible capacity cannot be used with capacity reservations or with the dedicated virtual machine host feature.
- Preemptible capacity does not support bare metal instances, burstable instances, or instances that have a minimum billing time.
- When you edit an instance that uses preemptible capacity, only the name of the instance can be changed. You cannot change the shape of the instance after it is launched, and you cannot convert a preemptible instance to an on-demand instance.
- After you launch a preemptible instance, you cannot start, stop, or reboot the instance.
- Preemptible instances do not support sending diagnostic interrupts.
- You cannot use preemptible instances to create instance configurations, and preemptible instances cannot be used in instance pools.
- Preemptible instances don't support instance migration after infrastructure maintenance events. During maintenance events that impact the underlying infrastructure, the capacity is reclaimed, and the instance is terminated.
- The standard compute instance service limits and compartment quotas apply to preemptible instances. If your request for compute instances exceeds your service limits, request a service limit increase before you create the instance. For more information, see Service Limits.
Supported Shapes and Images

The following shapes support preemptible instances.

- VM.Standard.E3.Flex series (Standard – E3 series)
- VM.Standard2 series (Virtual Machine Standard – X7 series)

Billing and Cost Management

Preemptible capacity costs 50% less than on-demand capacity in all regions.

- To see the costs associated with your capacity usage, view cost and usage reports in the Console, or use the cost analysis feature.
- For more information about billing, see the Oracle Compute Cloud Services section of Oracle PaaS and IaaS Universal Credits Service Descriptions.
- For details about monitoring your costs, see To monitor costs on page 1045.

Tracking Instance Preemption Events

You can use the Events service to receive notifications when a preemptible instance is terminated. An instancepreemptionaction event is emitted thirty seconds before the instance termination begins. For details about instance preemption event types and an example event, see Instance Event Types on page 2436.

For background information about creating automation to track events and steps to create event notifications, see Getting Started with Events on page 2384.

To create an event notification for when a preemptible instance is terminated, when you create the event rule, do the following:

1. For Condition, select Event Type.
2. For Service Name, select Compute.
3. For Event Type, select Instance - Preemption Action.

You can also use the Events service to invoke a function when a preemptible instance is terminated.

Required IAM Policy

The policies that enable users to create instances also allow them to create preemptible instances. For details, see Required IAM Policy on page 1024 in Creating an Instance on page 1023.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

Using the Console

Use the Console to manage preemptible instances.

To create a preemptible instance

1. Perform the initial steps to create an instance.
2. In the Placement section, click Show advanced options.
3. For Capacity type, select Preemptible capacity.
4. Choose whether to permanently delete the attached boot volume when the capacity is reclaimed.
5. Finish creating your instance, and then click Create.

To edit preemptible instances

When you edit an instance that uses preemptible capacity, only the name of the instance can be changed. You cannot change the shape of the instance after it is launched, and you cannot convert a preemptible instance to an on-demand instance.
1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click Edit.
4. Enter a new name. Avoid entering confidential information.
5. Click Save Changes.

To stop preemptible instances

Preemptible instances cannot be started, stopped, or rebooted.

To terminate preemptible instances

See Terminating an Instance.

To monitor costs

In the Console, you can access cost and usage reports to see the breakdown of costs for your preemptible instances, and you can use the cost analysis feature to track and optimize your spending.

- To view cost and usage reports: Open the navigation menu and click Governance & Administration. Under Cost Management, click Cost and Usage Reports. For more information, see Accessing Cost and Usage Reports on page 325.
- To view cost analysis: Open the navigation menu and click Governance & Administration. Under Cost Management, click Cost Analysis. For details instructions explaining how to work with the cost analysis tool, see Cost Analysis Overview on page 327.

In the cost and usage report, for preemptible instances, the description column includes the word Preemptible. The report shows the bill rate per hour for each resource. If the capacity is reclaimed in less than a minute, you are not charged for that time.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage preemptible instances:

- ListInstances
- LaunchInstance
- GetInstance
- UpdateInstance
- TerminateInstance
- GetInstanceDefaultCredentials

Capacity Reservations

Capacity reservations enable you to reserve instances in advance so that the capacity is available for your workloads when you need it. Capacity reservations provide the following benefits:

- Assurance that you have the capacity necessary to manage your workload. Reserved capacity is available for your tenancy to consume at any time.
- No size or time commitments. Create a reservation with as little or as much capacity as you need, and delete the reservation at any time to stop paying for it.

Capacity reservations are helpful in the following scenarios:

- **Disaster recovery**: Ensure that capacity is available when you need to failover to your secondary location.
- **Unplanned growth**: Reserve capacity as a buffer for unexpected workload spikes.
- **Planned migrations and new launches**: When you have large capacity requirements for migrations or new project launches, capacity reservations ensure that you'll have the capacity that you need.
- **Committed capacity for long-running projects**: When maintenance or seasonal adjustments cause your usage to vary, capacity reservations provide the needed capacity.
How Reserved Capacity Works

Capacity reservations allow you to reserve compute capacity in advance and use this capacity when you launch instances against the reservation. There is no minimum time or size commitment. You can create, modify, and terminate your capacity reservation at any time. When instances that use the reserved capacity are terminated, the capacity is returned to the reservation, and the unused capacity in the reservation increases. Unused reserved capacity is metered differently than used reserved capacity. For more information, see the Oracle Compute Cloud Services section of Oracle PaaS and IaaS Universal Credits Service Descriptions.

Using Reservations

When you create your capacity reservation, you specify the availability domain in the tenancy where you want to reserve capacity. You can then add a capacity configuration, which defines the amount of space that you want to reserve and the shape to use when launching instances against that capacity configuration. Optionally, you can specify the fault domain to reserve capacity in. Each capacity reservation can have multiple capacity configurations.

To use reserved capacity, specify the reservation ID when launching an instance. The instance being launched must have the same availability domain, instance shape, and fault domain as one of the capacity configurations in the reservation. As an advanced option, you can create default reservations, which allow you to configure your capacity reservation once for the availability domain within the root tenancy and use this reservation every time you launch an instance in that availability domain and tenancy. When instances that use reserved capacity are terminated, the capacity is returned to the reservation. When instances that use reserved capacity are stopped, the capacity is held by that instance for use when that instance is restarted.

Use instance pools to launch multiple instances that use reserved capacity at the same time. In the API, specify the capacity reservation ID in the instance configuration for the instance pool. In the Console, the reservation is automatically applied to the instance pool based on the instance configuration. As long as sufficient capacity is available, the instance pool launches instances using capacity from the associated reservation. You can also use the instance pool to simultaneously stop, start, or terminate multiple instances that use capacity from the associated reservation.

Support and Limitations

Capacity reservations have the following limitations and restrictions:

- When you create your capacity reservation, you specify the availability domain in the tenancy where you want to reserve capacity. Reservations are specific to that availability domain and tenancy. They cannot be shared between availability domains and tenancies, and they do not span entire regions and realms.
- Capacity reservations cannot be moved from one availability domain to another, nor can they be moved from one tenancy to another.
- Capacity reservations are not available with Free Tier accounts.
- Capacity reservations cannot be used with the dedicated virtual machine host feature.
- Capacity reservations do not support burstable instances.
- Capacity is allocated when the reservation is created. If there isn't enough capacity to complete the request, the reservation is not made, and an error occurs.
- Capacity reservations cannot have more than 30 capacity configurations. See Creating more than 30 capacity configurations results in an internal error.
- After you create a capacity configuration for a flexible shape, you cannot change the number of OCPUs or amount of memory assigned to the instances in that configuration. To include instances with a different number of OCPUs or amount of memory, create new capacity configurations in the reservation.
- In order to move an instance that uses on-demand capacity into a capacity reservation, the reservation must contain a capacity configuration for that shape, and the capacity configuration must contain enough unused capacity to accommodate the instance. If the capacity configuration doesn't have sufficient capacity for the instance, add capacity before moving the instance into the reservation.
- Service limits and compartment quotas apply to reserved capacity. If your request for reserved capacity exceeds your service limits, request a service limit increase before you reserve the capacity. When viewing limits, quotas, and usage in the Console, Reservable Cores and Reservable Memory indicate the service limit. Reserved Cores
and **Reserved Memory** indicate current usage. For more information, see Service Limits. Capacity reservations have two known issues with service limits: **No service category for capacity reservations when requesting service limit increases** and **Capacity reservation service limits inaccurate**.

### Billing and Cost Management

When you create a reservation, you are immediately charged for the reserved resources. When you no longer need a reservation, delete the reservation to stop incurring charges. Because reservations consume resources, reserved capacity incurs charges even when the capacity is unused. Unused reserved capacity is metered differently than used reserved capacity.

- To see the costs associated with your capacity reservation, view cost and usage reports in the Console.
- For more information about billing, see the Oracle Compute Cloud Services section of Oracle PaaS and IaaS Universal Credits Service Descriptions.
- For details about monitoring your costs, see To monitor costs on page 1050.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** to work in.

For administrators: The following examples shows typical policies that gives access to capacity reservations. Create the policy in the tenancy so that the access is easily granted to all compartments by way of policy inheritance. To reduce the scope of access to just the autoscaling configurations in a particular compartment, specify that compartment instead of the tenancy.

**Type of access**: Ability to launch an instance in a reservation.

```plaintext
Allow group <group_name> to use compute-capacity-reservations in tenancy
```

**Type of access**: Ability to manage capacity reservations.

```plaintext
Allow group <group_name> manage compute-capacity-reservations in tenancy
```

### Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

### Advanced Options

In addition to the standard capacity reservation features, advanced configuration options are available, such as default capacity reservations.

**Default Capacity Reservations**

With default reservations, you can configure your capacity reservation once and use this reservation every time you launch an instance in the availability domain and tenancy associated with the default reservation. To create a default reservation, when you create the capacity reservation, select the option to use this reservation as the default reservation. After you create the default reservation, all instances launched in that availability domain and tenancy use capacity from this reservation if possible.

Sometimes the instance cannot be launched using capacity from the default reservation. For example, the reservation might not have sufficient capacity, or the user might not have permission to use the reservation. In those situations, the instance is launched using **on-demand capacity**.

### Requirements

To use default reservations:
• The default capacity reservation must be in the root compartment.
• You can only have one default reservation in each availability domain.
• You must grant users who launch instances permission to use this reservation. For more information, see Required IAM Policy on page 1047.

Using the Console
Use the Console to manage capacity reservations and capacity configurations. Capacity reservations can have multiple capacity configurations within them.

Managing Capacity Reservations
In the Console, you can create and edit capacity reservations, launch and stop instances in a capacity reservation, and move instances in and out of capacity reservations.

To create a capacity reservation

For large capacity reservations, contact support. For smaller capacity reservations, follow these steps.

1. Open the navigation menu and click Compute. Under Compute, click Capacity Reservations.
2. Click Create Capacity Reservation.
3. In the Add Basic Details step, make the following selections, and then click Next.
   • For Name, enter a name for the capacity reservation.
   • For Create in Compartment, select the compartment for the reservation and all instances created with this reservation.
   • For Availability Domain, select the availability domain for the reservation and all instances created with this reservation.
   • To make this the default reservation, select Make this capacity reservation the default for this availability domain. If selected, when an instance is launched in this availability domain, it counts against this reservation, regardless of which compartment the instance is in. If a different capacity reservation is already set as the default in this availability domain, this capacity reservation replaces it as the default.
4. In the Add Capacity Configurations step, create one or more capacity configurations. In the Capacity Configuration dialog, make the following selections, and then click Next.
   • For Fault Domain, enter a fault domain. Alternately, you can select First available instead of a specific fault domain.
   • For Shape, select the shape to use for instances launched against this capacity configuration. If you select a flexible shape, enter values for Cores and Memory (in GB).
   • For Count, enter the total number of instances that can be launched with this capacity configuration.
   • Optionally, click + Another Shape, and repeat this step. To remove a row, click the Remove (x) button.
5. Review the capacity reservation and capacity configuration information, and then click Create.

To edit a capacity reservation

You can change the name of the capacity reservation, and you can decide whether the reservation should be the default reservation.

1. Open the navigation menu and click Compute. Under Compute, click Capacity Reservations.
2. In the list of capacity reservations, click the capacity reservation that you want to edit. The Capacity Reservation Details page opens.
3. On the Capacity Reservation Details page, click Edit. The Edit Capacity Reservation dialog opens.
4. In the Edit Capacity Reservation dialog, change either of the following fields, and then click Save Changes.
   • Name: Enter a new name value.
   • Select or clear Make this reservation the default for this availability domain.

To delete a capacity reservation

1. Open the navigation menu and click Compute. Under Compute, click Capacity Reservations.
2. In the list of capacity reservations, click the capacity reservation that you want to delete. The **Capacity Reservation Details** page opens.

3. On the **Capacity Reservation Details** page, click **Delete**. A confirmation dialog opens.

4. In the **Delete Reservation** dialog, click **Delete Reservation**.

To launch instances in a capacity reservation

1. Follow the steps for creating a Linux instance or for creating a Windows instance.

2. In the **Placement** section, click **Show Advanced Options**.

3. For **Capacity type**, select **Capacity Reservation**.

4. For **Capacity reservation in <compartment name>**, select the desired capacity reservation from the drop-down menu.

5. When you finish configuring the instance, click **Create**.

To stop instances in a capacity reservation

See **Stopping and Starting an Instance**.

To move instances into a capacity reservation

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.

2. Click the instance that you're interested in.

3. Click **Edit**.

4. In the **Edit Instance** pane, click **Show Advanced Options**.

5. In the **Placement** tab, select **Apply a capacity reservation**.

6. For **Capacity reservation in <compartment name>**, select the desired capacity reservation from the drop-down menu.

7. Click **Save Changes**.

To move instances out of a capacity reservation

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.

2. Click the instance that you're interested in.

3. Click **Edit**.

4. In the **Edit Instance** pane, click **Show Advanced Options**.

5. In the **Placement** tab, clear **Apply a capacity reservation**, and then click **Save Changes**.

*Managing Capacity Configurations*

You can add and edit capacity configurations in the Console. Each capacity configuration must be unique within the reservation. Multiple configurations with the same fault domain and instance shape are not allowed.

To add a capacity configuration

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Capacity Reservations**.

2. In the list of capacity reservations, click the capacity reservation that you want to add a capacity configuration to. The **Capacity Reservation Details** page opens.

3. Under **Capacity Configurations**, click **Add Capacity Configuration**.

4. In the **Add Configuration** pane, make the following selections, and then click **Add Configuration**.

   - For **Fault Domain**, enter a fault domain. Alternately, you can select **First available** instead of a specific fault domain.
   - For **Shape**, select the shape to use for instances launched against this capacity configuration. If you select a flexible shape, enter values for **Cores** and **Memory (in GB)**.
   - For **Count**, enter the number of instances that can be launched with this capacity configuration.
   - Optionally, click **+ Another Shape**, and repeat this step. To remove a row, click the **Remove (x)** button.

To edit a capacity configuration

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Capacity Reservations**.
2. In the list of capacity reservations, click the capacity reservation that you want to edit. The Capacity Reservation Details page opens.

3. Under Capacity Configurations, click the Actions icon ( MODIFY ) associated with the configuration that you want to edit, and then click Edit.

4. In the Edit Configuration pane, for Count, enter a new value. The count value cannot be less than the number of instances currently launched in this configuration.

**Note:**
The fault domain and shape of capacity configurations cannot be changed. To reserve capacity for different fault domains or shapes, add a new capacity configuration.

5. Click Save Changes.

To delete a capacity configuration and release capacity

1. Open the navigation menu and click Compute. Under Compute, click Capacity Reservations.

2. In the list of capacity reservations, click the capacity reservation that you want to release all capacity from. The Capacity Reservation Details page opens.

3. Under Capacity Configurations, click the Actions icon ( MODIFY ) associated with the configuration that you want to edit, and then click Delete Configuration.

4. In the Delete Configuration and Release Capacity dialog, click Delete Configuration. This change deletes the capacity configuration and releases the associated capacity from the reservation.

Monitoring Capacity Reservations

Monitor capacity usage and see the costs associated with your capacity reservation.

To view capacity usage

1. Open the navigation menu and click Compute. Under Compute, click Capacity Reservations.

2. In the list of capacity reservations, click the capacity reservation that you're interested in. The Capacity Reservation Details page opens.

3. Under Capacity Configurations, you can see the total reserved capacity and the total used capacity for each configuration.

To monitor costs

In the Console, you can access cost and usage reports to see the breakdown of costs for your capacity reservation, and you can use the cost analysis feature to track and optimize your spending.

- To view cost and usage reports: Open the navigation menu and click Governance & Administration. Under Cost Management, click Cost and Usage Reports. For more information, see Accessing Cost and Usage Reports on page 325.

- To view cost analysis: Open the navigation menu and click Governance & Administration. Under Cost Management, click Cost Analysis. For details instructions explaining how to work with the cost analysis tool, see Cost Analysis Overview on page 327.

In the cost and usage report, for capacity reservations, the product/Description column includes the words Capacity Reservation. If no capacity remains in the reservation because instances have been launched against all of the reserved capacity, the cost for the capacity reservation is zero. Launched instances are billed at the standard rate for the given shape.

The report shows the bill rate per hour for each resource. Resources are aggregated by the number of cores.

- Unused reserved capacity is billed at 85%. Instances launched against a capacity reservation are billed at 100%.
- If you launch an instance against a capacity reservation thirty minutes into the hour, you're billed at the reserved capacity rate for the first half of the hour and at the standard rate for the second half of the hour. These rates appear as separate line items.
• When an instance is launched from reserved capacity at the beginning of an hour for the whole hour, the launched instance is billed at the standard rate for the full hour.

For example, you have a capacity reservation with capacity for a single instance that uses one core. Fifteen minutes into the hour, you launch an instance against that reservation. The cost and usage report has two lines for this reservation:

• The first line shows reserved capacity billed at 85% for 15 minutes. The number in the usage/billedQuantity column is calculated by multiplying 85% by ¼ of an hour and the number of cores.
• The second line shows a standard instance billed at 100% for 45 minutes. The number in the usage/billedQuantity column is calculated by multiplying 100% by ¾ of an hour and the number of cores.

In the cost analysis report, the bar chart shows costs associated with capacity reservations. The legend indicates which bars represent capacity reservations. If no capacity remains in the reservation because instances have been launched against all of the reserved capacity, the cost for the capacity reservation is zero. Launched instances are billed at the standard rate for the given shape and are grouped with standard instances in the chart.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use these API operations to manage capacity reservations:

• ListComputeCapacityReservations
• ListComputeCapacityReservationInstances
• ListComputeCapacityReservationInstanceShapes
• CreateComputeCapacityReservation
• GetComputeCapacityReservation
• UpdateComputeCapacityReservation
• ChangeComputeCapacityReservationCompartment
• DeleteComputeCapacityReservation

Known Issues

• Creating more than 30 capacity configurations results in an internal error
• No service category for capacity reservations when requesting service limit increases
• Capacity reservation service limits inaccurate

Dedicated Virtual Machine Hosts

The Oracle Cloud Infrastructure Compute service's dedicated virtual machine host feature gives you the ability to run compute virtual machine (VM) instances on dedicated servers that are a single tenant and not shared with other customers. This feature lets you meet compliance and regulatory requirements for isolation that prevent you from using shared infrastructure. You can also use this feature to meet node-based or host-based licensing requirements that require you to license an entire server.

Support and Limitations

Shapes and capacity: When you create a dedicated virtual machine host, you select a shape for the host. The shape determines how much capacity is available and what types of instances can be launched on the host. For information about the dedicated virtual machine host shapes, see Dedicated Virtual Machine Host Shapes on page 982. Note that there is a difference between the number listed for billed OCPUs compared to available OCPUs. This is because some OCPUs are reserved for virtual machine management.

When you launch an instance on a dedicated virtual machine host, you can choose any of the VM shapes that are supported for that host. For details about these shapes, see VM Shapes on page 978.

You can mix VM instances with different supported shapes on the same dedicated virtual machine host. The size of each instance might impact the maximum number of instances that you can place on the dedicated virtual machine host. For more information, see Optimizing Capacity on a Dedicated Virtual Machine Host on page 1054.
**Billing:** You are billed for the dedicated virtual machine host as soon as you create it, but you are not billed for any of the individual VM instances you place on it. You will still be billed for image licensing costs if they apply to the image you are using for the VM instances.

**Supported features:** Most of the Compute features for VM instances are supported for instances running on dedicated virtual machine hosts. However, the following features are not supported:

- Autoscaling
- Capacity reservations
- Instance configurations
- Instance pools
- Burstable instances
- Reboot migration. You can use manual migration instead

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The simplest policy to enable users to work with dedicated virtual machine hosts is listed in Let users manage Compute dedicated virtual machine hosts on page 2810. It gives the specified group access to launch instances on dedicated virtual machine hosts and manage dedicated virtual machine hosts.

See Let users launch Compute instances on dedicated virtual machine hosts on page 2810 for an example of a policy that allows users to launch instances on dedicated virtual machine hosts without giving them full administrator access to dedicated virtual machine hosts.

**Managing Dedicated Virtual Machine Hosts**

**Creating Dedicated Virtual Machine Hosts**

You must create a dedicated virtual machine host before you can place any instances on it.

When creating a dedicated virtual machine host, you select an availability domain and fault domain to launch it in. All the VM instances that you place on the host will subsequently be created in this availability domain and fault domain.

You also select a compartment when you create the dedicated virtual machine host, but you can move the host to a new compartment later without impacting any of the instances placed on it. You can also create the instances in a different compartment than the dedicated virtual machine host, or move them to different compartments after they have been launched.

**Using the Console**

1. Open the navigation menu and click Compute. Under Compute, click Dedicated Virtual Machine Hosts.
2. Click Create Dedicated Virtual Machine Host.
3. Select the compartment to create the dedicated virtual machine host in.
4. Enter a name for the dedicated virtual machine host. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
5. Select the Availability domain for the dedicated virtual machine host.
6. In the Dedicated host shape section, select the shape to use for the dedicated virtual machine host. To see which VM shapes you can use to create instances on the host, click the down arrow in the row for a host shape.
7. (Optional) If you want to configure the fault domain or add tags, click Show Advanced Options. Then enter the following information:
   - **Fault domain:** The fault domain for the dedicated virtual machine host.
   - **Tags:** Optionally, you can add tags. If you have permissions to create a resource, you also have permissions to add free-form tags to that resource. To add a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether you should add tags, skip this option (you can add tags later) or ask your administrator.
8. Click Create.

**Using the CLI**

Open a command prompt and run:

```
oci compute dedicated-vm-host create --dedicated-vm-host-shape <shape_name> --wait-for-state ACTIVE --display-name <display_name> --availability-domain <availability_domain> --compartment-id <compartment_OCID>
```

<shape_name> is the shape for the dedicated virtual machine host.

It can take up to 15 minutes for the dedicated virtual machine host to be fully created. It must be in the ACTIVE state before you can launch an instance on it.

To query the current state of a dedicated virtual machine host using the CLI, run the following command:

```
oci compute dedicated-vm-host get --dedicated-vm-host-id <dedicatedVMhost_OCID>
```

**Using the API**

Use the CreateDedicatedVmHost operation.

**Deleting Dedicated Virtual Machine Hosts**

You can delete a dedicated virtual machine host after you terminate (delete) the instances that are placed on it.

**How do I see which instances are placed on a dedicated virtual machine host?**

In the Console: Go to the Details page for the dedicated virtual machine host. Then, under Resources, click Hosted Instances. Perform this step for each compartment in your tenancy that has instances running on the dedicated virtual machine host. To change the compartment for the Hosted Instances list, select a different compartment from the Table Scope list.

Using the CLI: To list the instances running on a dedicated virtual machine host, run the following command:

```
oci compute dedicated-vm-host list --compartment-id <compartment_OCID> --dedicated-vm-host-id <dedicatedVMhost_OCID>
```

Run this command for every compartment in your tenancy that has instances running on the dedicated virtual machine host that you want to delete.

Using the API: Use the ListDedicatedVmHostInstances operation.

**Using the Console**

1. Open the navigation menu and click Compute. Under Compute, click Dedicated Virtual Machine Hosts.
2. Click the dedicated virtual machine host that you want to delete.
3. Click Delete, and then confirm when prompted.

**Using the CLI**

Open a command prompt and run:

```
oci compute dedicated-vm-host delete --dedicated-vm-host-id <dedicated_VM_host_OCID>
```

**Using the API**

Use the DeleteDedicatedVmHost operation.
Instances on Dedicated Virtual Machine Hosts

Placing Instances on a Dedicated Virtual Machine Host

You place an instance on a dedicated virtual machine host at the time that you create the instance. The dedicated virtual machine host must have sufficient capacity for the shape of instance that you want to create.

How do I know if a dedicated virtual machine host has capacity for an instance?

In the Console, when you create an instance, you can only select from the dedicated virtual machine hosts that have sufficient capacity for the shape that you specify.

You can use the API, CLI, or SDKs to determine which dedicated virtual machine hosts have capacity for a particular shape. Use the ListDedicatedVmHosts API operation, passing the name of the shape that you want to use when launching the instance. For flexible shapes, you can also include the minimum number of OCPUs and amount of memory you want to provision.

The following example demonstrates how to use the CLI to return all the dedicated virtual machine hosts with sufficient capacity for you to place an instance launched using the VM.Standard2.16 shape:

```bash
oci compute dedicated-vm-host list --compartment-id <compartment_OCID> --instance-shape-name VM.Standard2.16
```

For more information, see Optimizing Capacity on a Dedicated Virtual Machine Host on page 1054.

Using the Console

1. Follow the steps to create an instance, until the Placement section.
2. In the Placement section, click Show advanced options.
3. For Capacity type, select Dedicated host.
4. Select the dedicated virtual machine host that you want to place the instance on.
5. Finish configuring the instance, and then click Create.

Using the API

Use the LaunchInstance operation to create the instance, passing the OCID of the dedicated virtual machine host in the dedicatedVmHostId parameter.

Auditing your Dedicated Virtual Machine Host

To fully meet requirements for some compliance scenarios, you might be required to validate that your instances are running on a dedicated virtual machine host and not using shared infrastructure. The Oracle Cloud Infrastructure Audit service provides you with the functionality to do this. Use the steps described in Viewing Audit Log Events on page 604 to access the log events for the dedicated virtual machine host.

The steps described in the To search log events section walk you through how to retrieve the log events with the data you need to verify that your instances are running on a dedicated virtual machine host. For this procedure:

- Ensure that you select the dedicated virtual machine host's compartment and not the compartment for the instances that are hosted on it.
- Use the dedicated virtual machine host's OCID as the search keyword.

After you have retrieved the log events for the dedicated virtual machine host, view the log event lower-level details, and check the contents of the responsePayload property. This property should contain the OCIDs for the instances that are running on the dedicated virtual machine host.

Optimizing Capacity on a Dedicated Virtual Machine Host

When designing your cloud footprint, we recommend that you plan to always launch the largest instance first. Here's why:

When you place instances on a dedicated virtual machine host, Oracle Cloud Infrastructure launches the instances in a manner to optimize performance. For example, a dedicated virtual machine host created based on the
**Compute**

DVH.Standard2.52 shape has two sockets with 24 cores configured per socket. Instances are placed so that each instance will only use resources that are local to a single physical socket. In scenarios where you are creating and terminating instances with a mix of shapes, this can result in an inefficient distribution of resources, meaning that not all OCPUs on a dedicated virtual machine host are available to be used. It might appear that a dedicated virtual machine host has enough OCPUs to launch an additional instance, but the new instance will fail to launch because of the distribution of existing instances.

Continuing this example, say that you want to launch instances using a shape with 16 OCPUs. On a DVH.Standard2.52 dedicated virtual machine host, you can only launch a maximum of two instances with 16 OCPUs. You cannot launch a third instance with 16 OCPUs, even though the dedicated virtual machine host has 16 remaining OCPUs. You can, however, launch additional instances using shapes with a smaller number of OCPUs.

What this means is, when you're placing an instance on a dedicated virtual machine host, you can only create the instance if the host has sufficient capacity based on the shape of the instance. In the Console, you can only choose from the hosts with sufficient capacity. Similarly, when you place an instance on a dedicated virtual machine host using the API, CLI, or SDKs, the operation will succeed only if the dedicated virtual machine host has sufficient capacity.

If you have a dedicated virtual machine host that doesn't have enough capacity to launch instances, you can do any of the following things:

- Terminate instances you no longer need on the dedicated virtual machine host to make capacity available.
- Choose a different, smaller shape for the instance you are trying to place on the dedicated virtual machine host.
- Create a new dedicated virtual machine host to place the instance on.

**Managing Compute Instances with Instance Pools**

You can simplify the management of your Compute instances using resources such as instance configurations and instance pools.

An instance configuration is a template that defines the settings to use when creating Compute instances.

An instance pool is a set of instances that is managed as a group.

**Instance Configurations**

An instance configuration defines the settings to use when creating Compute instances, including details such as the base image, shape, and metadata. You can also specify the associated resources for the instance, such as block volume attachments and network configuration, and you can associate the instance with a capacity reservation.

For steps to create an instance configuration, see Creating an Instance Configuration on page 1056.

To modify an existing instance configuration, create a new instance configuration with the desired settings.

For steps to delete an instance configuration, see Deleting an Instance Configuration on page 1068.

**Instance Pools**

Instance pools let you create and manage multiple Compute instances within the same region as a group. They also enable integration with other services, such as the Load Balancing service and IAM service.

You create an instance pool using an existing instance configuration. For steps, see Creating an Instance Pool on page 1058.

After you have created an instance pool, you can update the size of the pool, add and remove existing instances from the pool, and attach or detach load balancers. You can also update the instance pool to use a different instance configuration, or to place instances in a different availability domain, fault domain, or subnet. For more information, see Updating an Instance Pool on page 1060.

You can automatically adjust the number of instances in an instance pool based on performance metrics or a schedule. You can also stop and start instances in an instance pool based on a schedule. To do this, you enable autoscaling for the instance pool. For background information and steps, see Autoscaling on page 1070.
A cluster network is a special kind of instance pool that is designed for massive, high-performance computing jobs. For more information, see Managing Cluster Networks on page 1079.

For steps to delete an instance pool, see Deleting an Instance Pool on page 1069.

Caution: When you delete an instance pool, all of its resources are permanently deleted, including associated instances, attached boot volumes, and block volumes.

Instance Pool Lifecycle States

The following list describes the different lifecycle states for instance pools.

- **Provisioning**: When you create an instance pool, this is the first state the instance pool is in. Instances for the instance pool are being configured based on the specified instance configuration.
- **Starting**: The instances are being launched. At this point, the only action you can take is to terminate the instance pool.
- **Running**: The instances are created and running.
- **Stopping**: The instances are in the process of being shut down.
- **Stopped**: The instances are shut down.
- **Scaling**: After an instance pool has been created, if you update the instance pool size, it will go into this state while creating instances (for increases in pool size) or terminating instances (for decreases in pool size). At this point, the only action you can take is to terminate the instance pool.
- **Terminating**: The instances and associated resources are being terminated.
- **Terminated**: The instance pool, all its instances and associated resources are terminated.

When working with instance configurations and instance pools, keep the following things in mind:

- You can't delete an instance configuration if it is associated with at least one instance pool.
- You can use the same instance configuration for multiple instance pools. However, an instance pool can have only one instance configuration associated with it.
- If the instance pool has been in the scaling or provisioning state for an extended period of time, it might be because the number of instances that were requested has exceeded your tenancy’s service limits for that availability domain. For information about how to check your service limits, and steps to request a service limit increase, see Service Limits on page 243. If this occurs, you need to terminate the instance pool and re-create it.
- If you modify the instance configuration for an instance pool, existing instances that are part of that pool will not change. Any new instances that are created after you modify the instance configuration will use the new instance configuration. New instances will not be created unless you increase the size of the instance pool or terminate existing instances.
- If you decrease the size of an instance pool, the oldest instances are terminated first.

Creating an Instance Configuration

Instance configurations let you define the settings to use when creating compute instances.

Use an instance configuration when you want to create one or more instances in an instance pool. You can also use an instance configuration to launch individual instances that are not part of a pool using the SDKs, command line interface (CLI), or API.

To create an instance configuration in the Console, use an existing compute instance as a template. If you want to create an instance configuration by specifying a list of configuration settings, use the SDKs, CLI, or API.

Limitations and Considerations

When you create an instance configuration using an existing instance as a template, be aware of the following information:
• The instance configuration does not include any information from the instance's boot volume, such as installed applications, binaries, and files on the instance. To create an instance configuration that includes the custom setup from an instance, you must first create a custom image from the instance and then use the custom image to create a new instance. Finally, create the instance configuration based on the instance that you created from the custom image.

• The instance configuration does not include the contents of any block volumes that are attached to the instance. To include block volume contents with an instance configuration, first create a backup of the attached block volumes. Then, use the SDKs, CLI, or API to create the instance configuration, specifying the block volume backups in the list of configuration settings.

• Any instances created from the instance configuration are placed in the same compartment as the instance that was used as the basis for the instance configuration, regardless of the compartment of the instance configuration. For example, an instance in compartment A is used to create an instance configuration. You place the instance configuration in compartment B. Any instances created using that instance configuration will be located in compartment A.

• If the instance configuration is associated with a capacity reservation, that reservation is automatically applied to any instances or instance pools created using that instance configuration. As long as sufficient capacity is available, when the instances launch, they use capacity from the associated reservation.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks on page 2808.

**Tagging Resources**

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 239.

**To manage tags for an instance configuration**

1. Open the navigation menu and click Compute. Under Compute, click Instance Configurations.
2. Click the instance configuration that you're interested in.
3. Click the Tags tab to view or edit the existing tags. Or click Add tags to add new ones.

For more information, see Resource Tags on page 239.

**Using the Console**

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance whose image you want to use as a template to create the instance configuration.
3. Click More Actions, and then click Create Instance Configuration.
4. Select the compartment you want to create the instance configuration in.
5. Specify a name for the instance configuration. It doesn’t have to be unique, and it cannot be changed later in the Console (but you can change it with the API). Avoid entering confidential information.
6. Show Tagging Options: Optionally, you can add tags. If you have permissions to create a resource, you also have permissions to add free-form tags to that resource. To add a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether you should add tags, skip this option (you can add tags later) or ask your administrator.
7. Click Create Instance Configuration.
Using the CLI

To create an instance configuration using the CLI, open a command prompt and run the `instance-configuration create` command:

```bash
oci compute-management instance-configuration create --compartment-id <COMPARTMENT_OCID> --instance-details <file://path/to/file.json>
```

`<file://path/to/file.json>` is the path to a JSON file that defines the instance details. For information about how to generate an example of the JSON file, see Advanced JSON Options on page 5340.

For information about using the CLI, see Command Line Interface (CLI) on page 5316.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the `CreateInstanceConfiguration` operation to create an instance configuration.

Creating an Instance Pool

Use instance pools to create and manage multiple compute instances within the same region as a group.

When you create an instance pool, you use an instance configuration as the template to create new instances in the pool. You can also attach existing instances to a pool by updating the pool.

Optionally, you can associate one or more load balancers with an instance pool. If you do this, when you add an instance to the instance pool, the instance is automatically added to the load balancer's backend set. After the instance reaches a healthy state (the instance is listening on the configured port number), incoming traffic is automatically routed to the new instance.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks on page 2808.

Tagging Resources

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see Resource Tags on page 239.

Distributing Instances Across Fault Domains for High Availability

By default, the instances in a pool are distributed across all fault domains in a best-effort manner based on capacity. If capacity isn't available in one fault domain, the instances are placed in other fault domains to allow the instance pool to launch successfully.

In a high availability scenario, you can require that the instances in a pool are evenly distributed across each of the fault domains that you specify. When sufficient capacity isn't available in one of the fault domains, the instance pool will not launch or scale successfully, and a work request for the instance pool will return an "out of capacity" error. To fix the capacity error, either wait for capacity to become available, or update the placement configuration (the availability domain and fault domain) for the instance pool.

Prerequisites

Before you can create an instance pool, you need:

- An instance configuration. An instance configuration is a template that defines the settings to use when creating instances. When you create the instance pool, monitoring will be enabled by default on instances that support
Compute monitoring, regardless of the settings in the instance configuration. For more information, see Creating an Instance Configuration on page 1056.

**Note:**
You cannot create an instance pool from an instance configuration where the image source is a boot volume.

- If you want to associate the instance pool with a load balancer, you need a load balancer and backend set. For steps to create a load balancer, see Load Balancer Management on page 3206.

**Using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instance Pools**.
2. Click **Create Instance Pool**.
3. On the **Add Basic Details** page, do the following:
   a. Enter a name for the instance pool. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
   b. Select the compartment to create the instance pool in.
   c. Select the **Instance configuration** that you want to use.
   d. Specify the targeted **Number of instances** for the instance pool.
   e. **Show Tagging Options:** Optionally, you can add tags. If you have permissions to create a resource, you also have permissions to add free-form tags to that resource. To add a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether you should add tags, skip this option (you can add tags later) or ask your administrator.
4. Click **Next**.
5. On the **Configure Pool Placement** page, select the location where you want to place the instances. Do the following:
   a. Select the **Availability domain** to create the instances in.
   b. For the **Fault domains** box, do one of the following things:
      - If you want the system to make a best effort to distribute instances across fault domains based on capacity, leave the box blank.
      - If you want to require that the instances in the pool are distributed evenly in one or more fault domains, select the fault domains to place the instances in. The pool will not launch or scale successfully if sufficient capacity is unavailable in the selected fault domains. For more information, see Distributing Instances Across Fault Domains for High Availability on page 1058.
   c. In the **Primary VNIC** section, configure the network details for the instances:
      - **Virtual cloud network:** The virtual cloud network (VCN) to create the instances in.
      - **Subnet:** A subnet within the cloud network to attach the instances to. The subnets are either public or private. Private means the instances in that subnet can't have public IP addresses. For more information, see Access to the Internet on page 3609. Subnets can also be either AD-specific or regional (regional ones have "regional" after the name). We recommend using regional subnets. For more information, see About Regional Subnets on page 3694.
   d. If secondary VNICS are defined by the instance configuration, a **Secondary VNIC** section appears. Select the secondary VCN and subnet for the instance pool.
   e. If you want the instance pool to create instances in more than one availability domain, click **+ Another Availability Domain**. Then, repeat the previous steps.
Compute

6. If you want to associate a load balancer with the instance pool, select the **Attach a load balancer** check box. Then, do the following:
   
   a. Select the **Load balancer** to associate with the instance pool.
   
   b. Select the **Backend set** on the load balancer to add instances to.
   
   c. In the **Port** box, enter the server port on the instances to which the load balancer must direct traffic. This value applies to all instances that use this load balancer attachment.
   
   d. In the **VNIC** list, select the **VNIC** to use when adding the instance to the backend set. Instances that belong to a backend set are also called backend servers. The private IP address is used. This value applies to all instances that use this load balancer attachment.
   
   e. If you want to associate additional load balancers with the instance pool, click **+ Another Load Balancer**. Then, repeat the previous steps. Do this for each additional load balancer you want to associate with the instance pool.

For background information about load balancers, see **Overview of Load Balancing** on page 3192.

7. Click **Next**.

8. Review the instance pool details, and then click **Create**.

To track the progress of the operation and **troubleshoot errors** that occur during instance creation, use the associated **work request**.

**Using the CLI**

To create an instance pool, use the **instance-pool create** command:

```
oci compute-management instance-pool create --compartment-id <COMPARTMENT_OCID> --instance-configuration-id <INSTANCE_CONFIGURATION_OCID> --placement-configurations <file://path/to/file.json> --size <NUMBER_OF_INSTANCES>
```

<file://path/to/file.json> is the path to a JSON file that defines the placement configuration. For information about how to generate an example of the JSON file, see **Advanced JSON Options** on page 5340.

For information about using the CLI, see **Command Line Interface (CLI)** on page 5316.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

Use the **CreateInstancePool** operation to create an instance pool.

**Updating an Instance Pool**

You can change the size of an instance pool, attach existing instances to a pool, attach load balancers, and update various other properties.

For background information about instance pools and instance configurations, see **Managing Compute Instances with Instance Pools** on page 1055.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** to work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see **Let users manage Compute instance configurations, instance pools, and cluster networks** on page 2808.

**Updating the Size of a Pool**

You can manually update the number of instances for an instance pool.
When you increase the size of a pool, the pool creates new instances using the pool's instance configuration as a template. If you want to add existing instances to the pool, you can instead attach instances to the pool.

When you decrease the size of a pool, the pool terminates (deletes) the extra instances. The oldest instances are terminated first. If you need to perform tasks on an instance before it is deleted, you should instead detach the instance from the pool and then delete the instance separately.

To automatically adjust the number of instances in an instance pool based on performance metrics or a schedule, enable autoscaling for the instance pool.

**Using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instance Pools**.
2. Click the instance pool that you're interested in.
3. Click **Edit**.
4. Specify the updated number of instances for the instance pool, and then click **Save Changes**.

When you update the instance pool size, it triggers a scaling event. Keep the following things in mind:

- If the instance pool's lifecycle state is **Running**, the pool will create new instances or terminate existing instances at that time, to match the new size of the pool. Instances are terminated in the order that they were created, first-in, first-out.
- If the instance pool's lifecycle state is **Stopped**, for an increase in size, new instances will be configured for the pool, but won't be launched. For a decrease in size, the instances will be terminated.

To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated work request.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the instance pool has been in the scaling or provisioning state for an extended period of time, it may be because the number of instances requested has exceeded your tenancy's service limits for that shape and availability domain. Check your tenancy's service limits for Compute.</td>
</tr>
</tbody>
</table>

**Using the API**

To update the size of an instance pool, use the `UpdateInstancePool` operation.

**Using the CLI**

To update the size of an instance pool, use the `instance-pool update` command:

```
oci compute-management instance-pool update --instance-pool-id <INSTANCE_POOL_OCID> --size <NUMBER>
```

**Attaching an Instance to a Pool**

You can attach an existing instance to an instance pool. This lets you select which instances you want to manage as a group.

When you attach an instance, the pool size is increased.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If an autoscaling configuration is associated with the instance pool, ensure that the autoscaling policy defines a maximum pool size that's large enough for the expanded pool. You can do this by editing the autoscaling policy. If you attach an instance and it causes the pool size to increase above the maximum autoscaling target, a future autoscaling event might decrease the pool size and terminate instances.</td>
</tr>
</tbody>
</table>
If load balancers are attached to the pool, the instance is also added to the load balancers.

**Prerequisites**

To attach an instance to a pool, all of the following things must be true:

- The instance and the pool are running.
- The instance is the same machine type as the pool, either virtual machine or bare metal.
- The instance is in the same availability domain and fault domain as the pool.
- The instance's primary VNIC is in the same VCN and subnet as the pool.
- If secondary VNICs are defined, the instance's secondary VNIC is in the same VCN and subnet as the secondary VNICs used by other instances in the pool.
- The instance is not attached to another pool.

You also need the name or **OCID** of the instance that you want to attach.

**Using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Click **More Actions**, and then click **Attach Instance to Instance Pool**.
4. In the **Input type** list, select either **Instance name** or **Instance OCID**. Then, select the name of the instance or enter its OCID.
5. Click **Attach Instance**.

To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated **work request**.

**Using the API**

To attach an existing instance to an instance pool, use the **AttachInstancePoolInstance** operation.

**Using the CLI**

To attach an existing instance to an instance pool, use the **instance-pool-instance attach** command:

```
oci compute-management instance-pool-instance attach --instance-id <INSTANCE_OCID>
```

**Detaching an Instance from a Pool**

You can detach an instance from an instance pool when you no longer want to manage the instance as part of the pool.

When you detach an instance from a pool, you can choose whether to delete the instance or to retain it. You can also choose whether to replace the detached instance by creating a new instance in the pool. If you don't replace the detached instance, the pool size is decreased.

**Using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instance Pools**.
2. Click the instance pool that you're interested in.
3. Under **Resources**, click **Attached Instances**.
4. For the instance that you want to detach, click the Actions icon (three dots). Then, click **Detach Instance**.
5. If you want to delete the instance and its boot volume, select the **Permanently terminate (delete) this instance and its attached boot volume** check box.
Compute

6. If you want the pool to remain the same size after you detach the instance, you can provision a replacement instance. Select the Replace the instance with a new instance, using the pool’s instance configuration as a template for the instance check box.

7. Click Detach (or Detach and Terminate, if you're also deleting the instance).

   To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated work request.

Using the API

To detach an instance from an instance pool, use the DetachInstancePoolInstance operation.

Using the CLI

To detach an instance from an instance pool, use the instance-pool-instance detach command:

```bash
oci compute-management instance-pool-instance detach --instance-id <INSTANCE OCID>
```

Attaching a Load Balancer to a Pool

Optionally, you can associate a load balancer with an instance pool. If you do this, when you add an instance to the instance pool, the instance is automatically added to the load balancer's backend set. After the instance reaches a healthy state (the instance is listening on the configured port number), incoming traffic is automatically routed to the new instance. For background information about the Load Balancing service, see Overview of Load Balancing on page 3192.

Prerequisites

You must have a load balancer and backend set to associate with the instance pool. For steps to create a load balancer, see Load Balancer Management on page 3206.

Using the Console

1. Open the navigation menu and click Compute. Under Compute, click Instance Pools.
2. Click the instance pool that you're interested in.
4. Click Attach a Load Balancer.
5. Enter the following:
   - Load balancer: The load balancer to associate with the instance pool.
   - Backend set: The name of the backend set on the load balancer to add instances to.
   - Port: The server port on the instances to which the load balancer must direct traffic. This value applies to all instances that use this load balancer attachment.
   - VNIC: The VNIC to use when adding the instance to the backend set. Instances that belong to a backend set are also called backend servers. The private IP address is used. This value applies to all instances that use this load balancer attachment.
6. Click Attach.
7. If you want to associate additional load balancers with the instance pool, click + Another Load Balancer. Then, repeat the previous steps. Do this for each additional load balancer you want to associate with the instance pool.

   To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated work request.

Using the API

To attach a load balancer to an instance pool, use the AttachLoadBalancer operation.
**Using the CLI**

To attach a load balancer to an instance pool, use the `instance-pool attach-lb` command:

```
oci compute-management instance-pool attach-lb --backend-set-name <NAME> --instance-pool-id <INSTANCE_POOL_OCID> --load-balancer-id <LOAD_BALANCER_OCID> --port <PORT> --vnic-selection <PrimaryVnic_OR_displayName>
```

**Detaching a Load Balancer from a Pool**

You can detach a load balancer from an instance pool.

**Using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instance Pools**.
2. Click the instance pool that you're interested in.
3. Under **Resources**, click **Load Balancers**.
4. Click the Actions icon (three dots) for the load balancer you want to detach.
5. Click **Detach Load Balancer**, and then click **Detach** to confirm.

To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated **work request**.

**Using the API**

To detach a load balancer from an instance pool, use the `DetachLoadBalancer` operation.

**Using the CLI**

To detach a load balancer from an instance pool, use the `instance-pool detach-lb` command:

```
oci compute-management instance-pool detach-lb --backend-set-name <NAME> --instance-pool-id <INSTANCE_POOL_OCID> --load-balancer-id <LOAD_BALANCER_OCID>
```

**Updating the Instance Configuration for a Pool**

To update the instance configuration that an instance pool uses when creating instances, you can do either of the following things:

- Create a new instance configuration with the desired settings, and then attach the new instance configuration to the pool.
- If you only want to update the display name or tags of an existing instance configuration, you can update the pool's existing instance configuration. Use the `UpdateInstanceConfiguration` operation. For any other updates, create and then attach a new instance configuration with the settings you want to use.

**Using the Console**

To attach a new instance configuration to a pool:

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instance Pools**.
2. Click the instance pool that you're interested in.
3. Click **Edit**.
4. For **Instance configuration**, select the instance configuration that you want the pool to use when creating new instances.
5. Click **Save**.
Using the API
To attach a new instance configuration to a pool, use the UpdateInstancePool operation.

Using the CLI
To attach a new instance configuration to a pool, use the instance-pool update command:

```
oci compute-management instance-pool update --instance-pool-id <INSTANCE_POOL_OCID> --instance-configuration-id <INSTANCE_CONFIGURATION_OCID>
```

Renaming an Instance Pool
You can rename an instance pool without changing its Oracle Cloud Identifier (OCID).

Using the Console
1. Open the navigation menu and click Compute. Under Compute, click Instance Pools.
2. Click the instance pool that you're interested in.
3. Click Edit.
4. Enter a new name. Avoid entering confidential information.
5. Click Save.

Using the API
To rename an instance pool, use the UpdateInstancePool operation.

Using the CLI
To rename an instance pool, use the instance-pool update command:

```
oci compute-management instance-pool update --instance-pool-id <INSTANCE_POOL_OCID> --display-name <INSTANCE_POOL_NAME>
```

Updating the Placement for a Pool
You can update the location where the instances in an instance pool are placed. The placement includes the availability domains, fault domains, and subnets for the instances in the pool.

When you remove an availability domain from a pool, the pool permanently deletes all of its instances in that availability domain. The pool replaces the instances with new instances in the availability domains that are still associated with the pool.

Using the Console
1. Open the navigation menu and click Compute. Under Compute, click Instance Pools.
2. Click the instance pool that you're interested in.
3. Click Edit.
4. Select the Availability domain to create the instances in.
5. For the Fault domains box, do one of the following things:
   - If you want the system to make a best effort to distribute instances across fault domains based on capacity, leave the box blank.
   - If you want to require that the instances in the pool are distributed evenly in one or more fault domains, select the fault domains to place the instances in. The pool will not launch or scale successfully if sufficient capacity is unavailable in the selected fault domains. For more information, see Distributing Instances Across Fault Domains for High Availability on page 1058.
6. In the **Primary VNIC** section, configure the network details for the instances:
   - **Virtual cloud network**: The virtual cloud network (VCN) to create the instances in.
   - **Subnet**: A subnet within the cloud network to attach the instances to. The subnets are either public or private. Private means the instances in that subnet can’t have public IP addresses. For more information, see [Access to the Internet](https://docs.oracle.com/en-us/iaas/Content/Network/IW/Concepts/accessinginternet.htm) on page 3609. Subnets can also be either AD-specific or regional (regional ones have "regional" after the name). We recommend using regional subnets. For more information, see [About Regional Subnets](https://docs.oracle.com/en-us/iaas/Content/Network/IW/Concepts/regionsubs.htm) on page 3694.

7. If secondary VNICs are defined by the instance configuration, a **Secondary VNIC** section appears. Select the secondary VCN and subnet for the instance pool.

8. If you want the instance pool to create instances in more than one availability domain, click **+ Another Availability Domain**. Then, repeat the previous steps.

9. If you no longer want the pool to contain instances in a specific availability domain, click the **X** next to the availability domain that you want to remove. Any existing instances in that availability domain will be deleted and replaced with new instances in an availability domain that is still associated with the pool.

10. Click **Save**.

**Using the API**

To update the placement for an instance pool, use the `UpdateInstancePool` operation.

**Using the CLI**

To update the placement for an instance pool, use the `instance-pool update` command:

```
oci compute-management instance-pool update --instance-pool-id <INSTANCE_POOL_OCID> --placement-configurations <file://path/to/file.json>
```

*<file://path/to/file.json>* is the path to a JSON file that defines the placement configurations. For information about how to generate an example of the JSON file, see [Advanced JSON Options](https://docs.oracle.com/en-us/iaas/Content/API/Concepts/usingapi.htm#advancedjson) on page 5340.

**Tagging Resources**

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see [Resource Tags](https://docs.oracle.com/en-us/iaas/Content/Identity/Tasks/managingtags.htm) on page 239.

*To manage tags for an instance pool*

**Using the Console**:

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instance Pools**.
2. Click the instance pool that you're interested in.
3. Click the **Tags** tab to view or edit the existing tags. Or click **More Actions**, and then click **Add tags** to add new ones.

**Using the API**: Use the `UpdateInstancePool` operation.

**Stopping and Starting the Instances in an Instance Pool**

You can stop and start the instances in an instance pool as needed to update software or resolve error conditions.

**Stopping or Restarting an Instance Using the Instance's OS**

In addition to using the API and Console, you can stop and restart instances using the commands available in the operating system when you are logged in to the instance. Stopping an instance using the instance's OS does not stop billing for that instance. If you stop the instances in an instance pool this way, be sure to also stop the instance pool from the Console or API.
**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* to work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks on page 2808.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

**Resource Billing for Stopped Instances**

For both VM and bare metal instances, billing depends on the *shape* that you use to create the instance:

- **Standard shapes**: Stopping an instance pool pauses billing. However, stopped instances continue to count toward your service limits.
- **Dense I/O shapes**: Billing continues for stopped instance pools because the NVMe storage resources are preserved. Related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance pool.
- **GPU shapes**: Billing continues for stopped instance pools because GPU resources are preserved. Related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance pool.
- **HPC shapes**: Billing continues for stopped instance pools because the NVMe storage resources are preserved. Related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance pool.

Stopping an instance using the instance's OS does not stop billing for that instance. If you stop the instances in an instance pool this way, be sure to also stop the instance pool from the Console or API.

For more information about Compute pricing, see Compute Pricing. For more information about how instances running Microsoft Windows Server are billed when they are stopped, see How am I charged for Windows Server on Oracle Cloud Infrastructure? on page 1172.

**Using the Console**

**To start all instances in a pool**

1. Open the navigation menu and click **Compute**, Under **Compute**, click **Instance Pools**.
2. Click the instance pool that you're interested in.
3. Click **Start**.

**To stop all instances in a pool**

1. Open the navigation menu and click **Compute**, Under **Compute**, click **Instance Pools**.
2. Click the instance pool that you're interested in.
3. Click **Stop**.
4. Click **Stop** again.

The instances are shut down immediately, without waiting for the operating system to respond.

**To reboot all instances in a pool**

1. Open the navigation menu and click **Compute**, Under **Compute**, click **Instance Pools**.
2. Click the instance pool that you're interested in.
3. Click **Reboot**.
4. By default, the Console gracefully restarts the instances by sending a shutdown command to the operating system. After waiting 15 minutes for the OS to shut down, the instances are powered off and then powered back on.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the applications that run on the instances take more than 15 minutes to shut down, they could be improperly stopped, resulting in data corruption. To avoid this, shut down the instances using the commands available in the OS before you restart the instance using the Console.</td>
</tr>
</tbody>
</table>

If you want to reboot the instances immediately, without waiting for the OS to respond, select the Force reboot the instance pool by immediately powering off every instance in the pool, then powering them back on check box.

5. Click Reboot Instance Pool.

**Using the CLI**

For information about using the CLI, see Command Line Interface (CLI) on page 5316. To manage the lifecycle state of the instances in an instance pool using the CLI, open a command prompt and run any of the following commands.

To start (power on) the instances in the specified instance pool, use the `instance-pool start` command:

```bash
oci compute-management instance-pool start --instance-pool-id <INSTANCE_POOL OCID>
```

To stop (immediate power off) the instances in the specified instance pool, use the `instance-pool stop` command:

```bash
oci compute-management instance-pool stop --instance-pool-id <INSTANCE_POOL OCID>
```

To reset (immediate power off and power on) the instances in the specified instance pool, use the `instance-pool reset` command:

```bash
oci compute-management instance-pool reset --instance-pool-id <INSTANCE_POOL OCID>
```

To softreset (ACPI shutdown and power on) the instances in the specified instance pool, use the `instance-pool softreset` command:

```bash
oci compute-management instance-pool softreset --instance-pool-id <INSTANCE_POOL OCID>
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To manage the lifecycle state of the instances in an instance pool with the API, use these operations:

- StartInstancePool
- StopInstancePool
- ResetInstancePool
- SoftresetInstancePool

**Deleting an Instance Configuration**

You can permanently delete instance configurations that you no longer need.
**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* to work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks on page 2808.

**Using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instance Configurations**.
2. Click the instance configuration that you’re interested in.
3. Click **Delete**, and then confirm when prompted.

**Using the CLI**

To delete an instance configuration using the CLI, open a command prompt and run the `instance-configuration delete` command:

```
oci compute-management instance-configuration delete --instance-configuration-id <INSTANCE_CONFIGURATION_OCID>
```

For information about using the CLI, see Command Line Interface (CLI) on page 5316.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

In the API, use the `DeleteInstanceConfiguration` operation to delete an instance configuration.

**Deleting an Instance Pool**

You can permanently delete instance pools that you no longer need.

**Caution:**

When you delete an instance pool, the resources that are associated with the pool are permanently deleted. This includes instances that were created by the pool, instances that are attached to the pool, attached boot volumes, and block volumes.

If an autoscaling configuration applies to the instance pool, the autoscaling configuration will be deleted asynchronously after the pool is deleted. You can also manually delete the autoscaling configuration.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a *policy* by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which *compartment* to work in.

For administrators: For a typical policy that gives access to instance pools and instance configurations, see Let users manage Compute instance configurations, instance pools, and cluster networks on page 2808.

**Using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instance Pools**.
2. Click the instance pool that you're interested in.
3. Click More Actions, and then click Terminate.
4. Confirm when prompted.

To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated work request.

Using the CLI

To delete an instance pool using the CLI, open a command prompt and run the instance-pool terminate command:

```
oci compute-management instance-pool terminate instance-pool-id <INSTANCE_POOL_OCID>
```

For information about using the CLI, see Command Line Interface (CLI) on page 5316.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

In the API, use the TerminateInstancePool operation to delete an instance pool.

Autoscaling

Autoscaling lets you automatically adjust the number or the lifecycle state of compute instances in an instance pool. This helps you provide consistent performance for your end users during periods of high demand, and helps you reduce your costs during periods of low demand.

You can apply the following types of autoscaling to an instance pool:

- **Metric-based autoscaling**: An autoscaling action is triggered when a performance metric meets or exceeds a threshold.
- **Schedule-based autoscaling**: Autoscaling events take place at the specific times that you schedule.

Autoscaling is supported for virtual machine (VM) and bare metal instance pools that use Standard, DenseIO, and GPU shapes.

How Autoscaling Works: the Basics

You use autoscaling configurations to automatically manage the size and lifecycle state of your instance pools. When autoscaling automatically provisions instances in an instance pool, the pool scales out. When autoscaling removes instances from the pool, the pool scales in. You can also use autoscaling to stop and start instances in an instance pool based on a schedule.

When an instance pool scales in, instances are terminated in this order: the number of instances is balanced across availability domains, and then balanced across fault domains. Finally, within a fault domain, the oldest instance is terminated first.

An autoscaling configuration includes one or more autoscaling policies. These policies define the criteria that trigger autoscaling actions and the actions to take. Each autoscaling configuration can either have one metric-based autoscaling policy, or multiple schedule-based autoscaling policies. You can add a maximum of 50 schedule-based autoscaling policies to an autoscaling configuration.

Each instance pool can have only one autoscaling configuration.

**Metric-Based Autoscaling**

In metric-based autoscaling, you choose a performance metric to monitor, and set thresholds that the performance metric must reach to trigger an autoscaling event. When system usage meets a threshold, autoscaling dynamically resizes the instance pool in near-real time. As load increases, the pool scales out. As load decreases, the pool scales in.
Tip:

Avoid changing the value assigned to the initial number of instances after the pool has scaled. Lowering this value after the number of instances in the pool size has increased will cause instances in the pool to terminate. If you need to change this value, the new value should equal or exceed the number of instances currently in the pool.

Metric-based autoscaling relies on performance metrics that are collected by the Monitoring service, such as CPU utilization. These performance metrics are aggregated into one-minute time periods and then averaged across all instances in the instance pool. When three consecutive values (that is, the average metrics for three consecutive minutes) meet the threshold, an autoscaling event is triggered.

A cooldown period between metric-based autoscaling events lets the system stabilize at the updated level. The cooldown period starts when the instance pool reaches the Running state. Autoscaling continues to evaluate performance metrics during the cooldown period. When the cooldown period ends, autoscaling adjusts the instance pool's size again if needed.

Schedule-Based Autoscaling

You can use schedule-based autoscaling to scale the pool size based on demand or to stop and start instances on a schedule.

Schedule-based autoscaling is ideal for instance pools where demand behaves predictably based on a schedule, such as a month, date, or time of day. Schedules can be recurring or one-time. For example:

- An instance pool has heavy use during business hours. The pool has lighter use on evenings and weekends. You can schedule the pool to scale out on weekday mornings, and to scale in on weekday evenings.
- An instance pool has high demand on New Years Eve. You can schedule the pool to scale out every year on December 30, and to scale in on January 2.
- You're releasing a new application that runs in the instance pool, and expect that many people will start using the application after the public announcement. In advance, you can schedule the instances in the pool to start on the day of release.

A schedule-based autoscaling configuration can have multiple autoscaling policies, each with a different schedule and target pool size or lifecycle action. To configure scale-in and scale-out events, you must create at least two separate policies. One policy defines the target pool size and schedule for scaling in, and the other policy defines the target pool size and schedule for scaling out. Likewise, if you want to schedule stop and start events, you must create at least two separate policies. One policy defines the lifecycle action and schedule for stopping the instances, and the other policy defines the lifecycle action and schedule for starting the instances.

After a schedule-based autoscaling policy is run, the instance pool stays at the target pool size or lifecycle state until something else changes the pool size or lifecycle state, such as a different autoscaling policy. However, if you manually change the pool size or lifecycle state, schedule-based autoscaling does not readjust the pool size or lifecycle state until the next scheduled autoscaling policy is run.

When you use schedule-based autoscaling to stop or reboot instances, the information on the instances is preserved. When the instances are started after a shutdown, they are returned to the state they were in before the shutdown occurred.

You define autoscaling schedules using cron expressions. Autoscaling uses the Quartz cron implementation. You can use an online cron expression generator to verify your cron expressions; one example is FREEFORMATTER.

Provide all times in UTC.

Note:

Schedule-based autoscaling configurations include an attribute for cooldown period, which you see in the Console and when using the API, SDKs, and CLI. However, the cooldown period does not impact schedule-based autoscaling configurations.
Multiple Schedule Management

If multiple schedule-based autoscaling policies exist, the schedules might conflict. If a conflict occurs, Oracle chooses one lifecycle state policy and one autoscaling policy to run. The lifecycle state policy runs first.

For the lifecycle state policy, the policy with the highest priority action is chosen. The actions are prioritized as follows, listed from highest to lowest priority:

- Force Reboot
- Reboot
- Start
- Force Stop

For the autoscaling policy, the policy with the highest instance count is chosen.

To see how the autoscaling schedule is expected to affect the pool size in the future, view the pool size forecast.

About Cron Expressions

A cron expression is a string composed of six or seven fields that represent the different parts of a schedule, such as hours or days of the week. Cron expressions use this format:

<second> <minute> <hour> <day of month> <month> <day of week> <year>

The following table lists the values and special characters that are allowed for each field.

<table>
<thead>
<tr>
<th>Field</th>
<th>Allowed Values</th>
<th>Allowed Special Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Second</td>
<td>0</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td>Note: When using the API, CLI, or SDKs for autoscaling, you must specify 0 as the value for seconds, even though other values will create a valid cron expression. You don't need to provide any value for seconds when using the Console.</td>
<td></td>
</tr>
<tr>
<td>Minute</td>
<td>0-59</td>
<td>* - , /</td>
</tr>
<tr>
<td>Hour</td>
<td>0-23</td>
<td>* - , /</td>
</tr>
<tr>
<td>Day of the month</td>
<td>1-31</td>
<td>* - , ? / L W</td>
</tr>
<tr>
<td>Month</td>
<td>1-12 or JAN-DEC</td>
<td>* - , /</td>
</tr>
<tr>
<td>Day of the week</td>
<td>1-7 or SUN-SAT</td>
<td>* - , ? / L #</td>
</tr>
<tr>
<td>Year</td>
<td>1970-2099</td>
<td>* - , /</td>
</tr>
</tbody>
</table>

The special characters are described in the following table.

<table>
<thead>
<tr>
<th>Special Character</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Indicates all values for a field.</td>
<td>* in the month field means every month.</td>
</tr>
<tr>
<td>-</td>
<td>Indicates a range of values.</td>
<td>8-17 in the hour field means hours 8 through 17, or 8 a.m. through 5 p.m.</td>
</tr>
<tr>
<td>,</td>
<td>Indicates multiple values.</td>
<td>3,5 in the day-of-the-week field means Tuesday and Thursday.</td>
</tr>
<tr>
<td>Special Character</td>
<td>Description</td>
<td>Example</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td>?</td>
<td>Indicates no specific values. When you want to specify a day of the month, use ? in the day-of-the-week field. When you want to specify a day of the week, use ? in the day-of-the-month field.</td>
<td>0 0 10 ? * MON * means 10 a.m. on every Monday.</td>
</tr>
<tr>
<td>/</td>
<td>Use ( n/m ) to indicate increments. The value before the slash is the start time, and the number after the slash is the value to increment by.</td>
<td>0/20 in the minute field means the minutes 0, 20, and 40.</td>
</tr>
<tr>
<td>L</td>
<td>Last day of the week or last day of the month. Use ( xL ) in the day-of-the-week field to indicate the last ( x ) day of the month. Use ( L-n ) in the day-of-the-month field to indicate an offset of ( n ) days from the last day of the month. Do not use ( L ) with multiple values or a range of values.</td>
<td>L in the day-of-the-month field means January 31, February 28 in non-leap years, and so on. 6L in the day-of-the-week field means the last Friday of the month. L-5 means 5 days before the last day of the month.</td>
</tr>
<tr>
<td>W</td>
<td>The weekday (Monday - Friday) that is nearest to the given day. The value does not cross months. You can combine the L and W characters (LW) in the day-of-month field to indicate last weekday of the month. Do not use W with multiple values or a range of values.</td>
<td>10W means the nearest weekday to the 10th of the month. If the 10th is a Saturday, it means Friday the 9th. If the 10th is a Sunday, it means Monday the 11th. If the 10th is a Wednesday, it means Wednesday the 10th.</td>
</tr>
<tr>
<td>#</td>
<td>Use ( x#n ) to indicate the ( n )th ( x ) day of the month.</td>
<td>5#2 means the second Thursday of the month.</td>
</tr>
</tbody>
</table>
**Example Cron Expressions**

Use these example cron expressions as a starting point to create your own autoscaling schedules. Combine each cron expression with a target pool size to create an autoscaling policy. Then, include one or more autoscaling policies in an autoscaling configuration.

**Goal:** A one-time schedule with only one scaling event. At 11:00 p.m. on December 31, 2020, scale an instance pool to 100 instances. You'll need one autoscaling policy.

- Policy 1:
  - **Target pool size:** 100 instances
  - **Execution time:** 11:00 p.m. on the 31st day of December, in 2020
  - **Cron expression:** 0 0 23 31 12 ? 2020

**Goal:** A one-time schedule with a scale-out event and a scale-in event. At 10:00 a.m. on March 1, 2021, scale out to 75 instances. At 4 p.m. on March 7, 2021, scale in to 30 instances. You'll need two autoscaling policies.

- Policy 1 - scale out:
  - **Target pool size:** 75 instances
  - **Execution time:** 10:00 a.m. on the 1st day of March, in 2021
  - **Cron expression:** 0 0 10 1 3 ? 2021

- Policy 2 - scale in:
  - **Target pool size:** 30 instances
  - **Execution time:** 4:00 p.m. on the 7th day of March, in 2021
  - **Cron expression:** 0 0 16 7 3 ? 2021

**Goal:** A recurring daily schedule. On weekday mornings at 8:30 a.m., scale out to 10 instances. On weekday evenings at 6 p.m., scale in to two instances. You'll need two autoscaling policies.

- Policy 1 - morning scale out:
  - **Target pool size:** 10 instances
  - **Execution time:** 8:30 a.m. on every Monday through Friday, in every month, in every year
  - **Cron expression:** 0 30 8 ? * MON-FRI *

- Policy 2 - evening scale in:
  - **Target pool size:** 2 instances
  - **Execution time:** 6:00 p.m. on every Monday through Friday, in every month, in every year
  - **Cron expression:** 0 0 18 ? * MON-FRI *

**Goal:** A recurring weekly schedule. On Tuesdays and Thursdays, scale the pool to 30 instances. On all other days of the week, scale the pool to 20 instances. You'll need two autoscaling policies.

- Policy 1 - Tuesday and Thursday:
  - **Target pool size:** 30 instances
  - **Execution time:** 1 a.m. on every Tuesday and Thursday, in every month, in every year
  - **Cron expression:** 0 0 1 ? * TUE,THU *

- Policy 2 - all other days:
  - **Target pool size:** 20 instances
  - **Execution time:** 1 a.m. on Sunday through Monday, Wednesday, and Friday though Saturday, in every month, in every year
  - **Cron expression:** 0 0 1 ? * SUN-MON,WED,FRI-SAT *

**Goal:** A recurring monthly schedule. On all days of the month, set the pool size to 20 instances. On the 15th day of the month, scale out to 40 instances. You'll need two autoscaling policies.

- Policy 1 - daily pool size:
• Target pool size: 20 instances
• Execution time: Midnight on every day, in every month, in every year
• Cron expression: 0 0 0 * * ? *

Policy 2 - scale out:
• Target pool size: 40 instances
• Execution time: 12:05 a.m. on the 15th day of the month, in every month, in every year
• Cron expression: 0 5 0 15 * ? *

Tracking Autoscaling Events

You can use the Events service to monitor autoscaling actions. For example, an event is emitted when a scaling action occurs. For details about autoscaling event types and an example event, see Autoscaling Event Types on page 2431.

For steps to create event notifications, see Getting Started with Events on page 2384.

As an example, to create an event notification for a scaling action, when you create the event rule, do the following:

1. For Condition, select Event Type.
2. For Service Name, select Compute.
3. For Event Type, select Autoscaling Configuration - Scaling Action.

To filter notifications to scaling action errors:

1. Click + Another Condition to create an additional condition.
2. For Condition, select Attribute.
3. For Attribute Name, select actionType.
4. For Attribute Values, enter ERROR.

The possible attribute values for actionType are:

• SCALE_OUT
• SCALE_IN
• NO_ACTION
• ERROR
• LIMIT_EXCEEDED
• POWER_ACTION

You can also use the audit logs to track autoscaling actions. If errors occur during autoscaling events, you can find error details in the these logs, and you can use the audit logs to explore the details of autoscaling events.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: For a typical policy that gives access to autoscaling configurations, see Let users manage Compute autoscaling configurations on page 2809.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

Prerequisites

• You have an instance pool. Optionally, you can attach a load balancer to the instance pool.
• For metric-based autoscaling, monitoring is enabled on the instances in the instance pool, and the Monitoring service is receiving metrics that are emitted by the instance. When you initially create an instance pool using instances that support monitoring, monitoring is enabled by default, regardless of the settings in the pool's instance configuration.

• You have sufficient service limits to create the maximum number of instances that you want to scale to.

Using the Console

To create a metric-based autoscaling configuration

1. Open the navigation menu and click Compute. Under Compute, click Autoscaling Configurations.
2. Click Create Autoscaling Configuration.
3. On the Add Basic Details page, do the following:
   a. Enter a name for the autoscaling configuration. Avoid entering confidential information.
   b. Select the compartment to create the autoscaling configuration in.
   c. Select the Instance pool to apply the autoscaling configuration to.
   d. Show Tagging Options: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
4. Click Next.
5. On the Configure Autoscaling Policy page, select Metric-Based Autoscaling. Then, do the following:
   a. Enter a name for the autoscaling policy. Avoid entering confidential information.
   b. In the Cooldown in seconds box, enter the minimum amount of time to wait between scaling events. The cooldown period gives the system time to stabilize before rescaling. The minimum value is 300 seconds, which is also the default.
   c. Select the Performance metric that triggers an increase or decrease in the number of instances in the instance pool.
   d. In the Scale-out rule area, specify the threshold that the performance metric must reach to increase the pool size. Select a Scale-out operator and Threshold percentage. Then, enter the Number of instances to add to the pool.

   For example, when CPU utilization is greater than 90%, add 10 instances to the pool.
   e. In the Scale-in rule area, specify the threshold that the performance metric must reach to decrease the pool size. Select a Scale-in operator and Threshold percentage. Then, enter the Number of instances to remove from the pool.

   For example, when CPU utilization is less than 20%, remove 5 instances from the pool.
   f. In the Scaling limits area, specify the number of instances in the instance pool:
      • Minimum number of instances: The minimum number of instances that the pool is allowed to decrease to.
      • Maximum number of instances: The maximum number of instances that the pool is allowed to increase to.

      Important:

      The number of instances that can be provisioned is also limited by your tenancy's service limits.

      • Initial number of instances: The number of instances to launch in the instance pool immediately after autoscaling is enabled. After autoscaling retrieves performance metrics, the number of instances is automatically adjusted from this initial number to a number that is based on the scaling limits that you set.
6. Click Next.
7. Review the autoscaling configuration, and then click Create.

   Autoscaling runs. The cooldown period starts when the instance pool's state changes from Scaling to Running.
To create a schedule-based autoscaling configuration

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Autoscaling Configurations**.
2. Click **Create Autoscaling Configuration**.
3. On the **Add Basic Details** page, do the following:
   a. Enter a name for the autoscaling configuration. Avoid entering confidential information.
   b. Select the compartment to create the autoscaling configuration in.
   c. Select the **Instance pool** to apply the autoscaling configuration to.
   d. **Show Tagging Options**: If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags** on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
4. Click **Next**.
5. On the **Configure Autoscaling Policy** page, select **Schedule-Based Autoscaling**. Then, do the following:
   a. Enter a name for the autoscaling policy. Avoid entering confidential information.
   b. For **Action to perform**, select **Scale pool size** or **Change lifecycle state of all instances**.
      • If you select **Scale pool size**, in the **Target pool size** box, enter the number of instances that the pool should scale to at the scheduled time.
      
      | Important: |
      |---|
      | The number of instances that can be provisioned is also limited by your tenancy’s service limits. |
      
      • If you select **Change lifecycle state of all instances**, in the **Lifecycle action** menu, select the action to run on the instance pool.
   c. In the **Execution schedule** area, define the schedule for implementing this autoscaling policy in UTC. Use a Quartz cron expression. For more information about cron expressions, see **About Cron Expressions** on page 1072.
   d. To schedule more scaling events, click **+ Another Policy** and then repeat the previous steps.
6. When you're finished, click **Next**.
7. Review the autoscaling configuration, and then click **Create**.

Autoscaling runs at the scheduled time.

To edit an autoscaling configuration

You can change these characteristics of an autoscaling configuration:

* Name
* For metric-based autoscaling, the cooldown period between autoscaling actions

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Autoscaling Configurations**.
2. Click the autoscaling configuration that you're interested in.
3. Click **Edit**.
5. Click **Save Changes**.

To edit an autoscaling policy

You can change these characteristics of an autoscaling policy:

* Name
• For metric-based autoscaling:
  • Which performance metric triggers an autoscaling action
  • The minimum and maximum number of instances
  • The initial number of instances that the pool should have immediately after you update the autoscaling policy

Caution:
If you specify a smaller initial number of instances than the current pool size, instances will be terminated.

• Scale-out and scale-in operators and thresholds
• The number of instances to add or remove
• For schedule-based autoscaling, you can edit the target pool size, lifecycle action, or schedule for an existing policy, delete an existing policy, or add a new policy

1. Open the navigation menu and click Compute. Under Compute, click Autoscaling Configurations.
2. Click the autoscaling configuration that you're interested in.
3. In the Autoscaling Policies area, click Edit.
5. Click Save Changes.

To view the pool size forecast
To see how the autoscaling schedule is expected to affect the pool size in the future, view the pool size forecast.

1. Open the navigation menu and click Compute. Under Compute, click Autoscaling Configurations.
2. Click the autoscaling configuration that you're interested in.
4. Optionally, customize the forecast.
   • By default, the forecast shows active schedule-based policies. To see all schedule-based policies, under Policy, select All schedule-based policies.
   • For Time zone, select UTC time or local time.
   • To change the date range displayed in the forecast, click Start date or End date, and use the calendar picker to select new dates.

To enable or disable a schedule-based autoscaling policy
1. Open the navigation menu and click Compute. Under Compute, click Autoscaling Configurations.
2. Click the autoscaling configuration that you're interested in.
3. In the Autoscaling Policies area, under Status, toggle the Enabled or Disabled switch.

To disable an autoscaling configuration
1. Open the navigation menu and click Compute. Under Compute, click Autoscaling Configurations.
2. Click the autoscaling configuration that you're interested in.
3. Click Disable, and then confirm when prompted.

To delete an autoscaling configuration
When you delete an autoscaling configuration, the instance pool remains in its most recent state.

1. Open the navigation menu and click Compute. Under Compute, click Autoscaling Configurations.
2. Click the autoscaling configuration that you're interested in.
3. Click Delete, and then confirm when prompted.

To manage tags for an autoscaling configuration
1. Open the navigation menu and click Compute. Under Compute, click Autoscaling Configurations.
2. Click the autoscaling configuration that you're interested in.
3. Click the Tags tab to view or edit the existing tags. Or click Add Tags to add new ones.
For more information, see Resource Tags on page 239.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the Autoscaling API to manage autoscaling configurations and policies.

To update the autoscaling configuration with a new instance pool, create a new instance configuration and then point the instance pool to the new configuration:

- First, create a new instance configuration with the desired settings. You can do this using the Console. For steps, see Creating an Instance Configuration on page 1056. To do this using the API, use the CreateInstanceConfiguration operation.
- Next, update the instance pool used in the autoscaling configuration to point to the new instance configuration. To do this using the API, use the UpdateInstancePool operation to change the instanceConfigurationId. You cannot use the Console to update the instance configuration used by the instance pool.

**Managing Cluster Networks**

A cluster network is a pool of high performance computing (HPC), GPU, or Optimized instances that are connected with a high-bandwidth, ultra low-latency network. Each node in the cluster is a bare metal machine located in close physical proximity to the other nodes. A remote direct memory access (RDMA) network between nodes provides latency as low as single-digit microseconds, comparable to on-premises HPC clusters.

Cluster networks are designed for highly demanding parallel computing workloads. For example:

- Computational fluid dynamics simulations for automotive or aerospace modeling
- Financial modeling and risk analysis
- Biomedical simulations
- Trajectory analysis and design for space exploration
- Artificial intelligence and big data workloads

Cluster networks are built on top of the instance pools feature. Most operations in the instance pool are managed directly by the cluster network, though you can resize the underlying instance pool, monitor the pool, and add tags.

For more information about how to access and store the data that you want to process in your cluster networks, see FastConnect Overview on page 4052, Overview of File Storage on page 2529, Overview of Object Storage on page 4290, and Overview of Block Volume on page 640.

**Supported Shapes**

The following shapes support cluster networks:

- BM.HPC2.36
- BM.GPU4.8
- BM.Optimized3.36 (Intel)

Typically, to be able to create the multiple HPC or GPU instances that are contained in a cluster network, you must request a service limit increase.
Supported Regions and Availability Domains

Cluster networks are supported in the following regions:

- Regions in the Oracle Cloud Infrastructure commercial realm:
  - Australia East (Sydney)
  - Australia Southeast (Melbourne)
  - Germany Central (Frankfurt)
  - India West (Mumbai)
  - Japan Central (Osaka)
  - Japan East (Tokyo)
  - Netherlands Northwest (Amsterdam)
  - South Korea Central (Seoul)
  - UK South (London)
  - US East (Ashburn)
  - US West (Phoenix)
  - US West (San Jose)
- Regions in the Government Cloud realms:
  - UK Gov South (London)
  - US Gov East (Ashburn)

The availability domain that you create the cluster network in must have cluster network-capable hardware.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: For a typical policy that gives access to cluster networks, see Let users manage Compute instance configurations, instance pools, and cluster networks on page 2808.

Creating a Cluster Network

Use the following steps to create a cluster network.

Prerequisites

Create an instance configuration for the instance pool that is managed by the cluster network. To do this:

1. Create an instance with the following settings:
   - Image or operating system: Click Change Image, and then click Oracle Images. Select the Oracle HPC cluster networking image.
   - Shape: Click Change Shape. Select Bare Metal Machine. Then, select either the BM.HPC2.36 shape or the BM.GPU4.8 shape.

      For more information about these shapes, see Compute Shapes on page 973.

2. Create an instance configuration using the instance that you created in the previous step as a template.

   Optionally, you can delete the instance after you create the instance configuration.

Using the Console

1. Open the navigation menu and click Compute. Under Compute, click Cluster Networks.
2. Click Create Cluster Network.
3. Enter a name for the cluster network. It doesn't have to be unique, and you can change it later. Avoid entering confidential information.
4. Select the compartment to create the cluster network in.
5. Select the Availability Domain to run the cluster network in. Only the availability domains with cluster network-capable hardware can be selected.
6. In the Configure networking section, specify the network that you want to use to administer the cluster network. This network is separate from the closed RDMA network between nodes within the cluster. Enter the following information:
   - Virtual cloud network: The virtual cloud network (VCN) for the cluster network.
   - Subnet: The subnet for the cluster network.
7. In the Configure instance pool section, enter the following:
   - Instance pool name: A name for the instance pool that is managed by the cluster network. Avoid entering confidential information.
   - Number of instances: The number of instances in the pool.
   - Instance configuration: Select the instance configuration to use when creating the instances in the cluster network's instance pool, as described in the prerequisites.
8. Show Tagging Options: Optionally, you can add tags. If you have permissions to create a resource, you also have permissions to add free-form tags to that resource. To add a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether you should add tags, skip this option (you can add tags later) or ask your administrator.
9. Click Create Cluster Network.
   Instances are provisioned until the required number of instances in the pool are launched, subject to host capacity for nodes in the cluster's RDMA network.
   To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated work request.

Using the API

Use the CreateClusterNetwork operation.

Detaching Instances from a Cluster Network

You can remove specific nodes from a cluster network by detaching instances from the cluster network's underlying instance pool. The instances that you detach are no longer managed as part of the cluster network. If you want to remove instances from the cluster network by deleting instances, you can instead resize the cluster network.

When you detach an instance, you can choose whether to delete the instance or to retain it. You can also choose whether to replace the detached instance by creating a new instance in the cluster network. If you don't replace the detached instance, the size of the cluster network is decreased.

Using the Console

1. Open the navigation menu and click Compute. Under Compute, click Cluster Networks.
2. Click the cluster network that you're interested in.
3. On the Instance Pools page, click the instance pool that you want to detach instances from.
4. Under Resources, click Attached Instances.
5. For the instance that you want to detach, click the Actions icon (three dots). Then, click Detach Instance.
6. If you want to delete the instance and its boot volume, select the Permanently terminate (delete) this instance and its attached boot volume check box.
7. By default, the size of the underlying instance pool is reduced. If you want the cluster network to remain the same size after you detach the instance, you can provision a replacement instance. Select the Replace the instance with a new instance, using the pool's instance configuration as a template for the instance check box.
8. Click **Detach** (or **Detach and Terminate**, if you're also deleting the instance).
   
   To track the progress of the operation and **troubleshoot errors** that occur during instance creation, use the associated **work request**.

**Using the API**

To list the instances in a cluster network, use the **ListClusterNetworkInstances** operation.

To detach instances from a cluster network's underlying instance pool, use the **DetachInstancePoolInstance** operation.

**Resizing a Cluster Network**

You can change the number of instances in a cluster network by resizing the underlying instance pool.

When you increase the size, instances are provisioned until the required number of instances in the pool are launched, subject to host capacity for nodes in the cluster's RDMA network.

When you decrease the size, instances are terminated (deleted) in the order that they were created, first-in, first-out. If you want to remove a specific instance from the cluster network, you can instead **detach the instance** from the cluster network.

**Prerequisites**

The cluster network must be in the **Running** state.

**Using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Cluster Networks**.
2. Click the cluster network that you're interested in.
3. Click **Edit**.
4. In the **Number of instances** box, specify the updated number of instances for the instance pool.
5. Click **Save Changes**.

   To track the progress of the operation and **troubleshoot errors** that occur during instance creation, use the associated **work request**.

**Using the API**

Use the **UpdateClusterNetwork** operation.

**Editing the Name of a Cluster Network**

Use the following steps to rename a cluster network.

**Using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Cluster Networks**.
2. Click the cluster network that you're interested in.
3. Click **Edit Name**.
4. Enter a new name. Avoid entering confidential information.
5. Click **Save Changes**.

**Using the API**

Use the **UpdateClusterNetwork** operation.
Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

To manage tags for a cluster network

Using the Console:

1. Open the navigation menu and click Compute. Under Compute, click Cluster Networks.
2. Click the cluster network that you're interested in.
3. Click the Tags tab to view or edit the existing tags. Or click Add Tags to add new ones.

Using the API: Use the UpdateClusterNetwork operation.

Deleting a Cluster Network

You can terminate (delete) a cluster network that you no longer need.

Caution:

When you delete a cluster network, all of its resources are permanently deleted, including associated instances, attached boot volumes, and block volumes.

Using the Console

1. Open the navigation menu and click Compute. Under Compute, click Cluster Networks.
2. Click the cluster network that you're interested in.
3. Click Terminate, and then confirm when prompted.

To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated work request.

Using the API

Use the TerminateClusterNetwork operation.

Connecting to an Instance

You can connect to a running instance by using a Secure Shell (SSH) or Remote Desktop connection. Most UNIX-style systems include an SSH client by default. Windows 10 and Windows Server 2019 systems should include the OpenSSH client, which you need if you created your instance using the SSH keys generated by Oracle Cloud Infrastructure. For other Windows versions, you can download a free SSH client called PuTTY from http://www.putty.org.

Note:

If you created an instance without an SSH key, you can use the serial console to boot into maintenance mode and add or reset the SSH key for the opc user or reset the password for the opc user. Alternately, you can stop the instance, attach the boot volume to a new instance, and configure SSH on the new instance.

Required IAM Policy

To connect to a running instance with SSH, you don't need an IAM policy to grant you access. However, to SSH you need the public IP address of the instance (see Prerequisites on page 1084 below). If there's a policy that lets you launch an instance, that policy probably also lets you get the instance's IP address. The simplest policy that does both is listed in Let users launch compute instances on page 2807.
For administrators: Here's a more restrictive policy that lets the specified group get the IP address of existing instances and use power actions on the instances (e.g., stop, start, etc.), but not launch or terminate instances. The policy assumes the instances and the cloud network are together in a single compartment (XYZ):

```
Allow group InstanceUsers to read virtual-network-family in compartment XYZ
Allow group InstanceUsers to use instance-family in compartment XYZ
```

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

Prerequisites

You'll need the following information to connect to the instance:

- The public IP address of the instance. You can get the address from the Instance Details page in the Console. Open the navigation menu and click Compute. Under Compute, click Instances. Then, select your instance. Alternatively, you can use the Core Services API ListVnicAttachments and GetVnic operations.
- The default username for the instance. If you used a platform image for Linux, CentOS, or Windows to launch the instance, the username is opc. If you used an Ubuntu platform image to launch the instance, the username is ubuntu.
- For Linux instances: The full path to the private key portion of the SSH key pair that you used when you launched the instance. For more information about key pairs, see Managing Key Pairs on Linux Instances on page 1021.
- For Windows instances: If you're connecting to the instance for the first time, you will need the initial password for the instance. You can get the password from the Instance Details page in the Console.

Connecting to a Linux Instance

You connect to a Linux instance using SSH.

To connect to a Linux instance from a Unix-style system

1. Use the following command to set the file permissions so that only you can read the file:

   ```
   chmod 400 <private_key_file>
   ```

   `<private_key_file>` is the full path and name of the file that contains the private key associated with the instance you want to access.

2. Use the following SSH command to access the instance.

   ```
   ssh -i <private_key_file> <username>@<public-ip-address>
   ```

   `<private_key_file>` is the full path and name of the file that contains the private key associated with the instance you want to access.

   `<username>` is the default username for the instance. For Oracle Linux and CentOS images, the default username is opc. For Ubuntu images, the default username is ubuntu.

   `<public-ip-address>` is your instance IP address that you retrieved from the Console.

To connect to a Linux instance from a Windows system using OpenSSH

If the instance uses a key pair that was generated by Oracle Cloud Infrastructure, use the following procedure.
1. If this is the first time you are using this key pair, you must set the file permissions so that only you can read the file. Do the following:
   a. In Windows Explorer, navigate to the private key file, right-click the file, and then click Properties.
   c. Ensure that the Owner is your user account.
   d. Click Disable Inheritance, and then select Convert inherited permissions into explicit permissions on this object.
   e. Select each permission entry that is not your user account and click Remove.
   f. Ensure that the access permission for your user account is Full control.
   g. Save your changes.

2. To connect to the instance, open Windows PowerShell and run the following command:

```
ssh -i <private_key_file> <username>@<public-ip-address>
```

- `<private_key_file>` is the full path and name of the file that contains the private key associated with the instance you want to access.
- `<username>` is the default username for the instance. For Oracle Linux and CentOS images, the default username is opc. For Ubuntu images, the default username is ubuntu.
- `<public-ip-address>` is your instance IP address that you retrieved from the Console.

### To connect to a Linux instance from a Windows system using PuTTY

SSH private key files generated by Oracle Cloud Infrastructure are not compatible with PuTTY. If you are using a private key file generated during the instance creation process you need to convert the file to a .ppk file before you can use it with PuTTY to connect to the instance.

#### Convert a generated .key private key file:

1. Open PuTTYgen.
2. Click Load, and select the private key generated when you created the instance. The extension for the key file is .key.
3. Click Save private key.
4. Specify a name for the key. The extension for new private key is .ppk.
5. Click Save.

#### Connect to the Linux instance using a .ppk private key file:

If the instance uses a key pair that you created using PuTTY Key Generator, use the following procedure.

1. Open PuTTY.
2. In the Category pane, select Session and enter the following:
   - **Host Name (or IP address):**
     ```
     <username>@<public-ip-address>
     ```
     - `<username>` is the default username for the instance. For Oracle Linux and CentOS images, the default username is opc. For Ubuntu images, the default username is ubuntu.
     - `<public-ip-address>` is your instance public IP address that you retrieved from the Console
   - **Port:** 22
   - **Connection type:** SSH
3. In the Category pane, expand Window, and then select Translation.
4. In the Remote character set drop-down list, select UTF-8. The default locale setting on Linux-based instances is UTF-8, and this configures PuTTY to use the same locale.
5. In the Category pane, expand Connection, expand SSH, and then click Auth.
6. Click Browse, and then select your .ppk private key file.
7. Click Open to start the session.

If this is your first time connecting to the instance, you might see a message that the server's host key is not cached in the registry. Click Yes to continue the connection.

**Tip:**
If the connection fails, you may need to update your PuTTY proxy configuration.

---

**Connecting to a Windows Instance**

You can connect to a Windows instance using a Remote Desktop connection. Most Windows systems include a Remote Desktop client by default.

To enable Remote Desktop Protocol (RDP) access to the Windows instance, you need to add a stateful ingress security rule for TCP traffic on destination port 3389 from source 0.0.0.0/0 and any source port. You can implement this security rule in either a network security group that the Windows instance belongs to, or a security list that is used by the instance's subnet.

**To enable RDP access**

1. Open the navigation menu, click Networking, and then click Virtual Cloud Networks.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click the cloud network that you're interested in.
4. To add the rule to a network security group that the instance belongs to:
   a. Under Resources, click Network Security Groups. Then click the network security group that you're interested in.
   b. Click Add Rules.
   c. Enter the following values for the rule:
      - **Stateless**: Leave the check box cleared.
      - **Source Type**: CIDR
      - **Source CIDR**: 0.0.0.0/0
      - **IP Protocol**: RDP (TCP/3389)
      - **Source Port Range**: All
      - **Destination Port Range**: 3389
      - **Description**: An optional description of the rule.
   d. When done, click Add.
5. Or, to add the rule to a security list that is used by the instance's subnet:
   a. Under Resources, click Security Lists. Then click the security list you're interested in.
   b. Click Add Ingress Rules.
   c. Enter the following values for the rule:
      - **Stateless**: Leave the check box cleared.
      - **Source Type**: CIDR
      - **Source CIDR**: 0.0.0.0/0
      - **IP Protocol**: RDP (TCP/3389)
      - **Source Port Range**: All
      - **Destination Port Range**: 3389
      - **Description**: An optional description of the rule.
   d. When done, click Add Ingress Rules.

**Connecting to a Windows Instance from a Remote Desktop Client**

1. Open the Remote Desktop client.
2. In the **Computer** field, enter the public IP address of the instance. You can retrieve the public IP address from the Console.

3. The **User name** is opc. Depending on the Remote Desktop client you are using, you might have to connect to the instance before you can enter this credential.

4. Click **Connect** to start the session.

5. Accept the certificate if you are prompted to do so.

6. If you are connecting to the instance for the first time, enter the initial password that was provided to you by Oracle Cloud Infrastructure when you launched the instance. You will be prompted to change the password as soon as you log in. Your new password must be at least 12 characters long and must comply with Microsoft's password policy.

   Otherwise, enter the password that you created. If you are using a custom image, you might need to know the password for the instance that the image was created from. For details about Windows custom images, see Creating Windows Custom Images on page 992.

7. Press **Enter**.

**Connecting to an Instance on a Private Subnet Using a Bastion**

A subnet attached to an instance is either public or private. Instances on a private subnet can't have public IP addresses. Oracle Cloud Infrastructure Bastion provides restricted and time-limited access to instances that don't have public IP addresses.

Bastions let authorized users connect from specific IP addresses to instances using SSH sessions. When connected to a session, users can interact with the instance by using any software or protocol supported by SSH.

The Bastion service recognizes two types of sessions.

- **Managed SSH sessions** provide administrative access to the instance's operating system. To connect to an instance using this session type the Bastion plugin must be enabled on the instance, and plugins must be running. For more information about how to enable and run plugins, see Managing Plugins with Oracle Cloud Agent on page 1089.

- **Port forwarding sessions** (also known as SSH tunneling) create a secure connection between a specific port on the client machine and a specific port on the instance. Using this SSH connection you can relay other protocols like the Remote Desktop Protocol (RDP).

**Troubleshooting the SSH Connection**

If you're unable to connect to your instance using SSH, follow these troubleshooting steps to identify common problems.

- **Verify your connection**: In your terminal window, run `nc <public_ip> 22`.

  - **If the SSH banner displays**: You successfully connected to your instance using SSH. The underlying problem might be related to permissions. As a next step, verify your credentials. If the credentials you're using to SSH to the instance are incorrect, the connection fails.

    For Linux instances, you need the full path to the private key portion of the SSH key pair that you used when you launched the instance. For more information about key pairs, see Managing Key Pairs on Linux Instances on page 1021. For Windows instances, if you're connecting to the instance for the first time, you need the initial password for the instance. You can get the password from the Instance Details page in the Console.

  - **If the SSH banner does not display**: A network issue might be preventing the SSH connection from succeeding. Review the following suggestions.

- **Add a public IP address**: If your connection is routed over the internet and you're not using a bastion, the instance must have a public IP address in order for you to connect to the instance. Without a public IP address, the instance is not reachable. For more information about how to manage public IPv4 addresses on instances, see Public IP Addresses on page 3753.

- **Verify the network security lists**: Oracle Cloud Infrastructure provisions each cloud network with a default set of security lists to permit SSH traffic. If the security list that permits SSH connections is removed, you can't access your instance. Ensure a security list that opens port 22 is present. You can use the Console to view and manage your security lists. For more information about security lists, see Security Lists on page 3727.
• **Confirm that SSH is running on the instance:** The steps for confirming that SSH is running vary depending on the operating system. Review the documentation for your operating system to find information explaining how to confirm that SSH is running.

• **Capture serial console history:** To capture your instance's serial console data history, use the `console-history` resource in the CLI. This information can help determine the cause of connectivity problems. For more information, see `console-history` and Command Line Interface (CLI) on page 5316.

When using the CLI to capture the instance's serial console data history, you need to include the following option to ensure that full history is captured. Without this option, the data might be truncated: `--length 10000000`.

• **Connect to the serial console:** Serial console connections allow you to remotely troubleshoot malfunctioning instances. For more information, see Troubleshooting Instances Using Instance Console Connections on page 1180. From the serial console, you can interrupt the boot process to boot into maintenance mode. In maintenance mode, you can add or reset the SSH key for the opc user.

### Adding Users on an Instance

You can add additional users to a Compute instance.

If you created your instance using a Linux or CentOS platform image, you can use SSH to access your instance from a remote host as the opc user. If you created your instance using an Ubuntu platform image, you can use SSH to access your instance from a remote host as the ubuntu user. After signing in, you can add users to the instance.

If you created your instance using a Windows platform image, you can create new users after you sign in to the instance through a Remote Desktop client.

### Creating Additional Users on a Linux Instance

If you do not want to share your SSH key, you can create additional SSH-enabled users for a Linux instance. At a high level, you do the following things:

• Generate SSH key pairs for the users offline.
• Add the new users.
• Append a public key to the `~/.ssh/authorized_keys` file for each new user.

**Tip:**

If you re-create an instance from a platform image, users and SSH public keys that you added or edited manually (that is, users that weren’t defined in the machine image) must be added again.

If you need to edit the `~/.ssh/authorized_keys` file of a user on your instance, start a second SSH session before you make any changes to the file and ensure that it remains connected while you edit the file. If the `~/.ssh/authorized_keys` file becomes corrupted or you inadvertently make changes that lock you out of the instance, you can use the backup SSH session to fix or revert the changes. Before closing the backup SSH session, test all changes you made by logging in with the new or updated SSH key.

The new users then can SSH to the instance using the appropriate private keys.

**To create an additional SSH-enabled user:**

1. Generate an SSH key pair for the new user.
2. Copy the public key value to a text file for use later in this procedure.
3. Log in to the instance.
4. Become the root user:

```
sudo su
```

5. Create the new user:

```
useradd <new_user>
```

6. Create a `.ssh` directory in the new user’s home directory:

```
mkdir /home/<new_user>/.ssh
```

7. Copy the SSH public key that you saved to a text file into the `/home/new_user/.ssh/authorized_keys` file:

```
echo <public_key> > /home/<new_user>/.ssh/authorized_keys
```

8. Change the owner and group of the `/home/username/.ssh` directory to the new user:

```
chown -R <new_user>:<group> /home/<new_user>/.ssh
```

9. To enable `sudo` privileges for the new user, run the `visudo` command and edit the `/etc/sudoers` file as follows:

   a. In `/etc/sudoers`, look for:

   ```
   %<username> ALL=(ALL) NOPASSWD: ALL
   ```

   b. Add the following line immediately after the preceding line:

   ```
   %<group> ALL=(ALL) NOPASSWD: ALL
   ```

   The new user can now sign in to the instance.

### Creating Additional Users on a Windows Instance

1. Log in to the instance using a Remote Desktop client.
2. On the Start menu, click Control Panel.
3. Click User Accounts, and then click User Accounts again.
4. Click Manage User Accounts.
5. Click Manage Another Account.
6. Click Add User Account.
7. Enter a User name and Password.
8. Confirm the password, and then create a Password hint.
9. Click Next.
10. Verify the account, and then click Finish.

   The new user can now sign in to the instance.

### Managing Plugins with Oracle Cloud Agent

Oracle Cloud Agent is a lightweight process that manages plugins running on compute instances. Plugins collect performance metrics, install OS updates, and perform other instance management tasks.

To use plugins on an instance, the Oracle Cloud Agent software must be installed on the instance, the plugins must be enabled, and the plugins must be running. You might need to perform additional configuration tasks before you can use certain plugins.
**Supported Images**

**Oracle Cloud Agent:** Oracle Cloud Agent is supported on current platform images and on custom images that are based on current platform images. Oracle Cloud Agent is installed by default on current platform images.

If you use an older platform image, you must manually install the Oracle Cloud Agent software. Select an image dated after November 15, 2018 (except Ubuntu, which must be dated after February 28, 2019).

You might have success manually installing Oracle Cloud Agent on other images, though it has not been tested on other operating systems and there is no guarantee that it will work.

**Plugins:** Plugins are installed as part of Oracle Cloud Agent. The plugins that are supported for an instance depend on the version of Oracle Cloud Agent and on the image that you use to create the instance. To determine which plugins are supported for a particular image, use the Console to create an instance. Or, use the ListInstanceagentAvailablePlugins API operation, providing the OS name and OS version of the image.

**Note:**

On Arm-based Ampere A1 Compute shapes, the OS Management Service Agent and Custom Logs Monitoring plugins are not supported.

**Available Plugins**

Each Oracle Cloud Agent plugin provides functionality related to compute instances. This functionality can enable features that are part of the Compute service, and features that are part of other services.

The following Oracle Cloud Agent plugins are available.

<table>
<thead>
<tr>
<th>Plugin Name</th>
<th>Description</th>
<th>Steps to Configure and Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bastion</td>
<td>Allows secure shell (SSH) connections to an instance without public IP addresses using the Bastion service.</td>
<td>See Bastion.</td>
</tr>
<tr>
<td>Compute Instance Monitoring</td>
<td>Emits metrics about the instance's health, capacity, and performance. These metrics are consumed by the Monitoring service.</td>
<td>See Enabling Monitoring for Compute Instances on page 1154 and Compute Instance Metrics on page 1158.</td>
</tr>
<tr>
<td>Compute Instance Run Command</td>
<td>Runs scripts within the instance to remotely configure, manage, and troubleshoot the instance.</td>
<td>See Running Commands on an Instance on page 1112.</td>
</tr>
<tr>
<td>Custom Logs Monitoring</td>
<td>Ingests custom logs into the Logging service.</td>
<td>See Custom Logs on page 3404.</td>
</tr>
<tr>
<td>OS Management Service Agent</td>
<td>Manages updates and patches for the operating system environment on the instance.</td>
<td>See OS Management.</td>
</tr>
<tr>
<td>Vulnerability Scanning</td>
<td>Scans the instance for potential security vulnerabilities like OS packages that require updates.</td>
<td>See Scanning Overview</td>
</tr>
<tr>
<td>Block Volume Management</td>
<td>Configures Block Volume sessions for the instance.</td>
<td>See Enabling the Block Volume Management Plugin on page 670 and Attaching to Ultra High Performance Volumes on page 657.</td>
</tr>
</tbody>
</table>
Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users launch compute instances on page 2807 includes the ability to enable and disable individual plugins, as well as start and stop all plugins on an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family. In addition, you must use the following policy to allow users to access the available plugins:

Allow group PluginUsers to read instance-agent-plugins in compartment ABC

If you’re new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

Installing the Oracle Cloud Agent Software

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you create an instance using a current platform image or a custom image that's based on a current platform image, then Oracle Cloud Agent is installed by default. No action is needed.</td>
</tr>
</tbody>
</table>

If you want to manually install the Oracle Cloud Agent software on an instance that uses another supported image, use the following steps.

To manually install Oracle Cloud Agent on a Linux instance

1. Connect to the instance.
2. To download the Oracle Cloud Agent software, run one of the following scripts.

Oracle Linux

a. To determine whether the Oracle Cloud Agent software is installed, run one of the following commands. On Oracle Linux:

```
sudo yum info oracle-cloud-agent
```

On Oracle Linux Cloud Developer:

```
 rpm -qa | grep oracle-cloud-agent
```

The command returns the Oracle Cloud Agent version that is currently installed.

b. If Oracle Cloud Agent isn't installed, or if the installed version is not the latest version, install the latest version by running the following command:

```
sudo yum install -y oracle-cloud-agent
```

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you don't have access to the yum repository that has Oracle Cloud Agent, run one of the following scripts.</td>
</tr>
</tbody>
</table>

Oracle Linux 6.x

```
#!/bin/sh
cd ~
```
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/X6U59g28LU0aV3qRGG4yA-B029v6bIT-16sRqY0qg/n/imagegen/b/agents/o/oracle-cloud-agent-1.13.0-5327.el6.x86_64.rpm -v

Oracle Autonomous Linux 7.x, Oracle Linux 7.x

For Intel and AMD shapes (x86 processors):

#!/bin/sh
cd ~
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/PicX4Eis-ikveKvOXPt0j1WkI1z2-48IM9vFqg-XaqY05SdWHT2nE8MBcYavKGMr/n/imagegen/b/agents/o/oracle-cloud-agent-1.13.0-5437.el6.x86_64.rpm -v

For Arm-based shapes (aarch64 processors):

#!/bin/sh
cd ~
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/2eJ8bLMJQIQ5mLCW2zCmU1a_j7QAMTcMJach1WtR2AzvDnv1misVr1DGDHOY19gZ/n/imagegen/b/agents/o/oracle-cloud-agent-1.13.0-5437.el7.aarch64.rpm -v

Oracle Linux 8.x, Oracle Linux Cloud Developer 8.x

For Intel and AMD shapes (x86 processors):

#!/bin/sh
cd ~
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/mhdD1MvTPEeXD6esfbO4pxaKgiFmLLAeufXeVd6rKDe2RBBclJqkrKB7EMT8BCH/n/imagegen/b/agents/o/oracle-cloud-agent-1.13.0-5437.el8.x86_64.rpm -v

For Arm-based shapes (aarch64 processors):

#!/bin/sh
cd ~
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/b027p2UHTw5ymSGLsiQ7HJ2j2wkXJ7GakhrNd558GW6vPy-4Cfvebm0Heke53D1CU1/n/imagegen/b/agents/o/oracle-cloud-agent-1.13.0-5423.el8.aarch64.rpm -v

CentOS 7.x

#!/bin/sh
cd ~
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/PicX4Eis-ikveKvOXPt0jIYk12-z48IM9vFpq-XaqY05SdWHT2nE8MBcYavKGMr/n/imagegen/b/agents/o/oracle-cloud-agent-1.13.0-5437.el7.x86_64.rpm -v

CentOS 8.x

#!/bin/sh
cd ~
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/mhD1MvTEeXD6esfB04pXaKg1FlLAsufXeVd6rKDe2RBBc1JqkrKB7EM7P8BCH/n/imagegen/b/agents/o/oracle-cloud-agent-1.13.0-5437.el8.x86_64.rpm -v

Ubuntu 18.04 and Ubuntu 20.04

Note:
To install Oracle Cloud Agent on instances that use Ubuntu images, Snapcraft must be installed on the instance. Install Snapcraft by running the following commands, in sequence:

```
sudo apt update
sudo apt install snapd
```

```
sudo snap install oracle-cloud-agent --classic
```

This command installs and runs the Oracle Cloud Agent software.

3. To run the Oracle Cloud Agent software on the instance, enter one of the following commands.

**Oracle Linux**

```
sudo yum install -y <instance-agent-filename>
```

**CentOS**

```
sudo yum install -y <instance-agent-filename>
```

**Ubuntu**

No further action is needed. The command in the previous step installs and runs the software.

To manually install Oracle Cloud Agent on a Windows instance

1. Connect to the instance.
2. Download the Oracle Cloud Agent software from the following URL:
   https://objectstorage.us-phoenix-1.oraclecloud.com/p/D3uWpErcIjDeVKHTMPSMYzyyaqYXh17WJEzc2dCMvjUloWRL_fRncQ4L_mKerElR/n/imagegen/b/agents/o/OracleCloudAgentSetup_v1.13.0.msi
3. As a user with administrative privileges, enter the following command to run the Oracle Cloud Agent software on the instance.

```
msiexec /qb /i <instance-agent-filename>
```

To install Oracle Cloud Agent using cloud-init when creating an instance

If you want to install Oracle Cloud Agent on an instance that uses an older image as part of the instance launch, you can provide a cloud-init script (cloudbase-init on Windows instances) when you create the instance.

1. Follow the steps to create an instance, until the advanced options.
2. Click **Show Advanced Options**.
3. On the **Management** tab, in the **Initialization Script** section, select **Paste cloud-init script**. Then, copy and paste one of the following scripts, depending on the image.

### Oracle Linux

```
sudo yum install -y oracle-cloud-agent
```

**Note:**
If you don't have access to the yum repository that has Oracle Cloud Agent, copy and paste one of the following scripts.

#### Oracle Linux 6.x

```bash
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/
X6UpelmtxVo_T9d9hgVF1w-hmU59g28LU0aV3qRGG4yA-BO29v6bT-16skpQY0g/n/imagegen/b/agents/
o/oracle-cloud-agent-1.13.0-5327.el6.x86_64.rpm
yum install -y ~/ oracle-cloud-agent-1.13.0-5327.el6.x86_64.rpm -v
```

#### Oracle Linux 7.x

For Intel and AMD shapes (x86 processors):

```bash
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/PicX4Eis-
ikiw0XPePt0j1Wk1l2-z481M9vFqq-
XaqY0SdWHT2nE8MBcyYavKGMr/n/imagegen/b/agents/
o/oracle-cloud-agent-1.13.0-5437.el7.x86_64.rpm
-v
yum install -y ~/ oracle-cloud-agent-1.13.0-5437.el7.x86_64.rpm -v
```

For Arm-based shapes (aarch64 processors):

```bash
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/2eJ8bLMjQIQsmiWZxCMU1a_j7QAMTcMJach1WtR2AzvDnv1misVr1DGdHOY19gZ/
/n/imagegen/b/agents/o/oracle-cloud-agent-1.13.0-5423.el7.aarch64.rpm -v
yum install -y ~/oracle-cloud-agent-1.13.0-5423.el7.aarch64.rpm -v
```

#### Oracle Linux 8.x, Oracle Linux Cloud Developer 8.x

For Intel and AMD shapes (x86 processors):

```bash
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/
mhd11MtPEeXD6esfb04pxaKgiFmLLAsufXeVd6rKDe2RBBc1JqkrKB7EM7P8BCH/
/n/imagegen/b/agents/o/oracle-cloud-agent-1.13.0-5437.el8.x86_64.rpm -v
yum install -y ~/oracle-cloud-agent-1.13.0-5437.el8.x86_64.rpm -v
```
For Arm-based shapes (aarch64 processors):

```bash
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/b027lp2UHTw5ymG1siQ7HF2j2wkXxJ7GakhNd558GW6vPy-4Cfvebm0Heck53DiCU1/n/imagegen/b/agents/o/oracle-cloud-agent-1.13.0-5423.el8.aarch64.rpm -v
yum install -y ~/oracle-cloud-agent-1.13.0-5423.el8.aarch64.rpm -v
```

CentOS 7.x

```bash
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/PicX4Eis-ikveKvOXpT0jIwkiI2-z48IM9vFqg-xaqY05sdWHT2nE8MBcYavKGMr/n/imagegen/b/agents/o/oracle-cloud-agent-1.13.0-5437.el7.x86_64.rpm -v
yum install -y ~/oracle-cloud-agent-1.13.0-5437.el7.x86_64.rpm -v
```

CentOS 8.x

```bash
#!/bin/sh
curl -O https://objectstorage.us-phoenix-1.oraclecloud.com/p/mhdD1MvTPEeXD6esfb04pxaKgIfMLAsufxExVd6rKDe2RBbc1JqkrKB7EM7P8BCH/n/imagegen/b/agents/o/oracle-cloud-agent-1.13.0-5437.el7.x86_64.rpm -v
yum install -y ~/oracle-cloud-agent-1.13.0-5437.el7.x86_64.rpm -v
```

Ubuntu 18.04 and Ubuntu 20.04

To install Oracle Cloud Agent on instances that use Ubuntu images, `Snapcraft` must be installed on the instance. Install Snapcraft by running the following commands, in sequence:

```bash
sudo apt update
sudo apt install snapd
```

```
sudo snap install oracle-cloud-agent --classic
```

For legacy versions of Windows images, ensure that cloudbase-init is supported. See `WinRM and cloudbase-init on Windows images`.

```
#ps1_sysnative
cd \Users\opc\Desktop
Start-BitsTransfer -Source "https://objectstorage.us-phoenix-1.oraclecloud.com/p/D3uWpErcIj0ekVHTF6Szya9yXh1WJe2z2CMvn7loWRL_fRncQ4L_mKerElR/n/imagegen/b/agents/o/OracleCloudAgentSetup_v1.13.0.msi" -Destination "c:\Users\opc\Desktop\OracleCloudAgentSetup.msi"
msiexec /i "c:\Users\opc\Desktop\OracleCloudAgentSetup.msi" /quiet /L*V"c:\\Users\opc\Desktop\OracleCloudAgentSetup.log"
```

4. Click Create.
Managing Plugins Using the Console

To see which plugins are enabled for an instance

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click the Oracle Cloud Agent tab.

The list of plugins is displayed. Enabled plugins can have the following statuses:
- **RUNNING**: The plugin is running.
- **STOPPED**: The plugin is stopped.
- **NOT_SUPPORTED**: The plugin is not supported on this platform.
- **INVALID**: The plugin status is not recognizable by the service.

To enable or disable a plugin

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click the Oracle Cloud Agent tab.
4. Toggle the Enabled or Disabled switch for the plugin.

**Caution:**

Functionality that depends on the plugin, such as monitoring, autoscaling, or OS management, will not work when the plugin is disabled.

It takes up to 10 minutes for the change to take effect.

5. If you enabled a plugin, if necessary, perform any configuration tasks that are required before you can use the plugin. For information about how to configure each plugin, see the documentation for each plugin in Available Plugins on page 1090.

To stop all plugins on an instance

You can stop all of the plugins that are running on an instance. Any individual plugins that are enabled on the instance remain enabled, but the plugin processes stop running. The plugin processes will only start running again after you restart all plugins.

For example, if you want to troubleshoot plugins, you can stop all plugins and then disable the plugins that you think might have an error. Reenable the plugins one-by-one, restarting the plugins after you enable each plugin, to determine which plugin has an issue. For more information about troubleshooting plugins, see Step 4: Generate a Diagnostic File for Oracle Cloud Agent on page 1111.

To stop all plugins on an instance:

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click the Oracle Cloud Agent tab.
4. Click Stop Plugins.

**Caution:**

Functionality that depends on plugins, such as monitoring, autoscaling, and OS management, will not work when all plugins are stopped.

5. Click Stop Plugins.

It might take several minutes for all plugins to stop. Oracle Cloud Agent continues to run when plugins are stopped.

To start all plugins on an instance

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click the **Oracle Cloud Agent** tab.
4. Click **Start Plugins**.

It takes up to 10 minutes for the plugins to restart.

**Managing Plugins Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 5528 and [Security Credentials](#) on page 207. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 5351.

Use these API operations to manage Oracle Cloud Agent plugins:

- In the Core Services API:
  - **LaunchInstance** - enables or disables plugins, or stops all plugins, when you create an instance.
  - **GetInstance** and **ListInstances** - gets information about which plugins are enabled on an instance (or a list of instances).
  - **UpdateInstance** - enables or disables individual plugins, and stops or starts all plugins, for an existing instance.
- In the Oracle Cloud Agent API:
  - **ListInstanceAgentAvailablePlugins** - lists the plugins that are available for all instances. You can filter the results based on the image that you plan to use to launch an instance.
  - **ListInstanceAgentPlugins** - gets information about the plugins that are available on an existing compute instance.
  - **GetInstanceAgentPlugin** - gets information about a specific plugin on an existing compute instance.

**Updating the Oracle Cloud Agent Software**

We recommend always running the latest version of the Oracle Cloud Agent software.

If the instance can access the internet, then no action is needed. Oracle Cloud Agent periodically checks for newer versions and installs the latest version when an update is available.

**Note:**

Oracle Cloud Agent version 1.11.0 does not update itself automatically. See this [known issue](#) for more information.

If the instance does not have access to the internet, then you must manually update the Oracle Cloud Agent software. For example, a compute instance cannot access the internet if it does not have a public IP address, internet gateway, or service gateway. In this situation, Oracle Cloud Agent cannot complete its checks for newer versions.

**To see which version of Oracle Cloud Agent is installed**

**Connect to the instance** and then do one of the following things:

- For Oracle Linux and CentOS, run the following command:

```bash
sudo yum info oracle-cloud-agent
```

- For Oracle Linux Cloud Developer, run the following command:

```bash
rpm -qa | grep oracle-cloud-agent
```

- For Ubuntu, run the following command:

```bash
snap info oracle-cloud-agent
```
• For Windows, do one of the following things:
  • In Control Panel, select **Programs and Features** and then find the version number provided for "Oracle Cloud Agent."
  • In PowerShell, run the following command:

        Get-WmiObject -Class Win32_Product | Where-Object { $_.Name -eq "Oracle Cloud Agent" }

Example output:

<table>
<thead>
<tr>
<th>IdentifyingNumber</th>
<th>(exampleuniqueidentifier)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Oracle Cloud Agent</td>
</tr>
<tr>
<td>Vendor</td>
<td>Oracle Corporation</td>
</tr>
<tr>
<td>Version</td>
<td>0.0.10.0</td>
</tr>
<tr>
<td>Caption</td>
<td>Oracle Cloud Agent</td>
</tr>
</tbody>
</table>

**To manually update Oracle Cloud Agent on a compute instance**

Do one of the following things:

• Temporarily allow the instance to access the internet so that Oracle Cloud Agent can update itself.
• Redo the installation steps, using the latest version.

**Oracle Cloud Agent Release Notes**

**Linux versions**

<table>
<thead>
<tr>
<th>Version</th>

<td>------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| 1.12.0  | June 2, 2021 | Bastion:  
• Fix to only create the control plane and data plane clients once and not on each iteration of the bastion workflow.  
Block Volume Management:  
• Updated the plugin status to be running or stopped when it is running or stopped respectively.  
• Removed the default `/etc/multipath.conf` to avoid conflicts.  
• Improved the error message to report no volume attachments were found by the plugin.  
• Fixed a race condition by restarting the `multipathd` service.  
Ubuntu instances only:  
• Miscellaneous updates. |
| 1.11.4  | May 20, 2021 | Fixes an issue with the updater not updating the Oracle Cloud Agent software. See this known issue.                                      |
| 1.11.3  | May 14, 2021 | Miscellaneous updates.                                                                                                                 |
| 1.11.1  | May 3, 2021  | Replaces the Python updater with a Golang updater.  
Initial release of the Bastion plugin.                                                                                           |
| 1.10.0  | April 7, 2021 | Custom Logs Monitoring:  
• Added support for Ubuntu 16.04, 18.04, and 20.04.  
OS Management Service Agent:  
• Added osmsx_ctl to manage a flag file in future Autonomous Linux releases.  
• Added FIPS Object Model to the OS Management Service Agent build.  
Ubuntu instances only:  
• Added support for Custom Logs Monitoring. |

</tr>
</tbody>
</table>
## Troubleshooting

For troubleshooting steps, see Troubleshooting Oracle Cloud Agent on page 1104.

### Troubleshooting Oracle Cloud Agent

When using Oracle Cloud Agent, you might encounter the following problems:

- On the Oracle Cloud Agent tab of the Instance Details page, the status for all plugins is **Invalid**.
- In the Metrics section of the Console dashboard, you can't see any CPU, memory, network, or disk metrics for the instance.

If you encounter any of these problems, Oracle Cloud Agent might not be installed or running, or it might not be able to communicate with Oracle services. To diagnose the specific issue, follow these troubleshooting steps.

**Tip:**

In this topic, the instructions for Oracle Linux also apply to CentOS images.

### Step 1: Verify that Oracle Cloud Agent is Installed

Follow these steps to confirm that Oracle Cloud Agent is installed on your instance.

1. **Connect to the instance** and run one of the following commands, depending on your operating system.

   **Oracle Linux**

   ```bash
   rpm -q oracle-cloud-agent && echo "OCA Installed" || echo "OCA not Installed"
   ```

   If Oracle Cloud Agent is installed, a message similar to the following displays:

   ```bash
   oracle-cloud-agent-<version>.x86_64
   ```
Compute

**OCA Installed**

Ubuntu

```bash
snap list oracle-cloud-agent >/dev/null && echo "OCA Installed" || echo "OCA not Installed"
```

If Oracle Cloud Agent is installed, the following message displays:

**OCA Installed**

Windows Server

Run the command in Windows PowerShell as an administrator.

```powershell
Get-WmiObject -Class Win32_Product |where name -eq "Oracle Cloud Agent"
```

If Oracle Cloud Agent is installed, a message similar to the following displays:

<table>
<thead>
<tr>
<th>IdentifyingNumber</th>
<th>Oracle Cloud Agent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Oracle Cloud Agent</td>
</tr>
<tr>
<td>Vendor</td>
<td>Oracle Corporation</td>
</tr>
<tr>
<td>Version</td>
<td>&lt;version&gt;</td>
</tr>
<tr>
<td>Caption</td>
<td>Oracle Cloud Agent</td>
</tr>
</tbody>
</table>

2. If the message indicating that Oracle Cloud Agent is installed does not display after you run the command, install Oracle Cloud Agent. If Oracle Cloud Agent is installed, proceed to the next step to verify that it is running.

**Step 2: Verify that Oracle Cloud Agent is Running**

After you confirm that Oracle Cloud Agent is installed, follow these steps to confirm that it is running.

1. **Connect to the instance** and run one of the following commands to restart Oracle Cloud Agent.

   **Oracle Linux 6.x**

   ```bash
   initctl status oracle-cloud-agent
   ```

   Expected response if Oracle Cloud Agent is running:

   `oracle-cloud-agent start/running, process 13809`

   **Oracle Linux 7.x and later versions**

   ```bash
   systemctl is-enabled oracle-cloud-agent >/dev/null && echo "OCA is enabled" || echo "OCA is disabled" \\
   && systemctl is-active oracle-cloud-agent >/dev/null && echo "OCA is running" || echo "OCA is not running"
   ```

   Expected response if Oracle Cloud Agent is running:

   `OCA is enabled`
OCA is running

Ubuntu

snap services oracle-cloud-agent

Expected response if Oracle Cloud Agent is running:

<table>
<thead>
<tr>
<th>Service</th>
<th>Startup</th>
<th>Current</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>oracle-cloud-agent.oracle-cloud-agent</td>
<td>enabled</td>
<td>active</td>
<td>-</td>
</tr>
</tbody>
</table>

Windows Server

Run the command in Windows PowerShell as an administrator.

`sc.exe query "OCA"|findstr "RUNNING"`

Expected response if Oracle Cloud Agent is running:

```
STATE : 4 RUNNING
```

2. If the message indicating that Oracle Cloud Agent is running does not display after you run the command, run the diagnostic tool and then file a support ticket with the file that contains debugging information and logs for the plugins. If Oracle Cloud Agent is running, proceed to the next step to verify that it can connect to Oracle services.

**Step 3: Verify that Oracle Cloud Agent Can Connect to Oracle Services**

If you confirm that Oracle Cloud Agent is installed and running but the status for all plugins on the Instance Details page is Invalid or you cannot see any metrics in the Metrics section of the Console dashboard, Oracle Cloud Agent might not be able to connect to Oracle services. The following sections explore possible reasons that Oracle Cloud Agent is unable to connect to Oracle services. To diagnose the issue, follow these steps in order.

1. Verify that the instance can access the Instance Metadata Service endpoint.
2. Check for clock skew errors.
3. Verify that gateways are configured correctly.

**Verify that the Instance Can Access the Instance Metadata Service Endpoint**

These steps verify whether the instance can access the Instance Metadata Service endpoint.

1. Connect to the instance and run one of the following commands, depending on you operating system.

   **Oracle Linux and Ubuntu**

   ```
   ```

   If Oracle Cloud Agent is running, a message similar to the following displays:

   ```
   * About to connect() to 169.254.169.254 port 80 (#0)
   * Trying 169.254.169.254...
   * Connected to 169.254.169.254 (169.254.169.254) port 80 (#0)
   > GET /opc/v2/instance/ HTTP/1.1
   > User-Agent: curl/7.29.0
   > Host: 169.254.169.254
   > Accept: */*
   > Authorization: Bearer Oracle
   >
   < HTTP/1.1 200 OK
   < Server: server
   < Date: Wed, 24 Mar 2021 20:52:38 GMT
   ```
Windows Server

Run the command in Windows PowerShell as an administrator.

```
Invoke-WebRequest -Headers @{'Authorization'='Bearer Oracle'}
```

If Oracle Cloud Agent is running, a message similar to the following displays:

```
StatusCode : 200
```
2. If you get a successful response without proxy errors, check for clock skew errors. If proxy server errors occur, check your proxy server settings.

Check for Clock Skew Errors

Sometimes, the clock on an instance is not synchronized with the NTP service. Clock skew can cause TLS negotiations to fail, preventing the instance from connecting to Oracle services. Follow these steps to check for clock skew errors.

1. Connect to the instance and run one of the following commands to generate the monitoring.log file.

   **Linux**
   
   ```bash
   sudo tail -15 /var/log/oracle-cloud-agent/plugins/gomon/monitoring.log
   ```

   **Windows Server earlier than 2019**
   
   Run the command in Windows PowerShell as an administrator.
   
   ```powershell
   Get-Content -tail 15 C:\Users\OCA\AppData\Local\OracleCloudAgent\plugins\gomon\monitoring.log
   ```

   **Windows Server 2019**
   
   Run the command in Windows PowerShell as an administrator.
   
   ```powershell
   Get-Content -tail 15 C:\Windows\ServiceProfiles\OCA\AppData\Local\OracleCloudAgent\plugins\gomon\monitoring.log
   ```

   If there is a clock skew error, a message similar to the following displays:

   ```text
   failed to call: Service error:NotAuthenticated. Date 'Tue, 09 Mar 2021 06:39:35 UTC' is not within allowed clock skew.
   Current 'Tue, 09 Mar 2021 06:45:45 UTC', valid datetime range: ['Tue, 09 Mar 2021 06:40:45 UTC', 'Tue, 09 Mar 2021 06:50:46 UTC'].
   http status code: 401. Opc request id: <unique_id>
   ```
2. If a clock skew error occurs, configure the Oracle Cloud Infrastructure NTP service for your instance. If no clock skew error occurs, verify that gateways are configured correctly.

3. If you configured the NTP service in the previous step, after you complete the configuration, run one of the following commands to restart Oracle Cloud Agent:

   **Oracle Linux 6.x**
   ```bash
   sudo initctl restart oracle-cloud-agent
   ```

   **Oracle Linux 7.x and later versions**
   ```bash
   sudo systemctl restart oracle-cloud-agent
   ```

   **Ubuntu**
   ```bash
   sudo snap restart oracle-cloud-agent
   ```

   **Windows Server**
   Run the command in Windows PowerShell as an administrator.
   ```powershell
   net stop OCA
   net start OCA
   ```

4. Generate the `monitoring.log` file again.

   If Oracle Cloud Agent is running correctly, a successful response is **200 OK**. In the `monitoring.log`, look for a message similar to the following:

   ```text
   2021/03/18 03:12:44.391381 t2.go:139: Sent metrics status: 200; took: 387ms; with opc-request-id:<unique_ID>;
   2021/03/18 03:13:44.730102 t2.go:139: Sent metrics status: 200; took: 723ms; with opc-request-id:<unique_ID>;
   ```

**Verify Permissions for Windows Domain Joined Instances**

If you have a Windows instance that is joined to a domain, verify that the virtual account is granted the **Log on as a service** user right in the local Group Policy. To set permissions, follow the steps for enabling service log on through a local group policy in Microsoft’s **Enable Service Logon** guide. For **Log on as a service**, add the user **NT SERVICE ALL SERVICES** or the specific user.

**Verify that Gateways are Configured Correctly**

For Oracle Cloud Agent to communicate with Oracle services, gateways in subnets must be configured correctly. Follow these steps to verify and correct your configuration.

1. Configure the internet gateway, NAT gateway, or service gateway for the subnet in your VCN.
2. After you follow the configuration steps, restart the services using the commands in the **Verify that the Instance Can Access the Instance Metadata Service Endpoint** section. After you restart the services, check the `monitoring.log` file for successful requests to Oracle services.

**Change Proxy Server Settings**

Sometimes, local proxy servers prevent Oracle Cloud Agent from communicating with any services. Each proxy server is different.
Often, setting the `http_proxy`, `https_proxy`, and `no_proxy` environment variables for the `oracle-cloud-agent` and `oracle-cloud-agent-updater` services on the proxy client instances resolves proxy issues. After you set these environment variables, in the proxy server `access.log` file (or equivalent, depending on your system), verify that you see requests from the proxy client to services that Oracle Cloud Agent accesses.

**Note:**

In the following commands, replace `<proxy url>` and `<proxy port>` with your proxy URL and port.

**Oracle Linux**

1. Run the following command.

   ```shell
   sudo EDITOR=vi systemctl edit oracle-cloud-agent
   ```

2. In the editor window, add the following entries, and then save the file.

   ```
   Environment=http_proxy=<proxy url>:<proxy_port>
   Environment=https_proxy=<proxy url>:<proxy_port>
   Environment=no_proxy=localhost,127.0.0.1,169.254.169.254
   ```

3. Repeat the previous two steps for the `oracle-cloud-agent-updater` service.

4. Run the following commands, and then restart the services.

   ```shell
   sudo systemctl daemon-reload
   sudo systemctl restart oracle-cloud-agent oracle-cloud-agent-updater
   ```

**Ubuntu**

1. Run the following command.

   ```shell
   sudo EDITOR=vi systemctl edit snap.oracle-cloud-agent.oracle-cloud-agent
   ```

2. In the editor window, add the following entries, and then save the file.

   ```
   Environment=http_proxy=<proxy url>:<proxy port>
   Environment=https_proxy=<proxy url>:<proxy port>
   Environment=no_proxy=localhost,127.0.0.1,169.254.169.254
   ```

3. Repeat the previous two steps for the `snap.oracle-cloud-agent.oracle-cloud-agent-updater` service.

4. Run the following commands, and then restart the services.

   ```shell
   sudo systemctl daemon-reload
   sudo systemctl restart snap.oracle-cloud-agent.oracle-cloud-agent
   snap.oracle-cloud-agent.oracle-cloud-agent-updater
   ```

**Windows Server**

1. Run the following commands in Windows PowerShell as an administrator. Do not change the casing of the environment variables.

   ```powershell
   Set System environment variables for HTTP_PROXY, HTTPS_PROXY and NO_PROXY
   ```
2. Restart the oracle-cloud-agent and oracle-cloud-agent-updater services.

```plaintext
net stop OCA
net start OCA
net stop OCAU
net start OCAU
```

3. To verify that the Custom Logs Monitoring plugin is able to send metrics, tail the `monitoring.log` file.

**Windows Server 2019**

```
Get-Content C:\Windows\ServiceProfile\OCA\Appdata\Local\OracleCloudAgent\plugins\gomon\monitoring.log -Wait
```

**Windows Server versions earlier than 2019**

```
Get-Content C:\Users\OCA\Appdata\Local\OracleCloudAgent\plugins\gomon\monitoring.log -Wait
```

**Step 4: Generate a Diagnostic File for Oracle Cloud Agent**

To make it easier for Oracle support to help you troubleshoot issues with the Oracle Cloud Agent software, you can install the Oracle Cloud Agent diagnostic tool on your compute instances. When you run the diagnostic tool, it generates a file that contains debugging information and logs for the plugins that Oracle Cloud Agent manages.

After you complete the previous troubleshooting steps, run the diagnostic tool and then file a support ticket with the file that contains debugging information and logs for the plugins.

**To generate a diagnostic file on a Linux instance**

1. Connect to the instance.
2. Download the diagnostic tool by running the following command:

```bash
curl https://objectstorage.us-phoenix-1.oraclecloud.com/p/0CVrsM_C0Oh-mlo8Ay8hzhLr3nIn4-NjJFytpYUyVucLNN93BjJFWq4Lkc3WyRaB/n/imagegen/b/agents/o/oca-diagnostic-util-linux-01-12-21 > oca-diag-01-12-21
```
3. Change the permissions on the diagnostic tool to make it an executable:

```bash
chmod 744 ./oca-diag-01-12-21
```
4. Run the diagnostic tool:

```
./oca-diag-01-12-21
```

The tool generates a TAR file with a name in the format `oca-diag-<date>.<identifier>.tar.gz`. Provide the file when you open your support request.

**To generate a diagnostic file on a Windows instance**

1. Connect to the instance.
2. Open PowerShell as an administrator. Then, download the diagnostic tool by running the following command:

```powershell
$url = "https://objectstorage.us-phoenix-1.oraclecloud.com/p/SW_GzawLiTAoosId5x-4dZtCp21Vz1-5MTW3UOnzLzKqa3vN2H6l8pi_EEOweCu/n/imagegen/b/agents/o/oca-diagnostic-util-win-07-09-21.ps1"
$output_file = "C:\Users\opc\oca-diag-07-09-21.ps1"
```

Oracle Cloud Infrastructure User Guide
$wc.DownloadFile($url, $output_file)

**Note:**

If you get an error when you try to download the diagnostic tool, it might be due to the Transport Layer Security (TLS) version. Run the following command, and then try downloading the diagnostic tool again.

```
```

3. Change directories to the folder where the diagnostic tool is saved:

```
cd C:\Users\opc
```

4. Run the diagnostic tool:

```
.\oca-diag-07-09-21.ps1
```

The tool generates a ZIP file and saves it to C:\Users\opc\Desktop. Provide the file when you open your support request.

**Running Commands on an Instance**

You can remotely configure, manage, and troubleshoot compute instances by running scripts within the instance using the run command feature.

For example, the run command feature can help you automate tasks such as configuring secondary virtual network interface cards (VNICs), joining instances to an identity provider, troubleshooting SSH connectivity, or responding to cross-region disaster recovery scenarios.

You can run commands on an instance even when the instance does not have SSH access or open inbound ports.

The run command feature uses the Compute Instance Run Command plugin that is managed by the Oracle Cloud Agent software.

---

**Caution:**

Do not use the run command feature to provide or retrieve passwords, secrets, or other confidential information in plain text. To securely provide and retrieve confidential information, use an Object Storage location to store the script file and response. Use Oracle Cloud Infrastructure Vault to manage keys and secret credentials.

---

**Supported Images**

The run command feature is supported on compute instances that use the following platform images:

- Oracle Autonomous Linux
- Oracle Linux
- CentOS
- Windows Server

Custom images that are based on a supported platform image also support the run command feature.

---

**Supported Regions**

The run command feature is supported in all regions in the Oracle Cloud Infrastructure commercial realm.
Limitations and Considerations

- On Linux instances, the script runs in a Bash shell by default. To run the script with a different program, use `#!/<path_to_program>` as the first line of the script.
- On Windows instances, the script runs in a batch shell by default. To run the script with PowerShell, use `#ps1` as the first line of the script.

See an example PowerShell script

The following example uses PowerShell to query the instance metadata service and print the instance OCID:

```
#ps1
Write-Host ('Instance OCID is ' + ($instance.id))
```

- The maximum size for a script file that you upload directly to an instance in plain text is 4 KB. To provide a larger file, save the file in an Object Storage location.
- The output of a script when returned as plain text is limited to the last 1 KB. To save a larger response, save the output to an Object Storage location.
- When you use an Object Storage location to save the script file or response, the instance must have outbound connectivity such as a Network Access Translation (NAT) gateway, service gateway, or internet gateway. The instance must also allow egress traffic on port 443 for the Oracle Cloud Agent software, Object Storage, and IAM.
- Two scripts can run at a time by default. To change the default, update the run command configuration file:

```
cat /etc/oracle-cloud-agent/plugins/runcommand/config.yml
```

Set the following parameters:

```
logDir: /var/log/oracle-cloud-agent/plugins/runcommand
commandExecutionMaxWorkers: <number-of-parallel-scripts>
```

- A maximum of five scripts can be in flight at a time. A script is considered to be in flight if it has been received by the Compute Instance Run Command plugin, but not yet deleted from the queue.
- To perform long-running tasks, use the run command feature to schedule a cron job on the instance. Command orchestration is not supported.
- Each script runs once. If you want a script to run multiple times, use cron to configure a schedule for the script.
- Scripts that prompt for information are not supported. However, you can use the instance metadata service (IMDS) to programmatically retrieve information about the instance that the script runs on.
- When you create an instance from a custom image that already has permissions for the Compute Instance Run Command plugin configured, replace `101-oracle-cloud-agent-run-command` with `100-oracle-cloud-agent-run-command` in the configuration file.
- The exit codes that are returned are standard Linux error codes. An exit code of 0 indicates success.
- If you apply an optional timeout for a script, the default is 1 hour. The maximum is 24 hours.
- The maximum time that a script can run is 1 day.
- To monitor the resources that scripts consume, such as CPU utilization, use metrics.
- Canceling a script is a best-effort attempt. Commands can't be canceled after they have finished running or if they have expired.
- Script files and responses that are saved in plain text are retained for one month. Script files and responses that are saved in an Object Storage location are retained until you delete them.
- Do not run a script that causes the Oracle Cloud Agent software or the Compute Instance Run Command plugin to stop.

Running Commands with Administrator Privileges

If a command requiressudo permissions, you must grant sudo permissions to the Compute Instance Run Command plugin to be able to run the command. The plugin runs as the ocarun user.
Compute

You can use cloud-init to configure permissions at instance launch, or connect to an instance after it has launched and configure permissions manually. Do the following:

1. On the instance, create a sudoers configuration file for the Compute Instance Run Command plugin:
   
   ```
   vi ./101-oracle-cloud-agent-run-command
   ```

2. Allow the ocarun user to run all commands as sudo by adding the following line to the configuration file:

   ```
   ocarun ALL=(ALL) NOPASSWD:ALL
   ```

   You can optionally list specific commands. See the Linux man page for sudoers for more information.

3. Validate that the syntax in the configuration file is correct:

   ```
   visudo -cf ./101-oracle-cloud-agent-run-command
   ```

   If the syntax is correct, the follow message is returned:

   ```
   ./101-oracle-cloud-agent-run-command: parsed OK
   ```

4. Add the configuration file to /etc/sudoers.d:

   ```
   sudo cp ./101-oracle-cloud-agent-run-command /etc/sudoers.d/
   ```

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: To write policy for the run command feature, do the following:

1. Create a group that includes the users who you want to allow to issue commands, cancel commands, and view the command output for the instances in a compartment. Then, write the following policy to grant access for the group:

   ```
   Allow group RunCommandUsers to manage instance-agent-command-family in compartment ABC
   ```

2. Create a dynamic group that includes the instances that you want to allow commands to run on. For example, a rule inside the dynamic group can state:

   ```
   any { instance.id = 'ocid1.instance.oc1.phx.<unique_ID_1>',
   'ocid1.instance.oc1.phx.<unique_ID_2>' }
   ```

3. Write the following policy to grant access for the dynamic group:

   ```
   Allow dynamic-group RunCommandDynamicGroup to use instance-agent-command-execution-family in compartment ABC where request.instance.id=target.instance.id
   ```

   Note:

   If you create an instance and then add it to a dynamic group, it takes up to 30 minutes for the instance to start to poll for commands. If you create the dynamic group first and then create the instance, the instance starts to poll for commands as soon as the instance is created.
Compute

4. To allow the dynamic group to access the script file from an Object Storage bucket and save the response to an Object Storage bucket, write the following policies:

```
Allow dynamic-group RunCommandDynamicGroup to read objects in compartment ABC where all {target.bucket.name = '<bucket_with_script_file>'
Allow dynamic-group RunCommandDynamicGroup to manage objects in compartment ABC where all {target.bucket.name = '<bucket_for_command_output>'
```

If you’re new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

Prerequisites

- The Compute Instance Run Command plugin must be enabled on the instance, and plugins must be running. For more information about how to enable and run plugins, see Managing Plugins with Oracle Cloud Agent on page 1089.
- For platform images that were released before October 2020, the Oracle Cloud Agent software must be updated to a version that supports the Compute Instance Run Command plugin (version 1.5.1 or later).
- You have prepared the script that you want to run. We recommend that you test the command in a non-production environment before deploying it on instances that run production workflows.
- To provide the script file from an Object Storage location, upload the file to an Object Storage bucket in the same region as the target instance. Note the bucket and file name, or the Object Storage URL for the file. To use the same command across tenancies, create a pre-authenticated request that points to the file.
- To save the command output to an Object Storage location, create a bucket to save it in, in the same region as the target instance. Note the bucket name or the Object Storage URL for the bucket. You can optionally save the command output using a pre-authenticated request that points to an Object Storage location.

Using the Console

To create a command to run on an instance

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
4. Click Create Command.
5. Enter a name for the command. Avoid entering confidential information.
6. In the Timeout in seconds box, enter the amount of time to give the Compute Instance Run Command plugin to run the command on the instance before timing out. The timer starts when the plugin starts the command. For no timeout, enter 0.
7. In the Add script section, upload the script that you want the Compute Instance Run Command plugin to run on the instance. Select one of the following options:
   - Paste script: Paste the command in the box.
   - Select a file: Upload the script as a text (.txt) file. Either browse to the file that you want to upload, or drag and drop the file into the box.
   - Import from an Object Storage bucket: Select the bucket that contains the script file. In the Object name box, enter the file name.
   - Import from an Object Storage URL: Enter the Object Storage URL for the script file.
8. In the Output type section, select the location to save the output of the command:
   - Output as text: The output is saved as plain text. You can review the output on the Instance Details page.
   - Output to an Object Storage bucket: The output is saved to an Object Storage bucket. Select a bucket. In the Object name box, enter a name for the output file. Avoid entering confidential information.
   - Output to an Object Storage URL: The output is saved to an Object Storage URL. Enter the URL.
9. Click **Create Command**.

**To view the output of a command**

If the command output was saved to an Object Storage location, either download the response object from the bucket where it was saved or navigate to the Object Storage pre-authenticated request URL.

If the command output was saved as a plain text file, do the following:

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Run Command**.
4. Find the command in the list, click the Actions icon (three dots), and then click **View Command Details**.

**To cancel a command**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Run Command**.
4. Find the command in the list, click the Actions icon (three dots), and then click **Cancel Command**. Confirm when prompted.

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 5528 and [Security Credentials](#) on page 207. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 5351.

Use these API operations to work with the run command feature:

- `CreateInstanceAgentCommand`
- `GetInstanceAgentCommand`
- `GetInstanceAgentCommandExecution`
- `ListInstanceAgentCommands`
- `ListInstanceAgentCommandExecutions`
- `CancelInstanceAgentCommand`

**Troubleshooting the Compute Instance Run Command Plugin**

To troubleshoot the Compute Instance Run Command plugin, you can view the logs that the plugin generates. Connect to the instance and then use the following:

```
tail -f /var/log/oracle-cloud-agent/plugins/runcommand/runcommand.log
```

For easier visibility into the plugin's operations without having to connect to the instance, you can create custom logs using the Oracle Cloud Infrastructure Logging service.

**Log Errors**

This section describes how to resolve errors that appear in the log file.

**Failure to Poll**

If the Compute Instance Run Command plugin is failing to poll for commands, you might see the following error in the log file:

```
```

This error can occur when the dynamic group policy for the run command feature is not enabled or if the instance was recently added to the dynamic group. Instances don't belong to tenancy administrator groups by default, so you need...
Compute

to explicitly set dynamic group permissions for the instance. For instructions explaining how to enable the dynamic group policy, see Required IAM Policy on page 1114.

When you create an instance and then add it to a dynamic group, it takes up to 30 minutes for the instance to start to poll for commands. If you create the dynamic group first and then create the instance, the instance starts to poll for commands as soon as the instance is created.

To test the dynamic group policy as soon as you add the instance to a dynamic group, restart the service manually using one of the following commands:

**Oracle Linux 6.x**

```bash
sudo initctl restart oracle-cloud-agent
```

**Oracle Linux 7.x and Oracle Linux 8.x**

```bash
sudo systemctl restart oracle-cloud-agent
```

**Windows Server**

```bash
net restart ocarun
```

### Getting Instance Metadata

The instance metadata service (IMDS) provides information about a running instance, including a variety of details about the instance, its attached virtual network interface cards (VNICs), its attached multipath-enabled volume attachments, and any custom metadata that you define. IMDS also provides information to cloud-init that you can use for various system initialization tasks.

You can find some of this information in the Console on the Instance Details page, or you can get all of it by logging in to the instance and using the metadata service. The service runs on every instance and is an HTTP endpoint listening on 169.254.169.254. If an instance has multiple VNICs, you must send the request using the primary VNIC.

**Important:**

To increase the security of metadata requests, we strongly recommend that you update all applications to use the IMDS version 2 endpoint, if supported by the image. Then, disable requests to IMDS version 1.

### Upgrading to the Instance Metadata Service v2

The instance metadata service is available in two versions, version 1 and version 2. IMDSv2 offers increased security compared to v1.

When you disable IMDSv1 and allow requests only to IMDSv2, the following things change:

- All requests must be made to the v2 endpoints (/opc/v2). Requests to the v1 endpoints (/opc/v1 and /openstack) are rejected with a 404 not found error.
- All requests to the v2 endpoints must include an authorization header. Requests that do not include the authorization header are rejected.
- Requests that are forwarded using the HTTP headers Forwarded, X-Forwarded-For, or X-Forwarded-Host are rejected.

To upgrade the instance metadata service on a compute instance, use the following high-level steps:

1. Verify that the instance uses an image that supports IMDSv2.
2. Identify requests to the legacy v1 endpoints.
3. Migrate all applications to support the v2 endpoints.
4. Disable all requests to the legacy v1 endpoints.
Supported Images for IMDSv2

IMDSv2 is supported on the following platform images:

- Oracle Autonomous Linux 7.x images released in June 2020 or later
- Oracle Linux 8.x, Oracle Linux 7.x, and Oracle Linux 6.x images released in July 2020 or later

Other platform images, most custom images, and most Marketplace images do not support IMDSv2. Custom Linux images might support IMDSv2 if cloud-init is updated to version 20.03 or later and Oracle Cloud Agent is updated to version 0.0.19 or later. Custom Windows images might support IMDSv2 if Oracle Cloud Agent is updated to version 1.0.0.0 or later; cloudbase-init does not support IMDSv2.

Identifying Requests to the Legacy IMDSv1 Endpoints

To identify the specific IMDS endpoints that requests are being made to, and the agents that are making the requests, use the InstanceMetadataRequests metric.

To identify which versions of IMDS are enabled for an instance, do either of the following things:

- **Using the Console:**
  1. Open the navigation menu and click Compute. Under Compute, click Instances.
  2. Click the instance that you're interested in.
  3. In the Instance Details section, next to Instance Metadata Service, note the version numbers.
- **Using the API:** Use the GetInstance operation or the ListInstances operation. In the response, the areLegacyImdsEndpointsDisabled attribute in the InstanceOptions object returns false if both IMDSv1 and IMDSv2 are enabled for the instance. It returns true if IMDSv1 is disabled.

Disabling Requests to the Legacy IMDSv1 Endpoints

After you migrate all applications so that they make requests only to the IMDSv2 endpoints, you should disable all requests to the legacy IMDSv1 endpoints.

<table>
<thead>
<tr>
<th>Important</th>
</tr>
</thead>
<tbody>
<tr>
<td>Verify that the instance does not use the IMDSv1 endpoints before you disable requests to IMDSv1. If the instance still relies on IMDSv1 when you disable requests to it, you might lose some functionality.</td>
</tr>
</tbody>
</table>

Do either of the following things:

- **Using the Console:**
  1. Open the navigation menu and click Compute. Under Compute, click Instances.
  2. Click the instance that you're interested in.
  3. In the Instance Details section, next to Instance Metadata Service, click Edit.
  4. For Allowed IMDS version, select the Version 2 only option.
  5. Click Save Changes.
- **Using the API:** Use the UpdateInstance operation. In the request body, in the InstanceOptions object, pass the value true for the areLegacyImdsEndpointsDisabled attribute.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you disable IMDSv1 on an instance that does not support IMDSv2, you might not be able to connect to the instance when you launch it. To reenable IMDSv1: using the Console, on the Instance Details page, next to Instance Metadata Service, click Edit. Select the Version 1 and version 2 option, save your changes, and then restart the instance. Using the API, use the UpdateInstance operation.</td>
</tr>
</tbody>
</table>
Required IAM Policy

No IAM policy is required if you're logged in to the instance and using cURL to get the metadata.

For administrators: Users can also get instance metadata through the Compute API (for example, with GetInstance). The policy in Let users launch compute instances on page 2807 covers that ability. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

To require that legacy IMDSv1 endpoints are disabled on any new instances that are created, use the following policy:

```
Allow group InstanceLaunchers to manage instances in compartment ABC
where request.instanceOptions.areLegacyEndpointsDisabled= 'true'
```

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

Request Throttling

Oracle Cloud Infrastructure applies throttling to instance metadata service requests to prevent accidental or abusive use of resources. To avoid throttling, instead of querying security credentials for every transaction, cache the credentials until they are near expiration.

If you make too many requests too quickly, you might see some succeed and others fail. If you are experiencing throttling, Oracle recommends that you retry using an exponential back-off.

Getting Instance Metadata on Platform Images

You can get instance metadata for platform images by using cURL on Linux instances. On Windows instances, you can use cURL (if supported by the Windows version) or an internet browser.

All requests to the instance metadata service v2 must include the following header:

```
Authorization: Bearer Oracle
```

Instance metadata accessed using IMDSv2 is available at the following root URLs:

- All of the instance information:
  ```
  ```
- Information about the VNICs that are attached to the instance:
  ```
  ```
- Information about a volume attached to the instance with multipath-enabled attachment:
  ```
  ```

Instance metadata accessed using IMDSv1 is available at the following root URLs. No header is necessary.

- All of the instance information:
  ```
  ```
- Information about the VNICs that are attached to the instance:
  ```
  ```
• Information about a volume attached to the instance with multipath-enabled attachment:

The values for specific metadata keys are available as subpaths below the root URL.

To get instance metadata for Linux instances

1. Connect to a Linux instance using SSH.
2. Use cURL to issue a GET request to the instance metadata URL that you're interested in. For example:

   ```
   
```

To get instance metadata for Windows instances

The steps to get metadata on a Windows instance depend on which version of the instance metadata service you're requesting metadata from.

To get Windows instance metadata using IMDSv2:

1. Connect to a Windows instance by using a Remote Desktop connection.
2. Depending on whether your Windows version includes cURL, do either of the following:
   • If your Windows version includes cURL, use cURL to issue a GET request to the instance metadata URL that you're interested in. For example:

     ```
     
```
   • If your Windows version does not include cURL, you can get instance metadata in your internet browser. Navigate to the instance metadata URL that you're interested in, and pass a request that includes the authorization header. See the instructions for your browser for more information about including headers in a request. You might need to install a third-party browser extension that lets you include request headers.

To get Windows instance metadata using IMDSv1:

1. Connect to a Windows instance by using a Remote Desktop connection.
2. Open an internet browser and then navigate to the instance metadata URL that you're interested in.

Retries for Instance Metadata

The instance metadata service periodically experiences short periods of downtime for maintenance. Therefore, when you try to access IMDS endpoints, they might be unavailable. As a best practice, implement retry logic when accessing IMDS endpoints. The following strategy is recommended: retry up to three times with a 30 second timeout if you receive a 404, 429, or 5xx response. For more information and examples, see the SDK for Java documentation.

Metadata Keys

The instance metadata includes default metadata keys that are defined by Compute and cannot be edited, as well as custom metadata keys that you create.

Some metadata entries are directories that contain additional metadata keys. In the following tables, entries with a trailing slash indicate a directory. For example, `regionInfo/` is a directory that contains other metadata keys.

Metadata Keys for an Instance

The following metadata is available about an instance. The paths are relative to `http://169.254.169.254/opc/v2/instance/`. 

Oracle Cloud Infrastructure User Guide 1120
<table>
<thead>

</tbody>
</table>
| `regionInfo/realmKey`        | The key for the *realm* that the region is in.  
Example: `ocl`                                                                                                                                   |
| `regionInfo/realmDomainComponent` | The domain for the realm.  
Example: `oraclecloud.com`                                                                                                                       |
| `regionInfo/regionKey`       | The 3-letter key for the *region*.  
Example: `PHX`                                                                                                                                       |
| `regionInfo/regionIdentifier` | The region identifier.  
Example: `us-phoenix-1`                                                                                                                                  |
| `shape`                      | The *shape* of the instance. The shape determines the number of CPUs and the amount of memory allocated to the instance. You can enumerate all available shapes by calling the `ListShapes` operation. |
| `state`                      | The current lifecycle state of the instance. For a list of allowed values, see `Instance`.  
Example: `Running`                                                                                                                                |
| `timeCreated`                | The date and time the instance was created, in the format defined by `RFC3339`.                                                                 |
| `agentConfig/`               | A directory containing information about the Oracle Cloud Agent software and plugins running on the instance.                                      |
| `agentConfig/monitoringDisabled` | A Boolean value indicating whether the Oracle Cloud Agent software can gather performance metrics and monitor the instance using the monitoring plugins.  
The monitoring plugins are controlled by this parameter and by the per-plugin configuration in the `pluginsConfig` object. |
| `agentConfig/managementDisabled` | A Boolean value indicating whether the Oracle Cloud Agent software can run all the available management plugins.  
The management plugins are controlled by this parameter and by the per-plugin configuration in the `pluginsConfig` object. |
| `agentConfig/allPluginsDisabled` | A Boolean value indicating whether Oracle Cloud Agent can run all of the available plugins. This includes the management and monitoring plugins. |
| `agentConfig/pluginsConfig/` | A directory containing information about the plugins that Oracle Cloud Agent manages on the instance.                                           |
| `agentConfig/pluginsConfig/name` | The plugin name.                                                                                                                                 |

*Note: The `agentConfig` directory is used to manage the Oracle Cloud Agent software and plugins running on the instance.*

Metadata Keys for Attached VNICS

The following metadata is available about the VNICS that are attached to the instance. The paths are relative to http://169.254.169.254/opc/v2/vnics/.

<table>
<thead>
<tr>
<th>Metadata Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vnicId</td>
<td>The OCID of the VNIC.</td>
</tr>
<tr>
<td>privateIp</td>
<td>The private IP address of the primary privateIp object on the VNIC. The address is within the CIDR of the VNIC's subnet.</td>
</tr>
<tr>
<td>vlanTag</td>
<td>The Oracle-assigned VLAN tag of the attached VNIC. If the VNIC belongs to a VLAN as part of the Oracle Cloud VMware Solution, the vlanTag value is instead the value of the vlanTag attribute for the VLAN. See Vlan.</td>
</tr>
<tr>
<td>macAddr</td>
<td>The MAC address of the VNIC. If the VNIC belongs to a VLAN as part of the Oracle Cloud VMware Solution, the MAC address is learned. If the VNIC belongs to a subnet, the MAC address is a static, Oracle-provided value.</td>
</tr>
<tr>
<td>virtualRouterIp</td>
<td>The IP address of the virtual router.</td>
</tr>
<tr>
<td>subnetCidrBlock</td>
<td>The subnet's CIDR block.</td>
</tr>
<tr>
<td>nicIndex</td>
<td>Which physical network interface card (NIC) the VNIC uses. Certain bare metal instance shapes have two active physical NICs (0 and 1). If you add a secondary VNIC to one of these instances, you can specify which NIC the VNIC will use. For more information, see Virtual Network Interface Cards (VNICS) on page 3733.</td>
</tr>
</tbody>
</table>

Here's an example response that shows the VNICS that are attached to an instance:

```json
[  {   "vnicId": "ocid1.vnic.oc1.phx.exampleuniqueID",  "privateIp": "10.0.3.6",  "vlanTag": 11,  "macAddr": "00:00:00:00:00:01",  "virtualRouterIp": "10.0.3.1",  "subnetCidrBlock": "10.0.3.0/24",  "nicIndex": 0  },  {   "vnicId": "ocid1.vnic.oc1.phx.exampleuniqueID",   "privateIp": "10.0.4.3",   "vlanTag": 12,   "macAddr": "00:00:00:00:00:02",   "virtualRouterIp": "10.0.4.1",   "subnetCidrBlock": "10.0.4.0/24",  }
]```
Metadata Keys for Volumes Attached with Multipath-Enabled Attachments

The following metadata is available about the multipath-enabled attachments that are attached to the instance. The paths are relative to http://169.254.169.254/opc/v2/volumeAttachments/.

<table>
<thead>
<tr>
<th>Metadata Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>The OCID of the volume attachment.</td>
</tr>
<tr>
<td>instanceId</td>
<td>The OCID of the instance.</td>
</tr>
<tr>
<td>volumeId</td>
<td>The OCID of the volume.</td>
</tr>
<tr>
<td>ipv4</td>
<td>The IPv4 address of the iSCSI target.</td>
</tr>
<tr>
<td>iqn</td>
<td>The IQN of the iSCSI target.</td>
</tr>
<tr>
<td>port</td>
<td>The port of the iSCSI target.</td>
</tr>
<tr>
<td>multipathDevices</td>
<td>A list of secondary multipath devices with the properties IPv4, IQN, and port.</td>
</tr>
</tbody>
</table>

Here's an example response that shows the multipath-enabled attachments for an instance:

```
[  
  {  
    "id": "ocid1.volumeattachment.oc1.phx.exampleuniqueID",  
    "instanceId": "ocid1.instance.oc1.phx.exampleuniqueID",  
    "volumeId": "ocid1.volume.oc1.phx.exampleuniqueID"  
  },  
  {  
    "ipv4": "169.254.2.2",  
    "iqn": "iqn.2015-12.com.oracleiaas:exampleuniqueID",  
    "port": 3260,  
    "multipathDevices": [

        "ipv4": "exampleIP",  
        "iqn": "iqn.2015-12.com.oracleiaas:exampleuniqueID",  
        "port": 3260  
      },  
      {  
        "ipv4": "exampleIP",  
        "iqn": "iqn.2015-12.com.oracleiaas:exampleuniqueID",  
        "port": 3260  
      },  
      {  
        "ipv4": "exampleIP",  
        "iqn": "iqn.2015-12.com.oracleiaas:exampleuniqueID",  
        "port": 3260  
      },  
      {  
        "ipv4": "exampleIP",  
        "iqn": "iqn.2015-12.com.oracleiaas:exampleuniqueID",  
        "port": 3260  
      },  
      {  
        "ipv4": "exampleIP",  
        "iqn": "iqn.2015-12.com.oracleiaas:exampleuniqueID",  
        "port": 3260  
      }  
    ]  
  }  
]
```
Updating Instance Metadata

You can add and update custom metadata for a compute instance using the Command Line Interface (CLI) on page 5316 or REST APIs on page 5528.

When you create an instance using the LaunchInstance operation, you can specify custom metadata for the instance in the LaunchInstanceDetails datatype's metadata or extendedMetadata attributes.

To update an instance's metadata, use the UpdateInstance operation, specifying the custom metadata in the UpdateInstanceDetails datatype's metadata or extendedMetadata attributes.

The metadata attribute supports key/value string pairs. The extendedMetadata attribute supports nested JSON objects. The combined size of these two attributes can be a maximum of 32,000 bytes.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users launch compute instances on page 2807 includes the ability to update instance metadata. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

Using the API

When you use the UpdateInstance operation, the instance's metadata will be the combination of the values specified in the UpdateInstanceDetails datatype's metadata or extendedMetadata attributes. Any set of key/value pairs specified for these attributes in the UpdateInstance operation will replace the existing values for these attributes, so you need to include all the metadata values for the instance in each call, not just the ones you want to add. If you leave the attribute empty when calling UpdateInstance, the existing metadata values in that attribute will be used. You cannot specify a value for the same metadata key twice, as this will cause the UpdateInstance operation to fail due to there being duplicate keys.
To understand this, consider the example scenario where you created an instance using the `LaunchInstance` operation and specified the following key/value pair for the `metadata` attribute:

```
"myCustomMetadataKey" : "myCustomMetadataValue"
```

If you then call the `UpdateInstance` operation, and add new metadata by specifying additional key/value pairs in the `extendedMetadata` attribute, but you leave the `metadata` attribute empty, do not include the `myCustomMetadataKey` key/value in the `extendedMetadata` attribute, as this will cause the operation to fail since that key already exists. If you do specify values for the `metadata` attribute, you need to include the `myCustomMetadataKey` key/value to maintain it in the instance's metadata. In this case, you can specify it in either of the attributes.

There are two reserved keys, `user_data` and `ssh_authorized_keys`, that can only be set for an instance at launch time, they cannot be updated later. If you use the `metadata` attribute to add or update metadata for an instance, you need to ensure that you include the values specified at launch time for both these keys, otherwise the `UpdateInstance` operation will fail.

### Best Practices for Updating an Instance's Metadata

When using the `UpdateInstance` operation, we recommend the following:

- Use the `GetInstance` operation to retrieve the existing custom metadata for the instance to ensure that you include the values you want to maintain in the appropriate attributes when you call `UpdateInstance`. The metadata values are returned in the `metadata` and `extendedMetadata` attributes for the `Instance`. For a code example demonstrating this, see the `UpdateInstanceExample` in the SDK for Java on page 5351.

- Unless you are updating custom metadata that was added using the `metadata` attribute, use the `extendedMetadata` attribute to add custom metadata. Otherwise you need to include the launch time values for the `user_data` and `ssh_authorized_keys` reserved keys. If you use the `metadata` attribute to add values and you leave out the values for these reserved keys or specify different values for them, the `UpdateInstance` call will fail.

### Editing an Instance

You can edit the properties of a compute instance without having to rebuild the instance or redeploy your applications.

On supported instances, you can edit the following properties:

- Name. See Rename an Instance on page 1128.
- The shape that's used for the instance. Changing the shape affects the processor, number of OCPUs, memory, and other resources that are allocated to the instance. This lets you scale up your Compute resources for increased performance, or scale down to reduce cost. See Changing the Shape of an Instance on page 1128.
- The fault domain where the instance is placed. You can distribute your instances across fault domain to protect against unexpected hardware failures or maintenance outages. See Editing the Fault Domain for an Instance on page 1131.
- The launch options for the instance, which include the following properties:
  - The networking type for the virtual network interface card (VNIC). The networking interface handles functions such as disk input/output and network communication. Choose between paravirtualized and hardware-assisted (SR-IOV) networking. Paravirtualized networking provides more management flexibility. SR-IOV networking offers better performance.
  - The boot volume attachment type. Choose between paravirtualized and iSCSI attachment types.

See Editing the Launch Options for an Instance on page 1132.

- Whether in-transit encryption is used for the boot volume or block volume. See Enabling In-Transit Encryption Between an Instance and Boot Volumes or Block Volumes on page 1135.
- Whether a running instance is recovered to the same lifecycle state or stopped after a maintenance event or an infrastructure failure affects the underlying infrastructure. See Setting Instance Availability During Maintenance Events on page 1137.
• Whether a notification is sent before live migrating instances. See Setting Instance Availability During Maintenance Events on page 1137.

• Whether the instance is in a capacity reservation, and which capacity reservation the instance is in. See Changing the Capacity Reservation for an Instance on page 1138.

When you edit an instance, the instance's OCID remains the same.

Renaming an Instance

You can rename an instance without changing its Oracle Cloud Identifier (OCID).

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users launch compute instances on page 2807 includes the ability to rename an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

Using the Console

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click Edit.
4. Enter a new name. Avoid entering confidential information.
5. Click Save Changes.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use this API operation to rename an instance:

• UpdateInstance

Changing the Shape of an Instance

You can change the shape of a virtual machine (VM) instance without having to rebuild your instances or redeploy your applications. This lets you scale up your Compute resources for increased performance, or scale down to reduce cost.

When you change the shape of an instance, it affects the number of OCPUs, amount of memory, network bandwidth, and maximum number of VNICs for the instance. Optionally, you can select a shape that uses a different processor. The instance's public and private IP addresses, volume attachments, and VNIC attachments remain the same.
Compute

Supported Shapes
The shape series and image of the original shape determine which shapes you can select as a target for the new shape. You can resize instances that use these shapes:

- **VM Standard and Optimized shapes:**

  For both Linux and Windows images, you can change the number of OCPUs and the amount of memory allocated to a flexible shape. You can also change a Standard shape in one series to a Standard shape in another series. For example, you can change a fixed shape to a flexible shape.

  **Important:**
  - For Windows Server 2019 instances running on VM.Standard2 shapes, you can change the shape to a new shape only within the same series.
  - For Windows Server instances running on VM.Standard.E3 shapes, resize the shape to a maximum of 32 OCPUs. See this [known issue](#) for more information.

- **VM.Standard.A1 series:** You can change the number of OCPUs and the amount of memory allocated.
- **VM.GPU3 series:** Can be changed to any shape in the VM.GPU3 series.

These shapes cannot be changed:

- VM.Standard.E2.1.Micro series
- VM.GPU2 series
- VM instances that run on dedicated virtual machine hosts

Limitations and Considerations
Be aware of the following information:

- The image that’s used to launch the instance must be compatible with the new shape. To see which shapes are compatible, do either of the following things:
  - In the Console, on the Instance Details page, click the name of the image. Then, refer to the list of compatible shapes.
  - Using the API, call the ListShapes operation and pass the image OCID as a parameter.
- Some Marketplace images cannot be resized because of licensing constraints. If you want to resize a Microsoft SQL Server image, contact support.
- You must have sufficient service limits for the new shape. If you don’t have service limits, the instance will remain with the original shape.
- Different shapes are billed at different rates. When you change the shape of an instance, you are billed to the nearest second of usage for each shape that you use. For more information, see [Compute Pricing](#) and [Resource Billing for Stopped Instances](#) on page 1146.
- If the instance has secondary VNICs configured, you might need to reconfigure them after the instance is rebooted. For more information, see [Virtual Network Interface Cards (VNICs)](#) on page 3733.
- If the instance is running when you change the shape, it is rebooted as part of the change shape operation. If the applications that run on the instance take a long time to shut down, they could be improperly stopped, resulting in data corruption. To avoid this, shut down the instance using the commands available in the OS before you change the shape.
- When you change the shape from one hardware series to a different series, some hardware details such as the network interface name might change. This might cause problems for some guest OSs, particularly if the OS has been customized. If the OS fails to boot after you change the shape, then you should change the instance back to the original shape.
- If you created a regular instance using SR-IOV networking (the default for VM.Standard.E3.Flex instances), and want to change the instance to a burstable instance, you must also change the networking type to paravirtualized.
Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users launch compute instances on page 2807 includes the ability to change the shape of an instance. If the specified group doesn’t need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

Prerequisites

- If you want to change the instance to a smaller shape that supports fewer VNICs, detach the extra VNICs.

Using the Console

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click Edit.
4. Click Edit Shape. Then, select the shape that you want to scale to. The following options are available:
   - **AMD**: The flexible shapes that use current generation AMD processors and have a customizable number of OCPUs and amount of memory.
     - For **Number of OCPUs**, choose the number of OCPUs that you want to allocate to this instance by dragging the slider. You can select from 1 to 64 OCPUs.
     - If you want this to be a burstable instance, select the Burstable check box. Then, in the Burstable baseline per OCPU list, select the baseline OCPU utilization for the instance. This value is the percentage of OCPUs that you want to use most of the time.
     - For **Amount of memory (GB)**, choose the amount of memory that you want to allocate to this instance by dragging the slider. The amount of memory allowed is based on the number of OCPUs selected. For more information about the minimum memory, maximum memory, and ratio of memory to OCPUs for this shape, see Flexible Shapes on page 973.

      The other resources scale proportionately.
   - **Intel**: Standard and optimized shapes that use the current generation Intel processor. Optimized flexible shapes have a customizable number of OCPUs and amount of memory.
     - For **Number of OCPUs**, choose the number of OCPUs that you want to allocate to this instance by dragging the slider. You can select from 1 to 18 OCPUs.
     - For **Amount of memory (GB)**, choose the amount of memory that you want to allocate to this instance by dragging the slider. The amount of memory allowed is based on the number of OCPUs selected. For more information about the minimum memory, maximum memory, and ratio of memory to OCPUs for this shape, see Flexible Shapes on page 973.

      The other resources scale proportionately.
   - **Specialty and Previous Generation**: Standard shapes with previous generation Intel and AMD processors.

5. Click Change Shape.

   If the instance is running, it is rebooted.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.
Use this API operation to change the shape of an instance:

- `UpdateInstance`

**Editing the Fault Domain for an Instance**

You can change the fault domain where a virtual machine (VM) instance is placed.

A fault domain is a grouping of hardware and infrastructure that is distinct from other fault domains in the same availability domain. By properly leveraging fault domains you can increase the availability of applications running on Oracle Cloud Infrastructure. For more information and best practices, see [Fault Domains](https://docs.oracle.com/en-us/iaas/Content/ID/Concepts/faultdomains.htm) on page 932.

**Supported Shapes**

You can change the fault domain for instances that use these shapes:

- VM.Standard.E4 series
- VM.Standard.E3 series
- VM.Standard.E2 series
- VM.Standard2 series
- VM.Standard.B1 series
- VM.Standard1 series
- VM.GPU3 series
- VM.Optimized3 series

These shapes cannot be edited:

- VM.Standard.E2.1.Micro series
- VM.GPU2 series
- VM.DenseIO1 series
- VM.DenseIO2 series
- VM instances that run on dedicated virtual machine hosts
- Bare metal shapes

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in [Let users launch compute instances](https://docs.oracle.com/en-us/iaas/Content/Identity/Tasks/managing-users.htm) on page 2807 includes the ability to change the fault domain for an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only `manage instance-family`, and remove the statements involving `volume-family` and `virtual-network-family`.

If you're new to policies, see [Getting Started with Policies](https://docs.oracle.com/en-us/iaas/Content/Identity/Concepts/policy_iam.htm) on page 2799 and [Common Policies](https://docs.oracle.com/en-us/iaas/Content/Identity/Concepts/policy_common.htm) on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see [Details for the Core Services](https://docs.oracle.com/en-us/iaas/Content/API/Concepts/details.htm) on page 2855.

**Using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Click **Edit**.
4. Click **Edit Fault Domain**. Then, select a new fault domain.
5. Click **Save Changes**.

   If the instance is running, it is rebooted.
Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use this API operation to change the fault domain for an instance:

- UpdateInstance

Editing the Launch Options for an Instance

You can tune the compatibility and performance of virtual machine (VM) instances by changing the networking type or the boot volume attachment type.

Networking Launch Types

The networking interface handles functions such as disk input/output and network communication. The following networking types are available:

- **Paravirtualized networking**: For general purpose workloads such as enterprise applications, microservices, and small databases. Paravirtualized networking also provides increased flexibility to use the same image across different hardware platforms. Linux images with paravirtualized networking support live migration during infrastructure maintenance.

- **Hardware-assisted (SR-IOV) networking**: Single root input/output virtualization. For low-latency workloads such as video streaming, real-time applications, and large or clustered databases. Hardware-assisted (SR-IOV) networking uses the VFIO driver framework.

**Important:**
To use a particular networking type, both the shape and the image must support that networking type.

Shapes: The following table lists the default and supported networking types for VM shapes.

<table>
<thead>
<tr>
<th>Shape series</th>
<th>Default Networking Type</th>
<th>Supported Networking Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM.Standard1</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.Standard2</td>
<td>Paravirtualized</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.Standard.E2</td>
<td>Paravirtualized</td>
<td>Paravirtualized only</td>
</tr>
<tr>
<td>VM.Standard.E3</td>
<td>SR-IOV for regular instances Paravirtualized for burstable instances</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.Standard.A1.Flex</td>
<td>Paravirtualized</td>
<td>Paravirtualized only</td>
</tr>
<tr>
<td>VM.Standard.E4</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.DenseIO1</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.DenseIO2</td>
<td>Paravirtualized</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.GPU2</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.GPU3</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
<tr>
<td>VM.Optimized3</td>
<td>SR-IOV</td>
<td>Paravirtualized, SR-IOV</td>
</tr>
</tbody>
</table>

Images: Paravirtualized networking is supported on these platform images:

- **Oracle Linux 8, Oracle Linux Cloud Developer 8**: All images.
- **Oracle Linux 7, Oracle Linux 6**: Images published in March 2019 or later.
• **CentOS 8**: All images.
• **CentOS 7**: Images published in July 2019 or later.
• **Ubuntu 20.04**: All images.
• **Ubuntu 18.04**: Images published in March 2019 or later.
• **Windows Server 2019**: All images.
• **Windows Server 2016**: Images published in August 2019 or later.

SR-IOV networking is supported on all platform images, with the following exceptions:

• Images for Arm-based shapes do not support SR-IOV networking.
• On Windows Server 2019, when launched using a VM.Standard2 shape, SR-IOV networking is not supported.
• On Windows Server 2012 R2, SR-IOV networking is supported on platform images released in April 2021 or later.
• The Server Core installation option for Windows Server does not support SR-IOV networking.

**Boot Volume Attachment Types**

The following boot volume attachment types are available:

• **iSCSI**: A TCP/IP-based standard used for communication between a volume and attached instance.
• **Paravirtualized**: A virtualized attachment available for VMs. This is the default for boot volumes and remote block storage volumes on platform images.

**Supported Shapes**

You can edit the launch options for instances that use these shapes:

• VM.Standard.A1 series
• VM.Standard.E4 series
• VM.Standard.E3 series
• VM.Standard.E2 series
• VM.Standard2 series
• VM.Standard.B1 series
• VM.Standard1 series
• VM.DenseIO2 series
• VM.DenseIO1 series
• VM.GPU3 series
• VM.Optimized3 series

These shapes cannot be edited:

• VM.Standard.E2.1.Micro series
• VM.GPU2 series
• VM instances that run on dedicated virtual machine hosts

**Limitations and Considerations**

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Some instances might not function properly if you change the networking type or the boot volume attachment type. This happens due to shape and image compatibility and driver support. After the instance reboots and is running, connect to it. If the connection fails or the OS doesn't behave as expected, the changes are not supported. Revert the instance to the original settings.</td>
</tr>
</tbody>
</table>

Before you change the networking type or the boot volume attachment type, you must ensure that paravirtualized drivers are installed on the image. The steps depend on the image:

**Oracle Linux 7.x, CentOS 8.x, CentOS 7.x, Ubuntu 20.04, Ubuntu 18.04**
Paravirtualized drivers are installed on platform images.

The Oracle VirtIO Drivers for Microsoft Windows release 1.1.5 must be installed on platform images.

1. To determine whether the VirtIO drivers are installed, [connect to the instance](#) using a Remote Desktop connection. Then, do either of the following things:
   - Open **Control Panel > Program and Features**. If **Oracle Windows VirtIO Drivers** is installed, note the version number.
   - In Registry Editor, go to `HKEY_LOCAL_MACHINE\Software\Wow6432Node\Oracle Corporation\ Oracle Windows VirtIO Drivers`. If the VirtIO drivers are installed, note the version number.

2. If the drivers are not installed or a version that is not 1.1.5 is installed, download Oracle VirtIO Drivers release 1.1.5:
   a. Sign in to the [Oracle Software Delivery Cloud site](#).
   b. In the **All Categories** list, select **Release**.
   c. Type **Oracle Linux 7.7** in the search box and click **Search**.
   d. Add REL: **Oracle Linux 7.7.x** to your cart, and then click **Continue**.
   e. In the **Platforms/Languages** list, select **x86 64 bit**. Click **Continue**.
   f. Accept the license agreement and then click **Continue**.
   g. Select the check box next to **Oracle VirtIO Drivers Version for Microsoft Windows 1.1.5**. Clear the other check boxes.
   h. Click **Download** and then follow the prompts.

3. Install the drivers and then restart the instance. For steps, see [Installing the Oracle VirtIO Drivers for Microsoft Windows on Existing Microsoft Windows Guests](#).

**Oracle Linux 6.x**

For platform images, [connect to the instance](#) using a Secure Shell (SSH) connection. Then, run the following commands:

```bash
sudo bash
cd /boot/efi
echo "fs0:\EFI\redhat\grub.efi"> startup.nsh
chmod 500 startup.nsh
sync
```

**Images that are not platform images**

To verify that your system has paravirtualized drivers installed, run the following command:

```
lsinitrd | grep virtio
```

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** to work in.

For administrators: The policy in [Let users launch compute instances](#) on page 2807 includes the ability to edit the launch options for an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only `manage instance-family`, and remove the statements involving `volume-family` and `virtual-network-family`. 

Oracle Cloud Infrastructure User Guide 1134
If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

**Prerequisites**

- Detach (delete) all secondary VNICs and detach all block volumes. The primary VNIC and boot volume should remain attached.

**Using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Click **Edit**.
4. Click **Show Advanced Options**. The **Launch Options** tab displays.
5. To change the networking type, in the **Networking type** section, select from the following options:
   - **Hardware-assisted (SR-IOV) networking**: Single root input/output virtualization. For low-latency workloads such as video streaming, real-time applications, and large or clustered databases.
   - **Paravirtualized networking**: For general purpose workloads such as enterprise applications, microservices, and small databases. The image must have paravirtualized drivers, as described in Limitations and Considerations on page 1133.
     For more information, see Recommended Networking Launch Types on page 1025.
6. To change the boot volume attachment type, in the **Boot volume attachment type** section, select from the following options:
   - **iSCSI**: A TCP/IP-based standard used for communication between a volume and attached instance.
   - **Paravirtualized**: A virtualized attachment available for VMs. This is the default for boot volumes and remote block storage volumes on platform images.
7. Click **Save Changes**.
   If the instance is running, it is rebooted.
8. **Connect to the instance** after it reboots and is running. If the connection fails or the OS doesn't behave as expected, the changes are not supported. Revert the instance to the original settings.
9. If necessary, reattach any secondary VNICs and block volumes.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use this API operation to edit the launch options for an instance:

- **UpdateInstance**

**Enabling In-Transit Encryption Between an Instance and Boot Volumes or Block Volumes**

After you create a virtual machine (VM) instance, you can enable or disable in-transit encryption between the instance and its paravirtualized boot volume and block volume attachments.

All boot volume and block volume data at rest is always encrypted by the Oracle Cloud Infrastructure Block Volume service using the Advanced Encryption Standard (AES) algorithm with 256-bit encryption. For more information, see Block Volume Encryption on page 644.

**Important:**

See this known issue for more information about editing the in-transit encryption settings.
Supported Shapes and Images

You can enable or disable in-transit encryption for existing instances that use these VM shapes:

- VM.Standard.A1 series
- VM.Standard.E4 series
- VM.Standard.E3 series
- VM.Standard.E2 series
- VM.Standard2 series
- VM.Standard.B1 series
- VM.Standard1 series
- VM.DenseIO2 series
- VM.DenseIO1 series
- VM.GPU3 series
- VM.Optimized3 series

These shapes cannot be edited:

- VM.Standard.E2.1.Micro series
- VM.GPU2 series
- VM instances that run on dedicated virtual machine hosts

The following bare metal shapes support in-transit encryption by default for block volumes and boot volumes:

- BM.Standard.E3.128
- BM.Standard.E4.128

This setting is not configurable and applies to all volume attachments to the instance.

**Note:**

In-transit encryption is not enabled for these shapes in the following scenarios:

- Boot volumes for instances launched June 8, 2021 or earlier.
- Volumes attached to the instance June 8, 2021 or earlier

To enable in-transit encryption for the volumes in these scenarios, you need to detach the volume from the instance and then reattach it.

In-transit encryption is not supported on all other bare metal shapes.

In-transit encryption for boot volumes and block volumes is available for platform images. It is not supported in most cases for instances launched from custom images imported for "bring your own image" (BYOI) scenarios. To confirm support for certain Linux-based custom images, contact support.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users launch compute instances on page 2807 includes the ability to change the shape of an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

If you’re new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.
Using the Console

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click Edit.
4. Click Show Advanced Options.
5. In the Launch Options tab, select the Use in-transit encryption check box.
6. Click Save Changes.

If the instance is running, it is rebooted.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use this API operation to enable or disable in-transit encryption between an instance and its paravirtualized boot volume attachments:

- UpdateInstance

Setting Instance Availability During Maintenance Events

When the underlying infrastructure for a virtual machine (VM) instance needs to undergo planned maintenance or recover from an unexpected failure, Oracle Cloud Infrastructure automatically attempts to recover the instance by migrating it to healthy hardware.

When applicable, Oracle Cloud Infrastructure live migrates supported VM instances from the physical VM host that needs maintenance to a healthy VM host without disrupting running instances. If you do not want your instances live migrated, you can choose to receive a notification for the maintenance event. After you receive the notification, you have 14 days to reboot migrate your instance. The instance is only live migrated if you do not reboot the instance before the due date. If the instance can’t be live migrated, reboot migration is used instead.

After a migration, by default the instance is recovered to the same lifecycle state as before the maintenance event. If you have an alternate process to recover the instance after a reboot migration, you can optionally configure the instance to remain stopped after it is migrated to healthy hardware. You can then restart the instance on your own schedule.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don't have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users launch compute instances on page 2807 includes the ability to edit the maintenance recovery action for an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

Using the Console

You can use the Console to configure live migration options as well as the lifecycle state of instances after a migration.

Configuring live migration

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click **Edit**.
4. Click **Show Advanced Options**.
5. In the **Availability Configuration** tab, in the **Live migration** section, select an option:
   - **Let Oracle Cloud Infrastructure choose the best migration option**: Select this option to let Oracle Cloud Infrastructure choose the best option to **migrate the instance** to a healthy physical VM host if an underlying infrastructure component needs to undergo maintenance.
   - **Opt-in**: Select this option to have the instance **live migrated** to a healthy physical VM host without any notification or disruption. If live migration isn't successful, **reboot migration** is used. Some shapes do not support live migration.
   - **Opt-out**: Select this option to have a notification sent for the maintenance event. The instance is live migrated if you do not proactively reboot the instance before the due date.
6. Click **Save Changes**.

### Configuring the lifecycle state

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Click **Edit**.
4. Click **Show Advanced Options**.
5. In the **Availability Configuration** tab, for the **Restore instance lifecycle state after infrastructure maintenance** check box, select an option:
   - To reboot a running instance after it is recovered, select the check box.
   - To recover the instance in the stopped state, clear the check box.
6. Click **Save Changes**.

### Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use this API operation to edit the maintenance recovery action for an instance:

- **UpdateInstance**

### Changing the Capacity Reservation for an Instance

You can move instances into or out of capacity reservations without having to rebuild your instances. Capacity reservations allow you to reserve instances in advance so that the capacity is available for your workloads when you need it.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** to work in.

For administrators: The following examples shows typical policies that gives access to capacity reservations. Create the policy in the tenancy so that the access is easily granted to all compartments by way of **policy inheritance**. To reduce the scope of access to just the autoscaling configurations in a particular compartment, specify that compartment instead of the tenancy.

**Type of access**: Ability to launch an instance in a reservation.

Allow group `<group_name>` to use compute-capacity-reservations in tenancy
Type of access: Ability to manage capacity reservations.

Allow group <group_name> manage compute-capacity-reservations in tenancy

If you’re new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

Using the Console

You can use the Console to move instance into or out of capacity reservations.

To move instances into a capacity reservation

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click Edit.
4. In the Edit Instance pane, click Show Advanced Options.
5. In the Placement tab, select Apply a capacity reservation.
6. For Capacity reservation in <compartment name>, select the desired capacity reservation from the drop-down menu.
7. Click Save Changes.

To move instances out of a capacity reservation

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click Edit.
4. In the Edit Instance pane, click Show Advanced Options.
5. In the Placement tab, clear Apply a capacity reservation, and then click Save Changes.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use this API operation to move instances into and out of capacity reservations:

- UpdateInstance

Moving Compute Resources to a Different Compartment

You can move Compute resources such as instances, instance pools, and custom images from one compartment to another.

When you move a Compute resource to a new compartment, associated resources such as boot volumes and VNICS are not moved.

After you move the resource to the new compartment, inherent policies apply immediately and affect access to the resource through the Console. For more information, see Managing Compartments on page 3126.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The following policies allow users to move Compute resources to a different compartment:

Allow group ComputeCompartmentMovers to manage instance-family in tenancy
Allow group ComputeCompartmentMovers to manage compute-management-family in tenancy
Allow group ComputeCompartmentMovers to manage auto-scaling-configurations in tenancy
Allow group ComputeCompartmentMovers to manage dedicated-vm-hosts in tenancy

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

Security Zones

Security Zones ensure that your cloud resources comply with Oracle security principles. If any operation on a resource in a security zone compartment violates a policy for that security zone, then the operation is denied.

The following security zone policies affect your ability to move Compute resources from one compartment to another:

- You can't move a compute instance from a security zone to a standard compartment.
- You can't move a compute instance from a standard compartment to a compartment that is in a security zone.

Using the Console

To move an instance to a different compartment

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. In the List Scope section, select a compartment.
3. Click the instance that you're interested in.
4. Click More Actions, and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

To track the progress of the operation and troubleshoot errors that occur during instance creation, use the associated work request.

7. If there are alarms monitoring the instance, update the alarms to reference the new compartment. See To update an alarm after moving a resource on page 3542 for more information.
8. Optionally, move the resources that are attached to the instance to the new compartment.

To move an instance configuration to a different compartment

Note:

Most of the properties for an existing instance configuration, including the compartment, cannot be modified after you create the instance configuration. Although you can move an instance configuration to a different compartment, you will not be able to use the instance configuration to manage instance pools in the new compartment. If you want to update an instance configuration to point to a different compartment, you should instead create a new instance configuration in the target compartment. For steps, see Creating an Instance Configuration on page 1056.

1. Open the navigation menu and click Compute. Under Compute, click Instance Configurations.
2. In the List Scope section, select a compartment.
3. Click the instance configuration that you're interested in.
4. Click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

To move an instance pool to a different compartment

1. Open the navigation menu and click Compute. Under Compute, click Instance Pools.
2. In the List Scope section, select a compartment.
3. Click the instance pool that you're interested in.
4. Click More Actions, and then click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.
7. Optionally, update the instance pool with an instance configuration that points to the new compartment. Do the following:
   a. Create a new instance configuration in the new compartment. You can do this using the Console or the API. For steps, see Creating an Instance Configuration on page 1056.
   b. Update the instance pool with the new instance configuration. You can do this using the API. For steps, see Updating an Instance Pool on page 1060.
8. Optionally, move the instances and other resources that are associated with the instance pool to the new compartment.

To move an autoscaling configuration to a different compartment
1. Open the navigation menu and click Compute. Under Compute, click Autoscaling Configurations.
2. In the List Scope section, select a compartment.
3. Click the autoscaling configuration that you're interested in.
4. Click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

To move a custom image to a different compartment
1. Open the navigation menu and click Compute. Under Compute, click Custom Images.
2. In the List Scope section, select a compartment.
3. Click the custom image that you're interested in.
4. Click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.

To move a cluster network to a different compartment
1. Open the navigation menu and click Compute. Under Compute, click Cluster Networks.
2. In the List Scope section, select a compartment.
3. Click the cluster network that you're interested in.
4. Click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.
7. Optionally, move the instances and other resources that are associated with the cluster network to the new compartment.

To move a dedicated virtual machine host to a different compartment
1. Open the navigation menu and click Compute. Under Compute, click Dedicated Virtual Machine Hosts.
2. In the List Scope section, select a compartment.
3. Click the dedicated virtual machine host that you're interested in.
4. Click Move Resource.
5. Choose the destination compartment from the list.
6. Click Move Resource.
7. Optionally, move the instances that are placed on the dedicated virtual machine host to the new compartment.

Using the API
For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.
Use these API operations to move Compute resources to different compartments:

- ChangeInstanceCompartment
- ChangeInstanceConfigurationCompartment
- ChangeInstancePoolCompartment
- ChangeAutoScalingConfigurationCompartment
- ChangeImageCompartment
- ChangeClusterNetworkCompartment
- ChangeDedicatedVmHostCompartment

Moving a Compute Instance to a New Host

This topic provides information about how to relocate instances using reboot migration or a manual process and information about virtual machine (VM) migrations during infrastructure maintenance events.

**Note:**

- Dedicated virtual machine hosts: Dedicated virtual machine hosts do not support reboot migration. To relocate these instances, use the process described in Moving an Instance with Manual Migration on page 1143.
- Oracle Platform Services:
  For instances that were created with Oracle Platform Services and located in the compartment ManagedCompartmentForPaaS, you must use the interface for the specific Platform Service to reboot the instances.

Live Migration

During an infrastructure maintenance event, Oracle Cloud Infrastructure live migrates supported VM instances from the physical VM host that needs maintenance to a healthy VM host without disrupting running instances. By default, Oracle Cloud Infrastructure sends a notification about the upcoming maintenance event. After 14 to 16 days, the VM instances are live migrated if you do not proactively reboot the instance before the due date. Alternately, you can choose to have your instances automatically live migrated without a notification. If the instance can't be live migrated, reboot migration is used instead, and a short downtime occurs while the instance is reboot migrated.

When a live migration begins and ends, an event is emitted. For details about live migration event types, see Live Migration Event Types on page 2442. For information about creating automation to track events, see Getting Started with Events on page 2384.

For more information, see Infrastructure Maintenance on page 1148.

Supported Shapes and Images

The following image series support live migration when they use Linux operating systems and paravirtualized networking.

- VM.Standard.E2 series
- VM.Standard2 series
- VM.Standard1 series
- VM.Standard.E3.Flex series

Reboot Migration

For instances with a date in the Reboot Maintenance field (available in the Console, CLI, and SDKs), the instance is stopped, migrated to a healthy host, and restarted. A short downtime occurs during the migration. You can control when the downtime occurs by proactively reboot migrating the instance before the maintenance due date. If you reboot the instance using the Console, CLI, or SDK, the Reboot Maintenance field is cleared. This change indicates that the instance was moved successfully.
Prerequisites for Reboot Migration

1. Prepare the instance for reboot migration:
   - Ensure that any remote block volumes defined in `/etc/fstab` use the recommended options.
   - Ensure that any File Storage service (NFS) mounts use the `nofail` option.
   - If you use the Oracle-provided script to configure secondary VNICS, ensure it runs automatically at startup.

Moving an Instance with Reboot Migration

After you complete the prerequisites:

1. Stop any running applications.
2. Use the Console, CLI, or SDK to reboot the instance.

   Important:
   Reboot migration does not support rebooting the instance from the operating system.

3. Confirm that the Reboot Maintenance field no longer has a date.

Moving an Instance with Manual Migration

For instances without a date in the Reboot Maintenance field (available in the Console, CLI, and SDKs), you must move the instance manually. This method requires that you terminate the instance, and then launch a new instance from the retained boot volume. Instances that have additional VNICS, secondary IP addresses, remote attached block volumes, or that belong to a backend set of a load balancer require additional steps.

Limitations and Warnings for Manual Migration

Be aware of the following limitations and warnings when performing a manual migration:

- Any public IP addresses assigned to your instance from a reserved public pool are retained. Any that were not assigned from a reserved public IP address pool will change. Private IP addresses do not change.
- MAC addresses, CPUIDs, and other unique hardware identifiers do change during the move. If any applications running on the instance use these identifiers for licensing or other purposes, be sure to take note of this information before moving the instance to help you manage the change.
Prerequisites for Manual Migration

1. Before moving the instance, document all critical details:
   - The instance’s region, availability domain, and fault domain.
   - The instance’s display name.
   - All private IP addresses, names, and subnets. Note that the instance can have multiple VNICs, and each VNIC can have multiple secondary IP addresses.
   - All private DNS names. The instance can have multiple VNICs, and each VNIC can have multiple secondary IP addresses. Each private IP address can have a DNS name.
   - Any public IP addresses assigned from a reserved public pool. Note that the instance can have multiple VNICs, and each VNIC can have multiple secondary private IP addresses. Each VNIC and secondary private IP address can have an attached public IP address.
   - Any remote block volumes attached to the instance.
   - Any tags on the instance or attached resources.

2. Prepare the instance for manual migration:
   - Ensure that any remote block volumes defined in /etc/fstab use the recommended options.
   - Ensure that any File Storage service (NFS) mounts use the nofail option.
   - If you have statically defined any network interfaces belonging to secondary VNICs using their MAC addresses, such as those defined in /etc/sysconfig/network-scripts/ifcfg*, those interfaces will not start due to the change in the MAC address. Remove the static mapping.
   - If you use the Oracle-provided script to configure secondary VNICs, ensure it runs automatically at startup.

Moving an Instance Manually

After you complete the prerequisites:

1. Stop any running applications.
2. Ensure that those applications will not start automatically.

   **Caution:**
   When the relocated instance starts for the first time, remote block volumes, secondary VNICs, or any resource that relies on them, will not be attached.
   The absence of these resources can cause application issues.

3. If your instance has local NVMe storage (dense instances), you must back up this data:
   a. Create and attach one or more remote block volumes to the instance.
   b. Copy the data from the NVMe devices to the remote block volumes.

4. Unmount any remote block volumes or File Storage service (NFS) mounts.
5. Back up all remote block volumes. See Overview of Block Volume Backups on page 710 for more information.
6. Create a backup of the root volume.

   **Important:**
   Do not generalize or specialize Windows instances.
7. Terminate the instance:

   **Using the Console**

   To terminate the instance, follow the steps in Terminating an Instance on page 1147, ensuring that the **Permanently delete the attached boot volume** check box is cleared. This preserves the boot volume that is associated with the instance.

   **Using the API**

   To terminate the instance, use the `TerminateInstance` operation and pass the `preserveBootVolume` parameter set to `true` in the request.

   **Using the CLI**

   To terminate the instance, use the `terminate` operation and set the `preserve-boot-volume` option to `true`.

8. Create a new instance using the boot volume from the terminated instance.

9. In the launch instance flow, specify the private IP address that was attached to the primary VNIC. If the public IP address was assigned from a reserved IP address pool, be sure to assign the same IP address.

10. When the instance state changes to **RUNNING**, **Stop** the instance.

11. Recreate any secondary VNICs and secondary IP addresses.

12. Attach any remote block volumes.

   **Note:**
   This step includes any volumes used to back up local NVMe devices. Copy the data onto the NVMe storage on the new instance, and then detach the volumes.

13. Start the instance.

15. Configure the applications to start automatically, as required.

16. Recreate the required tags.

17. (Optional) After you confirm that the instance and applications are healthy, you can delete the volume backups.

### Stopping and Starting an Instance

You can stop and start an instance as needed to update software or resolve error conditions.

For steps to manage the lifecycle state of instances in an instance pool, see Stopping and Starting the Instances in an Instance Pool on page 1066.

### Stopping or Restarting an Instance Using the Instance's OS

In addition to using the API and Console, you can stop and restart instances using the commands available in the operating system when you are logged in to the instance. Stopping an instance using the instance's OS does not stop billing for that instance. If you stop an instance this way, be sure to also stop it from the Console or API.

### Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users launch compute instances on page 2807 includes the ability to stop or start an existing instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only `manage instance-family`, and remove the statements involving `volume-family` and `virtual-network-family`. 
If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

**Resource Billing for Stopped Instances**

For both VM and bare metal instances, billing depends on the shape that you use to create the instance:

- **Standard shapes**: Stopping an instance pauses billing. However, stopped instances continue to count toward your service limits.
- **Dense I/O shapes**: Billing continues for stopped instances because the NVMe storage resources are preserved. Related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance.
- **GPU shapes**: Billing continues for stopped instances because GPU resources are preserved. Related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance.
- **HPC shapes**: Billing continues for stopped instances because the NVMe storage resources are preserved. Related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance.
- **Optimized shapes**: Stopping a VM instance pauses billing. However, stopped instances continue to count toward your service limits. Billing for bare metal instances continues for stopped instances because the NVMe storage resources are preserved. Related resources continue to count toward your service limits. To halt billing and remove related resources from your service limits, you must terminate the instance.

Stopping an instance using the instance's OS does not stop billing for that instance. If you stop an instance this way, be sure to also stop it from the Console or API.

For more information about Compute pricing, see Compute Pricing. For more information about how instances running Microsoft Windows Server are billed when they are stopped, see How am I charged for Windows Server on Oracle Cloud Infrastructure? on page 1172.

**Hardware Reclamation for Stopped Bare Metal Instances**

When a bare metal instance remains in the stopped state for longer than 48 hours, the instance is taken offline and the physical hardware is reclaimed. The next time that you restart the instance, it starts on different physical hardware. There are no changes to the block volumes, boot volumes, and instance metadata, including the ephemeral and public IP addresses.

However, the following properties do change when a bare metal instance restarts on different physical hardware: the MAC addresses and the host serial number. You might also notice changes in the BIOS firmware version, BIOS settings, and CPU microcode. If you want to keep the same physical hardware, do not stop the instance using the Console or the API, SDKs, or CLI. Instead, shut down the instance using the instance's OS. When you want to restart the instance, use the Console or the API, SDKs, or CLI.

This behavior applies to Linux instances that use the following shapes:

- BM.Standard1.36
- BM.Standard.B1.44
- BM.Standard2.52
- BM.Standard.E2.64

**Using the Console**

**To start an instance**

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click **Start**.

**To stop an instance**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Click **Stop**.
4. By default, the Console gracefully stops the instance by sending a shutdown command to the operating system. After waiting 15 minutes for the OS to shut down, the instance is powered off.

   **Note:**
   If the applications that run on the instance take more than 15 minutes to shut down, they could be improperly stopped, resulting in data corruption. To avoid this, **shut down the instance using the commands available in the OS** before you stop the instance using the Console.

   If you want to stop the instance immediately, without waiting for the OS to respond, select the **Force stop the instance by immediately powering off** check box.

5. Click **Stop Instance**.

**To reboot an instance**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Click **Reboot**.
4. By default, the Console gracefully restarts the instance by sending a shutdown command to the operating system. After waiting 15 minutes for the OS to shut down, the instance is powered off and then powered back on.

   **Note:**
   If the applications that run on the instance take more than 15 minutes to shut down, they could be improperly stopped, resulting in data corruption. To avoid this, **shut down the instance using the commands available in the OS** before you restart the instance using the Console.

   If you want to reboot the instance immediately, without waiting for the OS to respond, select the **Force reboot the instance by immediately powering off, then powering back on** check box.

5. Click **Reboot Instance**.

**Using the API**

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

Use the **InstanceAction** operation to stop, start, or reboot an instance.

**Recovering a Virtual Machine (VM) During Planned Maintenance**

See **Recovering a Virtual Machine (VM) During Planned Maintenance** on page 1149.

**VM Recovery Due to Infrastructure Failure**

See **VM Recovery Due to Infrastructure Failure** on page 1149.

**Terminating an Instance**

You can permanently terminate (delete) instances that you no longer need. Any attached VNICs and volumes are automatically detached when the instance terminates. Eventually, the instance's public and private IP addresses are released and become available for other instances.
By default, the instance's boot volume is preserved when you terminate the instance. You can attach the boot volume to a different instance as a data volume, or use it to launch a new instance. If you no longer need the boot volume, you can permanently delete it at the same time that you terminate the instance.

**Caution:**

If your instance has NVMe storage, terminating the instance securely erases the NVMe drives. Any data that was on the NVMe drives becomes unrecoverable. Ensure that you back up any important data before you terminate an instance. For more information, see Protecting Data on NVMe Devices.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users launch compute instances on page 2807 includes the ability to terminate an instance (with or without an attached block volume).

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see Details for the Core Services on page 2855.

**Using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Click **More Actions**, and then click **Terminate**.
4. If you want to delete the boot volume that is associated with the instance, select the **Permanently delete the attached boot volume** check box.
5. Click **Terminate Instance**.

Terminated instances temporarily remain in the list of instances with the state **Terminated**.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the **TerminateInstance** operation to terminate an instance.

**Infrastructure Maintenance**

Oracle Cloud Infrastructure performs routine data center maintenance on the physical infrastructure for virtual machine (VM) instances. This maintenance includes tasks such as upgrading and replacing hardware or performing maintenance that halts power to the host. This topic provides details about infrastructure maintenance, VM migration options, and status metrics for monitoring infrastructure maintenance.

When the underlying infrastructure for a virtual machine instance needs to undergo planned maintenance or recover from an unexpected failure, Oracle Cloud Infrastructure automatically attempts to recover the instance by migrating it to healthy hardware. When possible, the instance is **live migrated**. If live migration isn't possible, the instance is **reboot migrated**. You can use compute **infrastructure health metrics** to monitor the status of your compute instances during maintenance.
Recovering a Virtual Machine (VM) During Planned Maintenance

Oracle Cloud Infrastructure performs routine data center maintenance on the physical infrastructure for VM instances. When an underlying infrastructure component needs to undergo maintenance, by default, you are notified in advance before the impact to your instances.

During an infrastructure maintenance event, Oracle Cloud Infrastructure live migrates supported VM instances from the physical VM host that needs maintenance to a healthy VM host without disrupting running instances. By default, Oracle Cloud Infrastructure sends a notification about the upcoming maintenance event. After 14 to 16 days, the VM instances are live migrated if you do not proactively reboot the instance before the due date. Alternately, you can choose to have your instances automatically live migrated without a notification.

If a VM instance cannot be live migrated, then the instance is stopped on the physical VM host that needs maintenance and reboot migrated to a healthy VM host. A live migration might not succeed if any of the following events happens during the migration: there is too much activity on the instance, a change to the instance is made using the API, or an internal error unrelated to the instance occurs. If you have an alternate process to recover the instances, you can optionally configure the instances to remain stopped after they are reboot migrated to healthy hardware.

If VM instances are scheduled for a maintenance reboot, you can proactively reboot (or stop and start) the instances at any time before the scheduled reboot. Proactively rebooting lets you control how and when your applications experience downtime. Customer-managed VM maintenance is supported on Standard and GPU instance shapes, including platform images and custom images that were imported from outside of Oracle Cloud Infrastructure.

To identify the VM instances that you can proactively reboot, do any of the following things:

**Using the Console: To see which instances in the current compartment are scheduled for a maintenance reboot**

1. Open the navigation menu and click **Compute**, Under **Compute**, click **Instances**.
   
   If the instance has a maintenance reboot scheduled and can be proactively rebooted, a warning icon appears next to the instance name.

2. Click the instance that you're interested in, and then check the **Maintenance Reboot** field for the instance. This field displays the date and start time for the maintenance reboot.

**Using the API: To see which instances in a compartment are scheduled for a maintenance reboot**

Use the **ListInstances** operation. The **timeMaintenanceRebootDue** field for the **Instance** returns the date and start time for the maintenance reboot.

**Using Search: To find all instances that are scheduled for a maintenance reboot**

1. In the top navigation bar, click **Search for resources, services, and documentation**, and then click **Advanced Resource Query**.

2. Click **Select Sample Query**, and then click **Query for all instances which have an upcoming scheduled maintenance reboot**.

3. Click **Search**.

If you choose not to reboot before the scheduled time, Oracle Cloud Infrastructure migrates your instances within a 24-hour period after the scheduled time.

An instance is no longer impacted by a maintenance event when the **Maintenance Reboot** field for the instance is blank.

**VM Recovery Due to Infrastructure Failure**

When the underlying infrastructure of a VM instance fails because of software or hardware issues, Oracle Cloud Infrastructure automatically attempts to recover the instance.

Standard and GPU VM instances are recovered using a reboot migration, which automatically restores the VM on a healthy host, whether that's the original physical host or a different physical host. The VM failure is detected within one minute of occurrence. If the host cannot be recovered immediately, a healthy move occurs, whereby the VM is moved to a different host. In this scenario, the process of migrating to and restarting on a healthy host automatically
Compute begins within five minutes. During the reboot, instance properties such as private and ephemeral public IP addresses, attached block volumes, and VNICs are preserved.

Dense I/O VM instances are recovered by rebooting the instance on the same physical host. If recovering a Dense I/O instance on the same physical host isn't possible, Oracle Cloud Infrastructure notifies you to terminate the instance within 14 days. If you don't terminate the instance before the deadline, Oracle Cloud Infrastructure disables the instance on the deadline and terminates it within the next seven days. The boot volume and remote attached data volume are preserved.

Oracle Cloud Infrastructure notifies you by email or announcements of any VM infrastructure failure events, with the status of the recovery action that was taken. You can also monitor the instance status metric to stay aware of any unexpected reboots.

You can choose not to have your VMs automatically restart by configuring your instances to remain stopped after they are recovered.

**Live Migration**

During an infrastructure maintenance event, Oracle Cloud Infrastructure live migrates supported VM instances from the physical VM host that needs maintenance to a healthy VM host without disrupting running instances. By default, Oracle Cloud Infrastructure sends a notification about the upcoming maintenance event. After 14 to 16 days, the VM instances are live migrated if you do not proactively reboot the instance before the due date. Alternately, you can choose to have your instances automatically live migrated without a notification. If the instance can't be live migrated, reboot migration is used instead, and a short downtime occurs while the instance is reboot migrated.

When a live migration begins and ends, an event is emitted. For details about live migration event types, see Live Migration Event Types on page 2442. For information about creating automation to track events, see Getting Started with Events on page 2384.

**Supported Shapes and Images**

The following image series support live migration when they use Linux operating systems and paravirtualized networking.

- VM.Standard.E2 series
- VM.Standard2 series
- VM.Standard1 series
- VM.Standard.E3.Flex series

**Reboot Migration**

For instances with a date in the Reboot Maintenance field (available in the Console, CLI, and SDKs), the instance is stopped, migrated to a healthy host, and restarted. A short downtime occurs during the migration. You can control when the downtime occurs by proactively reboot migrating the instance before the maintenance due date. If you reboot the instance using the Console, CLI, or SDK, the Reboot Maintenance field is cleared. This change indicates that the instance was moved successfully.

**Important:**

Use the Console, CLI, or SDK to reboot migrate the instance. Rebooting the instance from the operating system does not migrate the instance to new hardware.

For steps to take to reboot migrate your instance before the maintenance due date, see Moving an Instance with Reboot Migration on page 1143.

After a migration, by default the instance is recovered to the same lifecycle state as before the maintenance event. If you have an alternate process to recover the instance after a reboot migration, you can configure the instance to remain stopped after it is migrated to healthy hardware. For more information about using the Console to configure
migration options including the lifecycle state of instances after a migration, see Setting Instance Availability During Maintenance Events on page 1137.

Infrastructure Health Metrics

You can use metrics, alarms, and notifications to monitor the maintenance status of the infrastructure that your compute instances run on. The three primary metrics to consider for infrastructure maintenance are instance_status, maintenance_status, and health_status.

• **Instance health (up/down) status:** The instance_status metric lets you check whether a VM or bare metal instance is available (up) or unavailable (down) when in the running state. If the instance is unavailable for more than 30 minutes, contact support.

• **Instance maintenance status:** The maintenance_status metric lets you monitor whether a VM instance is scheduled for planned infrastructure maintenance.

• **Bare metal infrastructure health status:** The health_status metric helps you monitor the health of the infrastructure for bare metal instances, including hardware components such as the CPU and memory.

For more detailed information about working with health metrics, see Infrastructure Health Metrics on page 1165.

Using the Console

You can also view the instance status and maintenance reboot notifications in the Console on the Instance Details page. To see these fields:

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in to open the Instance Details page.
3. On the Instance Information tab, under Instance Details, see Instance Status and Maintenance Reboot.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Instance Status field only displays if the instance was unavailable in the past month.</td>
</tr>
</tbody>
</table>

Compute Metrics and Monitoring

You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

For details about enabling monitoring for compute instances, see Compute Health Monitoring for Bare Metal Instances on page 1151 and Enabling Monitoring for Compute Instances on page 1154.

There are multiple Monitoring service metric namespaces related to compute resources:

• **oci_computeagent:** Metrics related to the activity level and throughput of compute instances, as emitted by the Compute Instance Monitoring plugin. See Compute Instance Metrics on page 1158. To enable monitoring for compute instance metrics, see Enabling Monitoring for Compute Instances on page 1154.

• **oci_instancepools:** Metrics related to the lifecycle state of instances in instance pools. See Instance Pool Metrics on page 1163.

• **oci_compute_infrastructure_health:** Metrics related to the up/down status, health, and maintenance status of compute instances. See Infrastructure Health Metrics on page 1165.

• **oci_compute:** Metrics related to the instance metadata service (IMDS) that provides information about running compute instances. See Compute Management Metrics on page 1167.

Compute Health Monitoring for Bare Metal Instances

Compute health monitoring for bare metal instances is a feature that provides notifications about hardware issues with your bare metal instances. With the health monitoring feature, you can monitor the health of the hardware for your bare metal instances, including components such as the CPU, motherboard, DIMM, and NVMe drives. You can use the notifications to identify problems, letting you proactively redeploy your instances to improve availability.
Health monitoring notifications are emailed to the tenant administrator within one business day of the error occurring. This warning helps you to take action before any potential hardware failure and redeploy your instances to healthy hardware to minimize the impact on your applications.

You can also use the infrastructure health metrics available in the Monitoring service to create alarms and notifications based on hardware issues.

**Error Messages and Troubleshooting**

This section contains information about the most common health monitoring error messages and provides troubleshooting suggestions for you to try for your bare metal instance.

**A fault has been detected in one or more CPUs**

**Fault class:** CPU

**Details:** This error indicates that a processor or one or more cores have failed in your instance. Your instance might be inaccessible or there might be fewer available cores than expected.

**Troubleshooting steps:**

- If the instance is inaccessible, you must replace it using the steps in [Moving a Compute Instance to a New Host](#) on page 1142.
- If your instance is available, check for the expected number of cores:
  - On Linux-based systems, run the following command:
    ```shell
    nproc --all
    ```
  - On Windows-based systems, open Resource Monitor.
    Compare the core count to the expected values documented in [Compute Shapes](#) on page 973. If the number of cores is less than expected and this reduction impacts your application, we recommend that you replace the instance using the steps in [Moving a Compute Instance to a New Host](#) on page 1142.

**A fault in the memory subsystem was detected during instance launch or a recent reboot**

**Fault class:** MEM-BOOT

**Details:** This error indicates that one or more failed DIMMs were detected in your instance while the instance was being launched or rebooted. Any failed DIMMs have been disabled.

**Troubleshooting steps:** The total amount of memory in the instance will be lower than expected. If this impacts your application, we recommend that you replace the instance using the steps in [Moving a Compute Instance to a New Host](#) on page 1142.

To check for the amount of memory in the instance:

- On Linux-based systems, run the following command:
  ```shell
  awk 'S3=="kB"{S2=$2/1024**2;S3="GB";} 1' /proc/meminfo | column -t | grep MemTotal
  ```
- On Windows-based systems, open Resource Monitor.

The expected values are documented in [Compute Shapes](#) on page 973.

**A fault in the memory subsystem was detected**

**Fault class:** MEM-RUNTIME

**Details:** This error indicates that one or more non-critical errors were detected on a DIMM in your instance. The instance might have unexpectedly rebooted in the last 72 hours.

**Troubleshooting steps:**
• If the instance has unexpectedly rebooted in the last 72 hours, one or more DIMMs might have been disabled. To check for the total amount of memory in the instance:
  • On Linux-based systems, run the following command:

```
awk '$3=="kB"{$2=$2/1024**2;$3="GB";} 1' /proc/meminfo | column -t | grep MemTotal
```
  • On Windows-based systems, open Resource Monitor.

If the total memory in the instance is lower than expected, then one or more DIMMs have failed. If this impacts your application, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host on page 1142.

• If the instance has not unexpectedly rebooted, it is at increased risk of doing so. During the next reboot, one or more DIMMs might be disabled. We recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host on page 1142.

A fault in the instance management controller has been detected

**Fault class:** MGMT-CONTROLLER

**Details:** This error indicates that a device used to manage your instance might have failed. You might not be able to use the Console, CLI, SDKs, or APIs to stop, start, or reboot your instance. This functionality will still be available from within the instance using the standard operating system commands. You also might not be able to create a console connection to your instance. You will still be able to terminate your instance.

**Troubleshooting steps:** If this loss of control impacts your application, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host on page 1142.

A fault in the PCI subsystem has been detected

**Fault class:** PCI

**Details:** This error indicates that one or more of the PCI devices in your instance have failed or are not operating at peak performance.

**Important:**

The PCI fault class will be deprecated in the future. You should migrate to the PCI-NIC fault class for similar functionality.

**Troubleshooting steps:**

• If you cannot connect to the instance over the network, the NIC might have failed. Use the Console or CLI to stop the instance and then start the instance. For steps, see Stopping and Starting an Instance on page 1145.

  If you're still unable to connect to the instance over the network, you might be able to connect to it using a console connection. Follow the steps in Connecting to the Serial Console on page 1185 or Connecting to the VNC Console on page 1189 to establish a console connection and then reboot the instance. If the instance remains inaccessible, you must replace it using the steps in Moving a Compute Instance to a New Host on page 1142.

• An NVMe device may have failed.

  On Linux-based systems, run the command `sudo lsblk` to get a list of the attached NVMe devices.

  On Windows-based systems, open Disk Manager. Check the count of NVMe devices against the expected number of devices in Compute Shapes on page 973.

  If you determine that an NVMe device is missing from the list of devices for your instance, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host on page 1142.

A fault in the instance network interface card (NIC) has been detected

**Fault class:** PCI-NIC

**Details:** This error indicates that one or more of the instance network interface card (NIC) devices in your instance have failed or are not operating at peak performance.
**Troubleshooting steps:** If you cannot connect to the instance over the network, the NIC might have failed. Use the Console or CLI to stop the instance and then start the instance. For steps, see Stopping and Starting an Instance on page 1145.

If you're still unable to connect to the instance over the network, you might be able to connect to it using a console connection. Follow the steps in Connecting to the Serial Console on page 1185 or Connecting to the VNC Console on page 1189 to establish a console connection and then reboot the instance. If the instance remains inaccessible, you must replace it using the steps in Moving a Compute Instance to a New Host on page 1142.

**A fault in the instance software defined network interface has been detected**

**Fault class:** SDN–INTERFACE

**Details:** If you cannot connect to the instance or if you're experiencing networking issues, the software-defined network interface device might have a fault.

**Troubleshooting steps:** Although restarting the instance might temporarily resolve the issue, we recommend that you replace the instance using the steps in Moving a Compute Instance to a New Host on page 1142.

---

**Enabling Monitoring for Compute Instances**

This topic describes how to enable monitoring, specifically for the compute instance metrics, on compute instances. The compute instance metrics provide data about the activity level and throughput of the instance. These metrics are required to use features such as autoscaling, metrics, alarms, and notifications with compute instances. A compute instance emits these metrics only when the Compute Instance Monitoring plugin is enabled and running on the instance.

The Compute Instance Monitoring plugin is managed by the Oracle Cloud Agent software.

**Supported Images**

Compute instance metrics are supported on current platform images and on custom images that are based on current platform images.

If you use an older platform image, you must manually install the Oracle Cloud Agent software before you can use the Compute Instance Monitoring plugin. Select an image dated after November 15, 2018 (except Ubuntu, which must be dated after February 28, 2019).

You might have success enabling compute instance metrics on other images that support the Oracle Cloud Agent software, though the Compute Instance Monitoring plugin has not been tested on other operating systems and there is no guarantee that it will work.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: For more information about the IAM policies that are needed to create and update a compute instance, see Creating an Instance on page 1023.
Prerequisites

• Service gateways or public IP addresses: The compute instance must have either a public IP address or a service gateway to be able to send compute instance metrics to the Monitoring service.

If the instance does not have a public IP address, set up a service gateway on the virtual cloud network (VCN). The service gateway lets the instance send compute instance metrics to the Monitoring service without the traffic going over the internet. Here are special notes for setting up the service gateway to access the Monitoring service:

• When creating the service gateway, enable the service label called All &lt;region&gt; Services in Oracle Services Network. It includes the Monitoring service.

• When setting up routing for the subnet that contains the instance, set up a route rule with Target Type set to Service Gateway, and the Destination Service set to All &lt;region&gt; Services in Oracle Services Network.

For detailed instructions, see Access to Oracle Services: Service Gateway on page 4127.

• Oracle Cloud Agent: The Oracle Cloud Agent software must be installed on the instance. Oracle Cloud Agent is installed by default on current platform images. For steps to manually install Oracle Cloud Agent on older images, see Installing the Oracle Cloud Agent Software on page 1091.

• Compute Instance Monitoring plugin: For the instance to emit the compute instance metrics, the Compute Instance Monitoring plugin must be enabled on the instance and plugins must be running. For more information about how to enable and run plugins, see Managing Plugins with Oracle Cloud Agent on page 1089.

Enabling Monitoring for a New Compute Instance

To configure a new compute instance to emit the compute instance metrics, use the following steps.

Creating a Monitoring-Enabled Instance Using the Console

1. Follow the steps to create an instance, until the advanced options. Ensure that the instance has either a public IP address or a service gateway, as described in the prerequisites.

2. Click Show Advanced Options.

3. On the Oracle Cloud Agent tab, select the Compute Instance Monitoring check box.

Note:

If you're using an older platform image or a custom image that is not based on a recent platform image, you must manually install the Oracle Cloud Agent software. You can do this by providing a cloud-init script. For more information, see Installing the Oracle Cloud Agent Software on page 1091. Compare the date of the image to the date listed in Supported Images.

4. Click Create.

The newly created, monitoring-enabled instance emits compute instance metrics to the Monitoring service.

Creating a Monitoring-Enabled Instance Using the API

Use the LaunchInstance operation. Include the following parameters:

```json
{
    "agentConfig": {
        "isMonitoringDisabled": false,
        "areAllPluginsDisabled": false,
        "pluginsConfig": [ {
            "name": "Compute Instance Monitoring",
            "desiredState": "ENABLED"
        } ]
    }
}
```
Ensure that the instance has either a public IP address or a service gateway, as described in the prerequisites.

**Note:**

If you're using an older platform image or a custom image that is not based on a recent platform image, you must manually install the Oracle Cloud Agent software. You can do this by providing a cloud-init script. For more information, see Installing the Oracle Cloud Agent Software on page 1091. Compare the date of the image to the date listed in Supported Images.

### Enabling Monitoring for an Existing Compute Instance

To configure an existing Compute instance to emit the compute instance metrics, use the following steps.

**To enable monitoring on an existing compute instance using the Console**

1. Install the Oracle Cloud Agent software, if it is not already installed.
2. Enable the Compute Instance Monitoring plugin.
3. Confirm that plugins are running on the instance.
4. Ensure that the instance has either a public IP address or a service gateway, as described in the prerequisites.
5. To confirm that monitoring is enabled:
   a. Go to the Metrics page for the instance:
      1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
      2. Click the instance that you're interested in.
      3. Under **Resources**, click **Metrics**.
      4. In the **Metric Namespace** list, select **oci_computeagent**.
   b. If you see metric charts with data, then the Monitoring service is receiving compute instance metrics from this instance. For more information about these metrics, see Compute Instance Metrics on page 1158.

   If monitoring is not enabled (and the instance uses a supported image), then a button is available to enable monitoring. Click **Enable monitoring**.

**To enable monitoring on an existing compute instance using the API**

1. Install the Oracle Cloud Agent software, if it is not already installed.
2. Use the **UpdateInstance** operation. Include the following parameters:

   ```json
   {
     "agentConfig": {
       "isMonitoringDisabled": false,
       "areAllPluginsDisabled": false,
       "pluginsConfig": [
         {
           "name": "Compute Instance Monitoring",
           "desiredState": "ENABLED"
         }
       ]
     }
   }
   ```

3. Ensure that the instance has either a public IP address or a service gateway, as described in the prerequisites.

### Managing the Compute Instance Monitoring Plugin

For an instance to emit the compute instance metrics, the Compute Instance Monitoring plugin must be enabled on the instance and plugins must be running.

If you want to temporarily prevent the instance from emitting compute instance metrics, you can disable the Compute Instance Monitoring plugin. You can also stop all of the plugins that run on the instance, including the Compute Instance Monitoring plugin.
Functionality that depends on the plugin, such as monitoring and autoscaling, does not work when the plugin is disabled or stopped.

For more information about how to enable and run plugins, see Managing Plugins with Oracle Cloud Agent on page 1089.

### Troubleshooting: Finding Out if Monitoring Has Your Metrics

To determine whether Monitoring is receiving the compute instance metrics, you can either query the instance metrics, or view the instance properties to confirm that the Compute Instance Monitoring plugin is enabled and running.

**Using the Console: To find out whether Monitoring is receiving metrics by querying instance metrics**

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
4. In the Metric Namespace list, select `oci_computeagent`.
   
   If you see metric charts with data, then the Monitoring service is receiving metrics from this instance. For more information about these metrics, see Compute Instance Metrics on page 1158.

   If you see a message that monitoring is not enabled, or that the Oracle Cloud Agent software needs to be installed, then complete those tasks.

**Using the Console: To find out whether the Compute Instance Monitoring plugin is enabled and running**

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Click the Oracle Cloud Agent tab.
4. Confirm that the Compute Instance Monitoring plugin is enabled, and all plugins are running.

**Using the API: To find out whether Monitoring is receiving metrics by querying instance metrics**

Use the SummarizeMetricsData API operation. If metrics are returned, it indicates that the Monitoring service is receiving metrics from the instance.

**Using the API: To find out whether the Compute Instance Monitoring plugin is enabled and running**

Use the GetInstance operation (or ListInstances operation, for multiple instances).

In the response, if the `agentConfig` object returns the following values, it indicates that the Compute Instance Monitoring plugin is enabled and all plugins are running.

```
{
    "agentConfig": {
        "isMonitoringDisabled": false,
        "areAllPluginsDisabled": false,
        "pluginsConfig": [
            {  
                "name": "Compute Instance Monitoring",
                "desiredState": "ENABLED"
            }
        ]
    }
}
```

### Not seeing metrics for your instance?

If you don't see any metric charts, the instance might not be emitting metrics. See the following possible causes and resolutions.
Possible cause | How to check | Resolution |
---|---|---|
The Compute Instance Monitoring plugin is disabled on the instance or plugins are stopped. | Review the instance properties. | Enable the Compute Instance Monitoring plugin and start all plugins. |
The instance cannot access the Monitoring service because its VCN does not use the internet. | Review the instance's IP address. If it's not public, then a service gateway is needed. | Set up a service gateway. |
The instance does not use a supported image. | Review the supported images. | Create an instance with a supported image. |
Older images and custom images: No Oracle Cloud Agent software exists on the instance. | Connect to the instance and look for the software. | Install the Oracle Cloud Agent software. |
Something else is wrong with the Oracle Cloud Agent software. | (not applicable) | Follow the troubleshooting steps for Oracle Cloud Agent. |

### Compute Instance Metrics

You can monitor the health, capacity, and performance of your compute instances by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_computeagent` (the Compute Instance Monitoring plugin on compute instances).

You can view these metrics for individual compute instances, and for all the instances in an instance pool.

Resources: Monitoring-enabled compute instances.

#### Overview of Metrics for an Instance and Related Resources

This section gives an overall picture of the different types of metrics available for an instance and its storage and network devices. See the following diagram and table for a summary.
### Available Metrics: oci_computeagent

The compute instance metrics help you measure activity level and throughput of compute instances. The metrics listed in the following table are available for any monitoring-enabled compute instance. You must enable monitoring on the instance to get these metrics.

The metrics in this namespace are aggregated across all the related resources on the instance. For example, `DiskBytesRead` is aggregated across all the instance's attached storage volumes, and `NetworkBytesIn` is aggregated across all the instance's attached VNICs.

You also can use the Monitoring service to create custom queries.

Each metric includes the following dimensions:

- **availabilityDomain**
  The `availability domain` where the instance resides.

- **faultDomain**
  The `fault domain` where the instance resides.
imageId

The OCID of the image for the instance.

instancePoolId

The instance pool that the instance belongs to.

region

The region where the instance resides.

resourceDisplayName

The friendly name of the instance.

resourceId

The OCID of the instance.

shape

The shape of the instance.

<td>Network transmission throughput. Expressed as bytes transmitted.</td>
<td></td>
</tr>
</tbody>
</table>

1. This metric is a cumulative counter that shows monotonically increasing behavior for each session of the Oracle Cloud Agent software, resetting when the operating system is restarted.

2. The Networking service provides additional metrics (in the **oci_vcn** metric namespace) for each VNIC on the instance. For more information, see Networking Metrics on page 4211.

3. The Block Volume service provides additional metrics (in the **oci_blockstore** metric namespace) for each volume attached to the instance. For more information, see Block Volume Metrics on page 770.

### Using the Console

**To view default metric charts for a single Compute instance**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Metrics**.
4. In the **Metric Namespace** list, select **oci_computeagent**.

   The Metrics page displays a default set of charts for the current instance.

**Not seeing any metric charts for the instance?**

If you don't see any metric charts, the instance might not be emitting metrics. See the following possible causes and resolutions.

<table>
<thead>
<tr>
<th>Possible cause</th>
<th>How to check</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Compute Instance Monitoring plugin is disabled on the instance or plugins are stopped.</td>
<td>Review the instance properties.</td>
<td>Enable the Compute Instance Monitoring plugin and start all plugins.</td>
</tr>
<tr>
<td>The instance cannot access the Monitoring service because its VCN does not use the internet.</td>
<td>Review the instance's IP address. If it's not public, then a service gateway is needed.</td>
<td>Set up a service gateway.</td>
</tr>
</tbody>
</table>
### Possible cause | How to check | Resolution
--- | --- | ---
The instance does not use a supported image. | Review the supported images. | Create an instance with a supported image.
Older images and custom images: No Oracle Cloud Agent software exists on the instance. | Connect to the instance and look for the software. | Install the Oracle Cloud Agent software.
Something else is wrong with the Oracle Cloud Agent software. | (not applicable) | Follow the troubleshooting steps for Oracle Cloud Agent.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

**To view default metric charts for resources related to a Compute instance**

- **For an attached block volume:** While viewing the instance's details, under Resources, click Attached Block Volumes, and then click the volume that you're interested in. Click Metrics to see the volume's charts. For more information about the emitted metrics, see Block Volume Metrics on page 770.
- **For the attached boot volume:** While viewing the instance's details, under Resources, click Boot Volume, and then click the volume that you're interested in. Click Metrics to see the volume's charts. For more information about the emitted metrics, see Block Volume Metrics on page 770.
- **For an attached VNIC:** While viewing the instance's details, under Resources, click Attached VNICs, and then click the VNIC that you're interested in. Click Metrics to see the charts for the VNIC. For more information about the emitted metrics, see Networking Metrics on page 4211.

**To view default metric charts for all Compute instances in a compartment**

2. Select a compartment.
3. For Metric Namespace, select oci_computeagent.

   The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

**To view default metric charts for the instances in an instance pool**

1. Open the navigation menu and click Compute. Under Compute, click Instance Pools.
2. Click the instance pool that you're interested in.
4. In the Metric Namespace list, select oci_computeagent.

   The Metrics page displays a default set of charts for the current instance pool.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following APIs for monitoring:

- **Monitoring API** for metrics and alarms
- **Notifications API** for notifications (used with alarms)
**Instance Pool Metrics**

You can monitor the health, capacity, and performance of your Compute instance pools by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_instancepools`.

Resources: Compute instances pools.

**Overview of Metrics: oci_instancepools**

The instance pool metrics help you monitor the lifecycle state of instances in your instance pools.

**Required IAM Policy**

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

**Available Metrics: oci_instancepools**

The metrics listed in the following table are automatically available for each instance pool that you create. You do not need to enable monitoring on the instances in the pool to get these metrics.

You also can use the Monitoring service to create custom queries.

Depending on the metric, the following dimensions are available:

- **AvailabilityDomain**
  - The availability domain where the instance pool resides.

- **displayName**
  - The friendly name of the instance pool.

- **FaultDomain**
  - The fault domain where the instance pool resides.

- **region**
  - The region where the instance pool resides.

- **resourceId**
  - The OCID of the instance pool.

<td>AvailabilityDomain DisplayName FaultDomain region resourceId</td>
</tr>
</tbody>
</table>

Using the Console

To view default metric charts for a single instance pool

1. Open the navigation menu and click Compute. Under Compute, click Instance Pools.
2. Click the instance pool that you're interested in.
4. In the Metric Namespace list, select oci_instancepools.

The Metrics page displays a default set of charts for the current instance pool.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

To view default metric charts for all instance pools in a compartment

2. Select a compartment.
3. For Metric Namespace, select oci_instancepools.

The Service Metrics page dynamically updates the page to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
• Notifications API for notifications (used with alarms)

Infrastructure Health Metrics

You can monitor the health, capacity, and performance of the infrastructure for your Compute virtual machine (VM) and bare metal instances by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_compute_infrastructure_health`.

Resources: Compute instances.

Overview of Metrics: `oci_compute_infrastructure_health`

The compute infrastructure health metrics help you monitor the status and health of compute instances.

• **Instance health (up/down) status:** The `instance_status` metric lets you check whether a VM or bare metal instance is available (up) or unavailable (down) when in the running state. If the instance is unavailable for more than 30 minutes, contact support.

• **Instance maintenance status:** The `maintenance_status` metric lets you monitor whether a VM instance is scheduled for planned infrastructure maintenance.

• **Bare metal infrastructure health status:** The `health_status` metric helps you monitor the health of the infrastructure for bare metal instances, including hardware components such as the CPU and memory.

Based on the value of the metrics, you can proactively move affected instances to healthy hardware and thereby minimize the impact on your applications.

Required IAM Policy

To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: `oci_compute_infrastructure_health`

The metrics listed in the following table are automatically available for your instances. The `instance_status` metric is available for both VM and bare metal instances, the `maintenance_status` metric is available only for VM instances, and the `health_status` metric is available only for bare metal instances. You do not need to enable monitoring on the instance to get these metrics.

You also can use the Monitoring service to create custom queries.

The metric includes the following dimensions:

**faultClass**

The type of hardware issue:

• **CPU:** A fault has been detected in one or more CPUs.
• **MEM–BOOT:** A fault in the memory subsystem was detected during instance launch or a recent reboot.
• **MEM–RUNTIME:** A fault in the memory subsystem was detected.
• **MGMT–CONTROLLER:** A fault in the instance management controller has been detected.
• **PCI:** A fault in the PCI subsystem has been detected.
• **PCI–NIC:** A fault in the instance network interface card (NIC) has been detected.
• **SDN–INTERFACE:** A fault in the instance software defined network interface has been detected.

For troubleshooting suggestions and more information about these hardware issues, see Compute Health Monitoring for Bare Metal Instances on page 1151.
resourceDisplayName

The friendly name of the instance.

resourceId

The OCID of the instance.

maintenanceDueTime

The scheduled start time of the 24-hour maintenance window, in the format defined by RFC3339.

computeMaintenanceAction

The action that Oracle Cloud Infrastructure will perform on an instance during a scheduled maintenance event:

- **REBOOT**: The instance is migrated from the physical VM host that needs maintenance to a healthy VM host. If live migration is not possible, then the instance is reboot migrated.

recommendedAction

The action that you can take before the scheduled maintenance event, so that you can control how and when your applications experience downtime.

- **REBOOT**: You can proactively reboot the instance before the scheduled maintenance time. When you reboot an instance for maintenance, the instance is stopped on the physical VM host that needs maintenance, and then restarted on a healthy VM host. For more information, see Moving a Compute Instance to a New Host on page 1142.

</table>
### Compute Management Metrics

You can monitor requests to the instance metadata service on compute virtual machine (VM) and bare metal instances by using metrics, alarms, and notifications.

This topic describes the metrics emitted by the metric namespace `oci_compute`.

**Resources:** compute instances.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>maintenance_status</td>
<td>Maintenance Status</td>
<td>Count</td>
<td>The maintenance status of a VM instance. A value of 0 indicates that the instance is not scheduled for an infrastructure maintenance event. A value of 1 indicates that the instance is scheduled for an infrastructure maintenance event.</td>
<td>maintenanceDueTime, computeMaintenanceAction, recommendedAction, resourceDisplayName, resourceId</td>
</tr>
</tbody>
</table>

### Using the Console

#### To view infrastructure health metrics for a single Compute instance

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Metrics**.
4. In the **Metric Namespace** list, select `oci_compute_infrastructure_health`.

The Metrics page displays a default set of charts for the current instance.

For more information about monitoring metrics and using alarms, see **Monitoring** on page 3458. For information about notifications for alarms, see **Notifications Overview** on page 4248.

#### To view infrastructure health metrics for all Compute instances in a compartment

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Service Metrics**.
2. Select a compartment.
3. For **Metric Namespace**, select `oci_compute_infrastructure_health`.

The **Service Metrics** page dynamically updates to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see **Monitoring** on page 3458. For information about notifications for alarms, see **Notifications Overview** on page 4248.

### Using the API

For information about using the API and signing requests, see **REST APIs** on page 5528 and **Security Credentials** on page 207. For information about SDKs, see **Software Development Kits and Command Line Interface** on page 5351.

Use the following APIs for monitoring:

- **Monitoring API** for metrics and alarms
- **Notifications API** for notifications (used with alarms)

### Compute Management Metrics

Continue with the description of the metrics emitted by the metric namespace `oci_compute`.

**Resources:** compute instances.
Overview of Metrics: oci_compute
The instance metadata service (IMDS) provides metadata about an instance, its attached VNICs, and custom metadata that you supply. IMDS is available in two versions, version 1 and version 2. IMDSv2 offers increased security compared to the legacy v1.

Use the Compute management metric to identify requests to the legacy v1 endpoints. After you migrate any applications to support the v2 endpoints, you can disable all requests to the legacy v1 endpoints.

Required IAM Policy
To monitor resources, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

Available Metrics: oci_compute
The metric listed in the following table is automatically available for your instances. You do not need to enable monitoring on the instance to get this metric.

You also can use the Monitoring service to create custom queries.

The metric includes the following dimensions:

- **metadataVersion**
  The version of the instance metadata service that requests were made to.
- **path**
  The URL path that instance metadata requests were made to.
- **resourceId**
  The OCID of the instance.
- **userAgent**
  The source of the instance metadata request.
- **status**
  The HTTP response code for requests to instance metadata service.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Metric Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>InstanceMetadataRequests</td>
<td>Instance Metadata Requests V1 Versus V2</td>
<td>Sum</td>
<td>The number of requests to the instance metadata service, comparing the version 1 and version 2 endpoints.</td>
<td>metadataVersion path resourceId userAgent status</td>
</tr>
</tbody>
</table>

Using the Console

To view management metrics for a single compute instance

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
4. In the **Metric Namespace** list, select **oci_compute**.

The Metrics page displays a default set of charts for the current instance.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

To view management metrics for all compute instances in a compartment

1. Open the navigation menu and click **Observability & Management**. Under **Monitoring**, click **Service Metrics**.
2. Select a compartment.
3. For **Metric Namespace**, select **oci_compute**.

The Service Metrics page dynamically updates to show charts for each metric that is emitted by the selected metric namespace.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following APIs for monitoring:

- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)

**Compute NVMe Performance**

The content in the sections below apply to **Category 7** and **Section 3.a** of the Oracle PaaS and IaaS Public Cloud Services Pillar documentation.

Oracle Cloud Infrastructure provides a variety of instance configurations in both bare metal and virtual machine (VM) shapes. Each shape varies on multiple dimensions including memory, CPU cores, network bandwidth, and the option of local NVMe SSD storage found in DenseIO and HPC shapes.

Oracle Cloud Infrastructure provides a service-level agreement (SLA) for NVMe performance. Measuring performance is complex and open to variability.

An NVMe drive also has non-uniform drive performance over the period of drive usage. An NVMe drive performs differently when tested brand new compared to when tested in a steady state after some duration of usage. New drives have not incurred many write/erase cycles and the inline garbage collection has not had a significant impact on IOPS performance. To achieve the goal of reproducibility and reduced variability, our testing focuses on the steady state duration of the NVMe drive’s operation.

**Testing Methodology**

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before running any tests, protect your data by making a backup of your data and operating system environment to prevent any data loss. The tests described in this document will overwrite the data on the disk, and cause data corruption.</td>
</tr>
</tbody>
</table>

**Summary:** To capture the IOPS measure, first provision a shape such as the BM.DenseIO2.52 shape, and then use the Gartner Cloud Harmony test suite to run tests on an instance running the latest supported Oracle Linux 7 image for each NVMe drive target.

**Instructions:**

1. Launch an instance based on the latest supported Oracle Linux 7 image and select a shape such as the BM.DenseIO2.52 shape. For instructions, see Creating an Instance on page 1023.
Run the Gartner Cloud Harmony test suite tests on the instance for each NVMe drive target. The following is an example of a command that will work for all shapes and drives on the shape:

```
sudo ./run.sh `ls /dev/nvme[0-9]n1 | sed -e 's/\//\--target=\//\''
--nopurge --noprecondition --fio_direct=1 --fio_size=10g --test=iops
--skip_blocksize=512b --skip_blocksize=8k --skip_blocksize=16k
--skip_blocksize=32k --skip_blocksize=64k --skip_blocksize=128k
--skip_blocksize=1m
```

The SLA for NVMe drive performance is measured against 4k block sizes with 100% random write workload on DenseIO shapes where the drive is in a steady state of operation.

**Performance Benchmarks**

The following table lists the minimum IOPS for the specified shape to meet the SLA, given the testing methodology with 4k block sizes for 100% random write tests using the tests described in the previous section.

<table>
<thead>
<tr>
<th>Shape</th>
<th>Minimum Supported IOPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM.DenseIO1.4</td>
<td>200k</td>
</tr>
<tr>
<td>VM.DenseIO1.8</td>
<td>250k</td>
</tr>
<tr>
<td>VM.DenseIO1.16</td>
<td>400k</td>
</tr>
<tr>
<td>BM.DenseIO1.36</td>
<td>2.5MM</td>
</tr>
<tr>
<td>VM.DenseIO2.8</td>
<td>250k</td>
</tr>
<tr>
<td>VM.DenseIO2.16</td>
<td>400k</td>
</tr>
<tr>
<td>VM.DenseIO2.24</td>
<td>800k</td>
</tr>
<tr>
<td>BM.DenseIO2.52</td>
<td>3.0MM</td>
</tr>
<tr>
<td>BM.HPC2.36</td>
<td>250k</td>
</tr>
</tbody>
</table>

Although the NVMe drives are capable of higher IOPS, Oracle Cloud Infrastructure currently guarantees this minimum level of IOPS performance.

**Frequently Asked Questions**

**Q:** I suspect a slowdown in my NVMe drive performance. Is there a SLA violation?

**A:** We test hosts on a regular basis to ensure that our low-level software updates do not regress performance. If you have reproduced the testing methodology and your drive’s performance does not meet the terms in the SLA, please contact your Oracle sales team.

**Q:** Why does the testing methodology not represent a diversity of IO workloads such as random reads and writes to reflect real-world IO?

**A:** We focused on reproducibility and believe the tests provide a significant indicator of overall drive performance.

**Q:** Will Oracle Cloud Infrastructure change the tests in this document?

**A:** We will make changes to provide greater customer value through better guarantees and improved reproducibility.

**Microsoft Licensing on Oracle Cloud Infrastructure**

This topic provides information about the licensing requirements to use Microsoft products on Oracle Cloud Infrastructure.
For more information about how to bring your own Microsoft licenses to Oracle Cloud Infrastructure, see Licensing Options for Microsoft Windows on page 1177.

For information about how to move eligible Microsoft server application licenses to Oracle Cloud Infrastructure by enrolling in the License Mobility through Microsoft Software Assurance benefit, see Moving Microsoft Licenses to Oracle Cloud Infrastructure: Microsoft License Mobility on page 1178.

**Using Microsoft Windows on Oracle Cloud Infrastructure: FAQ**

Oracle Cloud Infrastructure is licensed to provide Microsoft software offerings. Oracle is a member of the Microsoft Partner Network, licensed to sell Microsoft software under the Service Provider License Agreement (SPLA). Oracle is also an authorized Microsoft Authorized Mobility Partner with an active Premier Support for Partners agreement with Microsoft.

For the latest Microsoft licensing requirements, refer to the Microsoft Product Terms.

If you can't find the answer to your question here, or you need more assistance running Microsoft products on Oracle Cloud Infrastructure, contact Oracle Support.

**General Questions**

**What OS editions of Microsoft Windows Server are supported?**

**Platform images**

These Windows versions are available for platform images:

- Windows Server 2012 R2 Standard, Datacenter
- Windows Server 2016 Standard, Datacenter
- Windows Server 2019 Standard, Datacenter

**Bring Your Own Image (BYOI)**

These Windows versions support custom image import:

- Windows Server 2012 Standard, Datacenter
- Windows Server 2012 R2 Standard, Datacenter
- Windows Server 2016 Standard, Datacenter
- Windows Server 2019 Standard, Datacenter

If you don't need to migrate your Windows OS licenses, you can use the Bring Your Own Image process to migrate your Windows image to Oracle Cloud Infrastructure.

**Is Windows Server 2019 available as a platform image?**

Yes, Windows Server 2019 is available as a platform image.

**Is Windows Server 2019 available as a Bring Your Own Image (BYOI) image?**

Yes, you can import your own Windows Server 2019 image for virtual machines only. For source image requirements and steps to import an image, see Importing Custom Windows Images on page 1002.

**What VM and bare metal options are available for Windows Server operating systems?**

The following table shows support for Microsoft Windows Server operating systems on Oracle Cloud Infrastructure.

<table>
<thead>
<tr>
<th>Use Case</th>
<th>Bare Metal Machines</th>

</tr>
</tbody>
</table>

Does Oracle Cloud Infrastructure support Bring Your Own Image (BYOI) for Windows Server?

Yes, you are permitted to import your own generalized custom image of Windows Server.

When you create an instance with an imported image on a VM or a shared bare metal machine, Oracle Cloud Infrastructure licenses the instance. For more information about imported images, see Creating Windows Custom Images on page 992.

If you want to use your own license, BYOI is supported only for bare metal machines on a dedicated host.

How am I charged for Windows Server on Oracle Cloud Infrastructure?

The cost of a Microsoft Windows Server license is an additional cost, on top of the underlying Compute instance price. You pay separately for the Compute instance and the Windows Server license. For more information about Microsoft Windows Server pricing, see Compute Pricing.

Billing for the Windows Server license is based on per-OCPU, per-second usage. Billing starts when an instance is in the "running" state and ends when you terminate (delete) the instance.

When an instance is stopped, billing for the Windows Server license depends on the shape that was used to create the instance. Billing pauses for instances that use a Standard shape. Billing continues for instances that use a Dense I/O shape, GPU shape, or HPC shape. Depending on the shape, you might also be billed for the underlying Compute instance when the instance is stopped.

How does Windows Server get updated with the latest patches?

You must update your VCN's security list to enable egress traffic for port 80 (HTTP) and port 443 (HTTPS) to install patches from Microsoft. Oracle Cloud Infrastructure enables automatic updates for Microsoft Windows Server and uses the default settings for applying Windows Server patches.

Can I take a snapshot image after customizing a running Window Server instance?

Yes, there are several options available on both bare metal and virtual machines:

- **Create a custom image**: Creates a custom image that you can use to launch other instances. Instances that you launch from your image include the customizations, configuration, and software installed when you created the image.
- **Clone a boot volume**: Makes a copy of an existing boot volume without needing to go through the backup and restore process. A boot volume clone is a point-in-time direct disk-to-disk deep copy of the source boot volume, so all the data that is in the source boot volume when the clone is created is copied to the boot volume clone.
- **Back up a block volume**: Makes a point-in-time backup of data on a block volume. You can restore a backup to a new volume either immediately after a backup or at a later time that you choose.
• **Back up a boot volume**: Makes a backup of a boot volume. Boot volume backup capabilities are the same as block volume backup capabilities and are in-region only. Windows boot volume backups cannot be copied across regions.

**Can I export a custom Windows Server image?**

Yes, exporting custom Windows Server operating system images is supported. When exporting Windows-based images, you are responsible for complying with the Microsoft Product Terms and all product use conditions, as well as verifying your compliance with Microsoft. For steps to export an image, see Image Import/Export on page 993.

**What support is available for Microsoft Windows Server on Oracle Cloud Infrastructure?**

Oracle Support provides limited assistance for Microsoft Windows Server platform images if the Windows Server version has not reached end of support with Microsoft. All other Microsoft software is supported directly by Microsoft Support. Oracle Support can help verify that the operating system boots, that the operating system connects to the network, and that attached storage connects and performs as expected. If you encounter other issues with Microsoft Windows Server, work directly with Microsoft Support to resolve the issue. For more information, see Support Options for Microsoft Windows on page 1179.

**How do I upgrade to a newer version of Windows Server?**

To upgrade to a newer version of Windows Server, you can do either of the following things:

• Obtain the installation media from Microsoft or your Microsoft reseller, and then upgrade the existing Compute instance. The license issued by Oracle Cloud Infrastructure remains in effect.
• Create a new Compute instance using the desired version of the Windows Server platform image, and then migrate your applications and data to the new instance.

**Licensing - Windows Server**

**What is BYOL?**

BYOL stands for "bring your own license." BYOL lets you use software licenses that you already own to deploy software on Oracle Cloud Infrastructure, without any additional licensing fees. This process uses the License Mobility through Microsoft Software Assurance benefit provided by Microsoft. You must have active Software Assurance with Microsoft to bring your licenses to Oracle Cloud Infrastructure.

**What is Microsoft License Mobility?**

License Mobility through Software Assurance is a Microsoft benefit that permits you to move your eligible Microsoft licenses to cloud service providers such as Oracle Cloud Infrastructure. Oracle is an Authorized Mobility Partner for License Mobility.

With License Mobility through Software Assurance, you can deploy eligible application servers on bare metal hosts or virtual shared hardware in Oracle Cloud Infrastructure. An example of an application eligible for License Mobility through Software Assurance is Microsoft SQL. Windows Server operating systems are not eligible.

You may move Microsoft licenses from on-premises or another Authorized Mobility Partner only after more than 90 days have passed since the last license move.

For more information about this Microsoft benefit, see License Mobility through Microsoft Software Assurance. For steps to move your Microsoft licenses to Oracle Cloud Infrastructure, see Moving Microsoft Licenses to Oracle Cloud Infrastructure: Microsoft License Mobility on page 1178.

**Is Oracle a Microsoft Authorized Mobility Partner?**

Yes, Oracle is an Authorized Mobility Partner for the Microsoft License Mobility through Software Assurance benefit.
Can I bring my own license for Microsoft Windows Server to Oracle Cloud Infrastructure?

Yes. You can bring your own license (BYOL) for Microsoft Windows Server on a dedicated bare metal or dedicated virtual machine host, subject to the Microsoft Product Terms. You are responsible for managing your own licenses to maintain compliance with Microsoft licensing terms. For more information, see Licensing Options for Microsoft Windows on page 1177.

The following table shows the BYOL requirements for Microsoft licenses on Oracle Cloud Infrastructure.

<table>
<thead>
<tr>
<th>Microsoft License</th>
<th>Bare Metal Machines and Dedicated Virtual Machine Hosts</th>
<th>Virtual Machines (Multi-Tenant Shared Host)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows Server</td>
<td>BYOL on a bare metal dedicated host is only eligible when using a KVM hypervisor. BYOL is not eligible for Microsoft Windows Server using platform images or when importing your own Microsoft Windows Server image.</td>
<td>Not eligible. Shared hosts must use platform images that include the Microsoft license.</td>
</tr>
<tr>
<td>SQL Server</td>
<td>Eligible. You must have License Mobility through Software Assurance.</td>
<td>Eligible. You must have License Mobility through Software Assurance.</td>
</tr>
<tr>
<td>Subject to the Microsoft Product Terms</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Microsoft 365 Apps for enterprise</td>
<td>Eligible.</td>
<td>Not eligible.</td>
</tr>
<tr>
<td>(Office 365 ProPlus) and Office</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Professional Plus</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Windows 7, Windows 8, and Windows 10</td>
<td>Eligible. You must have an Enterprise Agreement license with Software Assurance or a Windows Virtual Desktop Access (VDA) license.</td>
<td>Not eligible.</td>
</tr>
<tr>
<td>Other Microsoft applications</td>
<td>Eligible. Subject to the Microsoft Product Terms.</td>
<td>Eligible. You must have License Mobility through Software Assurance.</td>
</tr>
</tbody>
</table>

Application licenses such as SQL Server or System Center require License Mobility through Software Assurance when running on Oracle Cloud Infrastructure VM instances. License Mobility is not used for Microsoft Office, Windows clients, or Windows Server BYOL. Review the Microsoft Product Terms to validate which applications support License Mobility.

Direct questions about your licensing rights to Microsoft or your Microsoft reseller.

Can I use virtual machines and bring my own license for Microsoft Windows Server to Oracle Cloud Infrastructure?

You cannot migrate your Windows Server OS licenses when using Oracle Cloud Infrastructure virtual machines. However, you can bring your own hypervisor (KVM) to run a Windows Server VM with your own Windows Server OS license.
The following restrictions apply:

- You can use VMs with their own license only if you use bring your own hypervisor on a dedicated bare metal host.
- BYOL of Microsoft Windows Server is not supported for VMs running on a shared host. Oracle Cloud Infrastructure-provided VMs offer Windows Server.
  - You can use a bare metal instance under bring your own hypervisor.
  - You must install and manage a hypervisor (KVM or Hyper-V) and launch your own VMs. This will ensure isolation, because all Oracle VMs are running on a dedicated bare metal server.
- BYOL on a dedicated host (KVM hypervisor only) is permitted for Microsoft Windows Server.
- VMs can run Windows Server with a Visual Studio (MSDN) subscription license when used for development use only.

**Licensing - Other Microsoft Software**

**What other Microsoft applications can I bring to Oracle Cloud Infrastructure?**

Any Microsoft Server licenses permitted on Oracle Cloud Infrastructure must be eligible according to the latest Microsoft Product Terms. It is your responsibility to verify that the licensing agreements with Microsoft permit you to bring on-premises perpetual Microsoft licenses to Oracle Cloud Infrastructure and are eligible licensed products according to the latest Microsoft Product Terms. Microsoft application products that are currently eligible for License Mobility require an active Software Assurance benefit to move your license. For more information, see Moving Microsoft Licenses to Oracle Cloud Infrastructure: Microsoft License Mobility on page 1178.

**Can I bring my own SQL Server license to Oracle Cloud Infrastructure?**

Yes, you can bring your own SQL Server license using License Mobility through Active Software Assurance. The following restrictions apply:

- When you move your Microsoft SQL license using the license mobility process, the Microsoft Windows Server license is not included. Microsoft Windows Server licenses are not permitted to be moved under License Mobility. Windows Server operating systems must use the license issued by Oracle Cloud Infrastructure.
- Perpetual licenses can be moved from on-premises or other cloud providers only after more than 90 days have passed since the last license move.
- End-of-support versions are not supported on shared host virtual machines on Oracle Cloud Infrastructure.

Follow the license mobility process to move your SQL Server license to Oracle Cloud Infrastructure.

**Can I use my Visual Studio (MSDN) license on Microsoft Windows Server on Oracle Cloud Infrastructure?**

Yes, you can use your Visual Studio (MSDN) subscription license for non-production purposes on Oracle Cloud Infrastructure on either bare metal or virtual machine instances. You are responsible for complying with the Visual Studio subscription terms.

**Can I buy a Visual Studio (MSDN) subscription from Oracle Cloud Infrastructure?**

No, Oracle does not sell Visual Studio (MSDN) subscriptions. Contact Microsoft or your Microsoft reseller.

**Can I use a Visual Studio (MSDN) license for a production environment?**

No, Visual Studio (MSDN) subscription licenses are for development, testing, or demonstration purposes only.

**How can I remote access to a Windows Server instance on Oracle Cloud Infrastructure?**

Follow the steps to connect to a Windows instance. Windows operating systems permit remote access for a maximum of two users using Remote Desktop Services (RDS) for Administration purposes.

RDS Client Access Licenses (CALs) are required for each user or device using Remote Desktop.

**Does Oracle Cloud Infrastructure offer additional Remote Desktop Services licenses for applications running on Windows VMs?**

No, Oracle Cloud Infrastructure does not offer Microsoft RDS (Remote Desktop Server) Subscriber Access Licenses (SALs). You can bring your own license (BYOL) and use your RDS Client Access Licenses (CALs) on Oracle Cloud Infrastructure.
Compute

Infrastructure bare metal or virtual machines only if you have active Software Assurance coverage and move those licenses using the license mobility process.

Can I bring my own RDS CALs if I want more than two users to access my Windows Server instance?

Yes, you can use your Remote Desktop Services (RDS) Client Access Licenses (CALs) on Oracle Cloud Infrastructure if you use the Oracle Cloud Infrastructure bare metal offering. In addition, you can use virtual machines with their own Visual Studio (MSDN) subscription license if you bring your own hypervisor (KVM).

You can use your RDS CAL licenses on Oracle Cloud Infrastructure virtual machines only if you have active Software Assurance coverage and move your CALs using the license mobility process.

Can I bring my own System Center Management Licenses to Oracle Cloud Infrastructure?

You can bring Microsoft System Center server Management Licenses (server MLs) using the license mobility process. There are minimums to take into consideration with System Center Management License 2-core licenses and 16-core licenses. A virtual machine requires a minimum of 16 core licenses to be assigned to it, and more if the VM has more than 16 virtual cores.

System Center client Management Licenses (client MLs) are not eligible for license mobility and cannot be moved to Oracle Cloud Infrastructure.

Other Windows Server Questions

Are there user data capabilities when launching Windows Server images?

Yes, Windows platform images include cloudbase-init installed by default. You can use cloudbase-init to run PowerShell scripts, batch scripts, or other user data content on instance launch. Cloudbase-init is the equivalent of cloud-init on Linux-based images.

Can I use Windows Remote Management on Oracle Cloud Infrastructure?

Yes, Microsoft Windows Remote Management (WinRM) is enabled by default on Windows platform images. WinRM enables you to remotely manage the operating system.

What is Microsoft end of support?

Microsoft establishes the support lifecycle policy for its products. When a product reaches the end of its support lifecycle, Microsoft no longer provides security updates for the product. You should upgrade to the latest version to remain secure.

Can I use Windows Server 2008 R2 even though it's past the end-of-support date?

Windows Server 2008 R2 reached the end of its support lifecycle on January 14, 2020. Although you can continue to import your own Windows 2008 R2 images and run your existing instances, you are at a higher risk of security issues, incompatibility, or failures. Oracle does not provide any operating system support for end-of-support operating systems.

Oracle Cloud Infrastructure does not provide platform images after the end-of-support date. However, you can import your own image and launch it on a shared host VM.

There are no restrictions to running end-of-support operating systems on bare metal machines on a dedicated host. You may bring your own image (BYOI) of a Windows Server 2008 R2 image, but you must import a custom OS image and run the image on a dedicated host.

Can I purchase Microsoft Extended Security Updates for end-of-support Windows OSs?

Yes, you can purchase Extended Security Updates (ESUs) from Microsoft for use on Oracle Cloud Infrastructure.

For VMs on shared infrastructure, you must have an enterprise agreement in place with Microsoft. With that agreement in place, you can purchase ESUs per virtual core matching the number of OCPUs per VM instance, with a minimum requirement of 16 virtual core licenses per VM instance.

For bare metal machines, you must have an enterprise agreement in place with Microsoft. With that agreement in place, you can purchase ESUs per physical core of the dedicated bare metal host.

Oracle Cloud Infrastructure cannot purchase ESUs on your behalf.
You are fully responsible for purchasing the correct number of ESUs for your instances. Oracle Cloud Infrastructure does not keep track of whether you have enough ESUs.

**Licensing Options for Microsoft Windows**

You can choose to bring your own license (BYOL) for Microsoft applications that you want to run on Oracle Cloud Infrastructure, or use a license that is issued by Oracle.

The following table describes the licensing models that are available for using Microsoft Windows images on Oracle Cloud Infrastructure.

<table>
<thead>
<tr>
<th>Image</th>
<th>License</th>
<th>Additional Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Platform image</td>
<td>Issued by Oracle</td>
<td>VM instances on a shared host, bare metal instances, and VM instances launched on a dedicated host are all permitted. BYOL for platform images is not available.</td>
</tr>
<tr>
<td>Bring your own image (BYOI)</td>
<td>Issued by Oracle</td>
<td>VM instances on a shared host, bare metal instances, and VM instances launched on a dedicated host are all permitted. Import the image. Oracle will issue a license when an instance is created using the imported image.</td>
</tr>
<tr>
<td>Bring your own image (BYOI)</td>
<td>BYOL</td>
<td>Instances must be launched on a dedicated host. Create a bare metal instance using the KVM image from Marketplace. Then, copy your Windows guest OS to the hypervisor.</td>
</tr>
<tr>
<td>Bring your own Hyper-V</td>
<td>Issued by Oracle</td>
<td>Instances must be launched on a dedicated host. Create a bare metal instance using the Windows Server Datacenter platform image. Then, copy your on-premises guest OS to Hyper-V on the bare metal instance.</td>
</tr>
</tbody>
</table>

**Bringing Your Own Microsoft License**

You can BYOL for Microsoft application licenses that are eligible for License Mobility with active Software Assurance onto virtual machines and dedicated hosts. According to the Microsoft Product Terms, some of the applications that are permitted for BYOL include the following:

- Microsoft SQL Server
- Microsoft Exchange Server
- Microsoft SharePoint Server
- Microsoft System Center
- Microsoft Dynamics products
Any Microsoft Server licenses permitted on Oracle Cloud Infrastructure must be eligible according to the latest Microsoft Product Terms. It is your responsibility to verify that the licensing agreements with Microsoft permit you to bring on-premises perpetual Microsoft licenses to Oracle Cloud Infrastructure and are eligible licensed products according to the latest Microsoft Product Terms. Microsoft application products that are currently eligible for License Mobility require an active Software Assurance benefit to move your license. For more information, see Moving Microsoft Licenses to Oracle Cloud Infrastructure: Microsoft License Mobility on page 1178.

For Microsoft Windows Server OS, there are restrictions. BYOL is only permitted for eligible Windows OS licenses with active Software Assurance running on a dedicated bare metal host or a dedicated VM host using a KVM hypervisor.

For Windows clients (Windows 8 and Windows 10), BYOL is permitted for Enterprise Agreement licenses with an active Software Assurance benefit or with Windows Virtual Desktop Access (VDA) licenses.

Activating licenses can either be scripted on startup using the slmgr.vbs command line tool or by using your own Microsoft Key Management Service (KMS) server.

**Activating Licenses on a Dedicated Host**

When you bring your own Microsoft licenses, you are responsible for validating that your licensing agreements with Microsoft permit you to move your own licenses to Oracle Cloud Infrastructure. It is your responsibility to ensure that you comply with all Microsoft product terms and product use conditions.

**Moving Microsoft Licenses to Oracle Cloud Infrastructure: Microsoft License Mobility**

Microsoft Volume Licensing customers can move eligible Microsoft server application licenses purchased under a Volume Licensing agreement to Oracle Cloud Infrastructure. To do this, you must enroll in the License Mobility through Microsoft Software Assurance benefit. This benefit is included with an active Software Assurance contract. You don't need to purchase additional Microsoft software licenses, and there are no associated mobility fees.

For more information about this Microsoft benefit, see License Mobility through Microsoft Software Assurance.

**Eligibility Requirements**

To enroll in Microsoft License Mobility through Software Assurance, you must be a Microsoft Volume License customer with eligible server application products. The following are key requirements:

- Windows Server operating systems, desktop client operating systems, and desktop applications such as Microsoft Office are not eligible under License Mobility through Software Assurance. You can bring your own license (BYOL) outside of License Mobility onto a dedicated host. For more information, see Can I bring my own license for Microsoft Windows Server to Oracle Cloud Infrastructure? on page 1174.
- Active Software Assurance coverage is required on eligible licenses migrated to Oracle Cloud Infrastructure.
- All licenses that are used to run and access your licensed software require active Software Assurance coverage. This includes server licenses, processor licenses, Client Access Licenses (CALs), External Connector (EC) licenses, and server management licenses. Your rights to run licensed software and manage instances on Oracle Cloud Infrastructure expire with the expiration of the Software Assurance coverage on those licenses.
- Eligible Volume Licensing programs include the Microsoft Enterprise Agreement, Microsoft Enterprise Subscription Agreement, and Microsoft Open Value agreement, where Software Assurance is included, and other Volume Licensing programs where Software Assurance is an option, such as the Microsoft Open License agreement and the Microsoft Select Plus agreement.
- You may move Microsoft licenses from on-premises or another cloud services provider only after more than 90 days have passed since the last license move.
- Eligible Microsoft licenses on Oracle Cloud Infrastructure must be maintained for a minimum period of 90 days in a specific Oracle Cloud Infrastructure region. After the 90-day period, you may move the licensed software to a shared host in another Oracle Cloud Infrastructure region.
- Any Microsoft Server licenses permitted on Oracle Cloud Infrastructure must be eligible according to the latest Microsoft Product Terms. It is your responsibility to verify that the licenses you bring to Oracle Cloud Infrastructure are eligible according to the latest Microsoft Product Terms.
Enrolling in License Mobility through Software Assurance

All customers using License Mobility through Software Assurance must complete a license verification process. Microsoft verifies that you have eligible licenses with active Software Assurance and sends confirmation when the verification process is complete.

You can deploy your application server software before completing the verification process, but you must submit the license verification form within 10 days of deployment.

You are responsible for managing true ups and renewals as required under your Volume Licensing agreement.

You must submit a new form each time that you deploy additional licenses, when you renew your agreement, and when you deploy any previously unverified products.

To enroll in License Mobility through Software Assurance:

1. Verify that you are a Microsoft Volume Licensing customer with eligible application server licenses that are covered by active Software Assurance.
2. Download the license verification form:
   a. Go to the Microsoft Product Licensing search page.
   b. In the Document Type area, select License Verification.
   c. Filter the results by language, region, and business sector. Note that the verification form is not available in the WW (World Wide) region.
   d. Download the LicenseMobilityVerif document.
3. Complete the license verification form. To specify Oracle as the Authorized Mobility Partner, provide the following information:
   • Authorized Mobility Partner Name: Oracle America, Inc.
   • Authorized Mobility Partner Website URL: http://www.oracle.com/
   • Authorized Mobility Partner Email Address: microsoftlm_us_grp@oracle.com

   For instructions to complete the form, see the Microsoft License Mobility Verification Guide (PDF).
4. Submit the completed verification form to both Microsoft and Oracle:
   • Microsoft: Submit the form through your Microsoft reseller or directly to the email address in the form.
   • Oracle: Send the form to microsoftlm_us_grp@oracle.com.

Microsoft and Oracle verify that the product licenses for the workloads you deploy to Oracle Cloud Infrastructure are eligible according to the terms of your License Mobility through Software Assurance benefit. Microsoft will communicate your verification status to you and to Oracle as an Authorized Mobility Partner.

Support Options for Microsoft Windows

Oracle Support provides limited assistance for Microsoft Windows Server operating systems running on Oracle Cloud Infrastructure and for SQL Server images provided by Oracle Cloud Marketplace. For product issues, work directly with Microsoft Support.

Microsoft Windows Server

Oracle Support provides limited assistance for Microsoft Windows Server operating systems running on Oracle Cloud Infrastructure as long as the Windows Server version has not reached end of support with Microsoft. For details about Microsoft Windows lifecycles, see Lifecycle FAQ - Windows.

In order for Oracle to provide support for Bring Your Own Image (BYOI) images, the images must follow the guidelines outlined in Importing Custom Windows Images on page 1002 and must meet all Microsoft licensing requirements.

Under these conditions, Oracle Support can help verify that:

• the operating system boots
• the operating system connects to the network
• attached storage connects and performs as expected
If you encounter other issues with Microsoft Windows Server, work directly with Microsoft Support to resolve the issue. Microsoft Support provides assistance when you have an existing Premier Support agreement or when you pay for professional support.

**SQL Server**

Oracle Support provides limited assistance with SQL Server images provided by Oracle Cloud Marketplace. For product issues, work directly with Microsoft Support.

For SQL Server images provided by Oracle Cloud Marketplace, Oracle Support can help verify that the services start and that they allow local connections.

The following tasks fall outside the scope of Oracle Support and should be addressed directly with Microsoft Support. Microsoft Support provides assistance when you have an existing Premier Support agreement or when you pay for professional support.

- Query optimization
- Failover clustering
- Issues with third-party applications and with Microsoft applications that are not included in the Oracle Cloud Marketplace image. For example, *software fails to install* errors.
- Image configurations that diverge from Oracle's standard configurations. For example, requests such as *Roaming Profiles are going into read-only mode when our users log in via terminal server/RDS* are out of scope.
- Activities that breach the Microsoft license terms of use

**Troubleshooting Compute Instances**

For information about how to troubleshoot issues with compute instances, see the following topics:

- Troubleshooting Instances Using Instance Console Connections on page 1180. To interactively debug issues that happen during instance launch or during the OS boot sequence, use a serial console connection or a VNC console connection.
- Sending a Diagnostic Interrupt on page 1194. To debug a running virtual machine (VM) instance that becomes unresponsive, you can generate a copy of the system memory (also called a crash dump) by sending a diagnostic interrupt to the instance.
- Displaying the Console History for an Instance on page 1197. To analyze the most recent OS-level error messages and other serial console data for an instance, you can capture and download the serial console history.

**Troubleshooting Instances Using Instance Console Connections**

You can remotely troubleshoot malfunctioning instances using console connections. For example:

- An imported or customized image that does not complete a successful boot
- A previously working instance that stops responding

Two types of instance console connections exist: serial console connections and VNC console connections.

**Important:**

Instance console connections are for troubleshooting purposes only. To connect to a running instance for administration and general use, instead use a Secure Shell (SSH) or Remote Desktop connection. See Connecting to an Instance on page 1083.

To configure your console connection, follow these steps:

1. **Make sure you have the correct permissions.**
2. Complete the **prerequisites**, including creating your SSH key pair.
3. **Create the instance console connection.**
4. **Connect to the serial console** or **connect to the VNC console**.
5. If you're trying to connect to the serial console and you think the connection isn't working, **test your connection to the serial console using Cloud Shell**.
Note:

Some issues can be diagnosed using information in the console history. Console history lets you see serial output from your instance without having to connect to the instance remotely.

Required IAM Policies

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

To create instance console connections, an administrator needs to grant user access to manage instance console connections and to read instances through an IAM policy. The resource name for instance console connections is instance-console-connection. The resource name for instances is instance. The following policies grant users the ability to create instance console connections:

- Allow group <group_name> to manage instance-console-connection in tenancy
- Allow group <group_name> to read instance in tenancy

Instance console connections also support network sources. The following policies grant users the ability to create instance console connections with a network source:

- Allow group <group_name> to manage instance-console-connection in tenancy where request.networkSource.name='example-network-source'
- Allow group <group_name> to read instance in tenancy where request.networkSource.name='example-network-source'

If you're new to policies, see Getting Started with Policies and Common Policies.

Prerequisites

Complete these prerequisites before creating the instance console connection.

Installing an SSH Client and a Command-line Shell (Windows)

Windows does not include an SSH client by default. If you are connecting from a Windows client, you need to install an SSH client. You can use PuTTY plink.exe with Windows PowerShell or software that includes a version of OpenSSH such as:

- Git for Windows
- Windows Subsystem for Linux

The instructions in this topic frequently use PuTTY and Windows PowerShell.

If you want to make the console connection from Windows with Windows PowerShell, PowerShell might already be installed on your Windows operating system. If not, follow the steps at the link. If you are connecting to the instance from a Windows client using PowerShell, plink.exe is required. plink.exe is the command link connection tool included with PuTTY. You can install PuTTY or install plink.exe separately. For installation information, see http://www.putty.org.

Creating SSH Key Pairs

To create the secure console connection, you need an SSH key pair. The method to use for creating key pairs depends on your operating system. When connecting to the serial console, you must use an RSA key. The instructions in this section show how to create an RSA SSH key pair.

Creating the SSH key pair for Linux

For detailed instructions about creating an SSH key pair to use on Linux, see Managing Key Pairs on Linux Instances on page 1021.

To create an SSH key pair on the command line
If you’re using a UNIX-style system, you probably already have the `ssh-keygen` utility installed. To determine whether the utility is installed, type `ssh-keygen` on the command line. If the utility isn't installed, you can download OpenSSH for UNIX from [http://www.openssh.com/portable.html](http://www.openssh.com/portable.html) and install it.

1. Open a shell or terminal for entering the commands.
2. At the prompt, enter `ssh-keygen` and provide a name for the key when prompted. Optionally, include a passphrase.

The keys will be created with the default values: RSA keys of 2048 bits.

Alternatively, you can type a complete `ssh-keygen` command, for example:

```
ssh-keygen -t rsa -N "" -b 2048 -C "<key_name>" -f <path/root_name>
```

The command arguments are shown in the following table:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-t rsa</code></td>
<td>Use the RSA algorithm.</td>
</tr>
<tr>
<td><code>-N &quot;&lt;passphrase&gt;&quot;</code></td>
<td>A passphrase to protect the use of the key (like a password). If you don't want to set a passphrase, don't enter anything between the quotes. A passphrase is not required. You can specify one as a security measure to protect the private key from unauthorized use. If you specify a passphrase, when you connect to the instance you must provide the passphrase, which typically makes it harder to automate connecting to an instance.</td>
</tr>
<tr>
<td><code>-b 2048</code></td>
<td>Generate a 2048-bit key. You don't have to set this if 2048 is acceptable, as 2048 is the default. A minimum of 2048 bits is recommended for SSH-2 RSA.</td>
</tr>
<tr>
<td><code>-C &quot;&lt;key_name&gt;&quot;</code></td>
<td>A name to identify the key.</td>
</tr>
<tr>
<td><code>-f &lt;path/root_name&gt;</code></td>
<td>The location where the key pair will be saved and the root name for the files.</td>
</tr>
</tbody>
</table>

**Creating the SSH key pair for Windows using PuTTY**

If you are using a Windows client to connect to the instance console connection, use an SSH key pair generated by PuTTY.

**To create the SSH key pair using PuTTY**

1. Find `puttygen.exe` in the PuTTY folder on your computer, for example, `C:\Program Files (x86)\PuTTY`. Double-click `puttygen.exe` to open it.
2. Specify a key type of SSH-2 RSA and a key size of 2048 bits:
   - In the **Key** menu, confirm that the default value of **SSH-2 RSA key** is selected.
   - For the **Type of key to generate**, accept the default key type of **RSA**.
   - Set the **Number of bits in a generated key** to 2048 if not already set.
3. Click **Generate**.
Compute

4. To generate random data in the key, move your mouse around the blank area in the PuTTY window.

When the key is generated, it appears under **Public key for pasting into OpenSSH authorized_keys file.**

5. A **Key comment** is generated for you, including the date and timestamp. You can keep the default comment or replace it with your own more descriptive comment.

6. Leave the **Key passphrase** field blank.

7. Click **Save private key**, and then click **Yes** in the prompt about saving the key without a passphrase.

   The key pair is saved in the PuTTY Private Key (PPK) format, which is a proprietary format that works only with the PuTTY tool set.

   You can name the key anything you want, but use the .ppk file extension. For example, mykey.ppk.

8. Select **all** of the generated key that appears under **Public key for pasting into OpenSSH authorized_keys file.** copy it using Ctrl + C, paste it into a text file, and then save the file in the same location as the private key.

   (Do not use **Save public key** because it does not save the key in the OpenSSH format.)

   You can name the key anything you want, but for consistency, use the same name as the private key and a file extension of .pub. For example, mykey.pub.

9. Write down the names and location of your public and private key files. You need the public key when creating an instance console connection. You need the private key to connect to the instance console connection using PuTTY.

**Signing in to an instance from the serial console (optional)**

To troubleshoot instances and see serial output using the serial console, you don't need to sign in. To connect to a running instance for administration and general use with Secure Shell (SSH) or Remote Desktop connection, see **Connecting to an Instance** on page 1083.

If you want to sign in to an instance using an instance console connection, you can use Secure Shell (SSH) or Remote Desktop connection to sign in. If you want to sign in with a username and password, you need a user account with a password. Oracle Cloud Infrastructure does not set a default password for the opc user. Therefore, if you want to sign in as the opc user, you need to create a password for the opc user. Otherwise, add a different user with a password and sign in as that user.

**Connecting Through Firewalls**

If your system is behind a firewall, the system must be able to reach the console servers. The client system connecting to the serial console must be able to reach the serial or VCN console server (for example, instance-console.us-ashburn-1.oci.oraclecorp.com) over SSH using port 443, directly or through a proxy.

**Supported Instance Types**

Serial console connections are supported on the following types of instances:

- Virtual machine (VM) instances launched in September 2017 or later.
- Bare metal instances launched in November 2017 or later.

VNC console connections are supported on the following types of instances:

**Note:**

VNC connections to Ampere A1 Compute instances are read-only. As a workaround, use the **serial console** when making instance console connections.

- VM instances launched on October 13, 2017 or later
Most bare metal instances are supported, with the following exceptions.

**Unsupported bare metal instances**

- BM.Standard1.36
- BM.Standard2.52 - launched before February 21, 2019
- BM.Standard.B1.44
- BM.Standard.E2.64 - launched before September 17, 2020
- BM.HighIO1.36
- BM.DenseIO1.36
- BM.DenseIO2.52 - launched before February 21, 2019
- BM.GPU2.2 - launched before February 21, 2019
- BM.GPU3.8 - launched before February 21, 2019
- BM.HPC2.36 - launched before February 21, 2019

**Creating the Instance Console Connection**

Before you can connect to the serial console or VNC console, you need to create the instance console connection.

**Note:**

Instance console connections are limited to one client at a time. If the client fails, the connection remains active for approximately five minutes. During this time, no other client can connect. After five minutes, the connection is closed, and a new client can connect. During the five-minute timeout, any attempt to connect a new client fails with the following message:

```
channel 0: open failed: administratively prohibited: console access is limited to one connection at a time
Connection to <instance and OCID information> closed.
```

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Console Connection**.
4. Click **Create Console Connection**.
5. Upload the public key portion for the SSH key. You have three options for adding the SSH key.

   - **Generate SSH key pair**: You can have Oracle Cloud Infrastructure generate an SSH key pair to use. If you are using PowerShell or PuTTY to connect to the instance from a Windows client, you cannot use the generated SSH key pair without first converting it to a .ppk file.
     
     **To convert a generated .key private key file**
     
     a. Open PuTTYgen.
     b. Click **Load**, and select the private key generated when you created the instance. The extension for the key file is .key.
     c. Click **Save private key**.
     d. Specify a name for the key. The extension for new private key is .ppk.
     e. Click **Save**.
   
   - **Choose public key file**: Browse to a public key file on your computer. If you followed the steps in **Creating SSH Key Pairs** on page 1181 in the Prerequisites section to create a key pair, use this option to navigate to the .pub file.
   
   - **Paste public key**: Paste the content of your public key file into the text box.

6. Click **Create Console Connection**.

When the console connection has been created and is available, the state changes to **Active**.
**Connecting to the Serial Console**

After you create the console connection for the instance, you can connect to the serial console using a Secure Shell (SSH) connection. When connecting to the serial console, you must use an RSA key. You can use the same SSH key for the serial console that was used when you launched the instance, or you can use a different SSH key.

When you are finished with the serial console and have terminated the SSH connection, you should delete the serial console connection. If you do not disconnect from the session, Oracle Cloud Infrastructure terminates the serial console session after 24 hours and you must reauthenticate to connect again.

**Connecting from Mac OS X and Linux Operating Systems**

Use an SSH client to connect to the serial console. Mac OS X and most Linux and UNIX-like operating systems include the SSH client OpenSSH by default.

**To connect to the serial console for an instance using OpenSSH on Mac OS X or Linux**

1. On the instance details page in the Oracle Cloud Infrastructure Console, under **Resources**, click **Console Connection**.
2. Click the Actions icon (three dots), and then click **Copy Serial Console Connection for Linux/Mac**.
3. Paste the connection string into a terminal window on a Mac OS X or Linux system, and then press **Enter** to connect to the console.

   If you are not using the default SSH key or ssh-agent, modify the serial console connection string to include the identity file flag, `-i`, to specify the private key portion for the SSH key to use, for example `id_rsa`. Specify this flag for both the SSH connection and the SSH ProxyCommand, as shown in the following line:

   ```bash
   ssh -i /<path>/<ssh_key> -o ProxyCommand='ssh -i /<path>/<ssh_key> -W %h:%p -p 443...'
   ```

4. Press **Enter** again to activate the console. If the connection is active, a message appears in the console:

   **IMPORTANT:** Use a console connection to troubleshoot a malfunctioning instance.

5. In the Oracle Cloud Infrastructure Console, **reboot your instance**. You do not need to enter a username or password. If the instance is functional and the connection is active, the serial output appears in your console. If serial output does not appear in the console, the instance operating system is not booting.

For additional troubleshooting options, see **Troubleshooting Instances from Instance Console Connections**.

**Connecting from Windows Operating Systems**

The steps to connect to the serial console from **Windows Powershell** are different from the steps for OpenSSH. The following steps do not work in the Windows terminal.

**Important:**

If you are connecting to the instance from a Windows client using PowerShell, `plink.exe` is required. `plink.exe` is the command link connection tool included with PuTTY. You can install PuTTY or install plink.exe separately. For more information, see **Installing an SSH Client and a Command-line Shell (Windows)** on page 1181.

**To connect to the serial console for an instance on Microsoft Windows**

1. On the instance details page in the Oracle Cloud Infrastructure Console, under **Resources**, click **Console Connection**.
2. Click the Actions icon (three dots). Depending on which SSH client you are using, do one of the following:
   • If you are using Windows PowerShell, click Copy Serial Console Connection for Windows.
   • If you are using OpenSSH, click Copy Serial Console Connection for Linux/Mac.

   **Tip:**
   The copied connection string for Windows contains the parameter `-i` specifying the location of the private key file. The default value for this parameter in the connection string references an environment variable which might not be configured on your Windows client, or it might not represent the location where the private key file is saved. Verify the value specified for the `-i` parameter and make any required changes before proceeding to the next step.

3. Paste the connection string copied from the previous step into a text file so that you can add the file path to the private key file.
4. In the text file, replace `$env:homedrive$env:homepath\oci\console.ppk` with the file path to the `.ppk` file on your computer. This file path appears twice in the string. Replace it in both locations.
5. Paste the modified connection string into the PowerShell window or your OpenSSH client, and then press Enter to connect to the console.
6. Press Enter again to activate the console.
7. In the Oracle Cloud Infrastructure Console, reboot your instance. You do not need to enter a username or password. If the instance is functional and the connection is active, the serial output appears in your client. If serial output does not appear in the client, the instance operating system is not booting.

For additional troubleshooting options, see Troubleshooting Instances from Instance Console Connections.

**Connecting from Cloud Shell**

If you encounter issues when connecting to your instance's serial console using the steps for connection from Mac OS X, Linux, or Windows, test connecting to the serial console using Cloud Shell. Cloud Shell is a web browser-based terminal accessible from the Console, see Cloud Shell for more information. This procedure includes steps to access Cloud Shell. For an introductory walkthrough of using Cloud Shell, see Using Cloud Shell.

   **Note:**
   You cannot use Cloud Shell for VNC console connections. You can only use it for serial console connections.

To connect to the serial console for an instance using Cloud Shell

1. Sign in to the Console.
2. Click the Cloud Shell icon in the Console header as shown in the following screenshot:

This action displays the Cloud Shell in a "drawer" at the bottom of the console as shown in the following screenshot:
Welcome to Oracle Cloud Shell.

Your Cloud Shell machine comes with 5GB of storage for your home directory.

john_doe@cloudshell:~ (us-ashburn-1)$
3. Run the following command in Cloud Shell to generate an SSH key pair:

```
ssh-keygen -t rsa
```

4. At the prompt to enter the file in which to save the key, press Enter to use the default location.

5. At the passphrase prompt, press Enter for no passphrase, and then press Enter again to confirm.

6. Run the following command to display the public key, and then copy the output:

```
cat $HOME/.ssh/id_rsa.pub
```

7. Open the navigation menu and click Compute. Under Compute, click Instances.

8. Click the instance that you're interested in.

10. Click Create Console Connection.

11. Select Paste SSH Key and paste the public key contents you copied in step 6.

12. Click Create Console Connection.

After the console connection state changes to Active proceed to the next step.

13. Click the Actions icon (three dots), and then click Copy Serial Console Connection for Linux/Mac.

14. Paste the connection string copied from the previous step to Cloud Shell, and then press Enter to connect to the console.

15. Press Enter again to activate the console.

Connecting to the VNC Console

After you create the console connection for the instance, you need to set up a secure tunnel to the VNC server on the instance, and then you can connect with a VNC client.

The VNC console connection uses SSH port forwarding to create a secure connection from your local system to the VNC server attached to your instance's console. Although this method is a secure way to use VNC over the internet, owners of multiuser systems should know that opening a port on the local system makes it available to all users on that system until a VNC client connects. For this reason, we don't recommend using this product on a multiuser system unless you take proper actions to secure the port or you isolate the VNC client by running it in a virtual environment, such as Oracle VM VirtualBox.

To set up a secure tunnel to the VNC server on the instance using OpenSSH on Mac OS X or Linux

```
Note:
Mac OS X Screen Sharing.app Not Compatible with VNC Console Connections
The Mac OS X built-in VNC client, Screen Sharing.app does not work with VNC console connections in Oracle Cloud Infrastructure. Use another VNC client, such as Real VNC Viewer or Chicken.
```

1. On the instance details page in the Oracle Cloud Infrastructure Console, under Resources, click Console Connection.

2. Click the Actions icon (three dots), and then click Copy VNC Connection for Linux/Mac.

3. Paste the connection string copied from the previous step to a terminal window on a Mac OS X or Linux system, and then press Enter to set up the secure connection.

4. After the connection is established, open your VNC client and specify localhost as the host to connect to and 5900 as the port to use.

```
Note:
Remote management for Remote Desktop on OS X uses port 5900. Because VNC console connections in Oracle Cloud Infrastructure also use port 5900, VCN console connections are not compatible with
```
remote management. To use VCN console connections, disable remote management.

To set up a secure tunnel to the VNC server on the instance using PowerShell on Windows

If you are connecting to the VNC server on the instance from a Windows client using PowerShell, plink.exe is required. plink.exe is the command link connection tool included with PuTTY. You can install PuTTY or install plink.exe separately. For installation information, see http://www.putty.org.

1. On the instance details page in the Oracle Cloud Infrastructure Console, under Resources, click Console Connection.
2. Click the Actions icon (three dots), and then click Copy VNC Connection for Windows.

   **Tip:**

   The copied connection string for Windows contains the parameter -i specifying the location of the private key file. The default value for this parameter in the connection string references an environment variable which might not be configured on your Windows client, or it might not represent the location where the private key file is saved. Verify the value specified for the -i parameter and make any required changes before proceeding to the next step.

3. Paste the connection string copied from the previous step to Windows Powershell, and then press Enter to set up the secure connection.
4. After the connection is established, open your VNC client and specify localhost as the host to connect to and 5900 as the port to use.

   **Note:**

   Secure Connection Warning

   When you connect, you might see a warning from the VNC client that the connection is not encrypted. Because you are connecting through SSH, the connection is secure, so this warning is not an issue.

Troubleshooting Instances from Instance Console Connections

**Linux**

The following tasks describe steps specific to instances running Oracle Autonomous Linux 7.x, Oracle Linux 8.x, Oracle Linux 7.x, and Oracle Linux Cloud Developer 8.x, connecting from OpenSSH. Other operating system versions and SSH clients might require different steps.

After you are connected with an instance console connection, you can perform various tasks, such as:

- Edit system configuration files.
- Add or reset the SSH keys for the opc user.
- Reset the password for the opc user.

These tasks require you to boot into a bash shell in maintenance mode.

**To boot into maintenance mode**

1. Reboot the instance from the Console.
2. Depending on the version of Linux you're using, do one of the following.

   - For instances running Oracle Linux 8.x or Oracle Linux Cloud Developer 8.x, follow these steps.
     a. When the reboot process starts, immediately switch back to the terminal window and press Esc or F5 repeatedly until a menu appears.
     b. In the menu that appears, select Boot Manager, and press Enter.
     c. In the Boot Manager menu, select UEFI Oracle BlockVolume, and press Enter. Immediately press the up/down arrow key and continue pressing it until the boot menu appears. If Console messages start to
appear in the window, the opportunity to access the boot menu passed, and you need to start the reboot process again.

- For instances running Oracle Autonomous Linux 7.x or Oracle Linux 7.x, when the reboot process starts, switch back to the terminal window, and you see Console messages start to appear in the window. As soon as the GRUB boot menu appears, use the up/down arrow key to stop the automatic boot process, enabling you to use the boot menu.

3. In the boot menu, highlight the top item in the menu, and press e to edit the boot entry.

4. In edit mode, use the down arrow key to scroll down through the entries until you reach the line that starts with `linuxefi` for instances running Oracle Autonomous Linux 7.x, Oracle Linux 8.x, and Oracle Linux 7.x. For instances running Oracle Linux Cloud Developer 8.x, scroll down until you reach the line that starts with `linux`.

5. At the end of that line, add the following:

```
init=/bin/bash
```

6. Reboot the instance from the terminal window by entering the keyboard shortcut **CTRL+X**.

When the instance has rebooted, you see the Bash shell command line prompt, and you can proceed with the following procedures.

**To edit the system configuration files**

1. From the Bash shell, run the following command to load the SElinux policies to preserve the context of the files you are modifying:

```
/usr/sbin/load_policy -i
```

2. Run the following command to remount the root partition with read/write permissions:

```
/bin/mount -o remount, rw /
```

3. Edit the configuration files as needed to try to recover the instance.

4. After you have finished editing the configuration files, to start the instance from the existing shell, run the following command:

```
exec /usr/lib/systemd/systemd
```

Alternatively, to reboot the instance, run the following command:

```
/usr/sbin/reboot -f
```

**To add or reset the SSH key for the opc user**

1. From the Bash shell, run the following command to load the SElinux policies to preserve the context of the files you are modifying:

```
/usr/sbin/load_policy -i
```

2. Run the following command to remount the root partition with read/write permissions:

```
/bin/mount -o remount, rw /
```

3. From the Bash shell, run the following command to change to the SSH key directory for the opc user:

```
cd ~opc/.ssh
```

4. Rename the existing authorized keys file with the following command:

```
mv authorized_keys authorized_keys.old
```
5. Replace the contents of the public key file with the new public key file with the following command:

```
echo '<contents of public key file>' >> authorized_keys
```

6. Restart the instance by running the following command:

```
/usr/sbin/reboot -f
```

**To reset the password for the opc user**

1. From the Bash shell, run the following command to load the SELinux policies to preserve the context of the files you are modifying. This step is necessary to sign in to your instance using SSH and the Console.

```
/usr/sbin/load_policy -i
```

2. Run the following command to remount the root partition with read/write permissions:

```
/bin/mount -o remount, rw /
```

3. Run the following command to reset the password for the opc user:

```
sudo passwd opc
```

4. Restart the instance by running the following command:

```
sudo reboot -f
```

**Windows**

The Windows Special Administration Console (SAC) allows you to access a PowerShell console or command prompt from the serial terminal. By connecting to the instance's serial console and using SAC, you can interrupt the boot process and boot Windows in safe mode.

When you use SAC, you can create multiple user sessions or channels and switch between them. This feature enables you to use SAC commands while concurrently running command-line commands or viewing setup logs.

To use SAC in the serial console, first enable it on your Windows server. After you activate SAC, it provides a special console on the serial port. When enabled, the SAC> prompt appears in the serial output.

**To enable SAC in PowerShell**

Connect to your instance and run the following commands in Windows PowerShell.

1. Enable SAC:

```
bcdedit /ems '{current}' on
bcdedit /emssettings EMSPORT:1 EMSBAUDRATE:115200
```

2. Enable the boot menu:

```
bcdedit /set '{bootmgr}' displaybootmenu yes
bcdedit /set '{bootmgr}' timeout 15
bcdedit /set '{bootmgr}' bootems yes
```

3. Reboot the instance to apply the updated configuration:

```
shutdown -r -t 0
```

**To enable SAC in the command prompt**

Connect to your instance and run the following commands in the command prompt.
1. **Enable SAC:**
   
   ```
   bcdedit /ems {current} on
   bcdedit /emssettings EMSPORT:1 EMSBAUDRATE:115200
   ```

2. **Enable the boot menu:**
   
   ```
   bcdedit /set {bootmgr} displaybootmenu yes
   bcdedit /set {bootmgr} timeout 15
   bcdedit /set {bootmgr} bootems yes
   ```

3. **Reboot the instance to apply the updated configuration:**
   
   ```
   shutdown -r -t 0
   ```

**To use SAC in the serial console**

If SAC is enabled, the `SAC>` prompt appears in the serial output. For more information about SAC commands, see [Emergency Management Services Tools and Settings](#) in the Microsoft documentation.

- To see a list of SAC commands, enter `?` and then press Enter.
- To switch channels, press `ESC+TAB+<channel number>` together.
- If the instance has the boot menu enabled and is restarted after connecting through SSH, the Windows boot menu should display in the serial console output. The following list includes commands that you can use with the boot menu:
  - **Enter** - When the boot menu initiates and the operating system is highlighted, starts the operating system.
  - **Tab** - Switches to the Tools menu.
  - **Esc** - Exits the boot menu and restarts the instance.
  - **Esc and then 8 or F8** - Displays advanced options for the selected item.
  - **Esc + left arrow** - Returns to the initial boot menu.

**Exiting the Instance Console Connection**

**To exit the serial console connection**

When using SSH, the ~ character at the beginning of a new line is used as an escape character.

- To exit the serial console, enter:
  ```
  ~.
  ```

- To suspend the SSH session, enter:
  ```
  ~^z
  ```

The ^ character represents the CTRL key

- To see all the SSH escape commands, enter:
  ```
  ~?
  ```

**To exit the VNC console connection**

1. Close the VNC client.
2. In the Terminal or PowerShell window, type `CTRL C`.

When you are finished using the console connection, delete the connection for the instance.

**To delete the console connection for an instance**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Console Connection**.
4. Click the Actions icon (three dots), and then click **Delete**. Confirm when prompted.

**Tagging Resources**

You can add tags to your resources to help you organize them according to your business needs. You can add tags at the time you create a resource, or you can update the resource later with the desired tags. For general information about applying tags, see **Resource Tags** on page 239.

**To manage tags for an instance console connection**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click the instance that you're interested in.
3. Under **Resources**, click **Console Connection**.
4. For the console connection that you're interested in, click the Actions icon (three dots) and then click **Add Tags**. To view existing tags, click **View Tags**.

**Sending a Diagnostic Interrupt**

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td>This feature is for advanced users. Sending a diagnostic interrupt to a live system can cause data corruption or system failure.</td>
</tr>
</tbody>
</table>

You can send a diagnostic interrupt to debug an unresponsive or unreachable compute virtual machine (VM) instance. A diagnostic interrupt causes the instance's OS to crash and reboot. Before you send a diagnostic interrupt, you must configure the OS to generate a crash dump (also called a memory dump file) when it crashes. The crash dump captures information about the state of the OS at the time of the crash. After the OS restarts, you can analyze the crash dump to identify and debug the issue.

**Required IAM Policy**

To use Oracle Cloud Infrastructure, you must be granted security access in a **policy** by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which **compartment** to work in.

For administrators: The policy in **Let users launch compute instances** on page 2807 includes the ability to send a diagnostic interrupt to an instance. If the specified group doesn't need to launch instances or attach volumes, you could simplify that policy to include only **manage instance-family**, and remove the statements involving **volume-family** and **virtual-network-family**.

If you're new to policies, see **Getting Started with Policies** on page 2799 and **Common Policies** on page 2806. For reference material about writing policies for instances, cloud networks, or other Core Services API resources, see **Details for the Core Services** on page 2855.

**Prerequisites**

- The instance's OS must be configured to generate a crash dump file.
- The instance must be in the **Running** state. For more information, see **Stopping and Starting an Instance** on page 1145.
- There are no in-progress actions affecting the instance, such as block volumes or secondary VNICs in the process of being attached or detached.

**Configuring the OS to Generate a Crash Dump**

Before you send a diagnostic interrupt to an instance, you must configure the OS to generate a crash dump when it crashes. The diagnostic interrupt is received as a non-maskable interrupt (NMI) on the target instance.

The steps depend on the OS.
Linux

Note:

On Oracle Linux platform images, the OS is either fully configured or partially configured to generate a crash dump, depending on the image release date.

Oracle Linux 8

- **Images released in August 2020 or later:** The image is fully configured to generate a crash dump.
- **Earlier images:** The dump-capture kernel is installed and configured, but you must perform the other configuration steps.

Oracle Linux 7

- **Images released in August 2020 or later:** The image is fully configured to generate a crash dump.
- **Earlier images:** The dump-capture kernel is installed and configured, but you must perform the other configuration steps.

Oracle Linux 6

- **Images released in September 2020 or later:** The image is fully configured to generate a crash dump.
- **Earlier images:** The dump-capture kernel is installed and configured, but you must perform the other configuration steps.

1. Connect to the instance.
2. Install and configure the dump-capture kernel:
   a. Install kdump and kexec by running the following command:
      ```
sudo yum install kexec-tools
      ```
   b. Reserve memory on the kernel to save the crash dump. Do the following:
      1. Open the `/etc/default/grub` file in a text editor.
      2. In the line that starts with `GRUB_CMDLINE_LINUX_DEFAULT`, add the parameter `crashkernel=<memory-to-reserve>`. For example, to reserve 100 MB, add `crashkernel=100M`.
      3. Save the changes and close the file.
      4. Rebuild the GRUB file by running the following command:
         ```
sudo grub2-mkconfig -o /boot/grub2/grub.cfg
         ```
   3. Configure the kernel to crash when it receives a diagnostic interrupt. To do this, open the `/etc/sysctl.conf` file in a text editor and add the following line:
      ```
kernl.unknown_nmi_panic=1
      ```
   4. Apply the change to `/etc/sysctl.conf` by running the following command:
      ```
sysctl -p
      ```

Windows Server - Platform Image

If you use a Windows Server platform image that was released in April 2020 or later, the image is already configured to generate a crash dump.

If you use an image that was released before April 2020, do the following:
1. **Connect to the instance.**

2. Download the Oracle Windows VirtIO drivers:
   a. Sign in to the Oracle Software Delivery Cloud site.
   b. In the All Categories list, select Release.
   c. Type Oracle Linux 7.7 in the search box and click Search.
   d. Add REL: Oracle Linux 7.7.x to your cart, and then click Continue.
   e. In the Platforms/Languages list, select x86 64 bit. Click Continue.
   f. Accept the license agreement and then click Continue.
   g. Select the check box next to Oracle VirtIO Drivers Version for Microsoft Windows 1.1.5. Clear the other check boxes.
   h. Click Download and then follow the prompts.

3. Install the drivers and then restart the instance. For steps, see Installing the Oracle VirtIO Drivers for Microsoft Windows on Existing Microsoft Windows Guests.

**Windows Server - Customer-Provided Image**

Refer to the third-party documentation for your operating system for more information.

**Sending a Diagnostic Interrupt**

After you configure the instance's OS to generate a crash dump when it crashes, use the following procedures to send a diagnostic interrupt.

**To send a diagnostic interrupt using the Console**

1. Open the navigation menu and click **Compute**. Under **Compute**, click **Instances**.
2. Click **More Actions**, and then click **Send Diagnostic Interrupt**.
   
   **Caution:**
   Sending a diagnostic interrupt to a live system can cause data corruption or system failure.

3. Review the confirmation message and then click **Send Diagnostic Interrupt**.
   
   The lifecycle state that appears in the Console remains **Running** while the instance's OS crashes and restarts. Do not send multiple diagnostic interrupts.

4. Wait several minutes for the instance's OS to restart, and then **connect to the instance**. You can now retrieve and analyze the crash dump.

**To send a diagnostic interrupt using the API**

Use the **InstanceAction** operation, passing the value SENDDIAGNOSTICINTERRUPT as the action to perform.

**Analyzing a Crash Dump**

The crash dump is saved locally on the instance's OS.

- **Linux instances**: The default location where the crash dump is saved depends on the operating system.
  - Oracle Linux 8: Saved in /var/oled/crash.
  - Oracle Linux 7: For platform images released in March 2021 or later, saved in /var/crash. For older platform images, saved in /var/oled/crash.
  - Other Linux and UNIX-like operating systems: Saved in /var/crash/.

  To change the location, modify the /etc/kdump.conf file.

- **Windows instances**: The crash dump is saved in %SystemRoot%\memory.dmp. On most Windows systems, this is C:\Windows\memory.dmp.

  To analyze the crash dump, use a third-party tool such as the crash utility on Linux instances or WinDbg on Windows instances.
Displaying the Console History for an Instance

You can capture and display recent serial console data for an instance. The data includes configuration messages that occur when the instance boots, such as kernel and BIOS messages, and is useful for checking the status of the instance or diagnosing problems.

The console history captures up to a megabyte of the most recent serial console data for the specified instance. Note that the raw console data, including multi-byte characters, is captured.

The console history is a point-in-time record. To troubleshoot a malfunctioning instance using an interactive console connection, use a serial console connection or a VNC console connection.

Required IAM Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: The policy in Let users launch compute instances on page 2807 includes the ability to manage console history data. If the specified group doesn’t need to launch instances or attach volumes, you could simplify that policy to include only manage instance-family, and remove the statements involving volume-family and virtual-network-family.

Tagging Resources

You can apply tags to your resources to help you organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

Managing Console History Data

You can use the Console, CLI, or API to manage console history captures. Console history lets you see serial output from your instance without having to connect to the instance remotely. You can use this information to troubleshoot instance access issues.

Using the Console

On the instance details page in the Console, you can capture and download console histories, view and edit metadata details, and delete console history captures.

To capture the console history

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Under Resources, click Console history.
4. Click View current history.
5. Enter an optional name for the console history. Avoid entering confidential information.
6. **Show tagging options**: If you have permissions to create a resource, then you also have permissions to apply freeform tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
7. To download a copy of the console history, click Download.
8. Click Save and close.

To download console history captures

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Under Resources, click Console history.
4. In the console history list, for the console history capture that you want to download, click the the Actions icon (three dots), click Download, and then save the file.
To view console history captures

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Under Resources, click Console history.
4. In the console history list, for the console history capture that you want to view, click the the Actions icon (three dots), and then click View details.

To view and edit the metadata details of a console history capture

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Under Resources, click Console history.
4. In the console history list, click the the Actions icon (three dots) next to the console history, and then click View details.
5. Optionally, edit the name for the console history. Avoid entering confidential information.
6. To view or edit tags, click Show tagging options.
7. To edit or remove tags, click the edit icon next to the tag. To edit a tag, in the Edit Tag dialog, make any changes, and then click Save. To remove a tag, click Remove Tag.
8. Click Save and close.

To delete console history captures

1. Open the navigation menu and click Compute. Under Compute, click Instances.
2. Click the instance that you're interested in.
3. Under Resources, click Console history.
4. In the console history list, for the console history capture that you want to delete, click the the Actions icon (three dots), and then click Delete.
5. In the confirmation dialog, click Delete console history.

Using the CLI

For information about using the CLI, see Command Line Interface (CLI) on page 5316. To manage the serial console logs using the CLI, open a command prompt and run any of the following commands.

To capture the console history

Use the compute console-history capture command:

```
oci compute console-history capture --instance-id <instance-id>
```

See the CLI online help for a list of options:

```
oci compute console-history capture --help
```

To get the metadata details of a console history capture

Use the compute console-history get command:

```
oci compute console-history get --instance-console-history-id <instance-console-history-id>
```

See the CLI online help for a list of options:

```
oci compute console-history get --help
```

To get the details of console history content
Use the `compute console-history get-content` command:

```
oci compute console-history get-content --file <file_name> --instance-console-history-id <instance-console-history-id>
```

See the CLI online help for a list of options:

```
oci compute console-history get-content --help
```

**To edit console history metadata**

Use the `compute console-history update` command:

```
oci compute console-history update --instance-console-history-id <instance-console-history-id>
```

See the CLI online help for a list of options:

```
oci compute console-history update --help
```

**To list console history captures**

Use the `compute console-history list` command:

```
oci compute console-history list --compartment-id <COMPARTMENT_OCID>
```

See the CLI online help for a list of options:

```
oci compute console-history list --help
```

**To delete console history captures**

Use the `compute console-history delete` command:

```
oci compute console-history delete --instance-console-history-id <instance-console-history-id>
```

See the CLI online help for a list of options:

```
oci compute console-history delete --help
```

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following API operations to manage the console history data.

- To capture the console history, use the `CaptureConsoleHistory` method.
- To get details of console history metadata, use the `GetConsoleHistory` method.
- To get the details of console history content, use the `GetConsoleHistoryContent` method.
- To edit console history metadata, use the `UpdateConsoleHistory` method.
- To list console history captures, use the `ListConsoleHistories` method.
- To delete console history captures, use the `DeleteConsoleHistory` method.

**Updating the Linux iSCSI Service to Restart Automatically**

Oracle Cloud Infrastructure supports iSCSI attached remote boot and block volumes to Compute instances. These iSCSI attached volumes are managed by the Linux iSCSI initiator service, `iscsid`. In scenarios where this service
is stopped for any reason, such as the service crashes or a system administrator inadvertently stops the service, it's important that this service is automatically restarted immediately.

The following platform images distributed by Oracle Cloud Infrastructure are configured so that the iscsid service restarts automatically:

- Oracle Autonomous Linux 7 images.
- Oracle Linux 8 images.
- Oracle Linux Cloud Developer 8 images.
- Oracle Linux 7 images released February 26, 2019 and later. See the release notes for Oracle-Linux-7.6-Gen2-GPU-2019.02.20-0 and Oracle-Linux-7.6-2019.02.20-0.
- Oracle Linux 6 images released February 26, 2019 and later. See the release notes for Oracle-Linux-6.10-2019.02.22-0.
- CentOS 7 images released February 25, 2019 and later. See the release notes for CentOS-7-2019.02.23-0.

Instances created from earlier versions of CentOS 7.x and Oracle Linux platform images, or any versions of Ubuntu platform images, do not have this configuration. You should update these existing instances and custom images created from these images so that the iscsid service restarts automatically. You should also check this configuration on your imported paravirtualized custom images and any instances launched from these images and update the configuration as needed.

This topic describes how to update the iscsid service on an instance so that it will restart automatically.

**Note:**
Configuring an instance to automatically restart the iscsid service does not require a reboot and will increase the stability of your infrastructure.

### Oracle Linux 7

Run the following command to update the iscsid service on your Oracle 7 Linux instances:

```bash
sudo yum update -y iscsi-initiator-utils
```

After running this command, the version of the iscsid service should be 6.2.0.874 or newer.

Run the following command to check the version:

```bash
yum info iscsi-initiator-utils
```

This update does not require a system reboot and will not make any changes to your instances beyond configuring iscsid to restart automatically.

### Oracle Linux 6

Run the following command to update the iscsid service on your Oracle 6 Linux instances:

```bash
sudo yum update -y iscsi-initiator-utils
```

After running this command, the version of the iscsid service should be 6.2.0.873 or newer.

Run the following command to check the version:

```bash
yum info iscsi-initiator-utils
```

This update does not require a system reboot and will not make any changes to your instances beyond configuring iscsid to restart automatically.
CentOS 7.x

**Important:**
Do not directly edit the `systemd iscsid.service` file. You should instead create an override to ensure that the `restart` option isn't overwritten the next time the `iscsid` service is updated.

On your CentOS 7 instances run the following command to create an override file:

```
sudo systemctl edit iscsid.service
```

Paste and save the following into the file:

```
[Service]
Restart=always
```

Run the following commands to reload `systemd` and restart the `iscsid` service:

```
sudo systemctl daemon-reload
sudo systemctl restart iscsid
```

Ubuntu 18.04, Ubuntu 20.04

**Important:**
Do not directly edit the `systemd iscsid.service` file, instead create an override to ensure that the `restart` option isn't overwritten the next time the `iscsid` service is updated.

On your Ubuntu 18 and Ubuntu 20, instances run the following command to create an override file:

```
sudo systemctl edit iscsid.service
```

Paste and save the following into the file:

```
[Service]
Restart=always
```

Run the following commands to reload `systemd` and restart the `iscsid` service:

```
sudo systemctl daemon-reload
sudo systemctl restart iscsid
```

Testing the `iscsid` Service Update

Perform these steps to verify that the `iscsid` service has been updated successfully, and that it restarts automatically.

**Caution:**
Do not perform these steps on a production instance. If the `iscsid` service fails to restart, the instance may become unresponsive.

1. Run the following command to confirm that the `iscsid` service is running:

```
ps -ef | grep iscsid
```
2. Run the following command to stop the iscsid service:

   ```bash
   sudo pkill -9 iscsid
   ```

3. Wait 60 seconds and then run the following command to verify that the iscsid service has restarted:

   ```bash
   ps -ef | grep iscsid
   ```

## Developing with the Compute Service

You can use Oracle Cloud Infrastructure developer resources to perform tasks programmatically with the Compute service. The following resources apply to Compute:

- **Core services**: Covers most compute resources, including instances, shapes, and images; compute management resources such as instance pools; and resources that are not covered in the other references. The Core Services API also covers Networking and Block Volume.
- **Autoscaling**: Autoscaling lets you automatically adjust the number or the lifecycle state of compute instances in an instance pool.
- **Compute instance agent (Oracle Cloud Agent)**: Oracle Cloud Agent is a lightweight process that manages plugins running on compute instances. Plugins collect performance metrics, install OS updates, and perform other instance management tasks.
- **Work requests**: Many of the API operations that you use to create and configure cloud resources do not take effect immediately. In these cases, the operation spawns an asynchronous workflow to fulfill the request. Work requests provide visibility into the status of these in-progress, long-running workflows.

## APIs for Compute

These are the API references for Compute:

- Core Services API
- Autoscaling API
- Oracle Cloud Agent API
- Work Requests API

## CLIs for Compute

These are the CLI references for Compute:

- Command line reference for Compute
- Command line reference for compute management
- Command line reference for autoscaling
- Command line reference for Oracle Cloud Agent
- Command line reference for work requests

## SDKs, DevOps Tools, and Other Resources

For information about other programmatic resources that you can use to work with Compute, including SDKs, DevOps tools and plugins such as Terraform, and Cloud Shell, see Developer Guide on page 5302.

## Windows Generalized Image Support Files

To generalize a Windows custom image, download the appropriate file for your instance based on the shape of the instance. Then, follow the instructions in Creating Windows Custom Images on page 992.

The files apply to the following Windows versions:

- Windows Server 2019
- Windows Server 2016
- Windows Server 2012 R2
**VM Instances**
Use this download for all VM instances.
Download: oracle-cloud_windows-server_generalize_2019-02-06.SED.EXE

**Bare Metal Instances - AMD Shapes**
Use this download for AMD-based bare metal instances.
Download: oracle-cloud_windows-server-bm-gen2_generalize_2019-01-31.SED.EXE

**Bare Metal Instances - X7 Shapes**
Use this download for X7-based bare metal instances.

Troubleshooting
Overview of Container Engine for Kubernetes

Oracle Cloud Infrastructure Container Engine for Kubernetes is a fully-managed, scalable, and highly available service that you can use to deploy your containerized applications to the cloud. Use Container Engine for Kubernetes (sometimes abbreviated to just OKE) when your development team wants to reliably build, deploy, and manage cloud-native applications. You specify the compute resources that your applications require, and Container Engine for Kubernetes provisions them on Oracle Cloud Infrastructure in an existing OCI tenancy.

Container Engine for Kubernetes uses Kubernetes - the open-source system for automating deployment, scaling, and management of containerized applications across clusters of hosts. Kubernetes groups the containers that make up an application into logical units (called pods) for easy management and discovery. Container Engine for Kubernetes uses versions of Kubernetes certified as conformant by the Cloud Native Computing Foundation (CNCF). Container Engine for Kubernetes is itself ISO-compliant (ISO-IEC 27001, 27017, 27018).

You can access Container Engine for Kubernetes to define and create Kubernetes clusters using the Console and the REST API. You can access the clusters you create using the Kubernetes command line (kubectl), the Kubernetes Dashboard, and the Kubernetes API.

Container Engine for Kubernetes is integrated with Oracle Cloud Infrastructure Identity and Access Management (IAM), which provides easy authentication with native Oracle Cloud Infrastructure identity functionality.

For an introductory tutorial, see Creating a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes. A number of related Developer Tutorials are also available.

Ways to Access Oracle Cloud Infrastructure

You can access Oracle Cloud Infrastructure using the Console (a browser-based interface) or the REST API. Instructions for the Console and API are included in topics throughout this guide. For a list of available SDKs, see Software Development Kits and Command Line Interface on page 5351.

To access the Console, you must use a supported browser.

Oracle Cloud Infrastructure supports the following browsers and versions:

- Google Chrome 69 or later
- Safari 12.1 or later
- Firefox 62 or later

For general information about using the API, see REST APIs on page 5528.

Creating Automation with Events

You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2382.

See Container Engine for Kubernetes on page 2443 for details about Container Engine for Kubernetes resources that emit events.

Resource Identifiers

Most types of Oracle Cloud Infrastructure resources have a unique, Oracle-assigned identifier called an Oracle Cloud ID (OCID). For information about the OCID format and other ways to identify your resources, see Resource Identifiers on page 225.
Authentication and Authorization

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization, for all interfaces (the Console, SDK or CLI, and REST API).

An administrator in your organization needs to set up groups, compartments, and policies that control which users can access which services, which resources, and the type of access. For example, the policies control who can create new users, create and manage the cloud network, launch instances, create buckets, download objects, etc. For more information, see Getting Started with Policies on page 2799. For specific details about writing policies for each of the different services, see Policy Reference on page 2837.

If you’re a regular user (not an administrator) who needs to use the Oracle Cloud Infrastructure resources that your company owns, contact your administrator to set up a user ID for you. The administrator can confirm which compartment or compartments you should be using.

Note that to perform certain operations on clusters created by Container Engine for Kubernetes, you might require additional permissions granted via a Kubernetes RBAC role or clusterrole. See About Access Control and Container Engine for Kubernetes on page 1254.

Container Engine for Kubernetes Capabilities and Limits

In each region that is enabled for your tenancy, you can create three clusters (Monthly Universal Credits) or one cluster (Pay-as-You-Go or Promo) by default. Each cluster you create can have a maximum of 1000 nodes. A maximum of 110 pods can run on each node. See Service Limits on page 243.

Required IAM Service Policy

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

If you're new to policies, see Getting Started with Policies and Common Policies.

For more details about policies for Container Engine for Kubernetes, see:

• Policy Configuration for Cluster Creation and Deployment on page 1230
• Details for Container Engine for Kubernetes on page 2851

Container Engine and Kubernetes Concepts

This topic describes key concepts you need to understand when using Container Engine for Kubernetes.

Kubernetes Clusters

A Kubernetes cluster is a group of nodes (machines running applications). Each node can be a physical machine or a virtual machine. The node's capacity (its number of CPUs and amount of memory) is defined when the node is created. A cluster comprises:

• Control plane nodes (previously referred to as ‘master nodes’). Typically, there will be three control plane nodes for high availability.
• Worker nodes, organized into node pools.

Kubernetes Cluster Control Plane and Kubernetes API

The Kubernetes cluster control plane implements core Kubernetes functionality. It runs on compute instances (known as 'control plane nodes') in the Container Engine for Kubernetes service tenancy. The cluster control plane is fully managed by Oracle.
The cluster control plane runs a number of processes, including:

- kube-apiserver to support Kubernetes API operations requested from the Kubernetes command line tool (kubectl) and other command line tools, as well as from direct REST calls. The kube-apiserver includes admissions controllers required for advanced Kubernetes operations.
- kube-controller-manager to manage different Kubernetes components (for example, replication controller, endpoints controller, namespace controller, and serviceaccounts controller)
- kube-scheduler to control where in the cluster to run jobs
- etcd to store the cluster's configuration data

The Kubernetes API enables end users to query and manipulate Kubernetes resources (such as pods, namespaces, configmaps, and events).

You access the Kubernetes API on the cluster control plane through an endpoint hosted in a subnet of your VCN. This Kubernetes API endpoint subnet can be a private or public subnet. If you specify a public subnet for the Kubernetes API endpoint, you can optionally assign a public IP address to the Kubernetes API endpoint (in addition to the private IP address). You control access to the Kubernetes API endpoint subnet using security rules defined for security lists or network security groups.

**Note:**

In earlier releases, clusters were provisioned with public Kubernetes API endpoints that were not integrated into your VCN. You can continue to create such clusters using the CLI or API, but not the Console.

### Kubernetes Worker Nodes and Node Pools

Worker nodes constitute the cluster data plane. Worker nodes are where you run the applications that you deploy in a cluster.

Each worker node runs a number of processes, including:

- kubelet to communicate with the cluster control plane
- kube-proxy to maintain networking rules

The cluster control plane processes monitor and record the state of the worker nodes and distribute requested operations between them.

A node pool is a subset of worker nodes within a cluster that all have the same configuration. Node pools enable you to create pools of machines within a cluster that have different configurations. For example, you might create one pool of nodes in a cluster as virtual machines, and another pool of nodes as bare metal machines. A cluster must have a minimum of one node pool, but a node pool need not contain any worker nodes.

Worker nodes in a node pool are connected to a worker node subnet in your VCN.

### Pods

Where an application running on a worker node comprises multiple containers, Kubernetes groups the containers into a single logical unit called a pod for easy management and discovery. The containers in the pod share the same networking namespace and the same storage space, and can be managed as a single object by the cluster control plane. A number of pods providing the same functionality can be grouped into a single logical set known as a service.

For more information about pods, see the [Kubernetes documentation](https://kubernetes.io/docs/concepts/cluster-objects/pods-containers/).

### Services

In Kubernetes, a service is an abstraction that defines a logical set of pods and a policy by which to access them. The set of pods targeted by a service is usually determined by a selector.

For some parts of an application (for example, frontends), you might want to expose a service on an external IP address outside of a cluster.
Kubernetes ServiceTypes enable you to specify the kind of service you want to expose. A LoadBalancer ServiceType creates an Oracle Cloud Infrastructure load balancer on load balancer subnets in your VCN.

For more information about services in general, see the Kubernetes documentation. For more information about creating load balancer services with Container Engine for Kubernetes, see Creating Load Balancers to Distribute Traffic Between Cluster Nodes on page 1284.

**Manifest Files (or Pod Specs)**

A Kubernetes manifest file comprises instructions in a yaml or json file that specify how to deploy an application to the node or nodes in a Kubernetes cluster. The instructions include information about the Kubernetes deployment, the Kubernetes service, and other Kubernetes objects to be created on the cluster. The manifest is commonly also referred to as a pod spec, or as a deployment.yaml file (although other filenames are allowed). The parameters to include in a Kubernetes manifest file are described in the Kubernetes documentation.

**Admission Controllers**

A Kubernetes admission controller intercepts authenticated and authorized requests to the Kubernetes API server before admitting an object (such as a pod) to the cluster. An admission controller can validate an object, or modify it, or both. Many advanced features in Kubernetes require an enabled admission controller. For more information, see the Kubernetes documentation.

The Kubernetes version you select when you create a cluster using Container Engine for Kubernetes determines the admission controllers supported by that cluster. To find out the supported admission controllers, the order in which they run in the Kubernetes API server, and the Kubernetes versions in which they are supported, see Supported Admission Controllers on page 1343.

**Namespaces**

A Kubernetes cluster can be organized into namespaces, to divide the cluster's resources between multiple users. Initially, a cluster has the following namespaces:

- default, for resources with no other namespace
- kube-system, for resources created by the Kubernetes system
- kube-node-lease, for one lease object per node to help determine node availability
- kube-public, usually used for resources that have to be accessible across the cluster

For more information about namespaces, see the Kubernetes documentation.

**Preparing for Container Engine for Kubernetes**

Before you can use Container Engine for Kubernetes to create a Kubernetes cluster:

- You must have access to an Oracle Cloud Infrastructure tenancy. The tenancy must be subscribed to one or more of the regions in which Container Engine for Kubernetes is available (see Availability by Region on page 1209).
- Your tenancy must have sufficient quota on different types of resource (see Service Limits on page 243). More specifically:
  - Compute instance quota: To create a Kubernetes cluster, at least one compute instance (node) must be available in the tenancy. However, you'll probably want more than this minimum. For example, to create a highly available cluster in a region with three availability domains (ADs), at least three compute instances must be available (one in each availability domain).
  - Block volume quota: If you intend to create Kubernetes persistent volumes, sufficient block volume quota must be available in each availability domain to meet the persistent volume claim. Persistent volume claims must request a minimum of 50 gigabytes. See Creating a Persistent Volume Claim on page 1296.
  - Load balancer quota: If you intend to create a load balancer to distribute traffic between the nodes running a service in a Kubernetes cluster, sufficient load balancer quota must be available in the region. See Creating Load Balancers to Distribute Traffic Between Cluster Nodes on page 1284.
• Within your tenancy, there must already be a compartment to contain the necessary network resources (such as a VCN, subnets, internet gateway, route table, security lists). If such a compartment does not exist already, you will have to create it. Note that the network resources can reside in the root compartment. However, if you expect multiple teams to create clusters, best practice is to create a separate compartment for each team.

• Within the compartment, network resources (such as a VCN, subnets, internet gateway, route table, security lists) must be appropriately configured in each region in which you want to create and deploy clusters. For example, to create a highly available cluster in a region with three availability domains, the VCN must include:
  • For worker nodes: a regional subnet (recommended), or three AD-specific subnets (one in each of the availability domains).
  • For load balancers: optionally (but usually) an additional regional subnet (recommended), or an additional two AD-specific subnets (each in a different availability domain).

Best practice is to use regional subnets to make failover across availability domains simpler to implement.

When creating a new cluster, you can have Container Engine for Kubernetes automatically create and configure new network resources for the new cluster, or you can specify existing network resources. If you specify existing network resources, you or somebody else must have already configured those resources appropriately. See Network Resource Configuration for Cluster Creation and Deployment on page 1209.

• To create and/or manage clusters, you must belong to one of the following:
  • The tenancy's Administrators group
  • A group to which a policy grants the appropriate Container Engine for Kubernetes permissions. See Create Required Policy for Groups on page 1230.

• To perform Kubernetes operations on a cluster:
  • You must be able to run the Kubernetes command line tool kubectl. You can use the kubectl installation included in Cloud Shell, or you can use a local installation of kubectl (see Accessing a Cluster Using Kubectl on page 1248).
  • You must have set up your own copy of the cluster's kubeconfig configuration file (see Setting Up Cluster Access on page 1242). Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up.
  • You must have appropriate permissions to access the cluster (see About Access Control and Container Engine for Kubernetes on page 1254).

Availability by Region

Container Engine for Kubernetes is available in all the Oracle Cloud Infrastructure regions listed at Regions and Availability Domains on page 208. Refer to that topic to see region identifiers, region keys, and availability domain names.

In some cases, you might have to use shortened versions of availability domain names. For example, when defining a persistent volume claim (PVC), to request storage in a particular availability domain by specifying the value of the failure-domain.beta.kubernetes.io/zone Kubernetes label. To find out how to construct shortened versions of availability domain names, see failure-domain.beta.kubernetes.io/zone on page 1301.

Network Resource Configuration for Cluster Creation and Deployment

Before you can use Container Engine for Kubernetes to create and deploy clusters in the regions in a tenancy:

• Within the tenancy, there must already be a compartment to contain the necessary network resources (such as a VCN, subnets, internet gateway, route table, security lists and/or network security groups). If such a compartment does not exist already, you will have to create it. Note that the network resources can reside in the root compartment. However, if you expect multiple teams to create clusters, best practice is to create a separate compartment for each team.

• Within the compartment, network resources (such as a VCN, subnets, internet gateway, route table, security lists and/or network security groups) must be appropriately configured in each region in which you want to create and deploy clusters. When creating a new cluster, you can have Container Engine for Kubernetes automatically create and configure new network resources in the 'Quick Create' workflow. Alternatively, you can explicitly specify the
existing network resources to use in the 'Custom Create' workflow. If you specify existing network resources, you or somebody else must have already configured those resources appropriately, as described in this topic.

This topic describes the necessary configuration for each network resource. To see details of a typical configuration, see Example Network Resource Configurations on page 1215.

For an introductory tutorial, see Creating a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes. A number of related Developer Tutorials are also available.

**VCN Configuration**

The VCN in which you want to create and deploy clusters must be configured as follows:

- The VCN must have a CIDR block defined that is large enough for the number of subnets you specify for the clusters you create. For example, to create a highly available cluster in a region with three availability domains will typically require two regional subnets (recommended) or five AD-specific subnets to support the necessary number of worker nodes and load balancers. However, you can create clusters with fewer subnets. A /16 CIDR block would be large enough for almost all use cases (10.0.0.0/16 for example). The CIDR block you specify for the VCN must not overlap with the CIDR block you specify for pods and for the Kubernetes services (see CIDR Blocks and Container Engine for Kubernetes on page 1229).

- The VCN must have an appropriate number of subnets defined for worker nodes, load balancers and the Kubernetes API endpoint. Best practice is to use regional subnets to make failover across availability domains simpler to implement. See Subnet Configuration on page 1214.

- The VCN must have security rules defined (in either or both security lists for each subnet and/or network security groups). See Security Rule Configuration in Security Lists and/or Network Security Groups on page 1211.

- Oracle recommends DNS Resolution is selected for the VCN.

- If you are using public subnets, the VCN must have an internet gateway. See Internet Gateway Configuration on page 1210.

- If you are using private subnets, the VCN must have a NAT gateway and a service gateway. See NAT Gateway Configuration on page 1210 and Service Gateway Configuration on page 1210.

- If the VCN has a NAT gateway, service gateway, or internet gateway, it must have a route table with appropriate rules defined. See Route Table Configuration on page 1211.

See VCNs and Subnets on page 3693 and Example Network Resource Configurations on page 1215.

**Internet Gateway Configuration**

If you intend to use public subnets (for worker nodes, load balancers, or the Kubernetes API endpoint) and the subnets require access to/from the internet, the VCN must have an internet gateway. The internet gateway must be specified as the target for the destination CIDR block 0.0.0.0/0 as a route rule in a route table.

See VCNs and Subnets on page 3693 and Example Network Resource Configurations on page 1215.

**NAT Gateway Configuration**

If you intend to use private subnets (for worker nodes or the Kubernetes API endpoint) and the subnets require access to the internet, the VCN must have a NAT gateway. For example, if you expect deployed applications to download software or to access third party services.

The NAT gateway must be specified as the target for the destination CIDR block 0.0.0.0/0 as a route rule in a route table.

See NAT Gateway on page 4119 and Example Network Resource Configurations on page 1215.

**Service Gateway Configuration**

If you intend to use private subnets for worker nodes or the Kubernetes API endpoint, the VCN must have a service gateway.

Create the service gateway in the same VCN and compartment as the worker nodes subnet and the Kubernetes API endpoint subnet, and select the All <region> Services in Oracle Services Network option.

The service gateway must be specified as the target for All <region> Services in Oracle Services Network as a route rule in a route table.
See Access to Oracle Services: Service Gateway on page 4127 and Example Network Resource Configurations on page 1215.

**Route Table Configuration**

**Route Table for Worker Nodes Subnets**

If you intend to deploy worker nodes in a public subnet, the subnet route table must have a route rule that specifies the internet gateway as the target for the destination CIDR block 0.0.0.0/0.

If you intend to deploy worker nodes in a private subnet, the subnet route table must have:

- a route rule that specifies the service gateway as the target for All `<region>` Services in Oracle Services Network
- a route rule that specifies the NAT gateway as the target for the destination CIDR block 0.0.0.0/0

**Route Table for Kubernetes API Endpoint Subnets**

If you intend to deploy the Kubernetes API endpoint in a public subnet, the subnet route table must have a route rule that specifies the internet gateway as the target for the destination CIDR block 0.0.0.0/0.

If you intend to deploy the Kubernetes API endpoint in a private subnet, the subnet route table must have:

- a route rule that specifies the service gateway as the target for All `<region>` Services in Oracle Services Network
- a route rule that specifies the NAT gateway as the target for the destination CIDR block 0.0.0.0/0

**Route Table for Load Balancer Subnets**

If you intend to deploy load balancers in public subnets, the subnet route table must have a route rule that specifies the internet gateway as the target for the destination CIDR block 0.0.0.0/0.

If you intend to deploy load balancers in private subnets, the subnet route table can be empty.

**Notes about Route Table Configuration**

- To avoid the possibility of asymmetric routing, a route table for a public subnet cannot contain both a route rule that targets an internet gateway as well as a route rule that targets a service gateway (see Issues with access from Oracle services through a service gateway to your public instances).
- For more information about setting up route tables, see:
  - Internet Gateway on page 4114
  - NAT Gateway on page 4119
  - Access to Oracle Services: Service Gateway on page 4127
  - Example Network Resource Configurations on page 1215

**DHCP Options Configuration**

The VCN in which you want to create and deploy clusters must have DHCP Options configured. The default value for DNS Type of Internet and VCN Resolver is acceptable.

See DHCP Options on page 3789 and Example Network Resource Configurations on page 1215.

**Security Rule Configuration in Security Lists and/or Network Security Groups**

The VCN in which you want to create and deploy clusters must have security rules defined. You can define the security rules in either or both the following ways:

- In Security lists that are already associated with the subnets that you select for the worker nodes, for the Kubernetes API endpoint, and for load balancers (if specified) when you create a cluster.
- In Network security groups that you select for node pools, for the Kubernetes API endpoint, and for load balancers (if specified) when you create a cluster.
The worker nodes, Kubernetes API endpoint, and load balancer have different security rule requirements, as described in this topic. You can add additional rules to meet your specific needs.

If you specify security rules in both security lists and network security groups, all the security rules are applied (that is, the union of the security rules).

For more information, see:
- Example Network Resource Configurations on page 1215
- Security Rules on page 3710
- Security Lists on page 3727
- Network Security Groups on page 3718

Security Rules for the Kubernetes API Endpoint

The following ingress rules must be defined for the Kubernetes API endpoint, in a security list and/or in a network security group:

<table>
<thead>
<tr>
<th>State</th>
<th>Source</th>
<th>Protocol/Dest. Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stateful</td>
<td>Worker Nodes CIDR</td>
<td>TCP/6443</td>
<td>Kubernetes worker to Kubernetes API endpoint</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>communication</td>
</tr>
<tr>
<td>Stateful</td>
<td>Worker Nodes CIDR</td>
<td>TCP/12250</td>
<td>Kubernetes worker to control plane communication</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Stateful</td>
<td>Worker Nodes CIDR</td>
<td>ICMP 3,4</td>
<td>Path Discovery.</td>
</tr>
</tbody>
</table>

The following optional ingress rules can be defined for the Kubernetes API endpoint, in a security list and/or in a network security group:

<table>
<thead>
<tr>
<th>State</th>
<th>Source</th>
<th>Protocol/Dest. Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stateful</td>
<td>0.0.0.0/0 or specific subnets</td>
<td>TCP/6443</td>
<td>Client access to Kubernetes API endpoint</td>
</tr>
</tbody>
</table>

The following egress rules must be defined for the Kubernetes API endpoint, in a security list and/or in a network security group:

<table>
<thead>
<tr>
<th>State</th>
<th>Destination</th>
<th>Protocol/Dest. Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stateful</td>
<td>All &lt;region&gt; Services in Oracle Services Network</td>
<td>TCP/443</td>
<td>Allow Kubernetes control plane to communicate with OKE.</td>
</tr>
<tr>
<td>Stateful</td>
<td>Worker Nodes CIDR</td>
<td>TCP/ALL</td>
<td>All traffic to worker nodes.</td>
</tr>
<tr>
<td>Stateful</td>
<td>Worker Nodes CIDR</td>
<td>ICMP 3,4</td>
<td>Path Discovery.</td>
</tr>
</tbody>
</table>

Security Rules for Worker Nodes

Worker nodes are created with public or private IP addresses, according to whether you specify public or private subnets when defining the node pools in a cluster. Container Engine for Kubernetes must be able to access worker nodes.

The following ingress rules must be defined for worker nodes, in a security list and/or in a network security group:
<table>
<thead>
<tr>
<th>State</th>
<th>Source</th>
<th>Protocol/Dest. Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stateful</td>
<td>Worker Nodes CIDR</td>
<td>ALL/ALL</td>
<td>Allow pods on one worker node to communicate with pods on other worker nodes.</td>
</tr>
<tr>
<td>Stateful</td>
<td>Kubernetes API Endpoint CIDR</td>
<td>TCP/ALL</td>
<td>Allow Kubernetes control plane to communicate with worker nodes.</td>
</tr>
<tr>
<td>Stateful</td>
<td>0.0.0.0/0</td>
<td>ICMP 3,4</td>
<td>Path Discovery.</td>
</tr>
</tbody>
</table>

The following optional ingress rules can be defined for worker nodes, in a security list and/or in a network security group:

<table>
<thead>
<tr>
<th>State</th>
<th>Source</th>
<th>Protocol/Dest. Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stateful</td>
<td>0.0.0.0/0 or subnet CIDR</td>
<td>TCP/22</td>
<td>(optional) Allow inbound SSH traffic to worker nodes.</td>
</tr>
</tbody>
</table>

The following egress rules must be defined for worker nodes, in a security list and/or in a network security group:

<table>
<thead>
<tr>
<th>State</th>
<th>Destination</th>
<th>Protocol/Dest. Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stateful</td>
<td>Worker Nodes CIDR</td>
<td>ALL/ALL</td>
<td>Allow pods on one worker node to communicate with pods on other worker nodes.</td>
</tr>
<tr>
<td>Stateful</td>
<td>0.0.0.0/0</td>
<td>ICMP 3,4</td>
<td>Path Discovery.</td>
</tr>
<tr>
<td>Stateful</td>
<td>All &lt;region&gt; Services in Oracle Services Network</td>
<td>TCP/ALL</td>
<td>Allow nodes to communicate with OKE.</td>
</tr>
<tr>
<td>Stateful</td>
<td>Kubernetes API Endpoint CIDR</td>
<td>TCP/6443</td>
<td>Kubernetes worker to Kubernetes API endpoint communication.</td>
</tr>
<tr>
<td>Stateful</td>
<td>Kubernetes API Endpoint CIDR</td>
<td>TCP/12250</td>
<td>Kubernetes worker to control plane communication.</td>
</tr>
</tbody>
</table>

The following optional egress rules can be defined for worker nodes, in a security list and/or in a network security group:

<table>
<thead>
<tr>
<th>State</th>
<th>Destination</th>
<th>Protocol/Dest. Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stateful</td>
<td>0.0.0.0/0</td>
<td>TCP/ALL</td>
<td>(optional) Allow worker nodes to communicate with internet.</td>
</tr>
</tbody>
</table>

**Security Rules for Load Balancers**

Load balancers do not require pre-defined security rules.

The Kubernetes Cloud Controller Manager sets security rules automatically when Kubernetes services are deployed.

When deploying a service of type LoadBalancer, you can optionally:
* Use the security list management feature in Kubernetes to manage security list rules yourself (see Specifying Load Balancer Security List Management Options on page 1293).
* Specify network security groups (see Specifying Load Balancer Network Security Groups on page 1292).

**Subnet Configuration**

The characteristics of the cluster you want to create will determine the number of subnets to configure. Best practice is to use regional subnets to make failover across availability domains simpler to implement.

The VCN in which you want to create and deploy clusters must have at least two (optionally, three) different subnets:

- a Kubernetes API endpoint subnet
- a worker nodes subnet
- (optionally) one or two load balancer subnets

Although you can choose to combine the subnets, and also to combine security rules, this approach is not recommended because it makes security harder to manage.

The subnet CIDR blocks must not overlap with CIDR blocks you specify for pods running in the cluster (see CIDR Blocks and Container Engine for Kubernetes on page 1229).

The subnets must be configured with the following properties:

- **Route Table:** see Route Table Configuration on page 1211
- **DHCP options:** see DHCP Options Configuration on page 1211
- **Security List:** (only if you intend to use security rules in security lists to control access to clusters) see Security Rule Configuration in Security Lists and/or Network Security Groups on page 1211

See VCNs and Subnets on page 3693 and Example Network Resource Configurations on page 1215.

**Kubernetes API Endpoint Subnet Configuration**

The Kubernetes API endpoint subnet hosts an endpoint that provides access to the Kubernetes API on the cluster control plane.

The Kubernetes API endpoint subnet must be a regional subnet, and can be a private or a public subnet:

- If you specify a public subnet for the Kubernetes API endpoint, you can optionally assign a public IP address to the Kubernetes API endpoint subnet. The public IP address enables third party cloud services (such as SaaS CI/CD services) to access the Kubernetes API endpoint.
- If you specify a private subnet for the Kubernetes API endpoint, traffic can access the Kubernetes API endpoint subnet from another subnet in your VCN, from another VCN, or from your on-premise network (peered with FastConnect). You can also set up a bastion host on a public subnet to reach the Kubernetes API endpoint.

**Worker Node Subnet Configuration**

A worker node subnet hosts the worker nodes in a node pool.

The worker node subnet can be either a single regional subnet or multiple AD-specific subnets (one in each of the availability domains).

The worker node subnet can be either a public subnet or a private subnet. However, we recommend the worker node subnet is a private subnet for maximum security.

**Load Balancer Subnet Configuration**

Load balancer subnet(s) connect Oracle Cloud Infrastructure load balancers created by Kubernetes services of type LoadBalancer.

The load balancer subnets can be single regional subnets or AD-specific subnets (one in each of the availability domains). However, we recommend regional subnets.

The load balancer subnets can be either public or private subnets, depending on how applications deployed on the cluster will be accessed. If applications will be accessed internally from within your VCN, use private subnets for
the load balancer subnets. If applications will be accessed from the internet, use public subnets for the load balancer subnets.

### Example Network Resource Configurations

When creating a new cluster, you can use the 'Quick Create' workflow to create new network resources automatically. Alternatively, you can use the 'Custom Create' workflow to explicitly specify existing network resources. For more information about the required network resources, see Network Resource Configuration for Cluster Creation and Deployment on page 1209.

This topic gives examples of how you might configure network resources when using the 'Custom Create' workflow to create highly available clusters in a region with three availability domains:

- **Example 1:** Cluster with Public Kubernetes API Endpoint, Public Worker Nodes, and Public Load Balancers on page 1215
- **Example 2:** Cluster with Public Kubernetes API Endpoint, Private Worker Nodes, and Public Load Balancers on page 1219
- **Example 3:** Cluster with Private Kubernetes API Endpoint, Private Worker Nodes, and Public Load Balancers on page 1222
- **Example 4:** Cluster with Private Kubernetes API Endpoint, Private Worker Nodes, and Private Load Balancers on page 1226

For an introductory tutorial, see Creating a Cluster with Oracle Cloud Infrastructure Container Engine for Kubernetes. A number of related Developer Tutorials are also available.

**Note:**

The examples in this section show the use of security rules in security lists to control access to clusters. If you prefer network security groups over security lists, you can specify identical security rules for network security groups.

**Example 1: Cluster with Public Kubernetes API Endpoint, Public Worker Nodes, and Public Load Balancers**

This example assumes you want the Kubernetes API endpoint, worker nodes, and load balancers accessible directly from the internet.
## VCN

<table>

### Security List Rules for Public Kubernetes API Endpoint Subnet

The seclist-KubernetesAPIendpoint security list has the ingress and egress rules shown here.

#### Ingress Rules:

<table>
<thead>
<tr>
<th>State</th>
<th>Source</th>
<th>Protocol/Dest. Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stateful</td>
<td>10.0.1.0/24 (Worker Nodes CIDR)</td>
<td>TCP/6443</td>
<td>Kubernetes worker to Kubernetes API endpoint communication.</td>
</tr>
<tr>
<td>Stateful</td>
<td>10.0.1.0/24 (Worker Nodes CIDR)</td>
<td>TCP/12250</td>
<td>Kubernetes worker to control plane communication.</td>
</tr>
<tr>
<td>Stateful</td>
<td>10.0.1.0/24 (Worker Nodes CIDR)</td>
<td>ICMP 3,4</td>
<td>Path Discovery.</td>
</tr>
<tr>
<td>Stateful</td>
<td>0.0.0.0/0 or specific CIDR</td>
<td>TCP/6443</td>
<td>(optional) External access to Kubernetes API endpoint.</td>
</tr>
</tbody>
</table>

#### Egress Rules:

<table>
<thead>
<tr>
<th>State:</th>
<th>Destination</th>
<th>Protocol / Dest. Port</th>
<th>Description:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stateful</td>
<td>All &lt;region&gt; Services in Oracle Services Network</td>
<td>TCP/443</td>
<td>Allow Kubernetes control plane to communicate with OKE.</td>
</tr>
<tr>
<td>Stateful</td>
<td>10.0.1.0/24 (Worker Nodes CIDR)</td>
<td>TCP/ALL</td>
<td>All traffic to worker nodes.</td>
</tr>
</tbody>
</table>
## Container Engine for Kubernetes

### Security List Rules for Public Worker Nodes Subnet

Security List Rules for Private Worker Nodes Subnet

The seclist-workernodes security list has the ingress and egress rules shown here.

**Ingress Rules:**
Container Engine for Kubernetes

State: | Source | Protocol / Dest. Port | Description:
---|---|---|---
Stateful | 10.0.1.0/24 (Worker Nodes CIDR) | ALL/ALL | Allow pods on one worker node to communicate with pods on other worker nodes.
Stateful | 10.0.0.0/30 (Kubernetes API Endpoint CIDR) | TCP/ALL | Allow Kubernetes control plane to communicate with worker nodes.
Stateful | 0.0.0.0/0 | ICMP 3,4 | Path Discovery.
Stateful | 0.0.0.0/0 or subnet CIDR | TCP/22 | (optional) Allow inbound SSH traffic to worker nodes.

Egress Rules:

State: | Destination | Protocol / Dest. Port | Description:
---|---|---|---
Stateful | 10.0.1.0/24 (Worker Nodes CIDR) | ALL/ALL | Allow pods on one worker node to communicate with pods on other worker nodes.
Stateful | 0.0.0.0/0 | ICMP 3,4 | Path Discovery.
Stateful | All <region> Services in Oracle Services Network | TCP/ALL | Allow worker nodes to communicate with OKE.
Stateful | 10.0.0.0/30 (Kubernetes API Endpoint CIDR) | TCP/6443 | Kubernetes worker to Kubernetes API endpoint communication.
Stateful | 10.0.0.0/30 (Kubernetes API Endpoint CIDR) | TCP/12250 | Kubernetes worker to control plane communication.
Stateful | 0.0.0.0/0 | TCP/ALL | (optional) Allow worker nodes to communicate with internet.

Security List Rules for Private Load Balancer Subnet

The seclist-loadbalancers security list has the ingress and egress rules shown here.

**Ingress Rules:** None

**Egress Rules:** None

**CIDR Blocks and Container Engine for Kubernetes**

When configuring the VCN and subnets (for the Kubernetes API endpoint, worker nodes and load balancers) to use with Container Engine for Kubernetes, you specify CIDR blocks to indicate the network addresses that can be allocated to the resources. See Network Resource Configuration for Cluster Creation and Deployment on page 1209.

When creating a cluster with Container Engine for Kubernetes, you specify:

- CIDR blocks for the Kubernetes services
- CIDR blocks that can be allocated to pods running in the cluster (see Creating a Kubernetes Cluster on page 1234)
Note the following:

- The CIDR block you specify for the VCN must not overlap with the CIDR block you specify for the Kubernetes services.
- The Kubernetes API endpoint subnet only requires a small CIDR block, since the cluster only requires one IP address in this subnet. A /30 CIDR block of network addresses is sufficient for the Kubernetes API endpoint subnet.
- The CIDR blocks you specify for pods running in the cluster must not overlap with CIDR blocks you specify for the Kubernetes API endpoint, worker node, and load balancer subnets.
- Each pod running on a worker node is assigned its own network address. Container Engine for Kubernetes allocates a /25 CIDR block of network addresses for each worker node in a cluster, to assign to pods running on that node. A /25 CIDR block equates to 128 distinct IP addresses, of which one is reserved. So a maximum of 127 network addresses are available to assign to pods running on each worker node (more than sufficient, given that the number of pods per node is capped at 110).
- When you create a cluster, you specify a value for the cluster's **Pods CIDR Block** property, either implicitly in the case of the 'Quick Create' workflow or explicitly in the case of the 'Custom Create' workflow. You cannot change the cluster's **Pods CIDR Block** property after the cluster has been created. The cluster's **Pods CIDR Block** property constrains the maximum total number of network addresses available for allocation to pods running on all the nodes in the cluster, and therefore effectively limits the number of nodes in the cluster. By default, the cluster's **Pods CIDR Block** property is set to a /16 CIDR block, making 65,536 network addresses available for all the nodes in the cluster. Since 128 network addresses are allocated for each node, specifying a /16 CIDR block for the cluster's **Pods CIDR Block** property limits the number of nodes in the cluster to 512. This is generally sufficient. To support more than 512 nodes in a cluster, create a cluster in the 'Custom Create' workflow and specify a larger value for the cluster's **Pods CIDR Block** property. For example, specify a /14 CIDR block for the cluster's **Pods CIDR Block** property to create a cluster with 262,144 network addresses available for the nodes in the cluster (more than sufficient, given that the number of nodes per cluster is capped at 1000).

### Policy Configuration for Cluster Creation and Deployment

When a tenancy is created, an Administrators group is automatically created for the tenancy. Users that are members of the Administrators group can perform any operation on resources in the tenancy. If all the users that will be working with Container Engine for Kubernetes are already members of the Administrators group, there’s no need to create additional policies. However, if you want to enable users that are not members of the Administrators group to use Container Engine for Kubernetes, you must create policies to enable the groups to which those users do belong to perform operations on resources in the tenancy or in individual compartments. Some policies are required, some are optional. See [Create Required Policy for Groups](#) on page 1230 and [Create One or More Additional Policies for Groups](#) on page 1232.

Note that in addition to the above policies managed by IAM, you can also use the Kubernetes RBAC Authorizer to enforce additional fine-grained access control for users on specific clusters via Kubernetes RBAC roles and clusterroles. See [About Access Control and Container Engine for Kubernetes](#) on page 1254.

### Create Required Policy for Groups

To create, update, and delete clusters and node pools, users that are not members of the Administrators group must have permissions to work with cluster-related resources. To give users the necessary access, you must create a policy with a number of required policy statements for the groups to which those users do belong:

1. In the Console, open the navigation menu and click **Identity & Security**. Under **Identity**, click **Policies**. A list of the policies in the compartment you're viewing is displayed.
2. Select the tenancy's root compartment or an individual compartment containing cluster-related resources from the list on the left.
3. Click **Create Policy**.
4. Enter the following:
   - **Name**: A name for the policy (for example, `acme-dev-team-oke-required-policy`) that is unique within the compartment. If you are creating the policy in the tenancy's root compartment, the name must
be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.

- **Description:** A friendly description. You can change this later if you want to.
- **Statement:** The following required policy statements to enable users to use Container Engine for Kubernetes to create, update, and delete clusters and node pools:

  ```markdown
  Allow group <group-name> to manage instance-family in <location>
  
  Allow group <group-name> to use subnets in <location>
  
  Allow group <group-name> to read virtual-network-family in <location>
  
  Allow group <group-name> to inspect compartments in <location>
  
  Allow group <group-name> to use vnics in <location>
  
  Allow group <group-name> to use network-security-groups in <location>
  
  Allow group <group-name> to use private-ips in <location>
  
  Allow group <group-name> to manage public-ips in <location>
  
  The following required policy statement to enable users to perform any operation on cluster-related resources (this 'catch-all' policy effectively makes all users administrators insofar as cluster-related resources are concerned):

  ```markdown
  Allow group <group-name> to manage cluster-family in <location>
  ```
  
  In the above policy statements, replace <location> with either tenancy (if you are creating the policy in the tenancy's root compartment) or compartment <compartment-name> (if you are creating the policy in an individual compartment).

**Note:**

Depending on the type of cluster, some required policy statements might not be necessary:

- To work with "VCN-native" clusters (where the Kubernetes API endpoint is fully integrated with your VCN), the use network-security-groups and use public-ips policy statements are only necessary if the clusters' network security group and public IP address options are selected.
- To work with clusters where the public Kubernetes API endpoint is in an Oracle-managed tenancy, the use network-security-groups, use private-ips, and use public-ips policy statements are unnecessary.

For more information about VCN-native clusters, see Kubernetes Cluster Control Plane and Kubernetes API on page 1206.

- **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.
5. Click Create.

Create One or More Additional Policies for Groups

To enable users that are not members of the Administrators group to use Container Engine for Kubernetes, create additional policies to enable the groups to which those users do belong to perform operations on cluster-related resources as follows:

1. In the Console, open the navigation menu and click Identity & Security. Under Identity, click Policies. A list of the policies in the compartment you're viewing is displayed.
2. Select the tenancy's root compartment or an individual compartment containing cluster-related resources from the list on the left.
3. Click Create Policy.
4. Enter the following:
   - Name: A name for the policy (for example, acme-dev-team-oke-additional-policy) that is unique within the compartment. If you are creating the policy in the tenancy's root compartment, the name must be unique across all policies in your tenancy. You cannot change this later. Avoid entering confidential information.
   - Description: A friendly description. You can change this later if you want to.
   - Statement: A suitable policy statement to allow existing groups to perform operations on cluster-related resources. In the example policy statements below, replace <location> with either tenancy (if you are
creating the policy in the tenancy's root compartment) or compartment `<compartment-name>` (if you are creating the policy in an individual compartment):

- To enable users in the acme-dev-team group to automatically create and configure associated new network resources when creating new clusters in the 'Quick Create' workflow, policies must also grant the group:
  - VCN_READ and VCN_CREATE permissions. Enter a policy statement like:
    ```
    Allow group acme-dev-team to manage vcns in <location>
    ```
  - SUBNET_READ and SUBNET_CREATE permissions. Enter a policy statement like:
    ```
    Allow group acme-dev-team to manage subnets in <location>
    ```
  - INTERNET_GATEWAY_CREATE permission. Enter a policy statement like:
    ```
    Allow group acme-dev-team to manage internet-gateways in <location>
    ```
  - NAT_GATEWAY_CREATE permission. Enter a policy statement like:
    ```
    Allow group acme-dev-team to manage nat-gateways in <location>
    ```
  - ROUTE_TABLE_UPDATE permission. Enter a policy statement like:
    ```
    Allow group acme-dev-team to manage route-tables in <location>
    ```
  - SECURITY_LIST_CREATE permission. Enter a policy statement like:
    ```
    Allow group acme-dev-team to manage security-lists in <location>
    ```

- To enable users in the acme-dev-team-cluster-viewers group to simply list the clusters, enter a policy statement like:
  ```
  Allow group acme-dev-team-cluster-viewers to inspect clusters in <location>
  ```

- To enable users in the acme-dev-team-pool-admins group to list, create, update, and delete node pools, enter a policy statement like:
  ```
  Allow group acme-dev-team-pool-admins to use cluster-node-pools in <location>
  ```

- To enable users in the acme-dev-team-auditors group to see details of operations performed on clusters, enter a policy statement like:
  ```
  Allow group acme-dev-team-auditors to read cluster-work-requests in <location>
  ```

- To enable users in the acme-dev-team-sgw group to create a service gateway to enable worker nodes to access other resources in the same region without exposing data to the public internet, enter a policy statement like:
  ```
  Allow group acme-dev-team-sgw to manage service-gateways in <location>
  ```

- To enable users in the acme-dev-team group to access clusters using Cloud Shell, enter a policy statement like:
  ```
  Allow group acme-dev-team to use cloud-shell in <location>
  ```

Note that to access clusters using Cloud Shell, you’ll also need to set up the kubeconfig file appropriately (see Setting Up Cloud Shell Access to Clusters on page 1242). For more information about Cloud Shell, see Cloud Shell.
• **Tags:** If you have permissions to create a resource, then you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see Resource Tags on page 239. If you are not sure whether to apply tags, skip this option (you can apply tags later) or ask your administrator.

5. Click **Create**.

### Creating a Kubernetes Cluster

You can use Container Engine for Kubernetes to create new Kubernetes clusters. To create a cluster, you must either belong to the tenancy's Administrators group, or belong to a group to which a policy grants the CLUSTER_MANAGE permission. See Policy Configuration for Cluster Creation and Deployment on page 1230.

Using the Console, you first specify basic details for the new cluster (the cluster name, and the Kubernetes version to install on control plane nodes). You can then create the cluster in one of two ways:

- **Using default settings in the 'Quick Create' workflow** to create a cluster with new network resources as required. This approach is the fastest way to create a new cluster. If you accept all the default values, you can create a new cluster in just a few clicks. New network resources for the cluster are created automatically, including regional subnets for the Kubernetes API endpoint, for worker nodes, and for load balancers. The regional subnet for load balancers is public, but you specify whether the regional subnets for the Kubernetes API endpoint and for worker nodes are public or private. To create a cluster in the 'Quick Create' workflow, you must belong to a group to which a policy grants the necessary permissions to create the new network resources (see Create One or More Additional Policies for Groups on page 1232).

- **Using custom settings in the 'Custom Create' workflow**. This approach gives you the most control over the new cluster. You can explicitly define the new cluster's properties. And you can explicitly specify which existing network resources to use, including the existing public or private subnets in which to create the Kubernetes API endpoint, worker nodes, and load balancers.

Note that although you will usually define node pools immediately when defining a new cluster in the 'Custom Create' workflow, you don't have to. You can create a cluster with no node pools, and add node pools later. One reason to create a cluster that initially has no node pools is if you intend to install and configure a CNI network provider like Calico to support Kubernetes NetworkPolicy resources. If you install Calico on a cluster that has existing node pools in which pods are already running, you'll have to recreate the pods when the Calico installation is complete. For example, by running the kubectl rollout restart command. If you install Calico on a cluster before creating any node pools in the cluster (recommended), you can be sure that there will be no pods to recreate. See Example: Installing Calico and Setting Up Network Policies on page 1310.

Regardless of how you create a cluster, Container Engine for Kubernetes gives names to worker nodes in the following format:

\[
\text{oke-c<part-of-cluster-OCID>-n<part-of-node-pool-OCID>-s<part-of-subnet-OCID>-<slot>}
\]

where:

- \(\text{oke}\) is the standard prefix for all worker nodes created by Container Engine for Kubernetes
- \(\text{c<part-of-cluster-OCID>}\) is a portion of the cluster's OCID, prefixed with the letter \(c\)
- \(\text{n<part-of-node-pool-OCID>}\) is a portion of the node pool's OCID, prefixed with the letter \(n\)
- \(\text{s<part-of-subnet-OCID>}\) is a portion of the subnet's OCID, prefixed with the letter \(s\)
- \(<\text{slot}>\) is an ordinal number of the node in the subnet (for example, 0, 1)

For example, if you specified a cluster is to have two nodes in a node pool, the two nodes might be named:

- \(\text{oke-cywqiqrtipuyg-nsgaqk1gnst-st2qcfnmba-0}\)
- \(\text{oke-cywqiqrtipuyg-nsgaqk1gnst-st2qcfnmba-1}\)

Do not change the auto-generated names that Container Engine for Kubernetes gives to worker nodes.

To ensure high availability, Container Engine for Kubernetes:
• creates the Kubernetes Control Plane on multiple Oracle-managed control plane nodes (distributing the control plane nodes across different availability domains in a region, where supported)
• creates worker nodes in each of the fault domains in an availability domain (distributing the worker nodes as evenly as possible across the fault domains, subject to any other infrastructure restrictions)

Using the Console to create a Cluster with Default Settings in the 'Quick Create' workflow

To create a cluster with default settings and new network resources in the 'Quick Create' workflow using Container Engine for Kubernetes:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Kubernetes Clusters (OKE).
2. Choose a Compartment you have permission to work in.
3. On the Cluster List page, click Create Cluster.
4. In the Create Cluster dialog, select Quick Create and click Launch Workflow.
5. On the Create Cluster page, either just accept the default configuration details for the new cluster, or specify alternatives as follows:
   • Name: The name of the new cluster. Either accept the default name or enter a name of your choice. Avoid entering confidential information.
   • Compartment: The compartment in which to create the new cluster and the associated network resources.
   • Kubernetes Version: The version of Kubernetes to run on the control plane nodes and worker nodes of the cluster. Either accept the default version or select a version of your choice. Amongst other things, the Kubernetes version you select determines the default set of admission controllers that are turned on in the created cluster (see Supported Admission Controllers on page 1343).
   • Kubernetes API Endpoint: The type of access to the cluster's Kubernetes API endpoint. The Kubernetes API endpoint is either private (accessible by other subnets in the VCN) or public (accessible directly from internet):
     • Private Endpoint: A private regional subnet is created and the Kubernetes API endpoint is hosted in that subnet. The Kubernetes API endpoint is assigned a private IP address.
     • Public Endpoint: A public regional subnet is created and the Kubernetes API endpoint is hosted in that subnet. The Kubernetes API endpoint is assigned a public IP address as well as a private IP address. Private and public endpoints are assigned a security rule (as part of a security list) that grants access to the Kubernetes API endpoint (TCP/6443).
   For more information, see Kubernetes Cluster Control Plane and Kubernetes API on page 1206.
   • Kubernetes Worker Nodes: The type of access to the cluster's worker nodes. The worker nodes are either private (accessible through other VCN subnets) or public (accessible directly from internet):
     • Private: A private regional subnet is created to host worker nodes. The worker nodes are assigned a private IP address.
     • Public: A public regional subnet is created to host worker nodes. The worker nodes are assigned a public IP address as well as a private IP address.
   Note that a public regional subnet is always created to host load balancers in clusters created in the 'Quick Create' workflow, regardless of your selection here.
   • Shape: The shape to use for each node in the node pool. The shape determines the number of CPUs and the amount of memory allocated to each node. If you select a flexible shape, you can explicitly specify the number of CPUs and the amount of memory. The list shows only those shapes available in your tenancy that are supported by Container Engine for Kubernetes. See Supported Images (Including Custom Images) and Shapes for Worker Nodes on page 1240.
   • Number of Nodes: The number of worker nodes to create in the node pool, placed in the regional subnet created for the cluster. The nodes are distributed as evenly as possible across the availability domains in a region (or in the case of a region with a single availability domain, across the fault domains in that availability domain).
6. Either accept the default size of worker node boot volumes (as determined from the default image used for worker nodes) or click **Specify a Custom Boot Volume Size** and specify an alternative size for worker node boot volumes in **Boot Volume Size in GB**. If you do specify a custom boot volume size, it must be larger than the image's default boot volume size. The minimum and maximum sizes you can specify are 50 GB and 32 TB respectively. See **Custom Boot Volume Sizes** on page 690.

7. Either accept the defaults for advanced cluster options, or click **Show Advanced Options** and specify alternatives as follows:

   - **Enable image verification policies on this cluster**: (Optional) Whether to only allow the deployment of images from Oracle Cloud Infrastructure Registry that have been signed by particular master encryption keys. Specify the encryption key and the vault that contains it. See **Enforcing the Use of Signed Images from Registry** on page 1282.

   - **Public SSH Key**: (Optional) The public key portion of the key pair you want to use for SSH access to each node in the node pool. The public key is installed on all worker nodes in the cluster. Note that if you don't specify a public SSH key, Container Engine for Kubernetes will provide one. However, since you won't have the corresponding private key, you will not have SSH access to the worker nodes. Note that if you specify that you want the worker nodes in the cluster to be hosted in a private regional subnet, you cannot use SSH to access them directly (see **Connecting to Worker Nodes in Private Subnets Using SSH** on page 1262).

   - **Kubernetes Labels**: (Optional) One or more labels (in addition to a default label) to add to worker nodes in the node pool to enable the targeting of workloads at specific node pools.

8. Click **Next** to review the details you entered for the new cluster.

9. Click **Create Cluster** to create the new network resources and the new cluster.

   Container Engine for Kubernetes starts creating resources (as shown in the **Creating cluster and associated network resources** dialog):

   - the network resources (such as the VCN, internet gateway, NAT gateway, route tables, security lists, a regional subnet for worker nodes and another regional subnet for load balancers), with auto-generated names in the format oke-<resource-type>-quick--<cluster-name>--<creation-date>
   - the cluster, with the name you specified
   - the node pool, named pool1
   - worker nodes, with auto-generated names in the format oke-c<part-of-cluster-OCID>-n<part-of-node-pool-OCID>-s<part-of-subnet-OCID>--<slot>

   Do not change the resource names that Container Engine for Kubernetes has auto-generated. Note that if the cluster is not created successfully for some reason (for example, if you have insufficient permissions or if you've exceeded the cluster limit for the tenancy), any network resources created during the cluster creation process are not deleted automatically. You will have to manually delete any such unused network resources.

10. Click **Close** to return to the Console.

    Initially, the new cluster appears in the Console with a status of Creating. When the cluster has been created, it has a status of Active.

    Container Engine for Kubernetes also creates a Kubernetes kubeconfig configuration file that you use to access the cluster using kubectl.

**Using the Console to create a Cluster with Explicitly Defined Settings in the 'Custom Create' workflow**

To create a cluster with explicitly defined settings and existing network resources in the 'Custom Create' workflow using Container Engine for Kubernetes:

1. In the Console, open the navigation menu and click **Developer Services**. Under **Containers**, click **Kubernetes Clusters** (OKE).

2. Choose a **Compartment** you have permission to work in.

3. On the **Cluster List** page, click **Create Cluster**.

4. In the **Create Cluster** dialog, select **Custom Create** and click **Launch Workflow**.
5. On the **Create Cluster** page, either just accept the default configuration details for the new cluster, or specify alternatives as follows:

   - **Name:** The name of the new cluster. Either accept the default name or enter a name of your choice. Avoid entering confidential information.
   - **Compartment:** The compartment in which to create the new cluster.
   - **Kubernetes Version:** The version of Kubernetes to run on the cluster’s control plane nodes and worker nodes. Either accept the default version or select a version of your choice. Amongst other things, the Kubernetes version you select determines the default set of admission controllers that are turned on in the created cluster (see Supported Admission Controllers on page 1343).

6. Either accept the defaults for advanced cluster options, or click **Show Advanced Options** and set the options as follows:

   a. Specify whether to only allow the deployment of images from Oracle Cloud Infrastructure Registry that have been signed by particular master encryption keys. To enforce the use of signed images, select **Enable image verification policies on this cluster**, and then specify the encryption key and the vault that contains it. See Enforcing the Use of Signed Images from Registry on page 1282.

   b. Specify whether to encrypt Kubernetes secrets at rest in the etcd key-value store for the cluster using the Vault service:

      - **No Encryption:** Kubernetes secrets at rest in the etcd key-value store are not encrypted.
      - **Encrypt Using Customer-Managed Keys:** Encrypt Kubernetes secrets in the etcd key-value store and specify:

         - **Choose a Vault in `<compartment-name>`:** The vault that contains the master encryption key, from the list of vaults in the specified compartment. By default, `<compartment-name>` is the compartment in which you are creating the cluster, but you can select a different compartment by clicking **Change Compartment**.
         - **Choose a Key in `<compartment-name>`:** The name of the master encryption key, from the list of keys in the specified compartment. By default, `<compartment-name>` is the compartment in which you are creating the cluster, but you can select a different compartment by clicking **Change Compartment**. Note that you cannot change the master encryption key after the cluster has been created.

   c. Specify whether to control the operations that pods are allowed to perform on the cluster by enforcing pod security policies:

      - **Not Enforced:** Do not enforce pod security policies.
      - **Enforced:** Do enforce pod security policies, by enabling the PodSecurityPolicy admission controller. Only pods that meet the conditions in a pod security policy are accepted by the cluster. For more information, see Using Pod Security Policies with Container Engine for Kubernetes on page 1345.

      **Caution:**

      It is very important to note that when you enable a cluster’s PodSecurityPolicy admission controller, no application pods can start on the cluster unless suitable pod security policies exist, along with roles (or clusterroles) and rolebindings (or clusterrolebindings) to associate pods with policies. You will not be able to run application pods on a cluster with an enabled PodSecurityPolicy admission controller unless these prerequisites are met.

      We strongly recommend you use PodSecurityPolicy admission controllers as follows:

      - Whenever you create a new cluster, enable the Pod Security Admission Controller.
7. Click Next and specify the existing network resources to use for the new cluster on the Network Setup page:

- **VCN in <compartment-name>:** The existing virtual cloud network that has been configured for cluster creation and deployment. By default, <compartment-name> is the compartment in which you are creating the cluster, but you can select a different compartment by clicking Change Compartment. See VCN Configuration on page 1210.

- **Kubernetes Service LB Subnets:** Optionally, the existing subnets that have been configured to host load balancers. Load balancer subnets must be different from worker node subnets, can be public or private, and can be regional (recommended) or AD-specific. You don't have to specify any load balancer subnets. However, if you do specify load balancer subnets, the number of load balancer subnets to specify depends on the region in which you are creating the cluster and whether the subnets are regional or AD-specific.

If you are creating a cluster in a region with three availability domains, you can specify:

- Zero or one load balancer regional subnet (recommended).
- Zero or two load balancer AD-specific subnets. If you specify two AD-specific subnets, the two subnets must be in different availability domains.

If you are creating a cluster in a region with a single availability domain, you can specify:

- Zero or one load balancer regional subnet (recommended).
- Zero or one load balancer AD-specific subnet.

See Subnet Configuration on page 1214.

- **Kubernetes API Endpoint Subnet:** A regional subnet to host the cluster's Kubernetes API endpoint. The Kubernetes API endpoint is assigned a private IP address. The subnet you specify can be public or private. To simplify access management, Oracle recommends the Kubernetes API endpoint is in a different subnet to worker nodes and load balancers. For more information, see Kubernetes Cluster Control Plane and Kubernetes API on page 1206.

- **Use network security groups to control traffic:** Control access to the cluster's Kubernetes API endpoint using security rules defined for one or more network security groups (NSGs) that you specify. You can use security rules defined for NSGs instead of, or as well as, those defined for security lists. For more information about the security rules to specify for the NSG, see Security Rules for the Kubernetes API Endpoint on page 1212.

- **Assign a public IP address to the API endpoint:** If you selected a public subnet for the Kubernetes API endpoint, you can assign a public IP to the Kubernetes API endpoint (as well as the private IP address).

8. Either accept the defaults for advanced cluster options, or click Show Advanced Options and specify alternatives as follows:

- **Kubernetes Service CIDR Block:** The available group of network addresses that can be exposed as Kubernetes services (ClusterIPs), expressed as a single, contiguous IPv4 CIDR block. For example, 10.96.0.0/16. The CIDR block you specify must not overlap with the CIDR block for the VCN. See CIDR Blocks and Container Engine for Kubernetes on page 1229.

- **Pods CIDR Block:** The available group of network addresses that can be allocated to pods running in the cluster, expressed as a single, contiguous IPv4 CIDR block. For example, 10.244.0.0/16. The CIDR block you specify must not overlap with the CIDR blocks for subnets in the VCN, and can be outside the VCN CIDR block. See CIDR Blocks and Container Engine for Kubernetes on page 1229.

9. Click Next and specify configuration details for the first node pool in the cluster on the Node Pools page:

- **Name:** A name of your choice for the new node pool. Avoid entering confidential information.
- **Version:** The version of Kubernetes to run on each worker node in the node pool. By default, the version of Kubernetes specified for the control plane nodes is selected. The Kubernetes version on worker nodes must
be either the same version as that on the control plane nodes, or an earlier version that is still compatible. See Kubernetes Versions and Container Engine for Kubernetes on page 1350.

- **Shape:** The shape to use for each node in the node pool. The shape determines the number of CPUs and the amount of memory allocated to each node. If you select a flexible shape, you can explicitly specify the number of CPUs and the amount of memory. The list shows only those shapes available in your tenancy that are supported by Container Engine for Kubernetes. See Supported Images (Including Custom Images) and Shapes for Worker Nodes on page 1240.

- **Image:** The image to use on each node in the node pool. An image is a template of a virtual hard drive that determines the operating system and other software for the node. See Supported Images (Including Custom Images) and Shapes for Worker Nodes on page 1240.

- **Number of Nodes:** The number of worker nodes to create in the node pool, placed in the availability domains you select, and in the regional subnet (recommended) or AD-specific subnet you specify for each availability domain.

- **Network Security Group:** Control access to the node pool using security rules defined for one or more network security groups (NSGs) that you specify (up to a maximum of five). You can use security rules defined for NSGs instead of, or as well as, those defined for security lists. For more information about the security rules to specify for the NSG, see Security Rules for Worker Nodes on page 1212.

- **Specify a Custom Boot Volume Size:** Either accept the default size of worker node boot volumes (as determined from the image used for worker nodes) or click and specify an alternative size for worker node boot volumes in **Boot Volume Size in GB**. If you do specify a custom boot volume size, it must be larger than the image's default boot volume size. The minimum and maximum sizes you can specify are 50 GB and 32 TB respectively. See Custom Boot Volume Sizes on page 690.

- **Placement Configuration:**
  - **Availability Domain:** An availability domain in which to place worker nodes.
  - **Subnet:** A regional subnet (recommended) or AD-specific subnet configured to host worker nodes. If you specified load balancer subnets, the worker node subnets must be different. The subnets you specify can be public or private, and can be regional (recommended) or AD-specific. See Subnet Configuration on page 1214.

  Optionally click **Another Row** to select additional domains and subnets in which to place worker nodes.

  When they are created, the worker nodes are distributed as evenly as possible across the availability domains you select (or in the case of a single availability domain, across the fault domains in that availability domain).

- **Kubernetes Labels:** (Optional) One or more labels (in addition to a default label) to add to worker nodes in the node pool to enable the targeting of workloads at specific node pools.

- **Public SSH Key:** (Optional) The public key portion of the key pair you want to use for SSH access to each node in the node pool. The public key is installed on all worker nodes in the cluster. Note that if you don't specify a public SSH key, Container Engine for Kubernetes will provide one. However, since you won't have the corresponding private key, you will not have SSH access to the worker nodes. Note that you cannot use SSH to access directly any worker nodes in private subnets (see Connecting to Worker Nodes in Private Subnets Using SSH on page 1262).

10. (Optional) Click **Another node pool** and specify configuration details for a second and subsequent node pools in the cluster.

If you define multiple node pools in a cluster, you can host all of them on a single AD-specific subnet. However, it's best practice to host different node pools for a cluster on a regional subnet (recommended) or on different AD-specific subnets (one in each availability domain in the region).

11. Click **Next** to review the details you entered for the new cluster.
12. Click **Create Cluster** to create the new cluster.

   Container Engine for Kubernetes starts creating the cluster with the name you specified.

   If you specified details for one or more node pools, Container Engine for Kubernetes creates:
   - node pools with the names you specified
   - worker nodes with auto-generated names in the format `oke-c<part-of-cluster-OCID>-n<part-of-node-pool-OCID>-s<part-of-subnet-OCID>-<slot>`

   Do not change the auto-generated names of worker nodes.

13. Click **Close** to return to the Console.

   Initially, the new cluster appears in the Console with a status of Creating. When the cluster has been created, it has a status of Active.

   Container Engine for Kubernetes also creates a Kubernetes kubeconfig configuration file that you use to access the cluster using kubectl.

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 5528 and [Security Credentials](#) on page 207. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 5351.

Use the **CreateCluster** operation to create a cluster.

**Supported Images (Including Custom Images) and Shapes for Worker Nodes**

When creating a cluster using Container Engine for Kubernetes, you can customize the worker nodes in the cluster by specifying:

- The operating system image to use for worker nodes. The image is a template of a virtual hard drive that determines the operating system and other software for the worker node.
- The shape to use for worker nodes. The shape is the number of CPUs and the amount of memory to allocate to each newly created compute instance to be used as a worker node.

This topic includes information about the images and shapes provided by Oracle Cloud Infrastructure that are supported by Container Engine for Kubernetes for use in node pools. Note that some of the shapes might not be available in your particular tenancy.

To see a list of the supported images and the shapes available in your tenancy, enter:

```bash
oci ce node-pool-options get --node-pool-option-id all
```

**Supported Images**

Container Engine for Kubernetes supports the provisioning of worker nodes using some, but not all, of the latest Oracle Linux images provided by Oracle Cloud Infrastructure.

To see the images supported by Container Engine for Kubernetes:

- When using the Console to create a cluster in the 'Custom Create' workflow, view the list of values in the **Image** drop-down menu to see the list of supported images.
- When using the CLI, view the supported images (in the `data: sources:` section of the response) by entering:

  ```bash
  oci ce node-pool-options get --node-pool-option-id all
  ```

**Custom Images**

When specifying the image that Container Engine for Kubernetes uses to provision worker nodes in a node pool, you can specify your own custom image rather than one of the explicitly supported Oracle Linux images returned by the `oci ce node-pool-options get --node-pool-option-id all` command. Worker nodes provisioned from a custom image include thecustomizations, configuration, and software that were present when the
image was created. Note that Container Engine for Kubernetes only supports custom images that are based on one of the Oracle Linux images returned by the `oci ce node-pool-options get` command.

To provision worker nodes from a custom image, you must use the CLI or API and specify the custom image’s OCID when creating the node pool. For example, by running the `oci ce node-pool create` command and using the `--node-image-id` parameter to specify a custom image's OCID, as follows:

```bash
oci ce node-pool create \
--cluster-id ocid1.cluster.oc1.iad.aaaaaaaaaf_____jrd \
--name my-custom-linux-image \
--node-image-id ocid1.image.oc1.iad.aaaaaaaa6______nha \
--compartment-id ocid1.compartment.oc1..aaaaamaay_____t6q \
--kubernetes-version v1.15.7 \
--node-shape VM.Standard2.1 \
--placement-configs "[ { "availabilityDomain": "nFuS:US-ASHBURN-AD-1", "subnetId": "ocid1.subnet.oc1.iad.aaaaaaaa3______a6q" } ]" \
--size 1 \
--region=us-ashburn-1
```

Note the following additional considerations when using custom images:

- Container Engine for Kubernetes installs Kubernetes on top of a custom image, and Kubernetes or the installation software might change certain kernel configurations.
- Custom images must have access to a yum repository (public or internal).
- Custom images must not use a customized cloud-init. You can perform post-provisioning customization using SSH or Daemset.
- For the best support, ensure you create a custom image from the most up-to-date base image.

For more information about custom images and Oracle Cloud Infrastructure, see Managing Custom Images on page 989.

**Supported Shapes**

Container Engine for Kubernetes supports the provisioning of worker nodes using many, but not all, of the shapes provided by Oracle Cloud Infrastructure. More specifically:

- **Supported**: Flexible shapes; Bare Metal shapes, including standard shapes and GPU shapes; HPC shapes, except in RDMA networks; VM shapes, including standard shapes and GPU shapes; Dense I/O shapes.
- **Not Supported**: Dedicated VM host shapes; Micro VM shapes; HPC shapes on Bare Metal instances in RDMA networks.

Note that you might be unable to select some shapes in your particular tenancy due to service limits and compartment quotas, even though those shapes are supported by Container Engine for Kubernetes.

To see the shapes that are supported by Container Engine for Kubernetes and available in your tenancy:

- When using the Console to create a cluster in the 'Custom Create' workflow, view the list of values in the **Shape** drop-down menu to see the list of supported shapes.
- When using the CLI, view the supported shapes (in the `data: shapes:` section of the response) by entering:

```bash
oci ce node-pool-options get --node-pool-option-id all
```

You might be able to use the Compute service's Console pages (or the Compute service's CLI or API) to subsequently change the shape of a worker node after it has been created. However, bear in mind that Container Engine for Kubernetes only supports those shapes shown in the **Shape** drop-down menu or returned by the `oci ce node-pool-options get --node-pool-option-id all` command.

For more information about all the shapes provided by Oracle Cloud Infrastructure, see Compute Shapes on page 973.
Setting Up Cluster Access

To access a cluster using kubectl, you have to set up a Kubernetes configuration file (commonly known as a 'kubeconfig' file) for the cluster. The kubeconfig file (by default named config and stored in the $HOME/.kube directory) provides the necessary details to access the cluster. Having set up the kubeconfig file, you can start using kubectl to manage the cluster.

The steps to follow when setting up the kubeconfig file depend on how you want to access the cluster:

• To access the cluster using kubectl in Cloud Shell, run an Oracle Cloud Infrastructure CLI command in the Cloud Shell window to set up the kubeconfig file. Note that Cloud Shell access is currently only available to clusters that have a Kubernetes API endpoint with a public IP address.
  
  See Setting Up Cloud Shell Access to Clusters on page 1242.

• To access the cluster using a local installation of kubectl:
  
  • Generate an API signing key pair (if you don't already have one).
  • Upload the public key of the API signing key pair.
  • Install and configure the Oracle Cloud Infrastructure CLI.
  • Set up the kubeconfig file.
  
  See Setting Up Local Access to Clusters on page 1243.

Setting Up Cloud Shell Access to Clusters

When a cluster's Kubernetes API endpoint has a public IP address, you can access the cluster in Cloud Shell by setting up a kubeconfig file.

To set up the kubeconfig file:

Step 1: Set up the kubeconfig file

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Kubernetes Clusters (OKE).
2. Choose a Compartment you have permission to work in.
3. On the Cluster List page, click the name of the cluster you want to access using kubectl. The Cluster page shows details of the cluster.
4. Click the Access Cluster button to display the Access Your Cluster dialog box.
5. Click Cloud Shell Access.
6. Click Launch Cloud Shell to display the Cloud Shell window. For more information about Cloud Shell (including the required IAM policy), see Cloud Shell.
7. Run the Oracle Cloud Infrastructure CLI command to set up the kubeconfig file and save it in a location accessible to kubectl.

For example, enter the following command (or copy and paste it from the Access Your Cluster dialog box) in the Cloud Shell window:

```
oci ce cluster create-kubeconfig --cluster-id ocid1.cluster.ocl.phx.aaaaaaaaae... --file $HOME/.kube/config --region us-phoenix-1 --token-version 2.0.0 --kube-endpoint PUBLIC_ENDPOINT
```

where:
- `ocid1.cluster.ocl.phx.aaaaaaaaae...` is the OCID of the current cluster. For convenience, the command in the Access Your Cluster dialog box already includes the cluster's OCID.
- `--kube-endpoint PUBLIC_ENDPOINT` specifies to add the public IP address of the cluster's Kubernetes API endpoint to the kubeconfig file. For more information, see Kubernetes Cluster Control Plane and Kubernetes API on page 1206.

Note that if a kubeconfig file already exists in the location you specify, details about the cluster will be added as a new context to the existing kubeconfig file. The `current-context:` element in the kubeconfig file will be set to point to the newly-added context.

**Tip:**
For clipboard operations in the Cloud Shell window, Windows users can use Ctrl-C or Ctrl-Insert to copy, and Shift-Insert to paste. For Mac OS users, use Cmd-C to copy and Cmd-V to paste.

8. If you don't save the kubeconfig file in the default location (`$HOME/.kube`) or with the default name (`config`), set the value of the KUBECONFIG environment variable to point to the name and location of the kubeconfig file. For example, enter the following command in the Cloud Shell window:

```
export KUBECONFIG=$HOME/.kube/config
```

### Step 2: Verify that kubectl can access the cluster

Verify that kubectl can connect to the cluster by entering the following command in the Cloud Shell window:

```
$ kubectl get nodes
```

Information about the nodes in the cluster is shown.

You can now use kubectl to perform operations on the cluster.

### Setting Up Local Access to Clusters

When a cluster's Kubernetes API endpoint does not have a public IP address, you can access the cluster from a local workstation if your network is peered with the cluster's VCN. If there is a bastion host on a public subnet of the cluster's VCN, you can optionally complete an additional step to set up an SSH tunnel to the Kubernetes API endpoint.

To set up the kubeconfig file:

**Step 1: Generate an API signing key pair**

If you already have an API signing key pair, go straight to the next step. If not:

1. Use OpenSSL commands to generate the key pair in the required PEM format. If you're using Windows, you'll need to install Git Bash for Windows and run the commands with that tool. See How to Generate an API Signing Key on page 5304.
2. Copy the contents of the public key to the clipboard (you'll need to paste the value into the Console later).
Step 2: Upload the public key of the API signing key pair

1. In the top-right corner of the Console, open the Profile menu (-profile) and then click User Settings to view the details.
2. Click Add Public Key.
3. Paste the public key's value into the window and click Add.

Step 3: Install and configure the Oracle Cloud Infrastructure CLI

1. Install the Oracle Cloud Infrastructure CLI version 2.6.4 (or later). See Quickstart on page 5320.
2. Configure the Oracle Cloud Infrastructure CLI. See Configuring the CLI on page 5327.

Step 4: Set up the kubeconfig file

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Kubernetes Clusters (OKE).
2. Choose a Compartment you have permission to work in.
3. On the Cluster List page, click the name of the cluster you want to access using kubectl. The Cluster page shows details of the cluster.
4. Click the Access Cluster button to display the Access Your Cluster dialog box.
5. Click Local Access.
6. Create a directory to contain the kubeconfig file. By default, the expected directory name is $HOME/.kube.

   For example, on Linux, enter the following command (or copy and paste it from the Access Your Cluster dialog box) in a local terminal window:
   
   ```bash
   mkdir -p $HOME/.kube
   ```

7. Run the Oracle Cloud Infrastructure CLI command to set up the kubeconfig file and save it in a location accessible to kubectl.

   For example, on Linux, enter the following command (or copy and paste it from the Access Your Cluster dialog box) in a local terminal window:

   ```bash
   oci ce cluster create-kubeconfig --cluster-id ocid1.cluster.oc1.phx.aaaaaaaaae... --file $HOME/.kube/config --region us-phoenix-1 --token-version 2.0.0 --kube-endpoint PRIVATE_ENDPOINT|PUBLIC_ENDPOINT
   ```

   where:
   
   • `ocid1.cluster.oc1.phx.aaaaaaaaae...` is the OCID of the current cluster. For convenience, the command in the Access Your Cluster dialog box already includes the cluster's OCID.
   
   • `--kube-endpoint PRIVATE_ENDPOINT|PUBLIC_ENDPOINT` specifies whether to add the private IP address or the public IP address of the cluster's Kubernetes API endpoint to the kubeconfig file. For more information, see Kubernetes Cluster Control Plane and Kubernetes API on page 1206.

   Note that if a kubeconfig file already exists in the location you specify, details about the cluster will be added as a new context to the existing kubeconfig file. The current-context: element in the kubeconfig file will be set to point to the newly-added context.

8. If you don't save the kubeconfig file in the default location ($HOME/.kube) or with the default name (config), set the value of the KUBECONFIG environment variable to point to the name and location of the kubeconfig file. For example, on Linux, enter the following command (or copy and paste it from the Access Your Cluster dialog box) in a local terminal window:

   ```bash
   export KUBECONFIG=$HOME/.kube/config
   ```
Step 5: (Optional, for bastion host access) Set up an SSH tunnel

If there is a bastion host on a public subnet of the cluster’s VCN, you can optionally set up an SSH tunnel between the local workstation and the cluster's Kubernetes API endpoint:

1. Open the kubeconfig file you saved in the previous step.
2. Change the IP address specified for `server` in the kubeconfig file:
   a. Locate the line:
      
      ```
      server: https://x.x.x.x:6443
      ```
   b. Change the line to:
      
      ```
      server: https://127.0.0.1:6443
      ```
3. Set up an SSH tunnel to the cluster's Kubernetes API endpoint by entering:

   ```
   ssh -fNT -L 6443:<k8s-api-endpoint-ip>:6443 -i <bastion-ssh-private-key> 
opc@<bastion-public-ip>
   ```

   where:
   - `<k8s-api-endpoint-ip>` is the private IP address of the cluster's Kubernetes API endpoint.
   - `<bastion-ssh-private-key>` is the path to your private ssh key to access the bastion host.
   - `<bastion-public-ip>` is the public IP address of the bastion host.

For more information about bastion hosts, see Bastion Hosts: Protected Access for Virtual Cloud Networks.

Step 6: Verify that kubectl can access the cluster

1. Verify that kubectl is available by entering the following command in a local terminal window:

   ```
   kubectl version
   ```

   The response shows:
   - the version of kubectl installed and running locally
   - the version of Kubernetes (strictly speaking, the version of the kube-apiserver) running on the cluster's control plane nodes

   Note that the kubectl version must be within one minor version (older or newer) of the Kubernetes version running on the control plane nodes. If kubectl is more than one minor version older or newer, install an appropriate version of kubectl. See Kubernetes version and version skew support policy in the Kubernetes documentation.

   If the command returns an error indicating that kubectl is not available, install kubectl (see the kubectl documentation), and repeat this step.

2. Verify that kubectl can connect to the cluster by entering the following command in a local terminal window:

   ```
   kubectl get nodes
   ```

   Information about the nodes in the cluster is shown.

   You can now use kubectl to perform operations on the cluster.

Notes about Kubeconfig Files

Note the following about kubeconfig files:

- A single kubeconfig file can include the details for multiple clusters, as multiple contexts. The cluster on which operations will be performed is specified by the `current-context` element in the kubeconfig file.
Container Engine for Kubernetes

- A kubeconfig file includes an Oracle Cloud Infrastructure CLI command that dynamically generates an authentication token and inserts it when you run a kubectl command. The Oracle Cloud Infrastructure CLI must be available on your shell's executable path (for example, $PATH on Linux).
- The authentication tokens generated by the Oracle Cloud Infrastructure CLI command in the kubeconfig file are short-lived, cluster-scoped, and specific to individual users. As a result, you cannot share kubeconfig files between users to access Kubernetes clusters.
- The Oracle Cloud Infrastructure CLI command in the kubeconfig file uses your current CLI profile when generating an authentication token. If you have defined multiple profiles in different tenancies in the CLI configuration file (for example, in ~/.oci/config), specify which profile to use when generating the authentication token as follows. In both cases, <profile-name> is the name of the profile defined in the CLI configuration file:
  - Add --profile to the args: section of the kubeconfig file as follows:
    ```json
    user:
      exec:
        apiVersion: client.authentication.k8s.io/v1beta1
        args:
          - ce
          - cluster
          - generate-token
          - --cluster-id
          - <cluster ocid>
          - --profile
          - <profile-name>
        command: oci
        env: []
    ```
  - Set the OCI_CLI_PROFILE environment variable to the name of the profile defined in the CLI configuration file before running kubectl commands. For example:
    ```bash
    export OCI_CLI_PROFILE=<profile-name>
    ```
    ```bash
    kubectl get nodes
    ```
- The authentication tokens generated by the Oracle Cloud Infrastructure CLI command in the kubeconfig file are appropriate to authenticate individual users accessing the cluster using kubectl. However, the generated authentication tokens are unsuitable if you want other processes and tools to access the cluster, such as continuous integration and continuous delivery (CI/CD) tools. In this case, consider creating a Kubernetes service account and adding its associated authentication token to the kubeconfig file. For more information, see Adding a Service Account Authentication Token to a Kubeconfig File on page 1252.

**Upgrading Kubeconfig Files from Version 1.0.0 to Version 2.0.0**

Container Engine for Kubernetes currently supports kubeconfig version 2.0.0 files, and no longer supports kubeconfig version 1.0.0 files.

Enhancements in kubeconfig version 2.0.0 files provide security improvements for your Kubernetes environment, including short-lived cluster-scoped tokens with automated refreshing, and support for instance principals to access Kubernetes clusters. Additionally, authentication tokens are generated on-demand for each cluster, so kubeconfig version 2.0.0 files cannot be shared between users to access Kubernetes clusters (unlike kubeconfig version 1.0.0 files).

Note that kubeconfig version 2.0.0 files are not compatible with kubectl versions prior to version 1.11.9. If you are currently running kubectl version 1.10.x or older, upgrade kubectl to version 1.11.9 or later. For more information about compatibility between different versions of kubernetes and kubectl, see the Kubernetes documentation.

Follow the instructions below to determine the current version of kubeconfig files, and how to upgrade any remaining kubeconfig version 1.0.0 files to version 2.0.0.
**Determine the kubeconfig file version**

To determine the version of a cluster's kubeconfig file:

1. In a terminal window (the Cloud Shell window or a local terminal window as appropriate), enter the following command to see the format of the kubeconfig file currently pointed at by the KUBECONFIG environment variable:

   ```bash
   kubectl config view
   ```

2. If the kubeconfig file is version 1.0.0, you see a response in the following format:

   ```json
   users:
   - name: <username>
     user:
     token: <token-value>
   ```

   If you see a response in the above format, you have to upgrade the kubeconfig file. See [Upgrading Kubeconfig Files from Version 1.0.0 to Version 2.0.0](page 1246).

3. If the kubeconfig file is version 2.0.0, you see a response in the following format:

   ```json
   user:
   exec:
     apiVersion: client.authentication.k8s.io/v1beta1
     args:
      - ce
      - cluster
      - generate-token
      - --cluster-id
      - <cluster ocid>
     command: oci
     env: []
   ```

   If you see a response in the above format, no further action is required.

**Upgrade a kubeconfig version 1.0.0 file to version 2.0.0**

To upgrade a kubeconfig version 1.0.0 file:

1. In the case of a local installation of kubectl, confirm that Oracle Cloud Infrastructure CLI version 2.6.4 (or later) is installed by entering:

   ```bash
   oci -version
   ```

   If the Oracle Cloud Infrastructure CLI version is earlier than version 2.6.4, upgrade the CLI to a later version. See [Upgrading the CLI](page 5346).

2. Follow the appropriate instructions to set up the kubeconfig file for use in Cloud Shell or locally (see [Setting Up Cloud Shell Access to Clusters](page 1242) or [Setting Up Local Access to Clusters](page 1243)). Running the `oci ce cluster create-kubeconfig` command shown in the [Access Your Cluster](Access Your Cluster) dialog box upgrades the existing kubeconfig version 1.0.0 file. If you change the name or location of the kubeconfig file, set the KUBECONFIG environment variable to point to the new name and location of the file.

3. Confirm the kubeconfig file is now version 2.0.0:

   a. In a terminal window (the Cloud Shell window or a local terminal window as appropriate), enter:

      ```bash
      kubectl config view
      ```

   b. Confirm that that the response is in the following format:

      ```json
      user:
      exec:
      ```
## Accessing a Cluster Using Kubectl

You can use the Kubernetes command line tool `kubectl` to perform operations on a cluster you've created with Container Engine for Kubernetes. You can use the `kubectl` installation included in Cloud Shell, or you can use a local installation of `kubectl`. In both cases, before you can use `kubectl` to access a cluster, you have to specify the cluster on which to perform operations by setting up the cluster's kubeconfig file.

Note the following:

- An Oracle Cloud Infrastructure CLI command in the kubeconfig file generates authentication tokens that are short-lived, cluster-scoped, and specific to individual users. As a result, you cannot share kubeconfig files between users to access Kubernetes clusters. The generated authentication tokens are also unsuitable if you want other processes and tools to access the cluster, such as continuous integration and continuous delivery (CI/CD) tools. In this case, consider creating a Kubernetes service account and adding its associated authentication token to the kubeconfig file. For more information, see Adding a Service Account Authentication Token to a Kubeconfig File on page 1252.
- The version of `kubectl` you use must be compatible with the version of Kubernetes running on clusters created by Container Engine for Kubernetes. In the case of Cloud Shell, `kubectl` is regularly updated so it is always compatible with the versions of Kubernetes currently supported by Container Engine for Kubernetes. In the case of a local installation of `kubectl`, it is your responsibility to update `kubectl` regularly. For more information about compatibility between different versions of `kubectl` and `kubectl`, see the Kubernetes documentation.
- Currently, to access a cluster using `kubectl` in Cloud Shell, the Kubernetes API endpoint must have a public IP address.

### Accessing a Cluster Using kubectl in Cloud Shell

To access a cluster using `kubectl` in Cloud Shell:

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file for use in Cloud Shell, and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cloud Shell Access to Clusters on page 1242.
2. In the Cloud Shell window, enter `kubectl` followed by the command for the operation you want to perform on the cluster. For a list of available commands and options, see the kubectl documentation.

Note that you must have the appropriate permissions to run the command you enter. See About Access Control and Container Engine for Kubernetes on page 1254.

### Accessing a Cluster Using kubectl Installed Locally

To access a cluster using `kubectl` installed locally:

1. If you haven't already done so, install `kubectl` (see the kubectl documentation).
2. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file for use locally, and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Local Access to Clusters on page 1243.
3. In a local terminal window, enter `kubectl` followed by the command for the operation you want to perform on the cluster. For a list of available commands and options, see the `kubectl` documentation.

Note that you must have the appropriate permissions to run the command you enter. See About Access Control and Container Engine for Kubernetes on page 1254.

**Accessing a Cluster Using the Kubernetes Dashboard**

The Kubernetes Dashboard is a web-based management interface that enables you to:

- deploy and edit containerized applications
- assess the status of containerized applications
- troubleshoot containerized applications

The Kubernetes Dashboard is particularly useful for new Kubernetes users. For more information about the Kubernetes Dashboard (sometimes called the Web UI or the Dashboard UI), see the Web UI (Dashboard) topic in the Kubernetes documentation.

The Kubernetes Dashboard is not deployed in clusters by default. However, you can deploy the Kubernetes Dashboard in clusters you create with Container Engine for Kubernetes in the following ways:

- To manually deploy the Kubernetes Dashboard on an existing cluster, see the Kubernetes documentation. When you follow the instructions to manually deploy the Kubernetes Dashboard, it is deployed in the `kube-dashboard` namespace (not the `kube-system` namespace). The URL to display a manually deployed Kubernetes Dashboard is:

  ```
  http://localhost:8001/api/v1/namespaces/kube-dashboard/services/
  https:kubernetes-dashboard:/proxy/#!/login
  ```

- To have Container Engine for Kubernetes automatically deploy the Kubernetes Dashboard during cluster creation, create the cluster using the API and set the `isKubernetesDashboardEnabled` attribute to true. When Container Engine for Kubernetes automatically deploys the Kubernetes Dashboard, it is deployed in the `kube-system` namespace. The URL to display an automatically deployed Kubernetes Dashboard is:

  ```
  http://localhost:8001/api/v1/namespaces/kube-system/services/
  https:kubernetes-dashboard:/proxy/#!/login
  ```

Note the following:

- You cannot run the Kubernetes Dashboard in Cloud Shell.
- We do not recommend installing the Kubernetes Dashboard on production clusters due to the lack of extensible authentication support. If you do install the Kubernetes Dashboard, we recommend that you restrict access within the cluster, instead of exposing it externally via either a load balancer or an ingress controller. The Kubernetes Dashboard is a common attack vector used to gain access to Kubernetes clusters.
- You cannot specify that you want to install the Kubernetes Dashboard when creating a cluster using the Console. If you decide you do want to install the Kubernetes Dashboard, create the cluster using the API and set the `isKubernetesDashboardEnabled` attribute to true.
- You cannot use Container Engine for Kubernetes to deploy the Kubernetes Dashboard on existing clusters. You have to manually deploy the Kubernetes Dashboard on existing clusters.
- The commands to use to delete the Kubernetes Dashboard from a cluster will depend on the version of Kubernetes running on the cluster. See Notes about Deleting the Kubernetes Dashboard on page 1251.
- An Oracle Cloud Infrastructure CLI command in the `kubeconfig` file generates authentication tokens that are short-lived, cluster-scoped, and specific to individual users. As a result, you cannot share `kubeconfig` files between users to access Kubernetes clusters. The generated authentication tokens are also unsuitable if you want other processes and tools to access the cluster, such as continuous integration and continuous delivery (CI/CD) tools. In this case, consider creating a Kubernetes service account and adding its associated authentication token to the `kubeconfig` file. For more information, see Adding a Service Account Authentication Token to a Kubeconfig File on page 1252.
Accessing a Cluster using the Kubernetes Dashboard

To access a cluster using the Kubernetes Dashboard:

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 1242.

2. In a text editor, create a file (for example, called oke-admin-service-account.yaml) with the following content:

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  name: oke-admin
  namespace: kube-system
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: oke-admin
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: cluster-admin
subjects:
- kind: ServiceAccount
  name: oke-admin
  namespace: kube-system
```

The file defines an administrator service account and a clusterrolebinding, both called oke-admin.

3. Create the service account and the clusterrolebinding in the cluster by entering:

```bash
kubectl apply -f <filename>
```

where `<filename>` is the name of the file you created earlier. For example:

```bash
kubectl apply -f oke-admin-service-account.yaml
```

The output from the above command confirms the creation of the service account and the clusterrolebinding:

```
serviceaccount "oke-admin" created
clusterrolebinding.rbac.authorization.k8s.io "oke-admin" created
```

You can now use the oke-admin service account to view and control the cluster, and to connect to the Kubernetes dashboard.

4. Obtain an authentication token for the oke-admin service account by entering:

```bash
kubectl -n kube-system describe secret $(kubectl -n kube-system get secret | grep oke-admin | awk '{print $1}')
```

The output from the above command includes an authentication token (a long alphanumeric string) as the value of the `token` element, as shown below:

```
Name:       oke-admin-token-gwp2
Namespace:  kube-system
Labels:     <none>
Annotations: kubernetes.io/service-account.name: oke-admin
kubernetes.io/service-account.uid: 3a7fcd8e-e123-11e9-81ca-0a580aed8570
Type:       kubernetes.io/service-account-token
```
<table>
<thead>
<tr>
<th>Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>ca.crt: 1289 bytes</td>
</tr>
<tr>
<td>namespace: 11 bytes</td>
</tr>
<tr>
<td>token: eyJh______px1Q</td>
</tr>
</tbody>
</table>

In the example above, eyJh______px1Q (abbreviated for readability) is the authentication token.

5. Copy the value of the token: element from the output. You will use this token to connect to the dashboard.
6. In a terminal window, enter `kubectl proxy` to make the Kubernetes Dashboard available.
7. Open a browser and go to the following URL to display the Kubernetes Dashboard that was deployed when the cluster was created:

   http://localhost:8001/api/v1/namespaces/kube-system/services/https:kubernetes-dashboard:/proxy/#!/login

   Note that if you followed the instructions in the Kubernetes documentation to manually deploy the Kubernetes Dashboard on an existing cluster, it is deployed in the `kube-dashboard` namespace rather than the `kube-system` namespace. As a result, the URL to display the manually deployed Kubernetes Dashboard is:

8. In the Kubernetes Dashboard, select Token and paste the value of the token: element you copied earlier into the Token field.
9. In the Kubernetes Dashboard, click Sign In, and then click Overview to see the applications deployed on the cluster.

### Notes about Deleting the Kubernetes Dashboard

If you want to delete the Kubernetes Dashboard from a cluster, the commands to use will depend on the version of Kubernetes running on the cluster:

- For clusters running Kubernetes versions prior to version 1.16.8, run the following `kubectl` commands to delete the Kubernetes Dashboard:

  ```bash
  kubectl delete deployment kubernetes-dashboard -n kube-system
  kubectl delete sa -n kube-system kubernetes-dashboard
  kubectl delete svc -n kube-system kubernetes-dashboard
  kubectl delete secret -n kube-system kubernetes-dashboard-certs
  kubectl delete secret -n kube-system kubernetes-dashboard-key-holder
  kubectl delete cm -n kube-system kubernetes-dashboard-settings
  kubectl delete role -n kube-system kubernetes-dashboard-minimal
  kubectl delete rolebinding -n kube-system kubernetes-dashboard-minimal
  kubectl delete deploy -n kube-system kubernetes-dashboard
  ```

- For clusters running Kubernetes version 1.16.8 (or later), run the following `kubectl` commands to delete the Kubernetes Dashboard:

  ```bash
  kubectl delete deployment kubernetes-dashboard -n kube-system
  kubectl delete sa -n kube-system kubernetes-dashboard
  kubectl delete svc -n kube-system kubernetes-dashboard
  kubectl delete secret -n kube-system kubernetes-dashboard-certs
  kubectl delete secret -n kube-system kubernetes-dashboard-csrf
  kubectl delete secret -n kube-system kubernetes-dashboard-key-holder
  kubectl delete cm -n kube-system kubernetes-dashboard-settings
  kubectl delete role -n kube-system kubernetes-dashboard
  kubectl delete rolebinding -n kube-system kubernetes-dashboard
  kubectl delete clusterrole -n kube-system kubernetes-dashboard
  kubectl delete clusterrolebinding -n kube-system kubernetes-dashboard
  kubectl delete deploy -n kube-system kubernetes-dashboard
  ```
Adding a Service Account Authentication Token to a Kubeconfig File

When you set up the kubeconfig file for a cluster, by default it contains an Oracle Cloud Infrastructure CLI command to generate a short-lived, cluster-scoped, user-specific authentication token. The authentication token generated by the CLI command is appropriate to authenticate individual users accessing the cluster using kubectl and the Kubernetes Dashboard.

However, the generated authentication token is not appropriate to authenticate processes and tools accessing the cluster, such as continuous integration and continuous delivery (CI/CD) tools. To ensure access to the cluster, such tools require long-lived, non-user-specific authentication tokens.

One solution is to use a Kubernetes service account, as described in this topic. A service account has an associated service account authentication token, which is stored as a Kubernetes secret. Having created a service account, you bind it to a clusterrolebinding that has cluster administration permissions. You can then add the service account (and its service account authentication token) as a user definition in the kubeconfig file itself. Other tools can then use the service account authentication token when accessing the cluster.

Note that to run the commands in this topic, you must have the appropriate permissions. See About Access Control and Container Engine for Kubernetes on page 1254.

To add a service account authentication token to a kubeconfig file:

1. If you haven’t already done so, follow the steps to set up the cluster’s kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 1242.

2. In a terminal window, create a new service account in the kube-system namespace by entering the following kubectl command:

   \[kubectl -n kube-system create serviceaccount <service-account-name>\]

   For example, to create a service account called kubeconfig-sa, enter:

   \[kubectl -n kube-system create serviceaccount kubeconfig-sa\]

   The output from the above command confirms the creation of the service account. For example:

   \[serviceaccount/kubeconfig-sa created\]

   Note that creating the service account in the kube-system namespace is recommended good practice, and is assumed in the instructions in this topic. However, if you prefer, you can create the service account in another namespace to which you have access.

3. Create a new clusterrolebinding with cluster administration permissions and bind it to the service account you just created by entering the following kubectl command:

   \[kubectl create clusterrolebinding <binding-name> --clusterrole=cluster-admin --serviceaccount=kube-system:<service-account-name>\]

   For example, to create a clusterrolebinding called add-on-cluster-admin and bind it to the kubeconfig-sa service account, enter:

   \[kubectl create clusterrolebinding add-on-cluster-admin --clusterrole=cluster-admin --serviceaccount=kube-system:kubeconfig-sa\]

   The output from the above command confirms the creation of the clusterrolebinding. For example:

   \[clusterrolebinding.rbac.authorization.k8s.io/add-on-cluster-admin created\]
4. Obtain the name of the service account authentication token and assign its value to an environment variable by entering the following command (these instructions assume you specify TOKENNAME as the name of the environment variable):

```
TOKENNAME=`kubectl -n kube-system get serviceaccount/<service-account-name> -o jsonpath='{.secrets[0].name}'`
```

For example:

```
TOKENNAME=`kubectl -n kube-system get serviceaccount/kubeconfig-sa -o jsonpath='{.secrets[0].name}'`
```

5. Obtain the value of the service account authentication token and assign its value (decoded from base64) to an environment variable. These instructions assume you specify TOKEN as the name of the environment variable. The commands to enter depend on the operating system:

- To obtain the value of the service account authentication token in a MacOS, Linux, or Unix environment, enter the following command:

```
TOKEN=`kubectl -n kube-system get secret $TOKENNAME -o jsonpath='{.data.token}'| base64 --decode`
```

- To obtain the value of the service account authentication token in a Windows environment:

  a. Enter the following command:

  ```
kubectl -n kube-system get secret $TOKENNAME -o jsonpath='{.data.token}'
  ```

  b. Copy the output from the above command and paste it into a base64 decoder (for example, https://www.base64decode.org, https://www.base64decode.net, or similar).

  c. Copy the output from the base64 decoder.

  d. Enter the following command:

  ```
TOKEN=`[<base64-decoded-output>]`
  ```

   where <base64-decoded-output> is the output you copied from the base64 decoder.

6. Add the service account (and its authentication token) as a new user definition in the kubeconfig file by entering the following kubectl command:

```
kubectl config set-credentials <service-account-name> --token=$TOKEN
```

The service account (and its authentication token) is added to the list of users defined in the kubeconfig file.

For example, to add the kubeconfig-sa service account and its authentication token to the kubeconfig file, enter:

```
kubectl config set-credentials kubeconfig-sa --token=$TOKEN
```

The output from the above command confirms the service account has been added to the kubeconfig file. For example:

```
User "kubeconfig-sa" set.
```
7. Set the user specified in the kubeconfig file for the current context to be the new service account user you created, by entering the following kubectl command:

```
kubectl config set-context --current --user=<service-account-name>
```

For example:

```
kubectl config set-context --current --user=kubeconfig-sa
```

The output from the above command confirms the current context has been changed. For example:

```
Context "context-ctdzi7dhezd" modified.
```

8. (Optional) To verify that authentication works as expected, run a kubectl command to confirm that the service account user can be successfully authenticated using the service account authentication token.

For example, if you have previously deployed a sample Nginx application on the cluster (see Deploying a Sample Nginx App on a Cluster Using Kubectl on page 1280), enter the following command:

```
kubectl get pods
```

The output from the above command shows the pods running on the cluster. If the command runs successfully, the service account user in the kubeconfig file has been successfully authenticated using the service account authentication token.

9. Distribute the kubeconfig file as necessary to enable other processes and tools (such as continuous integration and continuous delivery (CI/CD) tools) to access the cluster.

```
Note:
```

If you subsequently want to remove access to the cluster from the service account, delete the Kubernetes secret containing the service account authentication token by entering the following command:

```
kubectl -n kube-system delete secret $TOKENNAME
```

### About Access Control and Container Engine for Kubernetes

To perform operations on a Kubernetes cluster, you must have appropriate permissions to access the cluster.

For most operations on Kubernetes clusters created and managed by Container Engine for Kubernetes, Oracle Cloud Infrastructure Identity and Access Management (IAM) provides access control. A user’s permissions to access clusters comes from the groups to which they belong. The permissions for a group are defined by policies. Policies define what actions members of a group can perform, and in which compartments. Users can then access clusters and perform operations based on the policies set for the groups they are members of.

IAM provides control over:

- whether a user can create or delete clusters
- whether a user can add, remove, or modify node pools
- which Kubernetes object create/delete/view operations a user can perform on all clusters within a compartment or tenancy

See Policy Configuration for Cluster Creation and Deployment on page 1230.

In addition to IAM, the Kubernetes RBAC Authorizer can enforce additional fine-grained access control for users on specific clusters via Kubernetes RBAC roles and clusterroles. A Kubernetes RBAC role is a collection of permissions. For example, a role might include read permission on pods and list permission for pods. A Kubernetes RBAC clusterrole is just like a role, but can be used anywhere in the cluster. A Kubernetes RBAC rolebinding maps a role to a user or group, granting that role’s permissions to the user or group for resources in that namespace. Similarly,
a Kubernetes RBAC clusterrolebinding maps a clusterrole to a user or group, granting that clusterrole's permissions to the user or group across the entire cluster.

IAM and the Kubernetes RBAC Authorizer work together to enable users who have been successfully authorized by at least one of them to complete the requested Kubernetes operation. You can use OCIDs to map Kubernetes RBAC rolebindings and clusterrolebindings to IAM users and groups.

When a user attempts to perform any operation on a cluster (except for create role and create clusterrole operations), IAM first determines whether the group to which the user belongs has the appropriate and sufficient permissions. If so, the operation succeeds. If the attempted operation also requires additional permissions granted via a Kubernetes RBAC role or clusterrole, the Kubernetes RBAC Authorizer then determines whether the user or group has been granted the appropriate Kubernetes role or clusterrole.

Typically, you’ll want to define your own Kubernetes RBAC roles and clusterroles when deploying a Kubernetes cluster to provide additional fine-grained control. When you attempt to perform a create role or create clusterrole operation, the Kubernetes RBAC Authorizer first determines whether you have sufficient Kubernetes privileges. To create a role or clusterrole, you must have been assigned an existing Kubernetes RBAC role (or clusterrole) that has at least the same or higher privileges as the new role (or clusterrole) you’re attempting to create.

By default, users are not assigned any Kubernetes RBAC roles (or clusterroles) by default. So before attempting to create a new role (or clusterrole), you must be assigned an appropriately privileged role (or clusterrole). A number of such roles and clusterroles are always created by default, including the cluster-admin clusterrole (for a full list, see Default Roles and Role Bindings in the Kubernetes documentation). The cluster-admin clusterrole essentially confers super-user privileges. A user granted the cluster-admin clusterrole can perform any operation across all namespaces in a given cluster.

Note that Oracle Cloud Infrastructure tenancy administrators already have sufficient privileges, and do not require the cluster-admin clusterrole.

**Example 1: Granting the Kubernetes RBAC cluster-admin clusterrole**

### Note:

The following instructions assume:

- You have the required access to create Kubernetes RBAC roles and clusterroles, either because you're in the tenancy's Administrators group, or because you have the Kubernetes RBAC cluster-admin clusterrole.

- The user to which you want to grant the RBAC cluster-admin clusterrole is not an OCI tenancy administrator. If they are an OCI tenancy administrator, they do not require the Kubernetes RBAC cluster-admin clusterrole.

Follow these steps to grant a user who is not a tenancy administrator the Kubernetes RBAC cluster-admin clusterrole on a cluster deployed on Oracle Cloud Infrastructure:

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 1242.

2. In a terminal window, grant the Kubernetes RBAC cluster-admin clusterrole to the user by entering:
Container Engine for Kubernetes

```
kubectl create clusterrolebinding <my-cluster-admin-binding> --clusterrole=cluster-admin --user=<user_OCID>
```

where:

- `<my-cluster-admin-binding>` is a string of your choice to be used as the name for the binding between the user and the Kubernetes RBAC cluster-admin clusterrole. For example, `jdoe_clst_adm`
- `<user_OCID>` is the user's OCID (obtained from the Console). For example, `ocid1.user.oc1..aaaaa...zutq` (abbreviated for readability).

For example:

```
kubectl create clusterrolebinding jdoe_clst_adm --clusterrole=cluster-admin --user=ocid1.user.oc1..aaaaa...zutq
```

**Example 2: Creating a Kubernetes role and rolebinding to enable a non-administrator user to read pods in a cluster**

Follow these steps to give a non-administrator user the necessary Oracle Cloud Infrastructure and Kubernetes RBAC permissions to view pods running on a Kubernetes cluster. In this example, a non-administrator user is given explicit access to the cluster (rather than as a member of a group).

As a tenancy administrator:

**Note:**

The following instructions assume you're in the tenancy's Administrators group, and therefore have the required permissions to create users, groups, and IAM policies.

1. Create a new Oracle Cloud Infrastructure IAM user account for the non-administrator user (for example, jdoe@acme.com). See To create a user on page 3113.
2. Make a note of the new IAM user account's OCID (for example, `ocid1.user.oc1..aa______tx5a`, abbreviated for readability).
3. Create a new Oracle Cloud Infrastructure IAM group (for example, called `acme-developer-group`), and add the new IAM user account to the group. See To create a group on page 3116.
4. Create a new Oracle Cloud Infrastructure policy that grants the new group the CLUSTER_USE permission on clusters, with a policy statement like:

   ```
   Allow group acme-developer-group to use clusters in <location>
   ```

   In the above policy statement, replace `<location>` with either tenancy (if you are creating the policy in the tenancy's root compartment) or compartment `<compartment-name>` (if you are creating the policy in an individual compartment). See To create a policy on page 3147.

As the cluster administrator:

**Note:**

The following instructions assume you have the required permissions to create and manage clusters, and the required access to create Kubernetes RBAC roles and clusterroles.

1. In a text editor, create the following manifest (for example, called `pod-reader-user.yaml`) to define a Kubernetes RBAC role and role binding to enable the new IAM user account to list pods in the kube-system namespace:

   ```
   kind: Role
   apiVersion: rbac.authorization.k8s.io/v1
   ```
where name: <user-ocid> specifies the OCID of the new IAM user account you created previously. For example, name: ocid1.user.oc1..aa______tx5a

2. Create the new role and rolebinding by entering:

   kubectl apply -f pod-reader-user.yml

**As the non-administrator user:**

1. Sign into the Console using the new IAM user account's credentials.
2. Configure cluster access by following the instructions in Setting Up Cluster Access on page 1242.
3. List the pods in the kube-system namespace by entering:

   kubectl get pods -n kube-system

**Example 3: Creating a Kubernetes role and rolebinding to enable a group to read pods in a cluster**

Follow these steps to give non-administrator users in a group the necessary Oracle Cloud Infrastructure and Kubernetes RBAC permissions to view pods running on a Kubernetes cluster. In this example, non-administrator users are given access to the cluster as members of a group.

**As a tenancy administrator:**

1. Create a new Oracle Cloud Infrastructure IAM user account for a non-administrator user (for example, jsmith@acme.com). See To create a user on page 3113.
2. Create a new Oracle Cloud Infrastructure IAM group (for example, called acme-developer-group), and add the new IAM user account to the group. See To create a group on page 3116.
3. Make a note of the new IAM group's OCID (for example, `ocid1.group.oc1..aa______m7dt`, abbreviated for readability).

4. Create a new Oracle Cloud Infrastructure policy that grants the new group the CLUSTER_USE permission on clusters, with a policy statement like:

   ```
   Allow group acme-developer-group to use clusters in <location>
   ```

   In the above policy statement, replace `<location>` with either `tenancy` (if you are creating the policy in the tenancy's root compartment) or `compartment <compartment-name>` (if you are creating the policy in an individual compartment). See To create a policy on page 3147.

As the cluster administrator:

```
Note:

The following instructions assume you have the required permissions to create and manage clusters, and the required access to create Kubernetes RBAC roles and clusterroles.
```

1. In a text editor, create the following manifest (for example, called `pod-reader-group.yaml`) to define a Kubernetes RBAC role and role binding to enable users in the new IAM group to list pods in the kube-system namespace:

   ```yaml
   kind: Role
   apiVersion: rbac.authorization.k8s.io/v1
   metadata:
     name: pod-reader-ks
     namespace: kube-system
   rules:
   - apiGroups: [""]
     resources: ["pods"]
     verbs: ["get", "watch", "list"]
   ---
   kind: RoleBinding
   apiVersion: rbac.authorization.k8s.io/v1
   metadata:
     name: pod-reader-ks-role-binding
     namespace: kube-system
   subjects:
   - kind: Group
     name: <group-ocid>
     apiGroup: rbac.authorization.k8s.io
   roleRef:
     kind: Role
     name: pod-reader-ks
     apiGroup: rbac.authorization.k8s.io
   ```

   where name: `<group-ocid>` specifies the OCID of the new IAM group you created previously. For example, name: `ocid1.group.oc1..aa______m7dt`

2. Create the new role and role binding by entering:

   ```
kubectl apply -f pod-reader-group.yaml
   ```

As the non-administrator user:

```
Note:

The following instructions assume you have the credentials of the new IAM user account created earlier as a member of the new IAM group. As such, you
```
have the required permissions to use Kubernetes clusters in the tenancy or compartment.

1. Sign in to the Console using the new IAM user account's credentials.
2. Configure cluster access by following the instructions in Setting Up Cluster Access on page 1242.
3. List the pods in the kube-system namespace by entering:

```
kubectl get pods -n kube-system
```

Example 4: Creating a Kubernetes clusterrole and clusterrolebinding to enable users and groups to list secrets in a cluster

Follow these steps to give non-administrator users in a group the necessary Oracle Cloud Infrastructure and Kubernetes RBAC permissions to view pods running on a Kubernetes cluster. In this example, a non-administrator user is given access to the cluster either explicitly or as member of a group.

As a tenancy administrator:

**Note:**
The following instructions assume you're in the tenancy's Administrators group, and therefore have the required permissions to create users, groups, and IAM policies.

1. Create a new Oracle Cloud Infrastructure IAM user account for a non-administrator user (for example, jjones@acme.com). See To create a user on page 3113.
2. If you intend to enable just this user to list secrets, make a note of the new IAM user account's OCID (for example, ocid1.user.oc1..aa______4gs6, abbreviated for readability).
3. Create a new Oracle Cloud Infrastructure IAM group (for example, called acme-developer-group), and add the new IAM user account to the group. See To create a group on page 3116.
4. If you intend to enable all users in this group to list secrets, make a note of the new IAM group's OCID (for example, ocid1.group.oc1..aa______e26f, abbreviated for readability).
5. Create a new Oracle Cloud Infrastructure policy that grants the new group the CLUSTER_USE permission on clusters, with a policy statement like:

```
Allow group acme-developer-group to use clusters in <location>
```

In the above policy statement, replace <location> with either tenancy (if you are creating the policy in the tenancy's root compartment) or compartment <compartment-name> (if you are creating the policy in an individual compartment). See To create a policy on page 3147.

As the cluster administrator:

**Note:**
The following instructions assume you have the required permissions to create and manage clusters, and the required access to create Kubernetes RBAC roles and clusterroles.

1. In a text editor, do one of the following, depending on whether you want to enable just the new IAM user or all users in the new IAM group to list secrets in a Kubernetes cluster:

   - If you want to enable just the new IAM user to list secrets in a Kubernetes cluster, create the following manifest (for example, called secrets-reader.yaml):

```
apiversion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:  
  name: secret-reader
```
rules:
  - apiGroups: ['"]
    resources: ['"secrets"]
    verbs: ['"get", "watch", "list"]
---

apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: read-secrets-global
subjects:
  - kind: User
    name: <user-ocid>
    apiGroup: rbac.authorization.k8s.io
roleRef:
  kind: ClusterRole
  name: secret-reader
  apiGroup: rbac.authorization.k8s.io

where name: <user-ocid> specifies the OCID of the new IAM user you created previously. For example, name: ocid1.user.oc1..aa______4gs6

- If you want to enable all users in the new IAM group to list secrets in a Kubernetes cluster, create the following manifest (for example, called secrets-reader.yaml):

```yaml
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: secret-reader
rules:
  - apiGroups: ['"]
    resources: ['"secrets"]
    verbs: ['"get", "watch", "list"]
---

apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: read-secrets-global
subjects:
  - kind: Group
    name: <group-ocid>
    apiGroup: rbac.authorization.k8s.io
roleRef:
  kind: ClusterRole
  name: secret-reader
  apiGroup: rbac.authorization.k8s.io
```

where name: <group-ocid> is the OCID of the new IAM group you created previously. For example, ocid1.group.oc1..aa______e26f

2. Create the new clusterrole and clusterrolebinding by entering:

```
kubectl apply -f secret-reader.yml
```

**As the non-administrator user:**

**Note:**

The following instructions assume you have the credentials of the new IAM user account created earlier as a member of the new IAM group. As such, you have the required permissions to use Kubernetes clusters in the tenancy or compartment either explicitly or as member of a group.

1. Sign in to the Console using the new IAM user account's credentials.
2. Configure cluster access by following the instructions in Setting Up Cluster Access on page 1242.
3. List the secrets in all namespaces by entering:

```
kubectl get secrets --all-namespaces
```

## Connecting to Worker Nodes Using SSH

If you provided a public SSH key when creating the node pool in a cluster, the public key is installed on all worker nodes in the cluster. On UNIX and UNIX-like platforms (including Solaris and Linux), you can then connect through SSH to the worker nodes using the `ssh` utility (an SSH client) to perform administrative tasks.

Note the following instructions assume the UNIX machine you use to connect to the worker node:

- Has the `ssh` utility installed.
- Has access to the SSH private key file paired with the SSH public key that was specified when the cluster was created.

How to connect to worker nodes using SSH depends on whether you specified public or private subnets for the worker nodes when defining the node pools in the cluster.

### Connecting to Worker Nodes in Public Subnets Using SSH

Before you can connect to a worker node in a public subnet using SSH, you must define an ingress rule in the applicable network security group or subnet security list to allow SSH access. The ingress rule must allow access to port 22 on worker nodes from source 0.0.0.0/0 and any source port, as follows:

<table>
<thead>
<tr>
<th>Type</th>
<th>Source CIDR</th>
<th>IP Protocol</th>
<th>Source Port Range</th>
<th>Dest. Port Range</th>
<th>Type and Code</th>
<th>Allows: and Description:</th>
</tr>
</thead>
</table>
| Stateful     | 0.0.0.0/0   | TCP         | All               | 22               | n/a           | Allows: TCP traffic for ports: 22 SSH Remote Login Protocol

Description: Enables SSH access.

To connect to a worker node in a public subnet through SSH from a UNIX machine using the `ssh` utility:

1. Find out the IP address of the worker node to which you want to connect. You can do this in a number of ways:

   - Using `kubectl`. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the `KUBECONFIG` environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 1242. Then in a terminal window, enter `kubectl get nodes` to see the public IP addresses of worker nodes in node pools in the cluster.

   - Using the Console. In the Console, display the Cluster List page and then select the cluster to which the worker node belongs. On the Node Pools tab, click the name of the node pool to which the worker node belongs. On the Nodes tab, you see the public IP address of every worker node in the node pool.

   - Using the REST API. Use the ListNodePools operation to see the public IP addresses of worker nodes in a node pool.
2. In the terminal window, enter `ssh opc@<node_ip_address>` to connect to the worker node, where `<node_ip_address>` is the IP address of the worker node that you made a note of earlier. For example, you might enter `ssh opc@192.0.2.254`.

Note that if the SSH private key is not stored in the file or in the path that the `ssh` utility expects (for example, the `ssh` utility might expect the private key to be stored in `~/.ssh/id_rsa`), you must explicitly specify the private key filename and location in one of two ways:

- Use the `-i` option to specify the filename and location of the private key. For example, `ssh -i ~/.ssh/my_keys/my_host_key_filename opc@192.0.2.254`
- Add the private key filename and location to an SSH configuration file, either the client configuration file (`~/.ssh/config`) if it exists, or the system-wide client configuration file (`/etc/ssh/ssh_config`). For example, you might add the following:

  ```
  Host 192.0.2.254
  IdentityFile ~/.ssh/my_keys/my_host_key_filename
  ```

For more about the `ssh` utility’s configuration file, enter `man ssh_config`

Note also that permissions on the private key file must allow you read/write/execute access, but prevent other users from accessing the file. For example, to set appropriate permissions, you might enter `chmod 600 ~/.ssh/my_keys/my_host_key_filename`. If permissions are not set correctly and the private key file is accessible to other users, the ssh utility will simply ignore the private key file.

**Connecting to Worker Nodes in Private Subnets Using SSH**

Worker nodes in private subnets have private IP addresses only (they do not have public IP addresses). They can only be accessed by other resources inside the VCN. Oracle recommends using bastion hosts to control external access (such as SSH) to worker nodes in private subnets. A bastion host is in a public subnet, has a public IP address, and is accessible from the internet. For more information about bastion hosts, see the white paper *Bastion Hosts: Protected Access for Virtual Cloud Networks*.

**Managing Kubernetes Clusters**

Read about how to use Container Engine for Kubernetes to manage Kubernetes clusters:

- Modifying Kubernetes Cluster Properties on page 1262
- Modifying Node Pool and Worker Node Properties on page 1264
- Encrypting Kubernetes Secrets at Rest in Etcd on page 1266
- Configuring DNS Servers for Kubernetes Clusters on page 1269
- Updating Worker Nodes by Creating a New Node Pool on page 1274
- Migrating to VCN-Native Clusters on page 1275
- Deleting a Kubernetes Cluster on page 1279

**Modifying Kubernetes Cluster Properties**

You can use Container Engine for Kubernetes to modify the properties of existing Kubernetes clusters.

You can change:

- the name of a cluster
- the number of node pools in a cluster by adding new node pools, or deleting existing node pools
- the version of Kubernetes to run on control plane nodes
- the enforcement of pod security policies
- access details for a cluster’s Kubernetes API endpoint
- some properties of node pools and worker nodes (see Modifying Node Pool and Worker Node Properties on page 1264)
However, note that you cannot change the master encryption key (if specified when the cluster was created).

Also note that you must not change the auto-generated names of resources that Container Engine for Kubernetes has created (such as the names of worker nodes).

**Using the Console**

To modify an existing Kubernetes cluster:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Kubernetes Clusters (OKE).
2. Choose a Compartment you have permission to work in.
3. On the Cluster List page, click the name of the cluster you want to modify.
4. Click Edit Cluster to:
   - Change the name of the cluster.
   - Change whether pod security policies are being enforced (by enabling the cluster's PodSecurityPolicy admission controller). Note that you must create pod security policies before enabling the PodSecurityPolicy admission controller of an existing cluster that is already in production. We also strongly recommend you first verify the cluster's pod security policies in a development or test environment. That way, you can be sure the pod security policies work as you expect and correctly allow (or refuse) pods to start on the cluster. Also note that if you disable a cluster's PodSecurityPolicy admission controller, any pod security policies (along with roles, rolebindings, clusterroles, and clusterrolebindings) you've defined are not deleted, they are simply not enforced. See Using Pod Security Policies with Container Engine for Kubernetes on page 1345.
   - Change access details for the Kubernetes API endpoint, including the use of network security groups and whether to assign a public IP address to the Kubernetes API endpoint subnet. See Kubernetes Cluster Control Plane and Kubernetes API on page 1206.

   Note that if you change the cluster's name or whether pod security policies are being enforced, save those changes before changing access details for the Kubernetes API endpoint.
5. If a newer version of Kubernetes is available than the one running on the control plane nodes in the cluster, the Upgrade Available button is enabled. If you want to upgrade the control plane nodes to a newer version, click Upgrade Available (see Upgrading the Kubernetes Version on Control Plane Nodes in a Cluster on page 1354).
6. Use the Cluster Details tab to see information about the cluster, including:
   - The status of the cluster, and of the node pools in the cluster.
   - The cluster's OCID.
   - The Kubernetes version running on the control plane nodes in the cluster.
   - The address of the Kubernetes API endpoint.
   - Whether pod security policies are being enforced.
7. Use the Node Pools tab to:
   - View information about each of the node pools in the cluster, including:
     - The status of the node pool.
     - The node pool's OCID.
     - The configuration currently used when starting new worker nodes in the node pool, including the Kubernetes version, the shape, and the image.
     - The availability domains, and different regional subnets (recommended) or AD-specific subnets hosting worker nodes.

   Note that you can change some of these node pool and worker node properties (see Modifying Node Pool and Worker Node Properties on page 1264).
   - Add a new node pool to the cluster by clicking the Add Node Pool button and entering details for the new node pool.
   - Delete a node pool by selecting Delete Node Pool from the Actions menu.
8. Use the **Quick Start** tab to:

   - Set up access to the cluster (see Setting Up Cluster Access on page 1242).
   - Download and deploy a sample Nginx application using the Kubernetes command line tool kubectl from the instructions in a manifest file (see Deploying a Sample Nginx App on a Cluster Using Kubectl on page 1280).

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the **Update Cluster** operation to modify an existing Kubernetes cluster.

**Modifying Node Pool and Worker Node Properties**

You can use Container Engine for Kubernetes to modify the properties of node pools and worker nodes in existing Kubernetes clusters.

You can change:

- the name of a node pool
- the version of Kubernetes to run on new worker nodes
- the number of worker nodes in a node pool, and the availability domains and subnets in which to place them
- the image to use for new worker nodes
- the shape to use for new worker nodes
- the boot volume size to use for new worker nodes
- the public SSH key to use to access new worker nodes

Note that you must not change the auto-generated names of resources that Container Engine for Kubernetes has created (such as the names of worker nodes).

Also note the following:

- Any changes you make to worker node properties will only apply to new worker nodes. You cannot change the properties of existing worker nodes.
- In some situations, you might want to update properties of all the worker nodes in a node pool simultaneously, rather than just the properties of new worker nodes that start in the node pool. For example, to upgrade all worker nodes to a new version of Oracle Linux. In this case, you can create a new node pool with worker nodes that have the required properties, and shift work from the original node pool to the new node pool using the `kubectl drain` command and pod disruption budgets. For more information, see Updating Worker Nodes by Creating a New Node Pool on page 1274.
- If you use the UpdateNodePool API operation to modify properties of an existing node pool, be aware of the **Worker node properties out-of-sync with updated node pool properties** known issue and its workarounds.
- Do not use the `kubectl delete node` command to scale down or terminate worker nodes in a cluster that was created by Container Engine for Kubernetes. Instead, reduce the number of worker nodes by changing the corresponding node pool properties using the Console or the API. The `kubectl delete node` command does not change a node pool's properties, which determine the desired state (including the number of worker nodes). Also, although the `kubectl delete node` command removes the worker node from the cluster's etcd key-value store, the command does not delete the underlying compute instance.

**Using the Console**

To modify the properties of node pools and worker nodes of existing Kubernetes clusters:

1. In the Console, open the navigation menu and click **Developer Services**. Under **Containers**, click **Kubernetes Clusters (OKE)**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the name of the cluster you want to modify.
4. On the **Cluster** page, click the name of the node pool that you want to modify.
5. Use the **Node Pool Details** tab to view information about the node pool, including:
   - The status of the node pool.
   - The node pool's OCID.
   - The configuration currently used when starting new worker nodes in the node pool, including:
     - The version of Kubernetes to run on worker nodes
     - The shape to use for worker nodes
     - The image to use on worker nodes
   - The availability domains, and different regional subnets (recommended) or AD-specific subnets hosting worker nodes.

6. (optional) Change properties of the node pool and worker nodes by clicking **Edit** and specifying:
   - **Name:** A different name for the node pool. Avoid entering confidential information.
   - **Version:** A different version of Kubernetes to run on new worker nodes in the node pool when performing an in-place upgrade. The Kubernetes version on worker nodes must be either the same version as that on the control plane nodes, or an earlier version that is still compatible (see Kubernetes Versions and Container Engine for Kubernetes on page 1350). To start new worker nodes running the Kubernetes version you specify, 'drain' existing worker nodes in the node pool (to prevent new pods starting and to delete existing pods) and then terminate each of the existing worker nodes in turn.

   You can also specify a different version of Kubernetes to run on new worker nodes by performing an out-of-place upgrade. For more information about upgrading worker nodes, see Upgrading the Kubernetes Version on Worker Nodes in a Cluster on page 1354.
   - **Shape:** A different shape to use for the nodes in the node pool. The shape determines the number of CPUs and the amount of memory allocated to each node. The list shows only those shapes available in your tenancy that are supported by Container Engine for Kubernetes. See Supported Images (Including Custom Images) and Shapes for Worker Nodes on page 1240.
   - **Image:** A different image to use on the nodes in the node pool. An image is a template of a virtual hard drive that determines the operating system and other software for the node. See Supported Images (Including Custom Images) and Shapes for Worker Nodes on page 1240.
   - **Network Security Group:** Control access to the node pool using security rules defined for one or more network security groups (NSGs) that you specify (up to a maximum of five). You can use security rules defined for NSGs instead of, or as well as, those defined for security lists. For more information about the security rules to specify for the NSG, see Security Rules for Worker Nodes on page 1212.
   - **Boot Volume Size in GB:** A different boot volume size for worker nodes. The default size of worker node boot volumes is determined from the image specified for worker nodes, but you can specify a custom boot volume size. If you do specify a custom boot volume size, it must be larger than the image's default boot volume size. The minimum and maximum sizes you can specify are 50 GB and 32 TB respectively (see Custom Boot Volume Sizes on page 690). If you change the boot volume size for worker nodes, consider extending the partition for the boot volume to take advantage of the larger size (see Extending the Partition for a Boot Volume on page 691).
   - **Public SSH Key:** (Optional) A different public key portion of the key pair you want to use for SSH access to the nodes in the node pool. The public key is installed on all worker nodes in the cluster. Note that if you don't specify a public SSH key, Container Engine for Kubernetes will provide one. However, since you won't have the corresponding private key, you will not have SSH access to the worker nodes. Note that you cannot use SSH to access directly any worker nodes in private subnets (see Connecting to Worker Nodes in Private Subnets Using SSH on page 1262).

7. (optional) Change the number and placement of worker nodes in the node pool by clicking **Scale** and specifying:
   - the number of worker nodes you want in the node pool after the scale operation is complete
   - the availability domains in which to place the worker nodes
   - the regional subnets (recommended) or AD-specific subnets to host the worker nodes
   - the network security groups with security rules to control traffic into and out of the node pool
8. Use the Nodes tab to see information about specific worker nodes in the node pool. Optionally edit the configuration details of a specific worker node by clicking the worker node's name.

Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351. Use the UpdateNodePool operation to modify an existing node pool.

Encrypting Kubernetes Secrets at Rest in Etcd

The control plane nodes in a Kubernetes cluster store sensitive configuration data (such as authentication tokens, passwords, and SSH keys) as Kubernetes secret objects in etcd. Etcd is an open source distributed key-value store that Kubernetes uses for cluster coordination and state management. In the Kubernetes clusters created by Container Engine for Kubernetes, etcd writes and reads data to and from block storage volumes in the Oracle Cloud Infrastructure Block Volume service. Although the data in block storage volumes is encrypted, Kubernetes secrets at rest in etcd itself are not encrypted by default.

For additional security, when you create a new cluster you can specify that Kubernetes secrets at rest in etcd are to be encrypted using the Oracle Cloud Infrastructure Vault service (see Overview of Vault on page 5006). Before you can create a cluster where Kubernetes secrets are encrypted in the etcd key-value store, you have to:

- know the name and OCID of a suitable master encryption key in Vault
- create a dynamic group that includes all clusters in the compartment in which you are going to create the new cluster
- create a policy authorizing the dynamic group to use the master encryption key

Having created the cluster and specified that you want Kubernetes secrets at rest in the etcd key-value store to be encrypted, you can optionally restrict the use of the master encryption key by modifying the dynamic group to include just that cluster.

Note the following:

- You can only select the option to encrypt the Kubernetes secrets in the cluster's etcd key-value store when creating a new cluster in the 'Custom Create' workflow. You cannot encrypt Kubernetes secrets in the cluster's etcd key-value store when creating a new cluster in the 'Quick Create' workflow. And you cannot encrypt Kubernetes secrets in the etcd key-value stores of clusters you previously created in the 'Custom Create' workflow.
- You can only select the option to encrypt Kubernetes secrets in the cluster's etcd key-value store if you specify Kubernetes version 1.13.x or later as the version of Kubernetes to run on the control plane nodes of the cluster.
- Policies must have been defined to authorize Container Engine for Kubernetes to use the master encryption key, and to authorize users to delegate key usage to Container Engine for Kubernetes in the first place. For more information, see Let a user group delegate key usage in a compartment and Let Block Volume, Object Storage, File Storage, and Container Engine for Kubernetes services encrypt and decrypt volumes, buckets, file systems, and Kubernetes secrets in Common Policies on page 2806.
- After you've specified a master encryption key for a new cluster and created the cluster, do not subsequently delete the master encryption key in the Vault service. As soon as you schedule a key for deletion in Vault, the Kubernetes secrets stored for the cluster in etcd become inaccessible. If you have already scheduled the key for deletion, it might still be in the Pending Deletion state. If that is the case, cancel the scheduled key deletion (see To cancel the deletion of a key on page 5021) to restore access to the Kubernetes secrets. If you allow the scheduled key deletion operation to complete and the master encryption key to be deleted, the Kubernetes secrets stored for the cluster in etcd are permanently inaccessible. As a result, cluster upgrades will fail. In this situation, you have no choice but to delete and recreate the cluster.

Master Encryption Keys in Other Tenancies

You can create a cluster in one tenancy that uses a master encryption key in a different tenancy. In this case, you have to write cross-tenancy policies to enable the cluster in its tenancy to access the master encryption key in the Vault service's tenancy. Note that if you want to create a cluster and specify a master encryption key that's in a different tenancy, you cannot use the Console to create the cluster.
For example, assume the cluster is in the ClusterTenancy, and the master encryption key is in the KeyTenancy. Users belonging to a group (OKEAdminGroup) in the ClusterTenancy have permissions to create clusters. A dynamic group (OKEAdminDynGroup) has been created in the cluster, with the rule ALL \{resource.type = 'cluster', resource.compartment.id = 'ocid1.compartment.oc1..<unique_ID>\}, so all clusters created in the ClusterTenancy belong to the dynamic group.

In the root compartment of the KeyTenancy, the following policies:

- use the ClusterTenancy's OCID to map ClusterTenancy to the alias OKE_Tenancy
- use the OCIDs of OKEAdminGroup and OKEAdminDynGroup to map them to the aliases RemoteOKEAdminGroup and RemoteOKEClusterDynGroup respectively
- give RemoteOKEAdminGroup and RemoteOKEClusterDynGroup the ability to list, view, and perform cryptographic operations with a particular master key in the KeyTenancy

```plaintext
Define tenancy OKE_Tenancy as ocid1.tenancy.oc1..<unique_ID>
Define dynamic-group RemoteOKEClusterDynGroup as ocid1.dynamicgroup.oc1..<unique_ID>
Define group RemoteOKEAdminGroup as ocid1.group.oc1..<unique_ID>
Admit dynamic-group RemoteOKEClusterDynGroup of tenancy ClusterTenancy to use keys in tenancy where target.key.id = 'ocid1.key.oc1..<unique_ID>'
Admit group RemoteOKEAdminGroup of tenancy ClusterTenancy to use keys in tenancy where target.key.id = 'ocid1.key.oc1..<unique_ID>'
```

In the root compartment of the ClusterTenancy, the following policies:

- use the KeyTenancy's OCID to map KeyTenancy to the alias KMS_Tenancy
- give OKEAdminGroup and OKEAdminDynGroup the ability to use master keys in the KeyTenancy
- allow OKEAdminDynGroup to use a specific master key obtained from the KeyTenancy in the ClusterTenancy

```plaintext
Define tenancy KMS_Tenancy as ocid1.tenancy.oc1..<unique_ID>
Endorse group OKEAdminGroup to use keys in tenancy KMS_Tenancy
Endorse dynamic-group OKEAdminDynGroup to use keys in tenancy KMS_Tenancy
Allow dynamic-group OKEAdminDynGroup to use keys in tenancy where target.key.id = 'ocid1.key.oc1..<unique_ID>'
```

See Accessing Object Storage Resources Across Tenancies on page 4420 for more examples of writing cross-tenancy policies.

Having entered the policies, you can now run a command similar to the following to create a cluster in the ClusterTenancy that uses the master key obtained from the KeyTenancy:

```plaintext
oci ce cluster create --name oke-with-cross-kms --kubernetes-version v1.16.8 --vcn-id ocid1.vcn.oc1.iad.<unique_ID> --service-lb-subnet-ids \"["ocid1.subnet.oc1.iad.<unique_ID>\\"]\" --compartment-id ocid1.compartment.oc1..<unique_ID> --kms-key-id ocid1.key.oc1.iad.<unique_ID>
```

**Using the Console**

To create a new cluster in the 'Custom Create' workflow where Kubernetes secrets are encrypted in the cluster's etcd key-value store:

1. Log in to the Console.
2. If you know the OCID of the master encryption key to use to encrypt Kubernetes secrets, go straight to the next step. Otherwise:
   - If a suitable master encryption key already exists in Vault but you're not sure of its OCID, follow the instructions in To view key details on page 5018 and make a note of the master encryption key's OCID.
   - If a suitable master encryption key does not already exist in Vault, follow the instructions in To create a new master encryption key on page 5018 to create one. Having created a new master encryption key, make a note of its OCID.
3. Create a new dynamic group containing all the clusters in the compartment in which you intend to create the new cluster:
   a. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Dynamic Groups**.
   b. Follow the instructions in **To create a dynamic group** on page 3119, and give the dynamic group a name (for example, `acme-oke-kms-dyn-grp`).
   c. Enter a rule that includes all clusters in the compartment in the format:

   ```
   ALL {resource.type = 'cluster', resource.compartment.id = '<compartment-ocid>'}
   ```

   where `<compartment-ocid>` is the OCID of the compartment in which you intend to create the new cluster.

   For example:

   ```
   ALL {resource.type = 'cluster', resource.compartment.id = 'ocid1.compartment.oc1..aaaaaaaa23______smwa'}
   ```

d. Click **Create Dynamic Group**.

Having created a dynamic group that includes all clusters in the compartment, you can now create a policy to give the dynamic group access to the master encryption key in Vault.

4. Create a new policy to enable use of the master encryption key:
   a. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Policies**.
   b. Follow the instructions in **To create a policy** on page 3147, and give the policy a name (for example, `acme-oke-kms-dyn-grp-policy`).
   c. Enter a policy statement to give the dynamic group access to the master encryption key, in the format:

   ```
   Allow dynamic-group <dynamic-group-name> to use keys in compartment <compartment-name> where target.key.id = '<key-OCID>'
   ```

   where:
   - `<dynamic-group-name>` is the name of the dynamic group you created earlier.
   - `<compartment-name>` is the name of the compartment containing the master encryption key.
   - `<key-OCID>` is the OCID of the master encryption key in Vault.

   For example:

   ```
   Allow dynamic-group acme-oke-kms-dyn-grp to use keys in compartment acme-kms-key-compartment where target.key.id = 'ocid1.key.oc1.iad.annrl______trfg'
   ```

d. Click **Create** to create the new policy.

5. Follow the instructions to create a new cluster in **Using the Console to create a Cluster with Explicitly Defined Settings in the ‘Custom Create’ workflow** on page 1236, select the **Encrypt Using Customer-Managed Keys** option, and select:

   - **Choose a Vault in `<compartment-name>`**: The vault that contains the master encryption key, from the list of vaults in the specified compartment. By default, `<compartment-name>` is the compartment in which you are creating the cluster, but you can select a different compartment by clicking **Change Compartment**.
   - **Choose a Key in `<compartment-name>`**: The name of the master encryption key, from the list of keys in the specified compartment. By default, `<compartment-name>` is the compartment in which you are creating the cluster, but you can select a different compartment by clicking **Change Compartment**. Note that you cannot change the master encryption key after the cluster has been created.
6. (Optional) Having created the cluster, for additional security:
   a. Make a note of the OCID of the new cluster you just created.
   b. Restrict the use of the master encryption key by modifying the dynamic group rule you created earlier to explicitly specify the OCID of the new cluster, rather than all clusters in the compartment. For example:

```
resource.id = 'ocid1.cluster.oc1.iad.aaaaaaaaaf______yg5q'
```

### Using the API

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351. Use the CreateCluster operation to create a cluster.

### Configuring DNS Servers for Kubernetes Clusters

#### Configuring Built-in DNS Servers (kube-dns, CoreDNS)

Clusters created by Container Engine for Kubernetes include a DNS server as a built-in Kubernetes service that is launched automatically. The kubelet process on each worker node directs individual containers to the DNS server to translate DNS names to IP addresses.

Prior to Kubernetes version 1.14, Container Engine for Kubernetes created clusters with kube-dns as the DNS server. However, from Kubernetes version 1.14 onwards, Container Engine for Kubernetes creates clusters with CoreDNS as the DNS server. CoreDNS is a general-purpose authoritative DNS server that is modular and pluggable.

Default CoreDNS behavior is controlled by a configuration file referred to as a Corefile. The Corefile is a Kubernetes ConfigMap, with a Corefile section that defines CoreDNS behavior. You cannot modify the Corefile directly. If you need to customize CoreDNS behavior, you create and apply your own ConfigMap to override settings in the Corefile (as described in this topic). Note that if you do customize CoreDNS default behavior, the customizations are periodically deleted during internal updates to the cluster.

When you upgrade a cluster created by Container Engine for Kubernetes from an earlier version to Kubernetes 1.14 or later, the cluster's kube-dns server is automatically replaced with the CoreDNS server. Note that if you customized kube-dns behavior using the original kube-dns ConfigMap, those customizations are not carried forward to the CoreDNS ConfigMap. You will have to create and apply a new ConfigMap containing the customizations to override settings in the CoreDNS Corefile.

For more information about CoreDNS customization and Kubernetes, see the Kubernetes documentation and the CoreDNS documentation.

To create a ConfigMap to override the settings in the CoreDNS Corefile:

1. Define a ConfigMap in a yaml file, in the format:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: coredns-custom
  namespace: kube-system
data:
  <customization-options>
```

For example:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: coredns-custom
  namespace: kube-system
data:
```
example.server:  # All custom server files must have a "server" file extension.
   # Change example.com to the domain you wish to forward.
   example.com {
      # Change 1.1.1.1 to your customer DNS resolver.
      forward . 1.1.1.1
   }

For more information about the ConfigMap options to use to customize CoreDNS behavior, see the Kubernetes documentation and the CoreDNS documentation.

2. Create the ConfigMap by entering:

   kubectl apply -f <filename>.yaml

3. Verify the customizations have been applied by entering:

   kubectl get configmaps --namespace=kube-system coredns-custom -o yaml

4. Force CoreDNS to reload the ConfigMap by entering:

   kubectl delete pod --namespace kube-system -l k8s-app=kube-dns

Configuring ExternalDNS to use Oracle Cloud Infrastructure DNS

ExternalDNS is an add-on to Kubernetes that can create DNS records for services in DNS providers external to Kubernetes. It sets up DNS records in an external DNS provider to make Kubernetes services discoverable via that DNS provider, and enables you to control DNS records dynamically. See ExternalDNS for more information.

Having deployed ExternalDNS on a cluster, you can expose a service running on the cluster by adding the external-dns.alpha.kubernetes.io/hostname annotation to the service. ExternalDNS creates a DNS record for the service in the external DNS provider you've configured for the cluster.

ExternalDNS is not itself a DNS server like CoreDNS, but a way to configure other external DNS providers. Oracle Cloud Infrastructure DNS is one such external DNS provider. See Overview of the DNS Service on page 2262.

For convenience, instructions are included below to set up ExternalDNS on a cluster and configure it to use Oracle Cloud Infrastructure DNS. These instructions are a summary based on the Setting up ExternalDNS for Oracle Cloud Infrastructure (OCI) tutorial, which is available on GitHub.

To set up ExternalDNS on a cluster and configure it to use Oracle Cloud Infrastructure DNS:

1. Create a new DNS zone in Oracle Cloud Infrastructure DNS to contain the DNS records that ExternalDNS will create for the cluster. See Creating a Zone on page 2265.

2. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 1242.

3. Create a Kubernetes secret containing the Oracle Cloud Infrastructure user authentication details for ExternalDNS to use when connecting to the Oracle Cloud Infrastructure API to insert and update DNS records in the DNS zone you just created.

   a. In a text editor, create a credentials file containing the Oracle Cloud Infrastructure user credentials to use to access the DNS zone:

   ```yaml
   auth:
      region: <region-identifier>
      tenancy: <tenancy-ocid>
      user: <user-ocid>
      key: |
        -----BEGIN RSA PRIVATE KEY-----
        <private-key>
        -----END RSA PRIVATE KEY-----
   ```
Container Engine for Kubernetes

-----END RSA PRIVATE KEY-----
fingerprint: <fingerprint>
# Omit if there is not a password for the key
passphrase: <passphrase>
compartment: <compartment-ocid>

where:

- `<region-identifier>` identifies the user's region. For example, `us-phoenix-1`
- `<tenancy-ocid>` is the OCID of the user's tenancy. For example, `ocid1.tenancy.oc1..aaaaaaaap...keq` (abbreviated for readability).
- `<user-ocid>` is the OCID of the user. For example, `ocid1.user.oc1..aaaaa...zutq` (abbreviated for readability).
- `<private-key>` is an RSA key, starting with `-----BEGIN RSA PRIVATE KEY-----` and ending with `-----END RSA PRIVATE KEY-----`
- `passphrase`: <passphrase> optionally provides the passphrase for the key, if one exists
- `<compartment-ocid>` is the OCID of the compartment to which the DNS zone belongs

For example:

```
auth:
  region: us-phoenix-1
  tenancy: ocid1.tenancy.oc1..aaaaaaaap...keq
  user: ocid1.user.oc1..aaaaa...zutq
  key: |
    -----BEGIN RSA PRIVATE KEY-----
    this-is-not-a-secret_Ef8aiAk7+I0...
    -----END RSA PRIVATE KEY-----
    fingerprint: bg:92:82:9f...
    # Omit if there is not a password for the key
    passphrase: Uy2kSl...
  compartment: ocid1.compartment.oc1..aaaaaaaa7______ysq
```

b. Save the credentials file with a name of your choosing (for example, `oci-creds.yaml`).

c. Create a Kubernetes secret from the credentials file you just created, by entering:

```
kubectl create secret generic <secret-name> --from-file=<credential-filename>
```

For example:

```
kubectl create secret generic external-dns-config --from-file=oci-creds.yaml
```

4. Deploy ExternalDNS on the cluster.

a. In a text editor, create a configuration file (for example, called `external-dns-deployment.yaml`) to create the ExternalDNS deployment, and specify the name of the Kubernetes secret you just created. For example:

```
apiVersion: v1
kind: ServiceAccount
metadata:
  name: external-dns
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: external-dns
rules:
  - apiGroups: [""]
```
resources: ["services","endpoints","pods"]
  verbs: ["get","watch","list"]
- apiGroups: ["extensions","networking.k8s.io"]
  resources: ["ingresses"]
  verbs: ["get","watch","list"]
- apiGroups: ["""]
  resources: ["nodes"]
  verbs: ["list"]
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: external-dns-viewer
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: external-dns
subjects:
- kind: ServiceAccount
  name: external-dns
  namespace: default
---
apiVersion: apps/v1
kind: Deployment
metadata:
  name: external-dns
spec:
  strategy:
    type: Recreate
  selector:
    matchLabels:
      app: external-dns
  template:
    metadata:
      labels:
        app: external-dns
    spec:
      serviceAccountName: external-dns
      containers:
      - name: external-dns
        image: k8s.gcr.io/external-dns/external-dns:v0.7.3
        args:
          - --source=service
          - --source=ingress
          - --provider=oci
          - --policy=upsert-only # prevent ExternalDNS from deleting any records, omit to enable full synchronization
          - --txt-owner-id=my-identifier
        volumeMounts:
          - name: config
            mountPath: /etc/kubernetes/
      volumes:
      - name: config
        secret:
        name: external-dns-secret
b. Save and close the configuration file.

c. Apply the configuration file to deploy ExternalDNS by entering:

```bash
kubectl apply -f <filename>
```

where `<filename>` is the name of the file you created earlier. For example:

```bash
kubectl apply -f external-dns-deployment.yaml
```

The output from the above command confirms the deployment:

```
serviceaccount/external-dns created
clusterrole.rbac.authorization.k8s.io/external-dns created
clusterrolebinding.rbac.authorization.k8s.io/external-dns-viewer created
deployment.apps/external-dns created
```

5. Verify that ExternalDNS has been deployed successfully and can insert records in the DNS zone you created earlier in Oracle Cloud Infrastructure by creating an nginx deployment and an nginx service:

a. In a text editor, create a configuration file (for example, called `nginx-externaldns.yaml`) to create an nginx deployment and an nginx service that includes the `external-dns.alpha.kubernetes.io/hostname` annotation. For example:

```yaml
apiVersion: v1
dkind: Service
metadata:
  name: nginx
  annotations:
    external-dns.alpha.kubernetes.io/hostname: example.com
spec:
  type: LoadBalancer
  ports:
  - port: 80
    name: http
    targetPort: 80
  selector:
    app: nginx
---

apiVersion: apps/v1
dkind: Deployment
metadata:
  name: nginx
spec:
  selector:
    matchLabels:
      app: nginx
template:
    metadata:
      labels:
        app: nginx
    spec:
      containers:
      - image: nginx
        name: nginx
        ports:
        - containerPort: 80
```
b. Apply the configuration file to create the nginx service and deployment by entering:

```
kubectl apply -f <filename>
```

where `<filename>` is the name of the file you created earlier. For example:

```
kubectl apply -f nginx-externaldns.yaml
```

The output from the above command confirms the deployment:

```
service/nginx created
deployment.apps/nginx created
```

c. Wait a couple of minutes, and then verify that a DNS record was created for the nginx service in the Oracle Cloud Infrastructure DNS zone (see Managing DNS Service Zones on page 2267).

### Updating Worker Nodes by Creating a New Node Pool

You can modify the properties of new worker nodes that start in an existing node pool (see Modifying Node Pool and Worker Node Properties on page 1264). However, in some situations, you might want to update properties of all the worker nodes in a node pool simultaneously, rather than just the properties of new worker nodes that start in the node pool. For example, to upgrade all worker nodes to a new version of Oracle Linux.

In this case, you can create a new node pool with worker nodes that have the required properties, and shift work from the original node pool to the new node pool. Having 'drained' existing worker nodes in the original node pool to prevent new pods starting and to delete existing pods, you can then delete the original node pool.

To update the properties of all worker nodes in a node pool by creating a new node pool:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Kubernetes Clusters (OKE).
2. Choose a Compartment you have permission to work in.
3. On the Cluster page, display the Node Pools tab, and then click Add Node Pool to create a new node pool and specify the required properties for its worker nodes.
4. If there are labels attached to worker nodes in the original node pool and those labels are used by selectors (for example, to determine the nodes on which to run pods), then use the `kubectl label nodes` command to attach the same labels to the new worker nodes in the new node pool. See Assigning Pods to Nodes in the Kubernetes documentation.
5. For each worker node in the original node pool, prevent new pods from starting and delete existing pods by entering `kubectl drain <node_name>` for each worker node.

For more information:

- about using kubectl, see Accessing a Cluster Using Kubectl on page 1248
- about the `drain` command, see `drain` in the Kubernetes documentation

**Recommended:** Leverage pod disruption budgets as appropriate for your application to ensure that there's a sufficient number of replica pods running throughout the drain operation.

After all the worker nodes have been drained from the original node pool and pods are running on worker nodes in the new node pool, you can delete the original node pool.

7. On the Cluster page, display the Node Pools tab, and then select Delete Node Pool from the Actions menu beside the original node pool.

The original node pool and all its worker nodes are deleted.
Migrating to VCN-Native Clusters

In earlier releases (before March 16, 2021), Container Engine for Kubernetes provisioned clusters with Kubernetes API endpoints that were not integrated into your own VCN. The Kubernetes API endpoint was public, and you could not restrict access to it. You can continue to create such clusters using the CLI or API, but not the Console.

After March 16, 2021, Container Engine for Kubernetes can provision clusters with their Kubernetes API endpoints in a subnet in your own VCN (these clusters are known as “VCN-native clusters”). You have more flexibility to configure VCN-native clusters to meet your own security and networking requirements. You can configure the Kubernetes API endpoint to make it privately accessible within your VCN (and a peered on-premise network), or to make it publicly accessible from the internet:

- To make the Kubernetes API endpoint privately accessible, host the Kubernetes API endpoint in a public or private subnet and do not assign a public IP address to it.
- To make the Kubernetes API endpoint publicly accessible from the internet, host the Kubernetes API endpoint in a public subnet and assign a public IP address to it.

You can control access to the Kubernetes API endpoint subnet using security rules defined for security lists or network security groups.

To take advantage of the security control offered by VCN-native clusters, you can migrate an existing cluster to integrate its Kubernetes API endpoint into your own VCN.

Cluster migration has the following stages:

- **Stage 1: Migration in progress**
  You start the migration by selecting the cluster to migrate, and then specifying the existing VCN and the private or public subnet to host the new Kubernetes API endpoint. The migration usually takes around 15 minutes.
  
  During this time, the Kubernetes API continues to be accessible via the public endpoint that is not integrated into your own VCN. However, cluster lifecycle operations (such as cluster updates, node pool creation and deletion) are unavailable.

- **Stage 2: Migration is complete, and pending decommission of the public Kubernetes API endpoint that is not integrated into your own VCN**
  When migration is complete, the cluster becomes accessible via the new Kubernetes API endpoint in your own VCN, as well as via the public Kubernetes API endpoint that is not integrated into your VCN. During this decommissioning period, update the configuration of your kubectl, tools, and CI/CD pipelines to use the new Kubernetes API endpoint. By default, you have 30 days to complete the updates, but you can reduce the decommissioning period to as little as 5 days, or increase it to more than 30 days. File a support ticket if you want to reduce or increase the time before the public Kubernetes API endpoint that is not integrated into your own VCN is decommissioned.

- **Stage 3: The public Kubernetes API endpoint that is not integrated into your own VCN is decommissioned**
  At the end of the decommissioning period (30 days after migration, or the time you request), the cluster ceases to be accessible via the public Kubernetes API endpoint that is not integrated into your VCN. The cluster is only accessible via the new Kubernetes API endpoint integrated into your VCN.

Migrating an Existing Cluster to be VCN-native

To migrate an existing cluster to integrate its Kubernetes API endpoint into your own VCN:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Kubernetes Clusters (OKE).
2. Choose a Compartment you have permission to work in.
   Migration required labels appear on the Cluster List page beside the names of clusters with Kubernetes API endpoints that are not integrated into your VCN.
3. On the Cluster List page, click the name of the cluster that you want to migrate.
   When you select a cluster that you can migrate, the Migrate Cluster button appears at the top of the Cluster Details page.
4. If you want the cluster's Kubernetes API endpoint to be publicly accessible from the internet and hosted in a new public subnet in the same VCN as the cluster (creating and configuring new network resources as required), perform an **Automatic Migration** as follows:

a. At the top of the **Cluster Details** page, click **Migrate Cluster** to integrate the cluster's Kubernetes API endpoint into your own VCN.

b. In the **Migrate to VCN-Native Cluster** dialog box, select **Automatic Migration** to create a new regional subnet in the cluster's VCN with a 10.0.0.0/28 CIDR block, along with security lists and route tables.

c. Click **Launch Workflow** and review the migration summary in the **VCN-Native Endpoint Cluster Migration** dialog box.

d. Click **Migrate** to create new network resources and migrate the cluster.

   Container Engine for Kubernetes starts migrating the cluster, as shown in the **Migrating Cluster** dialog.

e. Click **Close** to close the **Migrating Cluster** dialog.

5. If you want the cluster's Kubernetes API endpoint to be privately accessible within your VCN or publicly accessible from the internet, and hosted in an existing regional public or private subnet in the same VCN as the cluster, perform a **Custom Migration** as follows:

a. Confirm the following network resources already exist in the VCN and are configured correctly to host the Kubernetes API endpoint (if not, create and configure them appropriately):

   - a regional public or private subnet (see Kubernetes API Endpoint Subnet Configuration on page 1214)
   - if the subnet is public, an internet gateway (see Internet Gateway Configuration on page 1210)
   - if the subnet is private, a NAT gateway (see NAT Gateway Configuration on page 1210) and a service gateway (see Service Gateway Configuration on page 1210)
   - a route table with the necessary route rules (see Route Table for Kubernetes API Endpoint Subnets on page 1211)
   - a security list and/or network security group with the necessary ingress and egress rules (see Security Rules for the Kubernetes API Endpoint on page 1212)

   For example configurations, see Example Network Resource Configurations on page 1215.

b. At the top of the **Cluster Details** page, click **Migrate Cluster** to integrate the cluster's Kubernetes API endpoint into your own VCN.

c. In the **Migrate to VCN-Native Cluster** dialog box, select **Custom Migration**.

d. Click **Launch Workflow** and specify:

   - **Kubernetes API Endpoint Subnet**: The regional public or private subnet to host the cluster's Kubernetes API endpoint. The Kubernetes API endpoint is assigned a private IP address. To simplify access management, Oracle recommends the Kubernetes API endpoint is in a different subnet to worker nodes and load balancers. For more information, see Kubernetes Cluster Control Plane and Kubernetes API on page 1206.

   - **Use network security groups to control traffic**: Optionally, restrict the access to the cluster's Kubernetes API endpoint using one or more network security groups (NSGs) that you specify. For more information about the security rules to specify for the NSG, see Security Rules for the Kubernetes API Endpoint on page 1212.

   - **Assign a public IP address to the API endpoint**: If you selected a public subnet for the Kubernetes API endpoint, you can optionally assign a public IP address to the Kubernetes API endpoint (as well as the private IP address).

   e. Click **Migrate** to create new network resources and migrate the cluster.

   Container Engine for Kubernetes starts migrating the cluster.

   Migration usually takes around 15 minutes to complete. During this time, the Kubernetes API continues to be accessible via the public endpoint that is not integrated into your own VCN. However, cluster lifecycle operations (such as cluster updates, node pool creation and deletion) are unavailable.

   When migration is complete, the **Cluster Details** page shows the name of the **Kubernetes API Endpoint Subnet**, the IP address of the **Kubernetes API Private Endpoint**, and (if you assigned a public IP address to the Kubernetes API endpoint) the IP address of the **Kubernetes API Public Endpoint**.
The Cluster Details page also indicates that you have 30 days to update the configuration of your kubectl, tools, and CI/CD pipelines to access the new Kubernetes API endpoint (see Setting Up Access to a Migrated Cluster on page 1277). During this decommissioning period, the newly migrated cluster is accessible via both the new Kubernetes API endpoint in your VCN, and via the public Kubernetes API endpoint that is not integrated into your own VCN.

### Setting Up Access to a Migrated Cluster

Having migrated a cluster to integrate its Kubernetes API endpoint into your own VCN, you have to update the configuration of your kubectl, tools, and CI/CD pipelines to use the new Kubernetes API endpoint. At a minimum, you'll want to update the cluster's Kubernetes configuration file (commonly known as the 'kubeconfig' file) to enable access to the migrated cluster using kubectl, as described in this topic. You also need to update any manifest files that include references to the cluster's Kubernetes API endpoint IP address.

Follow the instructions in this topic to generate a new kubeconfig file. These instructions assume the cluster's kubeconfig file is saved in the default location (`$HOME/.kube`) and with the default name (`config`). If that is not the case, adapt the instructions accordingly.

1. In the terminal window where you normally run Oracle Cloud Infrastructure CLI commands, run the following command to update the cluster's existing kubeconfig file:

   ```bash
   oci ce cluster create-kubeconfig --cluster-id <cluster-ocid> --file <kubeconfig-file-location> --region <region-name> --token-version 2.0.0 --kube-endpoint PRIVATE_ENDPOINT|PUBLIC_ENDPOINT
   ```

   where:
   - `--cluster-id <cluster-ocid>` is the OCID of the existing cluster you want to make VCN-native.
   - `--file <kubeconfig-file-location>` is the location of the cluster's kubeconfig file.
   - `--region <region-name>` is the region in which the cluster is located.
   - `--kube-endpoint PRIVATE_ENDPOINT|PUBLIC_ENDPOINT` specifies whether to add the private IP address or the public IP address of the cluster's Kubernetes API endpoint to the kubeconfig file. For more information, see Kubernetes Cluster Control Plane and Kubernetes API on page 1206.

   For example:

   ```bash
   oci ce cluster create-kubeconfig --cluster-id ocid1.cluster.oc1.phx.aaaaaaaaae... --file $HOME/.kube/config --region us-phoenix-1 --token-version 2.0.0 --kube-endpoint PUBLIC_ENDPOINT
   ```

   Assuming the kubeconfig file already exists in the location you specify, details about the cluster are added as a new context to the existing kubeconfig file, including the cluster's new Kubernetes API endpoint in your own VCN. The current-context: element in the kubeconfig file is set to point to the newly-added context.

   For more information about setting up the kubeconfig file, see Setting Up Cluster Access on page 1242.

2. Verify that kubectl can connect to the cluster using the Kubernetes API endpoint in your own VCN by entering the following command:

   ```bash
   kubectl get nodes
   ```

   Information about the nodes in the cluster is shown.

   You can now use kubectl to perform operations on the cluster using the Kubernetes API endpoint in your own VCN.

   **Note:**

   Until the original API endpoint that is not integrated into your VCN is decommissioned, you can continue to generate the original kubeconfig file by omitting the `--kube-endpoint` option from the `oci ce cluster create-kubeconfig` command.
Frequently Asked Questions about Cluster Migration

What are VCN-native clusters?

Container Engine for Kubernetes creates Kubernetes clusters that are completely integrated into your Oracle Cloud Infrastructure Virtual Cloud Network (VCN). Worker nodes, load balancers, and the Kubernetes API endpoint are part of your own VCN, and you can configure them as public or private. Such clusters that are fully integrated into your own VCN are known as "VCN-native clusters".

How can I tell if a cluster is already a VCN-native cluster?

If you're not sure whether a cluster is already a VCN-native cluster, view information about the cluster (for example, on the Cluster Details page in the Console). If the cluster is already a VCN-native cluster, the cluster details include Kubernetes API Endpoint information. If the cluster is not yet a VCN-native cluster, the cluster details simply include the Kubernetes Address.

Do I have to migrate all my existing clusters?

No, you only have to migrate existing clusters that you want to turn into VCN-native clusters. If you don't want to integrate a cluster's Kubernetes API endpoint into your own VCN, simply don't migrate that cluster.

Does the migration involve any downtime?

While a cluster is being migrated to a VCN-native cluster, the cluster's Kubernetes API continues to be accessible via the public endpoint that is not integrated into your own VCN. However, cluster lifecycle operations (such as cluster updates, node pool creation and deletion) are unavailable.

Should I choose automatic migration or custom migration?

Automatic migration creates a regional subnet in the cluster's VCN with a 10.0.0.0/28 CIDR block, along with security lists and route tables. The subnet is public and the API endpoint is assigned a public IP address. Automatic migration only supports clusters with node pools in the same compartment as the cluster. For clusters with node pools in different compartments, perform a custom migration.

Custom migration enables you to choose an existing public or private regional subnet to host the cluster's Kubernetes API endpoint. You can optionally assign a public IP address to the Kubernetes API endpoint, and choose to use network security groups.

How do I configure a subnet in my VCN to host the Kubernetes API endpoint?

Refer to Network Resource Configuration for Cluster Creation and Deployment for details about configuring the Kubernetes API endpoint subnet, security lists, and route table.

I want to test the migration to a VCN-native cluster. How can I create a cluster with a Kubernetes API endpoint that is not integrated into my VCN?

In the terminal window where you normally run Oracle Cloud Infrastructure CLI commands, run the following command to create a test cluster with a Kubernetes API endpoint that is not integrated into your VCN:

```bash
oci ce cluster create --compartment-id <compartment-ocid> --kubernetes-version v<kubernetes-version-number> --name <cluster-name> --vcn-id <vcn-ocid>
```

where:

- `--compartment-id <compartment-ocid>` is the OCID of the compartment to which you want the test cluster to belong.
• `--kubernetes-version v<kubernetes-version-number>` is a supported version of Kubernetes (see Kubernetes Versions Supported by Container Engine for Kubernetes on page 1351). For example, `--kubernetes-version v1.19.7`

• `--name <cluster-name>` is a name of your choice for the test cluster. For example, `--name test-vcn-native-migration`

• `--vcn-id <vcn-ocid>` is the OCID of the VCN in which to create the test cluster.

Having created a test cluster with a Kubernetes API endpoint that is not integrated into your VCN, you can now migrate the test cluster to make it a VCN-native cluster. See Migrating an Existing Cluster to be VCN-native on page 1275.

Remember to delete the test cluster when you no longer need it.

**How do I increase or reduce the time until the decommission of the public Kubernetes API endpoint that is not integrated into my own VCN?**

The decommissioning period is the length of time during which a newly migrated cluster is accessible via both the new Kubernetes API endpoint in your own VCN, and via the public API endpoint that was not integrated into your VCN. The decommissioning period ensures there is no downtime while you update the configuration of your kubectl, tools, and CI/CD pipelines to use the new Kubernetes API endpoint.

The decommissioning period starts as soon as Container Engine for Kubernetes has migrated the cluster to integrate its Kubernetes API endpoint into your own VCN. By default, you have 30 days to complete the updates, but you can reduce the decommissioning period to as little as 5 days or increase it to more than 30 days. File a support ticket if you want to reduce or increase the decommissioning period, and specify:

• **Summary:** Request to modify Reclamation Extension in <region-name>

• **Region:** <region-name>

• **Component:** Control Plane

• **Details:** Include the following:
  - Tenancy: <tenancy-name>
  - Tenancy Id: <tenancy-ocid>
  - Cluster: <cluster-name>
  - Cluster Id: <cluster-ocid>
  - Requested expiration date/time: <date-and-time>

**Deleting a Kubernetes Cluster**

You can delete a cluster along with its control plane nodes, worker nodes, and node pools.

Note the following:

• When you delete a cluster, no other resources created during the cluster creation process or associated with the cluster (such as VCNs, internet gateways, NAT gateways, route tables, security lists, load balancers, and block volumes) are deleted automatically. If you want to delete these resources, you have to do so manually.

• Container Engine for Kubernetes creates the worker nodes (compute instances) in a cluster with auto-generated names in the format `oke-c<part-of-cluster-OCID>-n<part-of-node-pool-OCID>-s<part-of-subnet-OCID>-<slot>`. Do not change the auto-generated names of worker nodes. If you do change the auto-generated name of a worker node and then delete the cluster, the renamed worker node is not deleted. You would have to delete the renamed worker node manually.

**Using the Console**

To delete a Kubernetes cluster using Container Engine for Kubernetes:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Kubernetes Clusters (OKE).
2. Choose a Compartment you have permission to work in.
3. On the Cluster List page, click the Delete icon beside the cluster to delete, and confirm that you want to delete it.
You can also delete a cluster using the **Delete Cluster** button on the **Cluster** page.

**Using the API**

For information about using the API and signing requests, see [REST APIs](#) on page 5528 and [Security Credentials](#) on page 207. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 5351.

Use the **DeleteCluster** operation to delete a cluster.

**Managing Kubernetes Deployments**

Read about how to use Container Engine for Kubernetes to manage Kubernetes clusters:

- Deploying a Sample Nginx App on a Cluster Using Kubectl on page 1280
- Pulling Images from Registry during Deployment on page 1281
- Enforcing the Use of Signed Images from Registry on page 1282
- Creating Load Balancers to Distribute Traffic Between Cluster Nodes on page 1284
- Creating a Persistent Volume Claim on page 1296
- Supported Labels for Different Usecases on page 1301
- Adding OCI Service Broker for Kubernetes to Clusters on page 1303
- Example: Setting Up an Ingress Controller on a Cluster on page 1304
- Example: Installing Calico and Setting Up Network Policies on page 1310

**Deploying a Sample Nginx App on a Cluster Using Kubectl**

Having created a Kubernetes cluster using Container Engine for Kubernetes, you'll typically want to try it out by deploying an application on the nodes in the cluster. For convenience, the **Quick Start** tab (available from the **Cluster** page) makes it easy to view and copy the commands to:

- set up access to the cluster
- download and deploy a sample Nginx application using the Kubernetes command line tool kubectl from the instructions in a manifest file

To deploy the sample nginx application:

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See [Setting Up Cluster Access](#) on page 1242.

2. In a terminal window, deploy the sample Nginx application by entering:

   ```
   kubectl create -f https://k8s.io/examples/application/deployment.yaml
   ```

   **Tip:**
   If the command fails to connect to `https://k8s.io/examples/application/deployment.yaml`, go to the url in a browser and download the manifest file `deployment.yaml` to a local directory. Repeat the `kubectl create` command and specify the local location of the `deployment.yaml` file.

3. Confirm that the sample application has been deployed successfully by entering:

   ```
   kubectl get pods
   ```

You can see the Nginx sample application has been deployed as two pods, on two nodes in the cluster.
Pulling Images from Registry during Deployment

During the deployment of an application to a Kubernetes cluster, you'll typically want one or more images to be pulled from a Docker registry. In the application's manifest file you specify the images to pull, the registry to pull them from, and the credentials to use when pulling the images. The manifest file is commonly also referred to as a pod spec, or as a deployment.yaml file (although other filenames are allowed).

If you want the application to pull images that reside in Oracle Cloud Infrastructure Registry, you have to perform two steps:

- You have to use kubectl to create a Docker registry secret. The secret contains the Oracle Cloud Infrastructure credentials to use when pulling the image. When creating secrets, Oracle strongly recommends you use the latest version of kubectl (see the kubectl documentation).
- You have to specify the image to pull from Oracle Cloud Infrastructure Registry, including the repository location and the Docker registry secret to use, in the application's manifest file.

Note that you can configure clusters to only allow images to be pulled from Oracle Cloud Infrastructure Registry that have been signed by particular master encryption keys included in an image verification policy (see Enforcing the Use of Signed Images from Registry on page 1282).

To create a Docker registry secret:

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 1242.

2. In a terminal window, enter:

```bash
kubectl create secret docker-registry <secret-name> --docker-server=<region-key>.ocir.io --docker-username='<tenancy-namespace>/<oci-username>' --docker-password='<oci-auth-token>' --docker-email='<email-address>'
```

where:

- `<secret-name>` is a name of your choice, that you will use in the manifest file to refer to the secret . For example, ocirsecret
- `<region-key>` is the key for the Oracle Cloud Infrastructure Registry region you're using. For example, iad. See Availability by Region on page 4430.
- `ocir.io` is the Oracle Cloud Infrastructure Registry name.
- `<tenancy-namespace>` is the auto-generated Object Storage namespace string of the tenancy containing the repository from which the application is to pull the image (as shown on the Tenancy Information page). For example, the namespace of the acme-dev tenancy might be ansh81vru1zp. Note that for some older
tenancies, the namespace string might be the same as the tenancy name in all lower-case letters (for example, acme-dev).

- `<oci-username>` is the username to use when pulling the image. The username must have access to the tenancy specified by `<tenancy-name>`. For example, `jdoe@acme.com`. If your tenancy is federated with Oracle Identity Cloud Service, use the format `oracleidentitycloudservice/<username>`
- `<oci-auth-token>` is the auth token of the user specified by `<oci-username>`. For example, `k]j64r(1sJSSF-;)K8`
- `<email-address>` is an email address. An email address is required, but it doesn't matter what you specify. For example, `jdoe@acme.com`

Note the use of single quotes around strings containing special characters.

For example, combining the previous examples, you might enter:

```
kubectl create secret docker-registry ocirsecret --docker-server=phx.ocir.io --docker-username='ansh81vru1zp/jdoe@acme.com' --docker-password='k]j64r(1sJSSF-;)K8' --docker-email='jdoe@acme.com'
```

Having created the Docker secret, you can now refer to it in the application manifest file.

To specify the image to pull from Oracle Cloud Infrastructure Registry, along with the Docker secret to use, during deployment of an application to a cluster:

1. Open the application's manifest file in a text editor.
2. Add the following sections to the manifest file:
   a. Add a `containers` section that specifies the name and location of the container you want to pull from Oracle Cloud Infrastructure Registry, along with other deployment details.
   b. Add an `imagePullSecrets` section to the manifest file that specifies the name of the Docker secret you created to access the Oracle Cloud Infrastructure Registry.

Here's an example of what the manifest might look like when you've added the `containers` and `imagePullSecrets` sections:

```
apiVersion: v1
kind: Pod
metadata:
  name: ngnix-image
spec:
  containers:
    - name: ngnix
      image: phx.ocir.io/ansh81vru1zp/project01/ngnix-lb:latest
      imagePullPolicy: Always
      ports:
        - name: nginx
          containerPort: 8080
          protocol: TCP
      imagePullSecrets:
        - name: ocirsecret
```

3. Save and close the manifest file.

**Enforcing the Use of Signed Images from Registry**

For compliance and security reasons, system administrators often want to deploy software into a production system only when they are satisfied that:

- the software comes from a trusted source
- the software has not been modified since it was published, compromising its integrity
To meet these requirements, you can sign images stored in Oracle Cloud Infrastructure Registry. Signed images provide a way to verify both the source of an image and its integrity. Oracle Cloud Infrastructure Registry enables users or systems to push images to the registry and then sign them creating an image signature. An image signature associates an image with a master encryption key obtained from Oracle Cloud Infrastructure Vault.

Users or systems pulling a signed image from Oracle Cloud Infrastructure Registry can be confident both that the source of the image is trusted, and that the image's integrity has not been compromised. For more information, see Signing Images for Security on page 4445.

To further enhance security, you can configure clusters you've created with Container Engine for Kubernetes to only allow the deployment of images from Oracle Cloud Infrastructure Registry that have been signed by particular master encryption keys. At a high level, these are the steps to follow:

- Sign images in Oracle Cloud Infrastructure Registry with image signatures that use master encryption keys from Oracle Cloud Infrastructure Vault (see Signing Images for Security on page 4445).
- Create an image verification policy for a cluster that specifies which master encryption key(s) must have been used to sign images.
- Enable the cluster to use the image verification policy to enforce the use of suitably signed images.

Note the following:

- An image in Oracle Cloud Infrastructure Registry can be signed using multiple signatures, each associated with a different master encryption key. Provided a cluster's image verification policy includes at least one of the master encryption keys, the cluster allows the image to be pulled from Oracle Cloud Infrastructure Registry.
- You can specify up to five master encryption keys in a cluster's image verification policy.
- If you enable a cluster to use its image verification policy but do not specify the master encryption key(s) that must have been used to sign an image:
  - any signed image can be pulled from Oracle Cloud Infrastructure Registry, regardless of the master encryption keys used to sign it
  - any unsigned image can be pulled from Oracle Cloud Infrastructure Registry
- If you enable a cluster to use its image verification policy but Container Engine for Kubernetes cannot connect to Oracle Cloud Infrastructure Registry, no images can be pulled from Oracle Cloud Infrastructure Registry.
- Having enabled a cluster to use its image verification policy, you might later have an urgent requirement for a particular pod to pull an image that violates the policy. In this case, you can add the alpha.image-policy.k8s.io/break-glass: "true" annotation to the pod spec. Having added the annotation to the pod spec, the pod can pull any signed and unsigned images from Oracle Cloud Infrastructure Registry, regardless of the cluster's image verification policy.
- A cluster enforces the use of images signed by master encryption keys included in its image verification policy, provided:
  - images are pulled from Oracle Cloud Infrastructure Registry (rather than from other registries)
  - images are signed using master encryption keys obtained from Oracle Cloud Infrastructure Vault

Required IAM Policies for Enforcing the Use of Signed Images

To enable clusters to include master encryption keys in image verification policies, you must give clusters permission to use keys from Oracle Cloud Infrastructure Vault. To grant this permission to all clusters in the tenancy:

```
Allow any-user to use keys in tenancy where request.user.id=<CLUSTER_OCID>
```

To enable clusters to pull signed images from Oracle Cloud Infrastructure Registry, you must give clusters permission to access repositories in Oracle Cloud Infrastructure Registry. To grant this permission to all clusters in the tenancy:

```
Allow any-user to read repos in tenancy where request.user.id=<CLUSTER_OCID>
```

For examples of how to create more granular policies, see Encrypting Kubernetes Secrets at Rest in Etcd on page 1266.
Enforcing the Use of Signed Images

To enable a cluster to allow applications to pull only those images from Oracle Cloud Infrastructure Registry that have been signed using specific master encryption keys:

1. If you don’t already have access to an RSA asymmetric key in Oracle Cloud Infrastructure Vault, create one or more master encryption keys as RSA asymmetric keys. See To create a new master encryption key.
2. Define an image verification policy for the cluster and specify at least one master encryption key that must have been used to sign images:
   a. In the Console, open the navigation menu and click Developer Services. Under Containers, click Kubernetes Clusters (OKE).
   b. Choose a Compartment you have permission to work in.
   c. On the Cluster List page, select the cluster for which you want to define an image verification policy.
   d. Under Resources, click Image Verification.
   e. Click Edit Image Verification.
   f. Select Enable image verification policies on this cluster to enable the cluster to use the image verification policy you define.
   g. Select a master encryption key in Oracle Cloud Infrastructure Vault that must have been used to sign images.
      If you want to allow images signed by different keys to be pulled, you can specify multiple master encryption keys.
      Note that if you do specify multiple master encryption keys, an image need only be signed by one of those keys. An image does not have to be signed by all of the master encryption keys you specify. You can specify up to five master encryption keys in the cluster’s image verification policy.
   h. Click Save Image Verification Settings.

From now on, the cluster allows applications to pull only those images from Oracle Cloud Infrastructure Registry that have been signed using master encryption keys included in the image verification policy. Attempts to pull disallowed images are recorded in application logs (see Viewing Application Logs on Worker Nodes on page 1317).

3. Sign the images that you want the cluster to allow, using image signatures that associate the images with one or more of the master encryption keys in the image verification policy you’ve defined. See Signing Images for Security on page 4445.

4. (optional) To deploy an application that pulls a signed image from Oracle Cloud Infrastructure Registry, follow the steps in Pulling Images from Registry during Deployment on page 1281 and specify the image in the application’s manifest file.

Creating Load Balancers to Distribute Traffic Between Cluster Nodes

When you create a deployment, you can optionally create a load balancer service in the same compartment as the cluster to distribute traffic between the nodes assigned to the deployment. The key fields in the configuration of a load balancer service are the type of service being created and the ports that the load balancer will listen to.

Note:

Load balancer services you create appear in the Console. However, do not use the Console (or the Oracle Cloud Infrastructure CLI or API) to modify load balancer services. Any modifications you make will either be reverted by Container Engine for Kubernetes or will conflict with its operation and possibly result in service interruption.
Creating Load Balancers to Distribute HTTP Traffic

Consider the following configuration file, nginx_lb.yaml. It defines a deployment (kind: Deployment) for the nginx app, followed by a service definition with a type of LoadBalancer (type: LoadBalancer) that balances http traffic on port 80 for the nginx app.

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: my-nginx
  labels:
    app: nginx
spec:
  replicas: 3
  selector:
    matchLabels:
      app: nginx
  template:
    metadata:
      labels:
        app: nginx
    spec:
      containers:
        - name: nginx
          image: nginx:1.7.9
          ports:
            - containerPort: 80
---
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
spec:
  type: LoadBalancer
  ports:
    - port: 80
  selector:
    app: nginx
```

The first part of the configuration file defines an Nginx deployment, requesting that it be hosted on 3 pods running the nginx:1.7.9 image, and accept traffic to the containers on port 80.

The second part of the configuration file defines the Nginx service, which uses type LoadBalancer to balance Nginx traffic on port 80 amongst the available pods.

To create the deployment and service defined in nginx_lb.yaml while connected to your Kubernetes cluster, enter the command:

```
kubectl apply -f nginx_lb.yaml
```

This command outputs the following upon successful creation of the deployment and the load balancer:

```
deployment "my-nginx" created
service "my-nginx-svc" created
```

The load balancer may take a few minutes to go from a pending state to being fully operational. You can view the current state of your cluster by entering:

```
kubectl get all
```
The output from the above command shows the current state:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>po/my-nginx-431080787-0m4m8</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>3m</td>
</tr>
<tr>
<td>po/my-nginx-431080787-hqqcr</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>3m</td>
</tr>
<tr>
<td>po/my-nginx-431080787-n8125</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>3m</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>NAME</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>svc/kubernetes</td>
<td>203.0.113.1</td>
<td>&lt;NONE&gt;</td>
<td>443/TCP</td>
<td>3d</td>
</tr>
<tr>
<td>svc/my-nginx-svc</td>
<td>203.0.113.7</td>
<td>192.0.2.22</td>
<td>80:30269/TCP</td>
<td>3m</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESIRED</th>
<th>CURRENT</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>deploy/my-nginx</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3m</td>
</tr>
<tr>
<td>rs/my-nginx-431080787</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3m</td>
</tr>
</tbody>
</table>

The output shows that the `my-nginx` deployment is running on 3 pods (the `po/my-nginx` entries), that the load balancer is running (`svc/my-nginx-svc`) and has an external IP (192.0.2.22) that clients can use to connect to the app that’s deployed on the pods.

**Creating Load Balancers with SSL Support to Distribute HTTPS Traffic**

You can create a load balancer with SSL termination, allowing https traffic to an app to be distributed among the nodes in a cluster. This example provides a walkthrough of the configuration and creation of a load balancer with SSL support.

Consider the following configuration file, `nginx-demo-svc-ssl.yaml`, which defines an Nginx deployment and exposes it via a load balancer that serves http on port 80, and https on port 443. This sample creates an Oracle Cloud Infrastructure load balancer, by defining a service with a type of LoadBalancer (`type: LoadBalancer`).

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: nginx-deployment
spec:
  replicas: 2
  selector:
    matchLabels:
      app: nginx
  template:
    metadata:
      labels:
        app: nginx
    spec:
      containers:
      - name: nginx
        image: nginx
        ports:
        - containerPort: 80

---

kind: Service
apiVersion: v1
metadata:
  name: nginx-service
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-ssl-ports: "443"
    service.beta.kubernetes.io/oci-load-balancer-tls-secret: ssl-certificate-secret
spec:
  selector:
    app: nginx
```
Container Engine for Kubernetes

```yaml
type: LoadBalancer
ports:
  - name: http
    port: 80
    targetPort: 80
  - name: https
    port: 443
    targetPort: 80
```

The Load Balancer's annotations are of particular importance. The ports on which to support https traffic are defined by the value of `service.beta.kubernetes.io/oci-load-balancer-ssl-ports`. You can declare multiple SSL ports by using a comma-separated list for the annotation's value. For example, you could set the annotation's value to "443, 3000" to support SSL on ports 443 and 3000.

The required TLS secret, `ssl-certificate-secret`, needs to be created in Kubernetes. This example creates and uses a self-signed certificate. However, in a production environment, the most common scenario is to use a public certificate that's been signed by a certificate authority.

The following command creates a self-signed certificate, `tls.crt`, with its corresponding key, `tls.key`:

```bash
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout tls.key -out tls.crt -subj "/CN=nginxsvc/O=nginxsvc"
```

Now that you created the certificate, you need to store both it and its key as a secret in Kubernetes. The name of the secret must match the name from the `service.beta.kubernetes.io/oci-load-balancer-tls-secret` annotation of the load balancer's definition. Use the following command to create a TLS secret in Kubernetes, whose key and certificate values are set by `--key` and `--cert`, respectively.

```bash
kubectl create secret tls ssl-certificate-secret --key tls.key --cert tls.crt
```

You must create the Kubernetes secret before you can create the service, since the service references the secret in its definition. Create the service using the following command:

```bash
kubectl create -f manifests/demo/nginx-demo-svc-ssl.yaml
```

Watch the service and wait for a public IP address (EXTERNAL-IP) to be assigned to the Nginx service (nginx-service) by entering:

```bash
kubectl get svc --watch
```

The output from the above command shows the load balancer IP to use to connect to the service.

<table>
<thead>
<tr>
<th>NAME</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>nginx-service</td>
<td>192.0.2.1</td>
<td>198.51.100.1</td>
<td>80:30274/TCP</td>
<td>5m</td>
</tr>
</tbody>
</table>

The load balancer is now running, which means the service can now be accessed as follows:

- using http, by entering:
  ```bash
curl http://198.51.100.1
  ```
- using https, by entering:
  ```bash
curl --insecure https://198.51.100.1
  ```

The "--insecure" flag is used to access the service using https due to the use of self-signed certificates in this example. Do not use this flag in a production environment where the public certificate was signed by a certificate authority.
Note: When a cluster is deleted, a load balancer that's dynamically created when a service is created will not be removed. Before deleting a cluster, delete the service, which in turn will result in the cloud provider removing the load balancer. The syntax for this command is:

```bash
kubectl delete svc SERVICE_NAME
```

For example, to delete the service from the previous example, enter:

```bash
ekubectl delete svc nginx-service
```

**Updating the TLS Certificates of Existing Load Balancers**

To update the TLS certificate of an existing load balancer:

1. Obtain a new TLS certificate. In a production environment, the most common scenario is to use a public certificate that's been signed by a certificate authority.
2. Create a new Kubernetes secret. For example, by entering:

   ```bash
ekubectl create secret tls new-ssl-certificate-secret --key new-tls.key --cert new-tls.crt
   ```

3. Modify the service definition to reference the new Kubernetes secret by changing the `service.beta.kubernetes.io/oci-load-balancer-tls-secret` annotation in the service configuration. For example:

   ```yaml
apiVersion: v1
class: Service
metadata:
  name: nginx-service
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-ssl-ports: "443"
    service.beta.kubernetes.io/oci-load-balancer-tls-secret: new-ssl-certificate-secret
spec:
  selector:
    app: nginx
  type: LoadBalancer
  ports:
    - name: http
      port: 80
      targetPort: 80
    - name: https
      port: 443
      targetPort: 80
```

4. Update the service. For example, by entering:

   ```bash
kubectl apply -f new-nginx-demo-svc-ssl.yaml
```

**Creating Internal Load Balancers in Public and Private Subnets**

You can create Oracle Cloud Infrastructure load balancers to control access to services running on a cluster:

- When you create a cluster in the 'Custom Create' workflow you select an existing VCN that contains the network resources to be used by the new cluster. If you want to use load balancers to control traffic into the VCN, you select existing public or private subnets in that VCN to host the load balancers.
- When you create a cluster in the 'Quick Create' workflow, the VCN that's automatically created contains a public regional subnet to host a load balancer. If you want to host load balancers in private subnets, you can add private subnets to the VCN later.
Alternatively, you can create an internal load balancer service (often referred to simply as an 'internal load balancer') in a cluster to enable other programs running in the same VCN as the cluster to access services in the cluster. An internal load balancer is an Oracle Cloud Infrastructure private load balancer. A private load balancer has a private IP address assigned by the Load Balancing service, which serves as the entry point for incoming traffic. For more information about Oracle Cloud Infrastructure private load balancers, see Load Balancer Types on page 3192.

You can host internal load balancers in public subnets and private subnets.

To create an internal load balancer hosted on a public subnet, add the following annotation in the metadata section of the manifest file:

```
service.beta.kubernetes.io/oci-load-balancer-internal: "true"
```

To create an internal load balancer hosted on a private subnet, add both following annotations in the metadata section of the manifest file:

```
service.beta.kubernetes.io/oci-load-balancer-internal: "true"
service.beta.kubernetes.io/oci-load-balancer-subnet1: "ocid1.subnet.oc1..aaaaaa....vdfw"
```

where `ocid1.subnet.oc1..aaaaaa....vdfw` is the OCID of the private subnet.

For example:

```
apiVersion: v1
class: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-internal: "true"
    service.beta.kubernetes.io/oci-load-balancer-subnet1: "ocid1.subnet.oc1..aaaaaa....vdfw"
spec:
  type: LoadBalancer
  ports:
    - port: 8100
  selector:
    app: nginx
```

**Specifying Alternative Load Balancer Shapes**

The shape of an Oracle Cloud Infrastructure load balancer specifies its maximum total bandwidth (that is, ingress plus egress). By default, load balancers are created with a shape of 100Mbps. Other shapes are available, including 400Mbps and 8000Mbps.

To specify an alternative shape for a load balancer, add the following annotation in the metadata section of the manifest file:

```
service.beta.kubernetes.io/oci-load-balancer-shape: <value>
```

where `value` is the bandwidth of the shape (for example, 100Mbps, 400Mbps, 8000Mbps).

For example:

```
apiVersion: v1
class: Service
metadata:
```
name: my-nginx-svc
labels:
  app: nginx
annotations:
  service.beta.kubernetes.io/oci-load-balancer-shape: 400Mbps
spec:
  type: LoadBalancer
  ports:
  - port: 80
    selector:
      app: nginx

Note: Sufficient load balancer quota must be available in the region for the shape you specify. Enter the following kubectl command to confirm that load balancer creation did not fail due to lack of quota:

kubectl describe service <service-name>

Specifying Flexible Load Balancer Shapes

The shape of an Oracle Cloud Infrastructure load balancer specifies its maximum total bandwidth (that is, ingress plus egress). As described in Specifying Alternative Load Balancer Shapes on page 1289, you can specify different load balancer shapes.

In addition, you can also specify a flexible shape for an Oracle Cloud Infrastructure load balancer, by defining a minimum and a maximum bandwidth for the load balancer.

To specify a flexible shape for a load balancer, add the following annotations in the metadata section of the manifest file:

service.beta.kubernetes.io/oci-load-balancer-shape: "flexible"
service.beta.kubernetes.io/oci-load-balancer-shape-flex-min: <min-value>
service.beta.kubernetes.io/oci-load-balancer-shape-flex-max: <max-value>

where:

• <min-value> is the minimum bandwidth for the load balancer, in Mbps (for example, 10)
• <max-value> is the maximum bandwidth for the load balancer, in Mbps (for example, 100)

Note that you do not include a unit of measurement when specifying bandwidth values for flexible load balancer shapes (unlike for pre-defined shapes). For example, specify the minimum bandwidth as 10 rather than as 10Mbps.

For example:

apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-shape: "flexible"
    service.beta.kubernetes.io/oci-load-balancer-shape-flex-min: 10
    service.beta.kubernetes.io/oci-load-balancer-shape-flex-max: 100
spec:
  type: LoadBalancer
  ports:
    - port: 80
      selector:
        app: nginx
Specifying Load Balancer Connection Timeout

You can specify the maximum idle time (in seconds) allowed between two successive receive or two successive send operations between the client and backend servers.

To explicitly specify a maximum idle time, add the following annotation in the metadata section of the manifest file:

```
service.beta.kubernetes.io/oci-load-balancer-connection-idle-timeout: <value>
```

where `value` is the number of seconds.

For example:

```
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-connection-idle-timeout: 100
spec:
  type: LoadBalancer
  ports:
  - port: 80
    selector:
      app: nginx
```

Note that if you don't explicitly specify a maximum idle time, a default value is used. The default value depends on the type of listener:

- for TCP listeners, the default maximum idle time is 300 seconds
- for HTTP listeners, the default maximum idle time is 60 seconds

Specifying Load Balancer Reserved Public IP Addresses

When a Kubernetes service of type `LoadBalancer` is deployed on a cluster, Container Engine for Kubernetes creates an Oracle Cloud Infrastructure public load balancer to accept traffic into the cluster. By default, the Oracle Cloud Infrastructure public load balancer is assigned an ephemeral public IP address. However, an ephemeral public IP address is temporary, and only lasts for the lifetime of the public load balancer.

If you want the Oracle Cloud Infrastructure public load balancer that Container Engine for Kubernetes creates to have the same public IP address deployment after deployment, you can assign the load balancer a reserved public IP address from the pool of reserved public IP addresses. For more information about creating and viewing reserved public IP addresses, see Public IP Addresses on page 3753.

To assign a reserved public IP address to the Oracle Cloud Infrastructure public load balancer that Container Engine for Kubernetes creates, add the `LoadBalancerIP` property in the spec section of the manifest file that defines the `LoadBalancer` service, and specify the reserved public IP address.

For example:

```
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
spec:
  loadBalancerIP: 144.25.97.173
  type: LoadBalancer
```
ports:
  - port: 80
selector:
  app: nginx

Note the following:

- If you set the `loadBalancerIP` property of the `LoadBalancer` service, you cannot later directly change the IP address of the Oracle Cloud Infrastructure public load balancer that Container Engine for Kubernetes creates. If you do want to change the IP address of the public load balancer, delete the `LoadBalancer` service, specify a different reserved public IP address in the manifest file, and deploy the `LoadBalancer` service again.

- If you don’t set the `loadBalancerIP` property of the `LoadBalancer` service, you cannot later directly change the IP address of the Oracle Cloud Infrastructure public load balancer that Container Engine for Kubernetes creates from an ephemeral IP address to a reserved public IP address. If you do want to change the ephemeral IP address to a reserved public IP address, delete the `LoadBalancer` service, set the `loadBalancerIP` property to a reserved public IP address in the manifest file, and deploy the `LoadBalancer` service again.

- You can delete the `LoadBalancer` service and release the reserved public IP address for other uses (for example, to assign it to another `LoadBalancer` service).

- You cannot specify a reserved public IP address for a `LoadBalancer` service if the reserved public IP address is already assigned to another resource (such as a compute instance, or another `LoadBalancer` service).

- You cannot add the `loadBalancerIP` property to the manifest file for an internal `LoadBalancer` service (that is, a manifest file that includes the `service.beta.kubernetes.io/oci-load-balancer-internal: "true"` annotation).

- By default, the reserved public IP address that you specify as the `loadBalancerIP` property of the `LoadBalancer` service in the manifest file is expected to be a resource in the same compartment as the cluster. If you want to specify a reserved public IP address in a different compartment, add the following policy to the tenancy:

```text
ALLOW any-user to read public-ips in tenancy where request.principal.type = 'cluster'
ALLOW any-user to manage floating-ips in tenancy where request.principal.type = 'cluster'
```

**Specifying Load Balancer Network Security Groups**

Oracle Cloud Infrastructure network security groups (NSGs) enable you to control traffic into and out of resources, and between resources. The security rules defined for an NSG ensure that all the resources in that NSG have the same security posture. For more information, see Network Security Groups on page 3718.

You can use an existing NSG to manage access to the Oracle Cloud Infrastructure load balancer that Container Engine for Kubernetes creates when a Kubernetes service of type `LoadBalancer` is deployed on a cluster.

To add the Oracle Cloud Infrastructure load balancer created by Container Engine for Kubernetes to an NSG, add the following annotation in the metadata section of the manifest file:

```text
oci.oraclecloud.com/oci-network-security-groups: "<nsg-ocid>"
```

where `<nsg-ocid>` is the OCID of an existing NSG.

For example:

```yaml
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
labels:
  app: nginx
annotations:
```
Note the following:

- The NSG you specify must be in the same VCN as the Oracle Cloud Infrastructure load balancer.
- You can specify up to five NSGs, in a comma-separated list, in the format:

  
  \[
  \text{oci.oraclecloud.com/oci-network-security-groups: } "\text{nsg1-ocid},\text{nsg2-ocid},\text{nsg3-ocid},\text{nsg4-ocid},\text{nsg5-ocid}" \]

- To remove a load balancer from an NSG, or change the NSG that the load balancer is in, update the annotation and re-apply the manifest.

### Specifying Load Balancer Security List Management Options

You can use the security list management feature in Kubernetes to manage security list rules. This feature is useful if you are new to Kubernetes, or for basic deployments.

**Note:**

You might encounter scalability and other issues if you use the Kubernetes security list management feature in complex deployments, and with tools like Terraform. For these reasons, Oracle does not recommend using the Kubernetes security list management feature in production environments.

To specify how the Kubernetes security list management feature manages security lists, add the following annotation in the metadata section of the manifest file:

\[
\text{service.beta.kubernetes.io/oci-load-balancer-security-list-management-mode: } <\text{value}>\]

where \(<\text{value}>\) is one of:

- "All": All required security list rules for load balancer services are managed.
- "Frontend": Only security list rules for ingress to load balancer services are managed. You have to set up a rule that allows inbound traffic to the appropriate ports for node port ranges, the kube-proxy health port, and the health check port ranges.
- "None": No security list management is enabled. You have to set up a rule that allows inbound traffic to the appropriate ports for node port ranges, the kube-proxy health port, and the health check port ranges. Additionally, you have to set up rules to allow inbound traffic to load balancers.

For example:

```yaml
apiVersion: v1
class: Service
metadata:
  name: my-nginx-svc
type: LoadBalancer
spec:
  ports:
  - port: 80
    selector:
      app: nginx
```

```yaml
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-security-list-management-mode: "Frontend"
```
Specifying Load Balancer Listener Protocol

You can define the type of traffic accepted by the load balancer listener by specifying the protocol on which the listener accepts connection requests.

To explicitly specify the load balancer listener protocol, add the following annotation in the metadata section of the manifest file:

```yaml
service.beta.kubernetes.io/oci-load-balancer-backend-protocol: <value>
```

where `<value>` is the protocol that defines the type of traffic accepted by the listener. For example, "HTTP". To get a list of valid protocols, use the ListProtocols operation.

For example:

```yaml
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
labels:
  app: nginx
annotations:
  service.beta.kubernetes.io/oci-load-balancer-backend-protocol: "HTTP"
spec:
  type: LoadBalancer
  ports:
    - port: 80
  selector:
    app: nginx
```

Note that if you don't explicitly specify a protocol, "TCP" is used as the default value.

Specifying Load Balancer Health Check Parameters

An Oracle Cloud Infrastructure load balancer applies a health check policy to continuously monitor backend servers. A health check is a test to confirm backend server availability, and can be a request or a connection attempt. If a server fails the health check, the load balancer takes the server temporarily out of rotation. If the server subsequently passes the health check, the load balancer returns it to the rotation.

Health check policies include a number of parameters, which have default values. When you create a load balancer, you can override health check parameter default values by including annotations in the metadata section of the manifest file. Having created a load balancer, you can later add, modify, and delete those annotations. If you delete an annotation that specified a value for a health check parameter, the load balancer uses the parameter's default value instead.

To specify how many unsuccessful health check requests to attempt before a backend server is considered unhealthy, add the following annotation in the metadata section of the manifest file:

```yaml
service.beta.kubernetes.io/oci-load-balancer-health-check-retries: <value>
```

where `<value>` is the number of unsuccessful health check requests.
To specify the interval between health check requests, add the following annotation in the metadata section of the manifest file:

```
service.beta.kubernetes.io/oci-load-balancer-health-check-interval: <value>
```

where `<value>` is a numeric value in milliseconds. The minimum is 1000.

To specify the maximum time to wait for a response to a health check request, add the following annotation in the metadata section of the manifest file:

```
service.beta.kubernetes.io/oci-load-balancer-health-check-timeout: <value>
```

where `<value>` is a numeric value in milliseconds. A health check is successful only if the load balancer receives a response within this timeout period.

For example:

```
apiVersion: v1
kind: Service
metadata:
  name: my-nginx-svc
  labels:
    app: nginx
  annotations:
    service.beta.kubernetes.io/oci-load-balancer-health-check-retries: 5
    service.beta.kubernetes.io/oci-load-balancer-health-check-interval: 15000
    service.beta.kubernetes.io/oci-load-balancer-health-check-timeout: 4000
spec:
  type: LoadBalancer
  ports:
  - port: 80
    selector:
      app: nginx
```

Note that if you don't explicitly specify health check parameter values by including annotations in the metadata section of the manifest file, the following defaults are used:

<table>
<thead>
<tr>
<th>Annotation Not Included</th>
<th>Default Value Used</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>service.beta.kubernetes.io/oci-load-balancer-health-check-retries</code></td>
<td>3</td>
</tr>
<tr>
<td><code>service.beta.kubernetes.io/oci-load-balancer-health-check-interval</code></td>
<td>10000</td>
</tr>
<tr>
<td><code>service.beta.kubernetes.io/oci-load-balancer-health-check-timeout</code></td>
<td>3000</td>
</tr>
</tbody>
</table>

For more information about Oracle Cloud Infrastructure load balancer health check policies, see Health Check Management on page 3236.

**Preventing Nodes from Handling Load Balancer Traffic**

You can exclude particular worker nodes from the list of backend servers in an Oracle Cloud Infrastructure load balancer backend set. For more information, see `node.kubernetes.io/exclude-from-external-load-balancers` on page 1302.
Creating a Persistent Volume Claim

Container storage via a container's root file system is ephemeral, and can disappear upon container deletion and creation. To provide a durable location to prevent data from being lost, you can create and use persistent volumes to store data outside of containers.

A persistent volume offers persistent storage that enables your data to remain intact, regardless of whether the containers to which the storage is connected are terminated.

A persistent volume claim (PVC) is a request for storage, which is met by binding the PVC to a persistent volume (PV). A PVC provides an abstraction layer to the underlying storage. For example, an administrator could create a number of static persistent volumes that can later be bound to one or more persistent volume claims. If none of the static persistent volumes match the user's PVC request, the cluster may attempt to dynamically create a new PV that matches the PVC request.

With Oracle Cloud Infrastructure as the underlying IaaS provider, you can provision persistent volume claims by attaching volumes from the Oracle Cloud Infrastructure Block Volume service. The volumes are connected to clusters created by Container Engine for Kubernetes using FlexVolume and CSI (Container Storage Interface) volume plugins deployed on the clusters.

The minimum amount of persistent storage that a PVC can request is 50 gigabytes. If the request is for less than 50 gigabytes, the request is rounded up to 50 gigabytes.

For more information about persistent volumes, persistent volume claims, and volume plugins, see the Kubernetes documentation.

Provisioning Persistent Volume Claims on the Block Volume Service

The Oracle Cloud Infrastructure Block Volume service (the Block Volume service) provides persistent, durable, and high-performance block storage for your data. You can use the CSI volume plugin or the FlexVolume volume plugin to connect clusters to volumes from the Block Volume service. Using the CSI volume plugin has several advantages:

- In future, new functionality will only be added to the CSI volume plugin, not to the FlexVolume volume plugin (although Kubernetes developers will continue to maintain the FlexVolume volume plugin).
- The CSI volume plugin does not require access to underlying operating system and root file system dependencies.

The StorageClass specified for a PVC controls which volume plugin to use to connect to Block Volume service volumes. If you don't explicitly specify a value for `storageClassName` in the yaml file that defines the PVC, the cluster's default StorageClass is used. In clusters created by Container Engine for Kubernetes, the `oci` StorageClass is initially set up as the default. The `oci` StorageClass is used by the FlexVolume volume plugin.

In the case of the CSI volume plugin, the CSI topology feature ensures that worker nodes and volumes are located in the same availability domain. In the case of the FlexVolume volume plugin, you can use the `matchLabels` element to select the availability domain in which a persistent volume claim is provisioned. Note that you do not use the `matchLabels` element with the CSI volume plugin.

Regardless of the volume plugin you choose to use, if a cluster is in a different compartment to its worker nodes, you must create an additional policy to enable access to Block Volume service volumes. This situation arises when the subnet specified for a node pool belongs to a different compartment to the cluster. To enable the worker nodes to access Block Volume service volumes, create the additional policy with both the following policy statements:

- ALLOW any-user to manage volumes in TENANCY where request.principal.type = 'cluster'
- ALLOW any-user to manage volume-attachments in TENANCY where request.principal.type = 'cluster'

Note:

In the FlexVolume examples in this topic, the PVCs request storage in availability domains in the Ashburn region using the `failure-domain.beta.kubernetes.io/zone` label. For more information about using this label (and the shortened versions of availability domain labels)
Specifying the Volume plugin used by a Persistent Volume Claim

To explicitly specify the volume plugin to use to connect to the Block Volume service when provisioning a persistent volume claim, specify a value for `storageClassName` in the yaml file that defines the PVC:

- to use the CSI volume plugin, specify `storageClassName: "oci-bv"`
- to use the FlexVolume volume plugin, specify `storageClassName: "oci"`

Example 1: Dynamically Creating a Persistent Volume on the Block Volume Service for Use by the CSI Volume Plugin

In this example, the cluster administrator has not created any suitable PVs that match the PVC request. As a result, a block volume is dynamically provisioned using the CSI plugin specified by the `oci-bv` StorageClass's definition (provisioner: `blockvolume.csi.oraclecloud.com`).

You define a PVC in a file called `csi-bvs-pvc.yaml`. For example:

```yaml
apiVersion: v1
class: PersistentVolumeClaim
metadata:
  name: mynginxclaim
spec:
  storageClassName: "oci-bv"
  accessModes:
  - ReadWriteOnce
  resources:
    requests:
      storage: 50Gi
```

Enter the following command to create the PVC from the `csi-bvs-pvc.yaml` file:

```
kubectl create -f csi-bvs-pvc.yaml
```

The output from the above command confirms the creation of the PVC:

```
persistentvolumeclaim "mynginxclaim" created
```

Verify that the PVC has been created by running `kubectl get pvc`:

```
kubectl get pvc
```

The output from the above command shows the current status of the PVC:

```
NAME             STATUS      VOLUME            CAPACITY   ACCESSMODES   STORAGECLASS
mynginxclaim     Pending     /dev/lock         50Gi       RWX          oci-bv
```

The PVC has a status of `Pending` because the `oci-bv` StorageClass's definition includes `volumeBindingMode: WaitForFirstConsumer`.

You can use this PVC when creating other objects, such as pods. For example, you could create a new pod from the following pod definition, which instructs the system to use the `mynginxclaim` PVC as the nginx volume, which is mounted by the pod at `/data`:

```yaml
apiVersion: v1
```
kind: Pod
metadata:
  name: nginx
spec:
  containers:
    - name: nginx
      image: nginx:latest
      ports:
        - name: http
          containerPort: 80
      volumeMounts:
        - name: data
          mountPath: /usr/share/nginx/html
  volumes:
    - name: data
      persistentVolumeClaim:
        claimName: mynginxclaim

Having created the new pod, you can verify that the PVC has been bound to a new persistent volume by entering:

```
kubectl get pvc
```

The output from the above command confirms that the PVC has been bound:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>VOLUME</th>
<th>CAPACITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>mynginxclaim</td>
<td>Bound</td>
<td>ocid1.volume.oc1.iad.&lt;unique_ID&gt;</td>
<td>50Gi</td>
</tr>
<tr>
<td>RWO</td>
<td>oci-bv</td>
<td>4m</td>
<td></td>
</tr>
</tbody>
</table>

You can verify that the pod is using the new persistent volume claim by entering:

```
kubectl describe pod nginx
```

**Example 2: Dynamically Creating a Persistent Volume on the Block Volume Service for Use by the FlexVolume Volume Plugin**

In this example, the cluster administrator has not created any suitable PVs that match the PVC request. As a result, a block volume is dynamically provisioned using the FlexVolume volume plugin specified by the `oci` StorageClass's definition (provisioner: oracle.com/oci).

You define a PVC in a file called flex-bvs-pvc.yaml. For example:

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: mynginxclaim
spec:
  storageClassName: "oci"
  selector:
    matchLabels:
      failure-domain.beta.kubernetes.io/zone: "US-ASHBURN-AD-1"
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 50Gi
```

Note that the flex-bvs-pvc.yaml file includes the `matchLabels` element, which is only applicable in the case of the FlexVolume volume plugin.
Enter the following command to create the PVC from the flex-bvs-pvc.yaml file:

```
kubectl create -f flex-bvs-pvc.yaml
```

The output from the above command confirms the creation of the PVC:

```
persistentvolumeclaim "mynginxclaim" created
```

Verify that the PVC has been created and bound to a new persistent volume by entering:

```
kubectl get pvc
```

The output from the above command shows the current status of the PVC:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>VOLUME</th>
<th>CAPACITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>mynginxclaim</td>
<td>Bound</td>
<td>ocid1.volume.oc1.iad.&lt;unique_ID&gt;</td>
<td>50Gi</td>
</tr>
<tr>
<td></td>
<td>RWO</td>
<td>oci</td>
<td>4m</td>
</tr>
</tbody>
</table>

The PVC already has a status of Bound because the oci StorageClass's definition includes
`volumeBindingMode: Immediate.`

You can use this PVC when creating other objects, such as pods. For example, the following pod definition instructs
the system to use the mynginxclaim PVC as the nginx volume, which is mounted by the pod at /data.

```yaml
apiVersion: v1
kind: Pod
metadata:
  name: nginx
spec:
  containers:
    - name: nginx
      image: nginx:latest
      ports:
        - name: http
          containerPort: 80
      volumeMounts:
        - name: data
          mountPath: /usr/share/nginx/html
  volumes:
    - name: data
      persistentVolumeClaim:
        claimName: mynginxclaim
```

Having created the new pod, you can verify that it is running and using the new persistent volume claim by entering:

```
kubectl describe pod nginx
```

**Example 3: Creating a Persistent Volume from a Backup on the Block Volume Service for Use by the FlexVolume Volume Plugin**

In this example, the cluster administrator has created a block volume backup for you to use when provisioning a new
persistent volume claim. The block volume backup comes with data ready for use by other objects such as pods.

You define a PVC in a file called flex-pvcfrombackup.yaml file. You use the `volume.beta.kubernetes.io/oci-volume-source` annotation element to specify the source of the block volume to use when provisioning
a new persistent volume claim using the FlexVolume volume plugin. You can specify the OCID of either a block
volume or a block volume backup as the value of the annotation. In this example, you specify the OCID of the block volume backup created by the cluster administrator. For example:

```yaml
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: myvolume
  annotations:
    volume.beta.kubernetes.io/oci-volume-source:
      ocid1.volumebackup.oc1.iad.abuw...
spec:
  selector:
    matchLabels:
      failure-domain.beta.kubernetes.io/zone: US-ASHBURN-AD-1
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 50Gi
```

Note that the flex-pvcfrombackup.yaml file includes the `matchLabels` element, which is only applicable in the case of the FlexVolume volume plugin.

Enter the following command to create the PVC from the flex-pvcfrombackup.yaml file:

```
kubectl create -f flex-pvcfrombackup.yaml
```

The output from the above command confirms the creation of the PVC:

```
persistentvolumeclaim "myvolume" created
```

Verify that the PVC has been created and bound to a new persistent volume created from the volume backup by entering:

```
kubectl get pvc
```

The output from the above command shows the current status of the PVC:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>VOLUME</th>
<th>CAPACITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>myvolume</td>
<td>Bound</td>
<td>ocid1(volumebackup).oci.iad.&lt;unique_ID&gt;</td>
<td>50Gi</td>
</tr>
<tr>
<td>oci</td>
<td>4m</td>
<td></td>
<td>RWO</td>
</tr>
</tbody>
</table>

You can use the new persistent volume created from the volume backup when defining other objects, such as pods. For example, the following pod definition instructs the system to use the myvolume PVC as the nginx volume, which is mounted by the pod at /data.

```yaml
apiVersion: v1
kind: Pod
metadata:
  name: nginx
spec:
  containers:
    - name: nginx
      image: nginx:latest
      ports:
        - name: http
          containerPort: 80
          volumeMounts:
            - name: data
```
Having created the new pod, you can verify that it is running and using the new persistent volume claim by entering:

```
kubectl describe pod nginx
```

### Supported Labels for Different Usecases

Container Engine for Kubernetes uses a number of different labels when creating and managing clusters, including:

- `failure-domain.beta.kubernetes.io/zone` on page 1301
- `oci.oraclecloud.com/fault-domain` on page 1301
- `node.kubernetes.io/exclude-from-external-load-balancers` on page 1302

For more information about Kubernetes labels, see the Kubernetes documentation.

#### `failure-domain.beta.kubernetes.io/zone`

Container Engine for Kubernetes automatically adds the `failure-domain.beta.kubernetes.io/zone` label to each worker node (compute instance) in a cluster, according to the availability domain in which it is placed.

An availability domain is one or more data centers located within a region. A region is composed of one or more availability domains. Availability domains are isolated from each other, fault tolerant, and very unlikely to fail simultaneously. See Regions and Availability Domains on page 208.

You can use the `failure-domain.beta.kubernetes.io/zone` label in different ways:

- You can use the `failure-domain.beta.kubernetes.io/zone` label (in conjunction with the `oci.oraclecloud.com/fault-domain` label) to constrain the worker nodes on which to run a pod, in the case of a cluster with worker nodes in multiple availability domains. Include the `failure-domain.beta.kubernetes.io/zone` label in the pod specification to specify the availability domain in which worker nodes must have been placed.
- You can use the `failure-domain.beta.kubernetes.io/zone` label to specify the availability domain and region to provision persistent volume claims on the Block Volume service when using the FlexVolume volume plugin. See Creating a Persistent Volume Claim on page 1296.

When you specify a value for the `failure-domain.beta.kubernetes.io/zone` label, you must use the correct shortened version of the availability domain name in an Oracle Cloud Infrastructure region.

In most cases, the shortened versions of availability domain names are in the format `<region-identifier>-1-AD-<availability-domain-number>`. For example, `UK-LONDON-1-AD-1`, `UK-LONDON-1-AD-2`, `UK-LONDON-1-AD-3`, `AP-MELBOURNE-1-AD-1`, `ME-JEDDAH-1-AD-1`. To find out the region identifiers and availability domains to use, see Availability by Region on page 1209.

Note that the shortened versions of availability domain names in the Ashburn and Phoenix regions are exceptions, as shown below:

- For the Phoenix region, shortened versions of availability domain names are in the format `PHX-AD-<availability-domain-number>`. For example, `PHX-AD-1`, `PHX-AD-2`, `PHX-AD-3`.

#### `oci.oraclecloud.com/fault-domain`

Container Engine for Kubernetes automatically adds the `oci.oraclecloud.com/fault-domain` label to each worker node (compute instance) in a cluster, according to the fault domain in which it is placed.
A fault domain is a grouping of hardware and infrastructure that is distinct from other fault domains in the same availability domain. Each availability domain has three fault domains (named FAULT-DOMAIN-1, FAULT-DOMAIN-2, FAULT-DOMAIN-3). Every compute instance is placed in a fault domain. See Fault Domains on page 210.

You can constrain the worker nodes on which to run a pod by including the oci.oraclecloud.com/fault-domain label in the pod specification. Use the oci.oraclecloud.com/fault-domain label to specify the fault domain in which worker nodes must have been placed.

You'll typically use the oci.oraclecloud.com/fault-domain label to achieve high availability when a cluster is located in a region with a single availability domain.

For example:

```yaml
apiVersion: v1
kind: Pod
metadata:
  name: nginx
spec:
  containers:
  - name: nginx
    image: nginx:1.14.2
    ports:
    - containerPort: 80
      nodeSelector:
        oci.oraclecloud.com/fault-domain: FAULT-DOMAIN-3
```

If you apply the above example pod spec to a cluster, an nginx pod is only created if the cluster has worker nodes in FAULT-DOMAIN-3 in the availability domain. If the cluster only has worker nodes in FAULT-DOMAIN-1 or FAULT-DOMAIN-2, the pod is not created and remains in a pending status.

If a cluster has worker nodes in multiple availability domains, include both the failure-domain.beta.kubernetes.io/zone label and the oci.oraclecloud.com/fault-domain label in a pod specification to specify both the availability domain and the fault domain of the worker nodes on which to run the pod.

**node.kubernetes.io/exclude-from-external-load-balancers**

Container Engine for Kubernetes automatically enables the ServiceNodeExclusion feature gate on the clusters it creates. With the ServiceNodeExclusion feature gate enabled on a cluster, you can add a label to particular worker nodes to exclude them from the list of backend servers in an Oracle Cloud Infrastructure load balancer backend set. The fewer worker nodes included in a backend set, the faster the load balancer can be updated.

To exclude a worker node from the list of backend servers in a backend set, add the node.kubernetes.io/exclude-from-external-load-balancers label to the node by entering:

```
kubectl label nodes <node-name> node.kubernetes.io/exclude-from-external-load-balancers=true
```

For example:

```
kubectl label nodes 10.0.1.2 node.kubernetes.io/exclude-from-external-load-balancers=true
```

Note that having added the label to a node, the node is excluded from the list of backend servers regardless of the value of the label. For example, even if you specify node.kubernetes.io/exclude-from-external-load-balancers label=false, the worker node is still excluded from the list of backend servers.

To remove the label from the node, enter:

```
kubectl label nodes <node-name> node.kubernetes.io/exclude-from-external-load-balancers=
```
Adding OCI Service Broker for Kubernetes to Clusters

Service brokers offer a catalog of backing services to workloads running on cloud native platforms. The Open Service Broker API is a commonly-used standard for interactions between service brokers and platforms. The Open Service Broker API specification describes a simple set of API endpoints that platforms use to provision, gain access to, and manage service offerings. For more information about the Open Service Broker API, see resources available online including those at openservicebrokerapi.org.

OCI Service Broker for Kubernetes is an implementation of the Open Service Broker API. OCI Service Broker for Kubernetes is specifically for interacting with Oracle Cloud Infrastructure services from Kubernetes clusters. It includes service broker adapters to bind to the following Oracle Cloud Infrastructure services:

- Object Storage
- Autonomous Transaction Processing
- Autonomous Data Warehouse
- Streaming

You can add OCI Service Broker for Kubernetes to clusters you've created with Oracle Cloud Infrastructure Container Engine for Kubernetes to interact with the Oracle Cloud Infrastructure services listed above. Having added OCI Service Broker for Kubernetes to a cluster, you don't have to manually provision and de-provision the Oracle Cloud Infrastructure services each time you deploy or un-deploy an application on the cluster. Instead, you interact with the Oracle Cloud Infrastructure services by using kubectl to call the Open Service Broker APIs implemented by OCI Service Broker for Kubernetes.

OCI Service Broker for Kubernetes is available as a Helm chart, a Docker container, and as source code from Github. For more information about OCI Service Broker for Kubernetes, see the OCI Service Broker for Kubernetes documentation in the Github repository.

Adding OCI Service Broker for Kubernetes to a Cluster

To add OCI Service Broker for Kubernetes to a cluster, follow the detailed instructions in the Github repository. For convenience, here's a high-level summary of the steps involved:

1. Install OCI Service Broker for Kubernetes. During this step, you will typically:
   - Install the Service Catalog.
   - Install the svcat tool.
   - Deploy OCI Service Broker for Kubernetes.
   - Grant RBAC permissions and roles.
   - Register OCI Service Broker for Kubernetes.
   For more information about installation, see the OCI Service Broker for Kubernetes documentation in the Github repository.

2. Secure OCI Service Broker for Kubernetes. During this step, you will typically:
   - Restrict access to Service Catalog resources using RBAC permissions and roles.
   - Configure TLS for OCI Service Broker for Kubernetes.
   - Set up an Oracle Cloud Infrastructure user for use by OCI Service Broker for Kubernetes.
   - Set up appropriate policies to control access to resources (according to the Oracle Cloud Infrastructure services to be used).
   - Limit access to the OCI Service Broker for Kubernetes endpoint using NetworkPolicy.
   - Stand up an etcd cluster for Service Catalog and OCI Service Broker for Kubernetes.
   - Protect sensitive values by creating secrets.
   The security configuration to choose will depend on your particular requirements. For more information, see the OCI Service Broker for Kubernetes documentation in the Github repository.
3. Provision and bind to the required Oracle Cloud Infrastructure services. During this step, you will typically:
   • Provide service provision request parameters.
   • Provide service binding request parameters.
   • Provide service binding response credentials.

   The details to provide will depend on the Oracle Cloud Infrastructure service to bind to. For more information, see the OCI Service Broker for Kubernetes documentation in the Github repository.

**Example: Setting Up an Ingress Controller on a Cluster**

You can set up different open source ingress controllers on clusters you have created with Container Engine for Kubernetes.

This topic explains how to set up an example ingress controller along with corresponding access control on an existing cluster. Having set up the ingress controller, this topic describes how to use the ingress controller with an example hello-world backend, and how to verify the ingress controller is working as expected.

**Example Components**
The example includes an ingress controller and a hello-world backend.

**Ingress Controller Components**
The ingress controller comprises:

   • An ingress controller deployment called nginx-ingress-controller. The deployment deploys an image that contains the binary for the ingress controller and Nginx. The binary manipulates and reloads the `/etc/nginx/nginx.conf` configuration file when an ingress is created in Kubernetes. Nginx upstreams point to services that match specified selectors.
   • An ingress controller service called ingress-nginx. The service exposes the ingress controller deployment as a LoadBalancer type service. Because Container Engine for Kubernetes uses an Oracle Cloud Infrastructure integration/cloud-provider, a load balancer will be dynamically created with the correct nodes configured as a backend set.

**Backend Components**
The hello-world backend comprises:

   • A backend deployment called docker-hello-world. The deployment handles default routes for health checks and 404 responses. This is done by using a stock hello-world image that serves the minimum required routes for a default backend.
   • A backend service called docker-hello-world-svc. The service exposes the backend deployment for consumption by the ingress controller deployment.

**Setting Up the Example Ingress Controller**

In this section, you create the access rules for ingress. You then create the example ingress controller components, and confirm they are running.

**Creating the Access Rules for the Ingress Controller**

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 1242.

2. If your Oracle Cloud Infrastructure user is a tenancy administrator, skip the next step and go straight to Creating the Service Account, and the Ingress Controller on page 1305.
3. If your Oracle Cloud Infrastructure user is not a tenancy administrator, in a terminal window, grant the user the Kubernetes RBAC cluster-admin clusterrole on the cluster by entering:

```bash
kubectl create clusterrolebinding <my-cluster-admin-binding> --clusterrole=cluster-admin --user=<user-OCID>
```

where:

- `<my-cluster-admin-binding>` is a string of your choice to be used as the name for the binding between the user and the Kubernetes RBAC cluster-admin clusterrole. For example, `jdoe_clst_adm`
- `<user-OCID>` is the user's OCID (obtained from the Console). For example, `ocid1.user.oc1..aaaaa...zutq` (abbreviated for readability).

For example:

```bash
kubectl create clusterrolebinding jdoe_clst_adm --clusterrole=cluster-admin --user=ocid1.user.oc1..aaaaa...zutq
```

**Creating the Service Account, and the Ingress Controller**

1. Run the following command to create the `nginx-ingress-controller` ingress controller deployment, along with the Kubernetes RBAC roles and bindings:

```bash
kubectl apply -f https://raw.githubusercontent.com/kubernetes/ingress-nginx/controller-v0.44.0/deploy/static/provider/cloud/deploy.yaml
```

2. Create and save the file `cloud-generic.yaml` containing the following code to define the ingress-nginx ingress controller service as a load balancer service:

```yaml
kind: Service
apiVersion: v1
metadata:
  name: ingress-nginx
  namespace: ingress-nginx
  labels:
    app.kubernetes.io/name: ingress-nginx
    app.kubernetes.io/part-of: ingress-nginx
spec:
  type: LoadBalancer
  selector:
    app.kubernetes.io/name: ingress-nginx
    app.kubernetes.io/part-of: ingress-nginx
  ports:
  - name: http
    port: 80
    targetPort: http
  - name: https
    port: 443
    targetPort: https
```

3. Using the file you just saved, create the `ingress-nginx` ingress controller service by running the following command:

```bash
kubectl apply -f cloud-generic.yaml
```
Verifying the ingress-nginx Ingress Controller Service is Running as a Load Balancer Service

1. View the list of running services by entering:

```bash
kubectl get svc -n ingress-nginx
```

The output from the above command shows the services that are running:

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ingress-nginx</td>
<td>LoadBalancer</td>
<td>10.96.229.38</td>
<td>&lt;pending&gt;</td>
<td>80:30756/TCP,443:30118/TCP</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>1h</td>
</tr>
</tbody>
</table>

The EXTERNAL-IP for the ingress-nginx ingress controller service is shown as <pending> until the load balancer has been fully created in Oracle Cloud Infrastructure.

2. Repeat the `kubectl get svc` command until an EXTERNAL-IP is shown for the ingress-nginx ingress controller service:

```bash
kubectl get svc -n ingress-nginx
```

The output from the above command shows the EXTERNAL-IP for the ingress-nginx ingress controller service:

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ingress-nginx</td>
<td>LoadBalancer</td>
<td>10.96.229.38</td>
<td>129.146.214.219</td>
<td>80:30756/TCP,443:30118/TCP</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>1h</td>
</tr>
</tbody>
</table>

Creating the TLS Secret

A TLS secret is used for SSL termination on the ingress controller.

1. Output a new key to a file. For example, by entering:

```bash
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout tls.key -out tls.crt -subj "/CN=nginxsvc/O=nginxsvc"
```

To generate the secret for this example, a self-signed certificate is used. While this is okay for testing, for production, use a certificate signed by a Certificate Authority.

2. Create the TLS secret by entering:

```bash
kubectl create secret tls tls-secret --key tls.key --cert tls.crt
```

Setting Up the Example Backend

In this section, you define a hello-world backend service and deployment.
Creating the docker-hello-world Service Definition

1. Create the file `hello-world-ingress.yaml` containing the following code. This code uses a publicly available hello-world image from Docker Hub. You can substitute another image of your choice that can be run in a similar manner.

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: docker-hello-world
  labels:
    app: docker-hello-world
spec:
  selector:
    matchLabels:
      app: docker-hello-world
  replicas: 3
  template:
    metadata:
      labels:
        app: docker-hello-world
    spec:
      containers:
      - name: docker-hello-world
        image: scottsbaldwin/docker-hello-world:latest
        ports:
        - containerPort: 80
---
apiVersion: v1
kind: Service
metadata:
  name: docker-hello-world-svc
spec:
  selector:
    app: docker-hello-world
  ports:
  - port: 8088
    targetPort: 80
  type: ClusterIP
```

Note the docker-hello-world service's type is ClusterIP, rather than LoadBalancer, because this service will be proxied by the ingress-nginx ingress controller service. The docker-hello-world service does not need public access directly to it. Instead, the public access will be routed from the load balancer to the ingress controller, and from the ingress controller to the upstream service.

2. Create the new hello-world deployment and service on nodes in the cluster by running the following command:

```bash
kubectl create -f hello-world-ingress.yaml
```

Using the Example Ingress Controller to Access the Example Backend

In this section you create an ingress to access the backend using the ingress controller.

Creating the Ingress Resource

1. Create the file `ingress.yaml` and populate it with this code:

```yaml
apiVersion: networking.k8s.io/v1beta1
kind: Ingress
metadata:
  name: hello-world-ing
```
Container Engine for Kubernetes

```
annotations:
  kubernetes.io/ingress.class: "nginx"
spec:
tls:
  - secretName: tls-secret
rules:
  - http:
      paths:
        - backend:
            serviceName: docker-hello-world-svc
            servicePort: 8088
```

2. Create the resource by entering:

```
kubectl create -f ingress.yaml
```

Verifying that the Example Components are Working as Expected

In this section, you confirm that all of the example components have been successfully created and are operating as expected. The `docker-hello-world-svc` service should be running as a ClusterIP service, and the `ingress-nginx` service should be running as a LoadBalancer service. Requests sent to the ingress controller should be routed to nodes in the cluster.

Obtaining the External IP Address of the Load Balancer

To confirm the `ingress-nginx` service is running as a LoadBalancer service, obtain its external IP address by entering:

```
kubectl get svc --all-namespaces
```

The output from the above command shows the services that are running:

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>docker-hello-world-svc</td>
<td>ClusterIP</td>
<td>10.96.83.247</td>
</tr>
<tr>
<td>&lt;none&gt;</td>
<td>8088/TCP</td>
<td>16s</td>
<td></td>
</tr>
<tr>
<td>default</td>
<td>kubernetes</td>
<td>ClusterIP</td>
<td>10.96.0.1</td>
</tr>
<tr>
<td>&lt;none&gt;</td>
<td>443/TCP</td>
<td>1h</td>
<td></td>
</tr>
<tr>
<td>ingress-nginx</td>
<td>ingress-nginx</td>
<td>LoadBalancer</td>
<td>10.96.229.38</td>
</tr>
<tr>
<td>129.146.214.219</td>
<td>80:30756/TCP,443:30118/TCP</td>
<td>5m</td>
<td></td>
</tr>
<tr>
<td>kube-system</td>
<td>kube-dns</td>
<td>ClusterIP</td>
<td>10.96.5.5</td>
</tr>
<tr>
<td>&lt;none&gt;</td>
<td>53/UDP,53/TCP</td>
<td>1h</td>
<td></td>
</tr>
</tbody>
</table>

Sending cURL Requests to the Load Balancer

1. Use the external IP address of the `ingress-nginx` service (for example, 129.146.214.219) to curl an http request by entering:

```
curl -I http://129.146.214.219
```

Example output from the above command:

```
HTTP/1.1 301 Moved Permanently
Via: 1.1 10.68.69.10 (McAfee Web Gateway 7.6.2.10.0.23236)
Date: Thu, 07 Sep 2017 15:20:16 GMT
Server: nginx/1.13.2
Location: https://129.146.214.219/
Content-Type: text/html
Content-Length: 185
Proxy-Connection: Keep-Alive
```
The output shows a 301 redirect and a Location header that suggest that http traffic is being redirected to https.

2. Either cURL against the https url or add the -L option to automatically follow the location header. The -k option instructs cURL to not verify the SSL certificates. For example, by entering:

   curl -ikL http://129.146.214.219

Example output from the above command:

```
HTTP/1.1 301 Moved Permanently
Via: 1.1 10.68.69.10 (McAfee Web Gateway 7.6.2.10.0.23236)
Date: Thu, 07 Sep 2017 15:22:29 GMT
Server: nginx/1.13.2
Location: https://129.146.214.219/
Content-Type: text/html
Content-Length: 185
Proxy-Connection: Keep-Alive
Strict-Transport-Security: max-age=15724800; includeSubDomains;

HTTP/1.0 200 Connection established

HTTP/1.1 200 OK
Server: nginx/1.13.2
Date: Thu, 07 Sep 2017 15:22:30 GMT
Content-Type: text/html
Content-Length: 71
Connection: keep-alive
Last-Modified: Thu, 07 Sep 2017 15:17:24 GMT
ETag: "59b16304-47"
Accept-Ranges: bytes
Strict-Transport-Security: max-age=15724800; includeSubDomains;

<h1>Hello webhook world from: docker-hello-world-1732906117-0ztkm</h1>
```

The last line of the output shows the HTML that is returned from the pod whose hostname is docker-hello-world-1732906117-0ztkm.

3. Issue the cURL request several times to see the hostname in the HTML output change, demonstrating that load balancing is occurring:

   $ curl -k https://129.146.214.219
   <h1>Hello webhook world from: docker-hello-world-1732906117-6115l</h1>
   $ curl -k https://129.146.214.219
   <h1>Hello webhook world from: docker-hello-world-1732906117-7r89v</h1>
   $ curl -k https://129.146.214.219
   <h1>Hello webhook world from: docker-hello-world-1732906117-0ztkm</h1>
**Inspecting nginx.conf**

The `nginx-ingress-controller` ingress controller deployment manipulates the `nginx.conf` file in the pod within which it is running.

1. Find the name of the pod running the `nginx-ingress-controller` ingress controller deployment by entering:

   ```
kubectl get po -n ingress-nginx
   ```

   The output from the above command shows the name of the pod running the `nginx-ingress-controller` ingress controller:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>nginx-ingress-controller-110676328-h86xg</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>1h</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2. Use the name of the pod running the `nginx-ingress-controller` ingress controller deployment to show the contents of `nginx.conf` by entering the following `kubectl exec` command:

   ```
kubectl exec -n ingress-nginx -it nginx-ingress-controller-110676328-h86xg -- cat /etc/nginx/nginx.conf
   ```

3. Look for `proxy_pass` in the output. There will be one for the default backend and another that looks similar to:

   ```
   proxy_pass http://upstream_balancer;
   ```

   This shows that Nginx is proxying requests to an upstream called `upstream_balancer`.

4. Locate the upstream definition in the output. It will look similar to:

   ```
   upstream upstream_balancer {
       server 0.0.0.1:1234; # placeholder
       balancer_by_lua_block {
           tcp_udp_balancer.balance()
       }
   }
   ```

   The upstream is proxying via Lua.

**Example: Installing Calico and Setting Up Network Policies**

The Kubernetes networking model assumes containers (pods) have unique and routable IP addresses within a cluster. In the Kubernetes networking model, containers communicate with each other using those IP addresses, regardless of whether the containers are deployed on the same node in a cluster or on a different node. The Container Networking Interface (CNI) is the API that enables containers to communicate with the network using IP addresses.

By default, pods accept traffic from any source. To enhance cluster security, pods can be 'isolated' by selecting them in a network policy (the Kubernetes NetworkPolicy resource). A network policy is a specification of how groups of pods are allowed to communicate with each other and other network endpoints. NetworkPolicy resources use labels to select pods and to define rules that specify what traffic is allowed to the selected pods. If a NetworkPolicy in a cluster namespace selects a particular pod, that pod will reject any connections that are not allowed by any NetworkPolicy. Other pods in the namespace that are not selected by a NetworkPolicy will continue to accept all traffic. For more information about network policies, see the Kubernetes documentation.

Network policies are implemented by the CNI network provider. Simply creating the NetworkPolicy resource without a CNI network provider to implement it will have no effect. Note that not all CNI network providers implement the NetworkPolicy resource.
Clusters you create with Container Engine for Kubernetes have flannel installed as the default CNI network provider. Flannel is a simple overlay virtual network that satisfies the requirements of the Kubernetes networking model by attaching IP addresses to containers. For more information about flannel, see the flannel documentation.

Although flannel satisfies the requirements of the Kubernetes networking model, it does not support NetworkPolicy resources. If you want to enhance the security of clusters you create with Container Engine for Kubernetes by implementing network policies, you have to install and configure a network provider that does support NetworkPolicy resources. One such provider is Calico (refer to the Kubernetes documentation for a list of other network providers). Calico is an open source networking and network security solution for containers, virtual machines, and native host-based workloads. For more information about Calico, see the Calico documentation.

You can manually install Calico alongside flannel in clusters you have created using Container Engine for Kubernetes.

Note:
- Only the use of open source Calico is supported. Use of Calico Enterprise is not supported.
- If you install Calico on a cluster that has existing node pools in which pods are already running, you will have to recreate the pods when the Calico installation is complete. For example, by running the `kubectl rollout restart` command. If you install Calico on a cluster before creating any node pools in the cluster (recommended), you can be sure that there will be no pods to recreate.

Installing Calico manually

Having created a cluster using Container Engine for Kubernetes (using either the Console or the API), you can subsequently install Calico on the cluster (alongside flannel) to support network policies.

For convenience, Calico installation instructions are included below, based on Calico version 3.10. Note that Calico installation instructions vary between Calico versions. For information about installing different versions of Calico, always refer to the Calico documentation for installing Calico for network policy enforcement only.

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 1242.

2. In a terminal window, download the Calico policy-only manifest for the Kubernetes API datastore by entering:

```bash
curl https://docs.projectcalico.org/v3.10/manifests/calico-policy-only.yaml -o calico.yaml
```

Note that the url differs, according to the version of Calico that you want to install. Refer to the Calico documentation for instructions to install a particular version of Calico.

3. The calico.yaml file includes multiple references to the pod CIDR block value. In the downloaded calico.yaml file, the pod CIDR block value is initially set to 192.168.0.0/16. If the pod CIDR block value of the cluster created by Container Engine for Kubernetes is 192.168.0.0/16, skip this step. However, if the pod CIDR block value of the cluster created by Container Engine for Kubernetes is a different value (such as the default value of
Container Engine for Kubernetes

10.244.0.0/16), you have to change the initial value in the calico.yaml file. The steps below show one way to do that:

**a.** Set the value of an environment variable to the pod CIDR block value. For example, by entering a command like:

```bash
export POD_CIDR="10.244.0.0/16"
```

**b.** Replace the default value 192.168.0.0/16 in the calico.yaml file with the actual pod CIDR block value of the cluster created by Container Engine for Kubernetes. For example, by entering a command like:

```bash
sed -i -e "s?192.168.0.0/16?$POD_CIDR?g" calico.yaml
```

4. The calico.yaml file defines a deployment named calico-typha, which has a replica count of 1 by default. You might want to consider changing this default replica count for large clusters or production environments. Calico recommends:

- At least one replica for every 200 nodes, up to a maximum of 20.
- A minimum of three replicas in production environments to reduce the impact of rolling upgrades and failures (the number of replicas should always be less than the number of nodes, otherwise rolling upgrades will stall).

To change the replica count, open the calico.yaml file in a text editor and change the value of the `replicas` setting:

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: calico-typha
...
spec:
  ...
  replicas: <number-of-replicas>
```

Note that the way to set the replica count differs, according to the Calico version you've installed. Refer to the Calico documentation to find out how to set the replica count for the version you've installed.

5. Install and configure Calico by entering the following command:

```bash
kubectl apply -f calico.yaml
```

### Setting up Network Policies

Having installed Calico on a cluster you've created with Container Engine for Kubernetes, you can create Kubernetes NetworkPolicy resources to isolate pods as required.

For NetworkPolicy examples and how to use them, see the Calico documentation and specifically:

- Kubernetes policy, demo
- Kubernetes policy, basic tutorial
- Kubernetes policy, advanced tutorial

Note that the examples vary, according to the Calico version you've installed.

### Observing Kubernetes Clusters

Read about how to use Container Engine for Kubernetes to observe Kubernetes clusters:

- Monitoring Clusters on page 1313
- Viewing Work Requests on page 1314
- Viewing Kubernetes API Server Audit Logs on page 1317
- Viewing Application Logs on Worker Nodes on page 1317
Monitoring Clusters

Having created a cluster, you can monitor the overall status of the cluster itself, and the nodes and node pools within it.

In addition to monitoring the overall status of clusters, node pools, and nodes, you can monitor their health, capacity, and performance at a more granular level using metrics, alarms, and notifications. See Container Engine for Kubernetes Metrics on page 1319.

Using the Console

To monitor a Kubernetes cluster:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Kubernetes Clusters (OKE).
2. Choose a Compartment you have permission to work in.

The Status column on the Cluster List page shows a summary status for each individual cluster and its control plane nodes. Clusters can have one of the following statuses:

<table>
<thead>
<tr>
<th>Cluster Status</th>
<th>Explanation</th>
<th>Possible Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creating</td>
<td>Cluster is in the process of being created.</td>
<td>Application is being deployed.</td>
</tr>
<tr>
<td>Active</td>
<td>Cluster is running normally.</td>
<td>Control plane nodes are running normally.</td>
</tr>
<tr>
<td>Failed</td>
<td>Cluster is not running due to an unrecoverable error.</td>
<td>Possible reasons:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• a problem setting up load balancers</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• conflicts in networking ranges</td>
</tr>
<tr>
<td>Deleting</td>
<td>Cluster is in the process of being deleted.</td>
<td>Application no longer required, so resources in the process of being released.</td>
</tr>
<tr>
<td>Deleted</td>
<td>Cluster has been deleted. Application no longer required, so resources have been released.</td>
<td>Application no longer required, so resources have been released.</td>
</tr>
<tr>
<td>Updating</td>
<td>Version of Kubernetes on the control plane nodes is in the process of being upgraded.</td>
<td>A newly supported version of Kubernetes has become available.</td>
</tr>
</tbody>
</table>

Note that the cluster's summary status is not necessarily directly related to the status of node pools and nodes within the cluster.

3. On the Cluster List page, click the name of the cluster for which you want to see detailed status.
4. Display the cluster's Metrics tab to see more granular information about the health, capacity, and performance of the cluster. See Container Engine for Kubernetes Metrics on page 1319.
5. Display the Node Pools tab to see the summary status of each node pool in the cluster.
6. On the Node Pools tab, click the name of a node pool for which you want to see detailed status.
7. Display the node pool's Metrics tab to see more granular information about the health, capacity, and performance of the node pool. See Container Engine for Kubernetes Metrics on page 1319.
8. Display the **Nodes** tab to see the summary status of each worker node in the node pool.

Worker nodes can have one of the following statuses:

<table>
<thead>
<tr>
<th>Node Status</th>
<th>Explanation</th>
<th>Possible Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creating</td>
<td>Node is being created.</td>
<td>Compute instance in the process of being created.</td>
</tr>
<tr>
<td>Active</td>
<td>Node is running normally.</td>
<td>Node is running normally.</td>
</tr>
<tr>
<td>Updating</td>
<td>Node is in the process of being updated.</td>
<td>Container Engine for Kubernetes is performing an operation on the node.</td>
</tr>
<tr>
<td>Deleting</td>
<td>Node is in the process of being deleted.</td>
<td>Application no longer required, so resources in the process of being released.</td>
</tr>
<tr>
<td>Deleted</td>
<td>Node has been deleted.</td>
<td>Application no longer required, so resources have been released.</td>
</tr>
<tr>
<td>Inactive</td>
<td>Node still exists, but is not running.</td>
<td>Compute resource has a status of Stopped, Stopping, or Down For Maintenance.</td>
</tr>
</tbody>
</table>

9. Click **View Metrics** beside a worker node to see more granular information about the health, capacity, and performance of that node. See Container Engine for Kubernetes Metrics on page 1319.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the GetCluster and GetNodePool operations to monitor the status of Kubernetes clusters.

**Viewing Work Requests**

Many Container Engine for Kubernetes service requests do not take effect immediately. For example, the creation of a node pool isn't completed until all required instances are active. In these cases, the request is fulfilled asynchronously, and its progress tracked by an associated work request. A work request is an activity log that provides visibility into in-progress asynchronous operations, enabling you to track each step in the operation's progress. Each work request has an OCID that allows you to interact with it programmatically and use it for automation.

Work requests include information about the time the request started and finished. If an operation fails, a work request can help you determine which step of the process had an error. Some operations affect multiple resources. For example, creating a node pool also affects instances. A work request provides a list of the resources that an operation affects.

For more information, see Work Requests on page 299 and the Work Requests API.

**Node Pool Work Requests**

Resources managed by Container Engine for Kubernetes can only support one work request at a time. Work requests launched while another work request is in progress will fail and return a conflict. Because some operations depend on the completion of other operations, you must monitor each operation’s work request and confirm it has succeeded before proceeding to the next operation. A create node pool work request has a status of **Succeeded** when the workflow successfully creates an instance and the instance is registered with an **Active** status.
**Work Request Status**

The following table lists work request states:

<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accepted</td>
<td>The request is in the work request queue to be processed.</td>
</tr>
<tr>
<td>In Progress</td>
<td>A work request record exists for the specified request, but no associated WORK_COMPLETED record exists.</td>
</tr>
<tr>
<td>Succeeded</td>
<td>A work request record exists for this request and an associated WORK_COMPLETED record has the state Succeeded.</td>
</tr>
<tr>
<td>Failed</td>
<td>A work request record exists for this request and an associated WORK_COMPLETED record has the state Failed.</td>
</tr>
<tr>
<td>Canceling</td>
<td>The work request is in the process of canceling.</td>
</tr>
<tr>
<td>Canceled</td>
<td>The work request has been canceled.</td>
</tr>
</tbody>
</table>

**Required IAM Policy for Viewing Work Requests**

To use Oracle Cloud Infrastructure, you must be granted security access in a policy by an administrator. This access is required whether you're using the Console or the REST API with an SDK, CLI, or other tool. If you get a message that you don’t have permission or are unauthorized, verify with your administrator what type of access you have and which compartment to work in.

For administrators: Work requests inherit the permissions of the operation that spawns the work request. To enable users to view the work requests, logs, and error messages for an operation, write a policy that grants users permission to do the operation. For example, to let users see the work requests associated with launching instances, write a policy that enables users to launch instances.

To enable users to list all work requests in a tenancy, use the following policy:

```
Allow group SupportTeam to inspect work-requests in tenancy
```

If you're new to policies, see Getting Started with Policies on page 2799 and Common Policies on page 2806.

**Getting Work Request Details**

Get the details of a work request for a cluster or node pool resource.

Use one of the following methods to get the details of a work request for a selected cluster or node pool resource.

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Kubernetes Clusters (OKE).
2. Select the Compartment from the list.
3. On the Cluster List page, click the name of the cluster for which you want to get work request details.
4. If you want to get work request details for a particular node pool in the cluster, click Node Pools under Resources, and click the name of the node pool.
5. To view work requests, click Work Requests under Resources.
6. In the **Work Requests** list, find the work request for which you want to get details. For each recent work request, you can see the following:
   - **Operation Type**: The operation being performed by the work request.
   - **Status**: See [Work Request Status](#) on page 1315 for a list of statuses and their descriptions.
   - **ID**: OCID of the work request.
   - **Resource**: The name of the resource.
   - **Time Started**: UTC-based date-time group when the work request was started.
   - **Time Finished**: UTC-based date-time group when the work request was finished.

7. Click a particular work request to see:
   - **Log messages**: Information about the stage of the workflow and a timestamp for each stage.
   - **Error messages**: Information about errors and the timestamp of the error.
   - **Associated resources**: The name, type, and OCID of resources impacted by the work request.

To get the details of a work request using the CLI

Use the command line interface (CLI) to get the details of a work request for a cluster or node pool resource.

Enter the following command:

```
oci ce work-request get --work-request-id work_request_id [OPTIONS]
```

See the CLI online help for a list of options:

```
oci ce work-request get --help
```

See [oci ce work-request get](#) for a complete description of the command.

To get the details of a work request using the API

Use the API to get the details of a work request for a cluster or node pool resource.

Run the [GetWorkRequest](#) method to get the details of a work request for a cluster or node pool. See [GetWorkRequest](#) for a complete description.

**Listing Work Requests**

List the work requests for a cluster or node pool resource.

Use one of the following methods to display a list of work requests for a selected cluster or node pool resource.

To list the work requests using the Console

Use the OCI Console to list the work requests for a cluster or node pool resource.

1. In the Console, open the navigation menu and click **Developer Services**. Under **Containers**, click **Kubernetes Clusters (OKE)**.
2. Select the **Compartment** from the list.
3. On the **Cluster List** page, click the name of the cluster for which you want to list work requests.
4. If you want to get work request details for a particular node pool in the cluster, click **Node Pools** under **Resources**, and click the name of the node pool.
5. Click **Work Requests** under **Resources**.

   The **Work Requests** list shows recent work requests.

To list the work requests using the CLI

Use the command line interface (CLI) to list the work requests for a cluster or node pool resource.

Enter the following command:

```
oci ce work-request list --compartment-id compartment-OCID --resource-type CLUSTER|NODEPOOL --cluster-id cluster-OCID --resource-id resource-OCID [OPTIONS]
```
See the CLI online help for a list of options:

```
oci ce work-request list --help
```

See `oci ce work-request list` for a complete description of the command.

**To list the work requests using the API**

Use the API to list the work requests for a cluster or node pool resource.

Run the `ListWorkRequests` method to list the work requests for a cluster or node pool resource. See `ListWorkRequests` for a complete description.

---

**Viewing Kubernetes API Server Audit Logs**

It's often useful to understand the context behind activities happening in a cluster. For example, to perform compliance checks, to identify security anomalies, and to troubleshoot errors by identifying who did what and when.

You can use the Oracle Cloud Infrastructure Audit service to view all operations performed by:

- Container Engine for Kubernetes, which emits audit events whenever you perform actions on a cluster, such as create and delete.
- The Kubernetes API server, which emits audit events whenever you use tools like kubectl to make administrative changes to a cluster, such as creating a service. Kubernetes API server audit events are shown in the Oracle Cloud Infrastructure Audit service for clusters running Kubernetes version 1.13.x (or later). Note that events are only shown from 15 July, 2020 onward.

Note that in addition to viewing operations as described in this topic, you can also monitor the health, capacity, and performance of Kubernetes clusters themselves using `metrics`, `alarms`, and `notifications`. See Container Engine for Kubernetes Metrics on page 1319.

**Using the Console**

To view operations performed by Container Engine for Kubernetes and the Kubernetes API server as log events in the Oracle Cloud Infrastructure Audit service:

1. In the Console, open the navigation menu, click Identity & Security, and then click Audit.
2. Choose a Compartment you have permission to work in.
3. Search and filter to show the operations you're interested in:
   - To view operations performed by Container Engine for Kubernetes, enter ClustersAPI in the Keywords field and click Search.
   - To view operations performed by the Kubernetes API server, enter OKE API Server Admin Access in the Keywords field and click Search.

For more information about using the Oracle Cloud Infrastructure Audit service, see Viewing Audit Log Events on page 604.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the following operation to list audit log events:

- `ListEvents`

**Viewing Application Logs on Worker Nodes**

Having created a cluster using Container Engine for Kubernetes, you can use Oracle Cloud Infrastructure Logging to view and search the logs of applications running on worker node compute instances in the cluster.

Before you can collect and parse the application logs using Oracle Cloud Infrastructure Logging:
You must have already:

- Enabled monitoring for worker node compute instances (see Enabling Monitoring for Compute Instances on page 1154).
- Installed the Oracle Cloud Agent software on worker node compute instances. The agent enables you to specify which logs to collect and how to parse them. The agent is installed by default on worker node compute instances. To confirm that the agent is already installed, see Verify Agent Installation on page 3408.

You must have already:

- Created a dynamic group with a rule that includes worker nodes in the cluster's node pools as target hosts (see About Dynamic Groups on page 3118 and Selecting Target Hosts with Dynamic Groups on page 3411). For example:

  ```
  instance.compartment.id = 'ocid1.tenancy.oc1..<unique-id>'
  ```

- Created a policy for the dynamic group with a policy statement to allow the target hosts in the dynamic group to push logs to Oracle Cloud Infrastructure Logging (see Selecting Target Hosts with Dynamic Groups on page 3411). For example:

  ```
  allow dynamic-group <dynamic-group-name> to use log-content in tenancy
  ```

Having completed the above prerequisites, you can then define custom logs and associated agent configurations to view application logs on worker node compute instances. For more information about custom logs and agent configurations, see Custom Logs on page 3404.

Note that in addition to viewing application logs on worker node compute instances, you can also:

- Monitor the overall status of the cluster itself, node pools, and nodes. See Monitoring Clusters on page 1313.
- Monitor the health, capacity, and performance of clusters, node pools, and nodes at a more granular level using metrics, alarms, and notifications. See Container Engine for Kubernetes Metrics on page 1319.

Using the Console

To define a new custom log object and an associated agent configuration to enable you to view and search the logs of applications running on a cluster's worker node compute instances:

1. Open the navigation menu and click Observability & Management. Under Logging, click Logs.
2. Choose a Compartment you have permission to work in.
3. Click Create custom log to create a new custom log.
4. On the Create custom log page, specify:
   - Custom Log Name: A name of your choosing for the new custom log. Avoid entering confidential information.
   - Compartment: The compartment in which to create the new custom log.
   - Log Group: The log group in which to place the custom log. Optionally, click Create New Group to create a new log group (see Managing Logs and Log Groups on page 3350).
5. Click Create custom log.

A new custom log is created, and the Create agent configuration page is displayed.

For convenience, these instructions now describe how to create a new agent configuration associated with the new custom log (although you can create a new agent configuration later if you prefer).

6. On the Create agent configuration page, select Create new configuration and specify:
   - Configuration Name: A name of your choosing for the new agent configuration. Avoid entering confidential information.
   - Compartment: The compartment in which to create the new agent configuration.
7. In the **Agent configuration** panel on the **Create agent configuration** page, specify:

- **Choose host groups**: One or more host groups, as follows:
  - **Group type**: Select **Dynamic group**.
  - **Group**: An existing dynamic group that includes worker nodes in the cluster's node pools as target hosts. The dynamic group you select must have permission to access the compartment you specified for the agent configuration, and must also allow target hosts to push logs to Oracle Cloud Infrastructure Logging.

- **Configure log inputs**: One or more locations from which to obtain application logs as inputs to the custom log, as follows:
  - **Input type**: Select **Log path**.
  - **Input name**: A name of your choosing for the new log input.
  - **File paths**: The path to application logs on the worker node compute instance. For example, `/var/log/containers/*`

The **Select log destination** options are pre-populated with the custom log details you specified previously.

8. Click **Create custom log** to create the agent configuration associated with the custom log.

To view and search the contents of a custom log created for an application running on a cluster's worker node compute instances:

1. Open the navigation menu and click **Observability & Management**. Under **Logging**, click **Logs**.
2. Click the name of the custom log that you want to view. You can sort log entries by age, and filter by time.
3. (Optional) Click **Explore with Log Search** to open the central logging **Search** page. You can apply filters, and explore and visualize the log data in different ways (see Viewing Custom Logs in a Compute Instance on page 3412).

**Container Engine for Kubernetes Metrics**

You can monitor the health, capacity, and performance of Kubernetes clusters managed by Container Engine for Kubernetes using **metrics**, **alarms**, and **notifications**.

This topic describes the metrics emitted by Container Engine for Kubernetes in the `oci_oke` metric namespace.

**Resources**: clusters, worker nodes

**Overview of the Container Engine for Kubernetes Service Metrics**

Container Engine for Kubernetes metrics help you monitor Kubernetes clusters, along with node pools and individual worker nodes. You can use metrics data to diagnose and troubleshoot cluster and node pool issues.

To view a default set of metrics charts in the Console, navigate to the cluster you're interested in, and then click **Metrics**. You also can use the Monitoring service to create custom queries.

**Prerequisites**

IAM policies: To monitor resources, you must be given the required type of access in a **policy** written by an administrator, whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services as well as the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted and which **compartment** you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service: Monitoring or Notifications.

**Available Metrics: oci_oke**

The metrics listed in the following tables are automatically available for any Kubernetes clusters you create. You do not need to enable monitoring on the resource to get these metrics.

Container Engine for Kubernetes metrics include the following dimensions:

**RESOURCEID**

The **OCID** of the resource to which the metric applies.
RESOURCEDISPLAYNAME
The name of the resource to which the metric applies.

RESPONSECODE
The response code sent from the Kubernetes API server.

RESPONSEGROUP
The response code group, based on the response code's first digit (for example, 2xx, 3xx, 4xx, 5xx).

CLUSTERID
The OCID of the cluster to which the metric applies.

NODEPOOLID
The OCID of the node pool to which the metric applies.

NODESTATE
The state of the compute instance hosting the worker node. For example, ACTIVE, CREATING, DELETING, DELETED, FAILED, UPDATING, INACTIVE.

NODECONDITION
The condition of the worker node, as indicated by the Kubernetes API server. For example, Ready, MemoryPressure, PIDPressure, DiskPressure, NetworkUnavailable.

AVAILABILITYDOMAIN
The availability domain where the compute instance resides.

FAULTDOMAIN
The fault domain where the compute instance resides.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Using the Console**

*To view default metric charts for a single cluster*

1. In the Console, open the navigation menu and click **Developer Services**. Under **Containers**, click **Kubernetes Clusters (OKE)**.
2. Select the region you are using with Container Engine for Kubernetes.
3. Select the compartment containing the cluster for which you want to view metrics.
4. Click the name of the cluster for which you want to view metrics.
5. Under **Resources**, click **Metrics**.

The **Metrics** tab displays a chart for each metric for the cluster that is emitted by the Container Engine for Kubernetes metric namespace. To see metrics for a node pool in the cluster, display the **Node Pools** tab, click the name of the node pool, and display the **Metrics** tab. To see metrics for a worker node in the node pool, display the **Nodes** tab and click the **View Metrics** link beside the name of the worker node. For more information about the emitted metrics, see Available Metrics: oci_oke on page 1319.

For more information about monitoring metrics and using alarms, see Monitoring on page 3458. For information about notifications for alarms, see Notifications Overview on page 4248.

Not seeing the cluster metrics data you expect?

If you don't see the metrics data for a cluster that you expect, see the following possible causes and resolutions.
<table>
<thead>
<tr>
<th>Problem</th>
<th>Possible Cause</th>
<th>How to check</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>I know the Kubernetes API server returned some error responses but the API Server Response Count chart doesn't show them.</td>
<td>The responses might have been returned outside the time period covered by the API Server Response Count chart.</td>
<td>Confirm the Start Time and End Time cover the period when the responses were returned.</td>
<td>Adjust the Start Time and End Time as necessary.</td>
</tr>
<tr>
<td>I know the Kubernetes API server returned some error responses but the API Server Response Count chart doesn't show them, even though the responses were returned between the Start Time and End Time.</td>
<td>Although the responses were returned between the Start Time and End Time, the x-axis (window of data display) might be excluding the responses.</td>
<td>Confirm the x-axis (window of data display) covers the period when the responses were returned.</td>
<td>Adjust the x-axis (window of data display) as necessary.</td>
</tr>
<tr>
<td>I want to see data in the charts as a continuous line over time, but the line has gaps in it.</td>
<td>This is expected behavior. If there is no metrics data to show in the selected interval, the data line is discontinuous.</td>
<td>Increase the Interval (for example, from 1 minute to 5 minutes, or from 1 minute to 1 hour).</td>
<td>Adjust the Interval as necessary.</td>
</tr>
</tbody>
</table>

Using the API

For information about using the API and signing requests, see [REST APIs](#) on page 5528 and [Security Credentials](#) on page 207. For information about SDKs, see [Software Development Kits and Command Line Interface](#) on page 5351.

Use the following APIs for monitoring:
- Monitoring API for metrics and alarms
- Notifications API for notifications (used with alarms)
Autoscaling Kubernetes Clusters

You can automatically scale the nodes and pods of clusters you create using Container Engine for Kubernetes to optimize resource usage.

To enable cluster autoscaling by autoscaling node pools, you can deploy the Kubernetes Cluster Autoscaler (see Using the Kubernetes Cluster Autoscaler on page 1323).

To enable autoscaling by autoscaling pods, you deploy the Kubernetes Metrics Server to collect resource metrics from each worker node in the cluster (see Deploying the Kubernetes Metrics Server on a Cluster Using Kubectl on page 1333). Having deployed the Kubernetes Metrics Server, you can then use:

- the Kubernetes Horizontal Pod Autoscaler to adjust the number of pods in a deployment (see Using the Kubernetes Horizontal Pod Autoscaler on page 1334)
- the Kubernetes Vertical Pod Autoscaler to adjust the resource requests and limits for containers running in a deployment's pods (see Using the Kubernetes Vertical Pod Autoscaler on page 1338)

You can use the Kubernetes Cluster Autoscaler in a cluster with both the Kubernetes Horizontal Pod Autoscaler and the Kubernetes Vertical Pod Autoscaler.

Using the Kubernetes Cluster Autoscaler

You can use the Kubernetes Cluster Autoscaler to automatically resize a cluster's node pools based on application workload demands. By automatically resizing a cluster's node pools, you can ensure application availability and optimize costs.

The Kubernetes Cluster Autoscaler is a standalone program that:

- Adds worker nodes to a node pool when a pod cannot be scheduled in the cluster because of insufficient resource constraints.
- Removes worker nodes from a node pool when the nodes have been underutilized for an extended time, and when pods can be placed on other existing nodes.

The Kubernetes Cluster Autoscaler increases or decreases the size of a node pool automatically based on resource requests, rather than on resource utilization of nodes in the node pool.

The Kubernetes Cluster Autoscaler works on a per-node pool basis. You use a configuration file to specify which node pools to target for expansion and contraction, the minimum and maximum sizes for each node pool, and how you want the autoscaling to take place. Node pools not referenced in the configuration file are not managed by the Kubernetes Cluster Autoscaler.

To enable the Kubernetes Cluster Autoscaler to automatically resize a cluster's node pools based on application workload demands, always include resource request limits in pod specifications (requests: under resources:).

For more information about the Kubernetes Cluster Autoscaler, see Cluster Autoscaler and Frequently Asked Questions on GitHub.

Recommendations when using the Kubernetes Cluster Autoscaler in Production Environments

Consider the following recommendations:

- Always have at least one node pool in a cluster that is not managed by the Kubernetes Cluster Autoscaler. This node pool is required to run critical cluster add-ons. Also note that it is your responsibility to manually scale any node pools that are not managed by the Kubernetes Cluster Autoscaler.
- Always define multiple replicas for the Kubernetes Cluster Autoscaler deployment in the configuration file. If there is only one replica and it is evicted and cannot be rescheduled, the Kubernetes Cluster Autoscaler is unable to create more worker nodes.
- In the configuration file, set max-node-provision-time to 25 minutes. Typically, new worker nodes are provisioned and move to the Ready condition within 12 to 15 minutes. However, when many nodes are added to a node pool at the same time, it can take longer to provision them. Note that the Console displays a warning beside worker nodes that take more than 20 minutes to initialize. Assuming worker nodes move to the Ready condition within the time you specify for max-node-provision-time, you can ignore the warning.
• In the configuration file, you specify the maximum number of nodes allowed in the node pool. Make sure the maximum number of nodes you specify does not exceed the tenancy limit for the worker node shape defined for the node pool. The Kubernetes Cluster Autoscaler will never create more nodes than the tenancy limit. If you specify a number greater than the tenancy limit, the Kubernetes Cluster Autoscaler will periodically attempt to create additional nodes, but will not do so until the tenancy limit has been increased.

• When defining clusters that you want the Kubernetes Cluster Autoscaler to manage, we recommend creating multiple node pools with one availability domain specified per node pool.

• Always design applications to tolerate the disruptions that can occur when the Kubernetes Cluster Autoscaler removes worker nodes, or moves pods to a different worker node prior to removing an under-utilized worker node. For example, design applications that leverage pod disruption budgets (see Specifying a Disruption Budget for your Application in the Kubernetes documentation).

• Do not manually change node pools that are managed by the Kubernetes Cluster Autoscaler. For example, do not add or remove nodes using kubectl, or using the Console (or the Oracle Cloud Infrastructure CLI or API). The Kubernetes Cluster Autoscaler might override such changes, or they might modify its behavior. For example, if you want to remove all the nodes in a node pool managed by the Kubernetes Cluster Autoscaler, always use the Kubernetes Cluster Autoscaler to scale the node pool to zero.

Supported Kubernetes Cluster Autoscaler Parameters

You use parameters in a configuration file to control how the Kubernetes Cluster Autoscaler resizes a cluster's node pools (see What are the parameters to CA? in the Cluster Autoscaler FAQ on GitHub). You can use all the Kubernetes Cluster Autoscaler parameters when managing clusters created by Container Engine for Kubernetes, with the following exceptions:

• --node-group-auto-discovery : Not supported (cloud provider specific).
• --node-autoprovisioning-enabled=true : Not supported.
• --gpu-total : Not supported (cloud provider specific).
• --expander=price : Not supported (cloud provider specific).

Notes about the Kubernetes Cluster Autoscaler

Note the following:

• The Kubernetes Cluster Autoscaler adds and removes nodes to and from existing node pools in existing clusters. More specifically, note that the Kubernetes Cluster Autoscaler:

  • Does not create additional clusters.
  • Does not create additional node pools.
  • Does not create additional pods. Adding pods is supported by the Horizontal Pod Autoscaler (see Using the Kubernetes Horizontal Pod Autoscaler on page 1334).
  • Does not adjust CPU and memory requests and limits for containers. Adjusting limits is supported by the Vertical Pod Autoscaler (see Using the Kubernetes Vertical Pod Autoscaler on page 1338).
  • When removing worker nodes from a node pool, the Kubernetes Cluster Autoscaler respects pod scheduling and eviction rules. These rules can prevent the Kubernetes Cluster Autoscaler from removing a worker node.

For example, by default, the Kubernetes Cluster Autoscaler will not remove nodes running kube-system pods (such as coredns pods), with the exception of DaemonSet or mirror pods. You can control this behavior using the skip-nodes-with-system-pods configuration parameter (the default setting is true).

For more information, see What types of pods can prevent CA from removing a node? in the Cluster Autoscaler FAQ on GitHub.

• When you upgrade a cluster to a new version of Kubernetes, it is your responsibility to manually upgrade the Kubernetes Cluster Autoscaler to make it compatible with the cluster's new Kubernetes version. The Kubernetes Cluster Autoscaler is not upgraded automatically.

• You can use the Kubernetes Cluster Autoscaler to manage clusters you have created with Container Engine for Kubernetes that are running Kubernetes version 1.17 or later.
Working with the Cluster Autoscaler

The instructions below describe how to run the Kubernetes Cluster Autoscaler in a cluster to manage node pools:

- Create a compartment level dynamic group to allow nodes running the Kubernetes Cluster Autoscaler to manage node pools referenced in the Kubernetes Cluster Autoscaler configuration file
- Create a policy to allow instances (the cluster worker nodes) to manage node pools and other policy statements related to initializing worker nodes
- Copy and customize the Kubernetes Cluster Autoscaler configuration file
- Deploy the Kubernetes Cluster Autoscaler in the cluster and confirm successful deployment
- View the scaling operation
- Clean up

Step 1: Create a compartment level dynamic group

1. Log in to the Console.
2. Create a new dynamic group containing the worker nodes (compute instances) in the cluster:
   b. Select the compartment containing the cluster.
   c. Follow the instructions in To create a dynamic group on page 3119, and give the dynamic group a name (for example, acme-oke-cluster-autoscaler-dyn-grp).
   d. Enter a rule that includes the worker nodes in the compartment, in the format:

   ```
   ALL {instance.compartment.id = '<compartment-ocid>'}
   ```

   where `<compartment-ocid>` is the OCID of the compartment to which the cluster belongs.

   For example:

   ```
   ALL {instance.compartment.id = 'ocid1.compartment.oc1..aaaaaaaa23______smwa'}
   ```

   e. Click Create Dynamic Group.

Step 2: Create a policy to allow worker nodes to manage node pools

2. Follow the instructions in To create a policy on page 3147, and give the policy a name (for example, acme-oke-cluster-autoscaler-dyn-grp-policy).
3. Enter a policy statement to allow worker nodes to manage node pools (along with other policy statements related to initializing worker nodes), in the format:

   ```
   Allow dynamic-group acme-oke-cluster-autoscaler-dyn-grp to manage cluster-node-pools in compartment <compartment-name>
   Allow dynamic-group acme-oke-cluster-autoscaler-dyn-grp to manage instance-family in compartment <compartment-name>
   Allow dynamic-group acme-oke-cluster-autoscaler-dyn-grp to use subnets in compartment <compartment-name>
   Allow dynamic-group acme-oke-cluster-autoscaler-dyn-grp to read virtual-network-family in compartment <compartment-name>
   Allow dynamic-group acme-oke-cluster-autoscaler-dyn-grp to use vnics in compartment <compartment-name>
   ```
Allow dynamic-group acme-oke-cluster-autoscaler-dyn-grp to inspect compartments in compartment <compartment-name>

where:

- `<dynamic-group-name>` is the name of the dynamic group you created earlier. For example, acme-oke-cluster-autoscaler-dyn-grp
- `<compartment-name>` is the name of the compartment to which the cluster belongs. For example, acme-oke-cluster-autoscaler-compartment

For example:

Allow dynamic-group acme-oke-cluster-autoscaler-dyn-grp to manage cluster-node-pools in compartment acme-oke-cluster-autoscaler-compartment
Allow dynamic-group acme-oke-cluster-autoscaler-dyn-grp to manage instance-family in compartment acme-oke-cluster-autoscaler-compartment
Allow dynamic-group acme-oke-cluster-autoscaler-dyn-grp to use subnets in compartment acme-oke-cluster-autoscaler-compartment
Allow dynamic-group acme-oke-cluster-autoscaler-dyn-grp to read virtual-network-family in compartment acme-oke-cluster-autoscaler-compartment
Allow dynamic-group acme-oke-cluster-autoscaler-dyn-grp to use vnics in compartment acme-oke-cluster-autoscaler-compartment
Allow dynamic-group acme-oke-cluster-autoscaler-dyn-grp to inspect compartments in compartment acme-oke-cluster-autoscaler-compartment

4. Click Create to create the new policy.

**Step 3: Copy and customize the Cluster Autoscaler configuration file**

1. In a text editor, create a file called `cluster-autoscaler.yaml` with the following content:

```yaml
---
apiVersion: v1
kind: ServiceAccount
metadata:
  labels:
    k8s-addon: cluster-autoscaler.addons.k8s.io
    k8s-app: cluster-autoscaler
  name: cluster-autoscaler
  namespace: kube-system
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: cluster-autoscaler
  labels:
    k8s-addon: cluster-autoscaler.addons.k8s.io
    k8s-app: cluster-autoscaler
rules:
- apiGroups: [""]
  resources: ["events", "endpoints"]
  verbs: ["create", "patch"]
- apiGroups: [""]
  resources: ["pods/eviction"]
  verbs: ["create"]
- apiGroups: [""]
  resources: ["pods/status"]
  verbs: ["update"]
- apiGroups: [""]
  resources: ["endpoints"]
  resourceNames: ["cluster-autoscaler"]
  verbs: ["get", "update"]
- apiGroups: [""]
```

resources: ["nodes"]
  verbs: ["watch", "list", "get", "patch", "update"]
- apiGroups: [""]
  resources:
    - "pods"
    - "services"
    - "replicationcontrollers"
    - "persistentvolumeclaims"
    - "persistentvolumes"
  verbs: ["watch", "list", "get"]

  namespace: kube-system

---

apiVersion: apps/v1
kind: Deployment
metadata:
  name: cluster-autoscaler
  namespace: kube-system
  labels:
    app: cluster-autoscaler
spec:
  replicas: 3
  selector:
    matchLabels:
      app: cluster-autoscaler
  template:
    metadata:
      labels:
        app: cluster-autoscaler
      annotations:
        prometheus.io/scrape: 'true'
        prometheus.io/port: '8085'
    spec:
      serviceAccountName: cluster-autoscaler
      containers:
      - image: iad.ocir.io/oracle/oci-cluster-autoscaler:{{ image tag }}
        name: cluster-autoscaler
        resources:
          limits:
            cpu: 100m
            memory: 300Mi
          requests:
            cpu: 100m
            memory: 300Mi
        command:
          - ./cluster-autoscaler
          - --v=4
          - --stderrthreshold=info
          - --cloud-provider=oci
          - --max-node-provision-time=25m
          - --nodes=1:5:{{ node pool ocid 1 }}
          - --nodes=1:5:{{ node pool ocid 2 }}
          - --scale-down-delay-after-add=10m
          - --scale-down-unneeded-time=10m

Oracle Cloud Infrastructure User Guide
```
- --unremovable-node-recheck-timeout=5m
  imagePullPolicy: "Always"
env:
- name: OKE_USE_INSTANCE_PRINCIPAL
  value: "true"
```

2. In the `cluster-autoscaler.yaml` file you created, change the image path of the Kubernetes Cluster Autoscaler image to download from Oracle Cloud Infrastructure Registry. Images are available in a number of regions. For the best performance, choose the region closest to the one where the cluster is deployed:

a. In the `cluster-autoscaler.yaml` file, locate the following template line:

```
- image: iad.ocir.io/oracle/oci-cluster-autoscaler:{{ image_tag }}
```

b. Change the image path to one of the following, according to the location and Kubernetes version of the cluster in which to run the Kubernetes Cluster Autoscaler:

<table>
<thead>
<tr>
<th>Image Location</th>
<th>Kubernetes Version</th>
<th>Image Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Germany Central (Frankfurt)</td>
<td>Kubernetes 1.17</td>
<td>fra.ocir.io/oracle/oci-cluster-autoscaler:1.17-2021.03</td>
</tr>
<tr>
<td>Germany Central (Frankfurt)</td>
<td>Kubernetes 1.18</td>
<td>fra.ocir.io/oracle/oci-cluster-autoscaler:1.18-2021.03</td>
</tr>
<tr>
<td>Germany Central (Frankfurt)</td>
<td>Kubernetes 1.19</td>
<td>fra.ocir.io/oracle/oci-cluster-autoscaler:1.19-2021.03</td>
</tr>
<tr>
<td>UK South (London)</td>
<td>Kubernetes 1.17</td>
<td>lhr.ocir.io/oracle/oci-cluster-autoscaler:1.17-2021.03</td>
</tr>
<tr>
<td>UK South (London)</td>
<td>Kubernetes 1.18</td>
<td>lhr.ocir.io/oracle/oci-cluster-autoscaler:1.18-2021.03</td>
</tr>
<tr>
<td>US East (Ashburn)</td>
<td>Kubernetes 1.17</td>
<td>iad.ocir.io/oracle/oci-cluster-autoscaler:1.17-2021.03</td>
</tr>
<tr>
<td>US East (Ashburn)</td>
<td>Kubernetes 1.18</td>
<td>iad.ocir.io/oracle/oci-cluster-autoscaler:1.18-2021.03</td>
</tr>
<tr>
<td>US West (Phoenix)</td>
<td>Kubernetes 1.17</td>
<td>phx.ocir.io/oracle/oci-cluster-autoscaler:1.17-2021.03</td>
</tr>
<tr>
<td>US West (Phoenix)</td>
<td>Kubernetes 1.18</td>
<td>phx.ocir.io/oracle/oci-cluster-autoscaler:1.18-2021.03</td>
</tr>
<tr>
<td>Image Location</td>
<td>Kubernetes Version</td>
<td>Image Path</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------------</td>
<td>-----------------------------------------------</td>
</tr>
<tr>
<td>US West (Phoenix)</td>
<td>Kubernetes 1.19</td>
<td>phx.ocir.io/oracle/oci-cluster-autoscaler:1.19-2021.03</td>
</tr>
</tbody>
</table>

For example, if you want to run the Kubernetes Cluster Autoscaler in a Kubernetes 1.18 cluster located in the UK West region, specify the following image:

```yaml
- image: lhr.ocir.io/oracle/oci-cluster-autoscaler:1.18-2021.03
```

**Note:**

If you want to run the Kubernetes Cluster Autoscaler in a Kubernetes cluster where you have enabled image verification, do not simply specify an image path from one of the Oracle repositories in the `cluster-autoscaler.yaml` file. Instead, do the following:

i. Pull the image from an Oracle repository using the `docker pull` command. See [Pulling Images Using the Docker CLI](#) on page 4439.

ii. Tag the image (using the `docker tag` command), and then push the image to a repository in Oracle Cloud Infrastructure Registry that is geographically close to the cluster in which you want to run the Kubernetes Cluster Autoscaler (using the `docker push` command). See [Pushing Images Using the Docker CLI](#) on page 4436.

iii. Sign the image using a master key and key version in the Vault service, creating an image signature. See [Signing Images for Security](#) on page 4445.

iv. Specify the location of the signed image in the `cluster-autoscaler.yaml` file.

c. Save the `cluster-autoscaler.yaml` file.
3. In the `cluster-autoscaler.yaml` file you created, specify each of the cluster's node pools that you want the Kubernetes Cluster Autoscaler to manage.

You can specify multiple node pools in the `cluster-autoscaler.yaml` file. Note the recommendation is to always have at least one node pool that is not managed by the Kubernetes Cluster Autoscaler. Also note that it is your responsibility to manually scale any node pools you do not explicitly specify in the configuration file.

a. In the `cluster-autoscaler.yaml` file, locate the following template line:

   ```yaml
   - --nodes=1:5:{{ node pool ocid 1 }}
   ```

The `--nodes` parameter has the following format:

   ```yaml
   --nodes=<min-nodes>:<max-nodes>:<nodepool-ocid>
   ```

where:

- `<min-nodes>` is the minimum number of nodes allowed in the node pool. The Kubernetes Cluster Autoscaler will not reduce the number of nodes below this number.
- `<max-nodes>` is the maximum number of nodes allowed in the node pool. The Kubernetes Cluster Autoscaler will not increase the number of nodes above this number. Make sure the maximum number of nodes you specify does not exceed the tenancy limits for the worker node shape defined for the node pool.
- `<nodepool-ocid>` is one or more node pool OCIDs.

b. Change the value of the `--nodes` parameter to specify:

- The minimum number of nodes allowed in the node pool. For example, 1.
- The maximum number of nodes allowed in the node pool. For example, 5.
- The OCID of the node pool you want the Kubernetes Cluster Autoscaler to manage.

For example:

   ```yaml
   --nodes=1:5:ocid1.nodepool.oc1.iad.aaaaaaaaaeydq...
   ```

c. If you only want the Kubernetes Cluster Autoscaler to manage one node pool in the cluster, locate the following line in the `cluster-autoscaler.yaml` file and remove it:

   ```yaml
   - --nodes=1:5:{{ node pool ocid 2 }}
   ```

d. If you want the Kubernetes Cluster Autoscaler to manage a second node pool in the cluster, locate the following line in the `cluster-autoscaler.yaml` file and set appropriate values for the `--nodes` parameter:

   ```yaml
   - --nodes=1:5:{{ node pool ocid 2 }}
   ```

e. If you want the Kubernetes Cluster Autoscaler to manage more node pools, insert additional `--nodes` parameters in the `cluster-autoscaler.yaml` file and set appropriate values for them.

f. Save the `cluster-autoscaler.yaml` file.

4. In the `cluster-autoscaler.yaml` file you created, specify other parameters for the Kubernetes Cluster Autoscaler. For information about the parameters you can set, see Supported Kubernetes Cluster Autoscaler Parameters on page 1324.

5. Save and close the `cluster-autoscaler.yaml` file.

**Step 4: Deploy the Kubernetes Cluster Autoscaler in the cluster and confirm successful deployment**

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 1242.
2. Deploy the Kubernetes Cluster Autoscaler on the cluster by entering:

```
kubectl apply -f cluster-autoscaler.yaml
```

3. View the Kubernetes Cluster Autoscaler logs to confirm that it was successfully deployed and is currently monitoring the workload of node pools in the cluster, by entering:

```
kubectl -n kube-system logs -f deployment.apps/cluster-autoscaler
```

4. Identify which one of the three Kubernetes Cluster Autoscaler pods defined in the `cluster-autoscaler.yaml` file is currently performing actions, by entering:

```
kubectl -n kube-system get lease
```

5. Obtain a high-level view of the Kubernetes Cluster Autoscaler’s state from the configmap in the kube-system namespace, by entering:

```
kubectl -n kube-system get cm cluster-autoscaler-status -oyaml
```

**Step 5: View the Scaling Operation**

You can watch the Kubernetes Cluster Autoscaler you have deployed as it automatically scales worker nodes in a node pool. To make the scaling operation more obvious, consider the following suggestions (note these are for observation purposes only, and might be contrary to recommendations shown in Recommendations when using the Kubernetes Cluster Autoscaler in Production Environments on page 1323):

- Observe a cluster that has a single node pool (the node pool being managed by the Kubernetes Cluster Autoscaler).
- If the cluster you want to observe has more than one node pool, restrict pods to running on nodes on the single node pool being managed by the Kubernetes Cluster Autoscaler. See Assigning Pods to Nodes in the Kubernetes documentation.
- Start with one node in the node pool being managed by the Kubernetes Cluster Autoscaler.
- In the Kubernetes Cluster Autoscaler configuration file, you specify the maximum number of nodes allowed in the node pool. Make sure the maximum number of nodes you specify does not exceed the tenancy limit for the worker node shape defined for the node pool.

To view the Kubernetes Cluster Autoscaler automatically scaling worker nodes:

1. Confirm the current total number of worker nodes in the cluster by entering:

```
kubectl get nodes
```

2. Define a sample Nginx application by creating a file called `nginx.yaml` in a text editor, with the following content:

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: nginx-deployment
spec:
  selector:
    matchLabels:
      app: nginx
  replicas: 2
template:
  metadata:
    labels:
      app: nginx
  spec:
    containers:
      - name: nginx
```

---

**Oracle Cloud Infrastructure User Guide**

1332
image: nginx:1.14.2
ports:
- containerPort: 80
resources:
  requests:
    memory: "500Mi"

Notice that a resource request limit has been set.

3. Deploy the sample application by entering:

   kubectl create -f nginx.yaml

4. Increase the number of pods in the deployment to 100 (from 10) by entering:

   kubectl scale deployment nginx-deployment --replicas=100

   The Kubernetes Cluster Autoscaler now adds worker nodes to the node pool to meet the increased workload.

5. Observe the status of the deployment by entering:

   kubectl get deployment nginx-deployment --watch

6. After a few minutes, view the increased total number of worker nodes in the cluster by entering:

   kubectl get nodes

   Note that the number of worker nodes that you see will depend on the worker node shape and the maximum number of nodes specified in the Kubernetes Cluster Autoscaler configuration file.

**Step 6: Clean Up**

1. Delete the sample Nginx application by entering:

   kubectl delete deployment nginx-deployment

2. After ten minutes, confirm that the worker nodes have reduced to the original number, by entering:

   kubectl get nodes

   Note that after deleting the sample Nginx application and waiting, you might see fewer worker nodes but still more than the original number. This is probably because kube-system pods have been scheduled to run on those nodes. kube-system pods can prevent the Kubernetes Cluster Autoscaler from removing nodes because the Autoscaler's skip-nodes-with-system-pods parameter is set to true by default.

**Deploying the Kubernetes Metrics Server on a Cluster Using Kubectl**

You can deploy the Kubernetes Metrics Server on clusters you create using Container Engine for Kubernetes to enable autoscaling.

The Kubernetes Metrics Server is a cluster-wide aggregator of resource usage data. The Kubernetes Metrics Server collects resource metrics from the kubelet running on each worker node and exposes them in the Kubernetes API server through the Kubernetes Metrics API. Other Kubernetes add-ons require the Kubernetes Metrics Server, including:

- the Horizontal Pod Autoscaler (see Using the Kubernetes Horizontal Pod Autoscaler on page 1334)
- the Vertical Pod Autoscaler (see Using the Kubernetes Vertical Pod Autoscaler on page 1338)

Note that the Kubernetes Metrics Server is not intended to be used for anything other than autoscaling. For example, it is not recommended that you use the Kubernetes Metrics Server to forward metrics to monitoring solutions, nor as a source of monitoring solution metrics. For more information, see the Kubernetes Metrics Server documentation.

To deploy the Kubernetes Metrics Server on a cluster you've created with Container Engine for Kubernetes:
1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See Setting Up Cluster Access on page 1242.

2. If your Oracle Cloud Infrastructure user is a tenancy administrator or cluster administrator, skip the next step and go straight to the following step.

3. If your Oracle Cloud Infrastructure user is not a tenancy administrator or cluster administrator, ask a tenancy administrator or cluster administrator to grant your user the Kubernetes RBAC cluster-admin clusterrole on the cluster by entering:

   ```
kubectl create clusterrolebinding <my-cluster-admin-binding> --clusterrole=cluster-admin --user=<user-OCID>
   ```

   For more information, see About Access Control and Container Engine for Kubernetes on page 1254.

4. In a terminal window, deploy the Kubernetes Metrics Server by entering:

   ```
kubectl apply -f https://github.com/kubernetes-sigs/metrics-server/releases/download/<version-number>/components.yaml
   ```

   where `<version-number>` is the Kubernetes Metrics Server version that you want to deploy. For example, v0.3.6.

   Note that the Kubernetes Metrics Server is being actively developed, so the version number to specify will change over time. To find out the currently available versions, see the Kubernetes Metrics Server documentation.

   **Tip:**

   If the command fails to connect to https://github.com/kubernetes-sigs/metrics-server/releases/download/<version-number>/components.yaml, go to the url in a browser and download the manifest file components.yaml to a local directory. Repeat the kubectl apply command and specify the local location of the components.yaml file.

5. Confirm that the Kubernetes Metrics Server has been deployed successfully and is available by entering:

   ```
kubectl get deployment metrics-server -n kube-system
   ```

### Using the Kubernetes Horizontal Pod Autoscaler

You can use the Kubernetes Horizontal Pod Autoscaler to automatically scale the number of pods in a deployment, replication controller, replica set, or stateful set, based on that resource's CPU or memory utilization, or on other metrics. The Horizontal Pod Autoscaler can help applications scale out to meet increased demand, or scale in when resources are no longer needed. You can set a target metric percentage for the Horizontal Pod Autoscaler to meet when scaling applications. For more information, see Horizontal Pod Autoscaler in the Kubernetes documentation.

The Horizontal Pod Autoscaler is a standard API resource in Kubernetes that requires the installation of a metrics source, such as the Kubernetes Metrics Server, in the cluster. For more information, see Deploying the Kubernetes Metrics Server on a Cluster Using Kubectl on page 1333.

### Notes about the Horizontal Pod Autoscaler

Note the following:

- The Kubernetes Metrics Server only supports scaling based on CPU and memory utilization. Other implementations of the Kubernetes Metrics API support scaling based on custom metrics. Refer to the Kubernetes documentation for a list of alternative implementations (see Implementations), and for more information about scaling based on custom metrics (see Autoscaling on multiple metrics and custom metrics).
• You can scale applications manually by updating manifest files, without using the Horizontal Pod Autoscaler.

**Working with the Horizontal Pod Autoscaler**

The instructions below are based on the [Horizontal Pod Autoscaler Walkthrough](https://kubernetes.io/docs/tasks/run-applicationhorizontal-pod-autoscaler/) topic in the Kubernetes documentation. They describe how to:

• Verify that the Kubernetes Metrics Server has been installed on a cluster.
• Deploy a sample php-apache web server.
• Create a Horizontal Pod Autoscaler resource that will scale based on CPU utilization.
• Start generation of a sample load.
• View the scaling operation in action.
• Stop the sample load generation.
• Clean up, by removing the php-apache web server and the Horizontal Pod Autoscaler.

**Step 1: Verify the Kubernetes Metrics Server Installation**

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See [Setting Up Cluster Access](https://kubernetes.io/docs/tasks/administer-cluster-setting-up-cluster-access/) on page 1242.

2. Confirm that the Kubernetes Metrics Server has been deployed successfully on the cluster and is available by entering:

```
kubectl -n kube-system get deployment/metrics-server
```

If the command returns a `Not Found` error, then you must deploy the Kubernetes Metrics Server on the cluster before proceeding. See [Deploying the Kubernetes Metrics Server on a Cluster Using Kubectl](https://kubernetes.io/docs/tasks/administer-cluster-deploying-kubectl/) on page 1333.

**Step 2: Deploy a Sample Application**

Deploy a simple Apache web server application by entering:

```
kubectl apply -f https://k8s.io/examples/application/php-apache.yaml
```

The output from the above command confirms the deployment:

```
deployment.apps/php-apache created
service/php-apache created
```

The Apache web server pod that is created from the manifest file:

• Has a 500m CPU limit, which ensures the container will never use more than 500 millicores, or 1/2 of a core.
• Has a 200m CPU request allowance, which allows the container to use 200 millicores of CPU resources, or 1/5 of a core.
Step 3: Create a Horizontal Pod Autoscaler Resource

1. Create a Horizontal Pod Autoscaler resource to maintain a minimum of 1 and a maximum of 10 replicas, and an average CPU utilization of 50%, by entering:

```bash
kubectl autoscale deployment php-apache --cpu-percent=50 --min=1 --max=10
```

The output from the above command confirms the Horizontal Pod Autoscaler has been created.

```
horizontalpodautoscaler.autoscaling/php-apache autoscaled
```

The command creates a Horizontal Pod Autoscaler for the Apache web server deployment that:

- Maintains a minimum of 1 and a maximum of 10 replicas of the previously created pods controlled by the Apache web server deployment.
- Increases and decreases the number of replicas of the deployment to maintain an average CPU utilization of 50% across all pods.

If the average CPU utilization falls below 50%, the Horizontal Pod Autoscaler tries to reduce the number of pods in the deployment to the minimum (in this case, 1). If the average CPU utilization goes above 50 percent, the Horizontal Pod Autoscaler tries to increase the number of pods in the deployment to the maximum (in this case, 10). For more information, see How does the Horizontal Pod Autoscaler work? in the Kubernetes documentation.

For more information about the `kubectl autoscale` command, see autoscale in the Kubernetes documentation.

2. After a minute, confirm the current status of the Horizontal Pod Autoscaler by entering:

```bash
kubectl get hpa
```

The output from the above command shows the current status:

```
NAME       REFERENCE             TARGETS MINPODS MAXPODS REPLICAS AGE
php-apache Deployment/php-apache 0%/50%  1       10      1        10s
```

The `TARGETS` column shows the average CPU utilization across all pods controlled by the Apache web server deployment. Since no requests are being sent to the server, the above example shows the current CPU utilization is 0%, compared to the target utilization of 50%. Note that you might see different numbers, depending on how long you wait before running the command.

Step 4: Start Sample Load Generation

1. Run a container with a busybox image to create a load for the Apache web server by entering:

```bash
kubectl run -it --rm load-generator --image=busybox /bin/sh --
```

2. Generate a load for the Apache web server that will cause the Horizontal Pod Autoscaler to scale out the deployment by entering:

```bash
while true; do wget -q -O- http://php-apache; done
```
**Step 5: View the Scaling Operation**

1. After a minute, open a new terminal window and confirm the current status of the Horizontal Pod Autoscaler by entering:

   ```bash
   kubectl get hpa
   ```

   The output from the above command shows the current status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS</th>
<th>MINPODS</th>
<th>MAXPODS</th>
<th>REPLICAS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>250%/50%</td>
<td>1</td>
<td>10</td>
<td>1</td>
<td>1m</td>
</tr>
</tbody>
</table>

   In the above example, you can see the current CPU utilization has increased to 250%, compared to the target utilization of 50%. Note that you might see different numbers, depending on how long you wait before running the command.

   To achieve the utilization target of 50%, the Horizontal Pod Autoscaler will have to increase the number of replicas to scale out the deployment.

2. After another few minutes, view the increased number of replicas by re-entering:

   ```bash
   kubectl get hpa
   ```

   The output from the above command shows the current status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS</th>
<th>MINPODS</th>
<th>MAXPODS</th>
<th>REPLICAS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>50%/50%</td>
<td>1</td>
<td>10</td>
<td>5</td>
<td>5m</td>
</tr>
</tbody>
</table>

   In the above example, you can see that the Horizontal Pod Autoscaler has resized the deployment to 5 replicas, and the utilization target of 50% has been achieved. Note that you might see different numbers, depending on how long you wait before running the command.

3. Verify the deployment has been scaled out by entering:

   ```bash
   kubectl get deployment php-apache
   ```

   The output from the above command shows the current status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>5/5</td>
<td>5</td>
<td>5</td>
<td>5m</td>
</tr>
</tbody>
</table>

   Note that you might see different numbers, depending on how long you wait before running the command.

**Step 6: Stop Sample Load Generation**

1. In the terminal window where you created the container with the busybox image and generated the load for the Apache web server:
   a. Terminate the load generation by pressing Ctrl+C
   b. Close the command prompt by entering:

   ```bash
   exit
   ```

   The output from the above command confirms the session has ended:

   ```bash
   Session ended, resume using 'kubectl attach load-generator -c load-generator -i -t' command when the pod is running pod "load-generator" deleted
   ```
2. After a minute, confirm the current status of the Horizontal Pod Autoscaler by entering:

```bash
ekubectl get hpa
```

The output from the above command shows the current status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS</th>
<th>MINPODS</th>
<th>MAXPODS</th>
<th>REPLICAS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>0%/50%</td>
<td>1</td>
<td>10</td>
<td>5</td>
<td>10m</td>
</tr>
</tbody>
</table>

In the above example, you can see the current CPU utilization has reduced to 0%, compared to the target utilization of 50%. However, there are still 5 replicas in the deployment. Note that you might see different numbers, depending on how long you wait before running the command.

3. After another few minutes, view the reduced number of replicas by re-entering:

```bash
ekubectl get hpa
```

The output from the above command shows the current status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS</th>
<th>MINPODS</th>
<th>MAXPODS</th>
<th>REPLICAS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>0%/50%</td>
<td>1</td>
<td>10</td>
<td>1</td>
<td>15m</td>
</tr>
</tbody>
</table>

In the above example, you can see that the Horizontal Pod Autoscaler has resized the deployment to 1 replica.

Be aware that it will take time for the replica count to reduce to 1. Five minutes is the default timeframe for scaling in. Note that you might see different numbers, depending on how long you wait before running the command.

4. Verify the deployment has been scaled in by entering:

```bash
ekubectl get deployment php-apache
```

The output from the above command shows the current status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>1/1</td>
<td>1</td>
<td>1</td>
<td>15m</td>
</tr>
</tbody>
</table>

Note that you might see different numbers, depending on how long you wait before running the command.

**Step 7: Clean Up**

1. Delete the Horizontal Pod Autoscaler by entering:

```bash
ekubectl delete horizontalpodautoscaler.autoscaling/php-apache
```

Note that when you delete a Horizontal Pod Autoscaler, the number of replicas remains the same. A deployment does not automatically revert back to the state it had prior to the creation of the Horizontal Pod Autoscaler.

2. Delete the Apache web server deployment by entering:

```bash
ekubectl delete deployment.apps/php-apache service/php-apache
```

**Using the Kubernetes Vertical Pod Autoscaler**

You can use the Kubernetes Vertical Pod Autoscaler to automatically adjust the resource requests and limits for containers running in a deployment’s pods. The Vertical Pod Autoscaler can improve cluster resource utilization by:

- Setting the requests automatically based on usage to make sure the appropriate resource amount is available for each pod.
- Maintaining ratios between limits and requests that were specified in containers’ initial configurations.
- Scaling down pods that are over-requesting resources, based on their usage over time.
• Scaling up pods that are under-requesting resources, based on their usage over time.

The Vertical Pod Autoscaler has three components:

• **Recommender**: Monitors the current and past resource consumption and provides recommended CPU and memory request values for a container.
• **Updater**: Checks for pods with incorrect resources and deletes them, so that the pods can be recreated with the updated request values.
• **Admission Plugin**: Sets the correct resource requests on new pods (that is, pods just created or recreated by their controller due to changes made by the Updater).

For more information, see Vertical Pod Autoscaler and Managing Resources for Containers in the Kubernetes documentation.

You configure the Vertical Pod Autoscaler using the **VerticalPodAutoscaler** custom resource definition object. The **VerticalPodAutoscaler** object enables you to specify the pods to vertically autoscale, and which resource recommendations to apply (if any). For more information, see VerticalPodAutoscaler and Custom Resource Definition object in the Kubernetes documentation.

The Vertical Pod Autoscaler requires the installation of a metrics source, such as the Kubernetes Metrics Server, in the cluster. For more information, see Deploying the Kubernetes Metrics Server on a Cluster Using Kubectl on page 1333.

**Overriding Limit Ranges**

The Vertical Pod Autoscaler attempts to make recommendations within the minimum and maximum values specified by a limit range, if one has been defined. However, if the applicable limit range conflicts with the values specified in the resourcePolicy section of the VerticalPodAutoscaler manifest, the Vertical Pod Autoscaler gives priority to the resource policy and makes recommendations accordingly (even if the values fall outside the limit range). For more information, see Limit Ranges and Resource Policy Overriding Limit Range in the Kubernetes documentation.

**Creating Recommendations without Applying them**

You can use the Vertical Pod Autoscaler to create and apply recommendations, or simply to create recommendations (without updating pods). To simply create recommendations without applying them, set `updateMode: "Off"` in the updatePolicy section of the VerticalPodAutoscaler manifest.

When pods are created, the Vertical Pod Autoscaler analyzes the CPU and memory needs of the containers and records those recommendations in its Status field. The Vertical Pod Autoscaler does not take any action to update the resource requests for the running containers.

**Excluding Specific Containers**

You can use the Vertical Pod Autoscaler to create and apply recommendations to all the containers in a pod, or you can selectively exclude particular containers. To turn off recommendations for a particular container, in the resourcePolicy section of the VerticalPodAutoscaler manifest, specify a containerName and set mode: "Off" in the containerPolicies section.

**Notes about the Vertical Pod Autoscaler**

Note the following:

• Currently, you are recommended not to use the Vertical Pod Autoscaler with the Horizontal Pod Autoscaler on CPU or memory utilization metrics. However, note that you can use the Vertical Pod Autoscaler with the Horizontal Pod Autoscaler on custom and external metrics. See Support for custom metrics in the Kubernetes documentation.
• The Vertical Pod Autoscaler recommendations might exceed available resources (for example, node size, available size, available quota). Note that applying the recommendations might cause pods to go into a pending status.
Whenever the Vertical Pod Autoscaler updates pod resources, the pod is recreated, which causes all running containers to be restarted. Note that the pod might be recreated on a different node.

**Working with the Vertical Pod Autoscaler**

The instructions below walk you through deploying the Vertical Pod Autoscaler on a cluster. They describe how to:

- Verify that the Kubernetes Metrics Server has been installed on a cluster.
- Download and deploy the Vertical Pod Autoscaler.
- Deploy a sample application.
- View the scaling operation in action.
- View the recommendation.
- Clean up, by removing the sample application and the Vertical Pod Autoscaler.

**Step 1: Verify the Kubernetes Metrics Server Installation**

1. If you haven't already done so, follow the steps to set up the cluster's kubeconfig configuration file and (if necessary) set the KUBECONFIG environment variable to point to the file. Note that you must set up your own kubeconfig file. You cannot access a cluster using a kubeconfig file that a different user set up. See [Setting Up Cluster Access](#) on page 1242.

2. Confirm that the Kubernetes Metrics Server has been deployed successfully on the cluster and is available by entering:

   ```bash
   kubectl -n kube-system get deployment/metrics-server
   ```

   If the command returns a `Not Found` error, then you must deploy the Kubernetes Metrics Server on the cluster before proceeding. See [Deploying the Kubernetes Metrics Server on a Cluster Using Kubectl](#) on page 1333.

**Step 2: Download and Deploy the Vertical Pod Autoscaler**

1. Download the Vertical Pod Autoscaler source code from GitHub. For example, by entering:

   ```bash
   git clone -b vpa-release-0.8 https://github.com/kubernetes/autoscaler.git
   ```

2. Change to the `vertical-pod-autoscaler` directory:

   ```bash
   cd autoscaler/vertical-pod-autoscaler
   ```

3. If you have previously deployed the Vertical Pod Autoscaler, delete it by entering:

   ```bash
   ./hack/vpa-down.sh
   ```

4. Deploy the Vertical Pod Autoscaler by entering:

   ```bash
   ./hack/vpa-up.sh
   ```

5. Verify that the Vertical Pod Autoscaler pods have been created successfully by entering:

   ```bash
   kubectl get pods -n kube-system
   ```

   The output from the above command shows the pods:

   ```
   vpa-admission-controller-59d9965cfb-bzs8l 1/1 Running 0 6m34s
   vpa-recommender-5bcb58569-mqddss 1/1 Running 0 6m43s
   vpa-updater-5979cbf757-scw2d 1/1 Running 0 6m46s
   ```

   Note that you will probably see different names and numbers.
**Step 3: Deploy the Sample Application**

1. Deploy the sample hamster application to create a deployment and a corresponding Vertical Pod Autoscaler by entering:

   ```
kubectl apply -f examples/hamster.yaml
   ```

   The output from the above command confirms the deployment and creation:

   ```
verticalpodautoscaler.autoscaling.k8s.io/hamster-vpa created
deployment.apps/hamster created
   ```

   Deploying the hamster application creates a deployment with two pods and a Vertical Pod Autoscaler pointing at the deployment.

2. Verify that the hamster pods have been created successfully by entering:

   ```
kubectl get pods -l app=hamster
   ```

   The output from the above command confirms the creation:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>hamster-7cbfd64f57-mqqnk</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>54s</td>
</tr>
<tr>
<td>hamster-7cbfd64f57-rq6wv</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>55s</td>
</tr>
</tbody>
</table>

   Note that you will probably see different names for the hamster pods.

3. View the CPU and memory reservations using the `kubectl describe pod` command and one of the hamster pod names returned in the previous step. For example:

   ```
kubectl describe pod hamster-7cbfd64f57-rq6wv
   ```

   Note that the above command is an example only. You must use one of the hamster pod names that was returned when you ran the `kubectl get pods -l app=hamster` command in the previous step.

   In the requests section of the output, you can see the pod’s current CPU and memory reservations. For example:

   ```
Requests:
cpu:        100m
memory:     50Mi
   ```

   The Vertical Pod Autoscaler (specifically, the Recommender) analyzes the pods and observes their behavior to determine whether these CPU and memory reservations are appropriate. Note that you might see different CPU and memory reservations.

   The reservations are not sufficient because the sample hamster application is deliberately under-resourced. Each pod runs a single container that:

   • requests 100 millicores, but tries to utilize more than 500 millicores
   • reserves much less memory than it needs to run

**Step 4: View the Scaling Operation**

Having analyzed the original pods in the sample hamster application and determined that the CPU and memory reservations are inadequate, the Vertical Pod Autoscaler (specifically the Updater) relaunches the pods with different values as proposed by the Recommender. Note that the Vertical Pod Autoscaler does not modify the template in the deployment, but updates the actual requests of the pods.
1. Monitor the pods in the sample hamster application, and wait for the Updater to start a new hamster pod with a new name, by entering:

```
kubectl get --watch pods -l app=hamster
```

2. When you see that a new hamster pod has started, view its CPU and memory reservations using the `kubectl describe pod` command and the pod’s name. For example:

```
kubectl describe pod hamster-7cbfd64f57-wmg4
```

In the requests section of the output, you can see the new pod's CPU and memory reservations:

```
Requests:
cpu: 587m
memory: 262144k
```

In the above example, notice that the CPU reservation has increased to 587 millicores and the memory reservation has increased to 262,144 Kilobytes. The original pod was under-resourced and the Vertical Pod Autoscaler has corrected the original reservations with more appropriate values. Note that you might see different CPU and memory reservations.

**Step 5: View the Recommendation**

View the recommendations made by the Vertical Pod Autoscaler (specifically, by the Recommender) by entering:

```
kubectl describe vpa/hamster-vpa
```

The output from the above command shows the recommendations:

```
Name: hamster-vpa
Namespace: default
Labels: <none>
Annotations: kubectl.kubernetes.io/last-applied-configuration:
"apiVersion": "autoscaling.k8s.io/v1beta2",
"kind": "VerticalPodAutoscaler",

  - **Upper Bound:**  
    - **Cpu:** 1  
    - **Memory:** 500Mi  
**Events:** <none>  

Note that you might see different recommendations.

### Step 6: Clean Up

1. Remove the sample application by entering:

   ```bash
kubectl delete -f examples/hamster.yaml
```

2. In the `vertical-pod-autoscaler` directory, delete the Vertical Pod Autoscaler deployment by entering:

   ```bash
./hack/vpa-down.sh
```

### Using Admission Controllers

Read about how to use Container Engine for Kubernetes with Kubernetes admission controllers:

- [Supported Admission Controllers](#) on page 1343
- [Using Pod Security Policies with Container Engine for Kubernetes](#) on page 1345

### Supported Admission Controllers

The Kubernetes version you select when you create a cluster using Container Engine for Kubernetes determines the default set of admission controllers that are turned on in the created cluster. The set follows the recommendation given in the [Kubernetes documentation](#) for that version. This topic shows the supported admission controllers, the Kubernetes versions in which they are supported, and the order in which they run in the Kubernetes API server.

**Admission Controllers (sorted alphabetically)**

The table lists, in alphabetical order, the admission controllers that are turned on in the Kubernetes clusters you create using Container Engine for Kubernetes. For each admission controller, the table shows the Kubernetes version in which it is supported.
<table>
<thead>
<tr>
<th>Admission Controllers (in alphabetical order)</th>
<th>Supported in 1.17?</th>
<th>Supported in 1.18?</th>
<th>Supported in 1.19?</th>
<th>Supported in 1.20?</th>
</tr>
</thead>
<tbody>
<tr>
<td>DefaultIngressClass</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>DefaultStorageClass</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>DefaultTolerationSeconds</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>ExtendedResourceToleration</td>

### Using Pod Security Policies with Container Engine for Kubernetes

You can control the operations that pods are allowed to perform on a cluster you have created with Container Engine for Kubernetes by setting up pod security policies for the cluster. Pod security policies are a way to ensure that pods meet security-related conditions before they can be accepted by a cluster. For example, you can use pod security policies to:

- limit the storage choices available to pods
- restrict the host networking and ports that pods can access
- prevent pods from running as the root user
- prevent pods from running in privileged mode

You can also use pod security policies to provide default values for pods, by 'mutating' the pod.

Having defined a pod security policy for a cluster, you have to authorize the requesting user or target pod's service account to use the policy. You do this by creating a role (or clusterrole) to access the pod security policy, and then creating a rolebinding (or clusterrolebinding) between the role (or clusterrole) and the requesting user or target pod's service account. For more information about roles, clusterroles, and bindings, see About Access Control and Container Engine for Kubernetes on page 1254.

You specify whether a cluster enforces the pod security policies defined for it by enabling the cluster's PodSecurityPolicy admission controller. The PodSecurityPolicy admission controller acts on creation and modification of a pod and determines if the pod should be admitted to the cluster based on the requested security context in the pod spec and the cluster's pod security policies. If multiple pod security policies exist, the PodSecurityPolicy admission controller first compares the pod against non-mutating policies in alphabetical order and uses the first policy that successfully validates the pod. If no non-mutating pods validate the pod, the PodSecurityPolicy admission controller compares the pod against mutating policies in alphabetical order and uses the first policy that successfully validates the pod.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Caution 1:</strong></td>
</tr>
<tr>
<td>It is very important to note that when you enable a cluster's PodSecurityPolicy admission controller, no application pods can start on...</td>
</tr>
</tbody>
</table>
the cluster unless suitable pod security policies exist, along with roles (or clusterroles) and rolebindings (or clusterrolebindings) to associate pods with policies. You will not be able to run application pods on a cluster with an enabled PodSecurityPolicy admission controller unless these prerequisites are met.

We strongly recommend you use PodSecurityPolicy admission controllers as follows:

- Whenever you create a new cluster, enable the Pod Security Admission Controller.
- Immediately after creating a new cluster, create pod security policies, along with roles (or clusterroles) and rolebindings (or clusterrolebindings).

Caution 2:

You must create pod security policies before enabling the PodSecurityPolicy admission controller of an existing cluster that is already in production (that is, some time after you created it). If you decide to enable an existing cluster's PodSecurityPolicy admission controller, we strongly recommend you first verify the cluster's pod security policies in a development or test environment. That way, you can be sure the pod security policies work as you expect and correctly allow (or refuse) pods to start on the cluster.

When you enable the PodSecurityPolicy admission controller of a cluster you've created with Container Engine for Kubernetes, a pod security policy for Kubernetes system privileged pods is automatically created (along with the associated clusterrole and clusterrolebinding). This pod security policy, and the clusterrole and clusterrolebinding, enable the Kubernetes system pods to run. The pod security policy, clusterrole, and clusterrolebinding are defined in the kube-system.yaml file (see kube-system.yaml Reference on page 1349).

Note that you can create pod security policies for a cluster before enabling the cluster's PodSecurityPolicy admission controller. Also note that you can disable a cluster's PodSecurityPolicy admission controller that was previously enabled. In this case, any previously created pod security policies, roles (or clusterroles), and rolebindings (or clusterrolebindings) are not deleted. The pod security policies are simply not enforced. Any application pod will be able to run on the cluster.

For more information about pod security policies and the PodSecurityPolicy admission controller, see the Kubernetes documentation.

Creating a Pod Security Policy for Application Pods

To create a pod security policy for application pods, create a role to access the pod security policy, and create a rolebinding to enable the application pods to use the pod security policy:

1. Create the pod security policy for application pods:

   a. Define and save the pod security policy in a file. For example, in acme-app-psp.yaml).

      For example, this policy (taken from the Kubernetes documentation) simply prevents the creation of privileged pods:

      ```yaml
      apiVersion: policy/v1beta1
      kind: PodSecurityPolicy
      metadata:
        name: acme-app-psp
      spec:
        privileged: false  # Don't allow privileged pods!
        # The rest fills in some required fields.
        seLinux:
          rule: RunAsAny
        supplementalGroups:
      ```
Container Engine for Kubernetes

**Rule:** RunAsAny

**RunAsUser:**

**Rule:** RunAsAny

**FsGroup:**

**Rule:** RunAsAny

**Volumes:**

- `'*'`

**b.** Enter the following command to create the pod security policy:

```
kubectl create -f <filename>.yaml
```

For example:

```
kubectl create -f acme-app-psp.yaml
```

**2.** Create the role (or clusterrole) to access the pod security policy:

**a.** Define and save a role (or clusterrole) in a file. For example, in `acme-app-psp-crole.yaml`.

For example:

```
# Cluster role which grants access to the app pod security policy
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: acme-app-psp-crole
rules:
  - apiGroups:
    - policy
      resourceNames:
      - acme-app-psp
      resources:
      - podsecuritypolicies
      verbs:
      - use
```

**b.** Enter the following command to create the role (or clusterrole):

```
kubectl create -f <filename>.yaml
```

For example:

```
kubectl create -f acme-app-psp-crole.yaml
```

**3.** Create the rolebinding (or clusterrolebinding) to authorize the application pods to use the pod security policy:

**a.** Define and save the rolebinding (or clusterrolebinding) in a file. For example, in `acme-app-psp-crole-bind.yaml`.

For example:

```
# Role binding which grants access to the app pod security policy
apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
  name: acme-app-psp-binding
  namespace: acme-namespace
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: acme-app-psp-crole
subjects:
```
```yaml
# For all service accounts in acme-namespace
- apiGroup: rbac.authorization.k8s.io
  kind: Group
  name: system:serviceaccounts:acme-namespace
```

b. Enter the following command to create the rolebinding (or clusterrolebinding):

```
kubectl create -f <filename>.yaml
```

For example:

```
kubectl create -f acme-app-psp-crole-bind.yaml
```

Having defined a pod security policy and authorized application pods to use it by creating a role and rolebinding (or a clusterrole and clusterrolebinding), enable the cluster's PodSecurityPolicy admission controller to enforce the pod security policy (if it's not enabled already).

**Using the Console to Enable the PodSecurityPolicy Admission Controller**

To enable the PodSecurityPolicy admission controller when creating new clusters using the Console:

1. Log in to the Console.
2. Follow the instructions to create a new cluster in Using the Console to create a Cluster with Explicitly Defined Settings in the 'Custom Create' workflow on page 1236, click Show Advanced Options, and select the Pod Security Policies - Enforced option. This option enables the PodSecurityPolicy admission controller.

   No application pods will be accepted into the new cluster unless suitable pod security policies exist, along with roles (or clusterroles) and rolebindings (or clusterrolebindings) to associate pods with policies.
3. Follow the instructions to set the remaining cluster details, and click Create Cluster to create the new cluster.
4. Follow the instructions in Creating a Pod Security Policy for Application Pods on page 1346 to create pod security policies for the PodSecurityPolicy admission controller to enforce when accepting pods into the new cluster.

To enable the PodSecurityPolicy admission controller in existing clusters using the Console:

1. Follow the instructions in Creating a Pod Security Policy for Application Pods on page 1346 to create pod security policies for the PodSecurityPolicy admission controller to enforce when accepting pods into the existing cluster.

   We strongly recommend you first verify the pod security policies in a development or test environment. That way, you can be sure the pod security policies work as you expect and correctly allow (or refuse) pods to start on the cluster.

2. In the Console, open the navigation menu and click Developer Services. Under Containers, click Kubernetes Clusters (OKE).
3. Choose a Compartment you have permission to work in.
4. On the Cluster List page, click the name of the cluster you want to modify.

   From now on, no new application pods will be accepted into the cluster unless suitable pod security policies exist, along with roles (or clusterroles) and rolebindings (or clusterrolebindings) to associate pods with policies. Note that any currently running pods will continue to run regardless.
7. Click Save Changes.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

To enable the PodSecurityPolicy admission controller, use the:

- CreateCluster operation when creating new clusters
• **Update Cluster** operation when modifying existing clusters

**kube-system.yaml Reference**

The pod security policy, and the associated clusterrole and clusterrolebinding, for Kubernetes system privileged pods are automatically created when you enable a cluster's PodSecurityPolicy admission controller. These allow any pod in the kube-system namespace to run. They are created from definitions in the kube-system.yaml shown below:

```yaml
# Cluster role which grants access to the privileged pod security policy
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: oke-privileged-psp
rules:
- apiGroups:
  - policy
    resourceNames:
    - oke-privileged
    resources:
    - podsecuritypolicies
  verbs:
  - use

---

# Role binding for kube-system - allow kube-system service accounts - should take care of CNI i.e. flannel running in the kube-system namespace
# Assumes access to the kube-system is restricted
apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
```
Upgrading Clusters

Read about how to use Container Engine for Kubernetes to upgrade Kubernetes clusters:

- Kubernetes Versions and Container Engine for Kubernetes on page 1350
- Supported Versions of Kubernetes on page 1351
- Upgrading Clusters to Newer Kubernetes Versions on page 1352

Kubernetes Versions and Container Engine for Kubernetes

When you create a new Kubernetes cluster using Container Engine for Kubernetes, you specify:

- The version of Kubernetes to run on the control plane nodes in the cluster.
- The version of Kubernetes to run on the worker nodes in each node pool. Different worker nodes in the same node pool can run different versions of Kubernetes. Different node pools in a cluster can run different versions of Kubernetes.

The version of Kubernetes that you specify for the worker nodes in a node pool must be either the same Kubernetes version as that running on the control plane nodes, or an earlier Kubernetes version that is still compatible. In other words:

- The control plane nodes in a new cluster must run the same version of Kubernetes as the version running on worker nodes, or must be no more than two versions ahead.
- The worker nodes in a node pool must not run a more recent version of Kubernetes than the associated control plane nodes.

New Versions of Kubernetes

New Kubernetes versions are released periodically that contain new features and bug fixes.

Kubernetes version numbers have the format $x.y.z$ where $x$ is a major release, $y$ is a minor release, and $z$ is a patch release. For example, 1.20.8.

Kubernetes itself is supported for three minor versions at a time (the current release version and two previous versions).

As described in the Kubernetes documentation, a certain amount of version variation is permissible between control plane nodes and worker nodes in a cluster:

- The Kubernetes version on worker nodes can lag behind the version on the control plane nodes by up to two versions, but no more. If the version on the worker nodes is more than two versions behind the version on the control plane nodes, the Kubernetes versions on the worker nodes and the control plane nodes are incompatible.
- The Kubernetes version on worker nodes must never be more recent than the version on the control plane nodes.

For the Kubernetes versions currently and previously supported by Container Engine for Kubernetes, see Supported Versions of Kubernetes on page 1351.
Supported Versions of Kubernetes

When Container Engine for Kubernetes support for a new version of Kubernetes is announced, an older Kubernetes version ceases to be supported.

This topic lists:

- Kubernetes Versions Supported by Container Engine for Kubernetes on page 1351
- Kubernetes Versions Previously Supported by Container Engine for Kubernetes on page 1352

Kubernetes Versions Supported by Container Engine for Kubernetes

Container Engine for Kubernetes supports three versions of Kubernetes for new clusters. For a minimum of 30 days after the release of a new Kubernetes version, Container Engine for Kubernetes continues to support the fourth, oldest available version.

Container Engine for Kubernetes supports the following versions of Kubernetes for new clusters:

<table>
<thead>
<tr>
<th>Kubernetes Version</th>
<th>Supported by Container Engine for Kubernetes?</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.20.8</td>
<td>Yes</td>
<td>Support introduced: July 20, 2021</td>
</tr>
<tr>
<td>1.19.12</td>
<td>Yes</td>
<td>Support introduced: July 13, 2021</td>
</tr>
<tr>
<td>1.19.7</td>
<td>Yes</td>
<td>Support introduced: March 17, 2021</td>
</tr>
<tr>
<td>1.18.10</td>
<td>Yes</td>
<td>Support introduced: 1 December, 2020</td>
</tr>
<tr>
<td>1.17.13</td>
<td>Yes</td>
<td>Support for 1.17.x versions (initially 1.17.9) introduced: November 3, 2020</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Note that Kubernetes version 1.17.13 will not be available for selection after August 19, 2021. Oracle strongly recommends you upgrade clusters to a later version.</td>
</tr>
</tbody>
</table>

Notes about Container Engine for Kubernetes Support for Kubernetes Version 1.20

With the announcement of support for Kubernetes version 1.20.8, the container runtime used by Container Engine for Kubernetes changes from Docker to CRI-O. However, you don’t have to change any of your existing Docker images because Docker images are Open Container Initiative (OCI) compliant. As far as Kubernetes is concerned, all OCI-compliant images look the same.

Note the following:

- CRI-O is an implementation of the Kubernetes Container Runtime Interface (CRI), which enables the use of OCI-compatible runtimes. CRI-O can pull your existing Docker images and run them on your Kubernetes version 1.20.8 clusters.
- You might have a workflow in a cluster that relies on the underlying docker socket /var/run/docker.sock (a pattern often referred to as Docker in Docker). Starting with Kubernetes version 1.20.8, such a workflow no longer functions.
• If you previously used the Docker CLI to run commands on a host, you have to use crictl (a CLI for CRI-compatible container runtimes) instead.
• The upstream Kubernetes project is deprecating Docker as a container runtime after Kubernetes version 1.20.

To find out more:
• See the Kubernetes 1.20.8 Changelog for more information about Kubernetes 1.20.8
• See the Dockershim Deprecation FAQ for more information about the deprecation of the dockershim adapter (which previously enabled the kubelet to interact with Docker as if Docker were a CRI-compatible runtime)

Notes about Container Engine for Kubernetes Support for Kubernetes Version 1.19
Kubernetes version 1.19 is built with golang version 1.15. Golang no longer supports x509 certificates that contain only CommonName. Before upgrading to Kubernetes version 1.19, Oracle recommends you check whether any clusters have admission webhooks that use an x509 certificate containing only CommonName. If there is such a cluster, update the admission webhook to use a new x509 certificate that contains a Subject Alternative Name (SAN). If you don't update the admission webhook, kube-apiserver cannot call it. As a result, any deployment dependent on the admission webhook will not be deployed in the cluster.

Kubernetes Versions Previously Supported by Container Engine for Kubernetes

<table>
<thead>
<tr>
<th>Kubernetes Version</th>
<th>Supported by Container Engine for Kubernetes?</th>
<th>Support Ended</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.17.9</td>
<td>No</td>

<td>11 December, 2019</td>
</tr>
<tr>
<td>1.8.x</td>
<td>No</td>
<td>7 September, 2018</td>
</tr>
</tbody>
</table>

Upgrading Clusters to Newer Kubernetes Versions
After a new version of Kubernetes has been released and when Container Engine for Kubernetes supports the new version, you can upgrade the Kubernetes version running on control plane nodes and worker nodes in a cluster.

The control plane nodes and worker nodes that comprise the cluster can run different versions of Kubernetes, provided you follow the Kubernetes version skew support policy described in the Kubernetes documentation.
You upgrade control plane nodes and worker nodes differently:

- You upgrade control plane nodes by upgrading the cluster and specifying a more recent Kubernetes version for the cluster. Control plane nodes running older versions of Kubernetes are upgraded. Because Container Engine for Kubernetes distributes the Kubernetes Control Plane on multiple Oracle-managed control plane nodes to ensure high availability (distributed across different availability domains in a region where supported), you're able to upgrade the Kubernetes version running on control plane nodes with zero downtime.

Having upgraded control plane nodes to a new version of Kubernetes, you can subsequently create new node pools with worker nodes running the newer version. Alternatively, you can continue to create new node pools with worker nodes running older versions of Kubernetes (providing those older versions are compatible with the Kubernetes version running on the control plane nodes).

For more information about control plane node upgrade, see Upgrading the Kubernetes Version on Control Plane Nodes in a Cluster on page 1354.

- You upgrade worker nodes in one of two ways:
  - By performing an 'in-place' upgrade of a node pool in the cluster, specifying a more recent Kubernetes version for the existing node pool.
  - By performing an 'out-of-place' upgrade of a node pool in the cluster, replacing the original node pool with a new node pool for which you've specified a more recent Kubernetes version.

For more information about worker node upgrade, see Upgrading the Kubernetes Version on Worker Nodes in a Cluster on page 1354.

To find out more about the Kubernetes versions currently and previously supported by Container Engine for Kubernetes, see Supported Versions of Kubernetes on page 1351.

**Notes about Upgrading Clusters**

Note the following when upgrading clusters:

- Container Engine for Kubernetes only upgrades the Kubernetes version running on control plane nodes when you explicitly initiate the upgrade operation.
- After upgrading control plane nodes to a newer version of Kubernetes, you cannot downgrade the control plane nodes to an earlier Kubernetes version.
- Before you upgrade the version of Kubernetes running on the control plane nodes, it is your responsibility to test that applications deployed on the cluster are compatible with the new Kubernetes version. For example, before upgrading the existing cluster, you might create a new separate cluster with the new Kubernetes version to test your applications.
- The versions of Kubernetes running on the control plane nodes and the worker nodes must be compatible (that is, the Kubernetes version on the control plane nodes must be no more than two minor versions ahead of the version on the worker nodes). See the Kubernetes version skew support policy described in the Kubernetes documentation.
- If the version of Kubernetes currently running on the control plane nodes is more than one version behind the most recent supported version, you are given a choice of versions to upgrade to. If you want to upgrade to a version of Kubernetes that is more than one version ahead of the version currently running on the control plane nodes, you must upgrade to each intermediate version in sequence without skipping versions (as described in the Kubernetes documentation).
- To successfully upgrade control plane nodes in a cluster, the Kubernetes Dashboard service must be of type ClusterIP. If the Kubernetes Dashboard service is not of type ClusterIP (for example, if the service is of type NodePort), the upgrade will fail. In this case, change the type of the Kubernetes Dashboard service back to ClusterIP (for example, by entering `kubectl -n kube-system edit service kubernetes-dashboard` and changing the type).
- Prior to Kubernetes version 1.14, Container Engine for Kubernetes created clusters with kube-dns as the DNS server. However, from Kubernetes version 1.14 onwards, Container Engine for Kubernetes creates clusters with CoreDNS as the DNS server. When you upgrade a cluster created by Container Engine for Kubernetes from an earlier version to Kubernetes 1.14 or later, the cluster's kube-dns server is automatically replaced with the CoreDNS server. Note that if you customized kube-dns behavior using the original kube-dns ConfigMap, those customizations are not carried forward to the CoreDNS ConfigMap. You will have to create and apply a new
ConfigMap containing the customizations to override settings in the CoreDNS Corefile. For more information about upgrading to CoreDNS, see Configuring DNS Servers for Kubernetes Clusters on page 1269.

**Upgrading the Kubernetes Version on Control Plane Nodes in a Cluster**

When Container Engine for Kubernetes supports a newer version of Kubernetes than the version currently running on the control plane nodes in a cluster, you can upgrade the Kubernetes version running on the control plane nodes.

**Important:**

After you’ve upgraded control plane nodes to a newer Kubernetes version, you can’t downgrade the control plane nodes to an earlier Kubernetes version. It’s therefore important that before you upgrade the Kubernetes version running on the control plane nodes, you test that applications deployed on the cluster are compatible with the new Kubernetes version.

**Using the Console**

To upgrade the version of Kubernetes running on the control plane nodes:

1. In the Console, open the navigation menu and click **Developer Services**. Under **Containers**, click **Kubernetes Clusters (OKE)**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the name of the cluster where you want to upgrade the Kubernetes version running on the control plane nodes.

   If a newer Kubernetes version is available than the one running on the control plane nodes in the cluster, the **Upgrade Available** button is enabled at the top of the **Cluster** page.
4. Click **Upgrade Available** to upgrade the control plane nodes to a newer version.
5. In the **Upgrade Cluster Master** dialog box, select the Kubernetes version to which to upgrade the control plane nodes, and click **Upgrade**.

The Kubernetes version running on the control plane nodes is upgraded. From now on, the new Kubernetes version will appear as an option when you’re defining new node pools for the cluster.

**Using the API**

For information about using the API and signing requests, see REST APIs on page 5528 and Security Credentials on page 207. For information about SDKs, see Software Development Kits and Command Line Interface on page 5351.

Use the **UpdateCluster** operation to upgrade the version of Kubernetes running on the control plane nodes.

**Upgrading the Kubernetes Version on Worker Nodes in a Cluster**

You can upgrade the version of Kubernetes running on the worker nodes in a cluster in two ways:

- Perform an 'in-place' upgrade of a node pool in the cluster, by specifying a more recent Kubernetes version for new worker nodes starting in the existing node pool. First, you modify the existing node pool’s properties to specify the more recent Kubernetes version. Then, you 'drain' existing worker nodes in the node pool to prevent new pods starting, and to delete existing pods. Finally, you terminate each of the worker nodes in turn. When new worker nodes are started in the existing node pool, they run the more recent Kubernetes version you specified. See Performing an In-Place Worker Node Upgrade by Updating an Existing Node Pool on page 1355.

- Perform an 'out-of-place' upgrade of a node pool in the cluster, by replacing the original node pool with a new node pool. First, you create a new node pool with a more recent Kubernetes version. Then, you 'drain' existing worker nodes in the original node pool to prevent new pods starting, and to delete existing pods. Finally, you delete the original node pool. When new worker nodes are started in the new node pool, they run the more recent Kubernetes version you specified. See Performing an Out-of-Place Worker Node Upgrade by Replacing an Existing Node Pool with a New Node Pool on page 1355.

Note that in both cases:

- The more recent Kubernetes version you specify for the worker nodes in the node pool must be compatible with the Kubernetes version running on the control plane nodes in the cluster. See Upgrading Clusters to Newer Kubernetes Versions on page 1352.)
• You must drain existing worker nodes in the original node pool. If you don't drain the worker nodes, workloads running on the cluster are subject to disruption.

**Performing an In-Place Worker Node Upgrade by Updating an Existing Node Pool**

You can upgrade the version of Kubernetes running on worker nodes in a node pool by specifying a more recent Kubernetes version for the existing node pool. For each worker node, you first drain it to prevent new pods starting and to delete existing pods. You then terminate the worker node so that a new worker node is started, running the more recent Kubernetes version you specified. When new worker nodes are started in the existing node pool, they run the more recent Kubernetes version you specified.

To perform an in-place upgrade of a node pool in a cluster, by specifying a more recent Kubernetes version for the existing node pool:

1. In the Console, open the navigation menu and click **Developer Services**. Under **Containers**, click **Kubernetes Clusters (OKE)**.
2. Choose a **Compartment** you have permission to work in.
3. On the **Cluster List** page, click the name of the cluster where you want to change the Kubernetes version running on worker nodes.
4. On the **Cluster** page, display the **Node Pools** tab, and click the name of the node pool where you want to upgrade the Kubernetes version running on the worker nodes.
5. On the **Node Pool** page, click **Edit** and in the **Version** field, specify the required Kubernetes version for worker nodes.
   
   The Kubernetes version you specify must be compatible with the version that is running on the control plane nodes.
6. Click **Edit** to save the change.
   
   You now have to terminate existing worker nodes so that new worker nodes are started, running the Kubernetes version you specified.
7. For the first worker node in the node pool:
   a. Prevent new pods from starting and delete existing pods by entering:
   
   ```bash
   kubectl drain <node_name>
   ```

   For more information:
   • about using `kubectl`, see **Accessing a Cluster Using Kubectl** on page 1248
   • about the `drain` command, see `drain` in the Kubernetes documentation
   
   **Recommended:** Leverage pod disruption budgets as appropriate for your application to ensure that there's a sufficient number of replica pods running throughout the drain operation.
   b. On the **Node Pool** page, display the **Nodes** tab and click the worker node's name in the **Node Name** field.
   c. On the **Instances** page, select **Terminate** from the **More Actions** menu.

   The worker node is terminated and a new worker node is started in its place, running the Kubernetes version you specified.
8. Repeat the previous step for each remaining worker node in the node pool, until all worker nodes in the node pool are running the Kubernetes version you specified.

**Performing an Out-of-Place Worker Node Upgrade by Replacing an Existing Node Pool with a New Node Pool**

You can 'upgrade' the version of Kubernetes running on worker nodes in a node pool by replacing the original node pool with a new node pool that has new worker nodes running the appropriate Kubernetes version. Having drained existing worker nodes in the original node pool to prevent new pods starting and to delete existing pods, you can then delete the original node pool. When new worker nodes are started in the new node pool, they run the more recent Kubernetes version you specified.
To perform an 'out-of-place' upgrade of a node pool in a cluster, by creating a new node pool to 'upgrade' the Kubernetes version on worker nodes:

1. In the Console, open the navigation menu and click Developer Services. Under Containers, click Kubernetes Clusters (OKE).
2. Choose a Compartment you have permission to work in.
3. On the Cluster List page, click the name of the cluster where you want to change the Kubernetes version running on worker nodes.
4. On the Cluster page, display the Node Pools tab, and then click Add Node Pool to create a new node pool and specify the required Kubernetes version for its worker nodes.
   
   The Kubernetes version you specify must be compatible with the version that is running on the control plane nodes.
5. If there are labels attached to worker nodes in the original node pool and those labels are used by selectors (for example, to determine the nodes on which to run pods), then use the kubectl label nodes command to attach the same labels to the new worker nodes in the new node pool. See Assigning Pods to Nodes in the Kubernetes documentation.
6. For the first worker node in the original node pool, prevent new pods from starting and delete existing pods by entering:

   ```bash
   kubectl drain <node_name>
   ```

   For more information:
   - about using kubectl, see Accessing a Cluster Using Kubectl on page 1248
   - about the drain command, see drain in the Kubernetes documentation
   
   **Recommended:** Leverage pod disruption budgets as appropriate for your application to ensure that there's a sufficient number of replica pods running throughout the drain operation.
7. Repeat the previous step for each remaining worker node in the node pool, until all the worker nodes have been drained from the original node pool.
   
   When you have drained all the worker nodes from the original node pool and pods are running on worker nodes in the new node pool, you can delete the original node pool.
8. On the Cluster page, display the Node Pools tab, and then select Delete Node Pool from the Actions menu beside the original node pool.
   
   The original node pool and all its worker nodes are deleted.

**Running Applications on Arm-based Nodes**

To run an application on an Arm-based worker node in a cluster, the application has to run on a node in a node pool for which you've specified an Arm-based shape. The shape determines the number of CPUs and the amount of memory allocated to each node in the node pool. You can select Arm-based bare metal shapes and flexible VM shapes. These Ampere A1 Compute instances are based on the Ampere Altra processor (see Arm-Based Compute on page 986). For information about the OCPU count, memory, storage, and networking details of these shapes, see Compute Shapes on page 973.

You can specify an Arm-based shape for a node pool using the Console, the API, and the CLI when you create a new cluster. You can also specify an Arm-based shape when you create a new node pool. See the node pool configuration steps in Creating a Kubernetes Cluster on page 1234 and Updating Worker Nodes by Creating a New Node Pool on page 1274 respectively.

To view the number of reservable Arm-based cores available to you, use the Console. Open the navigation menu and click Governance & Administration. Under Governance, click Limits, Quotas and Usage.

Compared to other shapes, Arm-based shapes provide better price-performance, greater security isolation (because each core is single-threaded), and more consistent performance. Typically, developers use Arm-based worker nodes in Kubernetes clusters to develop and test applications.
When you deploy an application on a cluster you've created with Container Engine for Kubernetes, you have to specify in the pod spec the compute resources that are required. To deploy the application, the kube-scheduler determines which node has the necessary resources. If a cluster has node pools with Arm-based shapes and also node pools with other shapes (for example, AMD64 shapes), you can use a nodeSelector in the pod spec to specify that an application is to run on Arm-based worker nodes. See Defining a pod to run only on Arm-based nodes on page 1357.

If you want to deploy an application on both Arm-based and non-Arm-based worker nodes in the same cluster, use multi-architecture images (sometimes known as manifest lists) stored in an Open Container Initiative-compliant registry like Oracle Cloud Infrastructure Registry (see Overview of Container Registry on page 4428). You build multi-architecture images from a single source tree, with one image tag that includes images for both x86 and Arm architectures. You can build multi-architecture images using Docker Buildx, Podman, and Buildah.

Note the following:

- You can specify Arm-based shapes for node pools in clusters that have Kubernetes API endpoints hosted in a subnet of your VCN (known as native VCN clusters). Do not specify an Arm-based shape for node pools in a cluster if the cluster's Kubernetes API endpoint is not integrated into your VCN.
- You can specify Arm-based shapes for node pools in clusters running Kubernetes version 1.19.7 or later. Do not specify an Arm-based shape for node pools running earlier versions of Kubernetes.
- Having created a node pool with an Arm-based shape, you cannot change the node pool to have a non-Arm-based shape. Likewise, you cannot change a node pool with a non-Arm-based shape to have an Arm-based shape.
- When you specify an Arm-based shape for a node pool, you also specify an image that is compatible with the shape. See Compute Shapes on page 973.

### Defining a pod to run only on Arm-based nodes

If a cluster has node pools with Arm-based shapes and also node pools with other shapes (for example, AMD64 shapes), you can use a nodeSelector in the pod spec to specify that an application is to run only on Arm-based worker nodes. For example, the following configuration file defines a pod to run on any Arm-based node in the cluster:

```yaml
apiVersion: v1
kind: Pod
metadata:
  name: nginx
labels:
  env: test
spec:
  containers:
  - name: nginx
    image: nginx
    imagePullPolicy: IfNotPresent
    nodeSelector:
      kubernetes.io/arch: arm64
```

### Running Applications on GPU Nodes

To run an application on a GPU worker node in a cluster, the application has to run on a node in a node pool for which you've specified a GPU shape and a GPU image.

When you use Container Engine for Kubernetes to create clusters, you select a shape for the nodes in each node pool. The shape determines the number of CPUs and the amount of memory allocated to each node in the node pool. Among the shapes you can select are GPU (Graphics Processing Unit) shapes, with the GPUs themselves on NVIDIA graphics cards. Originally intended for manipulating images and graphics, GPUs are very efficient at processing large blocks of data in parallel. This capability makes GPUs a good option when deploying data intensive applications.
The massive parallel computing functionality of NVIDIA GPUs is accessed using CUDA (Compute Unified Device Architecture) libraries. Different GPUs (for example, NVIDIA® Tesla Volta™, NVIDIA® Tesla Pascal™) require specific versions of the CUDA libraries.

When you select a GPU shape for a node pool, you must also select a compatible Oracle Linux GPU image that has the CUDA libraries pre-installed.

When you deploy an application on a cluster you’ve created with Container Engine for Kubernetes, you have to specify in the pod spec the number of GPU resources that are required. To deploy the application, the kube-scheduler determines which node has the necessary resources. When an application pod is to run on a node with a GPU shape, the following are mounted into the pod:

- the requested number of GPU devices
- the node's CUDA library

The application is effectively isolated from the different types of GPU. As a result, CUDA libraries for different GPUs do not have to be included in the application container, ensuring the container remains portable.

Note the following:

- You can specify GPU shapes for node pools in clusters running Kubernetes version 1.19.7 or later. Do not specify a GPU shape for node pools running earlier versions of Kubernetes.
- You can use the Console, the API, or the CLI to specify a GPU image for use on a GPU shape (the image name includes 'GPU'). You can also use the API or the CLI to specify a non-GPU image for use on a GPU shape.
- Having created a node pool with a GPU shape, you cannot change the node pool to have a non-GPU shape. Likewise, you cannot change a node pool with a non-GPU shape to have a GPU shape.
- GPU shapes are not necessarily available in every availability domain.
- You can specify GPU shapes for node pools in clusters that have Kubernetes API endpoints hosted in a subnet of your VCN. Do not specify a GPU shape for node pools in a cluster if the cluster's Kubernetes API endpoint is not integrated into your VCN.

### Defining a pod to run only on nodes that have a GPU

The following configuration file defines a pod to run on any node in the cluster that has one available GPU resource (regardless of the type of GPU):

```yaml
apiVersion: v1
kind: Pod
metadata:
  name: test-with-gpu-workload
spec:
  restartPolicy: OnFailure
  containers:
  - name: cuda-vector-add
    image: k8s.gcr.io/cuda-vector-add:v0.1
    resources:
      limits:
        nvidia.com/gpu: 1
```

### Defining a pod to run only on nodes that do not have a GPU

The following configuration file defines a pod to run only on nodes in the cluster that do not have a GPU:

```yaml
apiVersion: v1
kind: Pod
metadata:
  name: test-with-non-gpu-workload
spec:
  restartPolicy: OnFailure
```
Troubleshooting

This section provides troubleshooting information for Container Engine for Kubernetes, including:

- Node Troubleshooting Using the Node Doctor Script on page 1359

Node Troubleshooting Using the Node Doctor Script

The Node Doctor script is pre-installed on worker node instances to help you resolve issues with the instances. Depending on how you run it, the Node Doctor script:

- Prints troubleshooting output that identifies potential problem areas, with links to documentation to address those areas.
- Gathers system information into a bundle. My Oracle Support (MOS) provides instructions to upload the bundle to a support ticket.

If you see worker nodes with a Kubernetes Node Condition other than "Active", or with a Node State other than "Ready", use the Node Doctor script to troubleshoot the issues.

You can run the Node Doctor script in the following ways:

- using SSH
- using the Run Command feature

The Worker Node Troubleshooting Guide is a convenient way to start the Node Doctor script from the Console.

The Worker Node Troubleshooting Guide provides dynamically populated commands to run the Node Doctor script using either SSH or the Run Command feature. To access the Worker Node Troubleshooting Guide, click the Troubleshoot Nodes button on the Node Pool Details page, select either SSH Connections or Run Command, and follow the instructions.

Note:

The Node Doctor script is pre-installed on worker node instances created from July 19, 2021. Worker nodes created before July 19, 2021 do not have the Node Doctor script pre-installed. To find out how to install the Node Doctor script, see Downloading, Installing, and Updating the Node Doctor Script on page 1361. Note that to install the Node Doctor script on such nodes, you must have SSH access to them.

Also note that Oracle releases new versions of the Node Doctor script periodically. Before running the Node Doctor script for the first time (even on worker nodes created after July 19, 2021), follow the instructions in Downloading, Installing, and Updating the Node Doctor Script on page 1361 to update the script to the latest version. It's also recommended good practice to update the Node Doctor script from time to time.

Using the Run Command Feature to Run the Node Doctor Script

You can use the Run Command feature to troubleshoot node issues and generate a support bundle using the Node Doctor script. For more information about using the Run Command feature, see Running Commands on an Instance on page 1112.

To run the Node Doctor script using the Run Command feature, do one of the following:

- Use the Worker Node Troubleshooting Guide. On the Node Pool Details page, click Troubleshoot Nodes to display the Worker Node Troubleshooting Guide, select Run Command, and follow the instructions.
- Follow the steps in this section.
**Required IAM Policy**

For administrators: To write a policy for the Run Command feature, do the following:

1. Write the following policy to allow any user to use the Run Command feature to issue commands, cancel commands, and view the command output for the instances in a compartment:

   ```
   Allow any-user to use instance-agent-command-execution-family in compartment id <compartment-ocid> where request.instance.id=target.instance.id
   ```

2. If you want to save the output from the Node Doctor script in an Object Storage bucket, write the following policy:

   ```
   Allow any-user to manage objects in compartment id <compartment-ocid-of-bucket> where all { request.principal.type='instance', request.principal.compartment.id='<compartment-ocid-of-node>', target.bucket.name = '<bucket-name>' }
   ```

   where:
   - `<compartment-ocid-of-bucket>` is the OCID of the compartment to which the Object Storage bucket belongs.
   - `<compartment-ocid-of-node>` is the OCID of the compartment to which the worker node instance belongs.

**Creating the Command to Run the Node Doctor Script**

To create the command to run the Node Doctor script on the instance:

1. On the Cluster Details page, click Node Pools and click the node pool containing the node you want to troubleshoot.
2. Under Nodes, click the name of the node you want to troubleshoot, to display the Instance Details page.
4. Click Create Command.
5. Enter a name for the command. Avoid entering confidential information.
6. In the Timeout in seconds box, enter the amount of time to give the Compute Instance Run Command plugin to run the command on the instance before timing out. The timer starts when the plugin starts the command. For no timeout, enter 0.
7. In the Add script section, upload the script that you want the Compute Instance Run Command plugin to run on the instance. Select the Paste script option and paste one of the following commands in the box:
   - `sudo /usr/local/bin/node-doctor.sh --check` to print troubleshooting output that identifies potential problem areas, with links to documentation to address those areas.
   - `sudo /usr/local/bin/node-doctor.sh --generate && /dev/null && cat /tmp/oke-support-bundle.tar` to gather system information in a bundle. My Oracle Support (MOS) provides instructions to upload the bundle to a support ticket.
8. In the Output type section, select the location to save the output of the command:
   - **Output as text**: The output is saved as plain text. You can review the output on the Instance Details page.
   - **Output to an Object Storage bucket**: The output is saved to an Object Storage bucket. Select a bucket. In the Object name box, enter a name for the output file. Avoid entering confidential information.
   - **Output to an Object Storage URL**: The output is saved to an Object Storage URL. Enter the URL.
9. Click Create Command.

**Viewing the Output of the Node Doctor Script**

How to view the output of the Node Doctor script depends on whether the output was saved to an Object Storage location or as a plain text file, as follows:
1. If the Node Doctor script output was saved to an Object Storage location, do one of the following:
   - Download the response object from the bucket where it was saved.
   - Navigate to the Object Storage pre-authenticated request URL.
2. If the Node Doctor script output was saved as a plain text file, do the following:
   a. Open the navigation menu and click Compute. Under Compute, click Instances.
   b. Click the instance that you’re interested in.
   c. Under Resources, click Run Command.
   d. Find the command in the list, click the Actions icon (three dots), and then click View Command Details.

**Using SSH to Run the Node Doctor Script**

If you have SSH access to a worker node, you can run the Node Doctor script using SSH to troubleshoot node issues and generate a support bundle using the Node Doctor script.

To run the Node Doctor script using SSH, do one of the following:

- Use the Worker Node Troubleshooting Guide. On the Node Pool Details page, click Troubleshoot Nodes to display the Worker Node Troubleshooting Guide, select SSH Connections, and follow the instructions.
- Follow the steps in this section.

1. Establish an SSH connection with the worker node instance on which you want to run the Node Doctor script.

   For detailed instructions to establish an SSH connection, see Connecting to Worker Nodes Using SSH on page 1261. At a high level, the steps are:
   a. Find out the IP address of the worker node instance that you want to troubleshoot, and make a note of it.

      For example, on the Cluster Details page, click Node Pools and then click the node pool containing the worker node. Click Nodes, and then click the name of the node you are interested in to display the Instance Details page. The instance's IP address is shown on the Instance Information tab.
   b. In a terminal window, enter `ssh opc@<node_ip_address>` to connect to the worker node, where `<node_ip_address>` is the IP address of the worker node instance that you made a note of earlier. For example, you might enter:

      ```bash
      ssh opc@192.0.2.254
      ```

      If the SSH private key is not stored in the file or in the path that the ssh utility expects (for example, the ssh utility might expect the private key to be stored in ~/.ssh/id_rsa), you must explicitly specify the private key filename and location. For more information, see Connecting to Worker Nodes Using SSH on page 1261.

   2. In the terminal window in which you have established the SSH connection with the worker node instance, enter one of the following commands:

      - `sudo /usr/local/bin/node-doctor.sh --check` to print troubleshooting output that identifies potential problem areas, with links to documentation to address those areas.
      - `sudo /usr/local/bin/node-doctor.sh --generate` to gather system information in a bundle. My Oracle Support (MOS) provides instructions to upload the bundle to a support ticket.

**Downloading, Installing, and Updating the Node Doctor Script**

Worker nodes created from July 19, 2021 already have the Node Doctor script pre-installed.

Worker nodes created before July 19, 2021 do not have the Node Doctor script pre-installed. To run the Node Doctor script on such a worker node, you must download and install the script. To download and install the Node Doctor script, you must have SSH access to the worker node.

---

**Note:**

Periodically, Oracle releases new versions of the Node Doctor script. Before running the Node Doctor script for the first time (even on worker nodes created after July 19, 2021), follow the final step in the instructions below to...
To download, install, and update the Node Doctor script on a worker node:

1. Establish an SSH connection with the worker node.

For detailed instructions to establish an SSH connection, see Connecting to Worker Nodes Using SSH on page 1261. At a high level, the steps are:

   a. Find out the IP address of the worker node instance that you want to troubleshoot, and make a note of it.

   For example, on the Cluster Details page, click Node Pools and then click the node pool containing the worker node. Click Nodes, and then click the name of the node to display the Instance Details page. The instance's IP address is shown on the Instance Information tab.

   b. In a terminal window, enter ssh opc@<node_ip_address> to connect to the worker node, where <node_ip_address> is the IP address of the worker node that you made a note of earlier. For example, you might enter:

   ```
   ssh opc@192.0.2.254
   ```

   If the SSH private key is not stored in the file or in the path that the ssh utility expects (for example, the ssh utility might expect the private key to be stored in ~/.ssh/id_rsa), you must explicitly specify the private key filename and location. For more information, see Connecting to Worker Nodes Using SSH on page 1261.

2. In the terminal window in which you have established the SSH connection with the worker node, download and install the Node Doctor script in the /usr/local/bin directory by entering:

   ```
   sudo curl -s -X GET https://objectstorage.<region-name>.oraclecloud.com/n/odx-oke/b/public/o/artifacts/prd/workernode/b42d2ec-276/node-doctor --output /usr/local/bin/node-doctor.sh
   ```

   where <region-name> is the region in which the cluster is located. For example:

   ```
   sudo curl -s -X GET https://objectstorage.us-ashburn-1.oraclecloud.com/n/odx-oke/b/public/o/artifacts/prd/workernode/b42d2ec-276/node-doctor --output /usr/local/bin/node-doctor.sh
   ```

   Before running the Node Doctor script for the first time, complete the next step.

3. When the Node Doctor script has been downloaded and installed on the worker node, get the latest version of the Node Doctor script by entering:

   ```
   sudo /usr/local/bin/node-doctor.sh --update
   ```

   It's recommended good practice to keep the Node Doctor script up-to-date by running the above command from time to time.

You can now use the Node Doctor script to troubleshoot worker node issues.

**Frequently Asked Questions About Container Engine for Kubernetes**

This topic provides answers to some frequently asked questions about Container Engine for Kubernetes.

**Does Container Engine for Kubernetes Support Alpha and Beta Features in Kubernetes?**

Periodically, Kubernetes releases new features. New Kubernetes features are introduced in the following stages, as described in the Kubernetes documentation and summarized below:

- **Alpha stage**: An Alpha feature is disabled by default, might contain bugs, and might change or be dropped at any time. The feature is recommended for short-lived testing clusters only.
• **Beta stage**: A Beta feature is usually enabled by default, has been well-tested, and will not be dropped. However, details of the feature might change in incompatible ways, and is recommended for non-business-critical use only.

• **General Availability stage**: A Generally Available (or Stable) feature is always enabled, and will appear in released software for many subsequent versions.

Container Engine for Kubernetes supports the use of Kubernetes Beta features that are enabled by default in Kubernetes. Container Engine for Kubernetes does not support Alpha features, nor Beta features that are disabled by default.

For more information about Kubernetes Alpha and Beta features, see the Kubernetes documentation.

**What Are VCN-Native Clusters?**

Container Engine for Kubernetes creates Kubernetes clusters that are completely integrated with your Oracle Cloud Infrastructure Virtual Cloud Network (VCN). Worker nodes, load balancers, and the Kubernetes API endpoint are part of your VCN, and you can configure them as public or private. Such clusters that are fully integrated with your VCN are known as "VCN-native clusters".

**Note:**

In earlier releases, clusters were provisioned with public Kubernetes API endpoints that were not integrated into your VCN.

You can continue to create such clusters using the CLI or API, but not the Console.
Data Science

This chapter explains how to use Data Science.

Data Science

Data Science is a fully managed and serverless platform for data science teams to build, train, and manage machine learning models in the Oracle Cloud Infrastructure.

Overview of Data Science

OCI Data Science is a fully managed and serverless platform for data science teams to build, train, and manage machine learning models using Oracle Cloud Infrastructure.
The Data Science Service:

- Model deployment as resources to deploy models as web applications (HTTP API endpoints).
- Provides data scientists with a collaborative, project-driven workspace.
- Enables self-service, serverless access to infrastructure for data science workloads.
- Includes Python-centric tools, libraries, and packages developed by the open source community and the Oracle Accelerated Data Science Library, which supports the end-to-end lifecycle of predictive models:
  - Data acquisition, profiling, preparation, and visualization.
  - Feature engineering.
  - Model training (including Oracle AutoML).
  - Model evaluation, explanation, and interpretation (including Oracle MLX).
- Integrates with the rest of the Oracle Cloud Infrastructure stack, including Functions, Data Flow, Autonomous Data Warehouse, and Object Storage.
- Includes policies, and vaults to control access to compartments and resources.
- Includes metrics that provide insight into the health, availability, performance, and utilization of your Data Science resources.
- Helps data scientists concentrate on methodology and domain expertise to deliver models to production.

Data Science Concepts

Review the following concepts and terms to help you get started with Data Science.

**Accelerated Data Science SDK**

The Oracle Accelerated Data Science (ADS) SDK is a Python library that is included as part of the OCI Data Science service. ADS has many functions and objects that automates or simplifies the steps in the Data Science workflow, including connecting to data, exploring and visualizing data, training a model with AutoML, evaluating models, and explaining models. In addition, ADS provides a simple interface to access the Data Science service model catalog and other OCI services including Object Storage. To familiarize yourself with ADS, see the Accelerated Data Science Library.

**Projects**

Projects are collaborative workspaces for organizing and documenting Data Science assets, such as notebook sessions and models.

**Notebook Sessions**

Data Science notebook sessions are interactive coding environments for building and training models. Notebook sessions come with many preinstalled open source and Oracle developed machine learning and data science packages.

**Conda Environments**

Conda is an open-source environment and package management system and was created for Python programs. It quickly installs, runs, and updates packages and their dependencies. Conda easily creates, saves, loads, and switches between environments on your local computer.

**Models**

Models define a mathematical representation of your data and business process. The model catalog is a place to store, track, share, and manage models.

**Model Deployments**

Model deployments is a managed resource in the Data Science service that allows you to deploy models stored in the model catalog as HTTP endpoints. Deploying machine learning models as web applications (HTTP API endpoints) serving predictions in real time is the most common way to productionized models. HTTP endpoints are flexible and can serve requests for model predictions.

You should also be familiar with the Oracle Cloud Infrastructure Key Concepts.
Ways to Access Data Science

You access Data Science using the Console, REST API, SDKs, or CLI.

Use any of the following options, based on your preference and its suitability for the task you want to complete:

- The OCI **Console** is an easy-to-use, browser-based interface. To access the Console, you must use a supported browser.
- The **REST APIs** provide the most functionality, but require programming expertise. API reference and endpoints provide endpoint details and links to the available API reference documents including the Data Science REST API.
- OCI provides **SDKs** that interact with Data Science without the need to create a framework.
- The **CLI** provides both quick access and full functionality without the need for programming.

Creating Automation Using Events

You can create automation based on state changes for your OCI resources by using the Event service types, rules, and actions.

These Data Science resources produce events:

- Projects
- Notebook Sessions
- Models
- Model Deployments

*Data Science event types* explains how to set up event notifications including examples.

Regions and Availability Domains

OCI services are hosted in regions and availability domains. A **region** is a localized geographic area, and an **availability domain** is one or more data centers located in that region.

Data Science is hosted in these regions:

- Australia East (Sydney)
- Australia Southeast (Melbourne)
- Brazil East (Sao Paulo)
- Brazil Southeast (Vindeho)
- Canada Southeast (Montreal)
- Canada Southeast (Toronto)
- Chile (Santiago)
- Dedicated Region Cloud@Customer (Chiyoda)
- Germany Central (Frankfurt)
- India South (Hyderabad)
- India West (Mumbai)
- Japan Central (Osaka)
- Japan East (Tokyo)
- Netherlands Northwest (Amsterdam)
- Saudi Arabia West (Jeddah)
- South Korea Central (Seoul)
- South Korea North (Chuncheon)
- Switzerland North (Zurich)
- UAE East (Dubai)
- UK South (London)
- UK West (Newport)
- US East (Ashburn)
• US West (Phoenix)
• US West (San Jose)
• US Gov West (Phoenix)
• US Gov East (Ashburn)
• US DoD North (Chicago)
• US DoD West (Phoenix)
• US DoD East (Ashburn)

For more information, see Regions and Availability Domains.

Limits on Data Science Resources

When you sign up for OCI, a set of service limits is configured for your tenancy. The service limit is the quota or allowance set on the resources.

Limits by Service includes Data Science limits and other OCI services. You can also request a service limit increase.

Note:
Failed and inactive notebook sessions and models count against your service limits. Only when you fully terminate an instance or delete a model is it not counted toward your quota.

Note:
GPU limits are set to zero by default so ask your system administrator to request a service limit increase to use GPUs.

Resource Identifiers

Most types of OCI resources have an Oracle assigned unique ID called an OCID (Oracle Cloud Identifier).

The OCID is included as part of the resource's information in both the Console and API. For information about the OCID format and other ways to identify your resources, see Resource Identifiers.

Authentication and Authorization

Each service in OCI integrates with Identity and Access Management for access to cloud resources through all interfaces (the OCI Console, SDKs, REST APIs, or the CLI).

An administrator in your organization must set up groups, compartments, and policies that control who can access which services and resources and the type of access. For example, About Data Science Policies on page 1481 create and manage Data Science projects, or launch notebook sessions.

Your administrator can confirm which compartments you should be using.

For general information on policies, see Getting Started with Policies. For specific details about writing policies for each of the services, see Policy Reference. For common policies used to authorize Data Science users, see Common Policies. For in-depth information about policies on granting users permissions for Data Science resources, see About Data Science Policies on page 1481.

Provisioning on the Oracle Cloud Infrastructure

The Data Science service offers a serverless experience for model development and deployment. When you create Data Science resources, such as notebook sessions, models, and model deployments, the underlying compute and storage infrastructure is provisioned and maintained for you.

You pay for the use of the underlying infrastructure (Block Storage, Compute, and Object Storage). You only pay for the infrastructure while you are using it with Data Science resources:
Notebook Sessions

- Notebook sessions are serverless, and all underlying infrastructure is service-managed.
- When creating a notebook session, you select the VM shape (the type of machine CPU or GPU, and the number of OCPU or GPUs) and amount of block storage (minimum of 50 GB).
- While a notebook session is active, you pay for Compute and Block Storage at the standard Oracle Cloud Infrastructure rates, see Deactivating Notebook Sessions on page 1384.
- You can deactivate your notebook session, which shuts down the Compute but retains the Block Storage. In this case, you are no longer be charged for Compute, but you continue to pay for the Block Storage. You can activate your notebook session to reattach this Block Storage to new Compute, see Deactivating and Activating Notebook Sessions on page 1384.
- When you terminate a notebook session, you are no longer charged for Compute or Block Storage, see Terminating Notebook Sessions on page 1385.

Models

- When you save a model to the model catalog, you are charged for the storage of the model artifact at the standard Object Storage rates in terms of GB per month.
- When you delete a model, you are no longer charged, see Deleting Models on page 1466.

Model Deployments

- When you deploy a model, you select the shape type and the number of replicas hosting the model servers. You can also select the load balancer bandwidth associated with your deployment.
- When a model deployment is active, you pay for the VMs that are hosting the model servers and the load balancer at the standard OCI rates.
- When you deactivate a model deployment, you are no longer charged for the VMs or the load balancer. You can activate a model deployment and billing resumes for both VMs and the load balancer.
- When you terminate a model deployment, you are no longer charged for the infrastructure associated with the model deployment.

Tip:

You can use Checking Your Balance and Usage to review the costs associated with your account. Also, you can use the Oracle Cloud Infrastructure Billing and Payment Tools to analyze your Data Science usage and manage your costs.

Compliance

Review the standards that the Data Science service is compliant with.

The service is compliant with these standards:

- HIPAA, used by healthcare companies to protect patient privacy.
- PCI-DSS, used by the credit card industry to protect consumers against fraud.

Using the Oracle Resource Manager to Configure Your Tenancy for Data Science

The Data Science service tenancy can be automatically configured, including OCI resources, using the OCI Resource Manager.

You can configure your tenancy with the Resource Manager using a predefined Data Science sample solution or your Terraform configuration.

Before You Begin

To configure a tenancy for the Data Science service, you must have:

- An Oracle Cloud Infrastructure tenancy.
- The OCID for the compartment where you want to create your stack.
- A user account that includes the following:
  - An API signing key, see Required Keys and OCIDs.
  - Required IAM permissions, see How Policies Work and Details for Resource Manager.
  - Make sure that your tenancy has service limits availabilities for the OCI resources.

**Tenancy Resources**

**Note:**
Model deployment resources are not supported by OCI Resource Manager so you must manually configure your tenancy.

The tenancy configuration includes these resources:

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
<th>Default Name</th>
<th>Optional?</th>
<th>Enabled By Default?</th>
<th>Number of Items Provisioned</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Science</td>
<td>Oracle Cloud Infrastructure Data Science Project</td>
<td>Data Science Project</td>
<td>True</td>
<td>False</td>
<td>1</td>
<td>-</td>
</tr>
<tr>
<td>Notebook</td>
<td>Oracle Cloud Infrastructure Data Science Notebooks</td>
<td>Data Science Notebook-x</td>
<td>True</td>
<td>False</td>
<td>1 or more</td>
<td>You can provision more than one notebook, and each notebook is suffixed with an index (x) starting from (0).</td>
</tr>
<tr>
<td>Functions</td>
<td>Oracle Cloud Infrastructure Function Application</td>
<td>Data Science App</td>
<td>True</td>
<td>False</td>
<td>1</td>
<td>Only the Oracle Cloud Infrastructure Functions Application is provisioned without a Function deployment. This is a placeholder application so you can deploy your model application later.</td>
</tr>

</table>

**Configuring a Tenancy Using a Sample Template**

Configuring a tenancy using a Resource Manager Terraform configuration is creating a stack, selecting a template, providing identifying information for the new stack, and updating variables. You can always edit your stack later.
Templates are available using the Console only.

1. Open the navigation menu and click **Developer Services** Under **Resource Manager**, click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
4. Click **Create Stack**.
5. Select **Template**.
6. Click **Select Template**.
7. Select **Data Science**, and then click **Select Template**.
8. Enter a **Name** for the new stack, or use the default.
9. (Optional) Enter a **Description**.
10. From the **Create in Compartment** drop-down, select the compartment where you want to create the stack. This compartment contains all the resources the stack creates.
   - A compartment from the list scope is set by default.
11. For **Terraform version**, select the version you want for the Terraform configuration.
12. (Optional) You can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags**. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
13. Click **Next**.
   - The **Configure Variables** panel displays variables auto-populated from the Terraform configuration for the Data Science template.
14. Review the IAM variables and change as needed. Don't use spaces in any of the variables.
   
   **Important:**
   - Do not add your private key or other confidential information to configuration variables.

15. Enter the network information or use the defaults to create a VCN, or select **Use Existing VCN** to enter the information to connect to an existing network.
16. (Optional) Select **Create a Project and Notebook Session** and enter a project and notebook configuration. We recommend that you do not create a project or notebook session until you need them, see **Creating Projects** on page 1380 and **Creating Notebook Sessions** on page 1382.
17. Select **Enable Vault Support** to enable storing secrets, encrypted passwords, and keys, and then enter vault values to create a vault.
18. Select **Provision Functions and API Gateway** to enable deploying models to Functions and use the API gateway, and then enter vault values to create a vault.
19. Click **Next** and review the stack configuration.
20. In the **Review** panel, verify your stack configuration.
21. Select **Run Apply** to apply the Terraform script and create the Data Science resources.
22. Click **Create** to create your stack.
   - The resources are created and attached to the stack. This operation may take several minutes to complete.

To see a list of the Data Science resources, under **Resources**, click **Associated Resources**.

The Data Science project and notebooks are in the service.

**Managing Stacks and Jobs** contains details about Resource Manager stacks.
Configuring a Tenancy Using a Terraform Configuration

Configuring a tenancy using a Resource Manager Terraform configuration is creating a stack, selecting a template, providing identifying information for the new stack, and updating variables. You can always edit your stack later.

Templates are available using the Console only.

1. Open the navigation menu and click **Developer Services** Under **Resource Manager**, click **Stacks**.
2. Choose a compartment you have permission to work in (on the left side of the page). The page updates to display only the resources in that compartment. If you're not sure which compartment to use, contact an administrator.
3. Click **Create Stack**.
4. Click **Select Solution**.
5. Select one of these Terraform configuration options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>My Configuration</strong></td>
<td>Drop your custom Terraform configuration folder or ZIP file into the text box or browse for it. Oracle Quickstart contains a simple Terraform configuration example and other information.</td>
</tr>
<tr>
<td><strong>Source Code Control System</strong></td>
<td>Select or create a source (like Git Hub) that identifies the repository and a branch if needed.</td>
</tr>
</tbody>
</table>

6. Enter a **Name** for the new stack, or use the default.
7. (Optional) Enter a **Description**.
8. Select the compartment where you want to create the stack. This compartment contains all the resources the stack creates.

A compartment from the list scope is set by default.
9. For **Terraform** version, select the version you want for the Terraform configuration.
10. (Optional) You can apply tags. If you have permissions to create a resource, you also have permissions to apply free-form tags to that resource. To apply a defined tag, you must have permissions to use the tag namespace. For more information about tagging, see **Resource Tags**. If you are not sure if you should apply tags, skip this option (you can apply tags later) or ask your administrator.
11. Click **Next**.

The **Configure Variables** panel displays variables auto-populated from the Terraform configuration for the Data Science template.
12. Review the IAM variables and change as needed. Don't use spaces in any of the variables.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not add your private key or other confidential information to configuration variables.</td>
</tr>
</tbody>
</table>
13. Enter the network information or use the defaults to create a VCN, or select **Use Existing VCN** to enter the information to connect to an existing network.
14. (Optional) Select **Create a Project and Notebook Session**? and enter a project and notebook configuration. We recommend that you do not create a project or notebook session until you need them, see **Creating Projects** on page 1380 and **Creating Notebook Sessions** on page 1382.
15. Select **Enable Vault Support**? to enable storing secrets, encrypted passwords, and keys, and then enter vault values to create a vault.
16. Select **Provision Functions and API Gateway**? to enable deploying models to Functions and use the API gateway, and then enter vault values to create a vault.
17. Click **Next** and review the stack configuration.
In the **Review** panel, verify your stack configuration.

Select **Run Apply** to apply the Terraform script and create the Data Science resources.

Click **Create** to create your stack.

To see a list of the Data Science resources, under **Resources**, click **Associated Resources**.

The Data Science **project** and **notebooks** are in the service.

**Managing Stacks and Jobs** contains details about Resource Manager stacks.

### Manually Configuring Your Tenancy for Data Science

Before you can use the Data Science service, you must complete these tasks to configure the service:

**Note:**

To deploy models with Oracle Functions, use Configuring Your Tenancy for Function Development.

1. Creating User Groups and Users for Data Science on page 1373, if they don’t already exist.
2. Creating Compartments for Network Resources and Data Science Resources in a Tenancy on page 1373, if they don’t already exist.
3. Creating the VCN and Subnets to Use with Data Science on page 1374 to create the VCN and subnets to use with Data Science, if they don’t already exist.
4. Creating Policies to Control Access to Network and Data Science Related Resources on page 1376, if they don’t already exist.

### Creating User Groups and Users for Data Science

Before you can start using Data Science, your tenancy administrator has to create OCI user accounts, create a group for these users to belong to, and then assign these user accounts to that group.

Define policies to give the user group access to your Data Science related resources. If a suitable group and user accounts exist, you don’t need to create a group though the Data Science policies have to be implemented in the group.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Groups**.
2. Click **Create Group** and create a new group.
3. Enter a meaningful name. For example, *acme-datascientists*.
4. Enter a description. Avoid entering confidential information.
5. Click **Create**.

You are advanced to the group detail page that you created.

6. Click **Add User to Group** and create one or more new users.
7. Select a user to add, and then click **Add**.

The selected user is added and appears in the group member list.

8. Repeat adding data scientist users until all of your users are added to the group you created:

A list of the users in your tenancy displays.

### Creating Compartments for Network Resources and Data Science Resources in a Tenancy

Before you can use Data Science, a tenancy administrator must create these resources:

- A compartment to contain network resources. A VCN, a public or private subnet, and other resources such as, an internet gateway or service gateway, a route table, and security lists.
• A compartment to contain Data Science resources (projects, notebook sessions, models, and work requests). The compartment can contain the resources for multiple services not just Data Science.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The same compartment can own both network resources, Data Science-related resources, and the resources of other OCI services. Alternatively, you can have multiple compartments for network resources and Data Science related resources, structuring them for what is best for your organization.</td>
</tr>
</tbody>
</table>

If you already have suitable compartments, there is no need to create new ones.

   A list of the compartments in your tenancy displays.
2. Click Create Compartment to create a new compartment, see To create a compartment.
3. Enter a meaningful name. For example, acme-network or acme-datascience-compartment.
4. (Optional) Enter a description. Avoid entering confidential information.
5. Click Create Compartment.
   The compartment is created, and added to the compartments list when it successfully creates.

**Creating the VCN and Subnets to Use with Data Science**

To create and use a Data Science notebook session, you must have a VCN that contains a subnet. Then, you can create the notebook session in that subnet.

All egress from a notebook session is routed through this subnet. To access data and install additional packages to use in the notebook session, you must configure the subnet with appropriate access.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>For a private subnet to have egress access to the internet, it must have a route to a NAT Gateway. For egress access to the public internet, we recommend that you use a private subnet with a route to a NAT Gateway. A NAT gateway gives instances in a private subnet access to the internet.</td>
</tr>
</tbody>
</table>

If you already have suitable VCN and subnets, you don’t need to create new ones. You can create an OCI VCN with these basic steps.

Each subnet in the VCN must have a CIDR block that provides at least one IP address for each concurrent notebook session. We recommend that you have a minimum of 12 free IP addresses for AD-specific subnets and a minimum of 32 free IP addresses for regional subnets.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>We strongly recommend that each subnet has a CIDR block that provides more than the minimum number of free IP addresses.</td>
</tr>
</tbody>
</table>

Use these steps to create a simple VCN and subnet to access the Public Internet from a Data Science notebook session:

1. Open the navigation menu and click Networking. Click Virtual Cloud Networks.
2. Select the compartment that you want to create the VCN in.
3. Click Start VCN Wizard.
4. Use the VCN with Internet Connectivity default and click Start VCN Wizard.
5. Choose the compartment to own the network resources.
6. Enter the following:

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>None of your CIDR blocks can overlap.</td>
</tr>
</tbody>
</table>

- **VCN Name**: A meaningful name for the cloud network. For example, *acme-datascience-vcn*. The name doesn't have to be unique within your tenancy and it cannot be changed later through the Console. Do not enter confidential information.
- **VCN CIDR Block**: The IP address to your VCN. For example, *10.0.0.0/16*.
- **Public Subnet CIDR Block**: The IP address to your public subnet. For example, *10.0.0.0/24*.
- **Private Subnet CIDR Block**: The IP address to your private subnet. For example, *10.0.1.0/24*.

7. Make sure that **Use DNS Hostnames in this VCN** is selected.

8. Click **Next**.

   A review of the VCN configuration is displayed.

9. Review your selections and click **Previous** to modify any.

10. Click **Create** to create the VCN and the related resources (three public subnets and an internet gateway).

   Use this VCN and its *private* subnet to use when you launch a notebook session.

11. (Optional) Click **View Virtual Cloud Network** to review your VCN and subnets.

### Creating the VCN and Subnets for Notebook Sessions Running on GPUs

For Tokyo (NRT), you can use the same VCN and subnet your are using for notebook sessions on CPU shapes, see [Creating the VCN and Subnets to Use with Data Science](#) on page 1374.

If you are working in the Frankfurt (FRA), Ashburn (IAD), or London (LHR) regions, you must create new subnets. GPU availability in those regions is limited to certain availability domains. You must create subnets that are availability domain-specific with access to the *public* internet.

Use these steps to create a simple VCN and an availability domain-specific subnet to access the *Public Internet* from a Data Science notebook session:

1. Open or create a notebook session.

2. Select the region-specific VCN that you created.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the VCN is not available in one of the GPU regions, then use <a href="#">Creating the VCN and Subnets to Use with Data Science</a> on page 1374 to create it.</td>
</tr>
</tbody>
</table>

3. Click **Create Subnet**.
4. Enter the following:

| Important: |
| None of your CIDR blocks can overlap. |

- **VCN Name**: A meaningful name for the cloud network. We recommend that you put the GPU shape family in the name of the subnet to differentiate them. The name doesn’t have to be unique within your tenancy and it cannot be changed later through the Console. Do not enter confidential information.

- **Subnet Type**: Select **Availability Domain-Specific**, and then select the proper availability domain for the GPU family shape you want to use. Ask the OCI Data Science team for the mapping between shape families and ADS.

- **Route Table**: Select the route table associated with the NAT gateway for public internet egress access.

- **Subnet Access**: Select **Private Subnet**.

- **Private Subnet CIDR Block**: The IP address to your private subnet. For example, `10.0.1.0/24`.

- **DNS Resolution**: Select **Use dns hostnames in this subnet**.

- **DHCP Options**: Select **Default DHCP Options for <VCN Name>**.

- **Security Lists**: Select the security list associated with the NAT Gateway you selected.

5. Click **Create Subnet**.

6. Repeat all of these steps for each availability domain you want to launch GPUs in.

### Creating Policies to Control Access to Network and Data Science Related Resources

Before you can start using Data Science, your tenancy administrator has to create a number of Oracle Cloud Infrastructure Identity and Access Management policies to grant access to Data Science-related and network resources.

Your administrator has to do all of these tasks:

#### Creating a Policy to Give Data Science Groups Access to Data Science Resources

When Data Science users create projects, notebook sessions, and models, they have to specify a compartment for those Data Science resources.

Users can only specify a compartment that their group has been granted access to. To enable groups to specify a compartment, you must create an identity policy to grant the user group access to that compartment. Specifying compartments is optional in the policy.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Policies**.
2. Use the **To create a policy** instructions and give the policy a meaningful name. For example, **acme-datascientists-manage-access**.
3. Add a policy statement to allow the group access to all Data Science related resources in a specified compartment. For example, for the **acme-datascientists group and acme-datascience-compartment**.

   ```
   allow group acme-datascientists to manage data-science-family
   in compartment acme-datascience-compartment
   ```

4. Click **Create**.

#### Creating a Policy to Give Data Science Groups Access to Network Resources

When you create a notebook session, you must specify a VCN and a subnet.

Users can only specify VCNs and subnets in specific compartments. Users must belong at a group that has been given access to the compartment that the VCN and subnet belong to.

1. Open the navigation menu and click **Identity & Security**. Under **Identity**, click **Policies**.
2. Follow the To create a policy instructions and give the policy a name. For example, acme-datascientists-manage-network-access.

3. Add a policy statement to allow the group access to the network resources in the specified compartment. For example, the acme-datascientists group and acme-network-compartment compartment.

   allow group acme-datascientists to use virtual-network-family in compartment acme-network

4. Click Create.

Creating a Policy to Give Data Science Service Access to Network Resources

When you create a notebook session, you specify a VCN and a subnet to host it. Then the Data Science service creates the notebook session in that subnet.

To enable the Data Science service to create a notebook session in a specified VCN and subnet, you must create an identity policy to grant the Data Science service access to those network resources.

2. Select the root compartment:
3. Use the To create a policy instructions and give the policy a name. For example, datascience-service-network-access.
4. Add a policy statement to allow Data Science access to the network resources in a specified compartment. For example, acme-network.

   allow service datascience to use virtual-network-family in compartment acme-network

5. Click Create.

Creating Dynamic Groups and Policies to Access Other Oracle Cloud Infrastructure Resources from Notebook Sessions

When a Data Science notebook session is running, it can access other Oracle Cloud Infrastructure resources. For example, you might want to:

- Access the Data Science model catalog to save or load models.
- List Data Science projects.
- Access data from an Object Storage bucket, perform some operation on the data, and then write the modified data back to the Object Storage bucket.
- Create and run a Data Flow application.
- Access your secrets stored in the Vault.

Users working in notebook sessions can use the notebook session's resource principal as an authentication mechanism with the preceding use cases. For more details on using resource principals, see Authenticating to the OCI APIs from a Notebook Session on page 1388.

Creating Dynamic Groups and Policies

To enable a notebook session to access another Oracle Cloud Infrastructure resource, you have to include the notebook session in a dynamic group, and then create a policy to grant the dynamic group access to that resource.

   A list of the dynamic groups in your tenancy displays.
2. Click Create and create a new dynamic group.
3. Enter a meaningful name. For example, acme-datascience-dyn-group.
4. Enter a description. Avoid entering confidential information.
5. Enter the Matching Rules. Resources that meet the rule criteria are members of the group. When specifying a rule for the dynamic group, consider what resource is going to be given access to some other resource as in these examples:

- To allow all notebook sessions, in the compartment identified by the OCID given in the 'resource.compartment.id' parameter, enter a rule similar to the following:

```
ALL {resource.type = 'datasciencenotebooksession',
    resource.compartment.id = 'ocid1.compartment.oc1..aaaaaaaafl______kzyq'}
```

- To allow a specific notebook session to access a resource, enter a rule similar to the following that adds the notebook session with the specified OCID to the dynamic group:

```
resource.id = 'ocid1.datasciencenotebooksession.oc1.iad.amaaaaaani______ci2q'
```

- Notebook sessions can be tagged with a key and value pair and any notebook with this tag is part of the dynamic group. For example, notebook sessions with the "department.operations.value = '8'" are part of the group:

```
ALL {resource.type = 'datasciencenotebooksession',
    tag.department.operations.value = '8'}
```

Free-form tags are not supported, see Resource Tagging.

6. Click Create.

Next, give the dynamic group permissions by writing one or more policies:

7. Click Policies.

8. Use the to create a policy instructions and give the policy a meaningful name. For example, acme-datascience-dyn-group-access.

   **Note:**
   
   Ensure that you select the root compartment for these policies.

9. When specifying a policy statement, consider what permissions you want notebooks sessions in the acme-datascience-dyn-group group to have. Following are some policy statements examples with descriptions of the access granted:

   - Manage all data science resources in a specific compartment. These resources would be resources like projects, model catalog, and so on.

```
allow dynamic-group acme-datascience-dyn-group to manage data-science-family
in compartment acme-compartment
```

- Allows a dynamic group of resources (like notebook sessions) to perform all CRUD operations, including calling the predict endpoint, on model deployment resources in a particular compartment. The manage verb can be changed to limit what the resources can do.

```
allow dynamic-group <your-dynamic-group> to manage data-science-model-deployments
in compartment <your-compartment-name>
```

- Read and write to a particular Object Storage bucket, enter a rule similar to the following:

```
allow dynamic-group acme-datascience-dyn-group to manage objects in
```
Create and run a Data Flow application, enter a rule similar to the following:

```plaintext
allow dynamic-group acme-datascience-dyn-group to manage dataflow-family
in tenancy
```

List compartments (useful for interacting with the model catalog), enter a rule similar to the following:

```plaintext
allow dynamic-group acme-datascience-dyn-group to read compartments
in tenancy
```

List users (useful for interacting with the model catalog), enter a rule similar to the following:

```plaintext
allow dynamic-group acme-datascience-dyn-group to read users
in tenancy
```

Manage secrets stored in a Vault, enter a rule similar to the following:

```plaintext
allow dynamic-group acme-datascience-dyn-group to manage secret-family
in tenancy
```

Read and write to all resources in a compartment, enter a rule similar to the following:

```plaintext
allow dynamic-group acme-datascience-dyn-group to manage all-resources
in compartment acme-compartment
```

10. Click **Create** to create the policy.

**Note:**

The resource principal token is cached for 15 minutes. Therefore, if you change the policy or the dynamic group, you have to wait for 15 minutes to see the effect of your changes.

For more information about dynamic groups, including the permissions required to create them, see Managing Dynamic Groups and Writing Policies for Dynamic Groups.

### Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

The API operations to configure tenancy resources are defined the various OCI services and links to the details are provided in each of the preceding topics.

### About Projects

Learn how to work with your Data Science projects.

Projects are containers that enable you to organize your work. They contain a collection of notebook sessions and models.

Projects are managed using the **Projects** page, where you can:

- Select a project to view its details and manage it. All notebook sessions and models in the project are listed.
- Use the Actions icon (three dots) to view project details, edit projects, move the project to another compartment, or delete the project.
- Use the **List Scope** filter to view projects in another compartment.
- Filter projects by status using the **Project State** drop-down list. The default is to view all status types.
• When there are tags applied to projects, you can further filter projects by clicking add or clear next to Tag Filters.

Creating Projects
You create a Data Science project to organize your notebook sessions and models.

1. Log into your tenancy using the Console with the necessary policies.
2. Open the navigation menu and click Analytics & AI. Under Machine Learning, click Data Science.
3. Click Create Project.
4. Select the compartment you want to add the project to.
5. (Optional but recommended) Enter a unique name (255 character limit) for the project. If you don't provide a name, a name is automatically generated for you. For example, datascienceproject20200108222435.
6. (Optional but recommended) Enter a description (400 character limit) for the project. If you don't add a description, it remains empty.
7. (Optional) Add tags to easily locate and track the project by selecting a tag namespace, then entering the key and value. To add more than one tag, click +Additional Tags.

Tagging describes the various tags that you can use organize and find projects including cost-tracking tags.

8. (Optional) To view the details for your project immediately after creation, select View detail page on clicking create

After you successfully create a project, you can create notebook sessions and models and associate them with the project. You and your collaborators can then organize and document your data science work within the projects.

Viewing Project Details
To open a project's detail page, you can click the project's name or the Actions icon (three dots), and click View Details.

From the Project Information tab, you can view these details:

Description:
A description of the project is one was defined.

OCID
A shortened version of the OCID is displayed. You can use the Show and Hide links to toggle the display of the full OCID. Use the Copy link to save the entire OCID to your clipboard to paste it elsewhere. For example, you could paste into a file and save it, then use it in your model scripts.

Created On:
The date and time when the notebook session was created.

Created By:
A shortened version of the OCID user that created the model. You can use the Show and Hide links to toggle the display of the full OCID user. Use the Copy link to save the entire OCID user to your clipboard to paste it elsewhere. For example, you could paste into other Data Science dialogs.

From the Tags tab, you can view the tags that have been applied to the model. To update or remove a tag, find the tag you want and click the pencil icon next to it. Enter the new tag then save it or remove the tag by clicking Remove Tag.

Editing Projects
You can click the project's name or the Actions icon (three dots), then click Edit to change the name and description of the project.
Applying Tags to Projects
You can click the project's name or the Actions icon (three dots), and click Add Tags. You can apply both defined and free form tags, see Working with Resource Tags.

Moving Project Resources
You can move a project resource from its current compartment to a different one. Moving a project does not move any of its notebook sessions or models to the new compartment.

For example, you may want to move a project to promote it from a development compartment to production compartment, or you could change the visibility of the project.

You can click the project's name or the Actions icon (three dots), and click Move Resource. Select the destination compartment and click Move Resource.

Deleting Projects
To delete a project, it cannot be associated with any Data Science resources. Before you can start to delete a project, you must first delete the notebook session and models associated with the project.

You can click the project's name or the Actions icon (three dots), and click Delete to delete a project.

The state of the project becomes "deleting" during the delete project operation. The service checks for the absence of associated resources. If successful, the project status is updated to deleted.

The delete project action is asynchronous and initiates a work request. You can use the work request to track the status of an operation. For general information about using work requests in OCI, see Work Requests and the Work Requests API.

Note:
Deleted projects exist in lists for 30 days after being deleted. You can filter them out of lists using the State filter.

Using the API
For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage projects:
- CreateProject
- GetProject
- UpdateProject
- ChangeProjectCompartment
- DeleteProject
- ListProjects

About Notebook Sessions
Learn how to work with your Data Science notebook sessions, which are interactive coding environments for building and training models.

After you choose a project, the Project Details page is displayed with a list of notebook sessions. This page is used to:
- Create notebook sessions.
- Select a notebook session to view its details and work with it.
- Use the Actions icon (three dots) to view details, edit, move a notebook resource, or delete a notebook session.
• **OCID**: Determine the OCID of a resource. A shortened version of the OCID is displayed though you can use Show and Hide to toggle the display of the OCID. Use the Copy link to save the entire OCID to your clipboard to paste it elsewhere. For example, you could paste into a file and save it, then use it in your model scripts.

• Use the List Scope filter to view notebook sessions associated with your selected project in another compartment.

• Filter notebook sessions by status using the Notebook Session State drop-down list. The default is to view all status types.

• When there are tags applied to notebook sessions, you can further filter notebook sessions by clicking add or clear next to Tag Filters.

### Creating Notebook Sessions

You create a notebook session to access a JupyterLab interface using a customizable compute, storage, and network configuration.

1. Log into your tenancy with suitable policies.
2. Open the navigation menu.
3. Under Data and AI, select Data Sciences, and then click Projects.
4. Select a compartment for the project.
5. Click the name of the project to contain the notebook session.
6. Click Create Notebook Session.
7. Select the compartment that you want to contain the notebook session.
8. (Optional but recommended) Enter a unique name for the notebook session (limit of 255 characters). If you don't provide a name, a name is automatically generated for you. For example, datasciencenotebooksession20200108222435.
9. Select one of these Data Science supported shapes:

<table>
<thead>
<tr>
<th>Shape Family</th>
<th>CPU or GPU</th>
<th>Availability</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM.Standard.E (with the exception of VM.Standard.E2.1)</td>
<td>CPU</td>
<td>All OC 1 regions</td>
</tr>
<tr>
<td>VM.Standard2</td>
<td>CPU</td>
<td>All OC 1 regions</td>
</tr>
<tr>
<td>VM.GPU2.1 (NVIDIA P100)</td>
<td>GPU</td>
<td>US East (Ashburn) Germany Central (Frankfurt)</td>
</tr>
<tr>
<td>VM.GPU3.1.X (NVIDIA V100)</td>
<td>GPU</td>
<td>US East (Ashburn) UK South (London) Japan East (Tokyo)</td>
</tr>
</tbody>
</table>

• VM Compute Shapes describes all of the available shapes.

• GPU Compute Shapes describes the supported shapes.

• Data Regions for Platform and Infrastructure Services shows you the regions that GPU is supported in.

10. Enter the block volume size you want to use between 50 GB and 10,240 GB (10 TB). You can change the value by 1 GB increments. The default value is 1,024 GB. Persisting Data and Files on your Notebook Session Block Volume on page 1385 provides more details.

11. Select the VCN compartment that contains the VCN that you want to use.

12. Select the VCN that you want to use.

13. Select the subnet compartment that contains the subnet that you want to use.

14. Select the subnet that you want to use.

15. (Optional) Add tags to the notebook session by selecting a tag namespace, then entering the key and the value. You can add more tags to the compartment by clicking +Additional Tags, see Working with Resource Tags.

16. (Optional) View the details for your notebook session immediately after creation by selecting Display notebook session details after creation.

17. Click Create.
You are advanced to the notebook sessions page. When it is complete, the status turns to active, and you can open the notebook session. The create notebook session action is asynchronous and initiates a work request. You can use the work request to track the status of an operation. For general information about using work requests in OCI, see Work Requests and the Work Requests API.

**Opening Notebook Sessions**

You can either click the notebook session’s name or the Actions icon (three dots), and click **Open** to open the notebook session’s JupyterLab interface in another tab. For more information on using JupyterLab, see JupyterLab Documentation.

**Note:**

You can *only* open an active notebook session.

**Viewing Notebook Session Details**

To open a notebook session’s detail page, you can either click the notebook session’s name or the Actions icon (three dots), and select **View Details**.

From the **Notebook Session Information** tab, you can view the:

- **OCID**
  
  A shortened version of the OCID is displayed. You can use the **Show** and **Hide** links to toggle the display of the full OCID. Use the **Copy** link to save the entire OCID to your clipboard to paste it elsewhere. For example, you could paste into a file and save it, then use it in your model scripts.

- **Other Details**
  
  These details are displayed:
  
  - **Created On:** The date and time when the notebook session was created.
  - **Created By:** The email address of the user that created the notebook.
  - **Block Storage Size (in GB):** The defined Block Storage.
  - **Compute Instance Shape:** The defined compute instance shape.

- **VCN**
  
  The subnet that was selected is displayed as a link so that you can go to the **VCN Details** page to manage it.

- **Subnet**
  
  The subnet that was selected is displayed as a link so that you can go to the **Subnet Details** page to manage it.

From the **Tags** tab, you can view the tags that have been applied to the model. To update or remove a tag, find the tag you want and click the pencil icon next to it. Enter the new tag then save it or remove the tag by clicking **Remove Tag**.

**Editing Notebook Sessions**

You can either click the notebook session’s name or the Actions icon (three dots), and click **Edit**. You can change the name of the notebook session and then save your changes.

When a notebook session is active, only the name can be edited. To edit other options, you have to **deactivate** it. Then activate it, which allows you to change any of the options like the block storage size, compute shape, compartment, VCN, and the subnet.

**Applying Tags to Notebook Sessions**

You can either click the notebook session’s name or the Actions icon (three dots), and click **Add Tags** or the **Tags** tab.
You can apply defined and free form tags to notebook sessions, see Working with Resource Tags.

**Moving Notebook Session Resources**

You can move a notebook session resource from its current compartment to a different one.

For example, you may want to move a notebook session to promote it from a development compartment to production compartment, or you could change the visibility of the notebook session.

You can either click the notebook session's name or the Actions icon (three dots), and click **Move Resource**. Select the destination compartment and click **Move Resource**.

**Deactivating and Activating Notebook Sessions**

**Deactivating Notebook Sessions**

Before you deactivate a notebook session, save your work to its attached block volume to retain your data. Any data on the boot volume of the notebook session is deleted after you deactivate it.

You can either click the notebook session's name or the Actions icon (three dots), and click **Deactivate** to deactivate a notebook session after you provide confirmation. When you deactivate a notebook session, the underlying compute terminates, while the attached block volume is detached and preserved.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
</table>

Any data or files stored on the compute local disk or held in memory are lost when you deactivate a notebook session. The data and files saved on the block volume are maintained while the notebook session is inactive. You can restore access to this block volume by activating the notebook session.

**Activating Notebook Sessions**

You can either click the notebook session's name or the Actions icon (three dots), and click **Activate** to activate a notebook session after you provide confirmation. When you activate a notebook session, a new compute shape is provisioned. The block volume from the previous notebook session is restored and attached to the new compute shape.

When you activate a notebook session, any previously saved data or files on the block volume of that deactivated notebook session are available in the activated notebook session.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>
</thead>
</table>

When activating a notebook session, you can only choose a VCN and subnet that allows your reactivated notebook session to remain in the same Availability Domain (AD). If you choose an AD-specific subnet that would change the AD of the notebook session, then the activation action fails because the block volume reattachment fails. We generally recommend that you use regional subnets to avoid this type of error.

While activating a notebook session, you can change the previously configured compute shape, block volume size, VCN, and subnet.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
</table>

If you choose to change the block volume size, then you must specify a larger value than the current block volume size.
Persisting Data and Files on your Notebook Session Block Volume

Files and data on the local disk of a notebook session compute are not persisted when the notebook session is deactivated or crashes. To persist files and data, you must save them to Oracle Cloud Infrastructure Block Volumes. A block volume is mounted in /home/datascience. You can access it from the JupyterLab file tree.

When you deactivate a notebook session, the files stored on the block volume are mounted back in /home/datascience after you activate your notebook session. To back up your data, push your code changes to a remote Git repository and save the data to OCI Object Storage.

Downloading a Dataset

You can download a dataset file (.csv) from a Data Science notebook session using the JupyterLab download option.

Locate and select the dataset you want to download. Right-click the file, and select Download. If your browser can open the file, the file is opened in a separate browser tab. Otherwise, the file is downloaded directly to your disk. This behavior is controlled by your browser settings.

Tip:

You can download other files from JupyterLab such as notebook example (.ipynb) files.

Terminating Notebook Sessions

You can either click the notebook session’s name or the Actions icon (three dots), and click Terminate to terminate a notebook session after you provide confirmation. The notebook session’s underlying compute is terminated, and the block volume is deleted. Deactivating Notebook Sessions on page 1384 explains how to retain block volume data.

Note:

Terminated notebook sessions exist in lists for 30 days after being terminated. You can filter them out of lists using the State filter.

The terminate notebook session action is asynchronous and initiates a work request. You can use the work request to track the status of an operation. For general information about using work requests in OCI, see Work Requests and the Work Requests API.

Caution:

If you want to keep the file changes in a notebook session’s file system and attached block volume, you must back it up before you terminate the notebook session. For example, you can copy files to an object storage bucket, or commit and push changes to a Git repository outside the notebook session. Otherwise, all file changes in the notebook session’s file system and attached block volume are lost.

Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage notebook sessions:

- CreateNotebookSession
- GetNotebookSession
- ActivateNotebookSession
- UpdateNotebookSession
- ChangeNotebookSessionCompartment
- DeactivateNotebookSession
Data Science

- DeleteNotebookSession
- ListNotebookSessions
- NotebookSessionShapeSummary Reference
- ListNotebookSessionShapes

About Notebook Session Metrics

You can monitor the health, capacity, and performance of Data Science notebook sessions by using metrics, alarms, and notifications.

There are metrics emitted by the oci_datascience metric namespace, which is the Data Science service. Data Science monitors running notebook sessions and collects and reports metrics including:

- CPU Utilization
- Memory Utilization
- Network Bytes In
- Network Bytes Out

Prerequisites

IAM policies:

To monitor resources, you must be given the required access in a policy. This is true whether you're using the Console or the REST API with an SDK, CLI, or other tool. The policy must give you access to the monitoring services and the resources being monitored. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you've been granted, and which compartment you should work in. For more information on user authorizations for monitoring, see the Authentication and Authorization section for the related service, Monitoring or Notifications.

For more information about the policy statement required to access metrics emitted by Data Science, see Creating Policies to Control Access to Network and Data Science Related Resources.

Data Science Metrics

Metrics are automatically available for any Data Science notebook session that you create in the oci_datascience namespace. You don't need to enable monitoring on OCI resources to get these metrics.

Data Science notebook session metrics include these dimensions:

**RESOURCEID**

The OCID of the notebook session.

**RESOURCEDISPLAYNAME**

The user-supplied display name of the notebook session.

**SHAPE**

The compute instance shape of the notebook session.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Display Name</th>
<th>Unit</th>
<th>Description</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>CpuUtilization</td>
<td>CPU Utilization</td>
<td>Percent</td>
<td>Activity level from the CPU. Expressed as a percentage of the total time (busy and idle) compared with the idle time.</td>
<td>resourceId, resourceDisplayName, shape</td>
</tr>
<tr>
<td>MemoryUtilization</td>
<td>Memory Utilization</td>
<td>Percent</td>
<td>Space currently in use. Measured by pages. Expressed as a Percentage of used pages compared with unused pages.</td>
<td>resourceId, resourceDisplayName, shape</td>
</tr>
<tr>
<td>Metric</td>

</tbody>
</table>

**Viewing Metrics from the Monitoring Service**

You can view the default metric charts for all the notebook sessions in a compartment using the Monitoring service.

2. Select the compartment that contains the project of the notebook session that you want to view the metrics for.
3. Select oci_dataScience as the Metric Namespace.

The Service Metrics page dynamically updates the page to show charts for each that is emitted by the selected metric namespace, see Data Science Metrics on page 1386.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

**Viewing Metrics from the Notebook Details Page**

You can view the default metric charts using the a notebook session details page in the Data Science service.

1. Open the navigation menu and click Analytics & AI. Under Machine Learning, click Data Science.
2. Select the region you are using with Data Science.
3. Select the compartment that contains the project of the notebook session that you want to view the metrics for.
4. Click the name of the project associated with the notebook session for which you want to view metrics.
5. Click the name of the notebook session that you want to view metrics for.

The Metrics page displays a chart for each metric that is emitted by the metric namespace for Data Science. For more information about the emitted metrics, see Data Science Metrics on page 1386.

For more information about monitoring metrics and using alarms, see Monitoring Overview. For information about notifications for alarms, see Notifications Overview.

If you don't see the metrics data for a notebook session that you expect, see the following possible causes and solutions.

<table>
<thead>
<tr>
<th>Problem</th>
<th>Possible Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>No data: Notebook creation date.</td>
<td>The notebook session was created before the metrics feature was available.</td>
<td>Deactivate then reactivate the notebook session to start the flow of metrics data.</td>
</tr>
<tr>
<td>No data: Permissions issue.</td>
<td>The user is missing a policy for metrics.</td>
<td>An administrator user needs to add a policy statement to read metrics for your user group.</td>
</tr>
<tr>
<td>No data: Misaligned chart time range.</td>
<td>The chart range (time period or x-axis window) doesn't cover the time of notebook session use.</td>
<td>Adjust the chart range or time period as necessary.</td>
</tr>
</tbody>
</table>
Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following APIs for:

- Monitoring API for metrics and alarms.
- Notifications API for notifications (used with alarms).

Using Notebook Sessions to Build and Train Models

Once you have a notebook session created, you can write and execute Python code using the machine learning libraries in the JupyterLab interface to build and train models.

Authenticating to the OCI APIs from a Notebook Session

When you are working within a notebook session, you are operating as the Linux user datascience. This user does not have an OCI Identity and Access Management (IAM) identity, so it has no access to the OCI API. OCI resources include Data Science projects and models and the resources of other OCI services, such as Object Storage, Functions, Vault, Data Flow, and so on. To access these resources from the notebook environment, use one of the two authentication approaches:

(Recommended) Authenticating Using a Notebook Session’s Resource Principal

A resource principal is a feature of IAM that enables resources to be authorized principal actors that can perform actions on service resources. Each resource has its own identity, and it authenticates using the certificates that are added to it. These certificates are automatically created, assigned to resources, and rotated, avoiding the need for you to store credentials in your notebook session.

The Data Science service enables you to authenticate using your notebook session's resource principal to access other OCI resources. Resource principals provides a more secure way to authenticate to resources compared to the OCI configuration and API key approach.

Your tenancy administrator must write policies to grant permissions for your resource principal to access other OCI resources, see Configuring Your Tenancy for Data Science.

You can authenticate with resource principals in a notebook session using the following interfaces:

Oracle Accelerated Data Science SDK:

Run the following in a notebook cell:

```python
import ads
ads.set_auth(auth='resource_principal')
```

For details, see the Accelerated Data Science documentation.

OCI Python SDK:

Run the following in a notebook cell.

```python
import oci
from oci.data_science import DataScienceClient
rps = oci.auth.signers.get_resource_principals_signer()
dsc = DataScienceClient(config={}, signer=rps)
```

OCI CLI:

Use the `--auth=resource_principal` flag with commands.
Note:

The resource principal token is cached for 15 minutes. If you change the policy or the dynamic group, you have to wait for 15 minutes to see the effect of your changes.

Important:

If you don't explicitly use the resource principals when invoking an SDK or CLI, then the configuration file and API key approach is used.

(Default) Authenticating Using OCI Configuration File and API Keys

You can operate as your own personal IAM user by setting up an OCI configuration file and API keys to access OCI resources. This is the default authentication approach.

To authenticate using the configuration file and API key approach, you must upload an OCI configuration file into the notebook session's /home/datasience/.oci/ directory. For the relevant profile defined in the OCI configuration file, you also need to upload or create the required .pem files.

Alternatively, you can use the included individual getting-started.ipynb notebooks to interactively create configuration and key files, see Overview of the Notebook Examples on page 1430.

You can use the api_keys.ipynb notebook to interactively create OCI configuration and API key files. To launch the api_keys.ipynb notebook, click Notebook Examples in the JupyterLab Launcher tab.

Working with Existing Code Files

You can create new files or work with your own existing files.

Uploading Files

Files can be uploaded from your local machine by clicking Upload in the JupyterLab interface or by dragging and dropping files.

Creating a Key Pair in a Notebook Session to Use with a Third-Party Version Control Provider

1. Open the JupyterLab environment.
2. Create a ~/.ssh/config file.
3. Edit the file and add your private key:

```bash
ssh-agent bash -c 'ssh-add <path_to_your_private_key>'
```

Cloning a Git Repository Without an Existing Private Key

If you don't have a private key, you can create one in the notebook session by running the ssh-keygen command in the JupyterLab environment.

These instructions use a Git repository as an example though the steps are similar for other repositories. Flows between third-party version control providers and internal Git servers may differ.

1. Copy your public key into your version control provider. For example, on GitHub.com under your avatar menu, click settings then click SSH and GPC keys, and then click New SSH key.
2. Go back to your notebook environment.
3. Add your private key with:

```bash
ssh-agent bash -c 'ssh-add <path_to_your_private_key>'
```

Now that you have added your private key, a new identity has been created.
4. Clone your repository on your notebook session environment. For example, you could clone a repository from GitHub.com.

```
git clone git@github.com:<your_account>/<your_repository>
```

5. If you are working with multiple version control hosts, we recommend that you edit your `~/.ssh/config` file and add the information about your Git host and the location of the private key for that particular host:

```
Host <your_host.com> IdentityFile <path_to_your_private_key>
```

**Using Additional Terminal Commands**

You can execute sftp, scp, curl, wget or rsync commands to pull files into your notebook session environment under the networking limitations imposed by your VCN and subnet selection.

**Installing Additional Python Libraries**

You can install a library that’s not preinstalled in the provided image.

Access to the public internet is required to install additional libraries. Install a library by opening a notebook session and running this command:

```
%%bash
pip install <library-name>==<library-version>
```

**Important:**

Data Science doesn't allow root privileges in notebook sessions. You can only install libraries using `yum` and `pip` as a normal user. Attempting to use `sudo` results in errors.

You can install any open source package available on a publicly-accessible Python Package Index (PyPI) repository. You can also install private or custom libraries from your own internal repositories.

**Note:**

The VCN or subnet that you used to create the notebook session must have network access to the source locations for the packages you want to download and install, see Manually Configuring Your Tenancy for Data Science on page 1373.

**Using the Provided Environment Variables in Notebook Sessions**

When you start up a notebook session, the service creates useful environment variables that you can use in your code:

```
NB_SESSION_COMPARTMENT_OCID
```

The compartment OCID of the current notebook session.

```
NB_SESSION_OCID
```

The OCID of the current notebook session.

```
PROJECT_OCID
```

The OCID of the project associated with the current notebook session.

```
USER_OCID
```

Your user OCID.

```
PROJECT_COMPARTMENT_OCID
```

The compartment OCID of the project associated with the current notebook session.
To access these environment variables in your notebook session, use the Python `os` library. For example:

```python
import os
project_ocid = os.environ['PROJECT_OCID']
print(project_ocid)
```

**Note:**
The `NB_SESSION_COMPARTMENT_OCID` and `PROJECT_COMPARTMENT_OCID` values do not update in a running notebook session if the resources has moved compartments after the notebook session was created.

---

**Using the Oracle Accelerated Data Science SDK**

The Oracle Accelerated Data Science (ADS) SDK is a Python library that is included as part of the OCI Data Science service notebook session resource. ADS offers a friendly user interface that covers many of the steps involved in the lifecycle of machine learning models, from connecting to different data sources to using AutoML for model training to model evaluation and explanation. ADS also provides a simple interface to access the OCI Data Science service model catalog and other OCI services including object storage.

**Note:**
For complete documentation on how to use the Accelerated Data Science SDK, see [Accelerated Data Science Library](#) and [Accessing the Conda Environment Notebook Examples](#) on page 1429.

---

**Connecting to Your Data**

You can connect to your data in these ways:

**Connecting to Data in Oracle Cloud Infrastructure Object Storage**

To retrieve your data, you must first set up a connection to Oracle Cloud Infrastructure Object Storage, see [Ways to Access Object Storage](#).

After this setup, you can use the OCI Python SDK in a notebook session to retrieve your data from Object Storage. Also, you can use the ADS SDK to pull data from Object Storage. Example notebooks are provided in the notebook session environment to show you the necessary steps, see [Accessing the Conda Environment Notebook Examples](#) on page 1429.

**Connecting to Data on the Autonomous Data Warehouse**

You can connect to the Autonomous Data Warehouse (ADW) from your notebook session. The `autonomous_database.ipynb` example notebook interactively illustrates this type of connection.

**Note:**
The VCN and subnet configuration that you selected when creating your notebook session should permit access to your ADW database. Contact your IT administrator to confirm that access with the networking configuration you selected is permitted.

To connect to ADW and pull data into a dataframe in your notebook session:

1. Go to the OCI Console, and access your ADW instance page.
2. Click **DB Connection** to download the wallet file.
3. Create your own password for the download action.
4. Create a folder for your wallet files on the notebook environment. We recommend that you create that folder in `/home/datascience`.
5. Upload your wallet files into your `<path_to_wallet_folder>` folder in JupyterLab by clicking **Upload**.
6. Open the sqlnet.ora file from the wallet files, then configure the METHOD_DATA to be:

```
METHOD_DATA = (DIRECTORY="<path_to_wallet_folder>")
```

7. Create a new notebook file, and set the following environment variables in a notebook cell:

```
%env TNS_ADMIN=<path_to_wallet_folder>
```

You can find SID names from the tnsname.ora file from the wallet file, and then set ADW_SID as an environment variable (the SID is an identifier that identifies the unique name of the Oracle Database):

```
%env ADW_SID=<your_SID_name>
```

Retrieve your ADW user name and password from your database administrator, and then store your credentials as environment variables in your notebook session:

```
%env ADW_USER=<your_username>
%env ADW_PASSWORD=<your_password>
```

8. In a separate notebook cell, run this command to test the connection to the database:

```
!sqlplus $ADW_USER/$ADW_PASSWORD@$ADW_SID
```

If it’s successful, you should see messages similar to:

```
SQL*PLUS Release 19.0.0.0.0 - Production on Tue Dec 17 16:14:32 2019
Copyright (c) 1982, 2019, Oracle. All rights reserved.
Last Successful login time: Mon Dec 16 2019 14:19:21 -08:00
Connected to:
Oracle Database 18c Enterprise Edition Release 18.0.0.0.0 - Production
   Version 18.4.0.0.0
SQL>
```

9. Define a URI as your connection source:

```
uri=f'oracle+cx_oracle://{os.environ["ADW_USER"]}:{os.environ["ADW_PASSWORD"]}@{os.environ["ADW_SID"]}''
```

10. In a different cell, import sqlalchemy and pandas, and then create an engine to connect to your database. Define your SQL query and pass it to the read_sql() method that is part of the Pandas Python library:

```
from sqlalchemy import create_engine
import pandas as pd
engine = create_engine(uri)
ds_01 = pd.read_sql('SELECT * from <table_name>', con=engine)
```

The returned object is a Pandas dataframe.

You can access notebook examples within notebook sessions that show you the different steps involved in connecting and querying data from ADW and other data sources.

**Connecting to Data on OCI Streaming**

The kafka-python Python client library is available in the notebook session. It is a client library for the Apache Kafka distributed stream processing system and it allows data scientists to connect to the Streaming service using its Kafka-compatible API. We provide the streaming.ipynb notebook example in the notebook session.
environment. It is a step-by-step approach to producing and consuming messages to and from a stream. The example includes:

• Creating a Stream Pool and a Stream.
• Storing your Streaming Credentials as Secrets in an OCI Vault.
• Retrieving your Secrets from the Vault.
• Producing Messages to a Stream.
• Consuming Messages from a Stream.

**Connecting to Data Using Oracle Vault**

In addition, you can use the OCI Vault service to centrally manage the encryption keys that protect your data and the credentials that you use to securely access resources. You can use the vault.ipynb example notebook to learn how to use vaults with Data Science, it includes:

• Creating a vault.
• Creating a key.
• Working with secrets.
• Listing resources.
• Deleting secrets, keys, and vaults.

**About Conda Environments**

We recommend that you use conda environments to package your Python dependencies inside your notebook sessions. Each conda environment that you create in your notebook session can correspond to a different notebook kernel in JupyterLab. Conda environments allow you to run notebooks in different kernels. Each kernel has a set of Python libraries associated with it. The base install has a very minimal set of libraries installed. The service is designed to use conda environments.

The notebook session environment includes the `odsc conda` CLI tool and the conda Environment Explorer.

The odsc conda CLI tool allows you to install, browse, search, and publish conda environments. You can access the odsc conda CLI documentation by executing `odsc conda -h` in a terminal window tab of your notebook session.

The Environment Explorer in JupyterLab helps you browse and search conda environments.

Although the conda CLI is available in a notebook session, we recommend that you use odsc conda to browse, install, clone, publish, and delete conda environments. It is preinstalled in notebook sessions and is available in a terminal window tab. The odsc conda CLI installs the necessary dependencies in your conda to make it available as a kernel in JupyterLab and creates the required manifest file that is necessary for each conda environment.

The Python3 conda environment is preinstalled in the notebook session. This conda environment is a Python 3 based conda environment and has a minimal set of libraries installed. We recommend that you install at least one Data Science conda environment or create your own.

**Important:**

Ensure that your VCN and subnet are configured to route traffic through either the NAT gateway or the service gateway so that the conda environments can be listed.

**Viewing the Conda Environments**

The Data Science service offers a series of prebuilt conda environments, and you can access them in the JupyterLab Launcher tab by clicking Environment Explorer to open in a new tab. It allows you to:

• Browse existing conda environments.
• Search conda environments.
• Install prebuilt conda environments in your notebook session using the provided instructions.
• When a conda is installed, you can clone it.
• Publish an installed conda environment to an Object Storage bucket that you own using the provided instructions.

Start using the **Environment Explorer** by browsing through these categories of conda environments by clicking each button. Notice that each environment category has a different tab color. Each environment is displayed in a separate environment card. Each version of an environment has its own separate card.

New conda environments are listed first and marked **NEW** at the top of the card. While deprecated environments are marked **Deprecated** next to the version number.

You can filter the cards using the buttons. For example, click **Published Conda Environments** to only view the published environments. By default, deprecated environments aren't displayed so you have to select **Show Deprecated** to see them. You can also filter by shape by clicking **CPU** or **GPU**. The environment buttons and **Show Deprecated** check box show the number of environments based on what is being filtered.

Searching is predictive based on the text you enter so you are advanced to the card with the highest occurrence of the entered text. The text is highlighted in yellow so that you easily can find it. You can search in these ways:

• Token returns items that are a fuzzy match of Token
• Example Token returns items that are a fuzzy match of Example and Token
• Example | Token returns items that are a fuzzy match of Example or Token
• "Example Token" returns items that are an exact match of Example Token
• "Token returns items that include Token
• !Token returns items that do not include Token
• ^Token returns items that start with Token
• !^Token returns items that do not start with Token
• Token$ returns items that end with Token
• !Token$ returns items that do not end with Token

Tip:
The bottom left displays the Python conda kernel and the state of the notebook next to the icons. You can change the conda environment by clicking this name or the name in the upper right corner of a notebook.

All Conda Environments
The All Conda Environments tab provides a card list of all the Data Science, Installed, and Published Conda Environments, see Installing Conda Environments in Your Notebook Session on page 1424 and Publishing a Conda Environment to an Object Storage Bucket in Your Tenancy on page 1426.

Data Science Conda Environments
The Data Science Conda Environments tab is in the Environment Explorer tab. This tab lists the conda environments that are offered in the Data Science service. These environments are curated by the Data Science service team. The environments are focused on providing specific tools and a framework (for example, PySpark) to do machine learning work (for example, General Machine Learning for GPUs). Or providing a comprehensive environment to solve business use cases.

You can use the odsc conda CLI to list Data Science conda environments directly from a terminal window with:

    odsc conda list

You can use the optional arguments -o to list the published conda environments or -l to list the Installed Conda Environments.

Each Data Science conda environment comes with its own set of notebook examples, which help you get started with the libraries installed in the environment. These environments are updated regularly, and new ones are periodically added to the list, see Data Science Environments on page 1396.

Note:
Older versions of a given Data Science conda environment remain available for installation. To use a Data Science conda environment, you must install it in your notebook session.

Caution:
To access the Data Science conda environment in your notebook session, you must configure your VCN and subnet so that traffic is routed through either the service or the NAT gateway. Otherwise, your notebook session cannot read the Data Science Environments.

Installed Conda Environments
The Installed Conda Environments tab in the Environment Explorer tab lists the conda environments that are currently installed and available to use in your notebook session.

Important:
All new notebook sessions have no conda environments installed so you have to install one of the Data Science conda environments, see Installing Conda Environments in Your Notebook Session on page 1424.

You can also create a conda environment in your notebook session. All created conda environments are in the Installed Conda Environments category.
You can install either Data Science or published conda environments. All Installed Conda Environments are stored in your Block Volume in the `/home/datascience/conda` directory.

When a notebook session is deactivated and reactivated, all previously installed conda environments are available to use again. Reactivation ensures that you don't have to reinstall Python dependencies after activating a notebook session.

### Published Conda Environments

The **Published Conda Environments** tab in the **Environment Explorer** tab lists all the Published Conda Environments that are available in your designated Object Storage bucket.

**Important:**

Before being able to list a published conda environment, you need to run `odsc conda init` specifying your bucket name and namespace, see **Publishing a Conda Environment to an Object Storage Bucket in Your Tenancy** on page 1426.

Alternatively, you can use the `odsc conda` CLI to list published conda environments directly from a terminal window by executing:

```
odsc conda list -o
```

If you haven't published any conda environments, then this tab is blank.

After a conda environment is installed in a notebook session, you can run notebooks, install additional Python libraries, and modify the versions of libraries inside that conda environment. Publishing a conda environment allows you to save or archive the conda environment to an Object Storage bucket that you manage.

Following are some of the benefits to publishing a conda environment:

**Ability to share with a team:**

Once a conda environment is published, it becomes available to other team members who have access to the same Object Storage bucket. You can install previously Published Conda Environments in your notebook session in the same way that you can install pre-built Data Science Environments. This lets data scientists manage and share environments across teams. You can share conda environments across notebook sessions, which was not possible previously.

**Model reproducibility:**

Whenever a model is saved to the model catalog, ADS allows you to publish the conda environment that the model was trained in. ADS keeps a reference of that environment in the `runtime.yaml` file, which is part of the model artifact. If you need to audit a model, you retrieve the exact conda environment that the model was trained in by reinstalling the training conda environment that is referred to in your `runtime.yaml` file.

**Important:**

Before you can publish environments, you need to specify the namespace and the bucket that you want to use to store the conda environments. You do this with the `odsc conda init` command. Make sure that you use either resource principals, or that you have setup the proper configuration and key files to let `odsc conda` read and write to the Object Storage bucket.

### Data Science Environments

All Data Science conda environments come with the OCI Python SDK and the **ADS SDK**. The version of ADS that comes with all condas includes all the functionalities of the library except for AutoML and model explanations (MLX) and is called ads-lite. AutoML and MLX are found only in the General Machine Learning for the CPU and GPU conda environments.
The conda environments use the CPU VM shape (VM.Standard2.X, VM.Standard.E2.X) environments and GPU (VM.GPU2.1 [NVIDIA P100], VM.GPU3.X [NVIDIA V100]) Compute shapes.

Accessing the Conda Environment Notebook Examples on page 1429 describes how to locate and access the included interactive example notebooks, and what each of them can be used for.

**Data Exploration and Manipulation**

*Data Exploration and Manipulation for CPU on Python 3.7 (version 1.0)*

### Deprecated Conda Environment Families

These conda environment families are deprecated:

**Classic CPU Notebook Session Kernel (version 1.0)**

A description of the Classic CPU Notebook Session Kernel (version 1.0).

<table>
<thead>
<tr>
<th>August 11, 2020</th>
</tr>
</thead>
</table>

### Release Date

<table>
<thead>
<tr>
<th>CPU Notebook Session Kernel (version 1.0)</th>
</tr>
</thead>
</table>

### Description

This conda environment corresponds to the CPU notebook session available in the August 2020 release. We provide this conda as a starting point to help you migrate to the other modular conda environments. This conda environment is no longer enhanced or modified.

### Python Version

3.6

### Slug Name

classic_cpu

### Object Storage Path

oci://service-conda-packs@id19sfrrra6z/service_pack/cpu/Classic CPU Notebook Session Kernel/1.0/classic_cpu
### Release Date

**August 11, 2020**

#### Top Libraries
- Oracle ADS v0+untagged.4506.g5075d66
- Oracle AutoML v0.4.2
- Oracle MLX v1.0.11
- scikit-learn v0.21.3
- xgboost v0.90
- lightGBM v2.3.1
- TensorFlow v2.0.0
- torch v1.0.0
- Keras v2.3.0
- Mxnet v1.5.0
- pyod v0.8.1

For a complete list of preinstalled Python libraries, see `classic-cpu.txt`.

#### Example Notebooks
- `getting-started.ipynb`
- `adsdataset_working_with.ipynb`
- `autonomous_database.ipynb`
- `binary_classification_attrition.ipynb`
- `binary_classification_transportation.ipynb`
- `class_weighting.ipynb`
- `classification_adult.ipynb`
- `classification_wine.ipynb`
- `data_visualizations.ipynb`
- `dataflow.ipynb`
- `datasetfactory_loading_data.ipynb`
- `mlx_ale.ipynb`
- `mlx_pdp_vs_ale.ipynb`
- `mlx_whatif.ipynb`
- `mlx_classification_attrition.ipynb`
- `mlx_classification_wine.ipynb`
- `mlx_regression_housing.ipynb`
- `model_catalog.ipynb`
- `model_deployment.ipynb`
- `model_evaluation.ipynb`
- `model_from_other_library.ipynb`
- `pyod_classification_fraud.ipynb`
- `projects.ipynb`
- `streaming.ipynb`
- `transforming_data.ipynb`
- `vault.ipynb`

**Natural Language Processing**

**Natural Language Processing for CPU on Python 3.7 (version 1.0)**

A description of the Natural Language Processing for CPU on Python 3.7 (version 1.0) conda environment.
### Description
The Natural Language Processing (NLP) for CPU conda environment is designed for users interested in working with text datasets and performing natural language processing tasks. The conda environment contains a curated list of libraries and frameworks common for natural language processing workloads. The libraries include NLTK, Hugging Face’s Transformers library, various wrapper around BERT like keybert, and NLP and deep-learning accelerating frameworks like pytorch-lightning and simpletransformers. The notebook examples included with this conda environment demonstrate how to use the packages to work with text data and perform tasks such as key-phrase extraction and part-of-speech tagging. Also, they showcase how to use the ADS built-in text support functionalities, such as data extraction from text documents in Object Storage.

### Python Version
3.7.8

### Slug Name
nlp_p37_cpu_v1

### Object Storage Path

**PyPGX**

*Parallel Graph AnalytiX 21.3 for CPU on Python 3.8*

A description of the Parallel Graph AnalytiX 21.3 for CPU on Python 3.8 (version 1.0) conda environment.
Python Parallel Graph AnalytiX (PyPGX) is a graph toolkit that provides a graph query language, optimized analytic algorithms, and graph machine learning. You can use it to extract hidden insights in datasets at scale and with high performance. Graph analysis is a data analysis methodology in which the dataset is represented as a graph. The graph vertices correspond to the data entities and edges to the relationships between them. Analyzing these graphs takes into account the fine-grained, arbitrary relationships that naturally occur in many datasets. This also enables the discovery of valuable insights about the data.

**Description**

This conda allows data scientists to leverage Apache Spark including the machine learning algorithms in MLlib. Use PySparkSQL to analyze structured and semi-structured data that is stored on Object Storage. PySpark leverages the full power of a notebook session by using parallel computing. For larger jobs, you can develop Spark applications and submit them to the Data Flow service. Support for PySpark version 3.0.2 was added. This version is compatible with the OCI Data Flow service.

| **Example Notebooks** | • getting-started.ipynb  
• api_keys.ipynb  
• dataflow.ipynb  
• model_catalog.ipynb  
• model_deployment.ipynb  
• project.ipynb  
• pyspark.ipynb  
• Develop and run PySpark applications in the notebook and deploy them to Data Flow without blocking the notebook.  
• vault.ipynb |

Use these configuration steps so that PySpark can connect to Object Storage:
1. Authenticate the user by generating the OCI configuration file and API keys, see SSH keys setup and prerequisites and Authenticating to the OCI APIs from a Notebook Session on page 1388

   **Important:**

   PySpark can't reach Object Storage if you authenticate using resource principals. Also, the key and configuration files can't have a passphrase.

   If you must have configuration and key files with a passphrase, you can download your files from Object Storage using the Python SDK, and then load the file in Spark context.

2. Configure the properties in the `/home/datascience/spark_config_dir/core-site.xml` file by providing your values between `<value> </value>`:

   - `fs.oci.client.hostname`
     The address of the Object Storage OCID of your tenancy (`ifs.oci.client.auth.tenantId:`).

   - `fs.oci.client.auth.userId`
     Your user OCID.

   - `fs.oci.client.auth.fingerprint`
     The fingerprint for the key pair being used.

   - `fs.oci.client.auth.pemfilepath`
     The full path and file name of the private key used for authentication.

   For details about these properties, see HDFS Connector for Object Storage.

**Conda Environment Manifest File and Metadata**

The `odsc conda` CLI generates the manifest file for each conda environment that contains the metadata for the environment. The metadata is displayed in each environment card displayed in the Environment Explorer tab. A manifest file, `<name>_manifest.yaml`, is stored under each conda environment directory in `/home/datascience/conda`.

An environment's metadata includes these parameters in the `manifest` section of the manifest YAML file:

`manifest_version`  

**Important:**

Do not modify this parameter.

The version of the current manifest file is updated by the `odsc conda` CLI after the environment is published so manually setting this value is not needed.
**name**

The name of the conda environment. This parameter is defined as `<environment-name>` in the `osdc` CLI commands.

**description**

A description of the conda environment, which is limited to 500 characters. Edit the manifest file directly if you want to modify the description.

**version**

The version of the conda environment. The version parameter does not necessarily reflect the version of any of the libraries installed in the conda environment. Versioning a conda environment allows you to keep track of environment lineage over time. This parameter is defined as `<environment-version>` in the `osdc` conda CLI commands.

**arch_type**

The type of hardware architecture supporting the conda environment at runtime. Two values are possible, `cpu` and `gpu`. Hardware checks are performed before installing a conda environment to a notebook session. The `odsc conda` check warns you of a mismatch between the notebook session architecture and the target architecture of the conda environment. Also, `odsc conda` detects the type of architecture of your notebook sessions, and sets the value to either `cpu` or `gpu` when you create a conda environment.

**notebooks**

| Important: |
| Do not modify this parameter. |

Instructs `odsc conda` which notebook examples are associated with this conda environment. Notebook examples are stored in `/home/datascience/conda/notebooks` and are deleted when you delete an installed conda environment.

**libraries**

Use this parameter to highlight a series of important libraries that are available in the conda environment. It is user-defined. You can modify the list if you decide to add new libraries or modify the versions of preinstalled libraries. These libraries are listed under Top Libraries in the environment card.

**commands**

Use this parameter to write commands to execute when a conda environment is installed. For example, some libraries require extra configurations and the storage of configuration files in a user's home directory. The `commands` parameter allows you to automate the configuration steps needed to run the conda environment. Supported commands include `MKDIR` to create directory, and `COPY` to copy files from the conda environment directory to some other path in `/home/datascience`.

You can look at the Data Science **Pyspark** conda environment for an example of an environment that applies the `COMMANDS` field.

**slug**

| Important: |
| Do not modify this parameter. |

A short string that uniquely identifies the conda environment. It is a combination of the name and version of the conda environment, which the `odsc conda` toolkit generates. This parameter is defined as `<environment-slug>` in the `odsc conda` CLI commands.

**type**

| Important: |
| Do not modify this parameter. |
The `odsc conda` CLI generates and edits this parameter, which defines the type of conda environment. There are two types, `data_science` and `user`. The `data_science` condas are defined and provided by the Data Science service team. A user-defined conda is a conda environment that a Data Science user creates or modifies.

**python**

The version of Python installed in the conda environment for documentation purposes. This parameter is user-defined. If you change the version of Python, ensure that you update this parameter in the manifest.

**pack_path**

Path to Object Storage where this conda environment is stored. This path is in the Data Science service tenancy when the environment is a Data Science environment. If the environment is published, the path is to a bucket in your (customer) tenancy. This parameter is updated after the environment is published.

**logo**

The associated conda environment logo. Not in use.

The remaining parameters defined in the manifest file are standard parameters expected by the `conda` CLI command. Whenever a conda environment is installed, created, cloned, or published, `odsc conda` modifies the content of the manifest file to reflect the current changes that you made. It includes changes to the manifest parameters in the preceding list made using `odsc conda` commands and changes to the list of Python libraries installed in the environment.

## Installing Conda Environments in Your Notebook Session

You can install either a Data Science or a Published Conda conda environment by clicking Install in the environment card. You can copy and execute the code snippet in a terminal window. The new environment is installed in a Block Volume under `/home/datascience/conda` folder. The folders in `/home/datascience/conda` correspond to the slugs of the conda environments.

Once the environment is ready to be used as a notebook kernel, the new environment entry is listed in the Installed Conda Environments tab in the Environment Explorer tab. Then a new kernel for that particular conda environment is available in the JupyterLab Launcher tab in the Notebook category. You can start working in that conda environment by clicking the environment kernel icon to open a new tab to open a new notebook file.

Alternatively, you can launch a new notebook by clicking File, select New, and then select a kernel for your notebook session.

**Important:**

Because all Installed Conda Environments are stored on the block volume drive in `/home/datascience`, these environments are available once the session is activated. You do not need to reinstall the conda environments after you deactivate the notebook session.

You can install a conda environment directly by using either of the following the `odsc conda` commands in a JupyterLab terminal window tab:

```bash
odsc conda install -s <environment-slug>
```

```bash
odsc conda install -n <environment-name> -v <environment-version>
```

The `<environment-slug>` is the slug of the environment you want to install. Alternatively, you can specify the name and version of the environment you want to install. The slug, name, and version of all environments are listed in each environment card in the Environment Explorer tab. You are prompted to change the version of the environment, which is optional.
By default, `odsc conda` looks for Data Science Conda environments with matching `<environment-slug>` value, or `<environment-name>` and `<environment-version>`. You can target the Object Storage bucket hosting your Published Conda Environments by adding the optional `-o` flag. For example:

```
odsc conda install -o -s <environment-slug>

odsc conda install -o -n <environment-name> -v <environment-version>
```

The `odsc conda` accesses your Object Storage bucket to find the conda environment with a matching slug or a combination of the name and version. Each environment manifest file is stored in Object Storage as object metadata. Then `odsc conda` queries the Object Storage object metadata API to find the correct conda environment to download and install in your notebook session.

### Cloning a Conda Environment in Your Notebook Session

After a conda environment is installed, you can clone it. Cloning provides you a sandbox environment that you can modify by installing more libraries. The original environment remains available locally in your notebook session and is unmodified. You can clone an Installed Conda Environment by clicking **Clone** in an environment card. Copy the `odsc conda clone` command, and then execute it in a terminal window tab. Provide a new name for the cloned environment and (optionally) a version number.

You can also clone directly in the terminal using this `odsc conda` command:

```
odsc conda clone -f <environment-slug> -e <target-environment-name>
```

The command defines the slug of the source environment and the name of the target environment. You are prompted to change the version of the conda environment, which is optional.

#### Important:

Your cloned environment can't have the same name and version as the source conda environment you want to clone. You can use the same name (with the command `odsc conda clone -f <environment-slug>`), but you must change the version.

#### Important:

Access the public internet from your notebook session to be able to clone a conda environment.

### Creating a Conda Environment

You can create a conda environment from a conda compatible environment file (`environment.yaml`) using the `odsc conda create` command. By default, the `create` option also installs additional libraries to ensure that the conda environment is compatible with JupyterLab and the OCI services. The most important libraries that are added are `oci.ipykernel`, `jupyterlab`, `nb_conda_kernels`, and `cx_oracle`. You can overwrite this default behavior by adding the optional argument `--empty`, `-e` then no extra libraries are added to your conda environment.

#### Note:

We strongly recommend that you **do not** use the `--empty` argument. Because the conda environment that you create may **not** be accessible as a kernel in JupyterLab.
You can create a conda environment from a conda compatible environment file with:

```
odsc conda create -n <environment-name> -v <environment-version> -f <environment.yaml>
```

If you want to create the environment from an empty base, use the `--empty` optional argument:

```
odsc conda create -n <environment-name> -v <environment-version> -f <environment.yaml> --empty
```

### Publishing a Conda Environment to an Object Storage Bucket in Your Tenancy

Before you can publish a conda environment or install a published conda environment, you need to configure `odsc conda` to use an Object Storage bucket using this command:

```
odsc conda init -b <your-bucket-name> -n <your-tenancy-namespace>
```

The `<your-bucket-name>` is the name of the object storage bucket in your tenancy containing Published Conda Environments, and `<your-tenancy-namespace>` is the namespace of your tenancy. You only need to run the `odsc conda init` command once per notebook session. Your bucket and namespace values persist through deactivation and activation of the notebook session.

You can publish a conda environment that you have installed in a notebook session. Publishing a conda environment consists of creating a **pack** of a conda environment and uploading it to a specified Object Storage. This allows conda environments to be shared among colleagues or to persist them across notebook sessions. We recommend that you publish conda environments to ensure that a model training environment can be reproduced.

You can publish a conda by clicking **Publish** in an installed environment card. Copy the code snippet, and then run it in a terminal window tab:

```
odsc conda publish -s <environment-slug>
```

The `<environment-slug>` is the slug of the environment you want to publish.

**Important:**

ADS warns you when you create the model artifact to publish your conda environment before saving the model to the model catalog. If you have already published the conda environment, you can provide ADS with the path on Object Storage to that conda environment when you save the model. References to training environments are stored in the `runtime.yaml` file that is part of the model artifact, see Managing Models on page 1464.

### Deleting an Installed Conda Environment from Your Notebook Session

You can remove any environment that is installed in your notebook session in the **Environment Explorer** tab. Find the environment card of the Installed Conda Environment and click **Delete**. Copy the code snippet, and then execute it in a terminal window tab.

The `odsc conda` command is:

```
odsc conda delete -s <environment-slug>
```

You can delete a published environment by manually removing it from the Object Storage bucket hosting your published conda environments.

It's possible to remove Published Conda environments so that they are no longer available for installation. You manually remove it from Object Storage the same way that you would delete any file from **Object Storage**.
Modifying an Installed Conda Environment in Your Notebook Session

There are multiple ways to modify the libraries in a conda environment. You can directly install libraries using pip or conda commands in a notebook. The libraries are installed in the conda environment corresponding to the notebook kernel.

Alternatively, you can install libraries from a terminal window tab. The conda environment has to be activated in the terminal and then you use the conda install command:

```
source activate <path-to-the-conda-environment> conda install --file <path-to-requirements-file>
```

The <path-to-the-conda-environment> is the path to the installed conda environment you want to install the libraries in. All Installed Conda Environments are stored in the /home/datascience/conda/<environment-slug> directory. The <path-to-requirements-file> is the path to the file listing all the libraries you want to install in the conda environment.

Selecting a Kernel to Run a Notebook

After a conda environment is installed in the notebook session, the corresponding notebook and console kernels are created in the JupyterLab Launcher tab. Each kernel label is the slug name of the conda environment. The slug name is a combination of the name and version of the conda environment. You can create a notebook that runs in a given conda environment by clicking a kernel icon.

Alternatively, you can launch a new notebook by clicking File, select New, and then select a kernel for your notebook. You are prompted with a kernel selection for your new notebook session. When you open a new notebook, the first cell contains useful tips that explains:

- How to check for public internet access:
  ```python
  import requests
  response = requests.get("https://oracle.com")
  assert response.status_code==200, "Internet connection failed"
  ```
- To set up the OCI configuration file and API key follow the instructions in the api_keys.ipynb notebook. Access it in the Launcher tab by clicking Notebook Examples, selecting the file, and then click Load Example.
- Typical cell imports and settings:
  ```python
  %load_ext autoreload
  %autoreload 2
  %matplotlib inline

  import warnings
  warnings.filterwarnings('ignore')

  import logging
  logging.basicConfig(format='%(levelname)s:%(message)s', level=logging.ERROR)

  import ads
  from ads.dataset.factory import DatasetFactory
  from ads.automl.provider import OracleAutoMLProvider
  from ads.automl.driver import AutoML
  from ads.evaluations.evaluator import ADSEvaluator
  from ads.common.data import MLData
  from ads.explanations.explainer import ADSExplainer
  from ads.explanations.mlX_global_explainer import MLXGlobalExplainer
  from ads.explanations.mlX_local_explainer import MLXLocalExplainer
  from ads.catalog.model import ModelCatalog
  from ads.common.model_artifact import ModelArtifact
  ```
- Useful environment variables

```python
import os

print(os.environ['NB_SESSION_COMPARTMENT_OCID'])
print(os.environ['PROJECT_OCID'])
print(os.environ['USER_OCID'])
print(os.environ['TENANCY_OCID'])
print(os.environ['NB_REGION'])
```

You can also change the conda environment selection after opening the notebook. The name of the kernel running the notebook is in the switch kernel button, which you click to select a new kernel. You are prompted to select a conda environment.

Alternatively you can click **Kernel**, then select **Change Kernel**. You are prompted to select a different conda environment, then click **Select**.

**Tips for Using GPUs**

From a JupyterLab terminal window, you can obtain the number of GPU machines and their specifications by entering this command:

`nvidia-smi`

The preinstalled GPU statistics allow you to monitor how the GPU machines are being used while building and training machine learning models. These statistics include utilization, memory, and power.

From a JupyterLab terminal window, enter:

`gpustat`

To get utilization, memory, and power statistics, enter:

`gpustat -u -p -c -i 3 --show-power`

The command details are in `gpustat`.

**Important:**

To delete the data stored in the memory of the GPU, we recommend that you shut down the kernel of the notebook running the GPU workload.
Selecting a Conda Environment to Run a Python Script

You can select a conda environment to run a Python script in the terminal. Activate the conda environment by running this command:

```
source activate <path-to-conda-environment>
```

After the conda environment has been activated, the slug of the environment appears between round brackets next to your terminal prompt. Any subsequent Python commands run in that terminal window tab runs in the active conda environment. To learn more about the conda CLI, see Conda Getting Started.

Accessing the Conda Environment Notebook Examples

There are various interactive example notebooks, included in the notebook session environment. You can use them to learn how to use the Data Science service. These examples are designed to help you understand its various features and solve business problems.

In contrast with previous releases of the notebook session environment, no notebook examples are preinstalled. Instead, notebook examples are attached to the service managed conda environments and are downloaded along with the conda environment when you install a Data Science conda environment in your notebook session. Notebooks are stored locally on your Block Volume drive in `/home/datascience/conda/notebooks/`.

Caution:
The notebook examples stored in `/home/datascience/conda/notebooks/<environment-slug>` are deleted when a conda environment is deleted. Do not store any of your notebooks in `/home/datascience/conda/notebooks`, because the notebooks are removed when a conda environment is deleted.

Use Opening Notebook Sessions on page 1383 to open the JupyterLab environment. The Launcher tab is opened by default. You can access the library of notebook examples in these two ways:

- Click the File menu, select New, and then select Notebook Examples.
- In the Launcher tab, click Notebook Examples.

Select a conda environment and an example notebook, and then click Load Example.

You can open a new launcher tab by clicking the plus sign (+) in the File Browser. In the Launcher tab, you can use these buttons:

Python 3

The Python 3 kernel is the conda environment contains a minimal set of libraries, including oci, cx_oracle, and numpy. We recommend that you install or create more conda environments.

A new notebook opens and the first cell contains useful tips that are the same as when you create a new notebook.

Notebook Examples

Provides a list of the notebook examples. Each opens in a new tab when loaded. Overview of the Notebook Examples on page 1430 contains a list of the examples you can choose to learn from.

If this button isn't displayed, then click the File menu, select New, and then select Notebook Examples to choose a notebook.

Each example is loaded with a temporary file name that you can change by right-clicking the tab name, and then clicking Rename Notebook.... Enter a new name, then click Rename.

Terminal

Opens a system shell terminal in a new tab.
Text File

Opens a text file in a new tab.

Show Contextual Help

Provides JupyterLab help about a function you select.

Overview of the Notebook Examples

The example notebooks demonstrate:

- Various features of ADS.
- How to incorporate various Data Science features like model catalog and other OCI services into your notebooks.
- Specific model business use cases.
- Various ways to classify data.

About the Model Catalog

Learn how to work with your Data Science model catalog.

Model Catalog

The model catalog is a centralized and managed repository of model artifacts. Models stored in the model catalog can be shared across members of a team and they can be loaded back into a notebook session. For example, models in the model catalog can also be deployed as HTTP endpoints using a model deployment resource.

A model entry in the model catalog has two components:

- A model artifact that is a ZIP archive that includes the saved model object. A Python script providing instructions about how to use the model for inference purposes (score.py), and a file documenting the runtime environment of the model (runtime.yaml). You can obtain artifact, score.py, and runtime.yaml examples from Github.
- Metadata about the provenance of the model including Git-related information and the script or notebook used to push the model to the catalog. You can document the resource that the model was trained in (either a notebook session or job run), and the Git reference to the training source code. This metadata is automatically extracted from your notebook session environment if you save your model artifact with ADS.

Model artifacts stored in the model catalog are immutable by design. Any changes you want to apply to a model requires that a new model is created. Immutability prevents unwanted changes, and ensures that any model in production can be tracked down to the exact artifact behind the model predictions.

Important:

Artifacts have a maximum size limit of 100 MB when saved from the console. The size limit is 2 GB from ADS, the OCI SDKs, and CLI.

Documenting Your Models

You can use these options to document how you trained the model, the use case, and the necessary prediction features.

Note:

ADS automatically populates the provenance and taxonomy on your behalf when you save a model with ADS.

Provenance

Model provenance is documentation that helps you improve the model reproducibility and auditability. These parameters are automatically extracted when you save a model with the ADS SDK.

When you are working inside a Git repository, ADS is able to obtain your Git information and populate the model provenance metadata fields automatically for you.

Taxonomy

Taxonomy allows you to describe the model you are saving to the model catalog. You can use preset fields to document the:

- Machine learning use case
- Machine learning model framework
Model Introspection Tests

Introspection in the context of machine learning models is a series of tests and checks run on a model artifact to test all aspects of the operational health of the model. These tests target the `score.py` and `runtime.yaml` with the goal to capture some of the most common errors and issues of the model artifact. Introspection tests results are part of the pre-defined model metadata. If you save your model using the Console, you can store the test results in JSON format in the Artifact Test Results field when you select Document model taxonomy. If you decide to save the model using the OCI Python SDK, use the `ArtifactTestResults` metadata key.

As part of our model artifact template, we included a Python script that contains a series of introspection test definitions. These tests are optional and you can run them before saving the model to the model catalog. You can then save the test results as part of the model metadata to display in the OCI Console.

Our Data Science blog contains more information about using model introspection.

Model Input and Output Schemas

The schema definition is a description of the features that are necessary to make a successful model prediction. The schema definition is a contract that defines what the required input payload that clients of the model must provide. The input and output schema definitions are used only for documentation purposes in this release of the model catalog. Schemas are in JSON file format.

You will likely want to define both schemas. At a minimum, an input schema is needed for any model predictions.

The output schema may not always be necessary. For example, when the model is returning a simple floating point value, there’s not as much value in defining a schema for such a simple output. You could convey that information in the description of the model.

Preparing a Model Artifact

After you have trained a model, you create the model artifact to save with your model in a model catalog. This creates centralized storage of model artifacts and enables you to track model metadata.

A model artifact is a ZIP archive of the files necessary to deploy your model as a model deployment or load it back in a notebook session.

We have provided various model catalog examples that include model artifacts for a variety of machine learning frameworks and model formats. We have examples for ONNX, Sk-learn, Keras, PyTorch, LightGBM, and XGBoost models. Get started by obtaining our model artifact template, which includes these files:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>score.py</code></td>
<td>Contains your custom logic for loading serialized model objects to memory, and define an inference endpoint (predict()).</td>
</tr>
<tr>
<td><code>runtime.yaml</code></td>
<td>Provides instructions about which conda environment to use when deploying the model using a Data Science model deployment.</td>
</tr>
<tr>
<td><code>README.md</code></td>
<td>Gives you a series of step-by-step instructions to prepare and save a model artifact to the model catalog. We highly recommend that you follow these steps.</td>
</tr>
<tr>
<td><code>artifact-introspection-test/requirements.txt</code></td>
<td>Lists the third-party dependencies that you must install in your local environment before running introspection tests.</td>
</tr>
<tr>
<td>File</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>artifact-introspection-test/model_artifact_validate.py</td>
<td>Provides an optional series of test definitions that you can run on your model artifact before saving it to the model catalog. These model introspection tests capture many of the most common errors when preparing a model artifact.</td>
</tr>
</tbody>
</table>

The model artifact directory structure should match this example:

```
|-- runtime.yaml
|-- score.py
|--<your-serialized-model>
|--<your-custom-module.py>
```

**Important:**

More Python modules that are imported in `score.py`. Any code used for inference should be zipped at the same level as `score.py` or any level below the file. If any required files are present at folder levels above the `score.py` file, they are ignored and could result in deployment failure.

**The score.py File**

This file contains the function definitions that are necessary to load your model to memory and make predictions. The two functions are called, `load_model()` and `predict()`. The function parameters are *not* customizable. For example, you can define data transformations in `predict()` before calling the inference method of your estimator object. You can load more than one estimator object to memory and perform an ensemble evaluation. The `predict()` function is behind the `/predict` endpoint of your model deployment. Ensure that the data type of the `data` parameter in `predict()` matches the payload format you expect with model deployment.

**Important:**

Model deployment only supports JSON payload. Make sure that the data parameter in `predict()` is a JSON blob.

This `score.py` template uses the `load_model()` to return the model estimator object. The `predict()` function takes in data and the model object returned by the `load_model()`. Both functions are customizable and require definitions. The body of `predict()` can include data transformations and other data manipulation tasks before a model prediction is made. Any custom Python modules can be imported in `score.py` if they are available in the artifact file or as part of the conda environment used for inference purposes like the template.

**Tip:**

You can define other helper functions in `score.py` that are invoked in `predict()`. For example, you could define a `data_transformation()` function that defines custom transformations.

Review the [Best Practices for Model Artifacts](#) on page 1439 to help you effectively create these files.

We have provided various model catalog examples and templates including the `score.py` files. We have examples for ONNX, scikit-learn, Keras, PyTorch, LightGBM, and XGBoost models.

**score.py Template**

```
""
    This boilerplate is based on a sklearn model serialized with cloudpickle.
    
    import json
    import os
""
```
from cl oudpickle import cl oudpickle

""
Replace with your own model object and your own serialization library
e.g. pickle, onnx, etc.
""
model_name = 'model.pkl'

""
Inference script. This script is used for prediction by scoring server
when schema is known.
""

def load_model(model_file_name=model_name):
    ""
    Loads model from the serialized format
    Returns
    -------
    model: a model instance on which predict API can be invoked
    ""
    model_dir = os.path.dirname(os.path.realpath(__file__))
    contents = os.listdir(model_dir)
    if model_file_name in contents:
        with open(os.path.join(os.path.dirname(os.path.realpath(__file__)),
                               model_file_name), "rb") as file:
            return cloudpickle.load(file)
    else:
        raise Exception('{0} is not found in model directory
                        {1}'.format(model_file_name, model_dir))

def predict(data, model=load_model()):
    ""
    Returns prediction given the model and data to predict
    Parameters
    --------
    model: Model instance returned by load_model API
    data: Data format as expected by the predict API of the core estimator.
    For eg. in case of sckit models it could be numpy array/List of list/Panda
    DataFrame
    Returns
    ------
    predictions: Output from scoring server
    Format: {'prediction':output from model.predict method}
    ""
    from pandas import read_json, DataFrame
    from io import StringIO
    data = read_json(StringIO(data)) if isinstance(data, str) else
    DataFrame.from_dict(data)
    pred = model.predict(data).tolist()
    return {'prediction': pred}

The ADS ADSModel.prepare() object uses the ONNX format by default. You can save a model to
the model catalog from a laptop or any other location to build an artifact manually from scratch using the
prepare_generic_model() method. These are examples of how you can modify score.py to use
prepare_generic_model() for different types of models:

The runtime.yaml File

In addition to score.py, the runtime.yaml file is required to be in your model artifact. The purpose of
runtime.yaml is:
To provide the necessary runtime conda environment reference for model deployment purposes. This is required if you want to deploy your model using the model deployment feature of the Data Science service.

We have provided various model catalog examples including `runtime.yaml` files.

Following is a description of each field in `runtime.yaml`. As the model artifact structure changes, this file evolves and so does the version. These are the fields for the current `MODEL_ARTIFACT_VERSION (3.0)`.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MODEL_ARTIFACT_VERSION</td>
<td>The version of this artifact format. This version is 3.0. This is automatically extracted by ADS when the model is saved in a notebook session.</td>
</tr>
<tr>
<td>MODEL_DEPLOYMENT.INFERENCE_CONDA_ENV.INFERENCE_ENV_SLUG</td>
<td>The slug of the conda environment you want to use for deployment and scoring purposes. In most cases, the inference environment is the same as the training environment thought that does not have to be the case. For example, you can train a model in one conda environment, serialize it as an ONNX model and then use the ONNX conda environment to deploy it.</td>
</tr>
<tr>
<td>MODEL_DEPLOYMENT.INFERENCE_CONDA_ENV.INFERENCE_ENV_TYPE</td>
<td>The type of the conda environment you want to use for deployment and scoring purposes. Two possible values either data_science or published.</td>
</tr>
<tr>
<td>MODEL_DEPLOYMENT.INFERENCE_CONDA_ENV.INFERENCE_ENV_PATH</td>
<td>The path on Object Storage of the conda environment you want to use for deployment and scoring purposes. The path follows this syntax, <code>oci://&lt;bucket-name&gt;@&lt;namespace&gt;/&lt;file-path&gt;</code>.</td>
</tr>
<tr>
<td>MODEL_DEPLOYMENT.INFERENCE_CONDA_ENV.INFERENCE_PYTHON_VERSION</td>
<td>The Python version of the conda environment you want to use for model deployment. The default version is python 3.6. The supported versions are python 3.6 and python 3.7.</td>
</tr>
</tbody>
</table>

**runtime.yaml Schema**

```yaml
{
    "title": "Model Artifact schema",
    "type": "object",
    "properties": { 
        "MODEL_ARTIFACT_VERSION": {"type":"string"},
        "MODEL_DEPLOYMENT": { 
            "type": "object",
            "title": "Model Deployment",
            "properties": { 
                "INFERENCE_CONDA_ENV": { 
                    "type": "object",
                    "title": "Inference Conda Env",
                    "properties": { 
                        "INFERENCE_ENV_SLUG": {"type":"string"},
                        "INFERENCE_ENV_TYPE": {"type":"string", "enum": ["published", "data_science"]},
                        "INFERENCE_ENV_PATH": {"type":"string"},
                        "INFERENCE_PYTHON_VERSION": {"type":"string"} 
                    } 
                } 
            } 
        } 
    } 
}
```
Data Science

Example File for Model Deployment

This is an example runtime.yaml file for a Data Science model deployment resource:

```
MODEL_ARTIFACT_VERSION: '3.0'
MODEL_DEPLOYMENT:
  INFERENCE_CONDA_ENV:
    INFERENCE_ENV_SLUG: envslug
    INFERENCE_ENV_TYPE: published
    INFERENCE_ENV_PATH: oci://<bucket-name>@<namespace>/<prefix>/
    <env>.tar.gz
    INFERENCE_PYTHON_VERSION: '3.7'
```

Additional Artifact Files

In addition to score.py and runtime.yaml, you can include any additional files that are necessary to run your model in your artifact. These might include:

- A serialized representation of your estimator object. For example, onnx, pk1, hdf5, or json.
- A CSV file, a lookup data table, and so on.
- Additional Python modules that are imported in score.py.

**Important:**

Additional Python modules that are imported in score.py. Any code used for inference should be zipped at the same level as score.py or any level below that. If any required files are present at folder levels above the score.py file, they are ignored and could result in deployment failure.

If you are saving your model using the OCI Console, CLI, or SDKs, just ZIP the files along with the score.py and runtime.yaml files.

If you are using ADS to save your model, then copy all the files in the directory where the artifact is temporarily created before saving the model to the catalog. ADS compresses the entire artifact directory and sends it to the model catalog.

**Note:**

The artifact has a size limit of 2 GB when the model is saved using ADS, the CLI, or SDKs. The limit is 100 MB when using the OCI Console.

Best Practices for Model Artifacts

**Writing a score.py File**

- Always ensure that the score.py and runtime.yaml files are in the top-level directory of your model artifact.

Any other files that need to be part of your artifact must be at the same level as those two files or in directories below them:

```
|-- runtime.yaml
`-- score.py
    `-- <your-serialized-models>
```

- Model deployment uses the score.py functions to load your model into memory and to make predictions.
• The function definitions, `load_model()` and `predict()`, are not editable. Only the body of these functions is customizable.
• The allowed path to write data to disk when using model deployment service is `/home/datascience`.
• You can access Object Storage using resource principals when the OCI identity permissions are defined correctly to enable it.

Packaging Custom Modules

Any custom module on which `score.py` or the serialized model depends should be written as separate Python scripts in the same top level directory as `score.py` or below. For example, `model.joblib` depends on a custom `DataFrameLabelEncoder` class, which is defined in the `dataframelabelencoder.py` script as in this example:

```python
from category_encoders.ordinal import OrdinalEncoder
from collections import defaultdict
from sklearn.base import TransformerMixin
from sklearn.ensemble import RandomForestClassifier
from sklearn.pipeline import make_pipeline
from sklearn.preprocessing import LabelEncoder

class DataFrameLabelEncoder(TransformerMixin):
    def __init__(self):
        self.label_encoders = defaultdict(LabelEncoder)

    def fit(self, X):
        for column in X.columns:
            if X[column].dtype.name in ['object', 'category']:
                self.label_encoders[column] = OrdinalEncoder()
                self.label_encoders[column].fit(X[column])
        return self

    def transform(self, X):
        for column, label_encoder in self.label_encoders.items():
            X[column] = label_encoder.transform(X[column])
        return X
```

The module is then imported by the `score.py` file:

```python
# Inference script. This script is used for prediction by scoring server when schema is known.

import json
import os
from joblib import load
import io
import pandas as pd
from dataframelabelencoder import DataFrameLabelEncoder

def load_model():
    # Loads model from the serialized format
    Returns
    -------
    model: a model instance on which predict API can be invoked
    
    model_dir = os.path.dirname(os.path.realpath(__file__))
```
```python
contents = os.listdir(model_dir)
model_file_name = "model.joblib"
# TODO: Load the model from the model_dir using the appropriate loader
# Below is a sample code to load a model file using 'cloudpickle' which
# was serialized using 'cloudpickle'
# from cloudpickle import cloudpickle
if model_file_name in contents:
    with open(os.path.join(os.path.dirname(os.path.realpath(__file__)),
                           model_file_name), "rb") as file:
        model = load(file)  # Use the loader corresponding to your model
else:
    raise Exception('{} is not found in model directory
{1}'.format(model_file_name, model_dir))

return model

def predict(data, model=load_model()) -> dict:
    
    Returns prediction given the model and data to predict

    Parameters
    ----------
    model: Model instance returned by load_model API
    data: Data format as expected by the predict API of the core estimator.
        For eg. in case of sckit models it could be numpy array/List of list/Panda DataFrame

    Returns
    -------
    predictions: Output from scoring server
        Format: { 'prediction': output from `model.predict` method }

    assert model is not None, "Model is not loaded"
    X = pd.read_json(io.StringIO(data)) if isinstance(data, str) else
    pd.DataFrame.from_dict(data)
preds = model.predict(X).tolist()
return { 'prediction': preds }
```

In the preceding example, the artifact structure should be:

```
|-- score.py
|-- dataframetablenonencoder.py
|-- model.joblib
|-- runtime.yaml
```

**Modifying load_model() and predict() signatures**

The `predict(data, model=load_model())` function expects the payload data and a model object and is returned by `load_model()` by default. Your use case may require that an additional parameter is passed to `predict()`. An example is a scaler or a lookup table. You can add parameters to those function if the parameter you add has a default value assigned.

In the following example, the predictions rely on a PCA model and a scaler object. It shows you how `predict()` can take an additional parameter called `scaler`. By default, the `load_scaler()` function returns a value to the `scaler` parameter. We recommend that you follow that pattern. If `predict()` or `load_model()` require
additional parameters, they must be set to default values returned by functions that are defined in score.py. This example adds parameters to predict():

```python
import json
import os
from cloudpickle import cloudpickle
model_pickle_name = 'pca.pkl'
scaler_pickle_name = 'scaler.pkl'

# Inference script. This script is used for prediction by scoring server when schema is known.

def load_model(model_file_name=model_pickle_name):
    ""
    Loads model from the serialized format
    Returns
    -------
    model:  a model instance on which predict API can be invoked
    ""
    model_dir = os.path.dirname(os.path.realpath(__file__))
    contents = os.listdir(model_dir)
    if model_file_name in contents:
        with open(os.path.join(os.path.dirname(os.path.realpath(__file__)),
                               model_file_name), "rb") as file:
            return cloudpickle.load(file)
    else:
        raise Exception('{} is not found in model directory
                        {}'.format(model_file_name, model_dir))

def load_scaler(model_file_name=scaler_pickle_name):
    ""
    Loads model from the serialized format
    Returns
    -------
    model:  a model instance on which predict API can be invoked
    ""
    model_dir = os.path.dirname(os.path.realpath(__file__))
    contents = os.listdir(model_dir)
    if model_file_name in contents:
        with open(os.path.join(os.path.dirname(os.path.realpath(__file__)),
                               model_file_name), "rb") as file:
            return cloudpickle.load(file)
    else:
        raise Exception('{} is not found in model directory
                        {}'.format(model_file_name, model_dir))

def predict(data, model=load_model(), scaler=load_scaler()):
    ""
    Returns prediction given the model and data to predict
    Parameters
    ----------
    model: Model instance returned by load_model API
data: Data format as expected by the predict API of the core estimator.
    For eg. in case of sckit models it could be numpy array/List of list/Panda DataFrame
    Returns
    -------
    predictions: Output from scoring server
    Format: {'prediction':output from model.predict method}
    ""
    from pandas import read_json, DataFrame
    from io import StringIO
```
X = read_json(StringIO(data)) if isinstance(data, str) else 
  DataFrame.from_dict(data)
X_s = scaler.transform(X)
return {'prediction':model.transform(X_s).tolist()[0]}

Testing a Model Artifact Before Saving

Before saving a model to the catalog, we recommend that you test the artifact thoroughly. This is a simple code snippet to test your model artifact before saving it to the catalog. The code snippet:

- Modifies the Python path by inserting the path to the model artifact.
- Loads the model into memory using load_model().
- Lastly, calls predict().

Before you run the code snippet, create a new notebook file in your notebook session, change the kernel, and then select the same conda environment that you want to use for model deployment (inference conda environment). Copy and paste the code snippet and execute the code.

Model Artifact Test Code Example

```python
import sys
from json import dumps

# The local path to your model artifact directory is added to the Python path.
# replace <your-model-artifact-path>
sys.path.insert(0, f"<your-model-artifact-path>")

# importing load_model() and predict() that are defined in score.py
from score import load_model, predict

# Loading the model to memory
_ = load_model()
# Making predictions on a JSON string object (dumps(data)). Here we assume
# that predict() is taking data in JSON format
predictions_test = predict(dumps(data), _)
predictions_test
```

The predictions_test method contains the predictions made by the model on the sample data JSON string payload. You should compare predictions_test against a known model outcome for a particular dataset. For example, data could be a sample of your training dataset. You can see an example in the Simple Model Deployment sample notebook about deploying an scikit-learn model.

Image Predictions Example

When doing image inferences, Base64 encoding is needed to send the image for inference. The model deployment HTTP endpoint doesn't support binary requests types directly.

The score.py predict() method handles the decoding from the received request as in this example

```python
"""
    Inference script. This script is used for prediction by scoring server
    when schema is known.
"""
import torch
import torchvision
import io
import base64
import numpy as np
```
from PIL import Image
import os

# COCO Labels
COCO_INSTANCE_CATEGORY_NAMES = ['__background__', 'person', 'bicycle', 'car', 'motorcycle']

model_name = 'PyTorch_Retinanet.pth'
def load_model(model_file_name=model_name):
    
    Loads model from the serialized format

    Returns
    -------
    model: Pytorch model instance
    
    model =
    torchvision.models.detection.retinanet_resnet50_fpn(pretrained=False,
    pretrained_backbone=False)
    cur_dir = os.path.dirname(os.path.abspath(__file__))
    model.load_state_dict(torch.load(os.path.join(cur_dir,
    model_file_name)))
    model.eval()
    return model

def predict(data, model=load_model()):
    
    Returns prediction given the model and data to predict

    Parameters
    ---------
    model: Model instance returned by load_model API
data: Data format in json

    Returns
    -------
    predictions: Output from scoring server
    Format: {'prediction':output from model.predict method}

    ---
    img_bytes = io.BytesIO(base64.b64decode(data.encode('utf-8')))
    image = Image.open(img_bytes)
    image_np = np.asarray(image)
    image_th = torch.from_numpy(image_np)
    image_th = image_th.permute(2, 0, 1)
    image_th = image_th.unsqueeze(0) / 255
    with torch.no_grad():
        pred = model(image_th)
        object_index_list = np.argwhere(pred[0].get("scores") > 0.5)
        label_index_list = pred[0].get("labels")
        labels = [COCO_INSTANCE_CATEGORY_NAMES[label_index_list[i]] for i in object_index_list]
        box_list = pred[0].get("boxes")
        boxes = [box_list[i].numpy().tolist() for i in object_index_list]
    return {'prediction': {
        'labels': labels,
        'boxes': boxes,
    }}
Preparing Model Metadata

Model metadata is optional though recommended.

Model Provenance Metadata

You can document the model provenance. This is optional. The following table lists the supported model provenance metadata:

<table>
<thead>
<tr>
<th>Metadata</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>git_branch</td>
<td>Branch of the Git repository.</td>
</tr>
<tr>
<td>git_commit</td>
<td>Commit id.</td>
</tr>
<tr>
<td>repository_url</td>
<td>URL of the remote Git repository.</td>
</tr>
<tr>
<td>script_dir</td>
<td>Local path to the artifact directory.</td>
</tr>
<tr>
<td>training_id</td>
<td>OCID of the resource used to train the model, notebook session or job run.</td>
</tr>
</tbody>
</table>

You can use and refer to these environment variables when you save a model with the OCI SDK:

- `NB_SESSION_OCID`

Example

```python
provenance_details = CreateModelProvenanceDetails(repository_url="EXAMPLE-repositoryUrl-Value",
                                                  git_branch="EXAMPLE-gitBranch-Value",
                                                  git_commit="EXAMPLE-gitCommit-Value",
                                                  script_dir="EXAMPLE-scriptDir-Value",
                                                  # OCID of the ML job Run
                                                  training_id="<<Notebooksession or ML Job Run OCID>>")
```

Model Taxonomy Metadata

You can document the model taxonomy. This is optional.

The metadata fields associated with model taxonomy allow you to describe the machine learning use case and framework behind the model. The defined metadata tags are the list of allowed values for use case type and framework for defined metadata and category values for custom metadata.

Preset Model Taxonomy

The following table lists the supported model taxonomy metadata:
<table>
<thead>
<tr>
<th>Metadata</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UseCaseType</td>
<td>Describes the machine learning use case associated with the model using one of the listed values like:</td>
</tr>
</tbody>
</table>
|                   | - binary_classification  
|                   | - regression  
|                   | - multinomial_classification  
|                   | - clustering  
|                   | - recommender  
|                   | - dimensionality_reduction/representation  
|                   | - time_series_forecasting  
|                   | - anomaly_detection  
|                   | - topic_modeling  
|                   | - ner  
|                   | - sentiment_analysis  
|                   | - image_classification  
|                   | - object_localization  
|                   | - other  |
| Framework         | The machine learning framework associated with the model using one of the listed values like: |
|                   | - scikit-learn  
|                   | - xgboost  
|                   | - tensorflow  
|                   | - pytorch  
|                   | - mxnet  
|                   | - keras  
|                   | - lightGBM  
|                   | - pymc3  
|                   | - pyOD  
|                   | - spacy  
|                   | - prophet  
|                   | - sktime  
|                   | - statsmodels  
|                   | - cuml  
|                   | - oracle_automl  
|                   | - h2o  
|                   | - transformers  
|                   | - nltk  
|                   | - emcee  
|                   | - pystan  
|                   | - bert  
|                   | - gensim  
|                   | - flair  
|                   | - word2vec  
|                   | - ensemble (more than one library)  
|                   | - other  |
| FrameworkVersion  | The machine learning framework version. This is a free text value. For example, PyTorch 1.9. |
| Algorithm         | The algorithm or model instance class. This is a free text value. For example, CART algorithm. |
| Hyperparameters   | The hyperparameters of the model object. This is a JSON format. |
**Example**

This example shows you how to document the model taxonomy, by capturing each key-value pair which creates a list of `Metadata()` objects:

```python
# create the list of defined metadata around model taxonomy:
defined_metadata_list = [
    Metadata(key="UseCaseType", value="image_classification"),
    Metadata(key="Framework", value="keras"),
    Metadata(key="FrameworkVersion", value="0.2.0"),
    Metadata(key="Algorithm", value="ResNet"),
    Metadata(key="hyperparameters", value="{"max_depth":"5","learning_rate":"0.08","objective":"gradient descent"}"
]
```

**Custom Model Taxonomy**

You can add your own custom metadata to document your model. The maximum allowed file size for the combined defined and custom metadata is 32000 bytes.

Each custom metadata has these four attributes:

<table>
<thead>
<tr>
<th>Field or Key</th>
<th>Required?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>Required</td>
<td>The key and label of your custom metadata.</td>
</tr>
<tr>
<td>value</td>
<td>Required</td>
<td>The value attached to the key.</td>
</tr>
<tr>
<td>category</td>
<td>Optional</td>
<td>The category of the metadata. Select one of these five values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Performance</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Training Profile</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Training and Validation Datasets</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Training Environment</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• other</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The category attribute is useful to filter custom metadata. This is handy when one has a large number of custom metadata for a given model.</td>
</tr>
<tr>
<td>description</td>
<td>Optional</td>
<td>A description of the custom metadata.</td>
</tr>
</tbody>
</table>

**Example**

This example shows how you can add custom metadata to capture the model accuracy, the environment, and the source of the training data:

```python
# Adding your own custom metadata:
custom_metadata_list = [
    Metadata(key="Image Accuracy Limit", value="70-90%",
    category="Performance",
```
Model Data Schemas Definition

You can document the model input and output data schemas. The input data schema definition provides the blueprint of the `data` parameter of the `score.py` file `predict()` function. You can think of the input data schema as the definition of the input feature vector that your model requires to make successful predictions. The output schema definition documents what the `predict()` function returns.

**Important:**

The maximum allowed file size for the combined input and output schemas is 32000 bytes.

The schema definition for both input feature vector and model predictions are used for documentation purposes. This guideline applies to tabular datasets only.

The schema of the model input feature vector and output predictions is a JSON object. The object has a top-level list with a key called `schema`. The schema definition of each column is a different entry in the list.

**Tip:**

You can use ADS to automatically extract the schema definition from a given training dataset.

For each column, the schema can be fully defined by assigning values to all these attributes:

<table>
<thead>
<tr>
<th>Field or Key</th>
<th>Type</th>
<th>Required?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>STRING</td>
<td>Required</td>
<td>The name of the column.</td>
</tr>
<tr>
<td>description</td>
<td>STRING</td>
<td>Optional</td>
<td>The description of the column.</td>
</tr>
<tr>
<td>required</td>
<td>BOOL</td>
<td>Required</td>
<td>Whether or not the column is a required input feature to make a model prediction.</td>
</tr>
<tr>
<td>dtype</td>
<td>STRING</td>
<td>Required</td>
<td>The data type of the column.</td>
</tr>
<tr>
<td>domain</td>
<td>OBJECT</td>
<td>Optional</td>
<td>The range of allowed values that the feature can take.</td>
</tr>
</tbody>
</table>

The `domain` field is a dictionary containing the following keys:
<table>
<thead>
<tr>
<th>Field or Key</th>
<th>Type</th>
<th>Required?</th>
<th>Description</th>
</tr>
</thead>
</table>
| domain.constraints      | LIST       | Optional  | Supports a list of predicates to constraints the range of allowed values for the feature. You can input a language specific string expression template, which can be evaluated by the language interpreter and compiler. With Python, the string format is expected to follow STRING. Constraints can be expressed using expressions or operators. • For integers and floats: `le, ge, lt, gt, eq` • For category: `in` You can apply more than one constraint. Example of an expression:

```json
{
  "schema": {
    "description": "Id",
    "domain": {
      "constraints": []
    }
  }
  "stats": {
    "25%": 365.75,
    "50%": 730.5,
    "75%": 1095.25,
    "count": 1460.0,
    "max": 1460.0,
    "mean": 730.5,
    "min": 1.0,
    "std": 421.6100093688479
  }
  "values": "Discreet numbers"
}

```

<table>
<thead>
<tr>
<th>name: Id required: false type: int64 description: MSSubClass domain: constraints: [] stats:</th>
</tr>
</thead>
<tbody>
<tr>
<td>25%: 20.0          50%: 50.0          75%: 70.0</td>
</tr>
<tr>
<td>Field or Key</td>
</tr>
<tr>
<td>---------------</td>
</tr>
<tr>
<td>domain.stats</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>domain.values</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>domain.name</td>
</tr>
<tr>
<td>domain.dtype</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Field or Key</td>
</tr>
<tr>
<td>-----------------</td>
</tr>
<tr>
<td>domain.dtype</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Example of an Input Data Schema

```python
schema:
  - description: Description of the column
domain:
    constraints:
      - expression: '\($x > 10 \text{ and } x < 100\) \text{ or } (x < -1 \text{ and } x > -500)\)' #
Here user can input language specific string expression template which can be evaluated by the language interpreter/compiler. In case of python the string format expected to follow string.Template recognized format.
language: python
stats: # This section is flexible key value pair. The stats will depend on what user wants to save. By default, the stats will be automatically generated based on the `feature_stat` in feature types
  mean: 20
  median: 21
  min: 5
values: numbers # The key idea is to communicate what should be the domain of values that are acceptable. Eg rational numbers, discreet numbers, list of values, etc
name: MSZoing # Name of the attribute
required: false # If it is a nullable column
```

Example of an Output Data Schema

```json
{
  "predictionschema": [
    {
      "description": "Category of SR",
      "domain": {
        "constraints": [],
        "stats": [],
        "values": "Free text"
      },
      "name": "category",
      "required": true,
      "type": "category"
    }
  ]
}
```

Model Introspection Tests

When you run the introspection tests they generate a local test_json_output.json file.

This is an example of the introspection test results in JSON format:

```json
{
  "score_py": {
    "category": "Mandatory Files Check",
```
"description": "Check that the file "score.py" exists and is in the top level directory of the artifact directory",
"error_msg": "File score.py is not present.",
"success": true
},

Saving Models to the Model Catalog

There are several ways that you can save a model to the model catalog after you have created it:

- Saving Models with the Accelerated Data Science SDK on page 1453
- Saving Models with the OCI Python SDK on page 1454
- Saving Models with the OCI Console on page 1459

Saving Models with the Accelerated Data Science SDK

When you train a model in a notebook session, you can use the Accelerated Data Science (ADS) SDK to save model artifacts to the model catalog. ADS creates the model artifact on your behalf. It captures all the relevant metadata like its provenance, and pushes a new model artifact to the model catalog.

The \texttt{model_catalog.ipynb} example notebook shows you how to save and load different models to and from the model catalog. The ADS Model Catalog documentation explains the integration with the model catalog.

ADS offers two different ways to save models to the model catalog. The first is by creating an \texttt{ADSMModel} object that supports models trained with scikit-learn, XGBoost, Keras, and LightGBM. Preparing and saving model artifacts to the model catalog is simply calling the \texttt{prepare()} and \texttt{save()} methods of the \texttt{ADSMModel} object. The goal is to make those steps as automated as possible with little to no intervention by a data scientist.

The alternative approach is often referred to as the \textit{generic} approach. ADS provides the \texttt{prepare_generic_model()} function to help you convert any type of model into an \texttt{ADSMModel} object. The generic approach is more work, but is very flexible. ADS assists you in preparing a model artifact by generating
standardized code that you modify to represent your use case. In particular, the `score.py` and `runtime.yaml` files. After you modify the files, you save the resulting `ADSModel` object and the model metadata ADS generates to the model catalog.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The maximum model artifact size that you can save using the ADS SDK is 2 GB.</td>
</tr>
</tbody>
</table>

### Saving Models with the OCI Python SDK

To create and save a model, you must first **create the model artifact.**

1. Save your model object to disk. You can use various tools to save your model (Joblib, cloudpickle, pickle, ONNX, and so on). We recommend that you save your model object in the top-level directory of your model artifact and at the same level as the `score.py` and `runtime.yaml` files.

2. Modify your `score.py` file to define the `load_model()` and `predict()` functions. Modify the body of both functions to support your model as follows:

   - **load_model():**
     
     Reads the model file on disk, and returns the estimator object. Ensure that you use the same library for serializing and de-serializing the model object.

   - **predict():**
     
     Contains two parameters, `data` and `model`. The required parameter is `data`, which represents a dataset payload while `model` is an optional parameter. By default, `model` is the object returned by `load_model()`. Ensure that the data type of the `data` parameter matches the payload format you expect with model deployment.

     By default, model deployment assumes that `data` is a JSON payload (MIME type `application/json`). The `predict()` function should be able to convert the JSON payload into a model object data format. For example, a Pandas dataframe or a Numpy array if that is the data format supported by the model object. The body of `predict()` can include data transformations, and other data manipulation tasks before a model prediction is made.

   A few more things to consider:

   - You can't edit the function signatures of `load_model()` and `predict()`. You can only edit the body of these functions to customize them.
   - Any custom Python modules can be imported using `score.py` if they are available in the artifact file. Or as part of the conda environment used for inference purposes.
   - You can save more than one model object in your artifact. You can load more than one estimator object to memory to perform an ensemble evaluation. In this case, `load_model()` can return an array of model objects that `predict()` processes.

3. **(Optional) Test the `score.predict()` function.**

   We recommend that you test the `predict()` function in your local environment before saving the model to the model catalog. The following code snippet shows you how to pass a JSON payload to predict that mimics the behavior of your model deployed using model deployment. This is a good way to ensure that the model object is read by `load_model()`. Also, that the predictions returned by your models are correct and in the format you expect. If you run this code snippet in a notebook session, you also get the output of any loggers you define in `score.py` in the output cell.

```python
import sys
from json import dumps

# The local path to your model artifact directory is added to the Python path.
# replace <your-model-artifact-path>
sys.path.insert(0, f"<your-model-artifact-path>"
```
# importing load_model() and predict() that are defined in score.py from score import load_model, predict

# Loading the model to memory
_ = load_model()

# Take a sample of your training or validation dataset and store it as data.
# Making predictions on a JSON string object (dumps(data)). Here we assume
# that predict() is taking data in JSON format
predictions_test = predict(dumps(data), _)
# Compare the predictions captured in predictions_test with what you expect for data:
predictions_test

4. **Modify the `runtime.yaml` file.**

This file provides a reference to the conda environment you want to use for the runtime environment for model deployment. Minimally, the file must contain the following fields:

```yaml
MODEL_ARTIFACT_VERSION: '3.0'
MODEL_DEPLOYMENT:
  INFERENCE_CONDA_ENV:
    INFERENCE_ENV_SLUG: <the-environment-slugname> # for example mlcpuv1
    INFERENCE_ENV_TYPE: <env-type> # can either be "published" or "data_science"
    INFERENCE_ENV_PATH: <conda-environment-path-on-object-storage>
    INFERENCE_PYTHON_VERSION: <python-version-of-conda-environment>
```

Following is an example of a `runtime.yaml` file. The data scientist is selecting the Data Science TensorFlow 2.3 for CPU conda environment.

```yaml
MODEL_ARTIFACT_VERSION: '3.0'
MODEL_DEPLOYMENT:
  INFERENCE_CONDA_ENV:
    INFERENCE_ENV_SLUG: tensorflow23_p37_cpu_v1
    INFERENCE_ENV_TYPE: data_science
    INFERENCE_ENV_PATH: oci://service-conda-packs@id19sfccra6z/service_pack/cpu/Tensorflow for CPU Python 3.7/1.0/tensorflow23_p37_cpu_v1
    INFERENCE_PYTHON_VERSION: '3.7'
```
5. (Optional) (Recommended) Before saving a model to the catalog, we recommend that you run a series of introspection tests on your model artifact.

The purpose of these tests is to identify any errors by validating `score.py` and `runtime.yaml` files with a set of checks to ensure that they have right syntax, parameters, and versions. Introspection tests are defined as part of the model artifact code template.

a) Python version 3.5 or greater is required to run the tests. Before running the tests locally on your machine, you must install the `pyyaml` and `requests` Python libraries. This installation is a one-time operation.

Go to your artifact directory. Run the following command to install the required third-party dependencies:

```
python3 -m pip install --user -r artifact-introspection-test/requirements.txt
```

b) Run the tests locally by replacing `<artifact-directory>` with the path to your model artifact directory:

```
python3 artifact-introspection-test/model_artifact_validate.py --artifact <artifact-path>
```

a) Inspect your test results.

The `model_artifact_validate.py` script generates two output files in the top-level directory of your model artifacts:

- `test_json_output.json`
- `test_html_output.html`

You can open either file to inspect the errors. If you are opening the HTML file, error messages are displayed in the red background.

b) Repeat steps 2-6 until all your tests run successfully. After the tests are running successfully, the model artifact is ready to be saved to the model catalog.

6. Create and save your model to the model catalog using the OCI SDK with an OCI configuration file, which is part of standard SDK access management.

a) Initialize the client with:

```
# Create a default config using DEFAULT profile in default location
# Refer to
# https://docs.cloud.oracle.com/en-us/iaas/Content/API/Concepts/sdkconfig.htm#SDK_and_CLI_Configuration_File
# for more info
import oci
from oci.data_science.models import CreateModelDetails, Metadata, CreateModelProvenanceDetails, UpdateModelDetails, UpdateModelProvenanceDetails
config = oci.config.from_file()
data_science_client = oci.data_science.DataScienceClient(config=config)

# Initialize service client with user principal (config file)
config = oci.config.from_file()
data_science_client = oci.data_science.DataScienceClient(config=config)

# Alternatively initialize service client with resource principal (for example in a notebook session)
# auth = oci.auth.signers.get_resource_principals_signer()
```
## # data_science_client = oci.data_science.DataScienceClient({},
signer=auth)

b) **(Optional) Document the model provenance.**

For example:

```python
# Create the model provenance details.
provenance_details =
    CreateModelProvenanceDetails(repository_url="EXAMPLE-repositoryUrl-Value",
git_branch="EXAMPLE-gitBranch-Value",
git_commit="EXAMPLE-gitCommit-Value",
script_dir="EXAMPLE-scriptDir-Value",
    # OCID of the ML job
    Run or Notebook session on which this model was trained
    training_id="<<Notebooksession or ML Job Run OCID>>"
)
```

c) **(Optional) Document the model taxonomy.**

For example:

```python
# Create the list of defined metadata around model taxonomy:
defined_metadata_list = [
    Metadata(key="UseCaseType", value="image_classification"),
    Metadata(key="Framework", value="keras"),
    Metadata(key="FrameworkVersion", value="0.2.0"),
    Metadata(key="Algorithm", value="ResNet"),
    Metadata(key="hyperparameters", value="{"max_depth":5,"learning_rate":0.08","objective":"gradient descent"}"
]
```

d) **(Optional) Add your custom metadata (attributes).**

For example:

```python
# Adding your own custom metadata:
custom_metadata_list = [
    Metadata(key="Image Accuracy Limit", value="70-90%",
    category="Performance",
    description="Performance accuracy accepted"),
    Metadata(key="Pre-trained environment",
    value="https://blog.floydhub.com/guide-to-hyperparameters-search-for-deep-learning-models/",
    category="Training environment",
    description="Environment link for pre-trained model"),
    Metadata(key="Image Sourcing", value="https://lionbridge.ai/services/image-data/",
    category="other",
    description="Source for image training data")
```
e) (Optional) Document the model input and output data schema definitions.

**Important:**

The schema definition for both the input feature vector and model predictions are used for documentation purposes. This guideline applies to tabular datasets only.

For example:

```python
import json
from json import load

# Declare input/output schema for our model - this is optional
# It must be a valid json or yaml string
# Schema like model artifact is immutable hence it is allowed only at
# the model creation time and cannot be updated
# Schema json sample in appendix
input_schema = load(open('SR_input_schema.json','rb'))
input_schema_str= json.dumps(input_schema)
output_schema = load(open('SR_output_schema.json','rb'))
output_schema_str= json.dumps(output_schema)
```

f) (Optional) Document the introspection test results.

For example:

```python
# Provide the introspection test results

test_results = load(open('test_json_output.json','rb'))
test_results_str = json.dumps(test_results)
def zipdir(target_zip_path, ziph, source_artifact_directory):
    ''' Creates a zip archive of a model artifact directory.
    
    Parameters:
    - target_zip_path: the path where you want to store the zip archive
    of your artifact
    - ziph: a zipfile.ZipFile object
    - source_artifact_directory: the path to the artifact directory.
    
    Returns a zip archive in the target_zip_path you specify.
    
    '''
    for root, dirs, files in os.walk(source_artifact_directory):
        for file in files:
            ziph.write(os.path.join(root, file),
                       os.path.relpath(os.path.join(root,file),
                       os.path.join(target_zip_path,'.')))

zipf = zipfile.ZipFile('<relpath-to-artifact-directory>.zip', 'w',
zipfile.ZIP_DEFLATED)
zipdir('.', zipf, '<relpath-to-artifact-directory>')"
h) Create the model in the model catalog:

```python
# creating a model details object:
model_details = CreateModelDetails(
    compartment_id='<compartment-ocid-of-model>',
    project_id='<project-ocid>',
    display_name='<display-name-of-model>',
    description='<description-of-model>',
    custom_metadata_list=custom_metadata_list,
    defined_metadata_list=defined_metadata_list,
    input_schema=input_schema_str,
    output_schema=output_schema_str)

# creating the model object:
model = data_science_client.create_model(model_details)
# adding the provenance:
data_science_client.create_model_provenance(model.data.id, provenance_details)
# adding the artifact:
with open('<relpath-to-artifact-directory>.zip', 'rb') as artifact_file:
    artifact_bytes = artifact_file.read()
data_science_client.create_model_artifact(model.data.id, artifact_bytes, content_disposition='attachment; filename="<relpath-to-artifact-directory>.zip"')
```

7. Now you can view the model details and view the model information including any optional metadata that you defined.

You can use these sample code files, and notebook example to further help you design your model store.

<table>
<thead>
<tr>
<th>Example</th>
<th>File</th>
</tr>
</thead>
<tbody>
<tr>
<td>Java SDK code</td>
<td>ModelStoreV2Example.java</td>
</tr>
<tr>
<td>Python SDK code</td>
<td>ModelStoreV2Example.py</td>
</tr>
<tr>
<td>Churn prediction model with xgboost notebook</td>
<td>ChurnPredictionNotebookExample.ipynb</td>
</tr>
</tbody>
</table>

**Saving Models with the OCI Console**

To document your model, you have to prepare the metadata before you create and save it.

Usually, we expect that models are saved to the catalog programmatically, either using ADS or the OCI Python SDK. However, we also provide these instructions to save a model directly in the Console.

Create a model, add metadata, define the training environment, specify predictions schemas, and save the model to the model catalog.

**Important:**

You can use the OCI Python SDK, the OCI CLI, and ADS to programmatically save larger models (up to 2 GB).

If you are saving a model trained elsewhere or want to use the Console, use these steps to save a model:

1. Log into your tenancy using the Console with the necessary policies.
2. Open the navigation menu and click Analytics & AI. Under Machine Learning, click Data Science.
3. Select the compartment that contains the project you want to use.
4. Click the name of the project.
5. Click Models to see all your model resources.
6. Create a model artifact ZIP archive on your local machine containing your `score.py` and `runtime.yaml` (and any other files needed to run your model). Click Download sample artifact ZIP to get sample files that you can modify to create your model artifact.

7. Click Create Model.

8. Select the compartment to contain the model.

9. (Optional but recommended) Enter a unique name and description for the model (limit of 255 characters). If you don't provide a name, a name is automatically generated for you.

   For example:
   
   model20200108222435

10. (Optional) Enter a description for the model

11. Click Select in the Upload model artifact box to upload the model artifact archive (a ZIP file). You can drag and drop the file into the Model Artifact box, or click select a file to navigate to it. You can get a sample artifact file by clicking Download sample artifact ZIP, modify the file, and return the Console to upload it.
12. (Optional but recommended) Click Select in the Document model provenance box.

a) Select Notebook session.

Enter or select the following:

**project**

The compartment selected applies to both the project and the notebook session and both must be in the same compartment. If that isn't the case, then use the OCID search instead.

You can change the compartment for both the project and notebook session.

The name of the project to use in the selected compartment.

Select the notebook that you trained the model in from the list of available notebook sessions for the selected project.

**OCID search**

If your notebook session is in a different compartment than the project, then identify the notebook session OCID that you trained the model in.

b) (Optional) Select Training code to identify Git and model training information.

Enter or select any of the following:

**Git Repository URL**

The URL of the remote repository.

**Git Commit**

The commit hash.

**Git Branch**

The name of the branch.

**Model Directory**

The directory path where the model artifact was temporarily stored. This could be a path in a notebook session or on your laptop for example.

**Training Script**

The name of the Python script or notebook in which the model is trained.

| Tip: |
| You can also populate model provenance metadata when you save a model to the model catalog using the OCI SDKs or the CLI. |

c) Click Select.
13. (Optional but recommended) Click **Select** in the **Document model taxonomy** box to specify what your model does, machine learning framework, hyperparameters, or to create custom metadata to document your model.

**Important:**
The maximum allowed size for all of the model metadata is 32000 bytes. The size is a combination of the preset model taxonomy and the custom attributes.

a) Click **Model taxonomy** or **Add custom attributes**. You can add both the preset labels and the custom label-value pairs by clicking both and adding the required information.

Enter or select the following:

- **model taxonomy**
  - **use case**
    - The type of machine learning use case to use from these choices:
      - binary_classification
      - regression
      - multinomial_classification
      - clustering_recommender
      - dimensionality_reduction/representation
      - time_series_forecasting
      - anomaly_detection
      - topic_modeling
      - sentiment_analysis
      - image_classification
      - object_localization
      - other

- **model framework**
  - The Python library you used to train the model from these choices:
    - scikit-learn
    - xgboost
    - tensorflow
    - pytorch
    - mxnet
    - keras
    - lightGBM
    - pymc3
    - pyOD
    - spacy
    - prophet
    - sktime
    - statsmodels
    - cuml
    - oracle_automl
    - h2o
    - transformers
    - nltk
    - emcee
    - pystan
• bert
• gensim
• flair
• word2vec
• ensemble (more than one library)
• other

**model framework version**
The version of the machine learning framework. This is a free text value. For example, the value could be 2.3.

**model algorithm or model estimator object**
The algorithm used or model instance class. This is a free text value. For example, `sklearn.ensemble.RandomForestRegressor` could be the value.

**model hyperparameters**
The hyperparameters of the model in JSON format.

**artifact test results**
The JSON output of the introspection test results run on the client side. These tests are included in the model artifact boilerplate code. You can run them optionally before saving the model in the model catalog.

**custom attributes**

**label**
The key label of your custom metadata

**value**
The value attached to the key

**category**
(Optional) The category of the metadata from these choices:

• Performance
• Training Profile
• Training and Validation Datasets
• Training Environment
• other

You can use the category to group and filter custom metadata to display in the Console. This is useful when you have a large number of custom metadata that you want to track.

**description**
(Optional) A unique description of the custom metadata.

b) Click **Submit**.

14. (Optional but recommended) Click **Select** in the **Document model input and output data schema** box to document the model predictions. You define **model prediction features** that the model requires to make a
Data Science

successful prediction. You also define input and output schemas that describe the predictions returned by the model (defined in the `score.py` file with the `predict()` function).

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The maximum allowed file size for the combined input and output schemas is 32000 bytes.</td>
</tr>
</tbody>
</table>

a) Select **Upload input schema** or **Upload output schema**.
b) Upload your schema JSON file by dragging and dropping the file into the **Upload** box or clicking **select a file** to navigate to it.
c) Click **Upload**.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can only document the input and output data schemas when you create the model. You cannot edit the schemas post model creation.</td>
</tr>
</tbody>
</table>

15. (Optional) Add tags to easily locate and track the project by selecting a tag namespace, then entering the key and value. To add more than one tag, click **+Additional Tags**.

   The Tagging service provides various tags that you can use to organize and find projects including cost-tracking tags.

16. (Optional) To view the details for your project immediately after creation, select **View detail page on clicking create**.

17. Click **Create**.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Models stored in the model catalog can also be deployed using <strong>model deployment</strong>.</td>
</tr>
</tbody>
</table>

### Moving Models Saved Under Previous Artifact Versions

For all models that were saved under an earlier version of the model artifact (version < 3.0), pre-defined values are assigned to the `INFERENCE_CONDA_ENV` environment variable. All models are assigned to the **Classic CPU Notebook Session Kernel (version 1.0)** environment.

This could be a problem if your model requires custom third-party dependencies or if the library versions in the Classic conda environment differ from the requirements of your model. The following sample simple migration plan takes advantage of the latest features in the model artifact and model deployment.

To move your artifact to version 3.0:

1. Download the model artifact using the OCI Console, SDKs, CLI, or with ADS.
2. Delete any `runtime.yaml` or `ds-runtime.yaml` files that were in your original artifact.
3. Replace with the latest `runtime.yaml` schema.
4. Enter your parameter values into `runtime.yaml`.
5. Test your model artifact before saving it to the model catalog.
6. Save the model to the model catalog.

### Managing Models

You can view, edit, move, and do other tasks with your Data Science models.

#### Viewing Model Details

On your project's home page, click **Models**.

From a **Models** view, you can:

- Select a model to view its details and work with it.
- Use the Actions icon (three dots) to view model details, edit it, move it to a different compartment, or delete it.
• For an **OCID**: you can use **Show** to see the full name of the user that created the notebook session. Use **Copy** to copy the name to your clipboard to use elsewhere.

• Get a sample artifact file by clicking **Download sample artifact ZIP**.

• Sort the list of models in the table by clicking **Name** and **Status**.

• Use the **List Scope** filter to view models associated with your selected project in another compartment.

• Filter models by status using the **Model State** drop-down list. The default is to view all status types.

• You can filter models based on their tags by clicking **add** or **clear** next to **Tag Filters**.

  From the **Tags** tab, you can view the tags that have been applied to the model. To update or remove a tag, find the tag you want and click the pencil icon next to it. Enter the new tag then save it or remove the tag by clicking **Remove Tag**.

### Viewing a Model's Information

The model information details tab displays the model information, such as the model artifact, model directory, git details, training script, description, created by, created on, OCID, and so.

The Git, model directory, and model training script metadata gives contextual information on the source code used to train the model stored in catalog. Diligent tracking of the provenance metadata significantly improves model reproducibility and auditability. All of these are optional.

From a **Model Information** view, you can:

• View the description, creator, creation date and time, and model artifact file name and size.

  For an **OCID**: you can use **Show** to see the full name of the user that created the notebook session. Use **Copy** to copy the name to your clipboard to use elsewhere.

• Select a resource like **Model Taxonomy** or **Associated Model Deployments**.

The default view is the **model's provenance**.

### Viewing Model Provenance

When **model provenance** has been defined, you can view how the model was trained.

The **Training resource** tab shows the notebook session or job run that trained the model. You can select them to manage them.

The **Model training source code** tab shows the Git details, model script, and the training script.

You can view any tags that are defined by clicking the **Tags** tab.

### Viewing Model Taxonomy

When **model taxonomy** has been defined, you can view the taxonomy description and any defined custom attributes. You can show all of the hyperparameters, and copy them to use elsewhere.

You can view any tags that are defined by clicking the **Tags** tab.

### Viewing Associated Model Deployments

If there are **associated model deployments**, then they are listed so that you can select a deployment to manage it.

You can view any tags that are defined by clicking the **Tags** tab.

### Viewing Model Introspection

When **model introspection** has been defined, you can view the tests that ran on the client-side before you save the model to the model catalog by clicking **score.py** or **runtime.yaml**. The status is shown for each use case test as success, failed, or not tested. We recommend that all of your tests are successful before you save the model.

Click the **Custom Model Attributes** tab to see the label, value, category, and description for the model if they were created for the model.

You can view any tags that are defined by clicking the **Tags** tab.
**Viewing Model Schemas**

When input and output model schemas have been defined, the contents of the uploaded files are displayed in separate fields. You can review and copy the contents.

You can view any tags that are defined by clicking the **Tags** tab.

**Editing Models**

You can either click the model's name or the Actions icon (three dots), and click **Edit**. You can change the name and description of the model and then save your changes.

If you added metadata to a model, you can edit the provenance and taxonomy. You can't edit the input and output schemas.

You can edit the model name and description, all other options are unchangeable. You can change a model by loading it back into a notebook session, making changes, and then saving the model as a new model.

**Downloading Models**

You can either click the model's name or the Actions icon (three dots), and click **Download Model Artifacts** to download the model artifact ZIP archive to your local machine.

**Applying Tags to Models**

You can either click the model's name or the Actions icon (three dots), and click **Add Tags** or the **Tags** tab.

You can apply both defined and free form tags to models using **Working with Resource Tags**.

**Moving Model Resources**

You can move a model resource from its current compartment to a different one.

For example, you may want to move a model to promote it from a development compartment to production compartment, or to change the visibility of the model.

You can click the model's name or the Actions icon (three dots), and then click **Move Resource**. Alternatively, you could select the destination compartment, and then click **Move Resource**.

**Deactivating and Activating Models**

**Deactivating Models**

Deactivating a model updates its state to inactive. Inactive models can't be used in a model deployment. Inactive models are not deleted and can later be reactivated.

You can either click the model's name or the Actions icon (three dots), and click **Deactivate**.

**Activating Models**

You can either click the model's name or the Actions icon (three dots), and click **Activate** to change an inactive model to an active model.

**Deleting Models**

You can either click the model's name or the Actions icon (three dots), and click **Delete**. Enter the exact name (case insensitive) of the model and click **Delete** to delete the model.

<table>
<thead>
<tr>
<th>Caution:</th>
</tr>

<tr>
<td>Deleted models exist in lists for 30 days after being deleted. You can filter them out of lists using the <strong>State</strong> filter.</td>
</tr>
</tbody>
</table>
Using the API

For information about using the API and signing requests, see REST APIs and Security Credentials. For information about SDKs, see Software Development Kits and Command Line Interface.

Use the following operations to manage models:
- CreateModel
- GetModel
- ActivateModel
- UpdateModel
- ChangeModelCompartment
- DeactivateModel
- DeleteModel
- ListModels
- CreateModelArtifact
- CreateModelProvenance
- GetModelArtifactContent
- GetModelProvenance
- UpdateModelProvenance

About Model Deployments

Learn how to work with your Data Science model deployments.

Model deployments are a managed resource in the OCI Data Science service that allows you to deploy machine learning models as HTTP endpoints in OCI. Deploying machine library models as web applications (HTTP API endpoints) serving predictions in real time is the most common way that models are productionized. HTTP endpoints are flexible and can serve requests for model predictions.

Figure 1: Flow for Model Deployment

Training

Training a model is the first step to deploy a model. You use notebook sessions to train open source and Oracle AutoML models.
Saving and Storing

Next, you store the trained model in the model catalog. You have these options to save your model to the model catalog:

- You can use the OCI Console, SDKs, and CLIs to save your model artifact in the model catalog.
- Use different frameworks like scikit-learn, TensorFlow, or Keras.

Model deployment requires that you specify an inference conda environment in the runtime.yaml model artifact file. This inference conda environment contains all your model dependencies and is installed in the model server container. You can specify either one of the Data Science conda environments or a published environment that you created.

A Model Deployment

After a model is saved to the model catalog, it becomes available for deployment as a Model Deployment resource. The service supports models running in a Python runtime environment and their dependencies can be packaged in a conda environment.

You can deploy and invoke a model using the OCI Console, SDK, and CLI.

Model deployments rely on these key components to deploy a model as an HTTP endpoint:
**Load balancer.**

When a model deployment is created, a load balancer must be configured. A load balancer provides an automated way to distribute traffic from one entry point to multiple model servers running in a pool of virtual machines (VMs). The bandwidth of the load balancer must be specified in Mbps and is a static value. You can change the load balancer bandwidth by editing the model deployment.

**A pool of VM instances hosting the model server, the conda environment, and the model itself.**

A copy of the model server is made to each compute instance in the pool of VMs.

A copy of the inference conda environment and the selected model artifact are also copied to each instance in the pool. Two copies of the model are loaded to memory for each OCPU of each VM instance in the pool. For example, if you select a VM.Standard2.4 instance to run the model server, then 4 OCPUs x 2 = 8 copies of the model are loaded to memory. Multiple copies of the model help to handle concurrent requests that are made to the model endpoint by distributing those requests among the model replicas in the VM memory. Ensure that select a VM shape with a large enough memory footprint to account for those model replicas in memory. For most machine learning models with sizes in MBs or the low GBs, memory is likely not an issue.

The load balancer distributes requests made to the model endpoint among the instances in the pool. We recommend that you use smaller VM shapes to host the model with a larger number of instances as opposed to selecting fewer though larger VMs.

**Model artifacts in the model catalog.**

Model deployment requires a model artifact that is stored in the model catalog and that the model is in an active state. Model deployment exposes the `predict()` function defined in the `score.py` file of the model artifact.

**Conda environment with model runtime dependencies.**

A conda environment encapsulates all the third-party Python dependencies (like Numpy, Dask, or XGBoost) that your model requires. There are two Python conda environments, `python 3.6` and `python 3.7`. The Python version you specify with `INSTRUCTION_PYTHON_VERSION` must match the version used when creating the conda pack.

Model deployment pulls a copy of the inference conda environment defined in the `runtime.yaml` file of the model artifact to deploy the model and its dependencies. The relevant information about the model deployment environment is under the `MODEL_DEPLOYMENT` parameter in the `runtime.yaml` file. The `MODEL_DEPLOYMENT` parameters are automatically captured when a model is saved using ADS in a notebook session. If you want to save a model to the catalog and deploy it using the OCI SDK, CLI, or the Console, you have to provide a `runtime.yaml` file as part of your model artifact that includes those parameters.

**Note:**

For all model artifacts saved in the model catalog without a `runtime.yaml` file, or when the `MODEL_DEPLOYMENT` parameter is missing from the `runtime.yaml` file, then a default conda environment is installed in the model server and used to load your model. The default conda environment that is used is the Classic CPU Notebook Session Kernel (version 1.0) with Python version 3.6.

Use these conda environments:

**Data Science conda environments**

A list of the conda environments is in Viewing the Conda Environments on page 1393.

In the following example, the `runtime.yaml` file instructs the model deployment to pull the published conda environment from the Object Storage path defined by `INSTRUCTION_ENV_PATH`.

```
MODEL_ARTIFACT_VERSION: '3.0'
```
Your published conda environments

You can create and publish conda environments for use in your model deployments.

In the following example, the runtime.yaml file instructs the model deployment to pull the published conda environment from the Object Storage path defined by INFERENCE_ENV_PATH. It then installs it on all instances of the pool hosting the model server and the model itself.

Zero Downtime Operations

Zero downtime operations for model deployments mean that the model inference endpoint (predict) is able to continuously serve requests without interruption or instability.

Model deployments support a series of operations that can be done while maintaining no downtime. This feature is critical for any application that consumes the model endpoint. You can apply zero downtime operations when the model is in an active state serving requests. These zero downtime operations allow you to swap the model for another one, change the VM shape, and the logging configuration while preventing downtime.

Logging Integration to Capture Logs Emitted from Model Deployment

Model deployment can be integrated with the OCI Logging service. This option allows you to emit logs from a model and then inspect these logs.

Policies, Authentication, and Authorization

You must create a group of users that are authorized to work with model deployments before you can deploy a model with a model deployment resource.

Alternatively, you could create a dynamic group of resources (like notebook sessions) that is authorized to create a deployment. In this case, anyone who can access the notebook session can take the identity of the notebook session and create a model deployment. The authentication method from the notebook session uses resource principals.

The same pattern applies when invoking the model endpoint after deployment. A group of users or resources need to be authorized to invoke the model.

We believe that the following examples are the most common policy statements for use with a model deployment and example model deployment policies contains more examples.
Manage Model Deployment Policies

Allows a group of users, `<your-group>` to perform all CRUD operations on models stored in the model catalog. Any user who wants to deploy a model through model deployment also needs to access the model they want to deploy.

```
allow group <your-group> to manage data-science-models in compartment <your-compartment-name>
```

Allows a group of users, `<your-group>` to perform all CRUD operations, including calling the predict endpoint, on model deployment resources in a particular compartment. The `manage` verb can be changed to limit what the users can do.

```
allow group <your-group> to manage data-science-model-deployments in compartment <your-compartment-name>
```

Allows a dynamic group of users (like notebook sessions) to perform all CRUD operations, including calling the predict endpoint, on model deployment resources in a particular compartment. The `manage` verb can be changed to limit what the resources can do.

```
allow dynamic-group <your-dynamic-group> to manage data-science-model-deployments in compartment <your-compartment-name>
```

The preceding policy examples are permissive. You can create more restrictive policies. A common example is to restrict who or what resources can invoke the predict endpoint of the model deployment.

Authorize Access to Predict Endpoint Policy

Allows a group of users, `<your-group>` to perform all CRUD operations, including calling the predict endpoint, on model deployment resources in a particular compartment. The `manage` verb can be changed to limit what the users can do.

```
allow group <your-group> to manage data-science-model-deployments in compartment <your-compartment-name>
```

Alternatively, you can authorize resources to do the same. Only the dynamic group of resources your specified dynamic group can call the model endpoint for model deployment resources that are created in a specific compartment.

```
allow dynamic-group <your-dynamic-group-2> to
{DATA_SCIENCE_MODEL_Deployment_PREDICT}
in compartment <your-compartment-name>
```

Give Model Deployment Access to Your Published Conda Bucket

(Optional) Allows a model deployment to access the published conda environments that are stored in your Object Storage bucket. This is required if you want to use Published Conda Environments to capture the third-party dependencies of your model.

```
Allow any-user to read objects in compartment <your-compartment-name>
where ALL { request.principal.type='datasciencemodeldeployment',
target.bucket.name=<your-published-conda-envs-bucket-name> }
```
**Give Model Deployment Access to the Logging Service**

(Optional) Allows a model deployment to emit logs to the Logging service. You need this policy if you are using Logging in your Model Deployment. This statement is very permissive. For example, you could restrict the permission to use log-content in a specific compartment.

```
allow any-user to use log-content in tenancy
where ALL {request.principal.type = 'datasciencemodeldeployment'}
```

**Give Model Deployment Access to an Object Storage Bucket**

(Optional) Allows a model deployment to access an Object Storage bucket that resides in your tenancy. For example, a deployed model reading files (a lookup CSV file) from an Object Storage bucket that you manage.

```
allow any-user to read objects in compartment <your-compartment-name>
where ALL { request.principal.type='datasciencemodeldeployment', target.bucket.name=<your-bucket-name> }
```

**Other Methods of Authentication and Authorization**

Model deployment only supports authorization and authentication defined by the [OCI Identity and Access Management (IAM) service](https://docs.oracle.com/en-us/iaas/Content/Identity/). Model deployment does not support other methods of authorization and authentication such as OAuth or basic access authentication.

**Creating a Model Deployment**

After you store a model in the model catalog, it can be deployed as an HTTP endpoint using the model deployments resource. Ensure that you have created the necessary policies, authentication, and authorization for your model deployments.

You can create a model deployment using these interfaces:

**Using the Console**

1. Log into your tenancy using the Console with the necessary policies.
2. Open the navigation menu and click Analytics & AI. Under Machine Learning, click Data Science.
3. Select the compartment that contains the project you want to use.
4. Click the name of the project.
5. Click Create Model Deployments.
6. Select the compartment to contain the model deployment.
7. (Optional but recommended) Enter a unique name and description for the model (limit of 255 characters). If you don't provide a name, a name is automatically generated for you.
   For example:
   ```
   modeldeployment20200108222435
   ```
8. (Optional) Enter a description for the model deployment
9. Select the model you want to deploy from the model catalog.
10. Select the compute shape.
11. Select the number of instances for the model deployment to replicate the model on.
12. (Optional) If you configured access or predict logging, you can:
   a) Select a log group.
   b) Select your custom log.
13. (Optional) Click **Show Advanced Options** to set load balancing and tags.
   a) (Optional) Select the load balancing bandwidth in Mbps or use the 10 Mbps default.

   Tips for load balancing:
   If you know the common payload size and the frequency of requests per second, you can use the following formula to estimate the bandwidth of the load balancer you need. We recommend that you add an additional 20% to allow for estimation errors and sporadic peak traffic.

   \[(\text{Payload size in KB}) \times (\text{Estimated requests per second}) \times 8 / 1024\]

   For example, if the payload is 1024 KB and you estimate 120 requests per second, then the recommended load balancer bandwidth would be:
   \[(1024 \times 120 \times 8 / 1024) \times 1.2 = 1152 \text{ Mbps}\]

   Remember that the maximum supported payload size is 10 MB. This is important when dealing with image payloads.

   **Important:**
   If the request payload size is more than the allocated bandwidth of the load balancer that was defined, then the request is rejected with a 429 status code.

   b) (Optional) Add tags to easily locate and track the project by selecting a tag namespace, then entering the key and value. To add more than one tag, click **+Additional Tags**.

   Tagging describes the various tags that you can use organize and find projects including cost-tracking tags.

14. Click **Create**.

**Using the OCI Python SDK**

We have developed an OCI Python SDK model deployment example that includes authentication.

**Note:**
You must upgrade the OCI SDK (v2.33.0 or later) before creating a deployment with the Python SDK using this command:

```
pip install --upgrade oci
```

**Using the OCI CLI**

You can use the OCI CLI to create a model deployment as in this example.

1. Deploy the model with:

   ```
   oci data-science model-deployment create \
   --compartment-id <MODEL_DEPLOYMENT_COMPARTMENT_OCID> \
   --model-deployment-configuration-details file://<MODEL_DEPLOYMENT_CONFIGURATION_FILE> \
   --project-id <PROJECT_OCID> \
   --category-log-details file://<OPTIONAL_LOGGING_CONFIGURATION_FILE> \
   --display-name <MODEL_DEPLOYMENT_NAME>
   ```

2. Use this model deployment JSON configuration file:

   ```
   {
   "deploymentType": "SINGLE_MODEL",
   "modelConfigurationDetails": {
   "bandwidthMbps": "YOUR_BANDWIDTH_SELECTION",
   "instanceConfiguration": {
   "instanceShapeName": "YOUR_VM_SHAPE",
   
   "modelId": "YOUR_MODEL_OCID",
   "scalingPolicy": { 
   ```
3. (Optional) Use this logging JSON configuration file:

```json
{
    "access": {
        "logGroupId": "<YOUR_LOG_GROUP_OCID>",
        "logId": "<YOUR_LOG_OCID>
    },
    "predict": {
        "logGroupId": "<YOUR_LOG_GROUP_OCID>",
        "logId": "<YOUR_LOG_OCID>
    }
}
```

**Notebook Examples**

We have provided notebook examples that show you how to train, prepare, save, deploy, and invoke model deployments for these frameworks:

**scikit-learn Examples**

Simple Model Deployment

Linear Regression

**XGBoost Example**

XGBoost ONNX

**PyTorch Example**

PyTorch Pretrained

**Invoking a Model Deployment**

After a model deployment is in an active `lifecycleState`, the predict endpoint can successfully receive requests made by clients. Invoking a model deployment means that you can pass feature vectors or data samples to the predict endpoint, and then the model returns predictions for those data samples.

From your model deployment detail page, click **Invoking Your Model**. The following details are displayed:

- The model HTTP endpoint.
- Sample code that enables you to invoke the model endpoint using the OCI CLI. Alternatively, you could use the OCI Python, and Java SDKs to invoke the model with the provide code sample.
- The payload size limit is 10 MB.

Use the sample code to invoke your model deployment.

Invoking a model deployment calls the predict endpoint of the model deployment URI. This endpoint takes sample data as input and is processed using the `predict()` function in the `score.py` model artifact file. The sample data is usually in JSON format though can be in other formats. Processing means that the sample data could be transformed then passed to a models inference method. The models can generate predictions that can be processed before being returned back to the client.

The model deployment HTTP endpoint doesn't support binary requests types directly. **Base64 encoding is needed to send binary requests for image inference.**

The API responses are:
<table>
<thead>
<tr>
<th>HTTP Status Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200 Success</td>
<td>Success.</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;data&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;prediction&quot;: [</td>
</tr>

<td>&quot;virginica&quot;</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td></td>
<td>},</td>
</tr>
<tr>
<td></td>
<td>&quot;headers&quot;: {</td>
</tr>
</tbody>
</table>
|                  |     "content-length": "28",
|                  |     "content-type": "application/json",
|                  |     "opc-request-id": "" |
|                  | }, |
|                  |   "status": "200 OK" |
|                  | } |
| 404              | Not Found or unauthorized. |
| 413              | The payload size limit is 10 MB. |
| 429              | Too Many Requests. |
| 500              | Internal Server Error. |
|                  | • Timeout |
|                  | • score.py file prediction returning an exception |

**Invoking with the OCI Python SDK**

This example code is a reference to help you invoke your model deployment:

```python
import requests
import oci
from oci.signer import Signer
import json

# model deployment endpoint. Here we assume that the notebook region is the same as the region where the model deployment occurs.
# Alternatively you can also go in the details page of your model deployment in the OCI console. Under "Invoke Your Model", you will find the HTTP endpoint
# of your model.
uri = <your-model-deployment-uri>
# your payload:
input_data = <your-json-payload-str>

if using_rps: # using resource principal:
    auth = oci.auth.signers.get_resource_principals_signer()
else: # using config + key:
    config = oci.config.from_file("~/.oci/config") # replace with the location of your oci config file
    auth = Signer(
        tenancy=config['tenancy'],
        user=config['user'],
        fingerprint=config['fingerprint'],
        private_key_file_location=config['key_file'],
        pass_phrase=config['pass_phrase'])
```
# post request to model endpoint:
response = requests.post(endpoint, json=input_data, auth=auth)

# Check the response status. Success should be an HTTP 200 status code
assert response.status_code == 200, "Request made to the model predict endpoint was unsuccessful"

# print the model predictions. Assuming the model returns a JSON object.
print(json.loads(response.content))

## Invoking with the OCI CLI

The OCI-CLI is included in the OCI Cloud Shell environment and is preauthenticated. This example invokes a model deployment with the CLI:

```bash
oci raw-request --http-method POST --target-uri <model-deployment-url>/predict --request-body '{"data": "data"}'
```

### Managing Model Deployments

You can view, edit, move, and do other tasks with your Data Science model deployments.

#### Viewing Model Deployments Details

1. On your project's home page, click **Model Deployments**.
2. Click the model deployment name. Alternatively, click the Actions icon (three dots) for the model deployment and select **View Details**.

The model deployment information details tab displays the model deployment information including:

- description if it was specified
- who created the model deployment
- when the deployment was created
- model deployment OCID
- model that was selected
- compute configuration including the VM shape name, the number of instances, and the load balancer bandwidth.

You can use these resources:

**Logs**

Logs display a table showing your predict and access log configuration.

**Work Requests**

Work Requests provides you with the status of each operation applied to your model deployment. You can click each operation and view the different log and error messages that are generated during the execution of that operation.

**Invoking your Model**

Invokes the predict endpoint of the model deployment. It displays the model deployment URI and with code snippets for the OCI CLI, Python SDK, and Java SDK.

From the **Tags** tab, you can view the tags that have been applied to the model. To update or remove a tag, find the tag you want and click the pencil icon next to it. Enter the new tag then save it or remove the tag by clicking **Remove Tag**.

**Editing Model Deployments**

You can either click the model deployment’s name or the Actions icon (three dots), and then click **Edit**. The parameters that can be changed depend on the lifecycleState of the model deployment.

When the model deployment is in an **Active** state, you can change these option groups **one** at a time with zero downtime to your model deployment:
Models and Compute

Select **Models** and **Compute** to adjust these options:

- Name
- Description
- Model
- VM compute shape
- VM compute instances count

Logging

Select **Logging** to adjust the logging configuration.

Load Balancer

Select **Show Advanced Options** to adjust the bandwidth for the load balancer.

Click **Submit** to save your changes. If you change more than one of the preceding groups, an error occurs.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can’t edit all of the options at one time when the model deployment resource is active. When the model deployment is <strong>Active</strong>, the load balancer bandwidth can only be changed by deactivating the deployment first.</td>
</tr>
</tbody>
</table>

When the model deployment is in an **Inactive** state, you can change all of the options at one time.

Applying Tags to Model Deployments

You can either click the model deployment’s name or the Actions icon (three dots), and click **Add Tags** or the **Tags** tab.

You can apply both defined and free form tags to model deployments using **Working with Resource Tags**.

Moving Model Deployment Resources

You can move a model deployment resource from its current compartment to a different one.

For example, you may want to move a model deployment to promote it from a development compartment to production compartment, or to change the visibility of the model.

You can click the model deployment’s name or the Actions icon (three dots), and then click **Move Resource**. Alternatively, you could the select the destination compartment, and then click **Move Resource**.

Deactivating and Activating Model Deployments

**Deactivating Model Deployments**

Deactivating a model deployment shuts down the instances that are associated with your deployment. Metering and billing of the model deployment instances and load balancer stop when a model deployment is deactivated. The deployment HTTP endpoint becomes unavailable. The model deployment metadata is saved. A deactivated model deployment can be reactivated. The same model HTTP endpoint is available upon reactivation and requests can be made to that model endpoint.

You can either click the model deployment’s name or the Actions icon (three dots), and click **Deactivate** to change an active model deployment as inactive. You can reactivate any inactive model deployment.

When a model deployment is in an Inactive state, you can change **all** of the options at one time and save the changes. The same isn’t true when a model deployment is Active.

**Activating Model Deployments**

You can either click the model deployment’s name or the Actions icon (three dots), and click **Activate** to change an inactive model deployment as active.
Deleting Model Deployments

You can either click the model deployment's name or the Actions icon (three dots), and click **Delete** to delete a model.

If you configured logs, you can delete the access and predict logs that are associated with your model deployment. By default the logs are not deleted.

**Note:**

Deleted model deployments exist in lists for 30 days after being deleted. You can filter them out of lists using the **State** filter.

Using Logging for Access and Predict Logs

Model deployment integrates with the [OCI Logging service](https://docs.oracle.com/en-us/oci/doc/logging) and offers the access and predict logs categories. This integration is optional.

Access Logs

The access log category is a custom log that captures detailed information about requests sent to the model endpoint. This information includes the time the request was received, error codes, and so on. If you are experiencing problems with your model deployment, access logs are generally the first log you want to look at.

The metadata captured by model deployment access logs are:

- **logEmissionTime**
  - The time, in UTC, when the log was emitted from the code.

- **message**
  - The request path.

- **modelLatency**
  - The time taken to process a request on the model server in milliseconds.

- **opcRequestId**
  - The request Id. This value is the same `requestId` that is retrieved in the response.

- **status**
  - The request response status code.

For example, an access log entry for model deployment could be:

```
"data": {
  "message": "POST /predict 1.1",
  "modelLatency": 4.43,
  "opcRequestId": "0BC0860C17DC46D79A0A1A7B4F139829",
  "status": 200
}
```

Predict Logs

Predict logs originate from logging (stdout and stderr) calls made custom code execution in the model artifact Python files. Predict logs can emit useful information about the model and are entirely customizable. Configuring access and predict logs is part of the **create** and **edit** actions.

The metadata captured by model deployment predict logs are:
MD_OCID
The model deployment OCID value.

level
The logger level. Also referred to as the severity level of the log message.

logEmissionTime
Time, in UTC, when the log was emitted from the code.

message
A custom message emitted from the model artifact Python code.

name
The name of the logger used.

For example, a predict log entry for model deployment could be:

```
"data": {
  "MD_OCID": "ocid1.datasciencemodeldeployment.oc1.iad.amaaaaav66vniauqakarfnyvn6gd2qt4fjqv2ffdntt",
  "level": "ERROR",
  "logEmissionTime": "2021-01-27T08:43:04.029Z",
  "message": "exception :: name 'function' is not defined",
  "name": "root"
},
```

Configuring the Access and Predict Logs
The access and predict logs emitted from model deployment can be accessed using the OCI Logging service. You can select a log configuration for access logs directly in the model deployment creation window. A log group is a logical container for organizing logs.

You create a log group with a custom log in the Logging service if you don't have one already:

1. Open the navigation menu and click Observedability & Management. Under Logging, click Log Groups.
2. Choose a compartment you have permission to work in and click Create Log Group.
   The Create Log Group panel is displayed.
3. Enter the following:
   • **Compartment**: The compartment in which you want to create the log group. This field is pre-filled based on your compartment choice.
   • **Name**: A name for this log group. The first character of a log group name must be a letter. For more, see Log and Log Group Names. Avoid entering confidential information.
   • **Description**: A friendly description.
   • (Optional) Enter tagging information.
4. Click Create
   The log group detail page is then displayed.
   You can create two separate logs for predict and access or you can use the same one for both.
5. Click Logs.
6. Click Create custom log.
7. Enter a name for the custom log.
8. Select the log group.
9. Click Create custom log.
Accessing the Access and Predict Logs
You can access the logs for your model deployment from the OCI Console under Solutions and Platform by selecting the Logging service and then click Search.

In the Search box, click Select logs to search. Select a compartment, a log group, and a log. Apply filters if necessary.

You should see log data in the Explore tab, see searching logs.

Troubleshooting
We have identified these areas to troubleshoot Data Science resources.

Debugging a Model Deployment Failure
After creating a new deployment or updating an existing employment, you might see a failure. These steps show how to debug the issue:

1. On your project's home page, click Model Deployments.
2. Click the model deployment name or click the Actions icon (three dots) for the model deployment and select View Details.
   Next, check the work requests
3. Under Resources, click Work Request.
   The work requests appear at the bottom of the page.
5. If any failures occur in the creation steps, under Resources, click Error Messages.
6. If the work request shows success, then review the OCI predict logs to identify any errors.
   Logs are attached to the model deployment when it's created.
7. If logs are attached, click the predict log name to see the log.

8. Click Explore with Log Search.
9. Change the filter time to increase the period.

Invoking a Model Deployment Failure
When a model deployment is in an active lifecycleState, the predict endpoint can be invoked. The prediction response can return a failure for multiple reasons. Use these suggestions to try to resolve these errors:

1. Ensure that the input passed in the request is in a valid JSON format and matches the expected input by the model.
2. Review the attached OCI access logs for errors.
3. Ensure that the user has the correct access rights.
4. Ensure that the score.py file does not contain errors.
5. If predictions are returning different results (success, fail) each time the prediction is called for the same input, it is possible that the allocated resources are not enough to server the model prediction. You can edit the load balancer bandwidth to increase it and the compute core count to serve more requests in parallel.

About Data Science Policies
To control who has access to Data Science and the type of access for each group of users, you must create policies.

By default, only the users in the Administrators group have access to all Data Science resources. For everyone else who's involved with Data Science, you must create new policies that assigns them proper rights to Data Science resources.

For a complete list of OCI policies, see Policy Reference.

Resource Types
Data Science offers both aggregate and individual resource-types for writing policies.
You can use aggregate resource types to write fewer policies. For example, instead of allowing a group to manage `data-science-projects`, `data-science-notebook-sessions`, `data-science-models`, and `data-science-work-requests`, you can have a policy that allows the group to manage the aggregate resource type `data-science-family`.

**Aggregate Resource Type**

`data-science-family`

**Individual Resource Types**

`data-science-projects`
`data-science-notebook-sessions`
`data-science-models`
`data-science-model-deployments`
`data-science-work-requests`

**Supported Variables**

To add conditions to your policies, you can either use OCI general variables or service-specific variables.

Data Science supports the [General Variables for All Requests](#) for use with projects, notebook sessions, and models, and these service specific variables:

### Data Science Policy Variables

<table>
<thead>
<tr>
<th>Operations for This Resource Type...</th>
<th>Can Use These Variables...</th>
<th>Variable Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>data-science-notebook-sessions</td>
<td>target.notebook-session.id</td>
<td>Entity (OCID)</td>
<td>Not available to use with <code>createNotebookSession</code></td>
</tr>
<tr>
<td></td>
<td>target.notebook-session.createdBy</td>
<td>String</td>
<td>Not available to use with <code>createNotebookSession</code></td>
</tr>
</tbody>
</table>

The user that creates a notebook is the only one who can open and use it:

**Examples of Various Operations**

```plaintext
allow group <data_science_hol_users> to manage <data_science_projects> in compartment <datascience_hol>

allow group <data_science_hol_users> to manage <data_science_models> in compartment <datascience_hol>

allow group <data_science_hol_users> to manage <data_science_work_requests> in compartment <datascience_hol>

allow group <data_science_hol_users> to inspect <data_science_notebook_sessions> in compartment <datascience_hol>

allow group <data_science_hol_users> to read <data_science_notebook_sessions>
```
in compartment <datascience_hol>

allow group <data_science_hol_users> to
  (DATA_SCIENCE_NOTEBOOK_SESSION_CREATE)
in compartment <datascience_hol>

allow group <data_science_hol_users> to
  (DATA_SCIENCE_NOTEBOOK_SESSION_DELETE, DATA_SCIENCE_NOTEBOOK_SESSION_UPDATE, DATA_SCIENCE_NOTEBOOK_SESSION_OPEN, DATA_SCIENCE_NOTEBOOK_SESSION_ACTIVATE, DATA_SCIENCE_NOTEBOOK_SESSION_DEACTIVATE)
in compartment <datascience_hol>
where target.notebook-session.createdBy = request.user.id

Details for Verbs + Resource Type Combinations

There are various OCI verbs and resource types that you can use to create a policy.

A policy syntax is like this: allow <subject> to <verb> <resource_type> in <location> where <conditions>.

The following describe the permissions and API operations covered by each verb for Data Science. The level of access is cumulative as you go from inspect to read to use to manage. A plus sign (+) in a table cell indicates incremental access compared to the cell directly above it, whereas "no extra" indicates no incremental access.

data-science-projects

The APIs covered for the data-science-projects resource-type are listed here. The APIs are displayed alphabetically for each permission.

<table>
<thead>
<tr>
<th>Permissions</th>
<th>APIs Fully Covered</th>
<th>APIs Partially Covered</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>DATA_SCIENCE_PROJECT_INSPECT</td>
<td>No extra</td>
</tr>
<tr>

</tbody>
</table>
Permissions Required for Each API Operation

You can use the data-science-projects, data-science-notebook-sessions, data-science-models and data-science-work-requests resource types.

For information about permissions, see Permissions.

The following table lists the API operations for OCI Data Science in a logical order, grouped by resource type. It lists the API operations in a logical order, grouped by resource type and the permissions required for resource types:

**Required Permissions**

<table>
<thead>
<tr>
<th>API Operation</th>
<th>Permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>ListProjects</td>
<td>DATA_SCIENCE_PROJECT_INSPECT</td>
</tr>
<tr>
<td>GetProject</td>

<tr>
<td>ListNotebookSessionShapes</td>
<td>DATA_SCIENCE_NOTEBOOK_SESSION_INSPECT</td>
</tr>
<tr>
<td>GetNotebookSession</td>
<td>DATA_SCIENCE_NOTEBOOK_SESSION_READ</td>
</tr>
<tr>
<td>UpdateNotebookSession</td>
<td>DATA_SCIENCE_NOTEBOOK_SESSION_UPDATE</td>
</tr>
<tr>
<td>ActivateNotebookSession</td>
<td>DATA_SCIENCE_NOTEBOOK_SESSION_READ and DATA_SCIENCE_NOTEBOOK_SESSION_UPDATE</td>
</tr>
<tr>
<td>DeactivateNotebookSession</td>
<td>DATA_SCIENCE_NOTEBOOK_SESSION_READ and DATA_SCIENCE_NOTEBOOK_SESSION_UPDATE</td>
</tr>
<tr>
<td>CreateNotebookSession</td>
<td>DATA_SCIENCE_NOTEBOOK_SESSION_CREATE and DATA_SCIENCE_PROJECT_READ</td>
</tr>
<tr>
<td>DeleteNotebookSession</td>
<td>DATA_SCIENCE_NOTEBOOK_SESSION_DELETE</td>
</tr>
<tr>
<td>OpenNotebookSession</td>
<td>DATA_SCIENCE_NOTEBOOK_SESSION_OPEN</td>
</tr>
</tbody>
</table>
### API Operation | Permissions
---|---
ModifyNotebookSessionCompartment | DATA_SCIENCE_NOTEBOOK_SESSION_MOVE
ListWorkRequests | DATA_SCIENCE_WORK_REQUEST_INSPECT or DATA_SCIENCE_PROJECT_INSPECT or DATA_SCIENCE_NOTEBOOK_SESSION_INSPECT or DATA_SCIENCE_MODEL_INSPECT or DATA_SCIENCE_MODEL_DEPLOYMENT_INSPECT
GetWorkRequest | DATA_SCIENCE_WORK_REQUEST_READ or DATA_SCIENCE_PROJECT_READ or DATA_SCIENCE_NOTEBOOK_SESSION_READ or DATA_SCIENCE_MODEL_READ or DATA_SCIENCE_MODEL_DEPLOYMENT_READ
CancelWorkRequest | DATA_SCIENCE_WORK_REQUEST_DELETE
ListWorkRequestLogs | DATA_SCIENCE_WORK_REQUEST_READ
ListWorkRequestErrors | DATA_SCIENCE_WORK_REQUEST_READ
ListModelDeployments | DATA_SCIENCE_MODEL_DEPLOYMENT_INSPECT
CreateModelDeployment | DATA_SCIENCE_MODEL_DEPLOYMENT_CREATE or DATA_SCIENCE_PROJECT_READ or DATA_SCIENCE_MODEL_READ
DeleteModelDeployment | DATA_SCIENCE_MODEL_DEPLOYMENT_DELETE
GetModelDeployment | DATA_SCIENCE_MODEL_DEPLOYMENT_READ
UpdateModelDeployment | DATA_SCIENCE_MODEL_DEPLOYMENT_UPDATE or DATA_SCIENCE_MODEL_READ
ActivateModelDeployment | DATA_SCIENCE_MODEL_DEPLOYMENT_READ or DATA_SCIENCE_MODEL_DEPLOYMENT_UPDATE
DeactivateModelDeployment | DATA_SCIENCE_MODEL_DEPLOYMENT_READ or DATA_SCIENCE_MODEL_DEPLOYMENT_UPDATE
ChangeModelDeploymentCompartment | DATA_SCIENCE_MODEL_DEPLOYMENT_MOVE
ListModelDeploymentShapes | DATA_SCIENCE_MODEL_DEPLOYMENT_INSPECT
PredictModelDeployment | DATA_SCIENCE_MODEL_DEPLOYMENT_PREDICT

### Policy Examples

**Note:**

The APIs covered for the aggregate data-science-family resource-type cover the APIs for data-science-projects, data-science-notebook-sessions, data-science-models and data-science-work-requests. For example, allow group `<group_name>` to manage data-science-family in
compartment <compartment_name> is the same as writing the following four policies:

- allow group <group_name> to manage <data_science_projects> in compartment <compartment_name>
- allow group <group_name> to manage data-science-notebook-sessions in compartment <compartment_name>
- allow group <group_name> to manage data-science-models in compartment <compartment_name>
- allow group <group_name> to manage data-science-work-requests in compartment <compartment_name>

**Example: List View**

Allows a group to simply view the list of all Data Science models in a specific compartment:

allow group <group_name> to inspect data-science-models in compartment <compartment_name>

The read verb for data-science-models covers the same permissions and API operations as the inspect verb with the DATA_SCIENCE_MODEL_READ permission and the API operations that it covers, such as GetModel and GetModelArtifact.

**Example: All Operations**

Allows a group to perform all the operations listed for DATA_SCIENCE_MODEL_READ in a specified compartment:

allow group <group_name> to read data-science-models in compartment <compartment_name>

The manage verb for data-science-models includes the same permissions and API operations as the read verb, plus the APIs for the DATA_SCIENCE_MODEL_CREATE, DATA_SCIENCE_MODEL_MOVE, DATA_SCIENCE_MODEL_UPDATE, and DATA_SCIENCE_MODEL_DELETE permissions. For example, a user can delete a model only with the manage permission or the specific DATA_SCIENCE_MODEL_DELETE permission. With a read permission for data-science-models, a user cannot delete the models.

**Examples: Manage All Resources**

Allows a group to manage all the resources for Data Science use:

allow group <group_name> to manage <data_science_family> in compartment <compartment_name>

Allows a group to manage all the Data Science resources, except for deleting the Data Science projects:

allow group <group_name> to manage <data_science_family> in compartment <compartment_name> where request.permission !='DATA_SCIENCE_PROJECT_DELETE'

The APIs covered for the data-science-projects resource-type are listed here. The APIs are displayed alphabetically for each permission.
**Examples for Model Deployments**

We identified these policy statements that you are likely to adopt in your tenancy for model deployments:

Allows a group of users, `<your-group>` to perform all CRUD operations on models stored in the model catalog. Any user who wants to deploy a model through model deployment also needs to access the model they want to deploy.

```
allow group <your-group> to manage data-science-models
in compartment <your-compartment-name>
```

Allows a group of users, `<your-group>` to perform all CRUD operations, including calling the predict endpoint, on model deployment resources in a particular compartment. The `manage` verb can be changed to limit what the users can do.

```
allow group <your-group> to manage data-science-model-deployments
in compartment <your-compartment-name>
```

Allows a dynamic group of resources (like notebook sessions) to perform all CRUD operations, including calling the predict endpoint, on model deployment resources in a particular compartment. The `manage` verb can be changed to limit what the resources can do.

```
allow dynamic-group <your-dynamic-group> to manage data-science-model-deployments
in compartment <your-compartment-name>
```

Alternatively, you can authorize resources to do the same. Only the dynamic group of resources your specified dynamic group can call the model endpoint for model deployment resources that are created in a specific compartment.

```
allow dynamic-group <your-dynamic-group-2> to
  (DATA_SCIENCE_MODEL_DEPLOYMENT_PREDICT)
in compartment <your-compartment-name>
```

(Optional) Allows a model deployment to access the published conda environments that are stored in your Object Storage bucket. This is required if you want to use Published Conda Environments to capture the third-party dependencies of your model.

```
Allow any-user to read objects in compartment <your-compartment-name>
where ALL { request.principal.type='datasciencemodeldeployment',
target.bucket.name=<your-published-conda-envs-bucket-name> }
```

(Optional) Allows a model deployment to emit logs to the Logging service. You need this policy if you are using Logging in your Model Deployment. This statement is very permissive. For example, you could restrict the permission to use log-content in a specific compartment.

```
allow any-user to use log-content in tenancy
where ALL {request.principal.type = 'datasciencemodeldeployment'}
```

(Optional) Allows a model deployment to access an Object Storage bucket that resides in your tenancy. For example, a deployed model reading files (a lookup CSV file) from an Object Storage bucket that you manage.

```
allow any-user to read objects in compartment <your-compartment-name>
where ALL { request.principal.type='datasciencemodeldeployment',
target.bucket.name=<your-bucket-name> }
```
Chapter 18

Data Transfer

This chapter explains how to migrate data to Oracle Cloud Infrastructure using Disk-Based Data Import and Data Transfer Appliance.

Overview of Data Transfer Service

Oracle offers offline data transfer solutions that let you migrate data to Oracle Cloud Infrastructure. You can also export data currently residing in Oracle Cloud Infrastructure to your data center offline. Moving data over the public internet is not always feasible because of high network costs, unreliable network connectivity, long transfer times, and security concerns. Our transfer solutions address these pain points, are easy to use, and provide faster data upload compared to over-the-wire data transfer.

Note:
To simplify this Data Transfer documentation, we generically refer to Object Storage to mean that you can transfer data into a bucket in either the Object Storage tier or Archive Storage tier.

DISK-BASED DATA TRANSFER

You send your data as files on encrypted USB 2.0/3.0 disk to an Oracle transfer site. Operators at the Oracle transfer site upload the files into your designated Object Storage bucket in your tenancy.

This transfer solution requires you to source and purchase the disk used to transfer data to Oracle Cloud Infrastructure. The disk is shipped back to you after the data is successfully uploaded.

See Data Import - Disk on page 1494 for details.

Note:
Disk-based data transfer is not supported for regions with FedRAMP authorization and regions with US Federal Cloud with DISA Impact Level 5 authorization.

APPLIANCE-BASED DATA TRANSFER

You send your data as files on secure, high-capacity, Oracle-supplied storage appliances to an Oracle transfer site. Operators at the Oracle transfer site upload the data into your designated Object Storage bucket in your tenancy.

This solution supports data transfer when you are migrating a large volume of data and when using a transfer disk is not a practical alternative. You do not need to write any code or purchase any hardware. Oracle supplies the transfer appliance and software required to manage the transfer.

See Data Import - Appliance on page 1541 for details.

APPLIANCE-BASED DATA EXPORT

You export your data from your Oracle Cloud Infrastructure Object Storage bucket to your data center using an Oracle-provided appliance.
This solution is useful if you have media content or processed datasets you need to share with a customer or business partner.
See Appliance Data Export on page 1610 for details.

**Supported Regions**
Learn about the supported regions for Data Transfer.
Data transfer and export are supported in the following regions:
- US East (Ashburn)
- US West (Phoenix)
- US DoD East (Ashburn)
- US DoD North (Chicago)
- US DoD West (Phoenix)
- Canada Southeast (Toronto)
- Germany Central (Frankfurt)
- UK South (London)
- Japan East (Tokyo)
- Japan Central (Osaka)

**Limits on Data Transfer Service Resources**
Learn about how to determine your limits on Data Transfer service resources.
When you sign up for Oracle Cloud Infrastructure, a set of service limits is configured for your tenancy. The service limit is the quota or allowance set on a resource. Verify that your service limits are set appropriately before you begin the data transfer process.
See Service Limits on page 243 for a list of applicable limits and instructions for requesting a limit increase. To set compartment-specific limits on a resource or resource family, administrators can use compartment quotas.

**Tagging Resources**
Learn about how to use tagging on your Data Transfer resources.
Apply tags to your resources to help organize them according to your business needs. You can apply tags at the time you create a resource, or you can update the resource later with the wanted tags. For general information about applying tags, see Resource Tags on page 239.

**Monitoring Resources**
Learn about how to monitor resources on your Data Transfer resources.
You can monitor the health, capacity, and performance of your Oracle Cloud Infrastructure resources by using metrics, alarms, and notifications. For more information, see Monitoring on page 3458 and Notifications Overview on page 4248.

**Automation for Objects Using the Events Service**
Learn how to use the Events service to automate certain Data Transfer events.
You can create automation based on state changes for your Oracle Cloud Infrastructure resources by using event types, rules, and actions. For more information, see Overview of Events on page 2382.
Events for objects are handled differently than other resources. Objects do not emit events by default. Use the Console, CLI, or API to enable a bucket to emit events for object state changes. You can enable events for object state changes during or after bucket creation.

**Notifications**
Learn how to set up notifications for certain Data Transfer events.
You can set up different types of notifications to alert you when any change happens to during your data transfer. See Notifications Overview on page 4248.

**Note:**
To fully utilize notifications, setup events that trigger the notifications. See Overview of Events on page 2382 for more information.

You can also set up notifications for appliance-based import and export jobs using a CLI command. The notifications run from the CLI provides a more convenient process than using the Notifications and Events services. Instructions for setting these CLI-based notifications are in the Preparation topics for appliance-based import and export.

### Data Encryption
Learn about how Data Transfer applies encryption to data files and tasks

Data Transfer uses the following encryption methods:
- Data at rest is encrypted with AES-256 encryption.
- Node-to-node communication is encrypted with GCM-AES-128.
- Console and API are using TLS and will default to AES-256.

### FastConnect
Learn about using FastConnect with Data Transfer jobs.

You can use Oracle Cloud Infrastructure FastConnect with your Data Transfer jobs. FastConnect provides an easy way to create a dedicated, private connection between your data center and Oracle Cloud Infrastructure. FastConnect provides higher-bandwidth options, and a more reliable and consistent networking experience compared to internet-based connections.

See FastConnect on page 4051 for more information.

### Site-to-Site VPN
Learn about using Site-to-Site VPN with Data Transfer jobs.

You can use Oracle Cloud Infrastructure Site-to-Site VPN with your Data Transfer jobs. Site-to-Site VPN provides an IPSec connection between your on-premises network your virtual cloud network (VPN).

See Site-to-Site VPN on page 3808 for more information.

### Inputting Text into Data Transfer
Learn what type of text you can input into Data Transfer.

You must use only ASCII text for all inputs to Data Transfer. This requirement applies to the browser-based Console and CLIs.

### What's Next
Now you are ready to prepare for your data transfer or export. See the following pages for more information on each of the data transfer or export methods:
- Data Import - Disk on page 1494
- Data Import - Appliance on page 1541
- Appliance Data Export on page 1610

### Data Import - Disk
Learn about how to import your data to Oracle Cloud Infrastructure using a customer-provided commercial hard disk drive.

Disk-Based Data Import is one of Oracle's offline data transfer solutions that lets you migrate data to Oracle Cloud Infrastructure. You send your data as files on an encrypted disk to an Oracle transfer site. Operators at the Oracle
transfer site upload the files into the designated Object Storage bucket in your tenancy. You are then free to move the uploaded data to other Oracle Cloud Infrastructure services as needed.

**Note:**
- Disk-based data transfer is not supported for regions with FedRAMP authorization and regions with US Federal Cloud with DISA Impact Level 5 authorization.
- Oracle does not certify or test disks you intend to use for disk import jobs. Calculate your disk capacity requirements and disk I/O to determine what USB 2.0/3.0 disk works best for your data transfer needs.
- Disks with a PIN code are not supported.

**Disk-Based Data Import Concepts**
Learn about the concepts around disk-based data import.

**IMPORT DISK**
An import disk is a user-supplied storage device that is specially prepared to copy and upload data to Oracle Cloud Infrastructure. You copy your data to the import disk and ship it in a parcel to Oracle to upload your data.

Disk-Based Data Import supports external USB 2.0/3.0 hard disk drives.

**Note:**
Pin-code protected devices and physical-key protected devices are currently not supported.

**TRANSFER DISK**
A transfer disk is the logical representation of an import disk that has been prepared to copy and upload data to Oracle Cloud Infrastructure.

**Note:**
The terms *transfer disk* and *import disk* both represent the disk being used to move your data to Oracle Cloud Infrastructure. *Transfer disk* is used in the context of configuring the disk within the transfer job and transfer package. *Import disk* is used when physically handling the disk, such as connecting it to the Data Host or mailing it to Oracle.

**TRANSFER JOB**
A transfer job is the logical representation of a data migration to Oracle Cloud Infrastructure. A transfer job consists of one or more transfer packages that each contain a single transfer disk.

**DATA TRANSFER UTILITY**
The Data Transfer Utility is the command line software that Oracle provides for you to prepare the transfer disk for your data and for shipment to Oracle. In addition, you can use this software to manage transfer jobs and packages.

**Note:**
You can only run Data Transfer Utility tasks for a supported Linux machine. Windows-based machines are not supported in disk-based transfer jobs.

**DATA HOST**
The host computer on your site that stores the data you intend to copy to the disk for migration to Oracle Cloud Infrastructure.
TRANSFER PACKAGE

A transfer package is the logical representation of the parcel containing the transfer disk that you ship to Oracle to upload to Oracle Cloud Infrastructure.

BUCKET

The logical container in Oracle Cloud Infrastructure Object Storage where Oracle operators upload your data. A bucket is associated with a single compartment in your tenancy whose policies that determine what actions a user can perform.

DATA TRANSFER ADMINISTRATOR

A new or existing IAM user that has the authorization and permissions to create and manage transfer jobs.

DATA TRANSFER UPLOAD USER

A temporary IAM user that grants Oracle personnel the authorization and permissions to upload the data from your transfer disk to your designated Oracle Cloud Infrastructure Object Storage bucket. Delete this temporary user after your data is uploaded to Oracle Cloud Infrastructure.

Roles and Responsibilities

Learn about the roles and responsibilities associated with disk-based data import.

Depending on your organization, the responsibilities of using and managing the data transfer may span multiple roles. Use the following set of roles as a guideline for how you can assign the various tasks associated with the data transfer.

• **Project Sponsor**: Responsible for the overall success of the data transfer. Project Sponsors usually have complete access to their organization's Oracle Cloud Infrastructure tenancy. They coordinate with the other roles in the organization to complete the implementation of data transfer project. The Project Sponsor is also responsible for signing legal documentation and setting up notifications for the data import.

• **Infrastructure Engineer**: Responsible for integrating the transfer appliance into the organization's IT infrastructure from where the data is being transferred. Tasks associated with this role include connecting the transfer appliance to power, placing it within the network, and setting the IP address through a serial console menu using the provided USB-to-Serial adapter.

• **Data Administrator**: Responsible for identifying and preparing the data to be transferred to Oracle Cloud Infrastructure. This person usually has access to, and expertise with, the data being migrated.

These roles correspond to the various phases of the data transfer described in the following section. A specific role can be responsible for one or more phases.

Disk Import Prerequisite Checklist

Learn about the prerequisite tasks for a disk import job.

Use this checklist for preparing to use the transfer disk for use in an import job. Check each item in order to ensure you are fully prepared for the data transfer.

- USB 2.0/3.0 external hard disk drive.
- Someone tasked to create labels for the FedEx, UPS, or DHL carriers.
- Linux machine running Oracle Linux 6 or greater, Ubuntu 14.04 or greater, or SUSE 11 or greater.
- Users interacting with the Linux machine must have root access.
- Physical access to the Linux machine to connect the hard disk drive.
- Linux operating system can create an EXT file system.
- Java 1.8 or Java 1.11 installed on Linux machine.
Data Transfer

- Hdparm 9.0 or later installed on Linux machine.
- Cryptsetup 1.2.0. or greater installed on Linux machine.
- Open firewall for Linux machine for preparation and copying to OCI Data Transfer on the IP address ranges. See Firewall Information on page 1656 for a list of IP addresses by OCI region.
- Open firewall for Linux machine for preparation and copying to OCI Object Storage IP address ranges. See Firewall Information on page 1656 for a list of IP addresses by OCI region.
- Download and install the Data Transfer Utility.
- Install OCI Command Line Interface.
- Generate public/private keys for users who will copy data on the Linux machine (run oci setup keys command)
- Administrative user on tenancy who can create users, groups, compartments, and add policies

Task Flow for Disk-Based Data Import
Learn about the role-based tasks associated with disk-based data import.

Here is a high-level overview of the tasks involved in transferring data to Oracle Cloud Infrastructure using Data Transfer Disk. Complete one phase before proceeding to the next one. Use the roles previously described to distribute the tasks across individuals or groups within your organization.
Data Transfer

Secure Disk Data Transfer to Oracle Cloud Infrastructure

Learn about how security is applied to disk-based data import.

This section highlights the security details of the Data Transfer Service process.

- The Data Transfer Utility uses the standard Linux dm-crypt and LUKS utilities to encrypt block devices.
- The dm-crypt software generates a master AES-256 bit encryption key that is used for all data written to or read from the disk. That key is protected by an encryption passphrase that the user must know to access the encrypted data.
- When the data transfer administrator uses the Data Transfer Utility to create a disk, Oracle Cloud Infrastructure creates a strong encryption passphrase that is displayed to the user and passed to dm-crypt. The passphrase is displayed to standard output only once and cannot be retrieved again. Copy this passphrase to a durable, secure location for future reference.
• For extra security, you can also encrypt your own data with your own encryption keys. Before copying your data to the transfer disk, you can encrypt your data with a tool and encryption key of your choosing. After the data has been uploaded, you would need to use the same tool and encryption key to access the data.
• All network communication between the Data Transfer Utility and Oracle Cloud Infrastructure is encrypted in-transit using Transport Layer Security (TLS).
• After copying your data to a transfer disk, generate a manifest file using the Data Transfer Utility. The manifest contains an index of all of the copied files and generated data integrity hashes. The Data Transfer Utility copies the `config_upload_user` configuration file and referenced IAM credentials to the encrypted transfer disk. This configuration file describes the temporary IAM data transfer upload user. Oracle uses the credentials and entries defined in the `config_upload_user` file when processing the transfer disk and uploading files to Oracle Cloud Infrastructure Object Storage.

**Note:**

Data Transfer Service Does Not Support Passphrases on Private Keys

While we recommend encrypting a private key with a passphrase when generating API signing keys, Data Transfer does not support passphrases on the key file required for the `config_upload_user`. If you use a passphrase, Oracle personnel cannot upload your data.

Oracle cannot upload data from a transfer disk without the correct credentials defined in this configuration file. See [Installing the Data Transfer Utility](#) on page 1500 for more information about the required configuration files.

• When you disconnect or lock a transfer disk using the Data Transfer Utility, the original encryption passphrase is required to once again access the disk. If the encryption passphrase is not known or lost, you cannot access the data on the transfer disk. To reuse a transfer disk, you must reformat the disk. Reformatting a disk removes all the data.
• Oracle retrieves the encryption passphrase for a transfer disk from Oracle Cloud Infrastructure. Oracle uses the passphrase to decrypt, mount the transfer disk, and upload the data to the designated bucket in the tenancy.
• After processing a transfer package, Oracle returns the transfer disk attached to the transfer package using the return shipping label you provide.
• To protect your data, we make the data on the disk unrecoverable before shipping the transfer disk back to you. To comply with customs regulations, we wipe the disk completely before shipping it back to international shipping addresses.

**Ways to Manage Disk Data Transfers**

Learn about the different methods available for running disk-based data imports.

We provide two ways to manage disk-based data transfers:

• The Data Transfer Utility is a full-featured command line tool for disk-based data transfers only (appliance-based data transfers use a different command line tool). For more information and installation instructions, see [Installing the Data Transfer Utility](#) on page 1500.
• The Console is an easy-to-use, partial-featured browser-based interface. For more information, see [Signing In to the Console](#) on page 63.

**Note:**

You can perform many data transfer tasks using either the Console or the Data Transfer Utility. However, there are some tasks you can only perform using the Data Transfer Utility (for example, creating and locking the transfer disk), describes the management tasks in detail and guides you to the appropriate management interface to use for each task.

**What's Next**

You are now ready to begin preparation for the Disk-Based Data Import. See [Preparing for Disk Data Transfers](#) on page 1500 for more information.
Preparing for Disk Data Transfers
Learn about how to prepare for a disk-based data import job.

This topic describes the tasks associated with preparing for the Disk-Based Data Import. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities on page 1496.

Import Disk Requirements
Learn about the requirements for running a disk-based data import job.

You are responsible for performing following tasks in order:

- Purchasing the required number of hard drives to migrate your data to Oracle Cloud Infrastructure. Use USB 2.0/3.0 external hard disk drives (HDD) with a single partitioned file system containing your data.
  
  **Note:**
  Oracle does not certify or test disks you intend to use for disk import jobs. Calculate your disk capacity requirements and disk I/O to determine what USB 2.0/3.0 disk works best for your data transfer needs.

- Copying the data to the HDDs following the procedures described in this import disk documentation.
- Shipping the disks to the specified Oracle data transfer site.

After the data is copied successfully to Oracle Cloud Infrastructure Object Storage, the hard drives are shipped back to you in the same encrypted state that they were received.

Installing the Data Transfer Utility
Learn about the installation of the Data Transfer Utility for running disk-based data import jobs.

This topic describes how to install and configure the Data Transfer Utility for use in disk-based data transfers. In addition, this topic describes the syntax for the Data Transfer Utility commands.

**Important:**

With this release, the Data Transfer Utility only supports disk-based data transfers. Use of the Data Transfer Utility for appliance-based transfers has been replaced with the Oracle Cloud Infrastructure command line interface (CLI).

The Data Transfer Utility is licensed under the Universal Permissive License 1.0 and the Apache License 2.0. Third-party content is separately licensed as described in the code.

**Note:**

The Data Transfer Utility must be run as the root user.

Prerequisites
Learn about prerequisites for installing the Data Transfer Utility.

To install and use the Data Transfer Utility, obtain the following:

- An Oracle Cloud Infrastructure account.
- The required Oracle Cloud Infrastructure users and groups with the required IAM policies.

See Creating the Required IAM Users, Groups, and Policies on page 1506 for details.
A Data Host machine with the following installed:

- Oracle Linux 6 or greater, Ubuntu 14.04 or greater, or SUSE 11 or greater. All Linux operating systems must have the ability to create an EXT file system.

**Note:**

Windows-based machines are not supported in disk-based transfer jobs.

- Java 1.8 or Java 1.11
- hdparm 9.0 or later
- Cryptsetup 1.2.0 or greater
- FireWall access: If you have a restrictive firewall in the environment where you are using the Data Transfer Utility, you may need to open your fireWall configuration to the following IP address ranges: 140.91.0.0/16.

You also need to open access to the object storage IP address ranges: 134.70.0.0/17.

**Installation**

Learn about how to install the Data Transfer Utility on different Linux operating systems.

Download and install the Data Transfer Utility installer that corresponds to your Data Host's operating system.

To install the Data Transfer Utility on Debian or Ubuntu

Install the Data Transfer Utility on a Debian or Ubuntu Linux operating system.

1. Download the installation .deb file.
2. Issue the `apt install` command as the **root** user that has write permissions to the `/opt` directory.
   
   ```bash
   sudo apt install ./dts-X.Y.Z.x86_64.deb
   ```
   
   X.Y.Z represents the version numbers that match the installer you downloaded.
3. Confirm that the Data Transfer Utility installed successfully.
   
   ```bash
   sudo dts --version
   ```
   
   Your Data Transfer Utility version number is returned.

To install the Data Transfer Utility on Oracle Linux or Red Hat Linux

Install the Data Transfer Utility on an Oracle Linux or Red Hat Linux operating system.

1. Download the installation .rpm file.
2. Issue the `yum install` command as the **root** user that has write permissions to the `/opt` directory.
   
   ```bash
   sudo yum localinstall ./dts-X.Y.Z.x86_64.rpm
   ```
   
   X.Y.Z represents the version numbers that match the installer you downloaded.
3. Confirm that the Data Transfer Utility installed successfully.
   
   ```bash
   sudo dts --version
   ```
   
   Your Data Transfer Utility version number is returned.

**Configuration**

Configure the Data Transfer Utility after installing it.

Before using the Data Transfer Utility, you must create a base Oracle Cloud Infrastructure directory and two configuration files with the required credentials. One configuration file is for the data transfer administrator, the IAM user with the authorization and permissions to create and manage transfer jobs. The other configuration file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf.
Base Data Transfer Directory

Create a base Oracle Cloud Infrastructure directory:

```bash
mkdir /root/.oci/
```

Configuration File for the Data Transfer Administrator

Create a data transfer administrator configuration file `/root/.oci/config` with the following structure:

```
[DEFAULT]
user=<The OCID for the data transfer administrator>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are: us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
```

For example:

```
[DEFAULT]
user=ocid1.user.oc1..unique_ID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..unique_ID.pem
tenancy=ocid1.tenancy.oc1..unique_ID
region=us-phoenix-1
```

For the data transfer administrator, you can create a single configuration file that contains different profile sections with the credentials for multiple users. Then use the `--profile` option to specify which profile to use in the command. Here is an example of a data transfer administrator configuration file with different profile sections:

```
[DEFAULT]
user=ocid1.user.oc1..unique_ID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..unique_ID.pem
tenancy=ocid1.tenancy.oc1..unique_ID
region=us-phoenix-1

[PROFILE1]
user=ocid1.user.oc1..unique_ID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..unique_ID.pem
tenancy=ocid1.tenancy.oc1..unique_ID
region=us-ashburn-1
```

By default, the `DEFAULT` profile is used for all Data Transfer Utility commands. For example:

```
dts job create --compartment-id compartment_id --bucket bucket_name --display-name display_name --device-type disk
```

Instead, you can issue any Data Transfer Utility command with the `--profile` option to specify a different data transfer administrator profile. For example:

```
dts job create --compartment-id compartment_id --bucket bucket_name --display-name display_name --device-type disk --profile profile_name
```

Using the example configuration file above, the `<profile_name>` would be `profile1`. 
Configuration File for the Data Transfer Upload User

Create a data transfer upload user `/root/.oci/config_upload_user` configuration file with the following structure:

```
[DEFAULT]
user=<The OCID for the data transfer upload user>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are: us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
```

For example:

```
[DEFAULT]
user=ocid1.user.oc1..unique_ID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..unique_ID.pem
tenancy=ocid1.tenancy.oc1..unique_ID
region=us-phoenix-1
```

**Important:**
Creating an upload user configuration file with multiple profiles is *not* supported.

Configuration File Entries

The following table lists the basic entries that are required for each configuration file and where to get the information for each entry.

**Note:**
Data Transfer Service does not support passphrases on the key files for both data transfer administrator and data transfer upload user.

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
<th>Required?</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>OCID of the data transfer administrator or the data transfer upload user, depending on which profile you are creating. To get the value, see <a href="#">Required Keys and OCIDs</a> on page 5303.</td>
<td>Yes</td>
</tr>
<tr>
<td>fingerprint</td>
<td>Fingerprint for the key pair being used. To get the value, see <a href="#">Required Keys and OCIDs</a> on page 5303.</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Data Transfer

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
<th>Required?</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>key_file</strong></td>
<td>Full path and filename of the private key. <strong>Important:</strong> The key pair must be in PEM format. For instructions on generating a key pair in PEM format, see Required Keys and OCIDs on page 5303.</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>tenancy</strong></td>
<td>OCID of your tenancy. To get the value, see Required Keys and OCIDs on page 5303.</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>region</strong></td>
<td>An Oracle Cloud Infrastructure region. See Regions and Availability Domains on page 208. Data transfer is supported in US East (Ashburn), US West (Phoenix), Germany Central (Frankfurt), and UK South (London).</td>
<td>Yes</td>
</tr>
</tbody>
</table>

You can verify the data transfer upload user credentials using the following command:

```
dts job verify-upload-user-credentials --bucket bucket_name
```

### Configuration File Location

The location of the configuration files is `/root/.oci/config`.

### Using the Data Transfer Utility

This section provides an overview of the syntax for the Data Transfer Utility.

**Important:**

The Data Transfer Utility must be run as the root user.

You can specify Data Transfer Utility command options using the following commands:

- `--option value` or `--option=value`

### Syntax

The basic Data Transfer Utility syntax is:

```
dts resource action [options]
```

This syntax is applied to the following:

- `dts` is the shortened utility command name
• job is an example of a <resource>
• create is an example of an <action>
• Other utility strings are [options]

The following examples show typical Data Transfer Utility commands to create a transfer job.

```
dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name "mycompany transfer1" --bucket mybucket --device-type disk
```

Or:

```
dts job create --compartment-id=compartment-id ocid.compartment.oc1..exampleuniqueID --display-name="mycompany transfer1" --bucket=mybucket --device-type=disk
```

**Note:**
In the previous examples, provide a friendly name for the transfer job using the `display-name` option. Avoid entering confidential information.

**Finding Out the Installed Version of the Data Transfer Utility**

You can get the installed version of the Data Transfer Utility using `--version` or `-v`. For example:

```
dts --version
0.6.183
```

**Accessing Data Transfer Utility Help**

All Data Transfer Utility help commands have an associated help component you can access from the command line. To view the help, enter any command followed by the `--help` or `-h` option. For example:

```
dts job --help
```

Usage:  job [COMMAND]
Transfer disk or appliance job operations -  {job action [options]}

Commands:
create                          Creates a new transfer disk or appliance
job.                           job.
show                           Shows the transfer disk or appliance job
details.                      Updates the transfer disk or appliance job
update                         Deletes the transfer disk or appliance job.
details.                      Closes the transfer disk or appliance job.
delete                         Lists all transfer disk or appliance jobs.
close                          Verifies the transfer disk or appliance
list                           upload user credentials.
verify-upload-user-credentials upload user credentials.

When you run the help option (`--help` or `-h`) for a specified command, all the subordinate commands and options for that level of the Data Transfer Utility are displayed. If you want to access the Data Transfer Utility help for a specific subordinate command, include it in the Data Transfer Utility string, for example:

```
dts job create --help
```

Usage:  job create --bucket=<bucket> --compartment-id=<compartmentId> [--defined-tags=<definedTags>] --device-type=<deviceType> --display-name=<displayName>
Creating the Required IAM Users, Groups, and Policies

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization.

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in.

Access to resources is provided to groups using policies and then inherited by the users that are assigned to those groups. Data transfer requires the creation of two distinct groups:

- Data transfer administrators who can create and manage transfer jobs.
- Data transfer upload users who can upload data to Object Storage. For your data security, the permissions for upload users allow Oracle personnel to upload standard and multi-part objects on your behalf and inspect bucket and object metadata. The permissions do not allow Oracle personnel to inspect the actual data.

The Data Administrator is responsible for generating the required RSA keys needed for the temporary upload users. These keys should never be shared between users.

For details on creating groups, see Managing Groups on page 3115.

An administrator creates these groups with the following policies:

- The data transfer administrator group requires an authorization policy that includes the following:

  Allow group group_name to manage data-transfer-jobs in compartment compartment_name
  Allow group group_name to manage objects in compartment compartment_name
  Allow group group_name to manage buckets in compartment compartment_name

  Alternatively, you can consolidate the manage buckets and manage objects policies into the following:

  Allow group group_name to manage object-family in compartment compartment_name

- The data transfer upload user group requires an authorization policy that includes the following:

  Allow group group_name to manage buckets in compartment compartment_name
  where all { request.permission='BUCKET_READ', target.bucket.name='<bucket_name>' }

  Allow group group_name to manage objects in compartment compartment_name
  where all { target.bucket.name='<bucket_name>',
  any { request.permission='OBJECT_CREATE', request.permission='OBJECT_OVERWRITE',
  request.permission='OBJECT_INSPECT' }}
To enable notifications, add the following policies:

- Allow group `group name` to manage ons-topics in tenancy
- Allow group `group name` to manage ons-subscriptions in tenancy
- Allow group `group name` to manage cloudevents-rules in tenancy
- Allow group `group name` to inspect compartments in tenancy

See [Notifications Overview](#) on page 4248 and [Overview of Events](#) on page 2382 for more information.

The Oracle Cloud Infrastructure administrator then adds a user to each of the data transfer groups created. For details on creating users, see [Managing Users](#) on page 3110.

**Important:**

For security reasons, we recommend that you create a unique IAM data transfer upload user for each transfer job and then delete that user once your data is uploaded to Oracle Cloud Infrastructure.

### Creating Object Storage Buckets

The Object Storage service is used to upload your data to Oracle Cloud Infrastructure. Object Storage stores objects in a container called a bucket within a *compartment* in your tenancy. For details on creating the bucket to store uploaded data, see [Managing Buckets](#) on page 4298.

### Configuring Firewall Settings

The firewall port number is 443 for all data transfer methods.

Ensure that your local environment's firewall can communicate with the Data Transfer Service running on the IP address ranges for your OCI region based on the following table. Also ensure that open access exists to the Object Storage IP address range. You only need to configure this IP access for the region where your data transfer job is associated.

<table>
<thead>
<tr>
<th>Region</th>
<th>Data Transfer</th>
<th>Object Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ashburn)</td>
<td>140.91.0.0/16</td>
<td>134.70.24.0/21</td>
</tr>
<tr>
<td>US West (Phoenix)</td>
<td>129.146.0.0/16</td>
<td>134.70.8.0/21</td>
</tr>
<tr>
<td>Germany Central (Frankfurt)</td>
<td>130.61.0.0/16</td>
<td>134.70.40.0/21</td>
</tr>
<tr>
<td>UK South (London)</td>
<td>132.145.0.0/16</td>
<td>134.70.56.0/21</td>
</tr>
<tr>
<td>Brazil East (Sao Paulo)</td>
<td>140.204.0.0/16</td>
<td>134.70.84.0/22</td>
</tr>
<tr>
<td>India West (Mumbai)</td>
<td>140.204.0.0/16</td>
<td>134.70.76.0/22</td>
</tr>
<tr>
<td>Japan East (Tokyo)</td>
<td>140.204.0.0/16</td>
<td>134.70.80.0/22</td>
</tr>
<tr>
<td>South Korea Central (Seoul)</td>
<td>140.204.0.0/16</td>
<td>134.70.96.0/22</td>
</tr>
<tr>

<td>140.204.0.0/16</td>
<td>134.70.112.0/22</td>
</tr>
<tr>
<td>Canada Southeast (Toronto)</td>
<td>140.204.0.0/16</td>
<td>134.70.116.0/22</td>
</tr>
</tbody>
</table>

### Creating Transfer Jobs

This section describes how to create a transfer job as part of the preparation for the data transfer. See [Transfer Jobs](#) on page 1526 for complete details on all tasks related to transfer jobs.
Tip:

You can use the Console or the Data Transfer Utility to create a transfer job.

A transfer job represents the collection of files that you want to transfer and signals the intention to upload those files to Oracle Cloud Infrastructure. A transfer job combines at least one transfer disk with a transfer package. Identify which compartment and Object Storage bucket that Oracle is to upload your data to. Create the transfer job in the same compartment as the upload bucket and supply a human-readable name for the transfer job.

Note:

It is recommended that you create a compartment for each transfer job to minimize the required access your tenancy.

Creating a transfer job returns a job ID that you specify in other transfer tasks. For example:

```
oci1.datatransferjob.region1.phx..exampleuniqueID
```

To create a transfer job using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Select the designated compartment you are to use for data transfers from the list.
   A list of transfer jobs that have already been created is displayed.
3. Click Create Transfer Job.
   The Create Transfer Job dialog appears.
4. Enter a Job Name. Avoid entering confidential information. Then, select the Upload Bucket from the list.
5. Select Disk for the Transfer Device Type.
6. Click Create Transfer Job.

To create a transfer job using the Data Transfer Utility

```
dts job create --bucket bucket --compartment-id compartment_id --display-name display_name
```

`display_name` is the name of the transfer job. Avoid entering confidential information.

For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob
```

Transfer Job :
ID : oci1.datatransferjob.oct1..exampleuniqueID
CompartmentId : ocid.compartment.oc1..exampleuniqueID
UploadBucket : MyBucket1
Name : MyDiskImportJob
Label : JZM9PAVW
CreationDate : 2019/06/04 17:07:05 EDT
Status : PREPARING
freeformTags : *** none ***
definedTags : *** none ***
Packages :
[1] :
  Label : PBNZOX9R
  TransferSiteShippingAddress : Oracle Data Transfer Service;
  Job:JZM9PAVW Package:PBNZOX9R ; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
  DeliveryVendor : FedEx
  DeliveryTrackingNumber : *** none ***
  ReturnDeliveryTrackingNumber : *** none ***
  Status : PREPARING
Optionally, you can specify one or more defined or free-form tags when you create a transfer job. For more information about tagging, see Resource Tags on page 239.

**Defined Tags**

To specify defined tags when creating a job:

```
dts job create --bucket bucket --compartment-id compartment_id --display-name display_name --defined-tags '{ "tag_namespace": { "tag_key": "value" } }'
```

For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob --defined-tags '{"Operations": {"CostCenter": "01"}}'
```

Transfer Job:

- **ID**: ocid1.datatransferjob.oc1..exampleuniqueID
- **CompartmentId**: ocid.compartment.oc1..exampleuniqueID
- **UploadBucket**: MyBucket1
- **Name**: MyDiskImportJob
- **Label**: JZM9PAVNH
- **CreationDate**: 2019/06/04 17:07:05 EDT
- **Status**: PREPARING
- **DefinedTags**:
  - **Operations**:
    - **CostCenter**: 01
- **Packages**:
  - **Label**: PBNZOX9RU
  - **TransferSiteShippingAddress**: Oracle Data Transfer Service;
    - Job: JZM9PAVNH Package: PBNZOX9RU；21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
  - **DeliveryVendor**: FedEx
  - **DeliveryTrackingNumber**: *** none ***
  - **ReturnDeliveryTrackingNumber**: *** none ***
  - **Status**: PREPARING
  - **Devices**: [*** none ***]
  - **UnattachedDevices**: [*** none ***]
  - **Appliances**: [*** none ***]

When you use the `dts job show` to display the details of a job, tagging details are also included in the output if you specified tags.

**Freeform Tags**

To specify freeform tags when creating a job:

```
dts job create --bucket bucket --compartment-id compartment_id --display-name display_name --freeform-tags '{ "tag_key": "value" }'
```

Note:

Users create tag namespaces and tag keys with the required permissions. These items must exist before you can specify them when creating a job. See Working with Defined Tags on page 4967 for details.
For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob --defined-tags '{"Operations": "01"}')
```

Transfer Job:
- ID: ocid1.datatransferjob.oc1..exampleuniqueID
- CompartmentId: ocid.compartment.oc1..exampleuniqueID
- UploadBucket: MyBucket1
- Name: MyDiskImportJob
- Label: JZM9PAVWH
- CreationDate: 2019/06/04 17:07:05 EDT
- Status: PREPARING
- FreeformTags:
  - Pittsburg_Team: brochures
- DefinedTags: *** none ***
- Packages:
  - Label: PBNZOX9RU
  - TransferSiteShippingAddress: Oracle Data Transfer Service;
  - Job: JZM9PAVWH Package: PBNZOX9RU; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
  - DeliveryVendor: FedEx
  - DeliveryTrackingNumber: *** none ***
  - ReturnDeliveryTrackingNumber: *** none ***
  - Status: PREPARING
  - Devices: [*** none ***]
  - UnattachedDevices: [*** none ***]
  - Appliances: [*** none ***]

When you use the to display the details of a job, tagging details are also included in the output if you specified tags.

### Multiple Tags

To specify multiple tags, comma separate the JSON-formatted key/value pairs:

```
dts job create --bucket bucket --compartment-id compartment_id --display-name display_name --device-type disk --freeform-tags '{"tag_key":"value"}', '{"tag_key":"value"}'
```

### Getting Transfer Job IDs

Each transfer job you create has a unique ID within Oracle Cloud Infrastructure. For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob --defined-tags '{"Operations": "01"}')
```

You will need to forward this transfer job ID to the Data Administrator.

To get the transfer job ID using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Select the Compartment from the list.
   
   The transfer jobs in that compartment are displayed.
3. Click the link under Transfer Jobs for the transfer job whose details you want to view.

   Alternatively, you can click the Actions icon (⋮), and then click View Details.

   The Details page for that transfer job appears.
4. Find the OCID field in the Details page and click Show to display it or Copy to copy it to your computer.
To get the transfer job ID using the CLI

dts job list --compartment-id compartment_id

For example:

dts job list --compartment-id ocid.compartment.oc1..exampleuniqueID

Transfer Job List :
[1] :
  ID           : ocid1.datatransferjob.oc1..exampleuniqueID
  Name         : MyDiskImportJob
  Label        : JVWK5YWPU
  BucketName   : MyBucket1
  CreationDate : 2020/06/01 17:33:16 EDT
  Status       : INITIATED
  FreeformTags : *** none ***
  DefinedTags  :
    Financials :
      key1 : nondefault

The ID for each transfer job is returned:

ID : ocid1.datatransferjob.oc1..exampleuniqueID

Tip:

When you create a transfer job using the dts job create CLI, the transfer job ID is displayed in the CLI's return.

Creating Upload Configuration Files

The Project Sponsor is responsible for creating or obtaining configuration files that allow the uploading of user data to the transfer appliance. Send these configuration files to the Data Administrator where they can be placed in the Data Host. The config file is for the data transfer administrator, the IAM user with the authorization and permissions to create and manage transfer jobs. The config_upload_user file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf.

Create a base Oracle Cloud Infrastructure directory and two configuration files with the required credentials.

Creating the Data Transfer Directory

Create a Oracle Cloud Infrastructure directory (.oci) on the same Data Host where the CLI is installed. For example:

mkdir /root/.oci/

The two configuration files (config and config_upload_user) are placed in this directory.

Creating the Data Transfer Administrator Configuration File

Create the data transfer administrator configuration file /root/.oci/config with the following structure:

```
[DEFAULT]
user=<The OCID for the data transfer administrator>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
```
region=<The region where the transfer job and bucket should exist. Valid values are: us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>

For example:

[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-phoenix-1

For the data transfer administrator, you can create a single configuration file that contains different profile sections with the credentials for multiple users. Then use the `##profile` option to specify which profile to use in the command.

Here is an example of a data transfer administrator configuration file with different profile sections:

[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-phoenix-1

[PROFILE1]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-ashburn-1

By default, the DEFAULT profile is used for all CLI commands. For example:

oci dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket MyBucket --display-name MyDisplay --device-type disk

Instead, you can issue any CLI command with the `--profile` option to specify a different data transfer administrator profile. For example:

oci dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket MyBucket --display-name MyDisplay --device-type disk --profile MyProfile

Using the example configuration file above, the `<profile_name>` would be profile1.

If you created two separate configuration files, use the following command to specify the configuration file to use:

oci dts job create --compartment-id compartment_id --bucket bucket_name --display-name display_name

**Creating the Data Transfer Upload User Configuration File**

The config_upload_user configuration file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf. Create this configuration file with the following structure:

[DEFAULT]
user=<The OCID for the data transfer upload user>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
Data Transfer

```
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are:
us-ashburn-1, us-phoenix-1, eu-frankfurt-1, and uk-london-1.>
```

Adding Object Storage Endpoints

Include the line `endpoint=url` for the Object Storage API endpoint in the upload user configuration file.

For example:

```
endpoint=https://objectstorage.us-phoenix-1.oraclecloud.com
```

Click here to view a list of endpoints.

A complete configuration including the Object Storage endpoint might look like this:

```
[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-phoenix-1
endpoint=https://objectstorage.us-phoenix-1.oraclecloud.com
```

Important:

Creating an upload user configuration file with multiple profiles is not supported.

Configuration File Entries

The following table lists the basic entries that are required for each configuration file and where to get the information for each entry.

```
<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
<th>Required?</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>OCID of the data transfer administrator or the data transfer upload user, depending on which profile you are creating. To get the value, see Required Keys and OCIDs on page 5303.</td>
<td>Yes</td>
</tr>
<tr>
<td>fingerprint</td>
<td>Fingerprint for the key pair being used. To get the value, see Required Keys and OCIDs on page 5303.</td>
<td>Yes</td>
</tr>
</tbody>
</table>
```

Note:

Data Transfer Service does not support passphrases on the key files for both data transfer administrator and data transfer upload user.
### Data Transfer

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
<th>Required?</th>
</tr>
</thead>
</table>
| **key_file** | Full path and filename of the private key.  
**Important:** The key pair must be in PEM format. For instructions on generating a key pair in PEM format, see Required Keys and OCIDs on page 5303. | Yes       |
| **tenancy** | OCID of your tenancy. To get the value, see Required Keys and OCIDs on page 5303.                          | Yes       |
| **region** | An Oracle Cloud Infrastructure region. See Regions and Availability Domains on page 208.  
Data transfer is supported in US East (Ashburn), US West (Phoenix), Germany Central (Frankfurt), and UK South (London). | Yes       |

You can verify the data transfer upload user credentials using the following command:

```bash
dts job verify-upload-user-credentials --bucket bucket_name
```

### Creating Transfer Packages

A transfer package is the virtual representation of the physical disk package that you are shipping to Oracle for upload to Oracle Cloud Infrastructure. See Transfer Packages on page 1538 for complete details on all tasks related to transfer packages.

Creating a transfer package requires the job ID returned from when you created the transfer job. For example:

```bash
ocid1.datatransferjob.region1.phx..exampleuniqueID
```

**To create a transfer package using the Console**

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Find the transfer job for which you want to create a transfer package.
3. Click the **Actions** icon (⋯), and then click **View Details**.
   
   Alternatively, click the hyperlinked name of the transfer job.
   
   A list of transfer packages that have already been created is displayed.
4. Click **Create Transfer Package**.
   
   The Create Transfer Package dialog appears.
5. Select a **Vendor** from the list.
6. Click **Create Transfer Package**.
The Data Transfer Package dialog appears displaying information such as the shipping address, the shipping vendor, and the shipping status.

To create a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts package create` to create a transfer package.

```
dts package create --job-id job_id
```

The following information is returned:

```
Transfer Package :
Label :
TransferSiteShippingAddress :
DeliveryVendor :
DeliveryTrackingNumber :
ReturnDeliveryTrackingNumber :
Status :
Devices :
```

Getting Transfer Package Labels

To get the transfer package label using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Find the transfer job for which you want to see the details.
3. Click the Actions icon ( ), and then click View Details.
   Alternatively, click the hyperlinked name of the transfer job.
4. Click Transfer Packages under Resources.
   A list of transfer packages associated with the transfer job is displayed.

To get the transfer package label using the Data Transfer Utility

```
dts job show --job-id job_id
```

For example:

```
dts job show --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```

```
Transfer Job :
ID : ocid1.datatransferjob.oc1..exampleuniqueID
CompartmentId : ocid.compartment.oc1..exampleuniqueID
UploadBucket : MyBucket1
Name : MyDiskImportJob
Label : JZM9PAVWH
CreationDate : 2019/06/04 17:07:05 EDT
Status : PREPARING
freeformTags : *** none ***
definedTags : *** none ***
Packages :
[1] :
   Label : PBNZOX9RU
   TransferSiteShippingAddress : Oracle Data Transfer Service;
Job:JZM9PAVWH Package:PBNZOX9RU ; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
   DeliveryVendor : FedEx
   DeliveryTrackingNumber : *** none ***
   ReturnDeliveryTrackingNumber : *** none ***
   Status : PREPARING
   Devices : [*** none ***]
   UnattachedDevices : [*** none ***]
```
### Data Transfer

| Appliances | [*** none ***] |

The transfer package label is displayed as part of the job details.

**Getting Shipping Labels**

You can find the shipping address in the transfer package details. Use this information to get a shipping label for the transfer package that is used to send the disk to Oracle.

After getting the shipping labels from the Console or Data Transfer Utility, go to the supported carrier you are using (UPS, FedEx, or DHL) and manually create both the SHIP TO ORACLE and RETURN TO CUSTOMER labels. See *Shipping Import Disks* on page 1522 and *Monitoring the Import Disk Shipment and Data Transfer* on page 1523 for information.

**To get the shipping address for a transfer package using the Console**

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Find the transfer job for which you want to see the details.
3. Click the *Actions* icon ( ), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer job.
   A list of transfer packages that have already been created is displayed.
4. Find the transfer package for which you want to see the details.
5. Click the *Actions* icon ( ), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer job.

**To get the shipping address for a transfer package using the Data Transfer Utility**

```
dts package show --job-id job_id --package-label package_label
```

For example:

```
dts package show --job-id ocid1.datatransferjob.oc1..exampleuniqueID --package-label PWA8O67MI
```

**Transfer Package**:

<table>
<thead>
<tr>
<th>Label</th>
<th>PWA8O67MI</th>
</tr>
</thead>
<tbody>
<tr>
<td>TransferSiteShippingAddress</td>
<td>Oracle Data Transfer Service; Job:JZM9PAVWH Package:PWA8O67MI ; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA</td>
</tr>
<tr>
<td>DeliveryVendor</td>
<td>[*** none ***]</td>
</tr>
<tr>
<td>DeliveryTrackingNumber</td>
<td>[*** none ***]</td>
</tr>
<tr>
<td>ReturnDeliveryTrackingNumber</td>
<td>[*** none ***]</td>
</tr>
<tr>
<td>Status</td>
<td>PREPARING</td>
</tr>
<tr>
<td>Devices</td>
<td>[*** none ***]</td>
</tr>
</tbody>
</table>

**Notifying the Data Administrator**

When you have completed all the tasks in this topic, provide the Data Administrator of the following:

- IAM login credentials
- Data Transfer Utility configuration files
- Transfer job ID
- Package label

**What's Next**

You are now ready to configure your system for the data transfer. See *Configuring Import Disk Data Transfers* on page 1517.
Data Transfer

Configuring Import Disk Data Transfers

This topic describes the tasks associated with configuring the Disk-Based Data Import. The Infrastructure Engineer role typically performs these tasks. See Roles and Responsibilities on page 1496.

Configuration for the Disk-Based Data Import consists of the following tasks:

- Attaching the import disk to the Data Host. Remove all partitions and any file systems. To prevent the accidental deletion of data, the Data Transfer Utility does not work with disks that already have partitions or file systems. Disks are visible to the host as block devices and must provide a valid response to the `hdparm -I device` Linux command.
- Sending the block device path to the Data Administrator.

What's Next

You are now ready to load your data to the transfer disk. See Copying the Data to the Import Disk on page 1517.

Copying the Data to the Import Disk

This topic describes the tasks associated with running the data transfer from the Data Host to the import disk. The Data Administrator role typically performs these tasks. See Roles and Responsibilities on page 1496.

Information Prerequisites

Before performing any disk copying tasks, you must obtain the following information:

- Disk block device path. The Infrastructure Engineer typically provides this information.
- IAM login information, Data Transfer Utility configuration files, transfer job ID, and package label. The Project Sponsor typically provides this information.

Creating the Transfer Disk

The transfer disk is the logical representation of the physical import disk that has been configured for use for receiving data as part of the disk-based data transfer. See Transfer Disks on page 1534 for complete details on all tasks related to transfer disks.

Note:

You can only use the Data Transfer Utility to create a transfer disk.

When you create a transfer disk for use with the disk on which you are copying your files, the Data Transfer Utility:

- Sets up the disk for encryption using the passphrase.
- Creates a file system on the disk.
- Mounts the file system at `/mnt/orcdts_label`.

For example:

```
/mnt/orcdts_DJZNWK3ET
```

When you register a transfer disk, Oracle Cloud Infrastructure generates a strong encryption passphrase that is used to encrypt the contents on the disk. The encryption passphrase is displayed to standard output to the data transfer administrator user and cannot be retrieved again. Create a local, secure copy of the encryption passphrase, so you can reference the passphrase again.
Creating a transfer disk requires the job ID returned from when you created the transfer job and the path to the attached disk (for example, /dev/sdb).

**To create a transfer disk using the Data Transfer Utility**

At the command prompt on the host, run `dts disk create` to create a transfer disk.

```
dts disk create --job-id job_id --block-device block_device
```

**Copying Files to the Disk**

Learn about copying files to the NFS share during a disk-based import job.

You can only copy regular files to the disk. You cannot copy special files, such as symbolic links, device special, sockets, and pipes, directly to the disk. See the following section for instructions on how to prepare special files.

**Important:**

- Individual files being copied to the disk cannot exceed 10,000,000,000,000 bytes (10 TB).
- Do not fill up the disk to 100% capacity. There must be space available to generate metadata and for the manifest file to perform the upload to Object Storage. At least 1 GB of free disk space is needed for this area.
- File name characters must be UTF-8 and cannot contain a new line or a return character. Before copying data to the appliance, check the filesystem or source with the following command:

  ```
  find . -print0 | perl -ne 'chomp; print 
  
  \"\n\" if /[[[:ascii:]][[:cntrl:]]/\''
  ```

- The maximum character file name length is 1024 characters.

Attach the disk to the Data Host and copy files to the mount point created by disk through the Data Transfer Utility.

**Note:**

Only Linux machines can be used as Data Hosts.

**Note:**

Copy all Files Before Disconnecting the Disk.

Do not disconnect the disk until you copy all files from the Data Host and generate the manifest file. If you accidentally disconnect the disk before copying all files, you must unlock the disk using the encryption passphrase. The encryption passphrase was generated and displayed when you created the transfer disk. If the generated encryption passphrase is not available, you must delete the transfer disk from the transfer job and re-create the transfer disk. All data previously copied to that disk is lost.

**Copying Special Files**

To transfer special files, create a tar archive of these files and copy the tar archive to the Data Transfer Appliance. We recommend copying many small files using a tar archive. Copying a single compressed archive file should also take less time than running copy commands such as `cp -r` or `rsync`.

Here are some examples of creating a tar archive and getting it onto the Data Transfer Appliance:

- Running a simple tar command:

  ```
  tar -cvzf /mnt/nfs-dts-1/filesystem.tgz filesystem/
  ```
• Running a command to create a file with md5sum hashes for each file in addition to the tar archive:

```
tar cvzf /mnt/nfs-dts-1/filesystem.tgz filesystem/ | xargs -I '{}' sh -c "test -f '{}' && md5sum '{}'")"| tee tarzip_md5
```

The tar archive file `filesystem.tgz` has a base64 md5sum once it is uploaded to OCI Object Storage. Store the `tarzip_md5` file where you can retrieve it. After the compressed tar archive file is downloaded from Object Storage and unpacked, you can compare the individual files against the hashes in the file.

**Manifest File and Locking Information**

Learn about how manifest file and locking works with disk-based import jobs.

Throughput for manifest file and locking is the average throughput for the disk used for disk import process. The manifest process initially opens threads based on 80% of available cores, but declines as the file count falls below the thread count.

**Note:**

- The sealing process uses a file tree walk and processes whichever files it comes across with no particular ordering.
- When the file count falls below the thread count based on 80% of available cores, the thread count/file count falls and throughput appears to drop.
- Only one file is processed per a thread because of hash/checksum computation.
- Smaller files are processed faster than larger files.
- Larger files can take hours to process.

**Generating the Manifest File**

**Note:**

You can only use the Data Transfer Utility to generate a manifest file. The amount of time to generate the manifest file depends on the size of the upload files, disk speed, and available processing power.

After copying your data to a transfer disk, generate a manifest file using the Data Transfer Utility. The manifest contains an index of all of the copied files and generated data integrity hashes. The Data Transfer Utility copies the `config_upload_user` configuration file and referenced IAM credentials to the encrypted transfer disk. This configuration file describes the temporary IAM data transfer upload user. Oracle uses the credentials and entries defined in the `config_upload_user` file when processing the transfer disk and uploading files to Oracle Cloud Infrastructure Object Storage.

**Note:**

Data Transfer Service Does Not Support Passphrases on Private Keys

While we recommend encrypting a private key with a passphrase when generating API signing keys, Data Transfer does not support passphrases on the key file required for the `config_upload_user`. If you use a passphrase, Oracle personnel cannot upload your data.

Oracle cannot upload data from a transfer disk without the correct credentials defined in this configuration file. See **Installing the Data Transfer Utility** on page 1500 for more information about the required configuration files.

**To create a manifest file using the Data Transfer Utility**

At the command prompt on the Data Host, run `dts disk manifest` to create a manifest file.

```
dts disk manifest --job-id job_id --disk-label disk_label--object-name-prefix object_name_prefix
```
**Data Transfer**

**Note:**

Do You Need to Regenerate the Manifest File?

If you add, remove, or modify any files on the disk after generating the manifest file, you must regenerate the file. If the manifest file does not match the contents of the target bucket, Oracle cannot upload the data.

**Locking the Transfer Disk**

**Note:**

You can only use the Data Transfer Utility to lock a transfer disk.

Locking a transfer disk safely unmounts the disk and removes the encryption passphrase from the Data Host.

*To lock a transfer disk using the Data Transfer Utility*

At the command prompt on the Data Host, run `dts disk lock` to lock a transfer disk.

```
dts disk lock --job-id job_id --disk-label disk_label --block-device block_device
```

**Unlocking the Transfer Disk**

**Note:**

You can only use the Data Transfer Utility to unlock a transfer disk.

When unlocking the transfer disk, you are prompted for the encryption passphrase that was generated when you created the transfer disk.

*To unlock a transfer disk using the Data Transfer Utility*

At the command prompt on the Data Host, run `dts disk unlock` to unlock a transfer disk.

```
dts disk unlock --job-id job_id --disk-label disk_label --block-device block_device --encryption-passphrase encryption_passphrase
```

**Attaching the Transfer Disk to the Transfer Package**

Attach a transfer disk to a transfer package after you have performed the following tasks:

1. Copied your data onto the disk.
2. Generated the required manifest file.
3. Run and reviewed the dry-run report.
4. Locked the transfer disk in preparation for shipment.

A disk can be attached to one package, detached, and then attached to another package. In some cases, you have attached a transfer disk to a transfer package, but have changed your mind about shipping that disk with the transfer package. You can also detach a transfer disk from one transfer package and attach that disk to a different transfer package.

*To attach a transfer disk to a transfer package using the Console*

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Find the transfer job associated with the transfer package for which you want to attach a disk.
3. Click the Actions icon (_generate icon), and then click View Details.
   A list of transfer packages is displayed.
4. Find the transfer package for which you want to attach a disk.
5. Click the **Actions** icon (.IsNotNull), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer package.
   A list of transfer disks is displayed.
6. Click **Attach Transfer Disks**.
   The Attach Transfer Disks dialog appears.
7. Select the **Transfer Disks** that you want to attach to the transfer package.
8. Click **Attach**.

*To attach a transfer disk to a transfer package using the Data Transfer Utility*

At the command prompt on the Data Host, run `dts disk attach` to attach a disk to a transfer package.

```bash
dts disk attach --job-id job_id --package-label package_label --disk-label disk_label
```

### Detaching the Transfer Disk from the Transfer Package

*To detach a transfer disk from a transfer package using the Console*

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Find the transfer package from which you want to detach a transfer disk.
3. Click the **Actions** icon (.IsNotNull), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer package.
   A list of transfer disks that have already been attached is displayed.
4. Find the transfer disk that you want to detach.
5. Click the **Actions** icon (.IsNotNull), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer disk.
6. Click **Detach Transfer Disk**.

*To detach a transfer disk from a transfer package using the Data Transfer Utility*

At the command prompt on the Data Host, run `dts disk detach` to detach a disk from a transfer package.

```bash
dts disk detach --job-id job_id --package-label package_label --disk-label disk_label
```

### Setting Tracking Details on the Transfer Package

After delivering the transfer package to the shipping vendor, update the transfer package with the tracking information.

**Important:**

Oracle cannot process a transfer package until you update the tracking information.

*To update the transfer package with tracking information using the Console*

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Find the transfer job for which you want to see the associated transfer packages.
3. Click the **Actions** icon (.IsNotNull), and then click **View Details**.
   A list of transfer packages that have already been created is displayed.
4. Find the transfer package that you want to update.
5. Click the **Actions** icon (.IsNotNull), and then click **View Details**.
6. Click **Edit**.
7. Enter the **Tracking ID** and the **Return Tracking ID**.
8. Click **Edit Transfer Package**.

**To update the transfer package with tracking information using the Data Transfer Utility**

At the command prompt on the host, run `dts package ship` to update the transfer package tracking information.

```
dts package ship --job-id job_id --package-label package_label --package-vendor vendor_name --tracking-number tracking_number --return-tracking-number return_tracking_number
```

**Notifying the Infrastructure Engineer**

After completing the tasks listed in this topic, notify the Infrastructure Engineer of the following:

- Disconnect the physical disk from the Data Host.
- Package the disk for shipment.

**What’s Next**

You are now ready to ship your disk with the copied data to Oracle. See **Shipping Import Disks** on page 1522.

**Shipping Import Disks**

This topic describes the tasks associated with shipping the import disk containing the copied data to Oracle. The Infrastructure Engineer role typically performs these tasks. See **Roles and Responsibilities** on page 1496.

**Disconnecting the Transfer Disk from the Data Host**

Do not disconnect the import disk until you copy all files from the Data Host and generate the manifest file. See **Copying the Data to the Import Disk** on page 1517 for more information.

**Printing Shipping Labels**

You should receive the shipping labels electronically from the Project Sponsor. Print them on the appropriate labels for shipping the import disk. See **Getting Shipping Labels** on page 1516 for more information.

**Packaging and Shipping the Import Disk**

**General**

Include the required return shipping label in the box when packaging the import disk for shipment.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you do not include the return shipping label inside the box, Oracle cannot process the transfer package.</td>
</tr>
</tbody>
</table>

Ensure that the transfer job and transfer package label are clearly readable on the outside of the box containing the import disk.

<table>
<thead>
<tr>
<th>Important:</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you are shipping transfer disks to London or Frankfurt, request that the shipping vendor requires a signature delivery.</td>
</tr>
</tbody>
</table>

**Listing Disk Delivery Vendors**

You can view the vendors available for delivery of your import disk to Oracle Cloud Infrastructure.
Data Transfer

Note:

- Available vendors for transfer disk delivery to Oracle Cloud Infrastructure can vary over time. Have the latest version of the Data Transfer Utility installed to view the current list.
- You can only use the Data Transfer Utility to lock an transfer disk.

To list the vendors available for delivering the transfer disk to Oracle Cloud Infrastructure

At the command prompt on the Data Host, run `dts package list-delivery-vendors` to list the available delivery vendors.

```
dts package list-delivery-vendors

Delivery Vendors:
[1] : FedEx
[3] : UPS
```

Shipping Import Disks Internationally

Create a commercial invoice when shipping transfer disks internationally. To ensure that packages are not held up in customs, follow these guidelines when creating the commercial invoice:

- Show a unique reference number.
- Show the "bill-to party" as follows:
  - For shipments to the European Union (Frankfurt) location:
    ORACLE Deutschland B.V. & Co. KG Riesstrasse 25 Munich, 80992 GERMANY
  - For shipments to the United States location:
    Oracle America, Inc. 500 Oracle Parkway REDWOOD CITY CA 94065 UNITED STATES.
  - Show the "ship-to party" as the address provided in the transfer package details. See Getting Shipping Labels on page 1516 for details.
  - State that "The value shown includes the value of software and data recorded onto the hard drive unit."
  - State that the "Goods are free of charge - no payment required."
  - State that the type of export is "Temporary."
  - Ensure that the commodity code shows the correct HS code for a hard drive unit as specified in the source country's HS code list.
  - State the description as the manufacture's description of the hard drive unit and include the words "Hard Disk Drive."
  - Ensure that the invoice is signed and includes the printed name of the signer.

What's Next

Now you can track your transfer disk shipment and review post transfer logs and summaries. See Monitoring the Import Disk Shipment and Data Transfer on page 1523.

Monitoring the Import Disk Shipment and Data Transfer

This topic describes the monitoring tasks to do after sending the import disk with the copied data to Oracle for data transfer to Oracle Cloud Infrastructure. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities on page 1496.
Tracking the Import Disk Shipment

When Oracle has processed the transfer (import) disk associated with a transfer package, the status of the transfer package changes to **Processed**. When Oracle has shipped the disk, the status of the transfer package changes to **Returned**.

To check the status of a transfer package using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Choose the data transfer package for which you want to display the details.
3. Click the **Actions** icon ( ), and then click **View Details**.
4. Look at the **Status**.

To check the status of a transfer package using the Data Transfer Utility

At the command prompt on the Data Host, run `dts package show` to show the status of a transfer package.

```
dts package show --job-id job_id --package-label package_label
```

For example:

```
dts package show --job-id ocid1.datatransferjob.oci1..exampleuniqueID --package-label PWA8067MI
```

Transfer Package :
Label: PWA8067MI
TransferSiteShippingAddress: Oracle Data Transfer Service; Job:JZM9PAVWH
Package: PWA8067MI; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
DeliveryVendor: *** none ***
DeliveryTrackingNumber: *** none ***
ReturnDeliveryTrackingNumber: *** none ***
**Status**: PREPARING
Devices: [*** none ***]

Reviewing the Upload Summary

Oracle creates upload summary log files for each uploaded import disk. These logs are placed in the bucket where the data was uploaded to Oracle Cloud Infrastructure. The upload summary file compares the import disk's manifest file to the contents of the target Oracle Cloud Infrastructure Object Storage bucket after file upload.

The top of the log report summarizes the overall file processing status:

- **P** - Present: The file is present in both the disk and the target bucket
- **M** - Missing: The file is present in the disk but not the target bucket. It was likely uploaded and then deleted by another user before the summary was generated.
- **C** - Name Collision: The file is present in the manifest but a file with the same name but different contents is present in the target bucket.
- **U** - Unreadable: The file is not readable from the disk
- **N** - Name Too Long: The file name on disk is too long and could not be uploaded

Complete file upload details follow the summary.
**Viewing Data Transfer Metrics**

After the import disk with your copied data is received by Oracle and the data transfer begins, you can view the metrics associated with the transfer job in the Transfer Appliance Details page in chart or table format.

### Tip:
Set up your notifications to alert you when the data transfer from the import disk to Oracle Cloud Infrastructure is occurring. When the state changes from ORACLE_RECEIVED to PROCESSING, you can start viewing data transfer metrics.

Select **Metrics** under **Resources** to display each of these measures:

- **Import Files Uploaded**: Total number of files uploaded for import.
- **Import Bytes Uploaded**: Total number of bytes uploaded for import.
- **Import Files Remaining**: Total number of files remaining for import upload.
- **Import Bytes Remaining**: Total number of bytes remaining for import upload.
- **Import Files in Error**: Total number of files in error for import.
- **Import Upload Verification Progress**: Progress of verification of files that have already been uploaded for import.

Select the **Start Time** and **End Time** for these measures, either by manually entering the days and times in their respective fields, or by selecting the Calendar feature and picking the times that way. As an alternative to selecting a start and end time, you can also select from a list of standard times (last hour, last 6 hours, and so forth) from the **Quick Selects** list for the period measured. The time period you specify applies to all the measures.

Specify the **Interval** (for example, 5 minutes, 1 hour) that each measure is recorded from the list.

Specify the **Statistic** being recorded (for example, Sum, Mean) for each measure from the list.

### Tip:
Mean is the most useful statistic for data transfer as it reflects an absolute value of the metric.

Choose additional actions from the **Options** list, including viewing the query in the **Metrics Explorer**, capturing the URL for the measure, and switching between chart and table view.

Click **Reset Charts** to delete any existing information in the charts and begin recording new metrics.

See **Monitoring** on page 3458 for general information on monitoring your Oracle Cloud Infrastructure services.

### Closing the Transfer Job

Typically, you would close a transfer job when no further transfer job activity is required or possible. Closing a transfer job requires that the status of all associated transfer packages be returned, canceled, or deleted. In addition, the status of the associated transfer disk must be complete, in error, missing, canceled, or deleted.

#### To close a transfer job using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Find the data transfer package for which you want to display the details.
3. Click the **Actions** icon ( xcb), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer job.
4. Click **Close Transfer Job**.

#### To close a transfer job using the Data Transfer Utility

At the command prompt on the host, run `dts job close` to close a transfer job.

```
dts job close --job-id job_id
```
What's Next
You have completed the process of setting up, running, and monitoring the import disk-based data transfer. After the disk contents is successfully migrated to Oracle Cloud Infrastructure, your physical disk is erased and returned to you.
If you determine that another disk-based data transfer is required, repeat the procedure from the beginning.

Disk Import Reference
This topic provides complete task details for certain components associated with Disk-Based Data Imports. Use this topic as a reference to learn and use commands associated with components included in the Disk-Based Data Import procedure.

Transfer Jobs
A transfer job represents the collection of files that you want to transfer and signals the intention to upload those files to Oracle Cloud Infrastructure. A transfer job combines at least one transfer disk with a transfer package. Identify which compartment and Object Storage bucket to which Oracle will upload your data.

Tip:
Create a compartment for each transfer job to minimize the required access your tenancy.

Creating Transfer Jobs
Create the transfer job in the same compartment as the upload bucket and supply a human-readable name for the transfer job.
Creating a transfer job returns a job ID that you specify in other transfer tasks. For example:

```
oci dts job create --bucket bucket --compartment-id compartment_id --display-name display_name
```

Tip:

```
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob
```

To create a transfer job using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Select the designated compartment you are to use for data transfers from the list.
   A list of transfer jobs that have already been created is displayed.
3. Click Create Transfer Job.
   The Create Transfer Job dialog appears.
4. Enter a Job Name. Avoid entering confidential information. Then, select the Upload Bucket from the list.
5. Select Disk for the Transfer Device Type.
6. Click Create Transfer Job.

To create a transfer job using the Data Transfer Utility

```
dts job create --bucket bucket --compartment-id compartment_id --display-name display_name
```

*display_name* is the name of the transfer job. Avoid entering confidential information.

For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob
```

Transfer Job :
ID : ocid1.datatransferjob.oc1..exampleuniqueID
CompartmentId : ocid.compartment.oc1..exampleuniqueID
UploadBucket : MyBucket1
Name : MyDiskImportJob
Label : JZM9PAVWH
When you use the `oci` command to display the details of a job, tagging details are also included in the output if you specified tags.

### Optionally, you can specify one or more defined or free-form tags when you create a transfer job. For more information about tagging, see Resource Tags on page 239.

#### Defined Tags

To specify defined tags when creating a job:

```bash
dts job create --bucket bucket --compartment-id compartment_id --display-name display_name --defined-tags '{ "tag_namespace": { "tag_key": "value" } }'
```

For example:

```bash
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob --defined-tags '{"Operations": {"CostCenter": "01"}}'
```

---

**Transfer Job:**
- **ID**: ocid1.datatransferjob.oc1..exampleuniqueID
- **CompartmentId**: ocid.compartment.oc1..exampleuniqueID
- **UploadBucket**: MyBucket1
- **Name**: MyDiskImportJob
- **Label**: JZM9PAVWH
- **CreationDate**: 2019/06/04 17:07:05 EDT
- **Status**: PREPARING
- **freeformTags**: *** none ***
- **definedTags**: 
  - **Operations**: 
    - **CostCenter**: 01
  
**Packages**:
- [1]:
  - **Label**: PBNZOX9RU
  - **TransferSiteShippingAddress**: Oracle Data Transfer Service;
  - **Job**: JZM9PAVWH Package: PBNZOX9RU ; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
  - **DeliveryVendor**: FedEx
  - **DeliveryTrackingNumber**: *** none ***
  - **ReturnDeliveryTrackingNumber**: *** none ***
  - **Status**: PREPARING
  - **Devices**: [*** none ***]
  - **UnattachedDevices**: [*** none ***]
  - **Appliances**: [*** none ***]When you use the `oci` command to display the details of a job, tagging details are also included in the output if you specified tags.

---

---
Note:

Users create tag namespaces and tag keys with the required permissions. These items must exist before you can specify them when creating a job. See Working with Defined Tags on page 4967 for details.

Freeform Tags

To specify freeform tags when creating a job:

```
dts job create --bucket bucket --compartment-id compartment_id --display-name display_name --freeform-tags '{ "tag_key":"value" }'
```

For example:

```
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyDiskImportJob --defined-tags '{"Operations": {"CostCenter": "01"}}'
```

Transfer Job:
- ID: ocid1.datatransferjob.oc1..exampleuniqueID
- CompartmentId: ocid.compartment.oc1..exampleuniqueID
- UploadBucket: MyBucket1
- Name: MyDiskImportJob
- Label: JZM9PAVWH
- CreationDate: 2019/06/04 17:07:05 EDT
- Status: PREPARING
- freeformTags:
  - Pittsburg_Team: brochures
- definedTags: *** none ***
- Packages:
  - [1]:
    - Label: PBNZOX9RU
    - TransferSiteShippingAddress: Oracle Data Transfer Service;
    - Job:JZM9PAVWH Package:PBNZOX9RU; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
    - DeliveryVendor: FedEx
    - DeliveryTrackingNumber: *** none ***
    - ReturnDeliveryTrackingNumber: *** none ***
    - Status: PREPARING
    - Devices: [*** none ***]
    - UnattachedDevices: [*** none ***]
    - Appliances: [*** none ***]

When you use the to display the details of a job, tagging details are also included in the output if you specified tags.

Multiple Tags

To specify multiple tags, comma separate the JSON-formatted key/value pairs:

```
dts job create --bucket bucket --compartment-id compartment_id --display-name display_name --device-type disk --freeform-tags '{ "tag_key":"value" }', '{ "tag_key":"value" }'
```

Listing Transfer Jobs

To display the list of transfer jobs using the Console:

Open the navigation menu and click Migration. Under Data Transfer, click Imports.
To display the list of transfer jobs using the Data Transfer Utility

```
dts job list --compartment-id compartment_id
```

For example:

```
dts job list --compartment-id ocid.compartment.oc1..exampleuniqueID
```

Transfer Job List :

[1] :
ID : ocid1.datatransferjob.oc1..exampleuniqueID
Name : MyDiskImportJob
Label : JVWK5YWPU
BucketName : MyBucket1
CreationDate : 2020/06/01 17:33:16 EDT
Status : INITIATED
FreeformTags : *** none ***
DefinedTags :
Financials :
    key1 : nondefault

When you use the Data Transfer Utility to list jobs, tagging details are also included in the output if you specified tags.

**Displaying Transfer Job Details**

To display the details of a transfer job using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Find the transfer job for which you want to display the details.
3. Click the Actions icon ( ), and then click View Details.

To display the details of a transfer job using the Data Transfer Utility

```
dts job show --job-id job_id
```

For example:

```
dts job show --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```

Transfer Job :
ID : ocid1.datatransferjob.oc1..exampleuniqueID
CompartmentId : ocid.compartment.oc1..exampleuniqueID
UploadBucket : MyBucket1
Name : MyDiskImportJob
Label : JZM9PAVWH
CreationDate : 2019/06/04 17:07:05 EDT
Status : PREPARING
FreeformTags : *** none ***
DefinedTags : *** none ***
Packages :
    [1] :
        Label : PBNZOX9RU
        TransferSiteShippingAddress : Oracle Data Transfer Service;
        Job:JZM9PAVWH Package:PBNZOX9RU ; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
        DeliveryVendor : FedEx
        DeliveryTrackingNumber : *** none ***
        ReturnDeliveryTrackingNumber : *** none ***
        Status : PREPARING
        Devices : [*** none ***]
When you use the Data Transfer Utility to display the details of a job, tagging details are also included in the output if you specified tags.

**Editing Transfer Jobs**

To edit the name of a transfer job using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Find the data transfer job that you want to edit.
3. Click the **Actions** icon ( ), and then click **Edit**.
4. Edit the name of the transfer job. Avoid entering confidential information.
5. Click **Save**.

To edit the name of a transfer job using the Data Transfer Utility

```bash
dts job update --job-id job_id --display-name display_name
```

*display_name* is the new name of the transfer job. Avoid entering confidential information.

For example:

```bash
dts job update --job-id ocid1.datatransferjob.ocl.phx.aaaaaaaa4tccxskptbexdy6ipmfqome5acvieqthlqvts6lltqv5qx02 --display-name MyRenamedJob
```

**Transfer Job** :
- **ID** : ocid1.datatransferjob.ocl..exampleuniqueID
- **CompartmentId** : ocid.compartment.ocl..exampleuniqueID
- **UploadBucket** : MyBucket1
- **Name** : **MyRenamedJob**
- **Label** : J2M9PAVWH
- **CreationDate** : 2019/06/04 17:07:05 EDT
- **Status** : PREPARING
- **freeformTags** : [*** none ***]
- **definedTags** : [*** none ***]
- **Packages** : [*** none ***]
- **UnattachedDevices** : [*** none ***]
- **Appliances** : [*** none ***]

To edit the tags associated with a transfer job using the Data Transfer Utility

The Data Transfer Utility **replaces** any existing tags with the new key/value pairs you specify.

To edit defined tags, provide the replacement key value pairs:

```bash
dts job update --job-id job_id --defined-tags '{ "tag_namespace": 
 { "tag_key": "value" }}'
```

For example:

```bash
dts job update --job-id ocid1.datatransferjob.ocl..exampleuniqueID --defined-tags '{"Operations": ["CostCenter": "42"]}'
```
Transfer Job:
ID: ocid1.datatransferjob.oc1..exampleuniqueID
CompartmentId: ocid.compartment.oc1..exampleuniqueID
UploadBucket: MyBucket1
Name: MyDiskImportJob
Label: JZM9PAVWH
CreationDate: 2019/06/04 17:07:05 EDT
Status: PREPARING
freeformTags: *** none ***
definedTags:
operations:
costcenter: 42
Packages: [*** none ***]
UnattachedDevices: [*** none ***]
Appliances: [*** none ***]

To edit free-form tags, provide the replacement key/value pairs:

dts job update --job-id job_id --freeform-tags '{ "tag_key":"value" }'

For example:

dts job update --job-id ocid1.datatransferjob.oc1..exampleuniqueID --freeform-tags '{"Chicago_Team":"marketing_videos"}'

Transfer Job:
ID: ocid1.datatransferjob.oc1..exampleuniqueID
CompartmentId: ocid.compartment.oc1..exampleuniqueID
UploadBucket: MyBucket1
Name: MyDiskImportJob
Label: JZM9PAVWH
CreationDate: 2019/06/04 17:07:05 EDT
Status: PREPARING
freeformTags:
definedTags: Chicago_Team: marketing_videos
Packages: [*** none ***]
UnattachedDevices: [*** none ***]
Appliances: [*** none ***]

To delete the tags associated with a transfer job using the Data Transfer Utility

The Data Transfer Utility replaces any existing tags with the new key/value pairs you specify. If you want to delete some of the tags, you would specify new tag string that does not contain the key/value pair you want to delete.

Partial tag deletion is handled in the same way as you edit tags:

• To edit free-form tags, provide the replacement key/value pairs:

dts job update --job-id job_id --freeform-tags '{ tag_key:"value" }'

• To edit defined tags, provide the replacement key value pairs:

dts job update --job-id job_id --defined-tags '{ tag_namespace: { tag_key:"value" } }'

To delete all free-form tags:

dts job update --job-id job_id --freeform-tags '{}'

Oracle Cloud Infrastructure User Guide
To delete all defined tags:

```
dts job update --job-id job_id --defined-tags '{}'
```

**Moving Transfer Jobs Between Compartments**

**Note:**
You can only use the Console to move disk-based data transfer jobs between compartments.

To move a transfer job to a different compartment using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Select the Compartment from the list.
   The transfer jobs in that compartment are displayed.
3. Click the link under Transfer Jobs for the transfer job that you want to move.
   The Details page for that transfer job appears.
   Alternatively, you can click the Actions icon (стрелка), and then click Move Resource.
4. Click Move Resource in the Details page.
   The Move Resource to a Different Compartment dialog appears.
5. Choose the compartment you want to which you want to move the transfer job from the list.
6. Click Move Resource.
   You are returned to the Details page for that transfer job.

To move a transfer job to a different compartment using the Data Transfer Utility

```
dts job move --job-id job_id compartment-id compartment_id [OPTIONS]
```

*compartment_id* is the compartment to which the data transfer job is being moved.

**Options are:**

- `--if-match`: The tag that must be matched for the task to occur for that entity. If set, the update is only successful if the object's tag matches the tag specified in the request.
- `--from-json`: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The `--generate-full-command-json-input` option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id --> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our “using CLI with advanced JSON options” link: https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions.

To confirm the transfer, display the list of transfer jobs in the new compartment. See Listing Transfer Jobs on page 1528 for more information.

**Verifying Upload User Credentials**

**Note:**
You can only use the CLI command to verify upload user credentials.

You can verify the current upload user credentials to see if there are any problems or updates required. If any configuration file is incorrect or invalid, the upload fails.
To verify the upload user credentials of a transfer job using the CLI

```
dts job verify-upload-user-credentials --bucket bucket
```

`bucket` is the upload bucket for the transfer job.

For example:

```
dts job verify-upload-user-credentials --bucket MyBucket1
```

created object BulkDataTransferTestObject in bucket MyBucket1
overwrote object BulkDataTransferTestObject in bucket MyBucket1
inspected object BulkDataTransferTestObject in bucket MyBucket1
read object BulkDataTransferTestObject in bucket MyBucket1

Depending on your user configuration, you may get an error message returned similar to the following:

```
ERROR : key_file /root/.oci/oci_api_key.pem is not a valid file
```

If a user credential issue is identified, fix it and rerun the `verify-upload-user-credentials` CLI to ensure that all problems are addressed. Then you can proceed with transfer job activities.

**Deleting Transfer Jobs**

Typically, you would delete a transfer job early in the transfer process and before you create any transfer packages or their associated disks. For example, you initiated the data transfer by creating a transfer job, but changed your mind. If you want to delete a transfer job later in the transfer process, you must first delete all transfer packages and their associated disks from the transfer job.

To delete a transfer job using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Find the data transfer job that you want to delete.
3. Click the **Actions** icon (), and then click **Delete**.
   Alternatively, you can delete a transfer job from the **View Details** page.
4. Confirm the deletion when prompted.

To delete a transfer job using the Data Transfer Utility

```
dts job delete --job-id job_id
```

For example:

```
dts job delete --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```

Confirm the deletion when prompted. The transfer job is deleted with no further action or return. To confirm the deletion, display the list of transfer jobs in the compartment. See **Listing Transfer Jobs** on page 1528 for more information.

**Closing Transfer Jobs**

Typically, you would close a transfer job when no further transfer job activity is required or possible. Closing a transfer job requires that the status of all associated transfer packages be returned, canceled, or deleted. In addition, the status of all associated transfer disks must be complete, in error, missing, canceled, or deleted.

To close a transfer job using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Find the data transfer package for which you want to display the details.
3. Click the **Actions** icon (⁺), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer job.

4. Click **Close Transfer Job**.

To close a transfer job using the Data Transfer Utility

```bash
dts job close --job-id job_id
```

For example:

```bash
dts job close --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```

Transfer Job :

<table>
<thead>
<tr>
<th></th>
<th>ocid1.datatransferjob.oc1..exampleuniqueID</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>ocid1.datatransferjob.oc1..exampleuniqueID</td>
</tr>
<tr>

<td>[*** none ***]</td>
</tr>
</tbody>
</table>

**Transfer Disks**

The section describes the creation and management transfer disks.

**Important:**

Before creating a transfer disk from an attached disk, remove all partitions and any file systems. To prevent the accidental deletion of data, the Data Transfer Utility does not work with disks that already have partitions or file systems. Disks are visible to the Data Host as block devices and must provide a valid response to the `hdparm -I device` Linux command.

**Creating Transfer Disks**

**Note:**

You can only use the Data Transfer Utility to create a transfer disk.

When you create a transfer disk, the Data Transfer Utility:

- Sets up the disk for encryption using the passphrase.
- Creates a file system on the disk.
- Mounts the file system at `/mnt/orcdts_label`.

For example:

```
/mnt/orcdts_DJZNWK3ET
```

When you register a transfer disk, Oracle Cloud Infrastructure generates a strong encryption passphrase that is used to encrypt the transfer disk. This passphrase is displayed in the return when you run the command. Create a local, secure copy of the encryption passphrase so you can reference the passphrase again. You cannot retrieve the passphrase after it is shown here. This passphrase is used to encrypt this disk and normally will not be needed again. However, if the system is restarted before all files are copied to the filesystem and the disk is then finalized through this CLI, you will need to provide the passphrase.
Creating a transfer disk requires the job ID returned from when you created the transfer job and the path to the attached disk (for example `/dev/sdb`).

To create a transfer disk using the Data Transfer Utility

```
dts disk create --job-id job_id --block-device block_device
```

When the run the disk create command, the CLI displays information regarding the creation of the disk, and prompts you to continue in several places. When the disk is created the following disk information is displayed:

```
dts disk create --job-id ocid1.datatransferjob.oci1..exampleuniqueID --block-device /dev/sdb
...
Transfer Disk :
  Label:               : DNKZQ1XKC
  SerialNumber:        : VB6fc3b4a1-5d90f001
  Status               : PREPARING
  EncryptionPassphrase : passphrase
```

**Important:**

Record the passphrase in a secure, local location.

**Displaying Transfer Disk Details**

**Note:**

You can only use the Data Transfer Utility to display details for a specified transfer disk.

To display the details of a disk using the Data Transfer Utility

```
dts disk show --job-id job_id --disk-label disk_label
```

For example:

```
dts disk show --job-id ocid1.datatransferjob.oci1..exampleuniqueID --disk-label DNKZQ1XKC
Transfer Disk :
  Label:               : DNKZQ1XKC
  SerialNumber:        : VB6fc3b4a1-5d90f001
  UploadStatusLogUrl   : JVPWPQV6U/DNKZQ1XKC/upload_summary.txt
  Status               : PREPARING
```

The path syntax for the upload status log URL is `<transfer_job_label>/disk_label>/upload_summary.txt`.

**Deleting Transfer Disks**

**Note:**

You can only use the Data Transfer Utility to delete a transfer disk.

Typically, you would delete a transfer disk during the disk preparation process. You created, attached, and copied data to the transfer disk, but have changed your mind about shipping the disk. If you want to reuse the disk, remove all file systems and create the disk again.

To delete a transfer disk using the Data Transfer Utility

```
dts disk delete --job-id job_id --disk-label disk_label
```
Data Transfer

For example:

```
dts disk delete --job-id ocid1.datatransferjob.oci1..exampleuniqueID --disk-label DNKZQ1XKC
```

Deleted Disk: DNKZQ1XKC

**Canceling Transfer Disks**

If you shipped a disk to Oracle, but have changed your mind about uploading the files, you can cancel the transfer disk.

Oracle cannot process canceled transfer disks. Oracle returns canceled transfer disks to the sender.

**Note:**

You can only use the Data Transfer Utility to cancel a transfer disk.

To cancel a transfer disk using the Data Transfer Utility

```
dts disk cancel --job-id job_id --disk-label disk_label
```

For example:

```
dts disk cancel --job-id ocid1.datatransferjob.oci1..exampleuniqueID --disk-label DNKZQ1XKC
```

Canceled Disk: DNKZQ1XKC

**Locking Transfer Disks**

**Note:**

You can only use the Data Transfer Utility to lock a transfer disk.

Locking a transfer disk safely unmounts the disk and removes the encryption passphrase from the Data Host.

To lock a transfer disk using the Data Transfer Utility

```
dts disk lock --job-id job_id --disk-label disk_label --block-device block_device
```

For example:

```
dts disk lock --job-id ocid1.datatransferjob.oci1..exampleuniqueID --disk-label DNKZQ1XKC --block-device /dev/sdb
```

Copying upload user credentials.
created object BulkDataTransferTestObject in bucket MyBucket1
overwrote object BulkDataTransferTestObject in MyBucket1
inspected object BulkDataTransferTestObject in bucket MyBucket1
read object BulkDataTransferTestObject in bucket MyBucket1
Scanning filesystem to validate manifest. If special files are encountered, they will be listed below.
validated manifest
/dev/sdb DNKZQ1XKC is encrypted and locked
Locked disk.

**Unlocking Transfer Disks**

If you need to unlock the transfer disk, you are prompted for the encryption passphrase that was generated when you created the transfer disk.
To unlock a transfer disk using the Data Transfer Utility

```bash
dts disk unlock --job-id job_id --disk-label disk_label --block-device block_device --encryption-passphrase encryption_passphrase
```

For example:

```bash
dts disk unlock --job-id ocid1.datatransferjob.oc1..exampleuniqueID --disk-label DNKZQ1XKC --block-device /dev/sdb --encryption-passphrase passphrase
```

Encryption passphrase ('q' to quit):
enabled cleartext read/write on device
Unlocked and mounted disk.

**Attaching Transfer Disks to Transfer Packages**

Attach a transfer disk to a transfer package after you have done the following tasks in order:

- Copied your data onto the disk.
- Generated the required manifest file.
- Run and reviewed the dry-run report.
- Locked the transfer disk in preparation for shipment.

**Note:**
You can only attach a single disk to each transfer package.

To attach a transfer disk to a transfer package using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Find the transfer job associated with the transfer package having the disk attached.
3. Click the **Actions** icon ( ), and then click **View Details**.
   A list of transfer packages is displayed.
4. Find the transfer package for which you want to attach a disk.
5. Click the **Actions** icon ( ), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer package.
   The transfer disk is displayed.
6. Click **Attach Transfer Disks**.
   The Attach Transfer Disks dialog appears.
7. Select the **Transfer Disks** that you want to attach to the transfer package.
8. Click **Attach**.

To attach a transfer disk to a transfer package using the Data Transfer Utility

```bash
dts disk attach --job-id job_id --package-label package_label --disk-label disk_label
```

For example:

```bash
dts attach --job-id ocid1.datatransferjob.oc1..exampleuniqueID --package-label PWA8O67MI --disk-label DNKZQ1XKC
```

Attached disk: DNKZQ1XKC to package: PWA8O67MI

See **Transfer Packages** on page 1538 for more information, including how to obtain the package label.
**Detaching Transfer Disks from Transfer Packages**

To detach a transfer disk to a transfer package using the Console:

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Find the transfer package for which you want to detach a transfer disk.
3. Click the **Actions** icon ( ), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer package.

   The attached transfer disk is displayed.

4. Click the **Actions** icon ( ), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer disk.

5. Click **Detach Transfer Disk**.

To detach a transfer disk to a transfer package using the Data Transfer Utility:

```
dts disk detach --job-id job_id --package-label package_label --disk-label disk_label
```

For example:

```
dts detach --job-id ocid1.datatransferjob.ocil..exampleuniqueID --package-label PWA8067MI --disk-label DNKZQ1XKC
```

Detached disk: DNKZQ1XKC from package: PWA8067MI

**Querying Transfer Disks**

You can query the transfer disk for information regarding the physical transfer disk such as the loops, sizes, and mountpoints.

**Note:**
You can only use the Data Transfer Utility to query the transfer disk.

To query the transfer disk using the Data Transfer Utility:

```
dts disk query
```

For example:

```
dts disk query
```

```
NAME   TYPE   SIZE UUID                                 LABEL
MOUNTPOINT
loop0  loop 140.7M                                                     /
snap/gnome-3-26-1604/92
loop1  loop   4.2M                                                     /
snap/gnome-calculator/501
sda    disk  40.8G
##sda1 part    12G xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxx                 /
sr0    rom   56.9M 2020-02-18-17-20-05-35               VBox_GAs_6.1.4 /
media/user/VBox_GAs_6.1.4
```

**Transfer Packages**

A transfer package is the virtual representation of the physical disk package that you are shipping to Oracle for upload to Oracle Cloud Infrastructure.
Creating Transfer Packages

Creating a transfer package requires the job ID returned from when you created the transfer job. For example:

```
ocid1.datatransferjob.region1.phx..exampleuniqueID
```

To create a transfer package using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Find the transfer job for which you want to create a transfer package.
3. Click the Actions icon (⋮), and then click View Details.

   Alternatively, click the hyperlinked name of the transfer job.

   A list of transfer packages that have already been created is displayed.
4. Click Create Transfer Package.

   The Create Transfer Package dialog appears.
5. Select a Vendor from the list.
6. Click Create Transfer Package.

   The Data Transfer Package dialog appears displaying information such as the shipping address, the shipping vendor, and the shipping status.

To create a transfer package using the Data Transfer Utility

```
dts package create --job-id job_id
```

For example:

```
dts package create --job-id ocid1.datatransferjob.oci1..exampleuniqueID
```

Transfer Package:

```
Label: PWA8O67MI
TransferSiteShippingAddress: Oracle Data Transfer Service; Job:JZM9PAVWH Package:PWA8O67MI; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
DeliveryVendor: *** none ***
DeliveryTrackingNumber: *** none ***
ReturnDeliveryTrackingNumber: *** none ***
Status: PREPARING
Devices: [*** none ***]
```

Displaying Transfer Package Details

To display the details of a transfer package using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Find the transfer job for which you want to see the details.
3. Click the Actions icon (⋮), and then click View Details.

   Alternatively, click the hyperlinked name of the transfer job.

   A list of transfer packages that have already been created is displayed.

To display the details of a transfer package using the Data Transfer Utility

```
dts package show --job-id job_id --package-label package_label
```
For example:

```
dts package show --job-id ocid1.datatransferjob.oci1..exampleuniqueID --package-label PWA8067MI
```

Transfer Package:

- **Label**: PWA8067MI
- **TransferSiteShippingAddress**: Oracle Data Transfer Service; Job: JZM9PAVWH Package: PWA8067MI; 21111 Ridgetop Circle; Dock B; Sterling, VA 20166; USA
- **DeliveryVendor**: *** none ***
- **DeliveryTrackingNumber**: *** none ***
- **ReturnDeliveryTrackingNumber**: *** none ***
- **Status**: PREPARING
- **Devices**: [*** none ***]

### Editing Transfer Packages

Edit the transfer package and supply the tracking information when you ship the package.

To edit a transfer package using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Find the transfer job for which you want to see the associated transfer packages.
3. Click the **Actions** icon ( ), and then click **View Details**.
4. Find the transfer package that you want to edit.
5. Click the **Actions** icon ( ), and then click **View Details**.
6. Click **Edit**.
7. Change the vendor and supply the tracking information as needed.
8. Click **Edit Transfer Package**.

### Deleting Transfer Packages

Typically, you would delete a transfer package early in the transfer process and before you create its associated transfer disk. You initiated the transfer job and package, but have changed your mind. If you delete a transfer package later in the transfer process, you must first detach the associated transfer disk. You cannot delete a transfer package once the package has been shipped to Oracle.

To delete a transfer package using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Find the transfer job for which you want to see the associated transfer packages.
3. Click the **Actions** icon ( ), and then click **View Details**.
4. Find the transfer package that you want to edit.
5. Click the **Actions** icon ( ), and then click **View Details**.
6. Click **Edit**.
7. Change the vendor and supply the tracking information as needed.
8. Click **Edit Transfer Package**.

To delete a transfer package using the Data Transfer Utility

```
dts package delete --job-id job_id --package-label package_label
```

For example:

```
dts package delete --job-id ocid1.datatransferjob.oci1..exampleuniqueID --package-label PWA8067MI
```
Data Transfer

Deleted package with label: PWA8O67MI

Canceling Transfer Packages

If you shipped a transfer package, but have changed your mind about uploading the data, you can cancel a transfer package. Before canceling a transfer package, you must first cancel the transfer disk associated with that transfer package. Oracle cannot process canceled transfer packages. Oracle returns canceled transfer packages to the sender.

To cancel a transfer package using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Find the transfer job for which you want to see associated transfer packages.
3. Click the Actions icon (.), and then click View Details.
4. Find the transfer package that you want to cancel.
5. Click the Actions icon (.), and then click View Details.
6. Click Cancel Transfer Package.

To cancel a transfer package using the Data Transfer Utility

dts package cancel --job-id job_id --package-label package_label

For example:

dts package cancel --job-id ocid1.datatransferjob.ocil..exampleuniqueID --package-label PWA8O67MI
Canceled package with label: PWA8O67MI

Data Import - Appliance

Appliance-Based Data Import is one of Oracle's offline data transfer solutions that lets you migrate petabyte-scale datasets to Oracle Cloud Infrastructure. You send your data as files on one or more secure, high-capacity, Oracle-supplied Data Transfer Appliances to an Oracle transfer site. Operators at the Oracle transfer site upload the files into the designated Object Storage bucket in your tenancy. You are then free to move the uploaded data to other Oracle Cloud Infrastructure services as needed.

Note:

• Consider using Disk-Based Data Import if the quantity of data you are importing is 34 TB or less. Using this option allows you to avoid waiting for Oracle to send you a data transfer appliance. See Data Import - Disk on page 1494 for more information.
• Appliance-Based Data Import is not available for free trial or Pay As You Go accounts.
• Data Transfer appliance availability is based on inventory per region. Oracle distributes appliances on a first come, first serve basis based on customer request. Appliances are not always immediately available. Because of inventory constraints, new Appliance-Based Data Import users are limited to a single appliance when it is their turn. Returning users are limited to two appliances.

Appliance-Based Data Import Concepts

TRANSFER JOB

A transfer job is the logical representation of a data migration to Oracle Cloud Infrastructure. A transfer job is associated with one or more import appliances.
DATA TRANSFER APPLIANCE

The Data Transfer Appliance (import appliance) is a high-storage capacity device that is specially prepared to copy and upload data to Oracle Cloud Infrastructure. You request an import appliance from Oracle, copy your data onto it, and then ship it back to Oracle for upload.

COMMAND LINE INTERFACE

The command line interface (CLI) is a small footprint tool that you can use on its own or with the Console to complete Oracle Cloud Infrastructure tasks, including Appliance-Based Data Import jobs.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.</td>
</tr>
</tbody>
</table>

HOST

A physical computer at the customer site on which one or more of the logical hosts (Control, Data, Terminal Emulation) is running. Depending on your computing environment, you can have any of the following:

- A separate physical host for each logical host
- All three logical hosts consolidated onto a single physical host
- Two logical hosts on one physical host and the third logical host on a separate physical host

All physical hosts must be on the network used for the data transfer.

CONTROL HOST

The logical representation of the host computer at your site from which you perform Data Transfer Service tasks. Depending on your needs, you may use one or more separate hosts (Control and Data) to run your Appliance-Based Data Import job.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can only run Oracle Cloud Infrastructure CLI commands from a Linux-based Control Host machine. You can run Console tasks from a browser running on a Windows machine.</td>
</tr>
</tbody>
</table>

DATA HOST

The logical representation of the host computer on your site that stores the data you intend to copy to Oracle Cloud Infrastructure.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only Linux machines can be used as Data Hosts.</td>
</tr>
</tbody>
</table>

TERMINAL EMULATION HOST

The logical representation of the host computer that uses terminal emulation software to communicate with, and allow you to command, the import appliance.

BUCKET

The logical container in Oracle Cloud Infrastructure Object Storage where Oracle operators upload your data. A bucket is associated with a single compartment in your tenancy whose policies that determine what actions a user can perform on a bucket and on all the objects in the bucket.

DATA TRANSFER ADMINISTRATOR

A new or existing IAM user that has the authorization and permissions to create and manage transfer jobs.
DATA TRANSFER UPLOAD USER
A temporary IAM user that grants Oracle personnel the authorization and permissions to upload the data from the import appliance to your designated Oracle Cloud Infrastructure Object Storage bucket. Delete this temporary user after your data is uploaded to Oracle Cloud Infrastructure.

APPLIANCE MANAGEMENT SERVICE
Software running on the import appliance that provides management functions. Users interact with this service though the Oracle Cloud Infrastructure CLI.

Appliance Specifications
Use NFS versions 3, 4, or 4.1 to copy your data onto the appliance. Here are some details about the appliance:

<table>
<thead>
<tr>
<th>Item Description</th>
<th>Specification</th>
</tr>
</thead>
</table>
| Storage Capacity   | • US East (Ashburn), US West (Phoenix), Germany Central (Frankfurt): 150 TB of protected usable space.  
                      • All other regions: 95 TB of protected usable space.                                         |
| Network Interfaces | • 10 GbE - RJ45  
                      • 10 GbE - SFP+  
                      You are responsible for providing all network cables. If you want to use SFP+, your transceivers must be compatible with Intel X520 NICs. |
| Provided Cables    | • NEMA 5–15 type B to C13  
                      • C13 - 14 power  
                      • USB - DB9 serial |
| Environmental      | • Operational temperature: 50–95°F (10–35°C)  
                      • Operational relative humidity: 8–90% non-condensing  
                      • Acoustics: < 75 dB @ 73°F (23° C)  
                      • Operational altitude: -1,000 ft - 10,000 ft (approx. -300–3048 m)) |
| Power              | • Consumption: 554 W  
                      • Voltage: 100–240 VAC  
                      • Frequency: 47–63 Hz  
                      • Conversion efficiency: 89% |
| Weight             | • Unit: 38 lbs (approx. 17 kg)  
                      • Unit + Transit Case: 64 lbs (approx. 29 kg) |
| Height             | 3.5” (approx. 9 cm) (2U) |
| Width              | 17” (approx. 43 cm) |
| Depth              | 24” (approx. 61 cm) |
| Shipping Case      | 11” x 25” x 28” (approx. 28 x 63.5 x 71 cm) |

Import File Constraints
All files being imported using the Data Transfer Appliance must conform to the following:
• Maximum file size - 10 TB
• Maximum file name length - 1024 characters

Roles and Responsibilities
Depending on your organization, the responsibilities of using and managing the data transfer may span multiple roles. Use the following set of roles as a guideline for how you can assign the various tasks associated with the data transfer.

• **Project Sponsor**: Responsible for the overall success of the data transfer. Project Sponsors usually have complete access to their organization's Oracle Cloud Infrastructure tenancy. They coordinate with the other roles in the organization to complete the implementation of data transfer project. The Project Sponsor is also responsible for signing legal documentation and setting up notifications for the data import.

• **Infrastructure Engineer**: Responsible for integrating the transfer appliance into the organization's IT infrastructure from where the data is being transferred. Tasks associated with this role include connecting the transfer appliance to power, placing it within the network, and setting the IP address through a serial console menu using the provided USB-to-Serial adapter.

• **Data Administrator**: Responsible for identifying and preparing the data to be transferred to Oracle Cloud Infrastructure. This person usually has access to, and expertise with, the data being migrated.

These roles correspond to the various phases of the data transfer described in the following section. A specific role can be responsible for one or more phases.

Appliance Import Prerequisite Checklist
Learn about the prerequisite tasks for an appliance import job.
Use this checklist for preparing to use the Data Transfer Appliance (import appliance) for use in an import job. Check each item in order to ensure you are fully prepared for the data transfer.

__ Administrative user to the tenancy who can create users, groups, compartments, add policies, and request import appliance entitlement.

__ Access to the main buyer or administrator who is VP-level or higher who can sign the terms and conditions document.

__ Linux machine running Oracle Linux, Ubuntu, or CentOS. See Requirements on page 5317 for the supported versions of each Linux operating system.

__ **Root** access for the prepare and copy on the Linux machine.

__ Someone who has physical access to where the import appliance will be installed.

__ Meet all appliance specifications and physical environment requirements.

__ Terminal emulation host that can connect to the import appliance using USB or DB-9 serial cable.

__ Terminal emulation host with one of the following installed: PuTTY for Windows, ZOC for OS X, PuTTY or Minicom for Linux.

__ Network connection to the import appliance consisting of either a 10GBase-T: Standard RJ-45 or SFP+ with transceiver compatible with Intel X520NICs.

__ IP address for the import appliance __________ .

__ Subnet mask length for the import appliance subnet __________ .

__ Default gateway for the import appliance network __________ .

__ NFS communication between the import appliance subnet and servers from where data will be copied

__ HTTP Proxy information if your corporation uses an internet proxy __________ .

__ Open firewall for Linux machine for preparation and copying to OCI Data Transfer on the IP address ranges. See Firewall Information on page 1656 for a list of IP addresses by OCI region.
__Open firewall for Linux machine for preparation and copying to OCI Object Storage IP address ranges. See the Firewall Information table below for a list of IP addresses by OCI region. See Firewall Information on page 1656 for a list of IP addresses by OCI region.

__Installation of OCI Command Line Interface.

__Generate public/ private keys for users who will copy data on the Linux machine (run `oci setup keys` command).

**Task Flow for Appliance-Based Data Import**

Here is a high-level overview of the tasks involved in the Appliance-Based Data Import to Oracle Cloud Infrastructure. Complete one phase before proceeding to the next one. Use the roles previously described to distribute the tasks across individuals or groups within your organization.
Secure Appliance Data Transfer to Oracle Cloud Infrastructure

This section highlights the security details of the Data Transfer Appliance process.

- Appliances are shipped from Oracle to you with a tamper-evident security tie on the transit case. A second tamper-evident security tie is included in the import appliance transit case for you to secure the case when you ship the case back to Oracle. The number on the physical security ties must match the numbers logged by Oracle in the import appliance details.

- When you configure the import appliance for the first time:
  - The import appliance generates a master AES-256 bit encryption key that is used for all data written to or read from the device. The encryption key never leaves the device.
  - The encryption key is protected by an encryption passphrase that you must know to access the encrypted data. The system securely fetches a provided encryption passphrase from Oracle Cloud Infrastructure and registers that passphrase on the import appliance.

  **Note:**
  The encryption passphrase is never stored on the import appliance.

  - All data is encrypted as the data is copied to an import appliance.
  - For more security, you can also encrypt your own data with your own encryption keys. Before copying your data to the import appliance, you can encrypt your data with a tool and encryption key of your choosing. After the data has been uploaded, you would need to use the same tool and encryption key to access the data.
  - All network communication between your appliance-based data transfer environment and Oracle Cloud Infrastructure is encrypted in-transit using Transport Layer Security (TLS).
  - After copying your data to a transfer appliance, the data transfer system generates a manifest file. The manifest contains an index of all of the copied files and generated data integrity hashes. The system also encrypts and copies the config_upload_user configuration file to the transfer appliance. This configuration file describes the temporary IAM data transfer upload user. Oracle uses the credentials and entries defined in the config_upload_user file when processing the transfer appliance and uploading files to Oracle Cloud Infrastructure Object Storage.

  **Note:**
  Data Transfer Service Does Not Support Passphrases on Private Keys
  While we recommend encrypting a private key with a passphrase when generating API signing keys, the Data Transfer Service does not support passphrases on the key file required for the config_upload_user configuration file. If you use a passphrase, Oracle personnel cannot upload your data.

Oracle cannot upload data from a transfer appliance without the correct credentials defined in this configuration file. See Preparing Upload Configuration Files on page 1559 for more information about the required configuration files.

- Oracle erases all of your data from the import appliance after it has been processed. The erasure process follows the NIST 800-88 standards.
- Keep possession of the security tie after you have finished unpacking and connecting the import appliance. Include it when returning the import appliance to Oracle. Failure to include the security tie can result in a delay in the data migration process.

**What's Next**

You are now ready to prepare the host for the Appliance-Based Data Import. See Preparing for Appliance Data Transfers on page 1548 for more information.
Preparing for Appliance Data Transfers

This topic describes the tasks associated with preparing for the Appliance-Based Data Import job. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities on page 1544.

Note:
You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

Installing and Using the Oracle Cloud Infrastructure Command Line Interface

The Oracle Cloud Infrastructure Command Line Interface (CLI) provides a set of command line-based tools for configuring and running Appliance-Based Data Import jobs. Use the Oracle Cloud Infrastructure CLI as an alternative to running commands from the Console. Sometimes you must use the CLI to complete certain tasks as there is no Console equivalent.

Minimum Required CLI Version

The minimum CLI version required for Appliance-Based Data Import is 2.12.1.

Determining CLI Versions

Access the following URL to see the currently available version of the CLI:
https://github.com/oracle/oci-cli/blob/master/CHANGELOG.rst

Enter the following command at the prompt to see the version of the CLI currently installed on your machine:

`oci --version`

If you have a version on your machine older than the version currently available, install the latest version.

Note:
Always update to the latest version of the CLI. The CLI is not updated automatically, and you can only access new or updated CLI features by installing the current version.

Linux Operating System Requirements

See Requirements on page 5317 for a list of the Linux operating systems that support the CLI.

Installing the CLI

Installation and configuration of the CLIs is described in detail in Command Line Interface (CLI) on page 5316.

Using the CLI

You can specify CLI options using the following commands:

- `--option value` or
- `--option=value`
Data Transfer

The basic CLI syntax is:

```
oci dts resource action options
```

This syntax is applied to the following:

- `oci dts` is the shortened CLI command name.
- `job` is an example of a `resource`.
- `create` is an example of an `action`.
- Other strings are `options`.

The following command to create a transfer job shows a typical CLI command construct.

```
oci dts job create --compartment-id ocid1.compartment.oc1..exampleuniqueID --bucket MyBucket --display-name MyApplianceImportJob --device-type appliance
```

**Note:**
In the previous examples, provide a friendly name for the transfer job using the `display-name` option. Avoid entering confidential information.

### Accessing Command Line Interface Help

All CLI help commands have an associated help component you can access from the command line. To view the help, enter any command followed by the `--help` or `-h` option. For example:

```
oci dts job --help
```

**NAME**

dts_job -

**DESCRIPTION**

Transfer disk or appliance job operations

**AVAILABLE COMMANDS**

- o change-compartment
- o close
- o create
- o delete
- o detach-devices-details
  ...

When you run the help option (`--help` or `-h`) for a specified command, all the subordinate commands and options for that level of CLI are displayed. If you want to access the CLI help for a specific subordinate command, include it in the CLI string, for example:

```
oci dts job create --help
```

**NAME**

dts_job_create -

**DESCRIPTION**

Creates a new transfer disk or appliance job.

**USAGE**

oci dts job create [OPTIONS]

**REQUIRED PARAMETERS**
Creating the Required IAM Users, Groups, and Policies

Each service in Oracle Cloud Infrastructure integrates with IAM for authentication and authorization.

To use Oracle Cloud Infrastructure, you must be given the required type of access in a policy written by an administrator, whether you’re using the Console or the REST API with an SDK, CLI, or other tool. If you try to perform an action and get a message that you don’t have permission or are unauthorized, confirm with your administrator the type of access you’ve been granted and which compartment you should work in.

Access to resources is provided to groups using policies and then inherited by the users that are assigned to those groups. Data transfer requires the creation of two distinct groups:

- **Data transfer administrators** who can create and manage transfer jobs.
- **Data transfer upload users** who can upload data to Object Storage. For your data security, the permissions for upload users allow Oracle personnel to upload standard and multi-part objects on your behalf and inspect bucket and object metadata. The permissions do not allow Oracle personnel to inspect the actual data.

The Data Administrator is responsible for generating the required RSA keys needed for the temporary upload users. These keys should never be shared between users.

For details on creating groups, see Managing Groups on page 3115.

An administrator creates these groups with the following policies:

- **The data transfer administrator group** requires an authorization policy that includes the following:

  ```
  Allow group group_name to manage data-transfer-jobs in compartment compartment_name
  Allow group group_name to manage objects in compartment compartment_name
  Allow group group_name to manage buckets in compartment compartment_name
  ```

  Alternatively, you can consolidate the manage buckets and manage objects policies into the following:

  ```
  Allow group group_name to manage object-family in compartment compartment_name
  ```

- **The data transfer upload user group** requires an authorization policy that includes the following:

  ```
  Allow group group_name to manage buckets in compartment compartment_name
  where all { request.permission='BUCKET_READ', target.bucket.name='<bucket_name>' } 
  Allow group group_name to manage objects in compartment compartment_name
  where all { target.bucket.name='<bucket_name>',
  any { request.permission='OBJECT_CREATE',
  request.permission='OBJECT_OVERWRITE',
  request.permission='OBJECT_INSPECT' }}
  ```

To enable notifications, add the following policies:

```
Allow group group_name to manage ons-topics in tenancy
Allow group group_name to manage ons-subscriptions in tenancy
Allow group group_name to manage cloudevents-rules in tenancy
Allow group group_name to inspect compartments in tenancy
```
See Notifications Overview on page 4248 and Overview of Events on page 2382 for more information.

The Oracle Cloud Infrastructure administrator then adds a user to each of the data transfer groups created. For details on creating users, see Managing Users on page 3110.

**Important:**

For security reasons, we recommend that you create a unique IAM data transfer upload user for each transfer job and then delete that user once your data is uploaded to Oracle Cloud Infrastructure.

**Requesting Appliance Entitlement**

If your tenancy is not entitled to use the Data Transfer Appliance, you must request the Data Transfer Appliance Entitlement before creating an appliance-based transfer job.

**Important:**

The main buyer or administrator, who is at a VP level or higher, receives an email notification and is required to e-sign a Terms and Conditions document. After Oracle has confirmed signature of the document, you can create an appliance-based transfer job. The email for the DocuSign does not go to the requester unless they are the main buyer or administrator who is at least at a VP level.

It can take up to 24 hours before the Terms and Conditions are sent.

To request the Data Transfer Appliance Entitlement using the Console

Open the Transfer Job page and click Request at the top. Otherwise, you are prompted to request the entitlement when attempting to create your first appliance-based transfer job.

Once requested, the status of your request is visible at the top of the Transfer Job page. For example:

**Data Transfer Appliance Entitlement:** Granted

It can take a while to get the Data Transfer Appliance Entitlement approved. After Oracle receives your request, a Terms and Conditions Agreement is sent to the account owner via DocuSign to use the appliance. The entitlement request is approved once the signature is received. The Data Transfer Appliance Entitlement is a tenancy-wide entitlement that you need to request once for each tenancy.

To request the Data Transfer Appliance Entitlement using the CLI

```
oci dts appliance request-entitlement --compartment-id compartment_id --name name --email email
```

Name is the name of the requester.

Email is the email address of the requester.

For example:

```
oci dts appliance request-entitlement --compartment-id ocid.compartment.oc1..exampleuniqueID --name "John Doe" --email jdoe@mycompany.com
```

```
{
  "data": {
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "creation-time": "2019-12-18T18:29:15+00:00",
    "defined-tags": {},
    "display-name": null,
    "freeform-tags": {},
    "id": "ocid1.datatransferapplianceentitlement.oc1..exampleuniqueID",
    "lifecycle-state": "CREATING",
  }
}
```
To show the status of a Data Transfer Appliance Entitlement request using the CLI

oci dts appliance show-entitlement --compartment-id compartment_id

For example:

oci dts appliance show-entitlement --compartment-id ocid.compartment.oc1..exampleuniqueID

{
  "data": {
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "defined-tags": null,
    "display-name": null,
    "freeform-tags": null,
    "id": null,
    "lifecycle-state": "ACTIVE",
    "lifecycle-state-details": "APPROVED",
    "requestor-email": "jdoe@mycompany.com",
    "requestor-name": "John Doe"
  }
}

Establishing the Data Transfer Appliance Entitlement Policy

Use the following policy to enable users in a specific group to request a Data Transfer Appliance Entitlement in your tenancy.

Allow group <group_name> to {DTA_ENTITLEMENT_CREATE} in tenancy

Appliance Entitlement Eligibility

Your request for a Data Transfer Appliance Entitlement in your tenancy may be denied if you are a free trial customer. If your request is denied, upgrade to a full account. You can also contact your Oracle Customer Support Manager or Oracle Support to determine your options for obtaining the entitlement.

Creating Object Storage Buckets

The Object Storage service is used to upload your data to Oracle Cloud Infrastructure. Object Storage stores objects in a container called a bucket within a compartment in your tenancy. For details on creating the bucket to store uploaded data, see Managing Buckets on page 4298.

Configuring Firewall Settings

The firewall port number is 443 for all data transfer methods.

Ensure that your local environment's firewall can communicate with the Data Transfer Service running on the IP address ranges for your OCI region based on the following table. Also ensure that open access exists to the Object Storage IP address range. You only need to configure this IP access for the region where your data transfer job is associated.

<table>
<thead>
<tr>
<th>Region</th>
<th>Data Transfer</th>
<th>Object Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ashburn)</td>
<td>140.91.0.0/16</td>
<td>134.70.24.0/21</td>
</tr>
</tbody>
</table>
Creating Transfer Jobs

This section describes how to create a transfer job as part of the preparation for the data transfer. See Transfer Jobs on page 1587 for complete details on all tasks related to transfer jobs.

A transfer job represents the collection of files that you want to transfer and signals the intention to upload those files to Oracle Cloud Infrastructure. Identify which compartment and Object Storage bucket to which Oracle is to upload your data. Create the transfer job in the same compartment as the upload bucket and supply a human-readable name for the transfer job.

Note:
It is recommended that you create a compartment for each transfer job to minimize the required access your tenancy.

Creating a transfer job returns a transfer job ID that you specify in other transfer tasks. For example:

```
oci.dts.job.create --bucket bucket --compartment-id compartment_id --display-name display_name --device-type device_type
```

display_name is the name of the transfer job. Avoid entering confidential information.

---

<table>
<thead>
<tr>
<th>Region</th>
<th>Data Transfer</th>
<th>Object Storage</th>
</tr>
</thead>
<tbody>
<tr>

<td>134.70.116.0/22</td>
</tr>
</tbody>
</table>

---
device_type should always be appliance for Appliance-Based Data Import jobs.  

For example:

```bash
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyApplianceImportJob --device-type appliance

{
  "data": {
    "attached-transfer-appliance-labels": [],
    "attached-transfer-device-labels": [],
    "attached-transfer-package-labels": [],
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "creation-time": "2019-12-18T19:43:58+00:00",
    "defined-tags": {},
    "device-type": "APPLIANCE",
    "display-name": "MyApplianceImportJob",
    "freeform-tags": {},
    "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "label": "JAKQVAGJF",
    "lifecycle-state": "INITIATED",
    "upload-bucket-name": "MyBucket1"
  },
  "etag": "2--gzip"
}
```

Optionally, you can specify one or more defined or freeform tags when you create a transfer job. For more information about tagging, see Resource Tags on page 239.

**Defined Tags**

To specify defined tags when creating a job:

```bash
oci dts job create --bucket bucket --compartment-id compartment_id --display-name display_name --device-type appliance --defined-tags '{ "tag_namespace": { "tag_key": "value" } }'
```

For example:

```bash
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyApplianceImportJob --device-type appliance --defined-tags '{"Operations": {"CostCenter": "01"}}'

{
  "data": {
    "attached-transfer-appliance-labels": [],
    "attached-transfer-device-labels": [],
    "attached-transfer-package-labels": [],
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "creation-time": "2019-12-18T19:43:58+00:00",
    "defined-tags": {
      "operations": {
        "costcenter": "01"
      }
    },
    "device-type": "APPLIANCE",
    "display-name": "MyApplianceImportJob",
    "freeform-tags": {},
    "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "label": "JAKQVAGJF",
    "lifecycle-state": "INITIATED",
```
"upload-bucket-name": "MyBucket1"
},
"etag": "2--gzip"
}

**Freeform Tags**

To specify freeform tags when creating a job:

```bash
oci dts job create --bucket bucket --compartment-id compartment_id
--display-name display_name --device-type appliance --freeform-tags
'{ "tag_key":"value" }'
```

For example:

```bash
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID
--display-name MyApplianceImportJob
--device-type appliance --freeform-tags '{"Pittsburg_Team":"brochures"}'
```

```json
{
"data": {
"attached-transfer-appliance-labels": [],
"attached-transfer-device-labels": [],
"attached-transfer-package-labels": [],
"compartment-id": "ocid.compartment.oc1..exampleuniqueID",
"creation-time": "2019-12-18T19:43:58+00:00",
"defined-tags": {},
"device-type": "APPLIANCE",
"display-name": "MyApplianceImportJob",
"freeform-tags": {
"Pittsburg_Team": "brochures"
},
"id": "ocid1.datatransferjob.oc1..exampleuniqueID",
"label": "JAKQVAGJF",
"lifecycle-state": "INITIATED",
"upload-bucket-name": "MyBucket1"
},
"etag": "2--gzip"
}
```

**Note:**

Users create tag namespaces and tag keys with the required permissions. These items must exist before you can specify them when creating a job. See [Working with Defined Tags](#) on page 4967 for details.

**Multiple Tags**

To specify multiple tags, comma separate the JSON-formatted key/value pairs:

```bash
oci dts job create --bucket bucket --compartment-id compartment_id
--display-name display_name --device-type appliance --freeform-tags
'{ "tag_key":"value" }, '{ "tag_key":"value" }'
```

**Notifications**

To include notifications, include the `--setup-notifications` option. See [Setting Up Transfer Job Notifications from the CLI](#) on page 1557 for more information on this feature.
Getting Transfer Job IDs

Each transfer job you create has a unique ID within Oracle Cloud Infrastructure. For example:

```
ocid1.datatransferjob.oc1.phx.exampleuniqueID
```

You will need to forward this transfer job ID to the Data Administrator.

To get the transfer job ID using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Select the Compartment from the list.
   The transfer jobs in that compartment are displayed.
3. Click the link under Transfer Jobs for the transfer job whose details you want to view.

   Alternatively, you can click the Actions icon ( ), and then click View Details.

   The Details page for that transfer job appears.
4. Find the OCID field in the Details page and click Show to display it or Copy to copy it to your computer.

To get the transfer job ID using the CLI

```
ocid dts job list --compartment-id compartment_id
```

For example:

```
ocid dts job list --compartment-id ocid.compartment.oc1..exampleuniqueID

{
    "data": [
        {
            "creation-time": "2019-12-18T19:43:58+00:00",
            "defined-tags": {},
            "device-type": "APPLIANCE",
            "display-name": "MyApplianceImportJob",
            "freeform-tags": {},
            "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
            "label": "JAKQVAGJF",
            "lifecycle-state": "INITIATED",
            "upload-bucket-name": "MyBucket1"
        },
        {
            "creation-time": "2019-10-03T16:52:26+00:00",
            "defined-tags": {},
            "device-type": "DISK",
            "display-name": "MyDiskImportJob",
            "freeform-tags": {},
            "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
            "label": "J2AWEOL5T",
            "lifecycle-state": "INITIATED",
            "upload-bucket-name": "MyBucket2"
        }
    ]
}
```

The ID for each transfer job is included in the return:

```
"id": "ocid.compartment.oc1..exampleuniqueID"
```
Setting Up Transfer Job Notifications from the CLI

You can generate notifications that send messages regarding changes to a new or existing appliance-based transfer job through the CLI. Using this feature creates a topic, subscription for a list of email addresses, and a rule that notifies you on all events related to the export job's activities and changes in state. This method provides a more convenient way to generate notifications tailored to appliance-based transfer jobs.

The CLI command to set up transfer job notifications is different depending on whether you are creating a new transfer job or updating an existing transfer job. In both cases, running the CLI command prompts you to enter the email addresses of each notification subscriber as a comma separated list. Each recipient is sent an email with a link to confirm they want to receive the notifications.

You are prompted to enter those email addresses you want included in the notifications, separated by commas ("."). When your list is complete, add a colon (":" ) followed by your own email address:

```
user1@mycompany.com, user2@mycompany.com : myemail@mycompany.com
```

For both of the notification commands, the following is returned:

```
If the commands fail to run, you can use the OCI CLI to do the setup manually:
export ROOT_COMPARTMENT_OCID=ocidv1:tenancy:oc1:exampleuniqueID
oci ons topic create --compartment-id $ROOT_COMPARTMENT_OCID --name DTSEExportTopic --description "Topic for data transfer service export jobs"
ioi ons subscription create --protocol EMAIL --compartment-id $ROOT_COMPARTMENT_OCID --topic-id $TOPIC_OCID --endpoint $EMAIL_ID
oci events rule create --display-name DTSExportRule --is-enabled true --compartment-id $ROOT_COMPARTMENT_OCID --actions '{"actions": ["actionType":"ONS","topicId":"$TOPIC_OCID","isDisabled":true]}' --condition '{"eventType": ["com.oraclecloud.datatransferservice.addapplianceexportjob","com.oraclecloud.datatransferservice.deleteapplianceexportjob","com.oraclecloud.datatransferservice.updateapplianceexportjob","com.oraclecloud.datatransferservice.moveapplianceexportjob"]}' --description "Rule for data transfer service to send notifications for export jobs"
Creating topic for export
```

To set up notifications when creating a transfer job using the CLI

To set up notifications when creating a transfer job, include the --setup-notifications option in the CLI:

```
oci dts job create --bucket bucket_name --compartment-id compartment_id --display-name display_name --device-type appliance ... --setup-notifications
```

To set up notifications for an existing export job using the CLI

To set up notifications for an existing transfer job:

```
oci dts job setup-notifications --job-id job_id
```

For example:

```
oci dts job setup-notifications --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```

If the commands fail to run, you can use the OCI CLI to do the setup manually:
oci ons topic create --compartment-id ocid1.tenancy.oc1..exampleuniqueID --name MyImportJob --description "Topic for data transfer service import job with OCID ocid1.datatransferjob.oc1..exampleuniqueID"

oci ons subscription create --protocol EMAIL --compartment-id $ROOT_COMPARTMENT_OCID --topic-id $TOPIC_OCID --subscription_endpoint $EMAIL_ID

oci events rule create --display-name MyImportJob --is-enabled true--compartment-id ocid1.tenancy.oc1..exampleuniqueID --actions '""actions": [{"actionType":"ONS","topicId":"$TOPIC_OCID","isEnabled":true}]}' --condition '{"eventType":"com.oraclecloud.datatransferservice.*transferjob","data": {"resourceId":"ocid1.datatransferjob.oc1..exampleuniqueID"}}' --description "Rule for data transfer service to send notifications for an import job with OCID ocid1.datatransferjob.oc1..exampleuniqueID"

Creating topic DTSImportJobTopic_2pwaqq

```
{  
  "data": {  
    "api-endpoint": "https://cell1.notification.us-phoenix-1.oraclecloud.com",  
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",  
    "defined-tags": {},  
    "description": "Topic for data transfer service import job with OCID ocid1.datatransferjob.oc1..exampleuniqueID",  
    "etag": null,  
    "freeform-tags": {},  
    "lifecycle-state": "ACTIVE",  
    "name": "DTSImportJobTopic_2pwaqq",  
    "time-created": "2020-07-15T18:26:07.179000+00:00",  
    "topic-id": "ocid1.onstopic.oc1..exampleuniqueID"  
  },  
  "etag": "2e5a567d"
}
```

Enter email addresses to subscribe to as a comma separated list. Example: jdoe@mycompany.com,rroe@mycompany.com : jsmith@mycompany.com

Creating subscription for jsmith@mycompany.com

```
{  
  "data": {  
    "compartment-id": "ocid1.tenancy.oc1..exampleuniqueID",  
    "created-time": 1594837577401,  
    "defined-tags": {},  
    "deliver-policy": 
      {"maxReceiveRatePerSecond":0,"backoffRetryPolicy":{"initialDelayInFailureRetry":60000,"maxRetryDuration":7200000,"policyType":"EXPONENTIAL"}},  
    "endpoint": "jsmith@mycompany.com",  
    "etag": "cac2f405",  
    "freeform-tags": {},  
    "id": "ocid1.onssubscription.oc1..exampleuniqueID",  
    "lifecycle-state": "PENDING",  
    "protocol": "EMAIL",  
    "topic-id": "ocid1.onstopic.oc1..exampleuniqueID"  
  },  
  "etag": "cac2f405"
}
```

Creating rule DTSImportJobRule_2pwaqq

```
{  
  "data": {  
    "actions": [],  
    "actions": [  
      {  
        "action-type": "ONS",  
        "description": null,
```
Preparing Upload Configuration Files

The Project Sponsor is responsible for creating or obtaining configuration files that allow the uploading of user data to the import appliance. Send these configuration files to the Data Administrator where they can be placed in the Control Host (if there are separate Control and Data Hosts). The config file is for the data transfer administrator, the IAM user with the authorization and permissions to create and manage transfer jobs. The config_upload_user file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf.

Create a base Oracle Cloud Infrastructure directory and two configuration files with the required credentials.

Creating the Data Transfer Directory

Create a Oracle Cloud Infrastructure directory (.oci) on the same Control Host machine where the Oracle Cloud Infrastructure CLI is installed. For example:

```
mkdir /root/.oci/
```

The two configuration files (config and config_upload_user) are placed in what ever location you choose.

**Note:**

You can store the configuration files anywhere on your Control Host. The root directory is only given as an example.

Creating the Data Transfer Administrator Configuration File

The data transfer administrator configuration file contains the required credentials for working with Oracle Cloud Infrastructure. You can create this file using a setup CLI or manually using a text editor.

Using the Setup CLI

Run the `oci setup config` command line utility to walk through the first-time setup process. The command prompts you for the information required for the configuration file and the API public/private keys. The setup dialog generates an API key pair and creates the configuration file.

For more information about how to find the required information, see:
Data Transfer

- Where to Get the Tenancy's OCID and User's OCID on page 5308
- Regions and Availability Domains on page 208

Manual Setup

If you want to set up the API public/private keys yourself and write your own configuration file, see SDK and Tool Configuration.

Tip:

Use the `oci setup keys` command to generate a key pair to include in the config file.

Create the data transfer administrator configuration file `/root/.oci/config` with the following structure:

```
[DEFAULT]
user=<The OCID for the data transfer administrator>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are: supported regions>
```

For example:

```
[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-phoenix-1
```

For the data transfer administrator, you can create a single configuration file that contains different profile sections with the credentials for multiple users. Then use the `--profile` option to specify which profile to use in the command. Here is an example of a data transfer administrator configuration file with different profile sections:

```
[DEFAULT]
user=ocid1.user.oc1..unique_ID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-phoenix-1

[PROFILE1]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-ashburn-1
```

By default, the DEFAULT profile is used for all CLI commands. For example:

```
oci dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket MyBucket --display-name MyDisplay --device-type appliance
```
Instead, you can issue any CLI command with the `--profile` option to specify a different data transfer administrator profile. For example:

```
ocid dts job create --compartment-id ocid.compartment.oc1..exampleuniqueID --bucket MyBucket --display-name MyDisplay --device-type appliance --profile MyProfile
```

Using the example configuration file above, the `profile_name` would be `profile1`.

If you created two separate configuration files, use the following command to specify the configuration file to use:

```
ocid dts job create --compartment-id compartment_id --bucket bucket_name --display-name display_name --config
```

**Creating the Data Transfer Upload User Configuration File**

The `config upload_user` configuration file is for the data transfer upload user, the temporary IAM user that Oracle uses to upload your data on your behalf. Create this configuration file with the following structure:

```
[DEFAULT]
user=<The OCID for the data transfer upload user>
fingerprint=<The fingerprint of the above user's public key>
key_file=<The _absolute_ path to the above user's private key file on the host machine>
tenancy=<The OCID for the tenancy that owns the data transfer job and bucket>
region=<The region where the transfer job and bucket should exist. Valid values are: supported regions>
```

**Adding Object Storage Endpoints**

Include the line `endpoint=url` for the Object Storage API endpoint in the upload user configuration file.

For example:

```
endpoint=https://objectstorage.us-phoenix-1.oraclecloud.com
```

Click [here](https://objectstorage.us-phoenix-1.oraclecloud.com) to view a list of endpoints.

A complete configuration including the Object Storage endpoint might look like this:

```
[DEFAULT]
user=ocid1.user.oc1..exampleuniqueID
fingerprint=4c:1a:6f:a1:5b:9e:58:45:f7:53:43:1f:51:0f:d8:45
key_file=/home/user/ocid1.user.oc1..exampleuniqueID.pem
tenancy=ocid1.tenancy.oc1..exampleuniqueID
region=us-phoenix-1
endpoint=https://objectstorage.us-phoenix-1.oraclecloud.com
```

**Important:**

Creating an upload user configuration file with multiple profiles is *not* supported.
Configuration File Entries

The following table lists the basic entries that are required for each configuration file and where to get the information for each entry.

Note:
Data Transfer Service does not support passphrases on the key files for both data transfer administrator and data transfer upload user.

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description and Where to Get the Value</th>
<th>Required?</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>OCID of the data transfer administrator or the data transfer upload user, depending on which profile you are creating. To get the value, see Required Keys and OCIDs on page 5303.</td>
<td>Yes</td>
</tr>
<tr>
<td>fingerprint</td>
<td>Fingerprint for the key pair being used. To get the value, see Required Keys and OCIDs on page 5303.</td>
<td>Yes</td>
</tr>
<tr>
<td>key_file</td>
<td>Full path and filename of the private key. Important: The key pair must be in PEM format. For instructions on generating a key pair in PEM format, see Required Keys and OCIDs on page 5303.</td>
<td>Yes</td>
</tr>
<tr>
<td>tenancy</td>
<td>OCID of your tenancy. To get the value, see Required Keys and OCIDs on page 5303.</td>
<td>Yes</td>
</tr>
<tr>
<td>region</td>
<td>An Oracle Cloud Infrastructure region. See Regions and Availability Domains on page 208. See Supported Regions on page 1493 for those regions that support Data Transfer.</td>
<td>Yes</td>
</tr>
</tbody>
</table>

You can verify the data transfer upload user credentials using the following command:

```
oci dts job verify-upload-user-credentials --bucket bucket_name
```

Requesting the Import Appliance

This section describes how to request an import appliance from Oracle for copying your data to Oracle Cloud Infrastructure. See Import Appliances on page 1596 for complete details on all tasks related to transfer jobs.
Oracle Cloud Infrastructure customers can use import appliances to migrate data for free. You are only charged for Object Storage usage once the data is successfully transferred to your designated bucket. All appliance requests still require approval from Oracle.

**Tip:**
To save time, identify the data you intend to upload and make data copy preparations before requesting the import appliance.

Creating an appliance request returns an Oracle-assigned appliance label. For example:

XA8XM27EVH

**To request an appliance using the Console**

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
   
   Choose the transfer job that for which you want to request an import appliance.

2. Click **Request Transfer Appliance** under **Transfer Appliances**.
   
   The Request Transfer Appliance dialog appears.

3. Provide the shipping address details where you want the import appliance sent.
   
   - **Company Name**: Required. Specify the name of the company that owns the data being migrated to Oracle Cloud Infrastructure.
   - **Recipient Name**: Required. Specify the name of the recipient of the import appliance.
   - **Recipient Phone Number**: Required. Specify the recipient’s phone number.
   - **Recipient Email Address**: Required. Specify the recipient’s email address.
   - **Care Of**: Optional intermediary party responsible for transferring the import appliance shipment from the delivery vendor to the intended recipient.
   - **Address Line 1**: Required. Specify the street address to where the import appliance is sent.
   - **Address Line 2**: Optional identifying address details like building, suite, unit, or floor information.
   - **City/Locality**: Required. Specify the city or locality.
   - **State/Province/Region**: Required. Specify the state, province, or region.
   - **Zip/Postal Code**: Specify the zip code or postal code.
   - **Country**: Required. Select the country.

4. Click **Request Transfer Appliance**.

**To request an appliance using the CLI**

oci dts appliance request --job-id job_id --addressee addressee --care-of care_of --address1 address_line1 --city-or-locality city_or_locality --state-province-region state_province_region --country country --zip-postal-code zip_postal_code --phone-number phone_number --email email [OPTIONS]

<options> are:

- --address2: Optional address of the addressee (line 2).
- --address3: Optional address of the addressee (line 3).
- --address4: Optional address of the addressee (line 4).
- --from-json: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The --generate-full-command-json-input option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id --> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our "using CLI with advanced JSON options" link: https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions.
Data Transfer

For example:

```bash
oci dts appliance request --job-id
ocid1.datatransferjob.oc1..exampleuniqueID --addressee MyCompany --care-of "John Doe" --address1 "123 Main Street" --city-or-locality Anytown --state-province-region NY --country USA --zip-postal-code 12345 --phone-number 8005551212 --email john.doe@mycompany.com
```

```json
{
    "data": {
        "appliance-delivery-tracking-number": null,
        "appliance-delivery-vendor": null,
        "appliance-return-delivery-tracking-number": null,
        "creation-time": "2020-05-20T22:08:13+00:00",
        "customer-received-time": null,
        "customer-returned-time": null,
        "customer-shipping-address": {
            "address1": "123 Main Street",
            "address2": null,
            "address3": null,
            "address4": null,
            "addressee": "MyCompany",
            "care-of": "John Doe",
            "city-or-locality": "Anytown",
            "country": "USA",
            "email": "john.doe@mycompany.com",
            "phone-number": "3115551212",
            "state-or-region": "NY",
            "zipcode": "12345"
        },
        "delivery-security-tie-id": null,
        "label": "XAKWEGKZ5T",
        "lifecycle-state": "REQUESTED",
        "next-billing-time": null,
        "return-security-tie-id": null,
        "serial-number": null,
        "transfer-job-id": "ocid1.datatransferjob.oc1..exampleuniqueID",
        "upload-status-log-uri": "JAKQVAGJF/XAKWEGKZ5T/upload_summary.txt"
    }
}
```

When you submit an appliance request, Oracle generates a unique label (label": "XAKWEGKZ5T") to identify the import appliance and your request is sent to Oracle for approval and processing.

### Setting Up Import Appliance Request Notifications from the CLI

You can generate notifications that send messages regarding changes to your import appliance request by using the `setup-notifications` command through the CLI. Running this command creates a topic, subscription for list of email addresses, and also a rule that notifies you on all events related to the import appliance request's activities and changes in state. This method provides a more convenient way to generate notifications tailored to import appliance requests.

Running the CLI command prompts you to enter the email addresses of each notification subscriber as a comma separated list. Each recipient is sent an email with a link to confirm they want to receive the notifications.

**Note:**

Setting up notifications from the CLI affects all import appliances in your tenancy. You cannot specify notifications for individual appliances.
Setting Up Notifications for a New Import Appliance Request

To include job notifications when requesting an import appliance, include the `--setup-notifications` option in the CLI:

```
oci dts appliance request --job-id job_id --addressee addressee --
address1 address_line1 --city-or-locality city_or_locality --state-or-
region state_or_region --country country --zip-code zip ... --setup-
notifications
```

Setting up Notifications for an Existing Import Appliance Request

To set up notifications for an existing import appliance request, run the `appliance setup-notifications` CLI on the appliance:

```
oci dts appliance setup-notifications --appliance-label appliance_label
```

Notifying the Data Administrator

When you have completed all the tasks in this topic, provide the Data Administrator of the following:

- IAM login credentials
- Oracle Cloud Infrastructure CLI configuration files
- Transfer job ID
- Appliance label

What's Next

You are now ready to configure your system for the data transfer. See Configuring Appliance Data Imports on page 1565.

Configuring Appliance Data Imports

This topic describes the tasks associated with configuring the Appliance-Based Data Import. The Infrastructure Engineer role typically performs these tasks. See Roles and Responsibilities on page 1544.

Note:

- Only use SFP+ transceivers that are compatible with Intel X520 NICs. Check Intel's current compatibility list to verify that the transceiver is compatible.
- 1 GBase-T: Standard RJ-45 is supported, but its use affects data copying performance.

Unpacking and Connecting the Import Appliance to the Network

When the shipping vendor delivers your import appliance, Oracle updates the status as Delivered and provides the date and time the appliance was received in the Transfer Appliance Details.

Important:

Your import appliance arrives in a transit case with a telescoping handle and wheels. The case amenities allow for easy movement to the location where you intend to place the appliance to upload your data.

Retain all packaging materials! When shipping the import appliance back to Oracle, you must package the appliance in the same manner and packaging in which the appliance was received.
Here are the tasks involved in unpacking and getting your import appliance ready to configure.

1. Inspect the tamper-evident security tie on the transit case.
   
   If the appliance was tampered with during transit, the tamper-evident security tie serves to alert you.

   **Caution:**
   
   If the security tie is damaged or is missing, do not plug the appliance into your network! Immediately file a Service Request (SR).

2. Remove and compare the number on the security tie with the number logged by Oracle.

   To see the security tie number logged by Oracle using the Console:
   
   a. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
   
   b. Find the transfer job and import appliance associated with the removed security tie.
   
   c. Click the **Actions** icon (●), and then click **View Details**.
   
   d. Look at the contents of the **Send Security Tie ID** field in the **Transfer Appliance Details** and compare that number with the number on the physical tag.

   To see the security tie number logged by Oracle using the CLI:

   ```
   oci dts appliance show --job-id job_id --appliance-label appliance_label
   ```

   For example:

   ```
   oci dts appliance show --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
   ```

   ```
   {
   "data": {
      "appliance-delivery-tracking-number": null,
      "appliance-delivery-vendor": null,
      "appliance-return-delivery-tracking-number": null,
      "creation-time": "2020-05-20T22:08:13+00:00",
      "customer-received-time": null,
      "customer-returned-time": null,
      "customer-shipping-address": {
         "address1": "123 Main Street",
         "address2": null,
         "address3": null,
         "address4": null,
         "addressee": "MyCompany",
         "care-of": "John Doe",
         "city-or-locality": "Anytown",
         "country": "USA",
         "email": "john.doe@mycompany.com",
         "phone-number": "3115551212",
         "state-or-region": "NY",
         "zipcode": "12345"
      },
      "delivery-security-tie-id": "exampleuniqueID",
      "label": "XAKWEGKZ5T",
      "lifecycle-state": "PROCESSING",
      "next-billing-time": null,
      "return-security-tie-id": "exampleuniqueID",
      "serial-number": "exampleuniqueserialnumber",
      "transfer-job-id": "ocid1.datatransferjob.oc1..exampleuniqueID",
      "upload-status-log-uri": "JAKQVAGJF/XAKWEGKZ5T/upload_summary.txt"
   }
   ```
Data Transfer

Compare the value of the `delivery-security-tie-id` attribute with the number on the physical tag to ensure they match.

**Caution:**

If the number on the physical security tie does not match the number logged by Oracle, do not plug the appliance into your network! Immediately file a Service Request (SR).

**Note:**

Keep possession of the security tie after you have finished unpacking and connecting the appliance. Include it when returning the appliance to Oracle. Failure to include the security tie can result in a delay in the data migration process.

3. Open the transit case and ensure that the case contains the following items:

   - Appliance unit and power cable (two types of power cables provided: C14 and C13 to 14)
   - USB to DB-9 serial cable
   - Return shipping instructions (retain these instructions)
   - Return shipping label, label sleeve, tie-on tag, and zip tie
   - Return shipment tamper-evident security tie (use this tie to ensure secure transit case back to Oracle)

4. Compare the number on the return shipment security tie with the number logged by Oracle.

   To see the security tie number logged by Oracle using the Console:
   
   a. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
   b. Find the transfer job and import appliance associated with the return shipment security tie.
   c. Click the **Actions** icon (⋮), and then click **View Details**.
   d. Look at the contents of the **Return Security Tie ID** field in the **Transfer Appliance Details** and compare that number with the number on the physical tag.

   To see the security tie number logged by Oracle using the CLI:

   ```
   oci dts appliance show --job-id job_id --appliance-label appliance_label
   ```

   For example:

   ```
   oci dts appliance show --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
   ```

   ```
   {  
     "data": {  
       "appliance-delivery-tracking-number": null,  
       "appliance-delivery-vendor": null,  
       "appliance-return-delivery-tracking-number": null,  
       "creation-time": "2020-05-22T22:08:13+00:00",  
       "customer-received-time": null,  
       "customer-returned-time": null,  
       "customer-shipping-address": {  
         "address1": "123 Main Street",  
         "address2": null,  
         "address3": null,  
         "address4": null,  
         "addressee": "MyCompany",  
         "care-of": "John Doe",  
         "city-or-locality": "Anytown",  
         "country": "USA"  
     },
   }
   ```
Compare the value of the `return-security-tie-id` attribute with the number on the physical tag to ensure they match.

**Caution:**

If the number on the return security tie does not match the number logged by Oracle, file a Service Request (SR). These security tie numbers must match or Oracle cannot upload data from your returned appliance.

5. Remove the import appliance from the case and place the appliance on a solid surface or in a rack.

**Caution:**

We recommend assistance lifting the appliance out of the transit case and placing the appliance in a rack or on a desk top. The total shipping weight is about 64 lbs (29 kg) and appliance weight is about 38 lbs (17 kg).

6. Connect the appliance to your local network using one of the following:
   - 10GBase-T: Standard RJ-45
   - SFP+: The transceiver must be compatible with Intel X520 NICs.

7. Attach one of the provided power cords to the appliance and plug the other end into a grounded power source.

8. Turn on the appliance by flipping the power switch on the back of the appliance.

**Connecting the Import Appliance to the Terminal Emulation Host**

Connect the import appliance to your designated Terminal Emulation Host computer using the provided USB to DB-9 serial cable.

**Note:**

You might need to download the driver for this cable on your Terminal Emulation Host: [https://www.cablestogo.com/product/26887/5ft-usb-to-db9-male-serial-rs232-adapter-cable#support](https://www.cablestogo.com/product/26887/5ft-usb-to-db9-male-serial-rs232-adapter-cable#support)

**Setting Up Terminal Emulation**

Appliance-based transfers require you to set up your host for terminal emulation so you can communicate with the appliance through the appliance's serial console. This communication requires installing serial console terminal emulator software. We recommend using the following:

- PuTTY for Windows
- ZOC for OS X
- PuTTY or Minicom for Linux

Configure the following terminal emulator software settings:

- Baud Rate: 115200
- Emulation: VT102
- Handshaking: Disabled/off
- RTS/DTS: Disabled/off

**Note:**
PuTTY does not allow you to configure all of these settings individually. However, you can configure the PuTTY default settings by selecting the **Serial** connection type and specifying "115200" for the **Serial Line** baud speed. This configuration is sufficient to use PuTTY as a terminal emulator for the appliance.

### Configuring the Import Appliance Networking

When the import appliance boots up, an appliance serial console configuration menu is displayed on the Terminal Emulation Host to which the appliance is connected.

Oracle Cloud Data Transfer Appliance
- For use with minimum dts version: dts-0.4.140
- See "Help" for determining your dts version

1) Configure Networking
2) Show Networking
3) Reset Authentication
4) Show Authentication
5) Show Status
6) Collect Appliance Diagnostic Information
7) Generate support bundle
8) Shutdown Appliance
9) Reboot Appliance
10) Help

Select a command:

**Note:**
It can take up to 5 minutes for the serial console menu to display. Press **Enter** if you do not see the serial console configuration menu after this amount of time.

The appliance supports a single active network interface on any of the 10-Gbps network ports. If only one interface is cabled and active, that interface is chosen automatically. When multiple interfaces are active, you are given the choice to select the interface to use.

To configure your import appliance networking:

1. Access the Terminal Emulation Host and select **Configure Networking** from the appliance serial console menu.
2. Provide the required networking information when prompted:
   - **IP Address**: IP address of the appliance.
   - **Subnet Mask Length**: The count of leading 1 bit in the subnet mask. For example, if the subnet mask is 255.255.255.0 then the length is 24.
   - **Default Gateway**: Default gateway for network communications.

For example:

```
Configure Networking:
^C to cancel

Configuring IP address, subnet mask length, gateway
Example:
IP Address : 10.0.0.2
```
When you configure a network interface, the appliance software generates a new client access token and appliance X.509/SSL certificate. The access token is used to authorize your Control Host to communicate with the Data Transfer Appliance’s Management Service. The x.509/SSL certificate is used to encrypt communications with the Data Transfer Appliance’s Management Service over the network. Provide the access token and SSL certificate fingerprint values displayed here when you use the CLI commands to initialize authentication on your host machine.

You can change the selected interface, network information, and reset the authentication material at any time by selecting **Configure Networking** again from the appliance serial console menu.

**Notifying the Data Administrator**

After completing the tasks in this topic, send the following import appliance information to the Data Administrator:

- Appliance IP address
- Access token
- SSL certificate fingerprint

**What’s Next**

You are now ready to load your data to the disk. See **Copying Data to the Import Appliance** on page 1570.

**Copying Data to the Import Appliance**

This topic describes the tasks associated with copying data from the Data Host to the import appliance using the Control Host. The Data Administrator role typically performs these tasks. See **Roles and Responsibilities** on page 1544.

**Note:**

You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

**Information Prerequisites**

Before performing any import appliance copying tasks, you must obtain the following information:

- Appliance IP address: This is typically provided by the Infrastructure Engineer.
### Data Transfer

- IAM login information, Data Transfer Utility configuration files, transfer job ID, and appliance label: This is typically provided by the Project Sponsor.

### Setting Up an HTTP Proxy Environment

You might need to set up an HTTP proxy environment on the Control Host to allow access to the public internet. This proxy environment allows the Oracle Cloud Infrastructure CLI to communicate with the Data Transfer Appliance Management Service and the import appliance over a local network connection. If your environment requires internet-aware applications to use network proxies, configure the Control Host to use your environment's network proxies by setting the standard Linux environment variables on your Control Host.

Assume that your organization has a corporate internet proxy at `http://www-proxy.myorg.com` and that the proxy is an HTTP address at port `80`. You would set the following environment variable:

```bash
export HTTPS_PROXY=http://www-proxy.myorg.com:80
```

If you configured a proxy on the Control Host and the appliance is directly connected to that host, the Control Host tries unsuccessfully to communicate with the appliance using a proxy. Set a `no_proxy` environment variable for the appliance. For example, if the appliance is on a local network at `10.0.0.1`, you would set the following environment variable:

```bash
export NO_PROXY=10.0.0.1
```

### Setting Firewall Access

If you have a restrictive firewall in the environment where you are using the Oracle Cloud Infrastructure CLI, you may need to open your firewall configuration to the following IP address ranges: `140.91.0.0/16`.

### Initializing Authentication to the Import Appliance

**Note:**
You can only use the Oracle Cloud Infrastructure CLI to initialize authentication.

Initialize authentication to allow the host machine to communicate with the import appliance. Use the values returned from the **Configure Networking** command. See Configuring the Transfer Appliance Networking for details.

**To initialize authentication using the CLI**

Perform this task using the following CLI. There is no Console equivalent.

```bash
oci dts physical-appliance initialize-authentication --job-id job_id --appliance-cert-fingerprint appliance_cert_fingerprint --appliance-ip ip_address --appliance-label appliance_label
```

For example:

```bash
```

When prompted, supply the access token and system. For example:

```bash
```

Retrieving the Appliance serial id from Oracle Cloud Infrastructure.

Access token ('q' to quit):
Found an existing appliance. Is it OK to overwrite it? [y/n] y
Registering and initializing the authentication between the dts CLI and the appliance

Appliance Info:
- encryptionConfigured : false
- lockStatus : NA
- finalizeStatus : NA
- totalSpace : Unknown
- availableSpace : Unknown

The Control Host can now communicate with the import appliance.

To show details about the connected appliance using the CLI

At the command prompt on the host, run `oci dts physical-appliance show` to show the status of the connected import appliance.

```
oci dts physical-appliance show
```

For example:

```
oci dts physical-appliance show
```

Appliance Info:
- encryptionConfigured : false
- lockStatus : NA
- finalizeStatus : NA
- totalSpace : Unknown
- availableSpace : Unknown

Configuring Import Appliance Encryption

Configure the import appliance to use encryption. Oracle Cloud Infrastructure creates a strong passphrase for each appliance. The command securely collects the strong passphrase from Oracle Cloud Infrastructure and sends that passphrase to the Data Transfer service.

If your environment requires Internet-aware applications to use network proxies, ensure that you set up the required Linux environment variables. See for more information.

**Important:**

If you are working with multiple appliances at the same time, be sure the job ID and appliance label that you specify in this step matches the physical appliance you are currently working with. You can get the serial number associated with the job ID and appliance label using the Console or the Oracle Cloud Infrastructure CLI. You can find the serial number of the physical appliance on the back of the device on the agency label.

**Note:**

You can only use the Oracle Cloud Infrastructure CLI to configure encryption.

To configure import appliance encryption using the CLI

At the command prompt on the host, run `oci dts physical-appliance configure-encryption` to configure import appliance encryption.

```
oci dts physical-appliance configure-encryption --job-id job_id --appliance-label appliance_label
```
For example:

```bash
oci dts physical-appliance configure-encryption --job-id
ocid1.datatransferjob.region1.phx..exampleuniqueID --appliance-label
XA8XM27EWH
```

Moving the state of the appliance to preparing...
Passphrase being retrieved...
Configuring encryption...
Encryption configured. Getting physical transfer appliance info...

```
{
  "data": {
    "availableSpaceInBytes": "Unknown",
    "encryptionConfigured": true,
    "finalizeStatus": "NA",
    "lockStatus": "LOCKED",
    "totalSpaceInBytes": "Unknown"
  }
}
```

Unlocking the Import Appliance

You must unlock the appliance before you can write data to it. Unlocking the appliance requires the strong passphrase that is created by Oracle Cloud Infrastructure for each appliance.

Unlock the appliance using one of the following ways:

- If you provide the `--job-id` and `--appliance-label` when running the `unlock` command, the data transfer system retrieves the passphrase from Oracle Cloud Infrastructure and sends it to the appliance during the unlock operation.
- You can query Oracle Cloud Infrastructure for the passphrase and provide that passphrase when prompted during the unlock operation.

**Important:**
It can take up to 10 minutes to unlock an appliance the first time. Subsequent unlocks are not as time consuming.

**Note:**
You can only use the Oracle Cloud Infrastructure CLI to unlock the import appliance.

To unlock the appliance and send the passphrase to the appliance using the CLI

```bash
oci dts physical-appliance unlock --job-id job_id --appliance-label appliance_label
```

For example:

```bash
oci dts physical-appliance unlock --job-id
ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
```

Retrieving the passphrase from Oracle Cloud Infrastructure

```
{
  "data": {
    "availableSpaceInBytes": "64.00GB",
    "encryptionConfigured": true,
    "finalizeStatus": "NOT_FINALIZED",
    "lockStatus": "NOT_LOCKED",
    "totalSpaceInBytes": "64.00GB"
  }
}
```
To query Oracle Cloud Infrastructure for the passphrase to unlock the import appliance using the CLI

```
oci dts appliance get-passphrase --job-id job_id --appliance-label appliance_label
```

For example:

```
oci dts appliance get-passphrase --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
{
  "data": {
    "encryption-passphrase": "passphrase"
  }
}
```

Run `dts physical-appliance unlock` without `--job-id` and `--appliance-label` and supply the passphrase when prompted to complete the task:

```
oci dts physical-appliance unlock
```

### Creating NFS Datasets

A dataset is a collection of files that are treated similarly. You can write up to 100 million files onto the import appliance for migration to Oracle Cloud Infrastructure. We currently support one dataset per appliance. Appliance-Based Data Import supports NFS versions 3, 4, and 4.1 to write data to the appliance. In preparation for writing data, create and configure a dataset to write to. See Datasets on page 1604 for complete details on all tasks related to datasets.

#### To create a dataset using the CLI

```
oci dts nfs-dataset create --name dataset_name
```

For example:

```
oci dts nfs-dataset create --name nfs-ds-1
Creating dataset with NFS export details nfs-ds-1
{
  "data": {
    "datasetType": "NFS",
    "name": "nfs-ds-1",
    "nfsExportDetails": {
      "exportConfigs": null,
      "state": "INITIALIZED"
    }
  }
}
```

#### Configuring Export Settings on the Dataset

To configure export settings on a dataset using the CLI

```
oci dts nfs-dataset set-export --name dataset_name --rw true --world true
```

For example:

```
oci dts nfs-dataset set-export --name nfs-ds-1 --rw true --world true
Settings NFS exports to dataset nfs-ds-1
{
  "data": {
```
Here is another example of creating the export to give read/write access to a subnet:

```sh
oci dts nfs-dataset set-export --name nfs-ds-1 --ip 10.0.0.0 --subnet-mask-length 24 --rw true --world false
```

Settings NFS exports to dataset nfs-ds-1

```json
"data": {
    "datasetType": "NFS",
    "name": "nfs-ds-1",
    "nfsExportDetails": {
        "exportConfigs": [
            {
                "hostname": null,
                "ipAddress": "10.0.0.0",
                "readWrite": true,
                "subnetMaskLength": "24",
                "world": false
            }
        ],
        "state": "INITIALIZED"
    }
}
```

**Activating the Dataset**

Activation creates the NFS export, making the dataset accessible to NFS clients.

*To activate the dataset using the CLI*

```sh
oci dts nfs-dataset activate --name dataset_name
```

For example:

```sh
oci dts nfs-dataset activate --name nfs-ds-1
```

Fetching all the datasets
Activating dataset small-files
Dataset nfs-ds-1 activated

**Setting Your Data Host as an NFS Client**

*Note:*

Only Linux machines can be used as Data Hosts.
Set up your Data Host as an NFS client:

- For Debian or Ubuntu, install the `nfs-common` package. For example:
  
  ```bash
  sudo apt-get install nfs-common
  ```

- For Oracle Linux or Red Hat Linux, install the `nfs-utils` package. For example:
  
  ```bash
  sudo yum install nfs-utils
  ```

**Mounting the NFS Share**

*To mount the NFS share*

At the command prompt on the Data Host, create the mountpoint directory:

```bash
mkdir -p /mnt/mountpoint
```

For example:

```bash
mkdir -p /mnt/nfs-ds-1
```

Next, use the `mount` command to mount the NFS share.

```bash
mount -t nfs appliance_ip:/data/dataset_name mountpoint
```

For example:

```bash
mount -t nfs 10.0.0.1:/data/nfs-ds-1 /mnt/nfs-ds-1
```

**Note:**
The appliance IP address in this example (10.0.0.1) may be different that the one you use for your appliance.

After the NFS share is mounted, you can write data to the share.

**Copying Files to the NFS Share**

Learn about copying files to the NFS share during an appliance-based import job.

You can only copy regular files to transfer appliances. You cannot copy special files, such as symbolic links, device special, sockets, and pipes, directly to the Data Transfer Appliance. See the following section for instructions on how to prepare special files.

**Important:**

- Individual files being copied to the transfer appliance cannot exceed 10,000,000,000,000 bytes (10 TB).
- Do not fill up the transfer appliance to 100% capacity. There must be space available to generate metadata and for the manifest file to perform the upload to Object Storage. At least 1 GB of free disk space is needed for this area.
- File name characters must be UTF-8 and cannot contain a new line or a return character. Before copying data to the appliance, check the filesystem or source with the following command:

  ```bash
  find . -print0 | perl -ne 'chomp; print $_, 
  \"\n\" if /[:^ascii:][:cntrl:]*/'
  ```

- The maximum character file name length is 1024 characters.
**Data Transfer**

**Copying Special Files**

To transfer special files, create a tar archive of these files and copy the tar archive to the Data Transfer Appliance. We recommend copying many small files using a tar archive. Copying a single compressed archive file should also take less time than running copy commands such as `cp -r` or `rsync`.

Here are some examples of creating a tar archive and getting it onto the Data Transfer Appliance:

- Running a simple tar command:
  
  ```
  tar -cvzf /mnt/nfs-dts-1/filesystem.tgz filesystem/
  ```

- Running a command to create a file with md5sum hashes for each file in addition to the tar archive:
  
  ```
  tar cvzf /mnt/nfs-dts-1/filesystem.tgz filesystem/ |xargs -I '{}' sh -c "test -f '{}' && md5sum '{}'"| tee tarzip_md5
  ```

The tar archive file `filesystem.tgz` has a base64 md5sum once it is uploaded to OCI Object Storage. Store the `tarzip_md5` file where you can retrieve it. After the compressed tar archive file is downloaded from Object Storage and unpacked, you can compare the individual files against the hashes in the file.

**Deactivating the Dataset**

**Note:**

Deactivating the dataset is only required if you are running appliance commands using the Data Transfer Utility. If you are using the Oracle Cloud Infrastructure CLI to run your Appliance-Based Data Import, you can skip this step and proceed to Sealing the Dataset on page 1577.

After you are done writing data, deactivate the dataset. Deactivation removes the NFS export on the dataset, disallowing any further writes.

*To deactivate the dataset using the CLI*

At the command prompt on the host, run `dts nfs-dataset deactivate` to deactivate the NFS dataset.

```
oci dts nfs-dataset deactivate --name dataset_name
```

For example:

```
oci dts nfs-dataset deactivate --name nfs-ds-1
```

**Sealing the Dataset**

Sealing a dataset stops all writes to the dataset. This process can take some time to complete, depending upon the number of files and total amount of data copied to the import appliance.

**Caution:**

If you do not seal the dataset, Oracle cannot upload your data into the tenancy bucket. The appliance is wiped clean of all data. You then have to request another appliance from Oracle and start from the beginning of the appliance-based import process.

If you issue the `seal` command without the `--wait` option, the seal operation is triggered and runs in the background. You are returned to the command prompt and can use the `seal-status` command to monitor the sealing status. Running the `seal` command with the `--wait` option results in the seal operation being triggered and continues to provide status updates until sealing completion.

The sealing operation generates a manifest across all files in the dataset. The manifest contains an index of the copied files and generated data integrity hashes.
Throughput for sealing is the average throughput for the NFS mount on the instance. The sealing process initially opens 40 threads and the thread count becomes smaller as the file count falls below 40.

**Note:**
- The sealing process uses a file tree walk and processes whichever files it comes across with no particular ordering.
- Up to 40 files are processed at a time.
- When the file count falls below 40, the thread count/file count falls and throughput appears to drop.
- Only one file is processed per a thread because of hash/checksum computation.
- Smaller files are processed faster than larger files.
- Larger files can take hours to process.

**To seal the dataset using the CLI**

```bash
oci dts nfs-dataset seal --name dataset_name [--wait]
```

For example:

```bash
oci dts nfs-dataset seal --name nfs-ds-1
Seal initiated. Please use seal-status command to get progress.
```

**To monitor the dataset sealing process using the CLI**

```bash
oci dts nfs-dataset seal-status --name dataset_name
```

For example:

```bash
oci dts nfs-dataset seal-status --name nfs-ds-1
{
  "data": {
    "bytesProcessed": 2803515612507,
    "bytesToProcess": 2803515612507,
    "completed": true,
    "endTimeInMs": 1591990408804,
    "failureReason": null,
    "numFilesProcessed": 182,
    "numFilesToProcess": 182,
    "startTimeInMs": 1591987136180,
    "success": true
  }
}
```

**Note:**
If changes are necessary after sealing a dataset or finalizing an appliance, you must reopen the dataset to modify the contents. See [Reopening a Dataset](#) on page 1607.

**Downloading the Dataset Seal Manifest**

After sealing the dataset, you can optionally download the dataset's seal manifest to a user-specified location. The manifest file contains the checksum details of all the files. The transfer site uploader consults the manifest file to determine the list of files to upload to object storage. For every uploaded file, it validates that the checksum reported by object storage matches the checksum in manifest. This validation ensures that no files got corrupted in transit.
To download the dataset seal manifest file using the CLI

```
oci dts nfs-dataset get-seal-manifest --name dataset_name --output-file output_file_path
```

For example:

```
oci dts nfs-dataset get-seal-manifest --name nfs-ds-1 --output-file ~/Downloads/seal-manifest
```

Finalizing the Import Appliance

**Note:**
You can only use the CLI commands to finalize the import appliance.

Finalizing an appliance tests and copies the following to the appliance:

- Upload user configuration credentials
- Private PEM key details
- Name of the upload bucket

**Caution:**
If you do not finalize the appliance, Oracle cannot upload your data into the tenancy bucket. This inability to upload data is because critical upload data is missing, such as upload user configuration credentials, key information, and the destination bucket.

The credentials, API key, and bucket are required for Oracle to be able to upload your data to Oracle Cloud Infrastructure Object Storage. When you finalize an appliance, you can no longer access the appliance for dataset operations unless you unlock the appliance. See Reopening a Dataset on page 1607 if you need to unlock an appliance that was finalized.

**Important:**
If you are working with multiple appliances at the same time, be sure the job ID and appliance label that you specify in this step matches the physical appliance you are currently working with. You can get the serial number associated with the job ID and appliance label using the Console or the Oracle Cloud Infrastructure CLI. You can find the serial number of the physical appliance on the back of the device on the agency label.

To finalize the import appliance

1. Seal the dataset before finalizing the import appliance. See Sealing the Dataset on page 1577.
2. Open a command prompt on the host and run `oci dts physical-appliance finalize` to finalize an appliance.

```
oci dts physical-appliance finalize --job-id job_id --appliance-label appliance_label
```

For example:

```
oci dts physical-appliance finalize --job-id ocid1.datatransferjob.region1.phx..exampleuniqueID --appliance-label XAKWEGKZ5T
```

Retrieving the upload summary object name from Oracle Cloud Infrastructure

Retrieving the upload bucket name from Oracle Cloud Infrastructure

Validating the upload user credentials

Create object BulkDataTransferTestObject in bucket MyBucket using upload user
Data Transfer

Overwrite object BulkDataTransferTestObject in bucket MyBucket using upload user
Inspect object BulkDataTransferTestObject in bucket MyBucket using upload user
Read bucket metadata MyBucket using upload user
Storing the upload user configuration and credentials on the transfer appliance
Finalizing the transfer appliance...
The transfer appliance is locked after finalize. Hence the finalize status will be shown as NA. Please unlock the transfer appliance again to see the correct finalize status
Changing the state of the transfer appliance to FINALIZED

{  
  "data": {  
    "availableSpaceInBytes": "Unknown",  
    "encryptionConfigured": true,  
    "finalizeStatus": "NA",  
    "lockStatus": "LOCKED",  
    "totalSpaceInBytes": "Unknown"  
  }  
}

Note:
If changes are necessary after sealing a dataset or finalizing an appliance, you must reopen the dataset to modify the contents. See Reopening a Dataset on page 1607.

What's Next
You are now ready to ship your import appliance with the copied data to Oracle. See Shipping the Import Appliance on page 1580.

Shipping the Import Appliance

Prepare ➔ Configure ➔ Copy ➔ Ship ➔ Monitor

This topic describes the tasks associated with shipping the import appliance containing the copied data to Oracle. The Infrastructure Engineer role typically performs these tasks. See Roles and Responsibilities on page 1544.

Note:
You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

Shutting Down the Import Appliance

Shut down the import appliance before packing up and shipping the appliance back to Oracle.

To shut down the import appliance

Using the terminal emulator on the host machine, select Shutdown from the appliance serial console.

Important:
The shutdown does not power off the appliance. Wait 10 minutes after issuing the shutdown, then turn the power switch off and disconnect the power cable.
Packing and Shipping the Import Appliance to Oracle

Return the import appliance to Oracle within 30 days. If you need the appliance beyond the standard 30-day window, you can file a service request to ask for an extension of up to 60 days.

Important:
Review and follow the instructions that were provided in the transit case with the appliance.

To pack and ship the import appliance
1. Unplug the power cord from the power source and detach the other end of the cord from the appliance.
2. Disconnect the appliance from your network.
3. Remove the return shipment tamper-evident security tie from the transit case.
4. Place the appliance, power cord, and serial cable in the transit case.

Caution:
Oracle recommends assistance lifting and placing the appliance back into the transit case. The total shipping weight is about 64 lbs (29 kg) and appliance weight is about 38 lbs (17 kg).

5. Close and secure the transit case with the return tamper-evident security tie.
6. Loop the top of the plastic tie-on tag with return shipping label through the handle of the transit case. Remove the protective tape from the back of the tie-on tag, exposing the adhesive area on which to secure the tag onto itself. Use the provided zip tie to secure the tie-on tag to the handle.
7. Return the transit case:
   - If a return label was included with the import appliance, attach the label and arrange with the shipping vendor to drop off or pick up the appliance.
   - If a return label was not included, open a service request with Oracle to arrange for the appliance’s return. See Using the Console to Manage Support Tickets on page 151.

The shipping vendor notifies Oracle when the appliance is shipped back to Oracle for upload to Oracle Cloud Infrastructure Object Storage.

What’s Next

Now you can track your return import appliance shipment to Oracle and review post transfer logs and summaries. See Monitoring the Import Appliance and Data Transfer on page 1581.

Monitoring the Import Appliance and Data Transfer

This topic describes the monitoring tasks to do after sending the import appliance with the copied data back to Oracle for data transfer to Oracle Cloud Infrastructure. The Project Sponsor role typically performs these tasks. See Roles and Responsibilities on page 1544.

Note:
You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

Monitoring the Status of Your Import Appliance Return Shipment

The shipping vendor notifies Oracle when your import appliance is picked up and shipped back for upload to Oracle Cloud Infrastructure Object Storage.
To monitor the status of your import appliance return shipment using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Find the transfer job and associated import appliance that you shipped back to Oracle for data upload.
3. Under Transfer Appliances, look at the Status field.

To monitor the status of your import appliance return shipment using the CLI

```
oci dts appliance show --job-id job_id --appliance-label appliance_label
```

For example:

```
oci dts appliance show --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
{
  "data": {
    "appliance-delivery-tracking-number": null,
    "appliance-delivery-vendor": null,
    "appliance-return-delivery-tracking-number": null,
    "creation-time": "2020-05-20T22:08:13+00:00",
    "customer-received-time": null,
    "customer-returned-time": null,
    "customer-shipping-address": {
      "address1": "123 Main Street",
      "address2": null,
      "address3": null,
      "address4": null,
      "addressee": "MyCompany",
      "care-of": "John Doe",
      "city-or-locality": "Anytown",
      "country": "USA",
      "email": "john.doe@mycompany.com",
      "phone-number": "3115551212",
      "state-or-region": "NY",
      "zipcode": "12345"
    },
    "delivery-security-tie-id": "exampleuniqueID",
    "label": "XAKWEGKZ5T",
    "lifecycle-state": "PROCESSING",
    "next-billing-time": null,
    "return-security-tie-id": "exampleuniqueID",
    "serial-number": "exampleuniqueserialnumber",
    "transfer-job-id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "upload-status-log-uri": "JARQVAGJF/XAKWEGKZ5T/upload_summary.txt"
  }
}
```

The import appliance status is indicated by the lifecycle-state attribute.

Import Appliance Status Values

Here are the import appliance status values, listed in alphabetic order:

**CANCELLED**

You can change your mind about uploading your data to Oracle Cloud Infrastructure Object Storage and cancel your import appliance. Ship the appliance back to Oracle and then cancel the appliance. Oracle always uses secure wipe tools on the boot and data areas whenever an appliance is returned.

**COMPLETE**

Oracle completed your import appliance data upload. Your data is available in your designated bucket in Oracle Cloud Infrastructure Object Storage.
CUSTOMER LOST
You have not returned the import appliance within the required 90 days.

DELIVERED
Oracle received a delivery confirmation from the shipping vendor that your import appliance was delivered. When the appliance is delivered, Oracle provides the date and time it was received in the appliance details. Appliance usage tracking begins.

ERROR
Oracle encountered an unrecoverable error trying to process your import appliance. Oracle cannot upload your data from the appliance. To protect your data, Oracle uses secure wipe tools on the boot and data areas any transfer appliance that cannot be processed. Complete another request for an appliance.

ORACLE PREPARING
Oracle approved your import appliance request. The status displays "Preparing" until the appliance is shipped to you.

ORACLE RECEIVED
Oracle received your import appliance shipment. The status displays "Oracle Received" until Oracle begins processing and uploading your data from the appliance.

ORACLE RECEIVED CANCELED
You canceled your import appliance after you shipped the appliance back to Oracle. Oracle received your canceled appliance does *not* upload any data from it.

PREPARING
You activated your import appliance. You can now copy your data onto the appliance. The status displays "Preparing" until you ship the appliance back to Oracle.

PROCESSING
Oracle is processing and uploading the data from your import appliance. The status displays "Processing" until Oracle completes uploading your data from the appliance.

REJECTED
Oracle denied your import appliance request.

**Important:**
If your appliance request is denied and you have questions, contact your Sales Representative or file a Service Request (SR).

REQUESTED
You successfully completed your request for an import appliance. The status displays requested until Oracle approves your appliance request.

RETURN SHIPPED
Oracle received confirmation from the shipping vendor that you shipped your import appliance back to Oracle. The status displays "Return Shipped" until Oracle receives your appliance.

RETURN SHIPPED CANCELED
You canceled your import appliance after the appliance was delivered to you or after you shipped the appliance back to Oracle. Oracle received confirmation from the shipping vendor that your canceled transfer appliance is on the way back to Oracle. The status displays "Return shipped cancelled" until Oracle receives your appliance.
**SHIPPING**

Oracle completed the necessary preparations and shipped your import appliance. When the appliance is shipped, Oracle provides the serial number of the appliance, the shipping vendor, and the tracking number in the appliance details. The status displays shipping until the appliance is delivered to you.

**Reviewing the Upload Summary**

Oracle creates upload summary log files for each uploaded appliance. These log files are placed in the bucket where data was uploaded to Oracle Cloud Infrastructure. The upload summary file compares the appliance’s manifest file to the contents of the target Oracle Cloud Infrastructure Object Storage bucket after file upload.

**Note:**

If you chose to upload your data to an Archive Storage bucket, you must first restore the log file object before you can download that file for review.

The top of the log report summarizes the overall file processing status:

- **P** - Present: The file is present in both the device and the target bucket
- **M** - Missing: The file is present in the device but not the target bucket. It was likely uploaded and then deleted by another user before the summary was generated.
- **C** - Name Collision: The file is present in the manifest but a file with the same name but different contents is present in the target bucket.
- **U** - Unreadable: The file is not readable from the disk
- **N** - Name Too Long: The file name on disk is too long and could not be uploaded

Complete file upload details follow the summary.

---

```
| Status | File | Size | Date/Time | MD5 (Base64) | Tag
|--------|------|------|-----------|--------------|------
| Present | file1.txt | 1024 | 2023-01-01 12:00:00 | 9c9f5e47532a | Original
| Present | file2.txt | 512  | 2023-01-01 11:59:59 | 5e47532a9f5e | Original
| Present | file3.txt | 1024 | 2023-01-01 12:00:00 | 5e479f532a53 | Original
```

If you upload more than 100,000 files, the upload details are broken into multiple pages. You can only download the first page from the Console. Download the rest of the pages directly from the Object Storage bucket. The subsequent pages have the same object name as the first page, but have an enumerated suffix.

**Verifying Uploaded File Integrity**

To verify object data integrity of files uploaded to Object Storage from the Data Transfer Appliance, a cryptographic hash using MD5 is provided for all objects uploaded to Object Storage from the Data Transfer Appliance. Oracle Cloud Infrastructure provides the object hash value in base64 encoding.

To download files imported into Object Storage and verify their integrity, run the following CLI command:

```
oci os object get --namespace object_storage_namespace --bucket-name bucket_name --name object_name --file file_location
```

For example:

```
oci os object get --namespace MyNamespace --bucket-name MyBucket1 --name JLA12B3C/XAABC12EFG/upload_summary.txt --file upload_summary.txt
```

Open the file and match the file names of the uploaded files with the MD5 column:
In this example, file_1.txt has the MD5 sum of: EoN8s6dgT/9pGYA7Yx1klQ==

To download file_1.txt, run the following CLI command:

```bash
oci os object get --namespace object_storage_namespace --bucket-name bucket_name --name object_name --file file_location
```

For example:

```bash
oci os object get --namespace example_namespace --bucket-name bucket-1 --name file_1.txt --file file_1.txt
```

Downloading object [####################################] 100%

Covert the base64 encoded hash value to hexadecimal, use the following command:

```bash
python -c 'print "BASE64-ENCODED-MD5-VALUE".decode("base64").encode("hex")'
```

For example:

```bash
python -c 'print "EoN8s6dgT/9pGYA7Yx1klQ==".decode("base64").encode("hex")'
```

12837cb3a7604fff6919803b631d6495

Now generate the md5sum on Linux and verify both values match:

```bash
md5sum file_name
```

For example:

```bash
md5sum file_1.txt
```

12837cb3a7604fff6919803b631d6495  file_1.txt

**Verifying Multipart Uploaded Files**

Large files are split into 1 GB parts when they are uploaded from the Data Transfer Appliance to Object Storage. You can verify the md5sum after downloading a file that was transferred in multiple parts using one of several available scripts. See the following for more information and links to these scripts:

https://github.com/oracle/oci-cli/issues/134
**Viewing Data Transfer Metrics**

After the import appliance with your copied data is received by Oracle and the data transfer begins, you can view the metrics associated with the transfer job in the Transfer Appliance Details page in chart or table format.

**Tip:**
Set up your notifications to alert you when the data transfer from the appliance to Oracle Cloud Infrastructure is occurring. When the state changes from ORACLE_RECEIVED to PROCESSING, you can start viewing data transfer metrics. If you included the `--setup-notification` option when you made your appliance request from the CLI, this alert occurs automatically. See Notifications Overview on page 4248 for more information.

Select **Metrics** under **Resources** to display each of these measures:

- **Import Files Uploaded**: Total number of files uploaded for import.
- **Import Bytes Uploaded**: Total number of bytes uploaded for import.
- **Import Files Remaining**: Total number of files remaining for import upload.
- **Import Bytes Remaining**: Total number of bytes remaining for import upload.
- **Import Files in Error**: Total number of files in error for import.
- **Import Upload Verification Progress**: Progress of verification of files that have already been uploaded for import.

Select the **Start Time** and **End Time** for these measures, either by manually entering the days and times in their respective fields, or by selecting the Calendar feature and picking the times that way. As an alternative to selecting a start and end time, you can also select from a list of standard times (last hour, last 6 hours, and so forth) from the Quick Selects list for the period measured. The time period you specify applies to all the measures.

Specify the **Interval** (for example, 5 minutes, 1 hour) that each measure is recorded from the list.

Specify the **Statistic** being recorded (for example, Sum, Mean) for each measure from the list.

**Tip:**
Mean is the most useful statistic for data transfer as it reflects an absolute value of the metric.

Choose additional actions from the **Options** list, including viewing the query in the Metrics Explorer, capturing the URL for the measure, and switching between chart and table view.

Click **Reset Charts** to delete any existing information in the charts and begin recording new metrics.

See Monitoring on page 3458 for general information on monitoring your Oracle Cloud Infrastructure services.

**Closing the Transfer Job**

Close the transfer job when no further transfer job activity is required or possible. Closing a transfer job requires that the status of all associated import appliances be returned, canceled, or deleted.

**To close a transfer job using the Console**

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Find the data transfer package for which you want to display the details.
3. Click the **Actions** icon (※), and then click **View Details**.
   Alternatively, click the hyperlinked name of the transfer job.
4. Click **Close Transfer Job**.

**To close a transfer job using the CLI**

```
oci dts job close --job-id job_id
```
For example:

```bash
oci dts job close --job-id ocid1.datatransferjob.oc1..exampleuniqueID
{
  "data": {
    "attached-transfer-appliance-labels": [],
    "attached-transfer-device-labels": [],
    "attached-transfer-package-labels": [],
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "creation-time": "2020-05-20T22:00:43+00:00",
    "defined-tags": {},
    "device-type": "APPLIANCE",
    "display-name": "MyApplianceImportJob",
    "freeform-tags": {},
    "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "label": "JGX4N1XLI",
    "lifecycle-state": "CLOSED",
    "upload-bucket-name": "MyBucket"
  },
  "etag": "1"
}
```

The `lifecycle-state` attribute value is "CLOSED."

What's Next

You have completed the process of setting up, running, and monitoring the Appliance-Based Data Import. If you determine that another appliance-based data transfers is required, repeat the procedure from the beginning.

Appliance Import Reference

This topic provides complete task details for certain components associated with Appliance-Based Data Imports. Use this topic as a reference to learn and use commands associated with components included in the Appliance-Based Data Import procedure.

Transfer Jobs

A transfer job is the logical representation of a data migration to Oracle Cloud Infrastructure. A transfer job is associated with one or more import appliances.

**Note:**

It is recommended that you create a compartment for each transfer job to minimize the required access your tenancy.

Creating Transfer Jobs

Create the transfer job in the same compartment as the upload bucket and supply a human-readable name for the transfer job.

Creating a transfer job returns a job OCID that you specify in other transfer tasks. For example:

```bash
ocid1.datatransferjob.oci1..exampleuniqueID
```

To create a transfer job using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Select the **Compartment** you are to use for data transfers from the list.
   
   A list of transfer jobs that have already been created is displayed.
3. Click **Create Transfer Job**.
   
   The Create Transfer Job dialog appears.
4. Enter a **Job Name**. Avoid entering confidential information. Then, select the **Upload Bucket** from the list.
5. Select **Disk** for the **Transfer Device Type**.
6. Click **Create Transfer Job**.

To create a transfer job using the CLI:

```bash
oci dts job create --bucket bucket --compartment-id compartment_id --display-name display_name --device-type device_type
```

*display_name* is the name of the transfer job. Avoid entering confidential information.

*device_type* should always be *appliance* for Appliance-Based Data Import jobs.

For example:

```bash
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyApplianceImportJob --device-type appliance
```

```json
{
  "data": {
    "attached-transfer-appliance-labels": [],
    "attached-transfer-device-labels": [],
    "attached-transfer-package-labels": [],
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "creation-time": "2019-12-18T19:43:58+00:00",
    "defined-tags": {},
    "device-type": "APPLIANCE",
    "display-name": "MyApplianceImportJob",
    "freeform-tags": {},
    "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "label": "JAKQVAGJF",
    "lifecycle-state": "INITIATED",
    "upload-bucket-name": "MyBucket1"
  },
  "etag": "2--gzip"
}
```

Optionally, you can specify one or more defined or freeform tags when you create a transfer job. For more information about tagging, see [Resource Tags](#) on page 239.

**Defined Tags**

To specify defined tags when creating a job:

```bash
oci dts job create --bucket bucket --compartment-id compartment_id --display-name display_name --device-type appliance --defined-tags '{ "tag_namespace": { "tag_key": "value" }}'
```

For example:

```bash
oci dts job create --bucket MyBucket1 --compartment-id ocid.compartment.oc1..exampleuniqueID --display-name MyApplianceImportJob --device-type appliance --defined-tags '{"Operations": {"CostCenter": "01"}}'
```

```json
{
  "data": {
    "attached-transfer-appliance-labels": [],
    "attached-transfer-device-labels": [],
    "attached-transfer-package-labels": [],
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "creation-time": "2019-12-18T19:43:58+00:00",
    "defined-tags": {
```

Oracle Cloud Infrastructure User Guide 1588
"operations": {
  "costcenter": "01"
}

"device-type": "APPLIANCE",
"display-name": "MyApplianceImportJob",
"freeform-tags": {},
"id": "ocid1.datatransferjob.oc1..exampleuniqueID",
"label": "JAKQVAGJF",
"lifecycle-state": "INITIATED",
"upload-bucket-name": "MyBucket1"
}
"etag": "2--gzip"

Freeform Tags

To specify freeform tags when creating a job:

```bash
oci dts job create --bucket bucket --compartment-id compartment_id
--display-name display_name --device-type appliance --freeform-tags '{ "tag_key": "value" }'
```

For example:

```bash
oci dts job create --bucket MyBucket1 --compartment-id
oci.compartment.oc1..exampleuniqueID --display-name MyApplianceImportJob
--device-type appliance --freeform-tags '{"Pittsburg_Team": "brochures"}'
```

```json
{
  "data": {
    "attached-transfer-appliance-labels": [],
    "attached-transfer-device-labels": [],
    "attached-transfer-package-labels": [],
    "compartment-id": "oci.compartment.oc1..exampleuniqueID",
    "creation-time": "2019-12-18T19:43:58+00:00",
    "defined-tags": {},
    "device-type": "APPLIANCE",
    "display-name": "MyApplianceImportJob",
    "freeform-tags": {
      "Pittsburg_Team": "brochures"
    },
    "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "label": "JAKQVAGJF",
    "lifecycle-state": "INITIATED",
    "upload-bucket-name": "MyBucket1"
  },
  "etag": "2--gzip"
}
```

**Note:**

Users create tag namespaces and tag keys with the required permissions. These items must exist before you can specify them when creating a job. See [Working with Defined Tags](#) on page 4967 for details.

Multiple Tags
To specify multiple tags, comma separate the JSON-formatted key/value pairs:

```
oci dts job create --bucket bucket --compartment-id compartment_id
   --display-name display_name --device-type appliance --freeform-tags
   '{ "tag_key":"value " }, '{ "tag_key":"value "}'
```

**Notifications**

To include notifications, include the `--setup-notifications` option. See Setting Up Transfer Job Notifications from the CLI on page 1557 for more information on this feature.

**Listing Transfer Jobs**

To display the list of transfer jobs using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Select the **Compartment** from the list.

   The transfer jobs in that compartment are displayed.

To display the list of transfer jobs using the CLI

```
oci dts job list --compartment-id compartment_id
```

For example:

```
oci dts job list --compartment-id ocid.compartment.oc1..exampleuniqueID

{
   "data": [
   {
      "creation-time": "2019-12-18T19:43:58+00:00",
      "defined-tags": {},
      "device-type": "APPLIANCE",
      "display-name": "MyApplianceImportJob",
      "freeform-tags": {},
      "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
      "label": "JAKQVAGJF",
      "lifecycle-state": "INITIATED",
      "upload-bucket-name": "MyBucket1"
   },
   {
      "creation-time": "2019-10-03T16:52:26+00:00",
      "defined-tags": {},
      "device-type": "DISK",
      "display-name": "MyDiskImportJob",
      "freeform-tags": {},
      "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
      "label": "J2AWEOL5T",
      "lifecycle-state": "INITIATED",
      "upload-bucket-name": "MyBucket2"
   }
   ]
}
```

When you use the CLI to list jobs, tagging details are also included in the output if you specified tags.

**Displaying Transfer Job Details**

To display the details of a transfer job using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Select the **Compartment** from the list.

   The transfer jobs in that compartment are displayed.
3. Click the link under **Transfer Jobs** for the transfer job whose details you want to view.

Alternatively, you can click the **Actions** icon (`,`) and then click **View Details**.

The Details page for that transfer job appears.

To display the details of a transfer job using the CLI

```bash
oci dts job show --job-id job_id
```

For example:

```bash
oci dts job show --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```

```json
{
  "data": {
    "attached-transfer-appliance-labels": [],
    "attached-transfer-device-labels": [],
    "attached-transfer-package-labels": [],
    "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
    "creation-time": "2019-12-18T19:43:58+00:00",
    "defined-tags": {},
    "device-type": "APPLIANCE",
    "display-name": "MyApplianceImportJob",
    "freeform-tags": {},
    "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "label": "JAKQVAGJF",
    "lifecycle-state": "INITIATED",
    "upload-bucket-name": "MyBucket1"
  },
  "etag": "2--gzip"
}
```

When you use the CLI command to display the details of a job, tagging details are also included in the output if you specified tags.

**Editing Transfer Jobs**

To edit the name of a transfer job using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Select the **Compartment** from the list.

The transfer jobs in that compartment are displayed.

3. Click the link under **Transfer Jobs** for the transfer job whose name you want to edit.

The Details page for that transfer job appears.

Alternatively, you can click the **Actions** icon (`,`) and then click **View Details**.

4. Click **Edit** in the Details page.

The Edit Transfer Job dialog appears.

5. Edit the name of the transfer job. Avoid entering confidential information.

6. Click **Edit Transfer Job**.

You are returned to the Details page for that transfer job.

To edit the name of a transfer job using the CLI

```bash
oci dts job update --job-id job_id --display-name display_name
```

*display_name* is the new name of the transfer job. Avoid entering confidential information.
For example:

```bash
oci dts job update --job-id ocid1.datatransferjob.oc1..exampleuniqueID --display-name MyRenamedJob
```

```json
{
    "data": {
        "attachment-transfer-appliance-labels": [],
        "attachment-transfer-device-labels": [],
        "attachment-transfer-package-labels": [],
        "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "creation-time": "2019-12-18T19:43:58+00:00",
        "defined-tags": {},
        "device-type": "APPLIANCE",
        "display-name": "MyRenamedJob",
        "freeform-tags": {},
        "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
        "label": "JAKQVAGJF",
        "lifecycle-state": "INITIATED",
        "upload-bucket-name": "MyBucket1"
    },
    "etag": "3"
}
```

**Editing Transfer Job Tags**

To edit the tags associated with a transfer job using the CLI

The CLI command replaces any existing tags with the new key/value pairs you specify. For more information about tagging, see [Resource Tags](#) on page 239.

To edit defined tags, provide the replacement key value pairs:

```bash
oci dts job update --job-id job_id --defined-tags '{ "tag_namespace": { "tag_key": "value" }}'
```

For example:

```bash
oci dts job update --job-id ocid1.datatransferjob.oc1..exampleuniqueID --defined-tags '{"Operations": {"CostCenter": "42"}}'
```

```json
{
    "data": {
        "attachment-transfer-appliance-labels": [],
        "attachment-transfer-device-labels": [],
        "attachment-transfer-package-labels": [],
        "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "creation-time": "2019-12-18T19:43:58+00:00",
        "defined-tags": {
            "operations": {
                "costcenter": "42"
            }
        },
        "device-type": "APPLIANCE",
        "display-name": "MyApplianceImportJob",
        "freeform-tags": {},
        "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
        "label": "JAKQVAGJF",
        "lifecycle-state": "INITIATED",
        "upload-bucket-name": "MyBucket1"
    },
    "etag": "2--gzip"
}
```
To edit free-form tags, provide the replacement key/value pairs:

```bash
oci dts job update --job-id <job_id> --freeform-tags '{ "tag_key":"value" }'
```

For example:

```bash
oci dts job update --job-id ocid1.datatransferjob.oc1..exampleuniqueID --freeform-tags '{"Chicago_Team":"marketing_videos"}'
```

```json
{
    "data": {
        "attached-transfer-appliance-labels": [],
        "attached-transfer-device-labels": [],
        "attached-transfer-package-labels": [],
        "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
        "creation-time": "2019-12-18T19:43:58+00:00",
        "defined-tags": {},
        "device-type": "APPLIANCE",
        "display-name": "MyApplianceImportJob",
        "freeform-tags": {
            "Chicago_Team": "marketing_videos"
        },
        "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
        "label": "JAKQVAGJF",
        "lifecycle-state": "INITIATED",
        "upload-bucket-name": "MyBucket1"
    },
    "etag": "2--gzip"
}
```

### Deleting Transfer Job Tags

To delete the tags associated with a transfer job using the CLI

The CLI command replaces any existing tags with the new key/value pairs you specify. If you want to delete some of the tags, specify a new tag string that does not contain the unwanted key/value pairs.

To delete all free-form tags:

```bash
oci dts job update --job-id job_id --freeform-tags '{}'
```

To delete all defined tags:

```bash
oci dts job update --job-id job_id --defined-tags '{}'
```

### Moving Transfer Jobs Between Compartments

To move transfer job to a different compartment using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Select the **Compartment** from the list.
   - The transfer jobs in that compartment are displayed.
3. Click the link under **Transfer Jobs** for the transfer job that you want to move.
   - The Details page for that transfer job appears.
   - Alternatively, you can click the **Actions** icon ( ), and then click **Move Resource**.
4. Click **Move Resource** in the Details page.
   - The Move Resource to a Different Compartment dialog appears.
5. Select the compartment you want to which you want to move the transfer job from the list.
6. Click **Move Resource**.
You are returned to the Details page for that transfer job.

To move a transfer job to a different compartment using the CLI

```
oci dts job move --job-id job_id compartment-id compartment_id [OPTIONS]
```

`compartment_id` is the compartment to which the data transfer job is being moved.

OPTIONS are:

- **--if-match**: The tag that must be matched for the task to occur for that entity. If set, the update is only successful if the object's tag matches the tag specified in the request.
- **--from-json**: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The `--generate-full-command-json-input` option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id --> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our "using CLI with advanced JSON options" link: https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions.

For example:

```
oci dts job move --job-id ocid1.datatransferjob.oc1..exampleuniqueID
compartment-id ocid.compartment.oc1..exampleuniqueID
```

To confirm the transfer, display the list of transfer jobs in the new compartment. See Listing Transfer Jobs on page 1590 for more information.

**Verifying Upload User Credentials**

**Note:**

You can only use the CLI command to verify upload user credentials.

You can verify the current upload user credentials to see whether there are any problems or updates required. If any configuration file is incorrect or invalid, the upload fails.

To verify the upload user credentials using the CLI

```
oci dts job verify-upload-user-credentials --bucket bucket
```

`bucket` is the upload bucket for the transfer job.

For example:

```
oci dts job verify-upload-user-credentials --bucket MyBucket1
```

```
created object BulkDataTransferTestObject in bucket MyBucket1
overwrote object BulkDataTransferTestObject in bucket MyBucket1
inspected object BulkDataTransferTestObject in bucket MyBucket1
read object BulkDataTransferTestObject in bucket MyBucket1
```

Depending on your user configuration, you may get an error message returned similar to the following:

```
WARNING: Permissions on /home/user/.oci/config_upload_user are too open.
To fix this please try executing the following command:
oci setup repair-file-permissions --file /home/user/.oci/config_upload_user
Alternatively to hide this warning, you may set the environment variable,
OCI_CLI_SUPPRESS_FILE_PERMISSIONS_WARNING:
export OCI_CLI_SUPPRESS_FILE_PERMISSIONS_WARNING=True
```
Error: The config file at /home/user/.oci/config_upload_user is invalid:

+Config Errors+-----------------------
+--------------------------------------------------------------
| Key         | Error           | Hint                        |
+-------------+-----------------+-----------------------------|
+--------------------------------------------------------------
| fingerprint | malformed       | openssl rsa -pubout -outform DER -in path to your private key | openssl md5 -c |
+--------------------------------------------------------------

If a user credential issue is identified, fix it and rerun the verify-upload-user-credentials CLI to ensure that all problems are addressed. Then you can proceed with transfer job activities.

Deleting Transfer Jobs

You can delete transfer jobs when they are in the Initiated, Preparing, and Close states.

To delete a transfer job using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Select the Compartment from the list.
   The transfer jobs in that compartment are displayed.
3. Find the data transfer job that you want to delete.
4. Click the Actions icon ( ), and then click Delete.
   Alternatively, you can delete a transfer job from the View Details page.
5. Confirm the deletion when prompted.

To delete a transfer job using the CLI

```
oci dts job delete --job-id job_id
```

For example:

```
oci dts job delete --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```

Confirm the deletion when prompted. The transfer job is deleted with no further action or return. To confirm the deletion, display the list of transfer jobs in the compartment. See Listing Transfer Jobs on page 1590 for more information.

Closing Transfer Jobs

Typically, you would close a transfer job when no further transfer job activity is required or possible. Closing a transfer job requires that the status of all associated transfer packages be returned, canceled, or deleted. In addition, the status of all associated transfer disks must be complete, in error, missing, canceled, or deleted.

When you close the transfer job, the status changes to Closed.

To close a transfer job using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Select the Compartment from the list.
   The transfer jobs in that compartment are displayed.
3. Find the data transfer package for which you want to display the details.
4. Click the **Actions** icon ( ), and then click **View Details**.

Alternatively, click the hyperlinked name of the transfer job.

5. Click **Close Transfer Job**.

To close a transfer job using the CLI

```
oci dts job close --job-id job_id
```

For example:

```
oci dts job close --job-id.ocid1.datatransferjob.oc1..exampleuniqueID
{
   
   "data": {
   
   "attached-transfer-appliance-labels": [],
   "attached-transfer-device-labels": [],
   "attached-transfer-package-labels": [],
   "compartment-id": "ocid.compartment.oc1..exampleuniqueID",
   "creation-time": "2020-05-20T22:00:43+00:00",
   "defined-tags": {},
   "device-type": "APPLIANCE",
   "display-name": "MyApplianceImportJob",
   "freeform-tags": {},
   "id": "ocid1.datatransferjob.oc1..exampleuniqueID",
   "label": "JGX4N1XLI",
   "lifecycle-state": "CLOSED",
   "upload-bucket-name": "MyBucket"
           
   },
   "etag": "1"
}
```

**Import Appliances**

This section describes tasks associated with the Oracle-provided import appliance.

**Requesting Appliances**

**Tip:**

To save time, identify the data you intend to upload and make data copy preparations before requesting the import appliance.

Creating an import appliance request returns an Oracle-assigned appliance label. For example:

```
XAKWEGKZ5T
```

To request an appliance using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.

Choose the transfer job for which you want to request an import appliance.

2. Under **Transfer Appliances**, click **Request Transfer Appliance**.

The Request Transfer Appliance dialog appears.
3. Enter the shipping address details where you want the import appliance sent.
   - **Company Name**: Required. Specify the name of the company that owns the data being migrated to Oracle Cloud Infrastructure.
   - **Recipient Name**: Required. Specify the name of the recipient who receives the import appliance.
   - **Recipient Phone Number**: Required. Specify the recipient’s phone number.
   - **Recipient Email Address**: Required. Specify the recipient's email address.
   - **Care Of**: Optional intermediary party responsible for transferring the import appliance shipment from the delivery vendor to the intended recipient.
   - **Address Line 1**: Required. Specify the street address where the import appliance is being sent.
   - **Address Line 2**: Optional identifying address details like building, suite, unit, or floor information.
   - **City/Locality**: Required. Specify the city or locality.
   - **State/Province/Region**: Required. Specify the state, province, or region.
   - **Zip/Postal Code**: Specify the zip code or postal code.
   - **Country**: Required. Select the country.

4. Click **Request Transfer Appliance**.

To request an appliance using the CLIs:

```
oci dts appliance request --job-id job_id --addressee addressee --care-of care_of --address1 address_line1 --city-or-locality city_or_locality --state-province-region state_province_region --country country --zip-postal-code zip_postal_code --phone-number phone_number --email email [OPTIONS]
```

<options> are:
- **--address2**: Optional address of the addressee (line 2).
- **--address3**: Optional address of the addressee (line 3).
- **--address4**: Optional address of the addressee (line 4).
- **--from-json**: Provide input to this command as a JSON document from a file using the file://path-to/file syntax. The ```-generate-full-command-json-input``` option can be used to generate a sample JSON file to be used with this command option. The key names are pre-populated and match the command option names (converted to camelCase format, e.g. compartment-id --> compartmentId), while the values of the keys need to be populated by the user before using the sample file as an input to this command. For any command option that accepts multiple values, the value of the key can be a JSON array. Options can still be provided on the command line. If an option exists in both the JSON document and the command line then the command line specified value will be used. For examples on usage of this option, please see our "using CLI with advanced JSON options" link: https://docs.cloud.oracle.com/iaas/Content/API/SDKDocs/cliusing.htm#AdvancedJSONOptions.

For example:

```
oci dts appliance request --job-id ocid1.datatransferjob.oc1..exampleuniqueID --addressee MyCompany --care-of "John Doe" --address1 "123 Main Street" --city-or-locality Anytown --state-province-region NY --country USA --zip-postal-code 12345 --phone-number 8005551212 --email john.doe@mycompany.com
```

```json
{
    "data": {
        "appliance-delivery-tracking-number": null,
        "appliance-delivery-vendor": null,
        "appliance-return-delivery-tracking-number": null,
        "creation-time": "2020-05-20T22:08:13+00:00",
        "customer-received-time": null,
        "customer-returned-time": null,
        "customer-shipping-address": {
            "address1": "123 Main Street",
            "address2": null,
            "address3": null,
            "address4": null,
```
When you submit an appliance request, Oracle generates a unique label ("label": "XAKWEGKZ5T") to identify the import appliance and your request is sent to Oracle for approval and processing.

**Monitoring the Appliance Request Status**

The time it takes to approve, prepare, and ship your appliance request varies and depends on various factors, including current available inventory. Oracle provides status updates daily throughout the appliance request and ship process.

To monitor the status of your appliance request using the Console

1. Open the navigation menu and click **Migration**. Under **Data Transfer**, click **Imports**.
2. Select the **Compartment** from the list.

   The transfer jobs in that compartment are displayed.
3. Find and select the transfer job for which you want to monitor associated appliance requests.
4. Under **Transfer Appliances**, find the appliance label Oracle assigned to your appliance request and look at the **Status** field.

Here are the key status values to look for when monitoring your appliance request:

- **Requested**: You successfully completed your request for an import appliance. The status displays **Requested** until Oracle approves your appliance request.
- **Rejected**: Oracle denied your appliance request.

  **Important:**

  If your appliance request is denied and you have questions, contact your Sales Representative or file a Service Request (SR).

- **Oracle Preparing**: Oracle approved your appliance request. The status displays **Oracle Preparing** until the import appliance is shipped to you.
- **Shipping**: Oracle completed the necessary preparations and shipped your import appliance. When the import appliance is shipped, Oracle provides the serial number of the import appliance, the shipping vendor, and the tracking number in the **Transfer Appliance Details**. The status displays **Shipping** until the import appliance is delivered to you.
- **Delivered**: The shipping vendor delivered your import appliance. When the import appliance is delivered, Oracle provides the date and time the import appliance was received in the **Transfer Appliance Details**. The status displays **Delivered**.
To monitor the status of your appliance request using the CLI

```
oci dts appliance show --job-id job_id --appliance-label appliance label
```

For example:

```
oci dts appliance show --job-id ocid1.datatransferjob.oc1..exampleuniqueID
--appliance-label XAKWEGKZ5T
```

```json
{
  "data": {
    "appliance-delivery-tracking-number": null,
    "appliance-delivery-vendor": null,
    "appliance-return-delivery-tracking-number": null,
    "creation-time": "2020-05-20T22:08:13+00:00",
    "customer-received-time": null,
    "customer-returned-time": null,
    "customer-shipping-address": {
      "address1": "123 Main Street",
      "address2": null,
      "address3": null,
      "address4": null,
      "addressee": "MyCompany",
      "care-of": "John Doe",
      "city-or-locality": "Anytown",
      "country": "USA",
      "email": "john.doe@mycompany.com",
      "phone-number": "3115551212",
      "state-or-region": "NY",
      "zipcode": "12345"
    },
    "delivery-security-tie-id": null,
    "label": "XAKWEGKZ5T",
    "lifecycle-state": "REQUESTED",
    "next-billing-time": null,
    "return-security-tie-id": null,
    "serial-number": null,
    "transfer-job-id": "ocid1.datatransferjob.oc1..exampleuniqueID",
    "upload-status-log-uri": "JAKQVAGJF/XAKWEGKZ5T/upload_summary.txt"
  }
}
```

The request status is displayed as the value for lifecycle-state.

**Displaying the List of Appliances**

To display the list of appliances using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Select the Compartment from the list.
   The transfer jobs in that compartment are displayed.
3. Choose the transfer job for which you want to display the list of associated import appliances.
   The list of import appliances is displayed below the transfer job details.

To display the list of appliances using the CLI

```
oci dts appliance list --job-id job_id
```

For example:

```
oci dts appliance list --job-id ocid1.datatransferjob.oc1..exampleuniqueID
```
Displaying Appliance Details

To display the details of an appliance using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Select the Compartment from the list.
   
   The transfer jobs in that compartment are displayed.
3. Find the transfer job for which you want to display the details of an associated import appliance.
   
   The list of appliances is displayed below the transfer job details.
4. Find the import appliance for which you want to display the details.
5. Click the Actions icon, and then click View Details.

To display the details of an appliance using the CLI

oci dts appliance show --job-id <job_id> --appliance-label <appliance_label>

For example:

oci dts appliance show --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T

{  
  "data": {  
    "appliance-delivery-tracking-number": null,  
    "appliance-delivery-vendor": null,  
    "appliance-return-delivery-tracking-number": null,  
    "creation-time": "2020-05-20T22:08:13+00:00",  
    "customer-received-time": null,  
    "customer-returned-time": null,  
    "customer-shipping-address": {  
      "address1": "123 Main Street",  
      "address2": null,  
      "address3": null,  
      "address4": null,  
      "addressee": "MyCompany",  
      "care-of": "John Doe",  
      "city-or-locality": "Anytown",  
      "country": "USA",  
      "email": "john.doe@mycompany.com",  
      "phone-number": "3115551212",  
      "state-or-region": "NY",  
      "zipcode": "12345"  
    },  
    "delivery-security-tie-id": "exampleuniqueID",  
    "label": "XAKWEGKZ5T",  
    "lifecycle-state": "PROCESSING",  
    "next-billing-time": null,  
    "return-security-tie-id": "exampleuniqueID",  
    "serial-number": "exampleuniqueserialnumber",  
  
  "data": {  
    "transfer-appliance-objects": [  
      {  
        "creation-time": "2020-05-20T22:08:13+00:00",  
        "label": "XAKWEGKZ5T",  
        "lifecycle-state": "PROCESSING",  
        "serial-number": null  
      }  
    ]  
  }  
}
Editing the Appliance Request Shipping Information

You can only edit the shipping information when the status is Requested.

To edit the appliance request shipping information using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Find the Requested import appliance that you want to edit the shipping information.
3. Click the Actions icon (i), and then click Edit.
4. Edit the shipping information for the import appliance.
5. Click Save.

To edit the appliance request shipping information using the CLI

```
oci dts appliance update-shipping-address --job-id job_id --appliance-label appliance_label --addressee addressee changed_fields
```

Include the addressee field even if it has not changed.

changed_fields represents one or more of the following shipping address fields that you want to update:

```
--care-of care_of --address1 address --city city --state addressee --zip zip --country country --phone-number phone_number email email
```

You only need to include those fields that are being updated. For example:

```
oci dts appliance update-shipping-address --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T --addressee MyCompany --care-of "Richard Roe" --phone-number 3115559876 --email richard.roe@mycompany.com
```

Confirm the update of the appliance request shipping information when prompted. The appliance details are displayed with the updated information.
Deleting an Appliance Request

You can delete an appliance request before Oracle approves the request—the status must be Requested. For example, you initiated the transfer by creating a transfer job and requested an appliance, but changed your mind.

To delete an appliance request using the Console

1. Open the navigation menu and click Migration. Under Data Transfer, click Imports.
2. Find the data transfer job and appliance request that you want to delete.
3. Click the Actions icon ( ⚙️ ), and then click Delete.

Alternatively, you can delete an appliance request from the Transfer Appliance Details page.

4. Confirm the deletion when prompted.

To delete an appliance request using the CLI

oci dts appliance delete --job-id job_id --appliance-label appliance_label

For example:

oci dts appliance delete --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T

Confirm the deletion when prompted.

Displaying Registered Appliances

You can display a list of all appliances registered through the initialize authentication command. See Initializing Authentication to the Import Appliance on page 1571 for more information.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can only use the CLI command to display a list of all appliances registered through the initialize authentication command.</td>
</tr>
</tbody>
</table>

To display the list of all registered appliances using the CLI

oci dts physical-appliance list

For example:

oci dts physical-appliance list

```bash
{
"data": [
{
"appliance_profile": "DEFAULT",
"endpoint": "https://10.20.20.7"
}
]
}
```
Unregistering Appliances

You can unregister an appliance previously registered through the initialize authentication command. See Initializing Authentication to the Import Appliance on page 1571 for more information.

To unregister an appliance using the CLI

```
oci dts physical-appliance unregister
```

Configuring Import Appliance Encryption

Configure the import appliance to use encryption. Oracle Cloud Infrastructure creates a strong passphrase for each appliance. The command securely collects the strong passphrase from Oracle Cloud Infrastructure and sends that passphrase to the Data Transfer service.

If your environment requires Internet-aware applications to use network proxies, ensure that you set up the required Linux environment variables. See for more information.

**Important:**

If you are working with multiple appliances at the same time, be sure the job ID and appliance label that you specify in this step matches the physical appliance you are currently working with. You can get the serial number associated with the job ID and appliance label using the Console or the Oracle Cloud Infrastructure CLI. You can find the serial number of the physical appliance on the back of the device on the agency label.

**Note:**

You can only use the Oracle Cloud Infrastructure CLI to configure encryption.

Configuring Appliance Encryption

**Note:**

You can only use the CLI command to configure encryption for appliances.

To configure appliance encryption using the CLI

At the command prompt on the host, run `oci dts physical-appliance configure-encryption` to configure import appliance encryption.

```
oci dts physical-appliance configure-encryption --job-id job_id --appliance-label appliance_label
```

For example:

```
oci dts physical-appliance configure-encryption --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
```

Moving the state of the appliance to preparing...
Passphrase being retrieved...
Configuring encryption...
Encryption configured. Getting physical transfer appliance info...

```
{       "data": {           "availableSpaceInBytes": "Unknown",           "encryptionConfigured": true,           "finalizeStatus": "NA",           "lockStatus": "LOCKED",           "totalSpaceInBytes": "Unknown"       }
```
Data Transfer

Initializing Authentication to the Appliance

**Note:**
You can only use the Oracle Cloud Infrastructure CLI to initialize authentication.

Initialize authentication to allow the host machine to communicate with the import appliance. Use the values returned from the [Configure Networking](#) command. See Configuring the Transfer Appliance Networking for details.

**Initializing Authentication**

**Note:**
You can only use the CLI command to initialize authentication for appliances.

To initialize authentication using the CLI

```bash
oci dts physical-appliance initialize-authentication --job-id job-id --appliance-cert-fingerprint appliance_cert_fingerprint --appliance-ip appliance_ip --appliance-label appliance_label
```

For example:

```bash
```

Retrieving the Appliance serial id from Oracle Cloud Infrastructure

Access token:
Registering and initializing the authentication between the CLI and the appliance

```json
{
  "data": {
    "availableSpaceInBytes": "Unknown",
    "encryptionConfigured": false,
    "finalizeStatus": "NA",
    "lockStatus": "NA",
    "totalSpaceInBytes": "Unknown"
  }
}
```

When prompted, supply the access token and system. The Control Host can now communicate with the import appliance.

**Datasets**

A dataset is a collection of files that are treated similarly. You can write up to 100 million files onto the appliance for import. We currently support one dataset per appliance.

**Note:**
You can only use the CLI to run dataset tasks.

**Creating the Dataset**

Appliance data transfer supports NFS version 3, 4, and 4.1 to write data to the import appliance. In preparation for writing data, create and configure a dataset to write to.
To create a dataset using the CLI

```bash
oci dts nfs-dataset create --name dataset_name
```

For example:

```bash
oci dts nfs-dataset create --name nfs-ds-1
```

Creating dataset with NFS export details nfs-ds-1

```
{
  "data": {
    "datasetType": "NFS",
    "name": "nfs-ds-1",
    "nfsExportDetails": {
      "exportConfig": null
    },
    "state": "INITIALIZED"
  }
}
```

**Activating the Dataset**

Activation creates the NFS export, making the dataset accessible to NFS clients.

To activate the dataset using the CLI

```bash
oci dts nfs-dataset activate --name dataset_name
```

For example:

```bash
oci dts nfs-dataset activate --name nfs-ds-1
```

Fetching all the datasets
Activating dataset small-files
Dataset nfs-ds-1 activated

**Configuring Export Settings on the Dataset**

To configure export settings on a dataset using the CLI

```bash
oci dts nfs-dataset set-export --name dataset_name --rw true --world true
```

For example:

```bash
oci dts nfs-dataset set-export --name nfs-ds-1 --rw true --world true
```

Settings NFS exports to dataset nfs-ds-1

```
{
  "data": {
    "datasetType": "NFS",
    "name": "nfs-ds-1",
    "nfsExportDetails": {
      "exportConfig": [
        {
          "hostname": null,
          "ipAddress": null,
          "readWrite": true,
          "subnetMaskLength": null,
          "world": true
        }
      ],
      "state": "INITIALIZED"
    }
  }
```
Here is another example of creating the export to give read/write access to a subnet:

```bash
oci dts nfs-dataset set-export --name nfs-ds-1 --ip 10.0.0.0 --subnet-mask-length 24 --rw true --world false
```

Settings NFS exports to dataset nfs-ds-1

```json
{
   "data": {
      "datasetType": "NFS",
      "name": "nfs-ds-1",
      "nfsExportDetails": {
         "exportConfigs": [
            {
               "hostname": null,
               "ipAddress": "10.0.0.0",
               "readWrite": true,
               "subnetMaskLength": "24",
               "world": false
            }
         ]
      }
   },
   "state": "INITIALIZED"
}
```

**Deactivating the Dataset**

> Note:

Deactivating the dataset is only required if you are running appliance commands using the Data Transfer Utility. If you are using the Oracle Cloud Infrastructure CLI to run your Appliance-Based Data Import, you can skip this step and proceed to **Sealing the Dataset** on page 1606.

After you are done writing data, deactivate the dataset. Deactivation removes the NFS export on the dataset, disallowing any further writes.

To deactivate the dataset using the CLI

```bash
dts nfs-dataset deactivate --name dataset_name
```

For example:

```bash
dts nfs-dataset deactivate --name nfs-ds-1
```

**Sealing the Dataset**

Sealing a dataset stops all writes to the dataset. This process can take some time to complete, depending upon the number of files and total amount of data copied to the import appliance.

If you issue the `seal` command without the `--wait` option, the seal operation is triggered and runs in the background. You are returned to the command prompt and can use the `seal-status` command to monitor the sealing status. Running the `seal` command with the `--wait` option results in the seal operation being triggered and continues to provide status updates until sealing completion.

> Important:

You can only copy regular files to transfer appliances. Special files (for example, symbolic links, device special, sockets, and pipes) cannot be copied.
To transfer special files, create a tar archive of these files and copy the tar archive to the transfer appliance.

The sealing operation generates a manifest across all files in the dataset. The manifest contains an index of the copied files and generated data integrity hashes.

To seal the dataset using the CLI

```bash
oci dts nfs-dataset seal --name dataset_name [--wait]
```

For example:

```bash
oci dts nfs-dataset seal --name nfs-ds-1
Seal initiated. Please use seal-status command to get progress.
```

**Monitoring the Dataset Sealing Process**

To monitor the dataset sealing process using the CLI

```bash
oci dts nfs-dataset seal-status --name dataset_name
```

For example:

```bash
oci dts nfs-dataset seal-status --name nfs-ds-1
{
   "data": {
      "bytesProcessed": 2803515612507,
      "bytesToProcess": 2803515612507,
      "completed": true,
      "endTimeInMs": 1591990408804,
      "failureReason": null,
      "numFilesProcessed": 182,
      "numFilesToProcess": 182,
      "startTimeInMs": 1591987136180,
      "success": true
   }
}
```

**Downloading the Dataset Seal Manifest**

After sealing the dataset, you can optionally download the dataset’s seal manifest to a user-specified location. The manifest file contains the checksum details of all the files. The transfer site uploader consults the manifest file to determine the list of files to upload to object storage. For every uploaded file, it validates that the checksum reported by object storage matches the checksum in manifest. This validation ensures that no files got corrupted in transit.

To download the dataset seal manifest file using the CLI

```bash
oci dts nfs-dataset get-seal-manifest --name dataset_name --output-file output_file_path
```

For example:

```bash
oci dts nfs-dataset get-seal-manifest --name nfs-ds-1 --output-file ~/Downloads/seal-manifest
```

**Reopening a Dataset**

If changes are necessary after sealing a dataset or finalizing an import appliance, you must reopen the dataset to modify the contents. Make the required changes and again seal the dataset. Resealing the dataset generates a new manifest.
Data Transfer

**Note:**

If an import appliance is rebooted or power cycled, follow the instructions in this topic to reopen the dataset.

**Step 1: Unlocking the Appliance**

You must unlock the appliance before you can write data to it. Unlocking the appliance requires the strong passphrase that is created by Oracle Cloud Infrastructure for each appliance.

Unlock the appliance using one of the following ways:

- If you provide the `--job-id` and `--appliance-label` when running the `unlock` command, the data transfer system retrieves the passphrase from Oracle Cloud Infrastructure and sends it to the appliance during the unlock operation.
- You can query Oracle Cloud Infrastructure for the passphrase and provide that passphrase when prompted during the unlock operation.

To unlock the appliance and send the passphrase to the appliance

```bash
oci dts physical-appliance unlock --job-id job_id --appliance-label appliance_label
```

For example:

```bash
oci dts physical-appliance unlock --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
```

Retrieving the passphrase from Oracle Cloud Infrastructure

```json
{
  "data": {
    "availableSpaceInBytes": "64.00GB",
    "encryptionConfigured": true,
    "finalizeStatus": "NOT_FINALIZED",
    "lockStatus": "NOT_LOCKED",
    "totalSpaceInBytes": "64.00GB"
  }
}
```

To query Oracle Cloud Infrastructure for the passphrase to provide to unlock the appliance

```bash
oci dts appliance get-passphrase --job-id job_id --appliance-label appliance_label
```

For example:

```bash
oci dts appliance get-passphrase --job-id ocid1.datatransferjob.oc1..exampleuniqueID --appliance-label XAKWEGKZ5T
```

```json
{
  "data": {
    "encryption-passphrase": "passphrase"
  }
}
```

Then, run `dts physical-appliance unlock` without `--job-id` and `--appliance-label` and supply the passphrase when prompted.

```bash
oci dts physical-appliance unlock
```

**Step 2: Reopening the Appliance**

Reopen the dataset to write data to the import appliance again.
To reopen an NFS dataset

```
oci dts nfs-dataset reopen --name dataset_name
```

Step 3: Repeat Steps to Write Data to the Appliance

Repeat the same tasks you performed when you originally wrote data to the import appliance beginning with activating the dataset in the Copying Files to the NFS Share on page 1576 section.

Displaying the List of Datasets

To display the list of datasets using the CLI

```
oci dts nfs-dataset list
```

For example:

```
oci dts nfs-dataset list
Listing NFS datasets
{
  "data": [
    {
      "datasetType": "NFS",
      "name": "nfs-ds-1",
      "nfsExportDetails": {
        "exportConfigs": [
          {
            "hostname": null,
            "ipAddress": null,
            "readWrite": true,
            "subnetMaskLength": null,
            "world": true
          }
        ],
        "state": "ACTIVE"
      }
    }
  ]
}
```

Displaying Dataset Details

To display the details of a transfer job using the CLI

```
oci dts nfs-dataset show --name dataset_name
```

For example:

```
oci dts nfs-dataset show --name MyDataset
{
  "data": {
    "datasetType": "NFS",
    "name": "nfs-ds-1",
    "nfsExportDetails": {
      "exportConfigs": [
        {
          "hostname": null,
          "ipAddress": null,
          "readWrite": true,
          "subnetMaskLength": null,
          "world": true
        }
      ]
    }
  }
}```
Deleting a Dataset
To delete a dataset using the CLI

```bash
oci dts nfs-dataset delete --name dataset_name
```

For example:

```bash
oci dts nfs-dataset delete --name nfs-ds-1
```

Confirm the deletion when prompted. The dataset is deleted with no further action or return. To confirm the deletion, display the list of datasets. See Displaying the List of Datasets on page 1609 for more information.

### Appliance Data Export

Data Export is Oracle's offline data export solution that lets you migrate petabyte-scale datasets from your Oracle Cloud Infrastructure Object Storage bucket to your data center using an Oracle-provided Data Transfer Appliance.

Use Data Export when you have stored terabytes or petabytes of data in Oracle Cloud Infrastructure and need to retrieve it from Object Storage more quickly than using the public internet. For example, you might have media content or processed datasets you need to share with a customer or business partner.

You cannot export data from multiple Object Storage buckets to the same export job. If you want to export data from more than one bucket, you must create an export job for each of the buckets.

**Note:**

- Data Export is not available for free trial or Pay As You Go accounts.
- Data Transfer appliance availability is based on inventory per region. Oracle distributes appliances on a first come, first serve basis based on customer request. Appliances are not always immediately available. Because of inventory constraints, new Data Export users are limited to a single appliance when it is their turn. Returning users are limited to two appliances.
- Data Export does not support exporting files from an Archive Storage bucket. Move your data from the Archive Storage bucket to an Object Storage bucket and then create an export job specifying the Object Storage bucket. See Overview of Archive Storage on page 566 for more information.

### Data Export Concepts

**EXPORT JOB**

An export job is the logical representation of an offline export of data from your Oracle Cloud Infrastructure Object Storage bucket to your data center. Exporting your data does not remove it from the original storage bucket on Oracle Cloud Infrastructure.

**Note:**

An export job is associated with a single export appliance. If your data export needs exceed the capacity of the appliance (150 TB), you need to create additional export jobs with their own dedicated appliances.
DATA TRANSFER APPLIANCE

The Data Transfer Appliance (export appliance) is a high-storage capacity device used to export data from Oracle Cloud Infrastructure to your data center. You request an export appliance from Oracle, specify the data files to be copied from your Object Storage bucket to the export appliance, and then have the export appliance containing the data shipped to you. After you receive the export appliance, copy your data to your data center. When you complete the copying of data, completely delete all the data from the export appliance before sending it back to Oracle.

COMMAND LINE INTERFACE

The command line interface (CLI) is a small footprint tool that you can use on its own or with the Console to complete Oracle Cloud Infrastructure tasks, including Appliance-Based Data Import jobs. See Command Line Interface (CLI) on page 5316 for more information.

Note:
You can only run Oracle Cloud Infrastructure CLI commands from a Linux host. This differs from running CLI commands for other Oracle Cloud Infrastructure Services on a variety of host operating systems. Appliance-based commands require validation that is only available on Linux hosts.

HOST

A physical computer at the customer site on which one or more of the logical hosts (Control, Data, Terminal Emulation) is running. Depending on your computing environment, you can have any of the following:
